In the soft-coal regions the percentages of slate and bone allowed in marketable coal and the regular market sizes vary in different localities, but in the anthracite-coal fields of Pennsylvania, these percentages and market sizes are nearly uniform. The specifications for anthracite coal usually demand the following sizes: Steamboat, 5 to 8 in., must be all coal; lump, 4 to 6 in., must contain no slate and not over 1 per cent. of bone; broken or grate, 3 to 5 in., must not contain over 1 per cent. slate, or 2 per cent. bone; egg, 2 to 3 in., must not contain over 2 per cent. slate, or 2 per cent. bone; stove, 1½ to 2 in., must not contain over 3 per cent. slate, or 3 per cent. bone. In many specifications, however, 4 per cent. slate and 3 per cent. bone are stated as the limits allowed; but this may be a clerical error, as what was probably intended was 3 per cent. slate and 4 per cent. bone; chestnut, commonly called "nut," ¾ to 1½ in., must not contain over 5 per cent. slate, or 5 per cent. bone. In some specifications the slate and bone in this size is limited to nearly the same percentages as stove coal. Pea, formerly called "peanut" coal, ½ to ¾ in., must not contain over 10 per cent. slate. The percentage of bone allowed here is not usually stated, good bone being classed as coal and bad bone as slate. Buck, or buckwheat No. 1, ⅜ to ½ in., must not contain over 15 per cent. slate, and not too much bone. Some specifications provide that buck must not contain over 15 per cent. of pieces that will sink in a liquid having a specific gravity of 1.7. This is a specific gravity test; often called the "acid test," because sulphuric acid was at first used as the liquid in which the tests were made. Rice, or buckwheat No. 2, ¼ to ⅜ in., is usually not limited in quality, because rice coal from breakers is always cleaner than buck; since the coal being more friable breaks to the smallest sizes in larger quantity than either slate or bone. Barley, about ⅛ to ¼ in. What is smaller than ⅛ or $\frac{3}{32}$ in. is called gunpowder or culm, and is generally allowed to go to waste, although it is nearly pure coal. Some of this is now being made into briquettes.

Recently, much of the slate and bone that formerly went to the culm dump is being ground down to the smallest sizes, it is probable that these small sizes will also be limited in quality in new specifications. Besides, the three smallest sizes, called "steam" coal, in distinction from the larger "domestic" sizes, are now largely sold by their actual heat value. Pure anthracite produces 11,500 B.t.u. per pound.

Methods of Cleaning Coal

There are seven different methods of cleaning coal, which are as follows: 1. Hand picking to remove the slate and bone. 2. Jigging. 3. Separation by frictional differentiation. 4. Separation by specific-gravity method. 5. Separation by washing. 6. Separation depending on the shape of the pieces. 7. Separation depending on difference in friability.

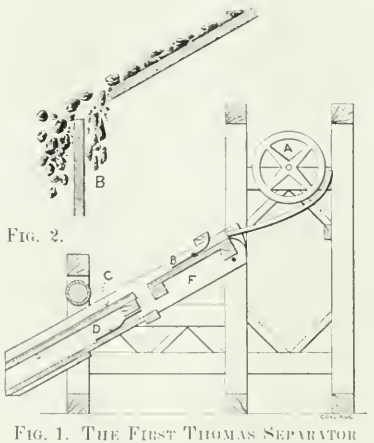

Fig. 2.

Fig. 1. The First Thomas Separator

Formerly, all the cleaning of anthracite coal was done by hand picking, costing from 8 to 30c. per ton, according to size and quality. In 1911, there were 6607 boys and 3201 men employed in the anthracite breakers of Pennsylvania to pick slate. The picking of coal by hand resulted in a loss of from 6 to 12 per cent. of the coal mined, owing to the fact that much of the coal is covered with a slate-colored veneer or layer of charcoal-like material as thin as paper, which deceives the pickers. Also a large percentage of salable bone is thrown out and lost in hand

*Mechanical engineer and industrial architect, Scranton, Penn.

picking. Thirty per cent. of good coal in the pickings usually represents about 9 per cent. of the coal mined.

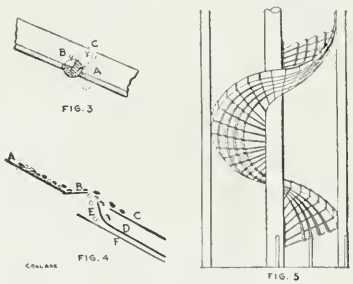
First Machines Were Jigs

Jigs of the most primitive construction were first used. These were gradually improved and a large number are still in use in anthracite breakers. The results obtained depend on the construction of the jig, the care with which it is attended, rate of feeding and the difference in the specific gravities of the coal, bone and slate. Some coals cannot be cleaned by jigging, owing to the coal being nearly as heavy as the bone.

Jigs equipped with elevators cause a large loss of the best coal, often amounting to 7 per cent., as shown by actual tests. The coal is caught in the boots of the elevator and crushed. Besides, there is a considerable loss of coal in the slate, in jigging. The expense in jigging is materially increased by corrosion, owing to the water being acidified by the action of the impurities in the coal.

Separation by Frictional Differentiation

This is the cheapest and most economical method of cleaning coal that has yet been found. It is based on the differences in friction between coal, bone, slate and rock, sliding on an inclined surface. Coal slides the quickest, bone next, slate next, and rock last, the friction of the rock on the inclined surface being greatest. By this method it is possible to separate the material into the following five classes: Coal, rough coal, called also "boney coal" or "good bone"; bone; "slaty coal" or "bad bone"; and rock. In the separation of anthracite coal, all but the clean coal, with its allowable percentage of bone and slate, are sent to the rolls to be broken to smaller sizes; except, of course, the rock, which is worthless and goes to the dump. The bone should be reduced one size smaller and the slate, two sizes smaller. Separators of this class are called "gravity pickers," because the coal slides down the



Improvements in Separators

incline by gravity. It would be more correct to call them "frictional separators." Specific gravity also plays a part in frictional separation, sometimes aiding and sometimes counteracting the separation of the impurities from the coal.

The Thomas Frictional Separator

The first patent for a frictional coal separator was granted to Septimus Thomas, in 1875. Without going into unnecessary details, the important principle of this machine is illustrated in Fig. 1. The coal is fed into the chute from a revolving screen *A*, which is not a part of the separator. A stream of coal as wide as the machine first passes under the apron *B*, the purpose of which is to prevent the tendency of the pieces to roll down the incline and start each piece to slide on the plane. As the different pieces of coal, bone, slate and rock have different velocities, they arrive at the opening above *C* at a different speed. The more swiftly sliding coal and bone jump this opening, while the slower-sliding slate and rock, for the most part, fall through the opening onto the lower chute *F*, which is provided with another apron *D* that serves the same purpose as the apron *B* in the chute above. In many separators of this kind that have been installed in the anthracite breakers, there are eight decks or chutes,

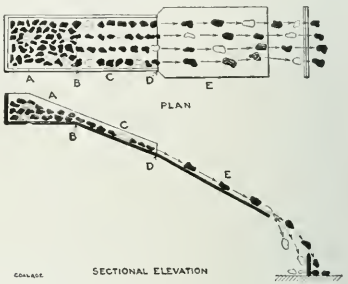


Fig. 6. Diagram Showing Features of the Langerfeld Separator

one under the other, to provide a more thorough separation of the coal from its impurities.

A number of improvements were made on this machine, both by Thomas and others, from time to time. In place of the opening (Fig. 1), a vertical partition *B* (Fig. 2) was fixed slightly below and in front of the end of the inclined plane. As illustrated in Fig. 2, the more quickly sliding coal and bone would fall beyond this partition, while the slower-sliding slate and rock would fall on the rear side of the partition, causing a more or less imperfect separation. It was soon observed that the principal difficulty was that the different pieces interfered with each other on the sliding plane. A piece of coal sliding behind a piece of slate overtakes it and accelerates its speed, while the speed of the coal is retarded. To overcome this difficulty intermittent feeding was adopted, the material being fed onto the incline in dashes or small amounts. While this was an improvement, the separation was still unsatisfactory.

The Emery Feeder

This improvement, in the manner of feeding the coal onto the incline plane, is shown in Fig. 3. It has been used in more breakers than any of the other improvements. It consists of a cylinder *A*, with a quarter section cut out, as shown at *B*. This cylinder was supported by two journals and rocked or turned to and fro, through a quarter of a revolution, by the arm *C*. This device provided a simple method of interrupting the flow of coal and produced good results.

In 1899, Caryl & Snyder introduced an important improvement, the principle of which is illustrated by the diagram, Fig. 4. The differentiating slide *A* terminated in a short apron *B*, inclined at such an angle as to give the material when it arrived at this point an upward direction. By thus throwing the pieces upward, the different flights or trajectories, resulting from the different

velocities of the material, caused them to separate more widely than before and made it possible to introduce two parters *C* and *D* beyond the opening. The lower deck or chute *D* was also provided with an apron *E*, inclined upward at its upper end. The swiftly flying coal was caught on the upper deck *C*, while the bone fell into the lower deck *D*. The slate and rock being the heaviest, and sliding more slowly, fell through the opening and was caught by the still lower deck *F*.

The Spiral Separator

In 1899, a patent was granted to Pardee for the spiral separator (Fig. 5), which depends on the frictional principle. Many of these machines were installed and gave good results in some breakers, while in others they were almost useless. They have been lately used, to a large extent, for repicking the slate that comes from the Emery pickers. Later, an adjustable spiral was patented by Rice, by which the inward pitch of the spirals could be altered so as to afford a better separation in different coals. Unfortunately, in this type of apparatus, the centrifugal action developed tends to send the rock the wrong way. The bone and slate being heavier than the coal have a tendency to move outward from the center and mix with the coal when the spirals are dry and dusty, or when the bone or slate has smooth surfaces.

Other Separators

Separators have been designed with inclined moving surfaces, and some of these have been used to advantage for partly separating the larger sizes of anthracite coal. A patent for such a machine was granted to Phillips, in 1896, and later, to Ayers. The machines, however, have a small capacity, and are therefore not useful for the sizes made in large quantities.

The Langerfeld Separator

In 1903, a patent was granted to the writer for a frictional separator designed to overcome the defects in the Thomas picker, in such a manner as to give a positive separation. This separator contains several new features, one of the chief of which is that the pieces are fed onto the chutes separately and apart, as illustrated in Fig. 6, showing the chute in plan and sectional elevation. The mixture of coal, bone, slate and rock, shown at *A*, is divided at *B*, in a manner to be described later, so that it passes onto the incline *C* in separate streams or files. In the diagram the coal is shown in solid black and the impurities in outline. At *D*, a single-piece feeder is so arranged that each piece is fed separately onto the chute *E* as shown in the figure. This arrangement of feeding allows no collisions between the pieces and permits each piece to arrive at the end of the chute, or slide, with a velocity determined by its kind.

It is upon this principle of feeding chiefly that the success of the separator depends. The same principle is applied throughout the system. This feeding mechanism has recently been perfected in every detail, so as to give the required capacity. The quantity of coal that can be fed into a separator, in this manner, can be positively cal-

Fig. 7. Showing a Series of Six Langerfeld Separators under One Roof

culated, by first ascertaining the number of pieces in a ton and then designing the machine to feed the required number of pieces a day. For example, the number of pieces in a ton of anthracite chestnut coal varies from 70,000 to 90,000, giving an average of 80,000 pieces per ton. The files of chestnut-size pieces, shown in sections *C* and *E*, Fig. 6, should be about 2 in. apart, and the pieces should be fed about 2 in. apart lengthwise or in the direction of slide. Experience has shown that from four to six pieces can be fed per second. The average run of coal of this size can be fed at the rate of six pieces per

FIG. 8. A PORTION OF A LANGERFELD SEPARATOR

second, but when the coal is very dirty, it has to be fed slower. This must be determined at the mine in question. But we may assume the average rate of feeding as five pieces per second.

In a thousand-ton breaker, the percentage of anthracite chestnut runs from 20 to 30 per cent., average 25 per cent., or 250 tons. Such breakers are usually built in two equal halves where the chestnut size is made, giving 125 tons of chestnut on each side of the breaker. In order to allow for delays and the subsequent rush of coal to make up for the time lost, it is necessary to calculate on 150 tons or better, 200 tons per day of, say nine hours; which gives an average of $(200 \times 80{,}000) \div (9 \times 60 \times 60) =$ say 500 pieces per second. Feeding at the rate of five pieces per second will then require 100 files in the feeder; and if these are 2 in. apart, the total feeding width must be 200 in. or nearly 17 ft. As this is an inconvenient width, the stream of coal is divided in half and two feeders, each 8 ft. wide, are used and have been found to give good results.

In Fig. 7 is shown a series of six Langerfeld separators under one roof. The construction of the separator is shown more in detail in Fig. 8, which represents one only of the series of separators. The coal first runs over a spreader that spreads it evenly from the width of the feed chute to the entire width of the machine, as shown above *A*, Fig. 8. A side elevation of the separator is shown in Fig. 9, while the movement of the coal through the separator is clearly illustrated by the diagram Fig. 10, which represents a vertical section through the several rolls, chutes and parters; and makes clear the separation of the several grades and qualities of material. The letters *A*, *B*, *C*, *D* refer to the same parts in Figs. 8 and 10, and likewise *A* and *B*, in Fig. 9. After passing over the spreader, the material is divided into two nearly equal streams, by a stream parter, consisting of the roller *A* and the parter *X*, Fig. 10, parallel to the roller and under its front downward-turning face.

As shown in Fig. 10, the parter *X* divides the stream of coal so that about one-half, consisting of the thicker pieces, is carried forward and the other half, consisting mostly of the thinner pieces, is carried backward under the roller. This partial separation sends nearly all the rock forward and nearly all the slate backward. This

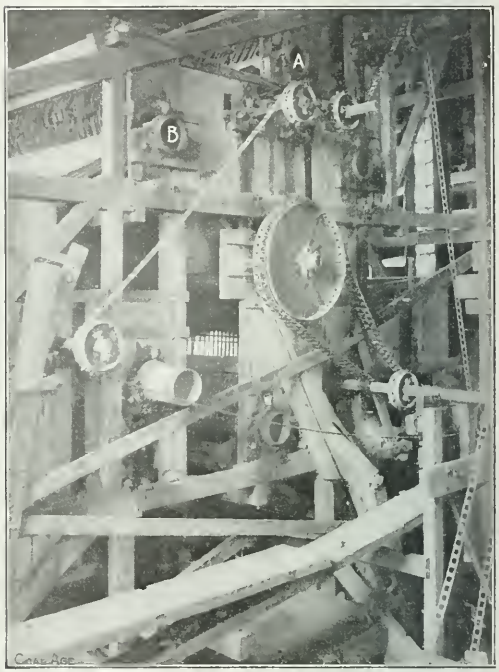

FIG. 9. SIDE VIEW OF STOVE-COAL SEPARATOR

separation is important as it facilitates the single-piece feeding that follows in each set, as illustrated in Fig. 10.

Leading to the top of each feed roller *B*, there is a channeled chute *E*, in which the pieces travel in files, as shown at *C* and *E*, Fig. 6. Above each roller *B* is a fringe of feeding fingers, which are clearly shown in Fig. 8. The purpose of these feeding fingers is to retard the movement of the pieces, separating them so that they are a certain distance apart, more or less, in each file or stream. The fingers are lifted each time a piece passes under it and drop back in time to catch the next following piece, so that no two pieces follow each other close enough to collide on the slide below the roller.

The channeled chute in each set is attached to a shaker *K*, Fig. 10. These shakers are perforated with small holes and let out the dirt and rub off much of the mud or particles that adhere to the moist pieces. The dirt falling into a hopper is carried away by a screw conveyor, shown at *V*, Fig. 10. From the roller *B* the material passes over the slide to the end *C*, from which it falls in a shower, as illustrated in the diagram, Fig.

10. These stream slides are made of corrugated soft steel or iron, as shown in Fig. 11. The advantage of this detail is that the coal is pulverized less and rides the ridges, as shown in Fig. 11, while the fine particles and dust slide down in the valleys between the ridges. The corrugations increase the efficiency of the slide very much over the old style of flat stone slab or plain steel. In those slides the coal and slate ride on the small particles and dust, with the result that the slate slides almost as quickly as the coal.

At the end *C* of the slide, the best coal has attained a velocity sufficient to send it over the parters *R*, Fig. 10, into the discharge chutes *D*. The purpose of the fringe *H* over these chutes is to prevent the breakage of the coal that has passed over the parter under a high velocity, which is reduced by the fringe sufficiently to avoid the breakage of the coal. The pieces that fall back of the parter pass down into another part of the machine designed for separating rough coal and bone from slate and rock. The construction shown in Fig. 12 is called an "invertor."

After passing over the roller *B*, in each set, and sliding down *F*, the pieces strike the invertor *G* that turns each piece over as it leaves the slide *F*, as illustrated in Fig. 12. There are many pieces that consist of a layer of slate or bone and a layer of coal. These are called capped pieces, and are classed as bone. They are apt to pass over with the coal if they slide on the coal side, and with the bone or slate if they slide on the other side; but the invertor makes the final separation of such pieces practically complete. Another advantage of the invertor is that it checks a rolling piece by acting to reverse its rotation, as shown in Fig. 12. When a piece rolls it moves faster than when sliding and may go to the wrong place. Again, the centrifugal action developed in passing the invertor causes the heavier pieces to rub harder against

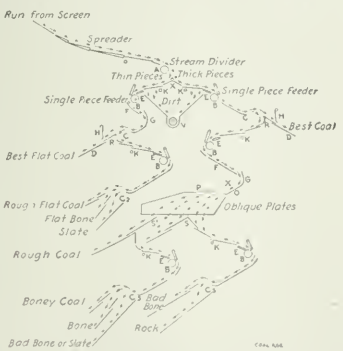

Fig. 10. Diagram Showing Course of Coal through Breaker

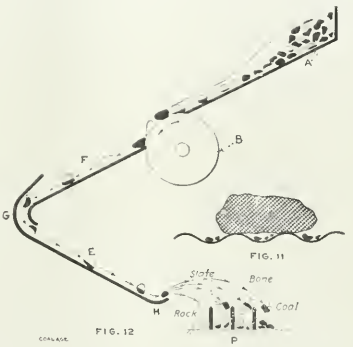
the deflecting sheet and retards their motion, which action assists in their proper separation.

The lower end of the second slide *E* is curved upward, as shown at *H*, Fig. 12, and, as previously explained, thus gives a greater divergence of the flying particles as they leave the chute, and makes possible a four-part separation; namely, coal, bone, slate and rock, by the insertion of three parters, as shown at *P*. In general, however, only a three-part separation is made in this part of the machine. In separators of this kind, designed for sizes larger than nut coal, the breakage of the coal is almost entirely prevented by giving the end plate a sidewise inclination, which causes the coal to slide to its proper place, instead of letting it fly or jump, as in the diagram, Fig. 12. This end plate is shown at *P*, Fig. 10. The end plate is warped or twisted so as to give the separation shown, the different materials sliding over the plate in the diverging curved lines indicated by the arrows. The parters *SS*, below the lower edge of this plate, carry the material to the proper places. These parters



Diagrams Showing Invertor and Section of Channeled Chute

are made adjustable to regulate the separation according to the condition of the material. I omitted to mention that Fig. 9 is a side view of the stove-coal machines, located at each end of the series of separators shown in Fig. 7.

In a breaker, the run-of-mine coal usually comes so clean as to require but little cleaning after sizing. In such cases, separators can be speeded to nearly double their intended capacity. But in a washery, or in breakers where very dirty coal is to be cleaned, the machines should be run at their intended speed. No boys are employed to pick slate, in the breaker shown in Fig. 7; but the wages saved by using these machines is a small item in comparison to the saving of coal and decrease in expenses and losses incident to the recleaning of condemned coal. A carefully conducted test made at one of the breakers equipped in the old way, showed a loss of 30 per cent. of the market value, in a car of chestnut coal that was run through the breaker a second time.

Automatic Regulation for Dry and Wet Coal

By the perfection recently made in another part of the machine, these separators are made automatic in separating runs that vary from dry to moist and wet coal; but the patents on this addition have not yet been issued. At the present time, these machines are set by means of a single lever, so as to separate dry, moist or wet runs. In breakers in which the run-of-mine changes in respect to being dry, moist, or wet, a runner is required to regulate the necessary changes. The regulation to which I refer is accomplished, at the present time, by moving the parters *RR*, Fig. 10, and the others in proportion, by suitable connections.

The Cost of Cleaning Coal

The cost of cleaning coal by means of such machines as I have described is about 1c. per ton, which covers all

expenses, including the average cost of renewing worn-out parts, in a dry breaker. In a wet breaker, the internal wear of the parts is greater on account of the acidity of the water, to which I have previously referred, and which increases the cost of separation to 1½ or 2c. per ton.

Separation by Specific Gravity

The separation of coal by specific-gravity methods cannot be done commercially, in large quantities. It costs too much. This method is of use only for the separation of samples for tests. Such a separation is accomplished by immersing the material in a liquid that is heavier than coal and lighter than bone or slate. The cheapest liquid for this purpose is sulphuric acid properly diluted. A less dangerous liquid to use is a solution of chloride of zinc. The average specific gravity of anthracite coal may be taken as 1.45; but pieces exceeding 1.75 are classed as slate.

The separation of coal from slate and bone by washing was accomplished in English collieries, many years ago, in the same manner that gold is washed in troughs, or sluices, with riffles on the bottom of the sluices. Two such sluiceways were used; and when one was full of bone and slate, the run of coal and the flow of water were turned into the other one, while the first was being cleaned; and this process was repeated, successively.

A few years ago a machine was patented in this country for washing the steam sizes of anthracite coal by dropping a sheet of such coal into a flowing stream of water. The coal being lightest, was carried the farthest down stream, the bone next and the slate and rock last. Good results were obtained, but there was little use for the machines.

Separation by Shape of Pieces

Separation depending on the shape of the pieces is too wasteful to be commercially useful, but, in most breakers, devices are used for separating flat pieces, because most of the slate is of that shape. There are, however, many flat pieces of coal as well as slate, and a further separation is necessary.

Separation by Crushing of Coal

Soft coal is often cleaned by crushing, in such a way as to crush the coal without crushing the slate, bone and sulphur. In most cases, this is done by dropping the material in revolving perforated cylinders, the drop being of sufficient height to break the coal, but not the slate, bone or sulphur. The fine coal passes out through the perforations, and the refuse passes out at the open end of the cylinder. Another method is to pass the coal through hammer crushers so adjusted as to crush only the coal. This method cannot be used at the present time, for anthracite coal; because fine anthracite coal brings a much lower price than the larger sizes.

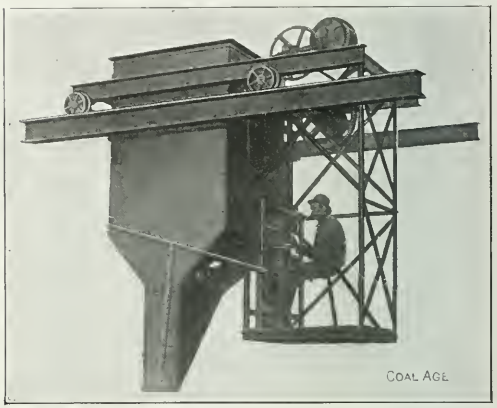
Knockers, or bumpers, are also used for cleaning soft coal. In this method, the coal is fed onto a slightly inclined plate near its middle. The plate is moved upward in the direction of its plane, slowly; then it is abruptly stopped and quickly moved in the opposite direction, which tends to move the slate upward on account of its greater weight, friction and momentum, while the coal moves downward. For anthracite coal, these machines would probably not be as economical as other separators, because there is considerably less difference in specific gravity between the anthracite coal and slate than there is between soft coal and slate.

Flexible System for Boiler Coal

Motor-driven coal hoppers, which can take coal from bunkers located anywhere and deliver it to any boiler in a battery, are coming more and more into favor. Their use does away with the system of overhead bunkers and individual chutes for each boiler, and permits all the coal to be concentrated in one bunker instead of in a series of pockets.

The bunkers can be placed at one end of the boiler room, or, for that matter, outside the building if necessary, so that the steam-generating plant can be designed and located with greater freedom, and plenty of space can be left above the boilers for light and air.

This system is also frequently preferred to conveyors



Traveling Hopper on Overhead Trackway

because it is cleaner, less liable to break down, cheaper in first cost, and does away with the difficulty of taking care of the surplus or overflow which a conveyor will carry on to the end of the line after the intermediate discharge gates are closed.

The hopper runs on a trackway parallel to the front of the boilers and is controlled by an operator in the same manner as an overhead crane. Accurate scales on the hopper make it possible to keep a precise record of the fuel burned by any boiler. If desired, a recording device can be installed so that a printed record of the weight of every discharge can be made by the operator. The hopper runs under the bunker and is filled by the operator, the scales indicating when it is full. It is then run into the boiler room to deliver its contents wherever it is wanted.

These hoppers are manufactured by the Bergen Point Iron Works, Bayonne, N. J., and Westinghouse motors are ordinarily used to propel them.

⁂

The production figures of 1912 are being compiled as rapidly as possible and from reports already received it appears that the total output of Alabama mines will be well over 18,000,000 tons, which is approximately a 21 per cent. increase over 1911. This abnormal increase in coal consumption bespeaks the wonderful industrial progress now being made in Alabama and adjacent states. Many new mines are being opened with the expectation of getting a goodly supply of the coal business that will naturally develop in connection with the Panama Canal trade. If adequate shipping facilities are furnished, the year of 1913 will show a substantial increase over last year's production.

WHO'S WHO—IN COAL MINING

It has been aptly said that some men can do business well. Others can do business very well. A few can do business superbly well. And there be found—at long intervals—an occasional one who can do business so completely well that he has distanced the bunch and stands alone in his chosen field. To this latter select class Francis Stuyvesant Peabody seems to belong.

Mr. Peabody was born at Chicago in 1859. His ancestors on one side of the family were Dutch, the other branch English, although the Peabody family has now passed the two-century mark in this country. And it is only fair to say in passing that he comes by the "Stuyvesant" legitimately, his mother belonging to one of the old Knickerbocker families.

FRANCIS STUYVESANT PEABODY

After knocking about from "pillar to post" in various of the country's then meager educational institutes, he succeeded in capturing a sheepskin at the Sheffield Scientific School of Yale, in 1881. Thus equipped, he went through the customary painful disillusionment of the cub-graduate, waiting for the world to offer him a position, and finally "getting a job" as railroad messenger. Two years in various capacities as bank messenger and traveling salesman convinced young Peabody of the fallacy of getting rich on a salary; so in the year of 1883 we find him embarking in the coal trade, his sole assets being a team of white mules, an indifferent wagon and a well cultivated taste for cigarettes. But that he has now distanced the bunch and stands alone, even his most bitter rivals cheerfully concede.

To understand the man it is necessary to study the environment and conditions under which he waged his successful battle with life. It is a well known fact that most of the leaders in the coal industry today came up from the operating end, but Mr. Peabody is an exception in this respect, having made his *début* in trade circles. His broad knowledge of the producing end of the game has been acquired entirely in the hard school of practical experience; that he was an apt student one has only to compare the photo of his maiden effort, the "Old slope" mine (shown on next page) with any of the present-day efficient and high-powered Peabody operations.

The merciless competition which has characterized the past history of the coal business in Illinois does not seem to present a very inviting prospect. But when Frank Peabody became a power in that field he performed a service for the industry that it can never repay. He brought together contending interests and abolished intrigue and secret methods of doing business that threatened ruin to the contending principals and effectually discredited the industry in financial circles.

Previous to this time price-wars of the most reckless sort were precipitated upon the slightest pretext, or no pretext at all, while the trade was surfeited with irresponsible adventurers and business integrity was rapidly diminishing into an unknown quantity. Obviously a legitimate enterprise could not exist in the face of such conditions, and it remained for Mr. Peabody to set up new standards and inculcate new principles into the trade. He attacked the job with his usual indomitable enthusiasm and gradually inaugurated a new era in the Chicago coal trade —rejuvenated it and gave it a new vigor and a new strength. One of the tangible evidences of his labors was the formation of an association which collected some two hundred thousand dollars in bad debts from scheming consumers and unscrupulous small dealers.

Frank Peabody is a radical optimist of the most pronounced type. We endeavored to impress him with the grave possibilities of labor's latent brute power of passivity. We called his attention to the alarming prognostications of our most eminent authorities on economics regarding the concentration of enormous wealth that is being effected by the modern interlocking directorates. In fact we bombarded him with a perfect broadside of the subtle innuendos of the present-day alarmists, but without avail. In every case, he stoutly affirmed these were but temporary problems that would automatically solve themselves in due time and prove stepping-stones to higher and better things.

The coal industry itself knows the man as a consistent altruist and a conservation enthusiast. On his periodical visits to the mines he is more apt to inquire how Bill Jones was killed up in the Tenth North air course last month than why the cost of haulage on the Main West increased three cents. The humanitarian aspects of the mine-workers commands his first interest and he was among the first to adopt the modern slogan of "safety first." He regards the recent legislation in Illinois, pro-

viding more comprehensive and effective safeguards for the miners as only the beginning of a broad general movement in that direction.

In the matter of conservation, he is inclined to shoulder the greatest responsibility on the consumer. He regards the meager percentage of efficiency obtained from burning the coal as the gravest menace to the principles of true conservation. While conceding that the mining companies are also wasting enormous tonnages, he believes that no concern can properly conserve its coal and remain solvent, without a broad comprehensive governmental regulation of the systems of mining. Even so he is of the opinion that the operators have materially benefited the conservation cause by educating the consumer up to using the finer grades of coal, which have in the past been

ruthlessly scattered along the highways to improve the roadbed.

In some respects the subject of our sketch differs from the usual type of self-made man who tends rigidly to business up to the last gasp and dies with his boots on. Thus we find that he insists on an annual pilgrimage abroad, is an ardent fisherman, an enthusiastic equestrian and as boastful of his presidency of the Hinsdale Golf Club as he is indifferent to like offices he holds in some of Chicago's powerful financial institutions. He is a member of many popular clubs. On the whole, Frank Peabody is a genial, hospitable personage who has a boundless liking for his fellowman and an innate courtesy so entirely unaffected that one is immediately impressed with its sincerity.

He credits his conspicuous success to an infinite capacity for hard work and a faculty of letting the other fellow do the worrying. The most casual observer, however, catches a gleam of other things behind the kindly brown eyes. An alert, questioning, appraising—in fact a "show me" look that makes you feel glad your business with him is legitimate business. It hints of a coldly impersonal and unbiased mind that has, perhaps, intuitively or subconsciously, proved his great mascot.

⁂

Paint Creek Strike at an End

The officials of the United Mines Workers of America have entered the country now under martial law along Paint, Cabin and Coal Creeks, by permission of Governor H. D. Hatfield. They are repared to instruct the mine workers to apply for their positions trusting in the assurances of the governor that the interpretation they put on the agreement will be accepted by the operators. The men have claimed that there was some ambiguity as to whether the adherents of the Union would be given an equal opportunity with others. There is no little rejoicing over the promising outlook for early peace.

Miners Less Efficient

A mathematical demonstration of the decrease in the efficiency of anthracite miners in recent years has just been prepared from the figures in the last report of the Department of Mines of Pennsylvania. When the breakers are not running, it is useless for the miners to cut coal, and hence, the only way to arrive at a right and just estimate of their efficiency is to divide the annual output of the mines by the product of the number of miners employed and the number of breaker days. The result of this calculation was as follows:

Year	No. of Miners Employed	Average No. of Days Worked	Total Miners' Working Days	Output in Tons	Average Production per Miner per Day
1901.....	37,804	195	7,371,780	59,905,951	$ 13
1902.....	36,392	116	4,221,472	36,911,549	$ 74
1903.....	36,823	211	7,769,653	67,171,951	$ 64

The variation of even a small fraction of a ton in the average production per day makes a tremendous difference on account of the great number of miners employed. As the variation in the above table is over a ton, it implies a decrease in efficiency of nearly 40,000 tons a day, when the highest and lowest figures are compared. This decrease in efficiency is attributed by James E. Roderick, chief of the Department of Mines, to the laxity with which miners' certificates have been issued by the Miners' Examining Boards to foreigners who cannot speak or understand English, and with whom the more intelligent and conscientious class of mine workers are unwilling to work as helpers for two years in order to qualify as miners themselves.

The great variation in the total number of working days also shows how costly to the mine workers are suspensions and strikes. In 1902, there were 3,150,308 fewer miners' working days than in the previous year. At the absurdly low estimate of $2 a day, this cost the miners alone $6,300,616. Since the miners form about a quarter of the total number of mine workers, the total loss in wages to all employees was approximately $25,000,000.

⁂

Rolled Cast-Steel Flanges for High-Pressure Piping

The *Zeit. für Dampfkessel und Maschinenbetrieb* for Feb. 14 and 21, 1913, has the following in substance to say regarding the use of rolled cast-steel flanges for high-pressure piping: The welded-flange joint is always liable to produce local stresses at the weld, which may result in a lowering of the coefficient of safety of the plant. The rolled joint is both cheaper and safer. The cast-steel flange, when properly made and annealed, is much superior to wrought iron, but not every steel foundry can do such special work.

The tests made at the Royal Testing Laboratory at Gross-Lichterfelde, West., have shown the superiority of the cast-steel flange over other types. This superiority was due partly to the construction of the joint, which was a series of grooves and sharp-edged threads. By this means the working face between the pipe and the flange, owing to the softer material in the pipe, is made much larger than is the case with the usual construction.

The Flooding of a Mine in Illinois

On Apr. 6, the recent flood invaded the mine of the Gallatin Coal Co., and caused about $25,000 of damage. The shaft lies near the Saline River at a village called Equality. The rising of the Ohio River flooded the Saline Valley and filled up the mine, where about 150 acres of 5-ft. coal has been taken out. After the water poured in, the compression of the air caused a remarkable phenomenon. According to some observers, the water spouted up from the shaft mouth to a height of 200 ft. Great difference of opinion exists as to the cause of this geyser-like action. We are conducting an inquiry into the cause of the strange occurrence.

Shall Labor Be Immune?

Mr. Gompers is making a persistent and determined effort to push through his bill providing exemption of the labor unions from restraint under the Sherman Act—a move which, it is strongly intimated, is regarded with favor by the President. The bill is being introduced in the form of a "rider," which immediately condemns it in the eyes of all honest men, since a just cause may stand on its own merits and does not have to be tucked under the skirts of a legitimate and necessary measure which our national assembly feels honor bound to enact.

Nor is this the most obnoxious feature of the case, as Mr. Gompers and his associates are seeking to accomplish their purpose by a miserable subterfuge, so transparent as to be at once obvious to all. That is, instead of openly and boldly demanding exemption from the Sherman Act, they are seeking to make it ineffective by forbidding the application of the regular funds to the prosecution of those cases wherein the labor unions are infringing upon it.

We have had a glaring example of the irresponsibility of organized labor in the numerous unjustified strikes in the anthracite fields, and it is to be hoped that our lawmakers will take cognizance of these incidents, and see fit to put the same check on labor as on capital. Mr. Taft vetoed a previous effort to put this bill through, and it will be interesting to note the attitude of our new administration on the question.

The Press of Pittsburgh

The press of Pittsburgh has ever been disposed to view the corporational activities in the environs of that city with friendly judgment. If it has failed to record the whole truth, the error in its verdict has been in smugness and complacency rather than in fierce and unrelenting criticism. The newspapers have almost never been disposed to break into the conscienceless condemnation so common in other cities, where corporations, good, bad and indifferent, are flayed with superlative criticism whether they do well or do ill. When the Pittsburgh Survey was published, the press of Pittsburgh rose to a man and called the inquiry unholy and a travesty on the fair name of the city and its industries. In fact, the Pittsburghers are proud of their commercial supremacy and more jealous of the honor of their industrial captains than are the citizens of other municipalities, yet strange to say, the newspapers of Pittsburgh have, with remarkable unanimity, condemned the company operating the Cincinnati mine.

The mine, we must admit, does not justify the adage which declares that only model mines explode. The pictures accompanying our review of the disaster sufficiently bear witness to the fact that the mine at Courtney was not a show colliery. It is a relic of former years, and this fact is not disguised by the presence of electric machinery and an electrically-driven fan.

But apparently the mine was a better working proposition than exterior appearances would tend to make us admit. It has had for a generation a reasonably good record of freedom from accident. So there is no apparent cause for condemnation, and one is led to ask why the newspapers are disposed to take an unfair view. The answer is furnished by stating the untimely attitude of the company. In the year 1913, it is an anachronism for a corporation having an accident of such magnitude at a mine, to debar photographers and reporters and to decline to answer any fair and reasonable questions.

Met by the State Constabulary, forbidden to photograph the company's tipple and drift mouths from other points than the public roads, the reporter is naturally made sore and nettled. Refused information by the company officials, the newspaper man is driven to obtain his facts from parties whose misfortunes alone make them partial witnesses, even if these men of themselves are naturally honest and reliable in their statements. In fact, the inquirer almost inevitably drifts to the professional agitator, the loud-mouthed sorehead and the theorist who talks for the prominence thus obtained.

It is said that the company has the reports of the foremen and firebosses under lock and key, and other evidences of the condition of the mine are hard to find. The public is naturally suspicious; we think entirely without real reason but certainly not without occasion.

The railroads have long learned that openness in such cases pays and the Pittsburgh Coal Co. may also find it to its advantage to appoint someone to distribute reliable news to those desirous of obtaining it. The early declaration that the explosion was not severe surely has not profited the corporation a whit. The report, true or false, that it discouraged the Bureau of Mines from sending its rescue team has not made it popular. But of all its blunders the worst was its treatment of the press in the persons of a number of young reporters who were willing to do the company and the mishap at its mine more than even justice. Can these young men be blamed for thinking that some foul thing needs enshrouding? Why, otherwise, should the company cover it up so completely or guard it with such jealous circumspection?

A Dangerous Bill

Although we have already called attention to the direful consequences to the coal industry of Ohio should the proposed "Green" bill become a law, we are pressed by the seriousness of the situation to again point out the dangers that will result from the enactment of such unfair legislation.

There seems to be little hope that the Miners' Union, which organization has fathered the bill, will reconsider its purpose and withdraw support of this hostile measure. It is to be hoped, therefore, that the citizens of Ohio will give careful thought to the proposed act before the bill becomes a law. Certainly, the experiences of other states, where laws have been enacted compelling the coal oprator to pay the miner for his coal on a "mine-run" basis, should have some influence in the legislative course pursued by Ohio.

Careful investigation will show that in all states where the "run-of-mine" system has been adopted, the number of accidents has increased, and the price of domestic coal to the consumer has been raised. It is inevitable that when a miner is paid for his coal, irrespective of the size of the product, he will use an excessive amount of powder in shooting. As a result, the roof is shattered and the falls of slate and rock are more frequent.

Whatever affects coal mining in Ohio will have a similar affect on other great industries of the state. Should the "Green" bill become a law, coal mining in Ohio will be put back where it was half a generation ago. From the enviable position it now holds near the top of the list of progressive mining states, it will retrograde to a position among the few remaining states, where ill-advised legislation preserves a condition that causes the coal operators to be held up to ridicule.

The widespread effect of such an act by the legislature of Ohio can best be understood when it is stated that there are 648 mines operating in that state. The output of these mines last year was approximately 34,000,000 tons, having a value of more than $35,000,000 at the mouth of the mines. Under the present agreement the miners are paid $1 per ton for all coal that goes over a 1¼-in. screen. There is also an equivalent mine-run price of 71.4c. per ton. This, therefore, is a difference of 28.6c. per ton, which fully compensates the miner for the fine coal. As the agreement now stands, it is to the interest of the miner to send out clean coal. Under the new proposed act, he would be encouraged to load out whatever impurities the coal might contain, so that he could receive pay for it.

In the year 1883, this same question was extensively discussed in Ohio. A commission was appointed and the following conclusions were arrived at by the majority of this commission, after having taken testimony from miners and operators in practically every mining district of the state.

CONCLUSIONS

From as fair and unprejudiced study of the testimony and the facts of the case as they were able to give, the commissioners agreed in the conclusions that if the payment of wages for mining was based on the weight of the coal sent out by the miner without consideration of its quality as to size, the plan would prove, for a time at least, prejudicial to the interests of both parties; to the operator by putting him to an inevitable disadvantage in the market, and to the miner by reducing or cutting off his work.

The claim that good miners would make the best possible good grades of coal because it is wisest for them to make such grades, we do not find to be founded. The weight of at least indirect testimony is strictly opposed to this view. The claim that as a body they would mine their coal as large as possible from a motive of pride in doing their work well, or as one witness expressed it, "The operators could safely trust to the conscience and pride of the miners," in this respect we find to be of still less weight. It seems to us to be negatived by experience and invalidated by the laws of human nature. Against the steady interest of self-interest in the way of relief from hard work, such motives do not hold their ground except in a small minority of cases.

Under the third and fourth heads, however, the present screen system fully sustains itself. It gives all due advantage to the skilled miner, and it proves itself in operation a thoroughly practicable working scheme. It is simple, intelligible and easy of execution. The fact that it has won its way against all competing systems to its present prominence goes far to show that the miners are not suffering injustice from its operation. A system essentially and innately unjust would not have been allowed by them to grow to its present proportions. A number of experienced miners testified that though the general sentiment of their body was opposed, they themselves considered the system a fair and satisfactory one.

In 1905 the Legislature of Arkansas passed a mine-run bill similar to the one now proposed in Ohio. A. H. Purdue, State Geologist of Arkansas, made a careful investigation of the matter, and we quote from his report as follows:

The proportion of fine coal increases unless the men have some incentive to do better work.

Thirty-five cents a ton is a conservative estimate of the decrease in value of the Arkansas coal as a result of the influence of the mine-run law.

The heavy shooting following the passage of the mine-run law has progressively increased the amount of rock falling in the rooms to triple that of 1905, prior to the law. It is, therefore, directly responsible for at least half the deaths due to this cause in 1908.

The estimate of the proportion of deaths due to the mine-run law is shown to be conservative by the fact that the number of deaths per million tons of coal mined has increased more than 40 per cent. since 1905.

The consumers suffer and are compelled to pay an increased price for coal of inferior quality.

The unfair treatment of the men who have spent their money developing the coal mines, the impairment of the value of the fuel supply of the state and its increase in price, will tend to discourage the investment of more money in industrial enterprises.

William Green, who introduced the bill, is a miner and was a few years ago president of the Ohio Miners' Organization. For two years he has been statistician of the United Mine Workers of America. Although he does not draw pay from the miners' union while the legislature is in session, we understand that his salary from the miners' organization will commence automatically upon adjournment, so that he is really an officer of the miners' union. He is president protem of the Senate, which fact gives him prestige in legislative matters.

The "Green" bill passed the Senate and went to the House of Representatives, where after two weeks' delay it passed by one vote. A few days later it was reconsidered and slightly amended. The bill is now in one of the committees and may or may not be brought up again at this session, which is about ready to adjourn.

There is no doubt whatever but that the only purpose of this measure on the part of the miners is to obtain a greater price for their labor with a less amount of work. To enact such a law would be unfair to every coal operator in the State of Ohio, since it will remove the only method by which he can make contracts with his employees. It will counteract effectively all plans designed to safeguard the lives of the miners, and strikes a destructive blow at our present popular ideas concerning the conservation of the nation's resources.

Coaling Steamships

SYNOPSIS—Description of a portable apparatus which can unload barges or vessels at a high rate of speed without employing numerous shovelers or trimmers.

One of the most modern and unique machines for coaling steamships is the De Mayo unloading elevator, manufactured by the Robins Conveying Belt Co., of New York.

This coal-handling device consists of a series of sheet-steel buckets of rugged construction, the backs of which form part of an endless steel belt. Between each two

THE DE MAYO UNLOADING ELEVATOR IN OPERATION

buckets is a steel plate of about the same height as the bucket itself, acting as a spacer. The buckets and the spacer plates are connected by hinged joints through which steel pins are passed the full width of the bucket and project at each end. At the upper and lower ends of the elevator are two cast-iron sprockets of special shape provided with teeth which engage the aforesaid pins.

The buckets are self-clearing by virtue of their special construction, so that the backs of the buckets as well as the intermediate plates act as a chute for conducting the coal or other material from the head sprockets into the telescopic chute. The entire machine is inclosed in a steel dust-proof casing and the motor is set at the head end inside the casing and is rendered accessible by doors in the housing.

The lower end of the casing is open, the corner angles forming four legs which sink into the material in the vessel. The machine is suspended from a boom or mast by a cable and its weight is allowed to rest on the material to be dug. During the greater part of the operation the buckets are self-filling, although it is necessary to have a man or two near the elevator to help break down the pile and allow it to run toward the foot of the elevator.

Power is brought to the motor by a flexible cable from the dock or vessel being coaled. The average machine requires a 10-hp. motor and the larger sizes, which are some 40 ft. in length, require a 15-hp. motor. The smaller machines can deliver 75 tons per hour and the larger ones 100 tons per hour of steam coal.

Several steamship companies are now bunkering their coal under this arrangement. They state that it costs them considerably less and requires not more than one-third of the time necessitated by older methods. It also eliminates the dirt and dust, which are such a frightful nuisance in the coaling of passenger ships.

As compared with the above stated capacities of the machine, we will add that under the present or old method of coaling vessels by means of tubs, a gang of six or seven men with a tub is able to put only 15 tons of coal per hour into ports, to say nothing of the dirt involved and the loss of coal overboard.

Another great advantage of the machine is its flexibility. It can be hung and swung anywhere and easily raised and lowered to conform with the height of vessels or cargoes. In coaling steamships, it is generally customary to have four to six loaders on each side of the ship, which clean up the coal to the bottom of the barges; when this operation is completed, all of the machines are raised simultaneously, the barges are moved to a new position and the operation recommenced.

This machine is not only adapted for handling coal, but any sort of semi-hard material such as phosphate, sulphur, salt, etc. It can be used for loading from barges into vessels, from vessels into barges, or from railroad cars into bins. In fact its field of operation is quite extensive.

The Nitrogen in Coal

In his book on the "Carbonization of Coal," Vivian B. Lewes discusses the source of nitrogen in the fuel. He believes that not all of it is derived from the original vegetation.

In growing plants, small traces of nitrogen are found combined so as to form extremely stable compounds. Some plant forms contain more nitrogen than others, but as a rule 0.1 to 0.2 per cent. will represent fairly the amount present. Little nitrogen is disengaged as the vegetation changes into coal. Moreover the coal represents only a small fraction of the original deposit from which it was formed. These two facts suffice to explain why coal contains from 1 to 2 per cent. of nitrogen.

Peat, however, which is regarded by most authorities as an intermediate stage in the conversion of vegetable matter, often contains more nitrogen than is present in coal. While the highest percentage I have ever found in coal is 1.8 per cent., I have found 2.5 and even 3 per cent., in specially rich peats; so that it is probable that in its growth or decay, the sphagnum has a special power of directly absorbing and assimilating the nitrogen of the air.

DISCUSSION BY READERS

Education in Coal Mining

Letter No. 8—The value of education for the coal miner is strikingly illustrated by the careers of many men who have risen to high places of authority. The man in the mines who does not study may have no trouble in holding his job; but the man who acquires an education and learns about the job ahead of him is pretty sure to rise, provided of course that he possesses the proper moral qualifications. The direct money value of an education is evident. If a man is an inside laborer at $2.62 per day, or a motorman at $2.95, he can feel reasonably certain that if he earns his certificate he can secure a position as fireboss at about $3.40, which is a rise of 30 per cent. and 15 per cent., respectively.

An education may be obtained by private study, and we are all familiar with notable examples of success due to this method being followed. There are, however, certain advantages in attending a mining class. In the first place, if one is enrolled in a class he is much more apt to advance faster in a given space of time. His class meetings are definite periods, in his weekly calendar, and he is a great deal more likely to attend them regularly than he is to sit down and study by himself with the same regularity. Also a properly conducted class will lead a man to study more systematically, as the instructor should be able to carry the work along definite lines, without allowing students to wander off into endless and profitless discussion.

In the class we are conducting, an effort is made to divide the work into three rather clearly defined groups, as follows:

1. Elementary branches—Arithmetic; spelling; grammar.

2. Bituminous mining law—Writing down sections from dictation; study of the outline of the state mining laws.

3. Mining Coures—Mine gases; ventilation; drainage; haulage.

Arithmetic is taught by means of problems that have appeared in state examination papers and also by problems based on requirements of the mining laws. The work in grammar is necessarily brief, consisting of a study of sentence and paragraph construction, with practice in the use of punctuation marks.

Great emphasis is given to the study of the mining law, both in the matter of helping each man to acquire a good working knowledge of the law, for the purpose of promoting greater safety in the mines; and also, because a man must be familiar with the law before he can expect to make a good showing in any state examination.

In the mining courses, by far the greatest attention is paid to the study of ventilation. Numerous problems illustrating the three laws of friction are worked out; and a close study is made of ventilating apparatus. The properties of mine gases are studied thoroughly, while many problems in percentage are worked out, in this connection.

Regarding the character of mining examinations, we feel that the unrestricted use of textbooks would be undesirable. It is better that a person acquire a sound knowledge of mining principles than that he become an adept in the use of the index of a mining pocketbook. However, since it is well nigh impossible to commit to memory the great mass of technical data and formulas that must be used, we believe that a certain portion or certain sessions of the examination might well be devoted exclusively to the solution of mathematical problems and in these, books should be allowed. This would form a good test of the candidates' ability to intelligently apply the formulas and constants required.

The whole question of the use of textbooks is, however, in my opinion, secondary to that of the practicability of the questions asked. The only fair and reasonable questions to be asked in examinations for certificates of competency to act as fireboss or mine foreman, are those that involve a knowledge of the regular work in the mine and the conditions that exist or may be met. All mathematical problems ought to be based on such actual work and conditions or on those that could easily occur.

M. D. Cooper, Mining Engineer,
Ellsworth Collieries Co.

Ellsworth, Penn.

Letter No. 9—I am not in favor of the use of textbooks in examinations for certificates of competency in mining; because, if a person is anxious to pass the examination and receive a certificate for either of the following classes in Illinois: Mine manager (mine foreman), mine examiner (fireboss), hoisting engineer, or mine inspector, he should be willing to give a part of his time to preparing for the examination.

The average man can learn and retain the formulas necessary to pass successfully any of the above examinations, and I believe that the person who, after a great amount of study is successful in passing the same, without the aid of textbooks, will be a better man than the fellow who would pass by using textbooks. I feel like our good friend, Mr. Pickett, that when it comes to questions, the answering of which involves the use of sines, cosines, tangents, etc., they should be given with the question.

I believe that the use of textbooks in examination would give the advantage to the candidate who had received the most in the way of schooling, as they are more familiar with the use of books and in that way would pass the examination more readily than the candidate who had been deprived of the opportunity of the same amount of schooling. A man, after reaching the age prescribed by law, provided he had the practical experience necessary, could take the examination and with the use of textbooks make the grade required to pass. Unless there was a rigid oral examination, this man would pass with a better grade than another man, who perhaps had a great deal more experience than he and who would be a much safer man to employ as a mine manager.

I have known young men to appear for examination three or more times and make the written grade every time, because they had taken a high-school course; but they would fail in the oral or practical questions, which was the most important part of the examination.

I recall one instance of a miner, living in one of the southern counties of our state, and who came before the mining board to take the examination for certificate as mine manager. The first time he came he did very poorly in his written work and did not reach the oral part of the examination, although he had had a very large experience. Textbooks would have done him no good, because he would have been unable to apply the formulas had they been given him. He was not at all discouraged, because of his failure, but went home with a fixed determination to show the board that he could and would pass the examination. In less than two years he had reached the place where he did not need textbooks to pass the written grade and in the oral, or practical part of the examination, he had no trouble.

From my experience in connection with the work of the State Mining Board of Illinois, I believe that the use of textbooks in the examinations would be a mistake and should not be considered. What is worth having is surely worth the effort put forth to acquire.

MARTIN BOLT.
Chief Clerk, State Mining Board.

Springfield, Ill.

Letter No. 10—I welcome the opportunity of joining in this discussion. Education, in the line of the actual mining or digging of coal, consists partly of demonstrations by a miner who has learned by experience how to do the work. In like manner, a child learns how to draw a bucket of water from a well by watching the father or mother do the work. A boy learns how to pitch ball by watching another boy pitch and then improves his own pitching by practice. Few boys are actually shown how to pitch by professional baseball players. They must show some natural ability before the expert takes them in hand.

But the coal digger receives instructions from the official from the first day he commences work. Advice is given him in the undermining of coal and he is shown how to set timbers, drill a hole, etc. He is told what to do and what not to do, with a view to insuring his own safety and that of others. He then gains proficiency through practice. A knowledge of percentage, ratios or decimals would not assist him in this class of work. But if a man is a good coal digger and realizes the importance of study, a technical education in the science and principles of coal mining will make him no less capable as a coal digger.

The demand at the present day, however, should be for educated mine officials, and it will be time enough to think about the educated coal digger when more interest is taken in this demand. Many men who aspire to the position of mine foreman have held or are holding minor official positions, and we must deal with the education and examination of these men first. It is invariably the case that such men have forgotten most of the arithmetic they learned at school, and many unfortunately did not get much schooling as boys and are unable to intelligently express their knowledge of mining, in writing. They should be given first a grounding in elementary mathematics and after that they should study mensuration, ventilation and gases, hydraulics, etc. At the same time they should attend lectures and be taught how to think clearly and quickly and how to commit the knowledge they have gained in the mine and at school, to paper. In their advanced studies, the planning of mine workings so as to concentrate operations and facilitate haulage and ventilation will prove most valuable to them when the time comes for the practical application of the knowledge gained at the mining school. But, unfortunately, the official still exists who scorns the mining school. He proclaims on every available occasion: "I am a practical miner, my school was the pit." The pit is a pretty good school, but the good pitman is like the good coal digger, he loses nothing by an education similar to the one mentioned at the beginning of this letter. In this age of science, strength of muscle is to strength of mind as burnt flax to beaten iron. The colliery official can spare the former but must possess the later.

The time is rapidly approaching when there will be a scarcity of officials possessing the necessary education. In states where laws have been suddenly passed demanding that all officials from the foreman down be certificated, it is found that men who wish to go to night schools range from 20 to 50 years of age, and but few young fellows between the ages of 14 and 24 desire to attend. It appears men generally get to be twenty and thirty years old before they realize what they have been losing. And it is indeed often pitiful to watch their struggles then. The mind is out of pitch and the man has lost all interest in study. He discovers that he is like a man who puts on skates for the first time. The solving of ordinary problems often looks hopeless to him.

What is the remedy for this condition? The progressive employer realizes the value of educated officials. Will an education boom do any good? The rescue helmet has had its boom, but it is a fact that as the number of educated officials increases, the need for rescue helmets will decrease. The education of the official is the first step to take to promote safety in mines, it produces better efficiency, and thereby more economy.

It is my opinion that mine foremen, assistant mine foremen and firebosses should not be allowed the use of textbooks at the examinations for this reason: If they know that such books will be available they will become mere copyists and will develop only slight independent mind faculties of their own. In their home work, they will rely upon the books and at the examinations will copy the text in addition to using the mathematical examples to aid them in working out problems. On the other hand, they will be put to a fair test if they are given the more intricate mathematical formulas embodied in the examination papers, but printed on a separate sheet. At the examinations for mine superintendents or higher mine officials and state mine inspectors, formulas should not be given, and certainly no textbooks allowed. A candidate who passes an examination where books are allowed gives no proof of his ability to efficiently fill the the position. It is regrettable that it is not customary to require that mine superintendents stand a severe examination.

I am not overlooking the fact that education does not enable all mining men to become capable officials. An education does not always produce that trait called executive ability, nor does it always supply a man with the necessary moral backbone. But the aspirant can console

himself with this truth: that the mine official of the future will, to a certain extent, be educated.

College education does not always produce capable men; but the *system* that is drilled into them at college goes far to produce that result. Where a man stays at college until he reaches the twenties, it is not surprising that, in a mine, he will often appear like a fish out of water. The college education that is likely to produce the best results is the "sandwich system." Under this arrangement the student is at college for six months of each year and the remaining portion of the year is spent underground and in the workshops on the surface.

Legislation to Regulate Timbering

I was pleased to note the great interest that was manifested by those who took part in the discussion of mine timbering. I notice, however, that some of those who discussed this question thought that no "hard and fast" rule could be laid down to regulate methods of timbering in coal mines. I believe, on the contrary, that such a conclusion is wrong, and that legislation is greatly needed to regulate the question of timbering, in coal mining.

I do not want to be considered as radical when I say that I believe thoroughly in "hard and fast" rules, in mining. In support of this statement I will point out a few facts that must be evident to every mining man.

First, consider what is meant by a new mining law. It is an attempt to compel mining men to abide by a "hard and fast" rule. For example, in the operation of a gaseous mine, where it is necessary to use safety lamps, mining laws require that all tobacco pipes and matches shall be left outside. Men using safety lamps are compelled by law to keep them at a safe distance from the swing of their pick, where they will not be liable to injury or accident. There are laws regulating ventilation, explosives, and the use and handling of the same, and the manner of mining and shooting coal. In some instances, the law specifies how timbers shall be set.

Everyone of these laws is a "hard and fast" rule. In my opinion, there should be such a "hard and fast" rule regulating the maximum distance at which timbers should be set apart. The suggestion has been made to employ a timberman to set timbers. In Durham, England, this was done and the cost deducted from the price of mining. In this country, this would undoubtedly give rise to trouble. I am a firm believer in systematic timbering and am convinced that this would go far toward reducing the number of accidents at the working face.

Study Course in Coal Mining

BY J. T. BEARD

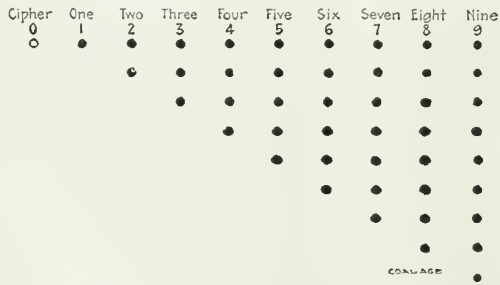
The Coal Age Pocket Book

ARITHMETIC

Arithmetic is the science of numbers. Numbers are used to express magnitude or quantity; as two, three, or four feet; two, three, or four apples; etc.

A unit is a single thing; as one foot, one apple, etc. One is the unit and foot or apple tells the kind. Numbers are used to express how many units are taken; as two feet means two units of one kind; three apples are three units of a kind.

The Digits and Cipher—There are ten characters used to express number, and by arranging these in certain ways, according to certain rules, it is possible to express any reasonable number or quantity. These ten characters are given below with their names and the spots or balls under each shows the number of units that character represents. The first character is called a "cipher" and is used to indicate no units. The remaining nine characters are called "digits."



Expressing Larger Numbers—To express numbers greater than 9, which is the highest digit, it is necessary to begin and count these same digits over again. This gives a series of digits or counts, and the number of the series is written before the cipher or digit, after the first series, as follows:

First series,	0	1	2	3	4	5	6	7	8	9	units
Second series	10	11	12	13	14	15	16	17	18	19	teens
Third series,	20	21	22	23	24	25	26	27	28	29	twenties
Fourth series,	30	31	32	33	34	35	36	37	38	39	thirties
Fifth series,	40	41	42	43	44	45	46	47	48	49	forties
Sixth series,	50	51	52	53	54	55	56	57	58	59	fifties
Seventh series,	60	61	62	63	64	65	66	67	68	69	sixties
Eighth series,	70	71	72	73	74	75	76	77	78	79	seventies
Ninth series,	80	81	82	83	84	85	86	87	88	89	eighties
Tenth series.	90	91	92	93	94	95	96	97	98	99	nineties

The Coal Age Pocket Book

Notation—The names of the first series of numbers have been given. The second series is called the "teens"; because, in this series, the names of most of the numbers end in "teen." The naming, in this series, is a little irregular; it is as follows: Ten 10, eleven 11, twelve 12, thirteen 13, fourteen 14, fifteen 15, sixteen 16, seventeen 17, eighteen 18, nineteen 19.

The numbers in each of the following series are named by writing the name of the series before the name of the digit and the cipher always taking the name of the series; thus, for the third series: Twenty (20), twenty one (21), twenty two (22), twenty three (23), etc.; and for the fourth series, likewise, thirty (30), thirty one (31), thirty two (32), etc., and so on throughout the ten series, the last number of the tenth series being ninety nine (99).

Beyond the tenth series, it is necessary to use another figure. Instead of two figures, three are now required to express a number, and a new period of ten series is started, which is the same as that just explained, except the figure one (1) precedes the other two figures of each number, to indicate this period. As before, the period has ten series.

One-hundred period											
First series,	100	101	102	103	104	105	106	107	108	109
Second series,	110	111	112	113	114	115	116	117	118	119
Third series,	120	121	122 etc.							
Fourth series,	130	131 etc.								
Fifth series,	140 etc.									
Sixth series,	150 etc.									
Seventh series,	160 etc.									
Eighth series,	170 etc.									
Ninth series,	180 etc.									
Tenth series,	190 etc.									199

There are evidently nine of these "hundreds" periods, corresponding to the nine digits, each of which, in turn, precedes the other two figures, as shown above. For example, the two-hundred period runs: Two hundred (200), two hundred and one (201), two hundred and two (202), etc., etc., to two hundred and ninety nine (299). Then follow, in turn, the three-hundred (300) period, four-hundred (400) period, etc., to the last period of the hundreds group, or the nine-hundred (900) period; the last number of this period being nine hundred and ninety nine (999).

Beyond this point, it is necessary to use four figures instead of three. This forms a new group of nine periods, called the "thousands" group or periods. As before, the nine digits, respectively and in turn, precede the other three figures, in each number of the group, which runs from one thousand (1,000), one thousand and one (1,001), one thousand and two (1,002), etc., etc., to nine thousand nine hundred and ninety nine (9,999).

Following this is the ten-thousand (10,000) group of five figures in each number and the hundred-thousand (100,000) group of six figures. Then comes millions, 7 figures; tens of millions, 8 figures; hundreds of millions, 9 figures. For example:

One hundred and sixty five million, two hundred and three thousand, six hundred and seventy nine...	165,203,679
Twenty million, four thousand, and six.....	20,004,006

EXAMINATION QUESTIONS

Mine Foremen's Examination, Northwestern Improvement Co., Roslyn, Wash.

(*Selected Questions*)

Ques.—What constitutes the make-up of a good mine foreman? What are his duties? What should be his first consideration; second consideration; third consideration?

Ans.—The principal qualifications of a good mine foreman are a wide experience and knowledge of mining in all its branches; a good judgment of mining conditions; a thorough knowledge of the mine of which he has charge; ability to handle men; skill in directing others and planning the work so as to accomplish the greatest results in the least time and at the smallest expense. A mine foreman must be fearless, firm, fair, just and considerate in all his dealings; a good judge of human nature and of what constitutes a day's work. He must be patient, industrious and sober.

It is the duty of the mine foreman to devote his entire time to the operations of the mine. He must superintend every detail of the work, either personally or through his assistants, and should, as far as possible, visit every working place at least every alternate day when the mine is working. He must inspect all machinery and appliances to see that they are in safe condition, giving particular attention to the ventilation and the drainage of the mine. He must inspect all airways, haulage roads and travelingways and remove all dangers found or that are reported to him, permitting no men to work in such places until the same are made safe. He must provide the needed supplies of timber and other material and must see that the mining laws and mine regulations are strictly obeyed.

The first and most important consideration is the safety of the men in his charge; second, the security and preservation of the property; third, the economical extraction of the coal so as to avoid undue loss and expense.

Ques.—If the safety lamp gives no indication of the presence of gas, is this fact proof that the atmosphere is safe to enter?

Ans.—No. The mine air may still contain poisonous gases in sufficient quantity to be dangerous or fatal to life. Air containing one-half of 1 per cent. of carbon monoxide gas may prove fatal to life in a short time. The presence of this gas would not be indicated by the safety lamp; but a caged mouse or bird, if carried into such an atmosphere, would betray by its actions that the air was not safe to breathe. These small animals are affected by the poisonous gases in much less time than is required to affect the human system.

Ques.—How would you proceed to remove firedamp (afterdamp?) from a section of a mine, after an explosion? What dangers would you expect and how would you overcome them?

Ans.—The removal of noxious or dangerous gases from a section of a mine, after an explosion, will depend on the conditions that exist in the mine. In general, the work must be conducted by first removing all men from the mine except those engaged in the work. Reliable men should be stationed at each approach to the return airway, leading from the affected section to prevent anyone from entering the return-air current. Only safety lamps should be used. The circulation of air should then be increased in that section of the mine, as much as possible, either by speeding the fan or by such a regulation of the air current as to supply a larger quantity of air to that particular section. The work must be performed on the intake side and its progress carefully watched, by making the necessary tests of the air, from time to time. Wherever necessary, temporary brattices should be erected so as to deflect the air current in such a manner as to sweep out the accumulated gases from the workings. In all cases, sufficient time should be given for the air to act upon the gases, diluting and removing them from their lodging places. Due precaution should be taken against unexpected roof falls driving the gas out upon the lamps of the workmen.

Ques.—An airway is 10 ft. 5 in. wide and 6 ft. 9 in. high; find the area of the airway. If the velocity of the air current is 450 ft. per min., what quantity of air is passing per minute in this airway?

Ans.—The sectional area of the airway is found as follows: 10 ft. 5 in. = 10.41 ft.; 6 ft. 9 in. = 6.75 ft. The sectional area is then $10.41 \times 6.75 = 70.27$ sq.ft., nearly. The quantity of air in circulation is then

$$Q = av = 70.27 \times 450 = \text{say } 31{,}620 \ cu.ft.$$

Ques.—The quantity of air passing in an airway is 120,000 cu.ft. per min., and the water gage produced is 2 in.; what are the units of work performed each minute and the horsepower producing the circulation in the airway?

Ans.—A water gage of 2 in. corresponds to a pressure on the air of $2 \times 5.2 = 10.4$ lb. per sq.ft. The work performed each minute, or the power on the air, is found by multiplying the quantity of air in circulation by the pressure in pounds per square foot. Thus,

$$U = Qp = 120{,}000 \times 10.4 = 1{,}248{,}000 \ ft.\text{-}lb.$$

The horsepower producing the circulation is the effective horsepower or the horsepower on the air, which is $1{,}248{,}000 \div 33{,}000 = 37.8$ hp.

Ques.—A slope is 2600 ft. long, measured on a pitch of 30 deg.; what will be the horizontal distance, and what is the vertical height of the slope? What is the pressure on a pump pumping water from the bottom of this slope, disregarding the pipe friction?

Ans.—The horizontal distance, or horizontal length of this slope is

$$2600 \times \cos 30^\circ = 2600 \times 0.866 = 2251.6 \ ft.$$

The corresponding vertical height of the slope is

$$2600 \times \sin 30^\circ = 2600 \times 0.5 = 1300 \ ft.$$

Since the water pressure due to a foot of vertical height is 0.434 lb. per sq.in., the pressure exerted on this pump is $1300 \times 0.434 = 564.2$ lb. per sq.in.

COAL AND COKE NEWS

Washington, D. C.

Representative Hamlin has introduced a bill (Apr. 23) to prohibit the interstate shipment or attempted shipment of convict-made goods, or products of mines in which convict labor is employed.

The bill requires that "no carrier of interstate commerce shall knowingly transport or accept for transportation any goods, wares or other articles of merchandise manufactured in whole or in part by convict labor, or knowingly transport or accept for transportation the products of any mine or factory in which convicts are employed or permitted to work, and which goods, wares or other articles of merchandise or products of mines are to be carried to any point in any state, district or territory of the United States outside of the state where produced or mined and each separate shipment prohibited herein shall constitute a separate and distinct offense."

The bill further provides that any agent of any interstate carrier who violates the law shall be adjudged guilty of a misdemeanor punishable by a fine of not less than $1000 or by imprisonment not to exceed six months. Furthermore the bill requires that "it shall be unlawful for any person, firm or corporation—to ship, attempt to ship or offer for shipment to any interstate carrier any goods, wares or other merchandise, or products of any mines—produced or manufactured wholly or in part by convict labor to any point in any district territory or state in the United States outside the state where such goods, wares or other merchandise or products of mines are made or produced." The same penalties are made to apply in this case as in the case of the violation of the earlier provisions of the measure.

Senator Crawford has introduced a bill which has been referred to the Committee on Public Lands, to provide for the leasing of public lands containing coal, reading in part as follows:

That all public lands and lands included in national forests containing workable deposits of coal are hereby classified as coal lands, and hereafter shall only be disposed of by leasing the same in the manner provided in this Act, and that the title in fee to all such coal lands shall remain in the United States.

Sec. 2. That any citizen of the United States of the age of twenty-one years who has not acquired title to coal lands from the United States, or any association of persons who are thus severally qualified, or any corporation duly empowered to transact business in the State or Territory in which the land is situated, not holding title to coal lands, may make application to the Secretary of the Interior to lease coal lands, and the Secretary of the Interior is hereby authorized to lease to such applicant or applicants not to exceed to any one person, association, or corporation two thousand five hundred and sixty acres of coal land, exclusive of the surface, in legal subdivisions of not less than one hundred and sixty acres each, which said subdivisions need not be contiguous, for a period not exceeding twenty-five years, as long as such person, association, or corporation shall conform to and abide by the terms of the lease and all of the laws of the United States and lawful regulations of the Department of the Interior as shall now or may hereafter be enacted or made.

Sec. 3—That the United States shall at all times have the preference right to purchase so much of the coal produced by any mine or mines operated under the provisions of this Act as may be deemed necessary for the use of its Army and Navy, and at such reasonable and remunerative price as may be fixed by the President, but the producer or producers of any coal so purchased who may be dissatisfied with the price thus fixed shall have the right to prosecute suits against the United States in the Court of Claims for the recovery of any additional sum or sums he or they may claim as justly due upon such purchase.

WILKES-BARRE, PENN.

Examinations for certificates for Mine Foreman and Assistant Mine Foreman were held at Pittston, Wilkes-Barre, Nanticoke and Plymouth on Apr. 22 and 23. Eighty-one men took the examination at Pittston, 65 at Wilkes-Barre, 49 at Plymouth and 55 at Nanticoke. The boards holding these examinations were presided over by Messrs. McDonald, Jennings, Davis, Williams and Walsh, state mine inspectors of the several districts contained in the Wyoming Valley.

The miners in the Five Foot Vein in the Henry Colliery of the Lehigh Valley Coal Co. are dissatisfied with the scale for rockwork, and at a meeting it was decided to refer the matter to the conciliation board for adjustment. Miners in the Red Ash Vein of the Dorrance Colliery of the same company, being dissatisfied with the yardage paid them, adopted another course of settling the dispute, but after being idle for eight days, decided to return to work, and allow the conciliation board to settle the trouble.

To bring the mining of coal to a point where all may have a chance to see the technical parts of the industry, the representatives of the different coal companies in and about Wilkes-Barre have prepared many interesting coal exhibits for the Greater Wilkes-Barre Industrial Exposition, to be held during the week of May 10-17.

Contractors have broken ground for a model village that is to be built around the Underwood Colliery of the Pennsylvania Coal Co, on the hills east of Throop. The village will consist of 28 double houses of extra-strong construction, to withstand mine settlings. The houses will be of timber, 28x40 ft. in size, and their sills or underframes are to be of 6-in. square Georgia pine, in single sticks for the length and breadth of the houses. Several frame dwelling houses are also to be erected for the colliery bosses. The village is to be laid out with wide streets and roomy garden plots for all the houses.

It will have a central plaza, and part of its equipment will be two public baths, one for men and one for women. The baths will be built of concrete, and modern in detail. Hower & Stender, contractors, of Scranton, are in charge of the construction work. The Underwood Colliery is to be one of the most modern in this part of the state. It will open up big tracts of virgin coal, and give employment to many men for several years. It is expected that the colliery will be ready for operation in a few weeks.

PENNSYLVANIA

Anthracite

Frackville—The Whip-Poor-Will breaker crashed to the ground recently in the course of a high wind storm. This colliery has not been in operation for the past five years.

Shamokin—Fifteen firemen, employed at the Reliance colliery, went on strike, Apr. 18, claiming that they were being overworked and demanding the assistance of more men.

A tie-up at the collieries of the Mineral R.R. & Mining Co. was caused by a strike of 2500 employees, Apr. 22. The men refused to work any longer until all the men at the mines had paid their back dues to the Mine Workers' organization.

Harrisburg—The McDermott bill, which proposed to make it unlawful to use the electric current in the mine where miners are loading or mining coal, or in gaseous mines, has been killed in the House on the second reading. If it had become a law it would have meant an increase in the price of coal.

Hazelton—The 1800 mine workers at the collieries of the Lehigh & Wilkes-Barre Coal Co. have voted to return to work after a two-day "button" strike.

Bituminous

Fayette City—Four miners were badly burned by an "after explosion" in O'Neil's mine, Apr. 18.

Finleyville—A terrific explosion killed perhaps over a hundred miners in the Cincinnati mine of the Monongahela River Consolidated Coal & Coke Co., Apr. 23. About 70 bodies have been recovered, but it is feared that many more are in the mine still.

Hakerton—The gigantic frame tipple of the Sterling Coal Co. has been destroyed by fire. The tipple was the largest in that section of the country and its destruction will cripple the workings.

WEST VIRGINIA

Charleston—By a vote of 84 to 9 the striking miners of Cabin and Paint Creeks accepted the proposition made recently by Governor Hatfield, with a view toward a settlement of the long strike. While the miners attempted to attach a construction to the proposition to the effect that there shall be no discrimination against union employees, they will leave the final construction to the governor. The operators accepted the proposition a week ago and have put it into effect in their mines.

The New River miners' convention has decided not to call a strike, pending efforts which they will make to have a conference with the operators of that field, to be held in Charleston, May 10. It is said that recognition of the union will be one of the points which the miners will insist upon. Should the operators decline a conference, the miners will then consider the question of a strike.

Wheeling—Two hundred miners employed in the Gaylord No. 2 mine have gone on strike and the mine is idle as a consequence. The refusal of the management to employ extra drivers caused the men to strike.

KENTUCKY

Louisville—The Louisville & Nashville R.R. Co. is authoritatively reported to have consented to an important concession to the operators in the Harlan County coal field, in the voluntary removal of the 10c. differential formerly charged on coal from that district to points north of the Ohio River over the rate from the Jellico district. The action of the road is almost wholly due to the efforts of the Southern Appalachian Coal Operators' Association, which has had the matter up with the company through its traffic committee for some time.

It is also possible that the same concession will be extended by the road to the Harlan operators with reference to Ohio River crossings and Kentucky points, although this is not an association matter, and has not been determined by the road. The removal of this differential is expected to give Harlan County coal a powerful impetus in the northwestern markets, where it has already established a high reputation.

Harlan—A systematic publicity campaign for Harlan County, Ky., and the Harlan coal fields, is being planned by the board of trade of Harlan, Ky., with a view to disseminating broadcast information regarding the resources of that section, which has experienced a remarkable development during the past two years, and which it is said is capable of still further and more extensive working. It is proposed to spend not less than $10,000 for this purpose.

One of the plans is the publication of a prospectus, showing the exact distribution of coal throughout the county, as far as possible. It is also the intention of the backers of the plan to make a powerful effort to induce the Southern Railway to build into the county to afford competition with the Louisville & Nashville, which now has a practical monopoly of the carrying of the coal and other products of the woods and mines of Harlan.

Spottsville—In the Henderson district, work has been begun with a view to reclaiming the coal mine at that place, which was completely flooded by the recent high water. It is not yet known how extensive the damage is which was done by the water, but it will reach $50,000 if the mine is not reclaimed.

OHIO

Columbus—A settlement of the miners' strike at the Trimble mine of the Hisylvania Coal Co., of Columbus, Ohio, was effected recently by John B. Moore, president of the local district of the United Mine Workers, and the officers of the company. By the terms of the settlement the company agreed to pay full wages to discharged men during the enforced idleness while a national representative of the Mine Workers conducts an investigation of the difference.

ILLINOIS

Galesburg—The Star Coal Co. has sustained a severe loss in the destruction by fire of the buildings of its large mine a short distance north of Cuba. The mine had been shut down for two weeks while improvements and repairs were being made. About 150 men are idle. The loss caused by the fire is estimated at approximately $30,000.

The company is undecided as to whether to rebuild or not.

FOREIGN NEWS

Beuthen, Germany—The strike of the miners in the upper Silesian coal fields is spreading rapidly. It is estimated that, to date, 25,000 men have laid down their tools.

South Wales—More than 50,000 miners in south Wales are expected to go out on strike as a protest against the employment of nonunion labor. An attempt to bring about an agreement with the employers has failed.

RECENT COAL AND COKE PATENTS

Automatic Dump Car—E. L. Stoltzfus, Gap, Penn., and I. B. Miller, Paradise, Penn. 1,057,683, Apr. 1, 1913. Filed Apr. 17, 1912. Serial No. 691,312.

Gravity Coal Bin—S. Otis, Chicago, Ill., assignor to Gravity Coal Bin Co. a corporation of Maine. 1,052,945, Feb. 11, 1913. Filed July 11, 1907. Serial No. 383,284.

Gravity Coal Screen and Bin.—S. Otis, Chicago, Ill., assignor to Gravity Coal Bin Co., a corporation of Maine, 1,052,946, Feb. 11, 1913. Filed July 7, 1907. Serial No. 383,285.

Method of Producing a Substantially Complete Combustion of Fuel. F. H. Brown, Philadelphia, Penn., 1,052,279, Feb. 11, 1913. Filed Dec. 9, 1908. Serial No. 466,530.

Igniting Device for Miners' Safety Lamps—P. Wolf, Zwickau, Germany, 1,052,783, Feb. 11, 1913. Filed April 30, 1912. Serial No. 694,190.

Adjustable Shoe for Mining Machines—C. E. Rogers, Logan, W. Va., 1,052,517 Feb. 11, 1913. Filed April 25, 1912. Serial No. 693,230.

Apparatus for Smoke Prevention and Fuel Economizing in Connection with Steam Generators. J. Rothwell, Walkden, Eng., 1,052,518, Feb. 11, 1913. Filed June 20, 1912. Serial No. 704,923.

Apparatus for Utilizing Coke Oven Heat—E. C. Morgan, assignor to Titlow Waste Heat Power Co., Uniontown, Penn. 1,054,859, March 4, 1913. Filed Jan. 28, 1909. Serial No. 474,641. Also 1,054,860, March 4, 1913. Filed April 26, 1909. Serial No. 492,133.

Miner's Lamp—A. L. Tombelaine, Villanuova-Minas, Spain. 1,044,001, March 4, 1913. Filed Dec. 15, 1911. Serial No. 665,884.

Coal and Ore Washer—H. W. Falker, Ashland, Penn. 1,055,731, March 11, 1913. Filed Sept. 7, 1912. Serial No. 719,067.

Apparatus for Handling Coke—W. Feicks, Bethlehem, Penn. 1,055,456, March 11, 1913. Filed March 31, 1910. Serial No. 552,667.

Retort Coke Oven—Chas H. Hughes, assignor to Semet Solvay Co., Syracuse, N. Y. 1,555,536. March 11, 1913. Filed August 19, 1912. Serial No. 715,736.

TRADE CATALOGS

The Joseph Dixon Crucible Co., Jersey City, N. J., has just issued a booklet entitled "Graphite for the Boiler." The action of graphite upon scale-forming impurities in boiler-feed water is not chemical. It neither dissolves the scale nor attacks the metal. The particles of graphite gradually penetrate existing scale and soften it to such an extent as to render it easily removable. Once removed scale can never firmly adhere to the boiler surfaces as long as graphite treatment is continued.

PERSONALS

John Mitchell, former president of the United Mine Workers of America, has been designated by Governor Sulzer, of New York, to be state labor commissioner.

C. J. Trager has resigned his position as senior inspector with the National Inspection Co., of Chicago, to accept the position of insurance manager of the Pittsburgh Coal Co. Mr. Trager took charge Apr. 16.

H. D. Johnson has recently started in the engineering business for himself. His specialties are civil, mining, consulting and economic engineering, and his office address is 617 Traders Bank Building, Scranton, Penn.

Earle Martin, of Chattanooga, Tenn., president of the Continental Coal Corporation of Tennessee and Wyoming, has resigned his position with that company. Vice-president H. L. Cory will assume the duties of president of the Tennessee company, while Vice-president W. L. Moss will assume the office of president of the Wyoming company.

CONSTRUCTION NEWS

Atlantic City, N. J.—Irwin & Leighton are estimating on plans for coal pockets and bins to be erected at Atlantic City for the Atlantic City R.R. W. Hunter is chief engineer.

Hazard, Ky.—It is reported that the work of preparing the D. Y. Combs property near this city for production by early fall is being pushed rapidly by the parties interested in its development.

Connellsville, Penn.—The Tide Water Coal Co.,, of Pittsburgh, has taken leases on 1000 acres of coal in Parker Township, near Bruin, W. Va., and has commenced the construction of a colliery.

Connellsville, Penn.—It is rumored that the Northwestern System of the Pennsylvania Lines is planning to extend the Cleveland & Pittsburgh branch from Powhatan, Ohio, to a point down the Ohio River, opposite New Martinsville, W. Va.

Rockford, Ill.—The construction of the Chicago & Northwestern extension south through central Illinois to connect with its line in the coal fields is being pushed rapidly. The road is being doubletracked to provide for a large traffic. This will give a new and shorter route between St. Louis and St. Paul.

Bristol, Tenn.—The Black Mountain Coal Land Corporation has awarded to the Montgomery Coal Washing & Manufacturing Co., of Birmingham, Ala., a contract for the construction of a coal-washing plant at Pockett, Ala., including jigs, settling tank, elevating machinery, screens, etc., with an hourly capacity of 150 tons.

Shenandoah, Penn.—The new shaft at the Hammond colliery will soon be connected with the breaker and the hoisting slopes will then be dispensed with. It is expected that the colliery will close down about May 1 in order to make the necessary connections. The work involved will require about one month's time.

Hazard, Ky.—The work of construction on the tipple, tracks, and other works of the Tennessee-Hazard Coal Co. has been placed under the direction of T. H. Hopkins, of Anthras, Tenn., a well known coal operator of that section, who will push the equipment of the company to early completion, the object being to start production during the current season.

Centralia, Penn.—The Rhoads Contracting Co., of Ashland, has started work on an extensive stripping contract for the Lehigh Valley Coal Co., at Centralia. Operations will be started on Mt. Carmel from the northwestern side of Centralia for a distance of 7 miles. The coal is of good quality and close to the surface and it is estimated that it will require from 7 to 10 years to get it all out.

St. Marys, Penn.—Work on the new Shawmut bridge across the Allegheny River, at Mahoning, has been resumed since the floods subsided and completion is promised in August. Operations at Furnace Run are progressing fast. The new tipple is finished and shipments will begin as soon as cars are provided by the Buffalo, Rochester & Pittsburgh R.R., which will handle the coal from these new mines till connection can be made with the Shawmut line by the completion of the bridge.

NEW INCORPORATIONS

Bergholz, Ohio—The Bergholz Coal Co. has filed papers with the secretary of state decreasing its capital stock from $20,000 to $10,000.

Los Angeles, Calif.—The Briquette Fuel Co., capital stock, $400,000. Directors: F. R. Thomas, F. W. Steddom, A. E. Steddom, Q. McCurdy and F. E. McCurdy.

Cleveland, Ohio—The Short Creek Coal Co.; capital stock, $600,000; to acquire coal lands and mine coal. Principal offices, Cleveland. Incorporators: J. J. Roby, E. B. Thomas and C. A. Niman.

Fairmont, W. Va.—The Fairmont & Cleveland Coal Co., capital stock, $600,000; to operate in Marion County. Incorporators: W. N. Engle, T. L. Henderson, R. R. Wallis, Anthony Bowen and J. R. Burns.

Wellston, Ohio—The Oreton Mining Co. has been incorporated with a capital stock of $100,000, to mine and deal in coal. The incorporators are: George B. Davis, E. B. Blair, George L. Cugle, C. Ims and N. M. Irwin.

INDUSTRIAL NEWS

Boise, Idaho—Coal has been discovered in Boise County on the farm of Julius Anson. The seam is 4 ft. thick and is a good commercial coal.

The Northern Briquetting Co. was organized last winter with a capital stock of $500,000. The new plant is to have an initial capacity of 50 tons of briquettes a day.

Colver, Penn.—The Ebensburgh Coal Co., which operates mines at Colver, is planning to start a dairy on its large farm. Holstein and Jersey cows have been purchased.

Plymouth, Penn.—The Kingston Coal Co. is installing a new electric pump on the river bank near Fletcherville Park, Plymouth, to furnish a supply of water for the Gaylord Colliery.

Williamson, W. Va.—The Leckie Collieries Co. expect to develop 1000 acres of coal at Williamson. They are getting a mine into shape which will have a daily capacity of 1500 tons.

Pottsville, Penn.—A large seam of coal has been opened near Pottsville by the St. Clair Coal Co., and it is claimed that this new operation will produce 10,000,000 tons of virgin anthracite.

Rochelle, Ill.—The Geo. D. Whitcomb Co. is moving into a new factory which they have just built. This step will enable them to more than double their present output of gasoline locomotives.

Punxsutawney, Penn.—Local men, said to be backed by New York Central R.R. interests, have leased 8000 acres of coal land at Marion Center. The acreage adjoins a large plot now held by the railroad. No price was mentioned.

Pittsburgh, Penn.—The Kendall Lumber Co., whose general offices are in the House Bldg., in Pittsburgh, Penn., has acquired some coal lands in West Virginia which it proposes to develop during the coming summer.

Connellsville, Penn.—The holdings of the Kingwood Coal & Coke Co., situated on the West Virginia Northern and the Morgantown & Kingwood railroads, in the vicinity of Kingwood, have been sold recently to Cleveland capitalists for $60,000.

Joplin, Mo.—The Ellsworth-Klaner Construction Co. has leased 240 acres of coal land, one mile south of Minton, Mo., and will develop it with a steam shovel. This land was recently purchased from L. C. Chancellor by E. V. and A. K. Lanyen.

Minot, N. D.—The Northern Briquetting Co. has purchased a building site, consisting of 5½ acres west of the Great Northern depot. It is understood that plans for building operations are under way and will be completed in a short time.

Rock Island, Ill.—The Carpenter Coal Co. has received a consignment of a new coal which is being put on the market, known as the Pocahontas. It is a crushed West Virginia smokeless, mixed with hydrocarbonized pine pitch under a pressure of 100 lb.

Seattle, Wash.—Sixteen students from the College of Mines, University of Washington, spent Apr. 5 to 14 in an inspection trip in the western part of the state. Rock tunneling, coal mining, placer mining and milling were among the subjects studied.

Mobile, Ala.—According to a statement made by Vice-president J. H. Bernhard, the Alabama & New Orleans Transportation Co. will operate barges between Tuscaloosa via Mobile and Gulfport to New Orleans, and will bring down 600,000 tons of coal annually.

Joliet, Ill.—The Murphy Linskey Kasher Coal Co. is planning to widen its field of operations. The company has recently purchased the mining property and rights of a Pontiac company at a court sale.

Batavia, N. Y.—It is said that an effort will be made to recommence work on a shaft which was sunk 40 years ago for the purpose of reaching and developing a bed of coal. Parties are endeavoring to obtain the necessary finances for this purpose.

Jellico, Tenn.—The Interstate Coal Co. has purchased the property of the Smith-Jellico Coal Co. in this section, aggregating about 1000 acres, and has also taken over the lease on the property held by the Anchor Coal Co. The purchaser will proceed to develop the property.

Salem, Ohio—The Salem Coal Co., which operated a mine east of Salem on the K. & O. electric line, has sold out its holdings to the Baldwin Mining Co. The purchaser contemplates improvements to the value of $10,000. The capacity of the mine will be largely increased.

Washington, Penn.—J. V. Thompson and others have closed a deal for 800 acres of coal land in Gilmore Township, Greene County, for $160,000. The land was bought from a number of farmers and adjoins a tract of 500 acres which was purchased by the same parties 2 weeks ago for $100,000.

Pittston, Penn.—The Delahunty Dyeing Machine Co. has placed upon the market a rivetless conveyor chain with one-piece inserted attachments. This chain requires the use of no tools of any kind and only slack enough to equal twice the diameter of the pin to enable anyone to either connect or disconnect the links.

Chicago, Ill.—A meeting of the St. Louis, Peoria & Northwestern R.R. has been called for June 18 to consider the purchase of the Macoupin County R.R. and the issuance of $10,000,000 in bonds to equip the roads. This purchase will mark the extension of the Chicago & Northwestern lines into the coal fields of Illinois.

DuQuoin, Ill.—It is rumored that a large gas company is soon to be formed in Illinois. The plan is to erect a monster coke plant at some central point, probably Marion, and to supply gas to the surrounding towns. Marion is located in the heart of the field and is considered the most practicable place for the location of the plant.

Williamson, W. Va.—The Skillet Fork Land Co. has taken over the 1600-acre tract of coal land on Gilbert Creek, owned by Lee Ellis. This purchase has again revived the talk of a railroad extension along the Guyan River. It is believed that the Chesapeake & Ohio will be the first road to build. The price paid was in the enighborhood of $60,000.

Philipsburg, Penn.—John Lodhrie, of Windber, has leased 400 acres of coal land near Dunio. A shaft will be sunk at once and it is expected that 1000 tons will be mined daily within a short time. The agreement provides that Mr. Lodhrie shall not mine less than 2000 tons of coal daily as soon as the developments contemplated are completed.

Connellsville, Penn.—W. E. Woods and M. A. Hadden have options on more than 16,000 acres of land in Jefferson Township and are now drilling test holes on their property. They have also taken options on about 6000 acres of land north of Sullivan and will shortly begin testing that, together with 12,000 acres west of Scott City which they have also optioned.

Pittsburg, Kan.—By order of the state inspector three mines belonging to the Central Coal & Coke Co., the Western Coal & Mining Co. and the Chapman Coal Co. have been closed down. The inspectors found unsanitary conditions, poor ventilation and an insufficient number of manholes. The companies promise to have the mines in good condition by next week.

Charleston, W. Va.—The West Virginia Equipment Co. has opened offices and salesrooms at 901 Kanawha St., Charleston, W. Va. This firm has secured the local agency for many of the best known and most reliable firms in the country manufacturing mining and power-plant equipment, and is, therefore, prepared to quote upon steam or mine specialties of all descriptions.

Salt Lake City, Utah—D. S. Tracy and W. Norton, of Ogden, have purchased from the government 280 acres of coal land in Carbon County for $40,600. The land lies near Spring Glen, on the Denver & Rio Grande. It is understood that the purchasers except other Ogden men to acquire adjoining lands and eventually open up a coal mine. The rate of the purchase was about $145 an acre.

Dante, Va.—Recent estimates state that the Carolina, Clichfield & Ohio R.R. carries annually over 15 lines 20,000,000 tons of coal from the mines about Dante to the southern and southeastern markets. This road is now being extended through the Virginia-Kentucky mountain from Dante to Elkhorn City, Ky., a distance of 10 miles. The new work will include the longest tunnel in the South.

Fort Scott, Kan.—It is reported that the Frisco road intends to develop the coal underlying the southern part of Bourbon County. The railroad has taken options on thousands of acres of farm lands in that district and has secured leases which were held by the Miller Bros. company. A 3-ft. seam is said to underly all this part of the county. Should coal be found the land is to be purchased for $100 an acre.

Royalton, Ill.—The mine of the Royal Big Muddy Co., which went into the hands of receivers over a year ago, has been taken over and is being put in operation by J. L. Mitchell, operator of the North mine at this place, and also of mines at Coffeen. During the past week there has been a strike at this mine, and the mine manager contends that it is another case of where the miners want to dominate the policy of the company.

Petersburg, Ind.—Jean, Brown & Co., coal operators, have leased about 100 acres east of this city, along the E. & I. R.R. and will sink a shaft for a railroad mine. Vein No. 2 will be worked at about a depth of 130 ft. The work of pumping out the Blackburn mines continues. It will take 90 days to complete the work. Operations have been resumed at the Littles mine and Ayrshire No. 7, and two more mines of the Ayrshire company will be pumped out in 30 days.

Wilkes-Barre, Penn.—The new breaker of the Madeira-Hill Co., purchaser of the Joseph Stark Colliery, at Hudson, has been placed in operation. This breaker replaces the one formerly operated in connection with Mr. Stark's mine, and when in full operation will have a capacity of 800 tons daily. All machinery, including the hoisting engines, is electrically operated, the current being supplied by the Lackawanna & Wyoming Valley R.R. Co., from the Plains power station.

Connellsville, Penn.—The moving picture machine has been put into action by the H. C. Frick Coke Co. as a means of bringing home to all their employees the value of the "safety first" campaign. The Frick company has been the pioneer in this movement and is still leading all the work in this line. A corps of men has started to make a tour of every plant of the company in the Upper and Lower Connellsville regions, and will give these educational entertainments at each plant.

Somerset, Penn.—It is predicted that Somerset may have another large coal operation along the Somerset & Cambria branch of the Baltimore & Ohio R.R. in the near future. The land in question consists of 750 acres of Miller vein and Prime C coal. It is supposed that the controlling force of the new venture is the Glazier Coal & Coke Co. This company has an option on the tract and will probably begin operations in the near future. The property now has 2 openings facing the Baltimore & Ohio R.R.

Baltimore, Md.—The Elkhorn Fuel Co. has become permanently organized and will at once proceed with the development of its 300,000 acres of southern coal land. The Chesapeake & Ohio Ry. will construct a branch from Beaver Creek, Ky., in order to provide transportation facilities to the new field. It is proposed to begin coal shipments by the end of the year. A great part of the lands will be leased on a royalty basis to operating companies. The Elkhorn Fuel Co. was incorporated last February with a capital stock of $30,000,000.

Philadelphia, Penn.—The Manor Real Estate Co. has practically completed the purchase of 18,000 acres of coal land in Indiana County, adjoining the Cambria County coal field. The average price was $400 an acre. Five drills are already testing the new field.

It is also stated that the Manor company has entered into negotiations with the Greenwich Coal Co. and will soon take over the holdings of that concern, amounting to several thousand acres and several fully equipped modern mines. Plans have already been made to extend the Cambria & Indiana R.R. and the Cherry Hill & Dixonville R.R. into the new field.

Clarksville, Ark.—J. E. Daley, president of the Scranton Anthracite Coal Co., has closed the preliminaries of a deal which involves $2,000,000 worth of coal mining property in Jackson County. The land in question occupies all the Spadra district except that owned by the Pennsylvania Mining Co.

The new company will be composed of Eastern capitalists. Branch agencies and storage yards will be established at Kansas City and Omaha. More than 1500 miners will be employed continuously. New machinery will be installed at a cost of $150,000 and the mines will be opened for a steady run about June 1.

Philadelphia, Penn.—It has been learned that a special meeting of the board of directors of the Lehigh Coal & Navigation Co. was held recently and a determination was reached to make a proposition for the purchase of a controlling interest in the Harwood Electric Co., west of Hazelton. The Harwood company has a total capital stock of $6,831,500 and was organized last year. Possession of this concern would mean for the L. C. & N. Co., the control of the power in the Lehigh, Schuylkill and Susquehanna Valleys.

In addition to its power plant the Harwood company owns the Harwood mine which is estimated to contain about 2,750,000 tons of marketable anthracite.

COAL TRADE REVIEWS

GENERAL REVIEW

The May anthracite trade is starting up with a good volume of business on hand, the West and Northwest opening up particularly strong. The April demand, while somewhat less than normal, was still larger than was anticipated. There is an excellent undertone to the market and a general feeling seems to pervade the trade that there will be another shortage the coming fall.

A general shortage of labor, together with the impending strike in the West Virginia field, has had a steadying effect on the Eastern bituminous market, which is in a somewhat precarious condition. There is only a modesrate buying by consumers and price cutting on the lower-grade fuels is reducing the demand for the better qualities, such as Pocahontas and New River. The accumulations at Hampton Roads are becoming so heavy that the yards are badly congested and the movement seriously restricted; the coastwise trade is light, but some relief may be obtained in the export business, which has developed to rather large proportions temporarily.

Lake shippers are opening up in a way that promises to result in a general and consistent smashing of all previous records. The demand in the Northwest is so heavy, that some are even inclined to believe that it will not be possible to supply the requirements during the time navigation is open; in such an event, this will throw a heavy load on the railroads in the Northwest just at a time when they are least prepared to handle it. Pittsburgh mine-run prices have advanced 10c. per ton to $1.50, and the majority of the companies are sold up for the season and may even have difficulty in meeting their contracts; at other outside points some large operators are already being forced into the open market to fill out their requirements. In all of the Lake shipping districts,reports of low prices have entirely disappeared and the producers are in a stronger position than at any time this year. In Ohio the railroads are calling for bids on fuel contracts which, together with a heavier steam consumption, is creating quite an active market; prices are hard and showing no tendency to decrease.

There is a shortage of cars in the Kentucky field, and a scarcity of the small steam grades because of the light demand for the domestic sizes. In the Southern market the steam coals have become slightly heavier, due to the sharp decline in the pig-iron market. Retailers in the flooded zone in the Middlewest are still short of supplies and continue holding at the winter circular except on certain grades; mines are working good, but the railroad service has not been fully restored. There is some concern being felt, even at this distant point, over the West Virginia labor situation. Contracting has been more than usually active during the week, the closing prices being stated as satisfactory to both consumers and producers.

BOSTON, MASS.

Bituminous—Prices on Pocahontas and New River continue firm, largely on account of the shortage of labor in the West Virginia fields and the threatened troubles in New River. There is only moderate buying, however, and many of the consumers are still awaiting developments in the hope that conditions will have eased materially by June or July. The accumulations at the Hampton Roads terminals are reported to be large, particularly on New River, but the export business is good and is expected to take care of any surplus. A considerable tonnage in New England has been lost to Pocahontas and New River by reason of lower prices on grades from Pennsylvania and from other districts in West Virginia.

All-rail there is a better movement and this in spite of an unusually large supply of water for the mills. A number of steam users, ordinarly dependent on Hampton Roads and Baltimore coals forwarded from tidewater points, are turning to rail delivery on account of the high prices held on the former, and the last week a considerable tonnage has been placed in that direction. Bituminous generally is in better shape than at any time since the January slump. There are fewer weak spots and for Georges Creek as well as for the choice Pennsylvania grades there is a better demand.

Anthracite—The demand for April coal in New England was much larger than was anticipated. Several of the dealers are disappointed in the proportion shipped them at the minimum price, but all cannot be served in a single month. May starts in with a good volume of business on hand, at least for the shippers who regularly look after this market. Independent coals are still quoted freely and at a discount from the company circular, but for the most part they go begging. An active demand for hard coal is reported in every direction and with the West starting up and the opinion that anthracite may be short again in the late fall becoming more general, it looks as if in the summer months the trade would not be so slow, after all.

Bituminous quotations at wholesale are about as follows:

	Clearfields	Camb. & Somer.	Georges Creek	Poca. & New R.
Mines*	$1 00@1.35	$1 25@1 45		
Philadelphia*.	2 25@2.60	2 50@2 70		
New York*	2 55@2.90	2 80@3 00		
Baltimore*			$2.85	
Hampton Roads*				$2 85
Providence†.				3.73@3.78
Boston†.				3.78@3.90

*F.o.b. †On cars.

PHILADELPHIA, PENN.

There seems to be a slightly better tone to the market, judging from the reports from various directions and the outlook for May business is much better than was anticipated when the spring or opening prices were first announced. This is doubtless due to the fact that the dealers are getting cleaned out of the coal laid in during the latter part of the winter, and are now in the market for fresh supplies. They have probably figured that the difference of 10c. per ton does not amount to much, anyhow. As a matter of fact, some of the coal that went into the stocks of the large companies, is now coming out again, to fill the current business; the mines are working full, and with the entire output, with the possible exception of some of the steam sizes, being absorbed, the outlook for the immediate future is excellent.

There seems to be a variety of opinion as regards business for the month of May. Some are optimistic, and claim that the tonnage will equal that of June, and that present indications are for even better business, while others point to the corresponding period of 1911, when business during the latter part of the month fell off considerably, that is, on direct sales. Most of the companies are kept busy during the late spring and early summer months, forwarding coal for stocking purposes in the Northwest and at the head of the Lakes, and a large proportion of this is not disposed of until the fall and winter.

The bituminous market still continues in a somewhat hazy condition, although it is reported that several large contracts have been consummated, at the prices of the operators. Taking the market in general, however, it is inclined to be dull. There seems to be a lack of the inferior coals, which were almost a glut during the past three or four weeks, and higher grade coals when sold, are realizing fairly good prices.

NEW YORK

Bituminous—There is a good heavy movement of soft coal on contract, but aside from this the local market is quite heavy and dull. There is little demand for spot coal, and odd tonnages are being offered at unusually low prices. However, supplies at tide are rather low, being somewhat reduced from last week, and the prompt market occupies a relatively strong position in that it is not being flooded with heavy shipments of consignment coal. On the whole, the local situation is regarded as normally favorable to the operators at the moment. One of the larger local companies reports that its contract requirements alone calls for approximately 70 per cent. of the highest production during last winter.

With most of their tonnage now fairly well covered, producers are showing a disposition to take drastic measures with consumers who are still holding off on contracts. Thus one operator who still has a number of contracts pending expects to withdraw his quotation shortly. The spot market is not quotably changed from last week, prices continuing nominally on the following basis: West Virginia steam, $2.55@2.60; fair grades, Pennsylvanias, $2.65@2.70; good grades of Pennsylvanias, $2.75@2.80; best Miller, Pennsylvania, $3.05@3.15; Georges Creek, $3.25@3.30.

Anthracite—The reduction of the anthracite discount from 50 to 40c. on Thursday of this week, has tended to bring about a further dullness in the anthracite trade. The market is more than normally supplied with coal for this season, but even so it is doubtful if all consumers will get as much as they require. The mines are working fairly heavy, except that the button strikes are still occurring periodically and restricting production to a certain extent. There appears to be a certain prescribed policy being adopted by the strikers now. Thus a certain colliery, or group of collieries, are subjected to the strike, which is persevered in until the union men accomplish their end and the trouble is then precipitated at another point.

Stove coal is still in the heaviest demand and is becoming quite short in supply. With the heavier production through April, the steam grades have naturally become somewhat longer and are now fairly easy with the exception of rice, which appears to be permanently in short supply. With the curtailed work at the mine, because of the button strikes, the car supply has been sufficient for all requirements. The indications are that May will see the trade rather less active than in previous years. The current market is about as follows:

	Circular	Individual—Lehigh	Individual—Scranton
Broken	$4 60	$4 45	$4 60
Egg	4 85	4 70	4 85
Stove	4 85	4 70	4 85
Chestnut	5 10	4 95	5 10
Pea	3 50	3 35@3.45	3 10@3.20
Buckwheat	2 75	2 25@2 45	2 50@2 75
Rice	2 25	1 90@2.00	2 25@2 35
Barley	1 75	1 45@1.70	1 60@1 75

PITTSBURGH, PENN.

Bituminous—Operators controlling the major part of the Pittsburgh district production have now advanced prices on mine-run and nut coal by 10c., this being in line with our report of last week, stating that some sales of lake coal had already been made at $1.50. Some operators who have formally taken the position on the higher prices quote them only on new inquiry, undertaking for the present at least to cover belated old customers at the former prices, but others are quoting the advances in every instance. No change is made in slack and nut, as they are relatively plentiful during the lake season, but an advance in these is naturally presaged for the fall, if conditions hold good. Prices are now quotable as follows: Slack, 90c.; nut and slack, $1.05; nut, $1.25; mine-run, $1.30@1.40; ¾-in., $1.40@$1.50; 1¼-in., $1.55@1.65, per ton at mine, Pittsburgh district

On the basis of production at the rate the operators are likely to achieve, making reasonable allowances for car and labor shortage, etc., the great majority of the companies are now sold up for the season. They may easily have difficulty in making full shipments against their present contract obligations, while on the other hand particularly good operations may result in free coal being offered from time to time. There appears to be considerable Lake demand still unsatisfied. Car supply is fairly satisfactory, but the movement is sometimes poor, closing mines occasionally for a day because the previous day's run is not moved; the first day of the week two important mines were reported closed from this cause. About 75 per cent. of the full rated capacity of the district is in operation.

Connellsville Coke—The market showed softening tendencies in the late days of last week, some prompt furnace coke being sold down to $2.10 and even $2, but the offerings were light at these figures and the cut prices were due simply to the light absorbing power of the market. The Producers' Coke Co. continued to quote $2.25. Last Sunday was the Greek Easter, and work at the opening of the week has been light, operators failing to make full shipments on contracts, which is likely to bring in inquiry later in the week and stiffen the market. Meanwhile it is quotable nominally at $2.25. Contract coke is purely nominal, the figure set by some operators being $2.50, for second-half. Foundry coke remains quotable at $3@3.50 for both prompt and contract, on recognized brands, but indifferent coke can be had for less.

BUFFALO, N. Y.

A Buffalo mine representative claims that his company has withdrawn quotations from the entire jobbing trade for the reason that their coal is sold so far ahead that they have to buy in the open market right along. Many of the other heavy operators also refuse to make any more sales as their entire output for the season is placed. This report from the bituminous trade is becoming common. The market has stiffened so steadily for several weeks that the seller is now more confident of the future than he has been at any time in several months. It appears that all sections are eager for coal, not because production is light, but because consumption is heavy. All reports of low-priced coal on the market have disappeared, though they were plenty enough a month or so ago. At that time even the bulls in the trade were beginning to weaken, most of them seeming to look for the market to break before long. The trade is now safe for several months at least, at prices that are decidedly more satisfactory than they were a year ago. As a rule all sellers have contracted as much as they care to this season and will not accept any more business except at their own prices.

The stiffness in bituminous is beginning to be felt in the steam sizes of anthracite, which in some instances have sold at an advance of 10c. a ton. Slack is strong, some dealers not being able to get as much of it as they need. With such conditions in effect all bituminous prices are strong, quotations being on the basis of $2.80 for Pittsburgh select lump, $2.65 for three-quarter, $2.55 for mine-run and $2.15 for slack. Coke is also stronger, the top price being $5 for best Connellsville foundry.

The general anthracite trade is quiet, jobbers and consumers even refusing to wake up as the end of the month approaches. There must be some Eastern trade, as the shipments for the Lakes are not sufficient to satisfy the needs, though the anthracite line trade is light. There was more coal held over by consumers than has been the case in recent years, which accounts for the light demand. Shipments by lake for the week were 131,000 tons.

BALTIMORE, MD.

The local market has shown considerable increased strength and there are some reports to the effect that the supplies are becoming inadequate. There seems to be a feeling among consumers that prices have touched the low point and, as a result, there is a general movement to cover requirements. The better grade coals became scarce toward the close of the week, Georges Creek selling around $1.70, with the next lower grade at about $1.45 on contract, and the demand strong. The low grades have shown no improvement, and are still being quoted at 70c. with the market being over-supplied.

Shipments appear to be rather light at the present time, a number of the mines taking advantage of the dull period to effect long-needed repairs. The car supply is also rather poor, considerable of the coal equipment having been withdrawn for use in repairing the tracks washed out by the flood. It is believed in some quarters that the long delay to traffic occasioned by the flood will set back the general movement so materially that there are probabilities of an acute situation developing the coming fall. It seems reasonable to believe that Lake shipments will not be up to the usual tonnage during the early part of the season, so that the total movement to the Northwest, by way of the Lakes, will not be up to requirements. In such an event, the deficiency will have to be made up by rail shipments which will throw a heavy strain on the roads just at a time when they are least prepared to handle it.

COLUMBUS, OHIO

Warmer weather during the past week caused a falling off in domestic business, but the greater activity of the Lake trade, coupled with a steady demand for steam grades have made the market in Ohio rather firm. Prices are ruling strong at about last week's level and outside of a slight weakness in fine coal, there is no tendency to decrease quotations.

One of the best features of the trade is the call on the part of several railroads for bids for fuel requirements for the coming year. None of the larger contracts have been awarded as yet although some action in that direction will likely be taken by May 1. Sales managers of the larger producing concerns are busy in the railroad fuel business now; it is believed that prices will average 5c. more on the ton than last year.

A number of steam contracts have also expired and they are being renewed generally at an advance of 5c. on the ton. Some of the steam users are buying their supply on the open market since the expiration of their contracts. There has been a slight let up in the demand for steam tonnage, but this condition is believed to be only temporary.

Retailers are trying to curtail their stocks for the coming summer. Outside of an occasional order for domestic sizes, there will be little doing in that department until the period for stocking up. Retail stocks are slightly larger than ordinary at this time of the year, due to the expected demand after the recent high waters.

Lake trade continues active and there is every indication for a good demand from the Northwest for the entire season. Dockmen are clamoring for coal and every effort will be made to ship a good tonnage. Prices on the docks are at the same level which prevailed in 1911. Last season a decline

of 10c. on the ton caused some trouble among lake shippers. Prices f.o.b. vessels are $2.10 instead of $2, the price in 1912.

Production shows a small increase in every mining section in Ohio. In the Hocking Valley, the output is estimated at 70 per cent. of the average and in the Pomeroy Bend district it is about 65 per cent. In the domestic fields the output has been small. In eastern Ohio production is slightly more than 50 per cent.

Quotations in the Ohio fields are as follows:

	Hocking	Pittsburgh	Pomeroy	Kanawha
Domestic lump	$1.50	...	$1 50	$1 50
¾-inch	1 35	$1 25	1.35	1.30
Nut	1.25	...	1.25	....
Mine-run	1 15	1 10	1 15	1 10
Nut, pea and slack	0 90	...	0 90	0 90
Coarse slack	0 80	0.85	0 80	0.80

HAMPTON ROADS, VA.

Shipments from tidewater during the last week have fallen off considerably at all the piers. The early part of the week saw some large export shipments for the Austrian and Italian Governments, these two countries so far this month having taken approximately 40,000 tons. There has also been a fair demand by the U. S. Navy, one of the large colliers taking about 13,000 tons. Coastwise business, however, has been slack during the entire week.

There has been no change in prices for standard coals which remain at $2.60 to $2.85 the latter being for contract business. There have been small sales of high-volatile coals at $2.45 and $2.50 but very little demand for this particular grade. On account of the small dumping during the week there is an accumulation of coal and the yards at the three ports are in a badly congested condition. Unless shippers arrange to move coal promptly there is a prospect of a shortage of cars and the railroads are urging shippers to make disposition of consignments.

Ground has been broken and work commenced on the coal storage plant at Sewalls Point, mention of which was made last week and it is expected when this is completed that it will take care of in the neighborhood of 50,000 tons.

Advices from England are that David A. Thomas, the British coal operator, who was here some months ago looking over the coal terminals of the different roads, sailed for this country on the S.S. "Olympic" Apr. 22. It is said that Mr. Thomas is expected in Norfolk again shortly to arrange for the exportation of coal to South America and that his shipments will probably amount to 4,000,000 tons during the first year.

BIRMINGHAM, ALA.

The local steam-coal market has grown slightly heavier during the week. There is an additional sympathetic weakness owing to the sharp decline in the pig-iron market, around which all other markets in this district revolve. It is believed that iron has touched bottom and that the steam coal and coke markets will not be seriously weakened by the closing down of any local furnace or steel plants.

The export tonnage from Alabama mines is the largest in the history of coal mining in Alabama. Dumping facilities are being enlarged at ports on the Gulf of Mexico to take care of increased export coal business already realized and the further increase that is sure to come with the opening of the Canal.

Prices on Montevalo fancy domestic lump (the highest price domestic coal in Alabama) are quoted as follows for the coming season: May delivery $3.15 with a 10c. advance in June, 15c. in July and August, 10c. in both September and October, reaching the maximum of $3.75, which price will be maintained through to February.

LOUISVILLE, KY.

The general situation in Kentucky remains unchanged except that there has been some easing up in the pressure for steam grades in certain sections, although there is still a noticeable scarcity of nut and slack. Western Kentucky operators report a sufficient production of these grades to meet requirements only; there is certainly little to be had in the spot market, and prices are exhibiting a gratifying steadiness.

Lump and block, and the cheaper domestic grades are practically unsalable at the present time and apparently with no prospects of any demand appearing in the immediate future. The customary storage season for these grades is now at hand but dealers appear to be holding off for some reason, in spite of the fact that prices are certainly attractive. This meager demand for the larger sizes is the cause of the short supply of the screened grades.

There has been some car shortage in nearly all the producing sections, especially on the lines of the Louisville & Nashville. This condition is ascribed to the heavy movement of perishable freight from the South, coal and other slow moving commodities being given little consideration at such a time. The long standing embargo of the Louisville & Nashville against Chicago, and other Northwestern points, together with the large amount of equipment still tied up or seriously delayed in the flood zone, is also operating against the favorable movement of coal.

Eastern Kentucky lump is quoted down to $1.40 and No. 2 mine-run at 85@90c.; Western Kentucky nut and slack is strong and active at 85c., with pea and slack at 35@50c.; nut is quoted at $1.05@1.10, lump, $1.30 to 1.25 and mine-run, 80@95 cents.

KNOXVILLE, TENN.

There has been a decided improvement in the local market within the past 30 days, due to the favorable weather. This is especially true of the territory north of the Ohio to which considerable domestic coal is now moving. Operators are well satisfied with sales for May and June, quite a number having disposed of their entire output for those months.

While there has been no advance in prices the market is strong, and with continued improvement, quotations are almost certain to advance. Operators are therefore well satisfied, as the demand for domestic after July 1 will naturally be strong. The flooded conditions in the North have caused a car shortage and there has been a strong demand from the flooded district. The steam market is satisfactory.

INDIANAPOLIS, IND.

Retailers in this city are still charging their winter schedule of prices, the highest in the history of the trade. The only exception is a reduction of 50c. in the price of Indiana lump from $3.75 to $3.25. They have not yet received any shipments from the Eastern fields since the reduction of prices at the mines there, so have none of the cheaper coal to offer.

The railroad service has not yet been sufficiently restored to permit of coal shipments. It is possible this has something to do with the running schedule at Indiana mines, which are getting in about four to five days a week, notwithstanding the spring weather which is limiting the demand for domestic grades. Operators report a normal business from steam users which the mines have been readily filling, with the probable exception of screenings. Prices hold steady at the recent level as follows: Mine-run $1 to $1.20; screenings 90c. to $1. Some mines and factories have not yet recovered from the unprecedented flood early in April, but with these exceptions, the industries of the state seem to be well engaged.

CHICAGO

Conditions in the Chicago market are comparatively quiet at present. The warm weather has caused dealers to concentrate their attention on the steam-trade business, and renewals of contracts are being made with evident satisfaction on the part of both the dealer and consumer.

Demand for Eastern coal is reported to be good, although some concern is felt over conditions in the West Virginia strike zone. The screenings situation is normal, and contracts are being generally renewed with Franklin County operators. The demand for Springfield coal is confined to the steam trade exclusively, with mines putting in about half time. Wholesalers are somewhat disappointed in finding that the large demand for anthracite, usually expected at this time when April prices end, failed to materialize.

A great deal of interest is being taken in gas coal. One Western buyer is in the market for 750,000 tons of this product. It is reported that there will be an increase of 10,000,000 tons in the consumption of gas coal in the Western territory this year. The price of Youghiogheny coal has advanced to $1.40 for three-quarter inch lump on contract. Prices for Kanawha have advanced to $1.25@1.30. Byproduct coke is quoted all the way from the circular price of $4.45 up to the premium price of $4.75. The hard cokes are firm.

Prevailing prices in Chicago are:

	Springfield	Franklin Co.	Clinton	W. Va.
Domestic lump	$1.97@2 07	$2 30@2.40	$2.27	
Egg		2.30@2.40		$3.95
Steam lump	$1 82@1 87		2 17	
Mine-run	1.82@1.87	2 20@2.30	1 97	3 30
Screenings		1 62 1.95@2 00	1.62	

Coke—Connellsville and Wise County, $6@6.25; byproduct egg, stove and nut, $4.45@4.75; gas house, $4.65@4.75.

DETROIT, MICH.

Bituminous—There seems to be no inclination on the part of the shippers to cut prices in order to get business, and, generally speaking, the situation at the moment, is materially stronger. More contracts are being closed, there does not seem to be any great amount of track coal, and the movement is quite normal for this period of the year. Consumers are uniformly hesitating at the advanced prices, but after additional inquiry at other points they are usually willing to close. The market in general is showing a strong, healthy tone, and dealers are very much encouraged over the outlook.

The prevailing quotations on soft coal are about as follows:

	W. Va. Splint	Gas	Hocking	Cambridge	No. 8 Ohio	Pocahontas	Jackson Hill
Domestic lump.	$1.50	.	.	.	....	$2 25	$2 00
Egg.....	1.50	.	$1 35	.	. .	2 25	2.00
1¼-in. lump....	1 25	.	.	.	.	....	. .
3-in. lump.....	1 15	$1 15	$1 15	$1 15	$1 15	. .	....
Mine-run.....	1 10	1.10	1 10	1 10	1 10	1.50	....
Slack.....	1 00	1.00	1 00	1 00	Open	Open	....

Anthracite—It is generally conceded that the local hard-coal trade is a trifle disappointing and rather below that of previous years. Shippers generally appear to have sold their April tonnages without any difficulty, but the demand as a whole has fallen below that of previous years. Consumers have grievances against the producers among which are the poor preparation and inadequate shipments last fall.

ST. LOUIS, MO.

Conditions are practically the same in St. Louis and adjacent territory as they have been for the past few weeks. A few steam contracts are being signed up, and as usual the operators are hungry for the business and are not taking into consideration the fact that there is liable to be a suspension on Apr. 1, 1914, with the usual car shortage previous to that time, and the season of high prices.

Aside from the big retail companies, no anthracite is being bought, inasmuch as the price war between the big companies still continues. During the past week there has been an accumulation of No. 1 washed nut, but the price has not dropped off any.

The prevailing circular is:

	Carterville and Franklin Co.	Big Muddy	Mt. Olive	Standard
2-in. lump.....	.....	.....	.....	$0.90
3-in. lump.....	.....	.....	$1.20	.....
6-in. lump.....	$1.15 @ 1.20	.....	1.25	1.05
Lump and egg.....	.....	$2.25	.....	.....
No. 1 nut.....	1.05 @ 1.15	.....	.....	.....
Screenings.....	0.90 @ 0.95	.....	.....	0.85
Mine-run.....	1.00 @ 1.10	.....	.....	0.80
No. 1 washed nut.....	1.35	.....	.....	.....
No. 2 washed nut.....	1.35	.....	.....	.....
No. 3 washed nut.....	1 35	.....	.....	.....
No. 4 washed nut.....	1.35	.....	.....	.....
No. 5 washed nut.....	1.10	.....	.....	.....

The St. Louis circular on hard coal for May is as follows: Chestnut, $7.50; stove and egg, $6.80; grate, $6.55. Smokeless lump and egg is $4.55 with mine-run $4; byproduct coke is $5 and gas house $4.75.

MINNEAPOLIS—ST. PAUL

It is generally thought that the dock men will hold firm this year on prices and some even look for an advance in dock quotations. Prices in cargo lots are higher and then, too, the Eastern offices are demanding more profit from the Northwestern interests and it would seem that the strife for tonnage is due to come to an end. The docks are now all activity as boats are expected at any time.

There was only a scattering buying during the first two weeks of this month by country merchants. This is the time for the visit of the tax assessor and everyone endeavors to bring stocks down to the minimum at this time of the year. Illinois coal is holding very firm for this season of the year and if prices continue firm the rest of the month there is not much chance for coal being sold this summer at the cost of production.

PORTLAND, ORE.

A cargo of coal arrived in the Columbia River this week from Australia. This is the first Australian coal brought to this section for several months or since last fall when a couple of cargoes arrived early in the season. The cargo represented less than 1000 tons, and came over virtually as ballast since the vessel had delivered a cargo of lumber and was booked to return to this coast.

Market conditions here are unchanged, and none are anticipated till summer rates are announced in a month or so.

PRODUCTION AND TRANSPORTATION STATISTICS

VIRGINIAN RAILWAY

Total shipments of coal over this road for March of the current year were 380,091 tons as compared with 303,159 tons for the same month last year. Shipments for the first two months of the year were: 1,233,244 tons for the current period and 914,605 tons in last year.

THE CAR SITUATION

American Ry. Association reports surpluses and shortages of coal equipment for two weeks ended Apr. 15, as follows:

	Surplus	Shortage	Net*

No important Dividends were announced during the week.

FINANCIAL DEPARTMENT

Delaware, Lackawanna & Western R. R.

The following are excerpts from President Wm. H. Truesdale's annual report for the year ended Dec. 31, 1912:

Earnings—The gross earnings were substantially larger than for any previous year, notwithstanding that our mining operations were suspended during April and May pending negotiations for a new schedule of wages for mine employees. The earnings from the transportation of coal were thus reduced by $816,421.

Coal Mining—The net income from the operations of this department was $2,111,897, or $427,629 more than in 1911.

From the coal produced there was also realized $1,773,611 ($32,206 less than in 1911), being the estimated value in the ground of such portion of the coal owned in fee as was mined during the year. Further progress has been made in the development of the new colliery, the Loomis, also, work is fairly under way in opening up the "Laurel Run" tract. Shafts are being sunk and other preparations made for mining the coal and preparing it for market through our Pettebone Breaker.

The tonnage produced from our collieries and washeries was 8,166,790 tons, or 278,894 tons less than in 1911, entirely due to the suspension of mining operations during the six weeks in April and May last covered by the negotiations for a new wage scale. The agreement finally reached involved a substantial increase in the wages for nearly all mine employees and covers the four years ending Mar. 31, 1916.

During the past 11 years there has been a continuous increase in the cost of mining coal; for 1912 the cost was 62c. per ton higher than in 1901. The wages of mine employees continue to increase steadily, and more employees are required each year to produce a given quantity of coal. The prices of all classes of material used are higher than ever before. In the older workings the output of coal very largely comes from either the surface veins or the thin ones lying below all those others which in the mining operation require a large amount of rock excavation and dead work. In the deeper and thinner veins the company has introduced a large number of coal-cutting machines, operated by electricity, which enable it to produce coal profitably from these veins, which it could not otherwise do. Regardless of all that is reasonably possible in the future, there is no doubt but that the cost of producing anthracite coal will in the future, as in the past, show a steady increase from year to year. The taxes levied on the coal properties also increased in 1912 more than 24%.

The outlook for the anthracite industry for the coming year seems very favorable, and present indications are that the demand for coal will be equal to the supply. It should be realized, however, that in all probability the maximum annual production of anthracite coal from the Pennsylvania fields has already been reached.

General Remarks—The Syracuse Binghamton & New York R.R. was leased to this company in perpetuity at a rental of 12% on the capital stock, effective Oct. 1, 1912, and has since been operated as a part of our system.

At the close of the year business generally throughout the country was in a highly prosperous condition, and the railway traffic of the country was at its maximum. The promise for 1913 is all that could be desired as respects volume of business and gross earnings, which, if no setback occurs and the crops of the new year are up to the average, should exceed 1912.

There is no cessation in the efforts made in Congrss and the state legislatures to secure the passage of additional laws regulating railway operations, increasing the number of employees, further decreasing their hours of service regardless of the reasonableness of so doing. There is no mistaking the trend of affairs. It is continuous toward the absolute control of all the activities of the railways by Government, national or state, stopping only at responsibility to the owners of them for their financial outcome.

EARNINGS, EXPENSES AND CHARGES

COAL AGE

Vol. 3 NEW YORK, MAY 10, 1913 No. 19

"TEACH thy tongue to say: I do not know."

Here's a proverb that can be traced back to the Talmud; from which we may infer that the "know it all" type is not a recent creation.

If you believe that there are no "know it alls" traveling with the mining fraternity, just inquire for the date of the next mine foreman's examination in your state and enter your name as a candidate but attend the sessions as a spectator. Allow us to add right here that you won't be bored to death, unless you're suffering from acute dyspepsia; and furthermore you needn't think that all of the fun will be at the expense of ignorant "cusses" who are trying to squeeze through; at any rate such hasn't been our experience.

The room where the oral part of the examination is held should be given the preference. There you'll not only be furnished with amusement but many things that have always appeared mysterious undoubtedly will be explained satisfactorily.

For example: when one of the applicants quotes a rule from a well-known book and innocently asks the examiner to explain something written therein, and the examiner in question suddenly remembers that he is needed in another room, it won't be very hard to imagine why some examiners insist that applicants for certificates leave all textbooks at home. If you read in the papers next day that Mr. So-and-So has declined to serve on the board another term because of business pressure, you can make him "dish" up the treats without half trying.

And don't think for a moment that just because you could have given the applicant a satisfactory answer that the examiner is a "dub." If you feel that way about it, before many moons you may be an examiner and some one else will get the treats.

Mr. Mining Man is there anything relating to the theory of mine ventilation that you do not know?

If you think we are joking, just reverse the question and try again; is there anything relating to the theory of mine ventilation that you *really* do know?

Considering that it is hard to decide which of these questions is ridiculous, it seems as if the average man might muster courage enough to admit, even in the presence of a beginner, that there are some things that cannot be answered off-hand.

Our examiners are not the only men connected with the industry who are ashamed at times to "fess up." Vast mining enterprises have been undertaken that were doomed to failure from the beginning, simply because some engineer ventured a random opinion rather than admit that he required time to investigate.

All of which leads us to believe that a new type of "high brows" is required in the mining industry today. Men who are able to pump information out of fellows who have had experience, and are then willing to pass the same on down the line in a manner that will provoke spontaneous discussion from both "high brows" and "low brows."

IDEAS AND SUGGESTIONS

Progressive Mine Management

By West Virginia Engineer

Coal mining is a business. Conditions must be carefully studied if the operation is to be successful. It is not only the good we do but also the good way in which we do things that brings lasting results.

Coal company officials should all coöperate in much the same way as a big family. There is a personal element in all systems; build it upward and let it be one of construction rather than one of destruction. Men must feel satisfied or they will not put forth their best efforts.

The mine official should instill interest in the work and have it done with the feeling of "all together men." Encourage, educate and train the worker. Bear in mind that selfishness and petty jealousies are often the cause of serious and unnecessary friction.

The handling of men efficiently is what increases production and lowers costs. We are all human and appreciate the good will and favor of friends. A helping hand to show an easier and better way to do some work, or a word of encouragement will surely make friends who in turn will be your well-wishers.

The men in charge must be big enough and broad minded enough to encourage those working under them; they should develop sound judgment, honesty and the spirit of fairness. Aggressiveness and competency in work should be rewarded, while the ones who shirk their duty should suffer.

An incentive for the things worth while must be sought for and encouraged. The times are progressive and successful men must be likewise. Often the experience and ideas of the most ordinary laborer will suggest worthy plans to the officials in charge.

Labor conditions are more varied than they were some years ago and naturally they must be handled differently. How often now do you find father and son working together in the same place, the former an experienced man teaching the latter to be a good miner? Good pick miners, who used to take a personal pride in their working places, are getting scarcer every year and at the present time can command almost anything within reason.

Knowledge is sufficient to correct most evils but the main trouble lies in the application. Have you ever warned a man about dangerous conditions or practices and then have him tell you that he has worked in the mines for 20 years? However, fools often serve as horrible examples.

It pays to lengthen the lives of your men and also to better their living conditions and surroundings. Discipline there must be, but make it of the sane kind. If necessary, discipline of a strict nature need not be feared. When you are in the right and working for the safety and best interests of all concerned the strictest discipline will only react for your advantage. Disrespectful familiarity must not be tolerated.

The great majority of accidents are avoidable, as they are usually the results of carlessness, recklessness or greed. Inspectors would do more good by trying to correct bad practices in the mine, rather than wait until they reach the office and write a report full of recommendations.

Playgrounds, reading clubs, Young Men's Christian Associations, churches, good schools, comfortable homes, with well fenced gardens, all encourage home life and contentment and help keep down the social unrest.

⁂

Coöperation as Related to Scientific Management

By A Colorado Engineer

Coal mining needs a change of attitude both on the part of the management and on the part of the workmen.

About every coal mine, there is, in the minds of men, a general understanding as to what constitutes a day's work; many employees feel that a certain maximum of effort must not be exceeded. Whether a man be track laying, timbering, road cleaning, machine cutting or what not, there is present in his mind a definite concept of what he or some other man has previously done at that particular work and has received a day's pay therefor.

Now this attitude of the workman is prompted not altogether by a desire to get something for nothing; it is partly the result of the attitude of his superiors, who sometimes lie awake nights trying to find a means of increasing that maximum of labor—without correspondingly increasing the rate of pay per day.

Were our workman engaged in marketing eggs instead of labor he would not be expected to deliver more than twelve eggs for the market price of a dozen, and further, did he at some time deliver fifteen eggs for the price of twelve, his purchaser would not get fifteen the next day, for the dozen price, however much he might expect such delivery. Again, were our workman still in the egg business, and at any time, for any reason whatever, whether of his making or not, unable to deliver a full dozen, he would expect pay for only what he was able to deliver.

A Much-Needed Change

The change needed is this: Workmen must be ready and willing at all times to deliver the full dozen and the management must be as willing and as ready to pay for any above the dozen delivered. The need for the change is in the necessity of establishing scientific management in coal mining.

To illustrate this need, let us suppose two mines equipped with the same type of mining machines and working the same seam of coal (this supposition is real with the unimportant exception that some of the details are not quite true). Calling these mines Nos. 1 and 2, let us suppose that at mine No. 1 a competent man is employed to look over every machine after each shift;

that the machines are in perfect running order at the beginning of every shift and that if any trouble arises during any shift, competent help is within telephone call of the machineman. Suppose we also assume that an assistant foreman sees that all working places are in proper condition for cutting; that all tracks are properly laid and kept in repair; that feed wires are always within reach of the machine cables; that bits are delivered to the machine properly sharpened and that at all times there is a complete set in a substantial box. All this and more to enable the machines to cut coal as continuously as possible.

Taking an Actual Assumption

Let us suppose that at mine No. 2 there is no definite system about anything. Bits are sharpened by an incompetent blacksmith. These bits are taken into the mine by the machinemen themselves, in a gunny sack or in an old tomato can. The machinemen must carry their own lubricating oil into the mine and must procure this oil from a material man who has other duties than attending to supplies, and who is often remote from his place of business. The machines are run without repairs until they are completely down and out. The mine tracks are in poor condition and derailments are frequent; the haulage system is inadequate, making delays and layoffs of common occurrence; pumps are often out of order and men must work ankle deep in water. In fact the condition of mine No. 2 is such that no one is working to his capacity.

Now suppose, which is a fact, that the machinemen of No. 1 mine demand the same rate per ton as is paid at No. 2 mine, and further suppose that the management of No. 1 mine demands that machinemen work at a rate per ton which will insure the men about the same return per month as is received by the men at mine No. 2.

Both attitudes are wrong. The condition at mine No. 1 is the result of several years patient work on the part of the management with the assistance of many men who occupy no official position. The fact that machinemen can cut more coal here than at No. 2 mine is not wholly due to the machinemen themselves. It is true that doing more units of useful work, the runners at No. 1 are entitled to a larger money return than those at No. 2; but since the increased efficiency is due to many hands and to many minds, any increase in profit should be distributed among those responsible.

When there is a general willingness to let everyone who contributes to higher efficiency share in the increased profits, scientific management will be well on its road to actual realization.

A Commendable Safety Provision

While the coal miner is slow to concede that his brethren in the metal end of the industry can teach him anything about the mining game, there are, nevertheless, important exceptions to this rule. One of these that has recently been brought to our attention is a provision the Anaconda Copper Mining Co., of Butte, Mont., has made whereby a substantial premium is offered the mine foreman having the least number of accidents during the year. In these days of keen competition, it is highly gratifying to find such a powerful and representative company as the Anaconda, with its 1800 miles of workings and 10,000 underground employees, establishing such a humanitarian precedent.

The new rule of this company provides, in brief, that the mine foreman having the least number of accidents during the year shall receive a prize of $750; there is also a second prize of $250. No doubt the least number of accidents per foreman is computed on the basis of the average number of men they have charge of, so that the man at the large mine has an equal chance. We believe this is offering inducements at the right point.

The Gamblers

By Berton Braley

(Written expressly for "Coal Age.")

We'll take a chance—that roof is loose and flaky,
It really ought to have another prop,
But though it seems to be uncommon shaky
I guess it isn't ready yet to drop.
We'll get another car out if we hurry,
And that means jingling silver in our pants,
The roof may fall and crush us?—We should worry!
We'll take a chance.

We'll take a chance—our holes are drilled for loading
Our tamping stick is missing—use a drill,
Although there's danger of the charge exploding
We'll take a chance, I don't believe it will;
Of course the rules forbid such methods, brother,
But nary sign of tamper meets my glance,
It's too much work to go and get another,
We'll take a chance.

We'll take a chance—there may be firedamp near us,
And if there *is*, it isn't any joke,
But there's no boss around to see or hear us,
So let's light up our pipes and have a smoke.
If there is damp—we'd be *some* smashed and busted
Which wouldn't be a pleasant circumstance,
But we can trust to luck—as we *have* trusted,
We'll take a chance.

We'll take a chance—we're not afraid of dangers,
There's nothing killed us *yet*, so we're all right,
To every sort of worry we are strangers,
And so you see us, always gay and bright;
Maybe some day the roof will fall and get us
The dynamite may go off in advance,
The gas explode, but we won't let it fret us,
We'll take a chance!

Wireless Telephony in Mines

Great interest is being aroused in colliery circles in South Yorkshire, England, by a series of experiments in wireless telephony which is being carried out at the Binnington Main Colliery, and which, it is hoped, will lead to easier and safer communication with the various parts of the mine.

If the system is capable of all that the inventor claims for it, the results will be far reaching, as it is stated that a conversation can be carried on through 1500 yd. of solid rock. Great reticence is being observed concerning this matter, but when the experiments have reached a more advanced stage, it is understood that further details will be available.

Substation Loads in Lackawanna Collieries

By H. M. Warren* and A. S. Biesecker†

SYNOPSIS—Defining the load factor as the ratio between the actual power entering the converter and the rating of the connected units, the authors show that the 24-hr. load factor is 12.5 and for 365 days is only 8.6 per cent. This is not for the central station but for the average of 15 substations in the anthracite region delivering direct-current only.

In view of the fact that practically no data of this nature are available and that the Lackawanna Railroad Co. has a large number of substations of which the rated connected loads widely differ, we were led to conduct a series of tests, the results of which form the basis of this paper.

Tests were made on 15 substations ranging in size from 150 to 700 kw. The apparatus in these stations consist of 60-cycle, six-phase diametrically connected synchronous converters delivering direct current at 275 volts, step-down transformers of either the single or three-phase

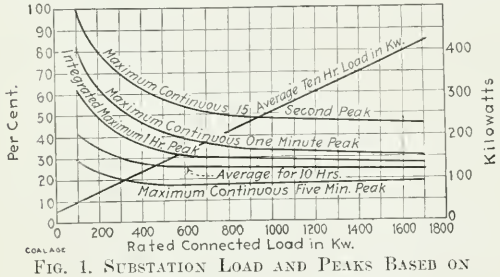

Fig. 1. Substation Load and Peaks Based on Synchronous Converter Input

type, and the necessary alternating-current and direct-current switching apparatus. These substations are usually located on the surface at the colliery, and the three-phase high-tension power is furnished from central stations.

Loads Comprise Mostly Small Units

The power apparatus driven from the substations consists of locomotives, hoists, pumps, and under-cutting machines. The locomotives vary in size from 7 to 13 tons and are usually geared to operate at a speed of from six to eight miles (9.6 to 12.8 km.) per hour at full load. Although the locomotive weights vary, about 80 per cent. of the total number weigh seven tons or less. All of the locomotives have double motor equipments with series-parallel controllers. The motor equipments average about 10 hp. (railway rating) per ton of locomotive weight The direct-current hoists operate on either slopes or planes and vary in size from 20 to 160 hp. As most of the large pumps are driven by alternating-current motors, the direct-current pumping sets are usually small in size and operate intermittently. The power required for undercutting machines is at present comparatively small. It is therefore, important to note that about 75 per cent. of all direct-current power supplied from these substations is used by locomotives and that 80 per cent. of all locomotives are rated at 70 hp. or less.

How Tests Were Conducted

The tests on these substations were conducted as follows: In order to obtain accurate readings, an alternating-current single-phase watt-hour meter with high-geared dials was obtained. This was connected in one phase of the alternating-current end of the synchronous converter and readings taken every half hour. A record of the peaks was obtained by connecting a graphic ammeter which was geared to give a paper speed of 7½ in. (18.8 cm.) per minute in the direct-current side of the converter. A note was also made of the machines operating in the mine at the time of the tests.

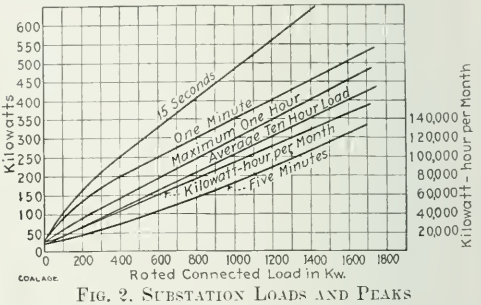

Fig. 2. Substation Loads and Peaks

The rated connected loads were based on the following motor ratings:

Electric locomotive—10 hp. per ton.
Hoist motors (railway type)—one hour rating.
Pumps—Name plate—continuous rating.
Undercutting machines—one hour rating.

The total of these horsepower ratings was reduced to kilowatts in determining the kilowatt rating of the total connected load.

The Factors Determined

After the above test data were obtained, a tabulation was made showing the maximum peaks for 15 sec., one minute, five minutes, and one hour; the average load for a ten-hour day; the kilowatt-hours per month, and the rated connected kilowatt load for each substation.

In working up these data, the 15-sec. and also the one- and five-minute peaks were measured on the graphic ammeter paper as block peaks, while the one-hour peaks were taken from the watt-hour meter readings and are, therefore, the integrated peaks. However, after determining the direct-current peaks, an amount equivalent to the synchronous converter losses was added, so that all tabulations were made on the converter input basis.

From the tabulations, a set of curves was then plotted as shown in Fig. 2. On this chart the abscissa represents the rated connected load in kilowatts. The lower curve

*Electrical engineer, Delaware, Lackawanna & Western R.R. Coal Department, 237 Harrison Ave., Scranton, Penn.

†Electrical Department, Delaware, Lackawanna & Western R.R. Coal Department, 323 Taylor Ave., Scranton, Penn.

Note—A paper presented at the Pittsburgh meeting of the American Institute of Electrical Engineers, Pittsburgh, Penn., Apr. 18, 1913, entitled "Characteristics of Substation Loads at the Anthracite Collieries of the Lackawanna R.R. Co."

representing the kilowatt-hours per month is read on the right-hand margin, while other curves are read in kilowatts on the left-hand margin. From this chart other curves and factors were derived which will be discussed later.

The Diversity Factor

From the above, we have been able to make some interesting deductions regarding diversity factors and load factors. Diversity factor has been defined as the ratio of

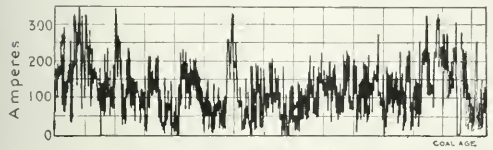

Fig. 3. Direct-Current Chart (Multiply by 4). Rated Connected Load, 465 Kw. Voltage 275

the sum of the maxima of the subdivisions of any part of the system to the coincident maximum demand observed at the point of supply. For the present we will, therefore, consider the subdivisions as loads taken by the individual locomotive, hoist, etc., and the point of supply as the alternating-current side of the converters.

In order to illustrate how the diversity factor increases from unity to higher values as the number of units and consequently the rated connected load is increased, we have shown in Figs. 3 and 4, sections of graphic ammeter charts taken at different substations. Fig. 3 shows the load on a small substation to which the rated connected load was only 465 kw., while Fig. 4 shows a similar curve for a substation to which the rated connected load was 1720 kw. From tests made on a seven-ton locomotive, rated at 70 hp. or 52.5 kw., we find that the maximum continuous peaks in per cent. of its rating for 15 seconds,

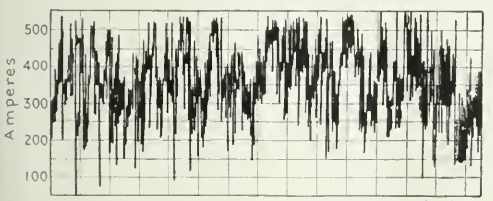

Fig. 4. Direct-Current Chart (Multiply by 4). Rated Connected Load, 1720 Kw. Voltage 275

one minute and five minutes, are 180, 100 and 60 respectively. Based on the above as peaks for a single unit the diversity factor for 15 seconds, one minute, and five minutes for various rated loads, are as shown in Fig. 5.

The Load Factors for Connected Loads

Load factor is usually defined as the ratio of the average load for a certain period to the rating of the substation. However, as the load factors on the substations are not considered in this paper, we have expressed all load factors as the ratio of the average loads on the substations to the *rated connected loads*. By so doing, any data contained in the paper become applicable to other similar installations.

Fig. 6 shows a 10-hour load curve taken on one of the largest substations. This curve was plotted from watt-hour meter readings taken every half hour. It will be noted that it has about the same characteristics as are generally found in shops or factories where the consumption of power depends on the activity of the employes operating the machines.

However, there is a low point in this curve which occurs about nine o'clock. This is due to the fact that there is a certain amount of coal mined and loaded during the night which is ready for the locomotive crews at seven o'clock in the morning. After this night coal is pulled out, the crews ease up for a while and take a morning lunch. During this time, the day miners have been loading coal which keeps the locomotives busy until about 11:30 when the load begins to drop again. The substation on which the above curve was taken had a rated connected load of 1720 kw. which consisted of eight 10-ton, and twenty 7-ton locomotives, and a small hoist.

Annual Connected Load Factor Only 8.6

The average ten-hour load factor was 24.6 per cent. whereas the average for all substations was 24 per cent.

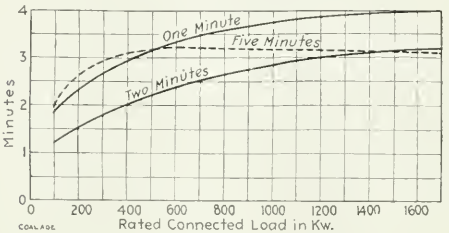

Fig. 5. Diversity Factors

The following tabulations give the load factors for various lengths of time for this largest station and the average of fifteen stations tested:

CONNECTED-LOAD FACTORS AT SUBSTATIONS

Station	Largest Percent	Average Percent
1 hour	32	29
8 hours	26	25 5
10 hours	24 6	24
24 hours	14	12 5
Annual, 365 days	9 6	8 6
Night, 14 hours	6 6	6 2

The 24-hour load factors give the average loads during a twenty-four hour working day and this might be considered as the annual load factor. However, as the average mine is not operated over 250 days during the year, the load factor on this basis for all stations tested is 8.6 per cent. It is interesting to note that the ratio of the power used during the ten-hour working day to the total used during the 24 hours was 73 per cent. on the largest station and 79 per cent. was the average for all stations. The average 14-hour night load is, therefore, 6.2 per cent. of the rated connected load.

In the application of data obtained from these tests, it will be noted that the peaks call for substation apparatus designed to carry and commutate high overloads and that the annual load factors are very low. Regardless of the question of taking care of the peaks, we find that the load increases so rapidly, due to new apparatus being installed, that it does not always pay to figure closely when deciding on the size of a substation. Some of the first stations installed for this work had 150-kw. and 200-kw. converters. These have been transferred

until now it is difficult to find a mine where the load is not too heavy for them.

Converters under 200 Kw. Not Advisable

We would, therefore, not recommend a converter smaller than 200 kw. and in case there is a probability of the load growing rapidly, a 300-kw. unit would be cheaper eventually. There are certain conditions where motor-generator sets work out more advantageously even though the initial cost may be much higher.

Let us assume a condition where the substation is to be located near an alternating-current motor-driven coal breaker, both of which are to be fed from a central station over a transmission line. The breaker motors will pull a load on which the power factor will be poor and this load together with the hoisting and pumping load will be so large in comparison to the substation load that the small amount of leading current obtainable from a converter, will not compensate for the lagging current taken by the induction motors.

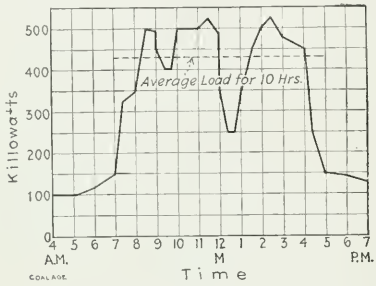

Fig. 6. A Typical Substation Load

The above will result in poor voltage regulation on transformers and transmission line and the attending bad effects due to poor factors on a central station. If instead of using a converter we install a synchronous motor-generator set with interpoles on the generator and a motor having a ratio 30 to 40 per cent. in excess of the generator, we are in a position to correct the power factor, and better both the direct-current and alternating-current voltage regulation.

Where it is necessary to transform to a lower voltage for the synchronous motor, it will often be possible to wind the breaker motors and synchronous motor on the set for the same voltage and feed them from one bank of transformers. By combining the leading current with the lagging on the low-tension side of one bank, the kilowatt-ampere rating is very much reduced from that required for separate transformers. There is also a decrease in the cost per kilowatt-ampere due to the units being larger.

Electric firing in series means that the arrangement of the charges is such as to permit the electric current to pass from the positive wire of the circuit to the fuse of a number of different charges in turn and from the last fuse to the negative wire. The firing of all fuses is simultaneous. Firing in parallel means that each detonator has a direct connection with the positive and negative wires, so that each fuse is supplied with a portion of the total current. The firing is simultaneous. Series firing is easier to arrange than the parallel system. It calls for more wire than parallel firing and takes a big voltage but little current, while the parallel system calls for a big current and a low voltage. For simultaneous firing the series system is the best. Low-tension fuses give better results than high-tension fuses.

Briquette Production in the United States

The output of briquettes in 1912 showed a small increase over that of 1911, and the industry may now be considered as passing out of the experimental stage and assuming a more substantial and permanent character. In 1912, at 19 plants, 220,064 short tons, valued at $952,261, were produced as compared with 218,243 tons, valued at $808,721, in 1911.

Of these plants seven used anthracite culm, nine used bituminous, or semi-bituminous slack, one used residue from gas manufactured from oil, one used mixed anthracite culm and bituminous slack, and one used peat.

The largest producer of briquettes was the Berwind Fuel Co., of Superior, Wis., whose output was a little in excess of 50,000 short tons. This plant has a capacity of between 35 and 40 tons of briquettes per hour.

The quantity of raw material available for the manufacture of briquettes is ample, and may be obtained at slight cost. The most desirable material for a smokeless product is anthracite culm, a large supply of which now exists and more is being produced daily in the anthracite region. It is not too much to believe or to hope that in the near future the small sizes of anthracite, such as buckwheat and smaller, that are now sold for making steam, in competition with bituminous coal, and at prices below the actual cost of production, will become more valuable as a raw material for briquette manufacture.

The output of these small sizes exceeds 20,000,000 tons annually, exclusive of 3,000,000 or 4,000,000 tons which are recovered from the culm banks by washeries. The present revenue from this product will not exceed $30,000,000, such coal being worth from 50 cents to $1.50 a ton, the price depending on the size.

As briquetted fuel, it should be worth as much as stove or egg coal, and the cost of briquetting ranges from $1 to $1.50 a ton. The uniform size of this fuel makes it highly desirable for domestic purposes. Furthermore, if properly handled, this fuel does not produce clinkers. Slack, from non-coking bituminous, sub-bituminous and semi-anthracite coals, is another cheap and abundant raw material. It is obtainable in all the coal-mining regions of the Middle West, where, at many places, it is now wasted or almost given away. Some slack piles have been burned to prevent their cumbering the ground, while others ignite spontaneously.

The vast and almost untouched areas of lignite in North Dakota and Texas contain enormous supplies of fuel that European experience has taught is well adapted to briquetting, and which is much more usable in that form than in the raw state.

The large areas of peat beds in the United States are also available as a source of raw material. They are generally remote from the coalfields and briquetted fuel from peat, when properly prepared, makes an excellent substitute for coal. The peat now produced in this country is used for stable litter, fertilizer, etc.; none is used for fuel.

While the briquet industry in the United States is still in its infancy, the production of this fuel has nearly twice doubled since 1907, the production in that year being 56,524 short tons, while in 1912, as stated above, it was 220,064 tons.

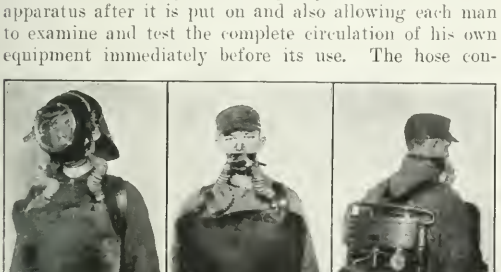
An Improved Breathing Apparatus

SYNOPSIS—A description of the principal changes in and advantages of the Model 12 Westphalia mine-rescue apparatus.

The accompanying illustrations show the new type of Westphalia mine-rescue apparatus, Model 12, being introduced by S. F. Hayward & Co. In this model a number of important improvements have been made, which add to the efficiency, simplicity and ease of operation of the equipment.

This type is made more compact in form and fits the body much closer. There are no projecting parts, making free movement possible under the most severe conditions, thus allowing the wearer to go into low and confined places in the mine and perform whatever work may be necessary with a minimum of effort.

The supply and discharge tubes are both connected at the bottom of the breathing bag on the left side, obviating the necessity of making any connections in the apparatus after it is put on and also allowing each man to examine and test the complete circulation of his own equipment immediately before its use. The hose con-



THREE VIEWS OF THE NEW APPARATUS

necting the breathing bag to the face piece is made extremely flexible and non-collapsing, allowing the unrestrained movement of the head without any possibility of disarranging the connections.

The apparatus can be stored complete with the regenerator ready for immediate service and can be quickly put on as it is only necessary to fit the helmet on the head or properly place the mouth-piece and screw up the nose clips to be ready for instant service.

The automatic reducing valve has been made slightly shorter and more compact, and is so arranged that the injector jet can be inspected without removing the valve from its connections. The reducing valve maintains a circulation in the apparatus of about 2.1 cu.ft. per min., so that the wearer has at his disposal approximately 254 cu.ft. of richly oxygenated and pure air during the working period of two hours.

THE REGENERATOR CONSTRUCTION IS SATISFACTORY

The present construction of the regenerator is most satisfactory, as has been demonstrated during its use for several years past.

The regenerating substance is arranged in several compartments, held in wire cages placed in shelf-like form exposing the entire surface of the material in the circulation of the exhaled air. This system absorbs carbon dioxide to an extent that has never been approached by any other similar apparatus.

In cases where the regenerator has been handled roughly or dispatched by train or motor car without proper packing, it occasionally develops that minute particles of the chemical will sift out of the regenerator. To overcome the possibility of these small grains entering the circulation tubes of the apparatus, a small trap has been fitted to the pipe at the bottom of the regenerator.

The regenerator can be quickly exchanged or refilled, either the interchangeable or refillable type being furnished, as may be desired.

The breathing bags, which are used to equalize the varying demand of the wearer during his labors, are fitted on the chest. They have been increased in size and are now large enough to provide for the demands made upon them even during the greatest exertion of the helmet man. They are protected on the outside from being cut or torn by means of a cover, which is attached with straps and swivels to the shoulder straps and back carriage and is sufficiently free to allow unimpaired expansion.

The supply and discharge tubes connect with and pass through the breathing bag in such a manner that it is possible for one to crawl on his stomach with his weight on the breathing bag, without cutting off the air supply. This is a highly desirable feature when working in small openings and one which we do not think is embodied in other types of apparatus.

It will be noticed that the pressure gage is placed in the back in a protected position, but is supplied for front reading when desired. The same apparatus can be used equally well for either mouth or helmet breathing, as it is only necessary to unscrew the couplings on the hose at the top of breathing bags and attach either device that may be most advantageous.

A feature to be noticed is that there are no valves whatsoever either in the face attachments or the entire circulating system, to become clogged with saliva or disarranged. Notwithstanding the absence of the valves, it is impossible to rebreathe any of the exhaled air until it has passed through the regenerators and been purified.

The helmet is made exceedingly light and strong and has the advantage over other types in having the face washer curved inward, so that it will fit almost any type of face; this also allows an air-tight fit to be made around the face without any uncomfortable pressure against the temples.

When about to install a rope-haulage system, examine the roof of the gangways to be traversed, as this is often the deciding factor. When the roof is bad it is difficult, expensive and impractical to maintain a double track. When the grade is irregular and too low to allow the empty cars to run by gravity, the main and tail-rope haulage give good results. The cost of maintenance of such a system is not high, as there is only one track. This low cost is somewhat overcome by the wear on ropes and cars, due to the high speed needed to handle the output on a single road. There is always apt to be an irregular and intermittent delivery of coal at the shaft as well as a poor supply of cars at the inside parting. Notwithstanding these defects, this system gives the best results under an exceedingly bad roof.

Shrinkage of Carload Lots of Lignite Coal

By J. G. Crawford*

SYNOPSIS—An investigation and compilation of some interesting data on the shrinkage of Western lignites. The tests were made in minute detail and all possible conditions effecting the results carefully considered.

In connection with the weighing of car loads of coal it is desirable to know the amount of natural shrinkage in transit. This shrinkage depends upon the character and grade (size) of the coal, the amount of surface moisture thereon and the kind and size of equipment in which it is loaded. The tests herein referred to were made for determining the probable maximum shrinkage of a certain lignite coal from dry workings, of various grades loaded in both box- and open-cars.

Coal Used

The coal used was from Monarch Vein of Sheridan County, Wyoming, and in order that no appreciable amount of the fuel might be dried slightly in the mine, that used for this test was loaded in railroad cars on the second of two consecutive working days.

The size of each grade of coal used on these tests is shown in the following table:

Size of Openings and Kind of Screen

Grade	Over	Through
Slack		¾-in. square rotary
Pea	¾-in. square rotary	1-in. square rotary
Nut	1-in. square rotary	3-in. stationary bar
Egg	3-in. stationary bar	6-in. stationary bar
Lump	6-in. stationary bar	
Mine-run		
Egg-run		5-in. shaking bar

In order that the size of the coals will be better understood it should be stated that with these arrangements about 10% slack and 30% 5-in. bar-screened lump is obtained.

A proximate analysis of this coal is as follows:

Moisture, 23.14; Volatile matter, 36.63; Fixed carbon, 36.58; Ash, 3.65; Sulphur, 0.49; B.t.u., 10,137.

Loading of Coal—The coal was loaded July 29 and 30, 1909, in cars as shown:

Kind of Coal	Number of Cars Box	Number of Cars Open	Capacity* Box	Capacity* Open
¾-in. slack	0	2		100
¾x1-in. pea	2	2	60	100
1x3-in. nut	3	2	2–60 1–50	100
3x6-in. egg	2	2	70	100
6-in. lump	3	2	60	100
Mine-run	0	4		100
5-in. egg-run	0	3		100
Total	10	17		

*In thousands of pounds.

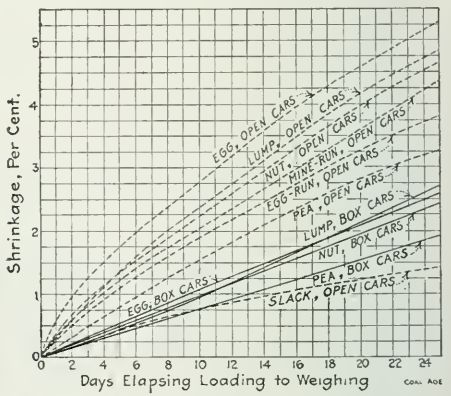
The open cars were, with the exception of those in which the slack was loaded, steel cars 40 ft. long. The two cars used for slack were 40-ft. composite steel and wood but they were light weighed both before and after the series of tests and the weight of these cars was found not to have varied. The box cars were wooden.

The open cars were loaded to full visible capacity and care was taken to provide against falling off in transit. The box-cars were loaded, with one exception, to above noted capacity. All box-car doors were closed. Condition of equipment was such that there was no leakage through doors or drop bottoms.

Weighing of Coal—All empty cars were weighed before loading. The loaded cars were weighed daily at Dietz, Wyoming, in the same position on the same scales about 4 p.m. Cars were watched day and night to prevent stealing.

Weather Conditions

In referring to the days elapsing between loading and weighing, July 29 will be used as the basing point as 24 of the 27 cars were loaded on that day. An open car of slack was left standing on the Dietz scales day and night, which practically covered the bed of the scales. As soon as any rain fell, the observer on duty would visit the scales and find out how much the rain had increased the weight of the car and thus the amount of rainfall per open car was determined.



Shrinkage Curves of Carload Lots of Lignite Coal

The weather conditions including the tenth day were practically ideal and during this time the total amount of rainfall did not exceed 50 lb. per open car which was divided into six light sprinkles on the fourth and ninth days. This weight had to be estimated as each shower was insufficient to "break" the scales. On the eleventh day the rainfall increased the weight of each open car 100 pounds.

From the twelfth to twenty-fourth days, inclusive, there were eight light sprinkles, four on the twelfth day and one each on the thirteenth, fifteenth, eighteenth and twenty-fourth days. The sprinkle on the latter day was the only one which affected the weight of the car on the scales, and this shower amounted to only 20 lb. per open car. The total amount of these eight showers probably did not exceed 50 lb. per open car and as they were divided throughout the thirteen days they would have no appreciable affect on the results. The tests were discontinued on the twenty-fifth day because a rain of 125 lb. per open car occurred.

During the entire 24 days, therefore, the only rain which had an influence on the results was the 100 lb. per open car which fell on the eleventh day. The only effect that this 100 lb. of rain had was to retard the shrinkage so that the actual shrinkage obtained from

*547 N. Jackson Boulevard, Chicago, Ill.

the twelfth to the twenty-fourth days was *about* two days behind what it would have been providing no rain had fallen on the eleventh day. It was possible to eliminate the affect of this rain by plotting for each kind of coal and class of car, the observed weighings as ordinates and the days between loading and weighing as abscissa. A smooth curve was then drawn through the weights of the first ten days and then another through the weights for the twelfth to twenty-fourth days inclusive. The curve through the first ten-day readings was then extended parallel to the curve through the readings from the twelfth to twenty-fourth days.

Temperature—The temperature readings were taken every hour and the average of these for the entire series of tests was 74.2 which is high for this locality as the temperature at nights is low. The more important temperature results are as follows:

	Deg. F.
Highest individual reading	106
Lowest individual reading	43
Highest daily average	80 0
Lowest daily average	62 2
Average entire series	74 2

Results of Tests—Under "Weather Conditions" was described the method of deriving a curve to show the net weight for each day after loading of each grade of coal in each class of equipment, had no rain fallen. The accompanying figure gives similar curves to show the per cent. shrinkage for each grade of coal loaded in each class of equipment had no rain fallen on the eleventh day. The results of these tests are also given in tabular form herewith.

Conclusions

The results show in detail the shrinkage under various conditions and it is interesting to note that in open cars for the same grades of coal, is about twice that of coal loaded in box-cars. As shrinkage is accompanied by deterioration the advisability of using box-cars, where possible, is emphasized. The shrinkage takes place mainly on or near the top of the coal in open cars, this portion soon slacking and thus protecting the rest. The deterioration in open cars, therefore, is greater near the top of the cars and not only is the coal in box-cars in uniformly better condition at the end of a given time but it does not contain as much of the badly slacked product.

The results show, as would be expected, that the shrinkage is dependent on the size of the coal and the amount of slack contained, both of these factors influencing the freedom with which the air can circulate and the size also determining the amount of exposed surface per unit volume of coal. The curves and the accompanying table probably show the maximum shrinkage which will be obtained under the temperature conditions specified and in hot, dry and clear weather. A greater shrinkage would be obtained on coal of this character from a wet mine, that used being from dry workings as noted.

The additional shrinkage which would have occurred had the cars been hauled in freight trains during the 25 days, instead of being held on track at one point, would not have been great. One open car of pea coal was weighed at Sheridan and then hauled to Edgemont 223 miles east, back-hauled to Sheridan and reweighed, the two weighings at Sheridan being made within 60 hr. of each other. The difference between the two, after a haulage of 446 miles was only 100 lb. and had the car have been standing, a greater shrinkage than this would have been expected. That a greater shrinkage did not take place was probably due to the fact that the coal had been rained on slightly, although on arrival at Sheridan for reweighing the coal did not show any traces of this.

TABLE SHOWING PERCENT. SHRINKAGE OF VARIOUS GRADES MONARCH VEIN COAL, FOR ONE TO TWENTY-FIVE DAYS ELAPSING BETWEEN LOADING AND WEIGHING, LOADED IN BOTH BOX AND OPEN CARS

Antartic Coal Fields

Prof. D. W. Edgeworth David is quoted in the Australian press as saying:

In reference to the scientific discoveries of Scott's party there can be no doubt they will prove of immense interest and importance. In the first place, it is stated that a good collection has been obtained of fossil plants associated with the seams of coal discovered by Shackleton at Buckley's Island, at the head of the Beardmore Glacier. Frank Wild, of Shackleton's party, was the actual discoverer of seven seams of coal outcropping in a great cliff face of sandstone and shale. Thickness of these seams was 7 ft., inclusive of a few clay bands, and Wild chopped small specimens of the coal out with his ice ax. These have been analyzed in Sydney, and show the coal to be of workable quality. It is almost certain that this coal field will prove to be perhaps one of the largest of the unworked coal fields of the world, as it has been traced about 650 miles north of the Beardmore Glacier.

Our British Coal-Mining Letter

Special Correspondence

SYNOPSIS—Modern machinery being hard to maintain in maximum efficiency, cards of instruction should be issued to those operating it especially where untrained men are employed in charge of complex apparatus. It is shown that pneumatophores need to be aided in operation by an injector but the suction action should be corrected by an equalizer. Turbines are gaining rapidly in popularity especially as supplementary to such engines as are wasteful of steam.

In a paper read before the Association of Mining Electrical Engineers in East Scotland, a suggestion, not without value in other directions, was made by H. J. Humphreys. He directed attention to the prevailing ignorance of those who have the oversight and working of electrical apparatus, apart, of course, from the trained electrician. The proposal of Mr. Humphreys is that the colliery manager and the electrical engineer of the colliery should collaborate in preparing a card of instructions for each class of men having to operate the electrical plant. The card should bear a number of instructions in terse simple language, printed in bold type, and each instruction should be followed by a short explanatory note, giving the reason for the instruction. Each card should also contain an admonition requiring the recipient to study the existing "Special Rules" relating to electricity, also requesting him to ask for further information on any points which he may not understand. In addition, there should be a note of warning of the serious dangers of disregarding rules.

Mr. Humphreys considers that cards of instruction would be useful for the following classes of men: (1) Authorized persons operating switches at the upper landing; (2) authorized persons operating switches below ground; (3) motor drivers; (4) coal-cutters; (5) firebosses; (6) "brushers" and repairers and (7) roadmen.

Other instructions may be drawn up to meet individual requirements, and, of course, it is recognized that it is impossible to draw up a set of rules applicable to all collieries. The actual form must depend on the needs of the particular place and the character of the plant.

Dangers of Injectors in Rescue Apparatus

John Cadman has directed attention to a danger in the use of such mine-rescue apparatus as depends on the successful action of an injector. In a discussion by G. Blake Walker before the South Staffordshire and Warwickshire Institute of Mining Engineers, he said that when he first purchased two pneumatophores, similar in general principle, they were both far inferior to any kind of rescue-apparatus manufactured today, and the whole of the circulation of the respirable air was dependent on the efforts of the lungs of the wearer. The apparatus became foul in about half an hour, due partly to difficulty in the absorption of the CO_2 and to the intermittent supply of oxygen.

To overcome this the injector was introduced, resulting in (1) the oxygen supply being definitely regulated; (2) the flow of oxygenated air being maintained at a constant volume throughout the apparatus and so regulated as to meet exactly the needs of the wearer. With the apparatus not fitted with an injector, it was necessary to adopt a bypass to give the man sufficient oxygen when doing strenuous work.

The Injector Sucks Air

With the early non-injector type, it was found that the regenerative system was inefficient; often the percentage of carbon dioxide rose to 3 and 4 per cent., while the heating of the exhaled air was excessive. These troubles were removed with the introduction of the injector. Mr. Walker referred to the special point raised in Dr. Cadman's paper; namely, the danger that, while the object for which the injector was introduced was to force air through one part of the apparatus; the reflex action given by suction in the other part of the appliance was not sufficiently considered.

Now that attention has been drawn to its liability to cause trouble, Mr. Walker says it appears to admit of a simple and obvious remedy, and by fitting an equalizing receptacle to the pneumatophore, constant pressure can be maintained, as can easily be seen by applying a water-gage. With the apparatus not fitted with this receptacle, the inhalation shows a minus pressure and the exhalation a plus pressure. With the equalizing bag, when the equalizing receptacle is inflated, the pressure in that receptacle comes to the assistance of the breather and maintains the pressure throughout the apparatus at the plus value, while again the effect of breathing restores to the equalizing receptacle the amount of air which is extracted from it.

Turbines at Mines

C. H. Bailey and R. H. N. Vaudrey addressing the Association of Birmingham Students of the Institute of Civil Engineers, stated that many mines are being equipped with turbines, mostly of the mixed-pressure type. A large number of mines, otherwise efficiently and economically operated exhaust large quantities of steam into the air throughout the year.

The turbine has to compete successfully against gas engines, Diesel and other heavy-oil engines and steam engines, and has to justify its introduction by superior economy and by freedom from stoppages either of short or long duration. When steam is used for hoisting engines, the turbine will almost certainly be an economical factor at a large colliery plant, as there will be in all probability much steam which will be exhausted at a pressure several pounds higher than that of the atmosphere.

The authors summarized the economy resulting from turbines as follows: Above 200 kw. the steam turbine is more efficient than the reciprocating engine. The first cost of small turbines is about the same as for reciprocating engines; but for large units the prime cost is only about half the cost of the reciprocating-engine set, including condensing plant. The steam consumption of a turbine of 2000-kw. output may be about 15 per cent. less than that of a quadruple-expansion engine, and the maintenance is considerably less. Buildings and foundations for a turbine are less costly and depreciation and repairs are also less.

Coal Preparation in Franklin Co., Illinois

By R. Dawson Hall

SYNOPSIS—The coal of Franklin County, Illinois, is of superior quality, containing less sulphur than that mined in the northern portion of the state. The coal, passing through the shaker screens on the tipple, is rescreened at all the mines before shipment. In one mine the coal is cleaned in spirals and 4 per cent. of ash is removed.

The coal of Franklin County is the best in the state of Illinois, and there has been, therefore, little need to clean it. The retail coal dealers frequently advertise the coal as a washed fuel, but there are no washeries in the county. The coal has the general appearance of a fuel which has been improved by washing and readily sells as if so prepared.

Dry Cleaning at a Bituminous Colliery

There is now one plant, the Wilmington Star Mining Co.'s mine, at West Frankfort, where dry cleaning has been introduced, and the pressure on the other companies to meet competition will doubtless result in many others being built. There is a tendency to wait and find out whether the Wilmington Star Mining Co. is satisfied with its investment before other companies follow suit.

All the evidence points, however, to the fact that the dry cleaning process is more than justified and that the Wilmington Star Mining Co. does not regret its action. Consequently it is to be anticipated that before long all the plants in the county will not only rescreen, but clean their coal.

The coal of Franklin County, on an average, contains 11 per cent. of ash. Dry cleaning reduces this percentage to 7 per cent. The waste or bone from the cleaning plant is taken to the boilers and is consumed to make power for the colliery. This waste is 26 per cent. ash.

It is surprising that a seam so clean as this at West Frankfort should show such improvement under mechanical preparation. It would be easy to understand it if the coal were full of slate partings. But, in the whole 9 ft. 3 in. to 12 ft. 6 in. of coal, there is but one small parting, known as the "blue band," which varies from a mere trace up to one inch in thickness.

Where Dirt Often Enters Clean Coal

In every mine, however, a certain amount of rock falls either in first mining or in pulling back the pillars. It is usual in the Franklin County field to leave coal in the roof until returning with the ribs, when all the roof coal which can be recovered is secured. Sometimes, and in fact quite usually, the pillar is lost and all that is obtained is that part of the coal in the roof between the room pillars.

This roof rubbish and the unimportant parting in the coal, furnishes the opportunity to the Wilmington Star Mining Co. to better their ash percentage 4 per cent. They cannot fail to have an advantage over those companies which are cleaning solely by an inspection of the coal as it enters the car. In most mines two men attend to the "placing" of the car and the loading. Both of these men at intervals watch for the few pieces of pyrite or bone as they fall from the chute or roll over in the "gondola."

Ziegler District Colliery Co., Christopher, Ill. Rescreen in Rearground on Right

Pyrite and Calcite

The pyrite in the Franklin County coals is of bright metallic luster. It seems to appear in small bodies rather than disseminated in partings. It does not, however, disintegrate and destroy the integrity of the coal, nor does it whiten on weathering like much of the bisulphide of iron in the coal of central Pennsylvania. Inconsiderable veins of calcite may be found, mere flakes of mineral on the dividing planes of the coal. To show that the appearances of pyrite have largely a scientific interest and little ef-

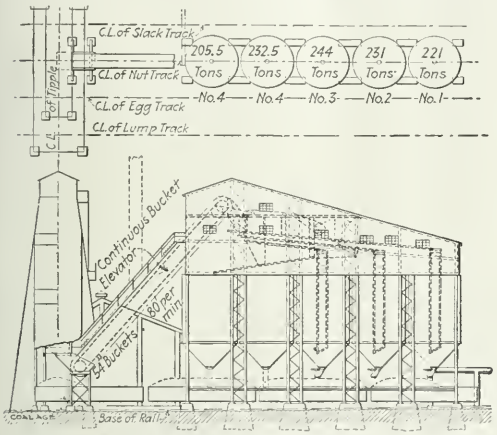
THE NEW RESCREENER AT THE MINE OF THE UNITED COAL CO., BUCKNER, ILL.

terville and Marion are all in the adjoining county of Williamson, which is regarded as part of the same field.

Spiralizing and Dry Cleaning

It is significant that the cleaning of coal by the dry process has started at a point where the coal is of unusually high grade. The superintendant, Mr. Buchanan, has



Side View and Plan of the Buckner Rescreener

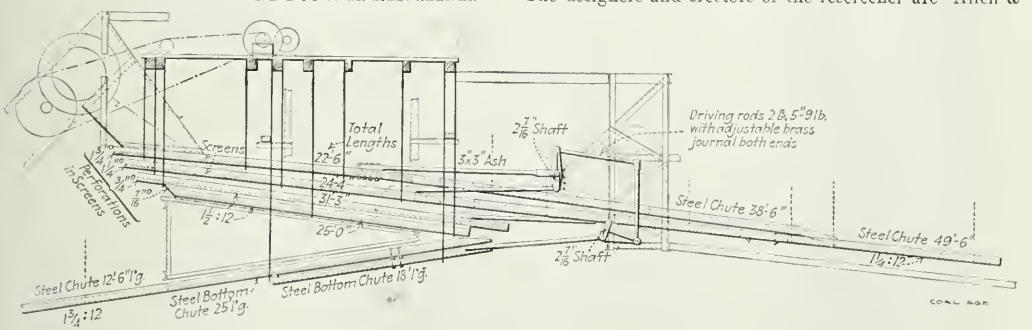
conveyed to the boiler room. The slate passes toward the center and thus is collected separately from the impure coal.

The bins beneath this rescreening and cleaning plant will hold 1200 tons of coal and 300 tons of bone. The plant is now being arranged to store egg coal also. This is transferred to the rescreener by a separate conveyor and goes directly to a bin without any rescreening, the purpose being simply to stock the coal at times when the loading of egg coal would interfere with operation.

The Buckner Rescreener

All the mines of Franklin County have their rescreener. The degree to which the rescreening has been carried varies considerably from plant to plant. That at the Buckner mine, near Christopher, is perhaps as complete as any. Certain recent additions are not shown in the plans and elevations. The wrought-iron posts between the bins have been stiffened by a filling of concrete and a conveyor to carry the fine coal or "duff" to the boilers is being installed.

There are four water-tube boilers in two batteries, built by the Model Automatic Smokeless Model Stoker Co., of Dayton, Ohio. At present these are being stoked with screenings by hand, but when the conveyor is completed, the fuel used will be duff and the stoking will be automatic. The storage capacity of the tipple is 1134 tons. The designers and erectors of the rescreener are Allen &



Elevation of Shaker Screens in Buckner Rescreener, Showing Mode of Actuation

traveled in every coal-producing state in the Union, and in several foreign countries, and he is not disposed to follow the lead of others, but to introduce commendable innovations. The coal is screened at the tipple into three sizes; lump, that which passes over a screen having circular openings 6 in. in diameter; egg, that which passes through the lump screen and is held by a screen which has 3-in. openings, and smaller sizes which pass through both screens.

The coal is then carried by a large 36-in. 7-ply conveyor belt, manufactured by B. F. Goodrich, having a capacity of 2000 tons per day, to shaker screens supported from below by Parrish arms. Here it is sized into 5 sizes, known on the market as Nos. 1, 2, 3, 4 and 5. These screens are driven by a 75-hp., 220-volt, 4-pole motor, having a speed of 500 revolutions per minute.

The cleaning of the coal is provided by 28 spirals. The clean coal in passing down the spiral falls off to one side and is carried downward by the outer spiral casing. The bone coal remaining on the inner spiral is carried down to a gate at its foot, and thence to a bin, from which it is

Garcia, of Chicago, and the mine is owned by the United Coal Mining Co.

Roller Screens in Preparation Plants

It should be noted that both the screeners described, screen the coal through shaker screens, but this is not the general practice. They are generally used on the tipple, but roller screens are usually installed in the rescreener. In the Ziegler District Colliery, the coal larger than 2 in. in diameter is conveyed to the rescreener. It passes in this building into a roller screen 20 ft. long, with 1¼-in. circular openings. So only two sizes of coal are made in this rescreening plant; coal between 1¼ in. and 2 in., and coal under 1¼ in.

Coal of a uniform size can be burned with less smoke and waste than a fuel of mixed sizes. The commercial demand for careful rescreening is not unreasonable, as the consumer gets a real benefit and is willing to pay an increased price. It is likely that in a few years, the operators of many districts will introduce improved methods of sizing coal.

Geology of the Panther Creek Valley, Penn.

By W. B. Richards*

SYNOPSIS—An interesting description of the geology in one of the important anthracite fields. A detailed study of all the measures in the coal horizon is given, with special reference to those which are coal-bearing. The customary complexities, common to the anthracite district as a whole, are well shown.

The Panther Creek Valley is, roughly, 12 miles long, averaging two miles wide, and contains 8000 acres or 12½ sq.mi., about one thirty-eighth of the entire anthracite coal lands in Pennsylvania. It is located at the extreme eastern end of the Southern Anthracite Coal Field, between Mauch Chunk on the Lehigh River, in Carbon County, and Tamaqua on the Little Schuylkill River, in Schuylkill County. It narrows to a sharp point at the spoon end of the basin, a mile east of Mauch Chunk, or at the top of the Mt. Pisgah Plane, the elevation of which is 1375 ft. or 843 ft. above the Lehigh River.

The conglomerate rocks which form the rim of the valley in the Sharp Mountain on the south, and the Locust Mountain on the north, belong to the Carboniferous, which era is subdivided, geologically, in three periods as follows:

First—The Subcarboniferous, consisting of the Pocono sandstone and Mauch Chunk Red Shale.

Second—The Pottsville conglomerate and the coal measures.

Third—The Permian.

The coal measures, designated by the State Geologist as Formation No. XIII, are the thirteenth distinct formation in Pennsylvania. In 1837, Henry D. and William B. Rodgers, State Geologists of Pennsylvania and Virginia, adopted a plan of numbering the formations beginning at the bottom.

As shown on the accompanying columnar section, historical geology has been divided into four time periods:

1. *Cenezoic Time*—The age of man and mammals; the glacial period was in the first half of this time.

2. *Mesozoic Time*—Age of reptiles, amphibia, birds, land plants and insects of high type.

3. *Paleozoic Time*—Age of invertebrates, which is divided into the following eras:

Cambrian—No form higher than invertebrates.
Silurian—Invertebrates predominate.
Devonian—Fishes are abundant.
Carboniferous—Land plants assume great importance.

4. *Azoic Time*—No fossils known. This is the Archean era. Mostly metamorphic or changed rocks. Perhaps, in part, original crust of the earth.

Stripping Operation on the Mammoth Vein at the Greenwood Colliery

*Engineer, L. C. & N. Co., Lansford, Penn.
Note—Abstract of paper read before the Panther Valley Mining Institute.

The Archean rocks, which are named from the Greek for beginning, underly all the formations in which appear traces of vegetable or animal life. Therefore, they constitute the base of all countries, wherever life rocks occupy the surface; this is the copper- and iron-bearing strata of Lake Superior.

Paleozoic Time

Paleozoic rocks (named from the Greek for ancient life) are the prevailing kind exposed to view over the eastern half of the North American Continent; they extend from the northern boundary of New York, southward to the coal regions of Pennsylvania. A brief *résumé* of the 13 formations of the Paleozoic Time will now be given.

Formation No. 1—Chiques sandstone (not ordinary sandstone but a quartzite) is the oldest of our fossiliferous rocks. The finest exposure is a great rock mass which towers above the east bank of the Susquehanna for a mile above Columbia, in Lancaster County, where Chiquesalunga Creek enters the river. At the White Spot on the mountain behind Reading, it has been famous since the early settlement of that great valley.

Formation No. 2—The Great Valley limestone; this is noted for the superior fertility of limestone land, and derives its name, not only for its unusual width, but for its extraordinary length, being quite persistent over a course of 1000 miles from Canada to Alabama. It occurs in Pennsylvania over a distance of 150 miles, in some places 20 miles wide, and is bounded by mountain ranges 1000 ft. high. In it we have cement rock in Lehigh County; limestone quarries in Berks and Lebanon Counties; magnetic ore mines at Cornwall, Lebanon County; and zinc mines in Lehigh County.

Formation No. 3—This is the Utica and Hudson River Slate, exposed in Northampton and Lehigh Counties, in which are found the roofing slates of Slatington.

Formation No. 4—This is the Oneida conglomerate (named after Oneida County, N. Y.), and the Medina Red and White sandstone (named after Medina in Western New York) exposed at Delaware, Lehigh and Schuylkill Water Gaps.

The Medina White sandstone is not only characterized by its purer color, but by its massiveness. It constitutes the real backbone of the mountains, cropping out along their crests. There is not a known valuable mineral of any kind in either of these formations.

Formation No. 5—This is the Clinton, Niagara and Salina rocks, which are noted for their red color, particularly prominent in the Bloomsburg red shale.

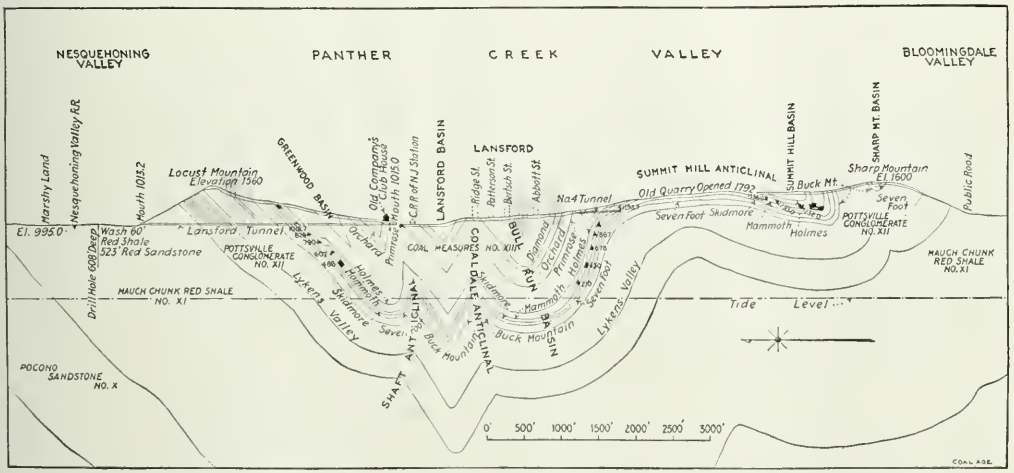
The Clinton deposits (named after town of Clinton, N. Y.) are olive-green slates, calcareous gray and red shales, with several sandstones of a peculiar character and numerous thin strata of limestone; these latter are filled with small shells which were converted by the chemical action of the rainfall, for variable distances beneath the surface, into beds of fossil iron-ore, some of which is mined at Danville, Penn. The formation is exposed at the Delaware, Lehigh and Schuylkill Water Gaps, at Danville and Bloomsburg, in Montour County, and also in Fulton, Bedford, Huntington and Blair Counties. Not a single fossil of any description has been found in these rocks; red beds are usually nonfossiliferous.

The Niagara formation of New York cannot be recognized in this district as a distinct formation. The lower portion is shale and the upper limestone, which latter is largely of coral origin, indicating clear seas during the time of its formation. This limestone comprises the upper 85 ft. and the shale the lower 80 ft. of the Niagara Falls; the recession of the falls is slowly going on due to the undermining of the limestone by the erosion of the shale.

The Lower Salina (named from the town of Salina, N. Y.) is the Bloomsburg red shale in Pennsylvania, exposed in the cap at Fort Clinton, Penn. At Salina, N. Y., it contains gypsum and rock salt; wells 70 to 75 ft. deep are sunk and salt obtained by evaporation.

Formation No. 6—This is the Lower Helderberg (named after a range of mountains in New York State) and it is mainly a limestone formation. Many of its beds are covered with coral.

Formation No. 7—This is the Oriskany shale and sandstone, and Candagalli grit. Oriskany takes its name from the Oriskany Falls, a few miles west of Utica, N. Y. It



Cross-Section of the Panther Creek Valley on the Line of the Lansford Tunnel

is made up of grains of sharp quartz fragments, so loosely cemented as to readily disintegrate, under the action of air, into heaps of glass sand. Glass factories have hitherto relied upon this material for the principal part of their stock in New York State.

In Pennsylvania, the outcrop of the Oriskany extends in straight, curved and zigzag lines, through nineteen counties, varying in character from sandy shale to massive flint; in some places it is crowded with shells and at others almost entirely free from them; it is also sometimes highly ferruginous, even containing iron enough to furnish furnace ore. Its outcrop in the Steinberg Ridge, 17 miles through Carbon County and 15 miles further in Schuylkill County.

The Candagalli grit is the upper part of the Oriskany sandstone and it is almost a nonfossiliferous rock. It is usually a sandy shale, dark or nearly black, weathering from grayish to brownish gray.

Formation No. 8-A (Upper Helderberg)—This is composed of Onondaga and corniferous limestone. The Onondaga limestone (named after Onondaga County, New York) is a deposit of fine, groundup corals and crinoids. The corniferous limestone, so called from the flint or hornstone, is often imbedded in it. The paint mines of Lehigh County are in this formation.

Formation No. 8-B—The Marcellus Black Slate outcrops on the Lehigh River a mile below Bowmans, Penn., and through Carbon and Schuylkill Counties to an anticlinal point several miles west of Schuylkill Haven.

Formation No. 8-C—The Hamilton sandstone and shale is named after the town of Hamilton, N. Y.

Formation No. 8-D—The Tully limestone is named from the village of Tully, Onondaga County, N. Y.

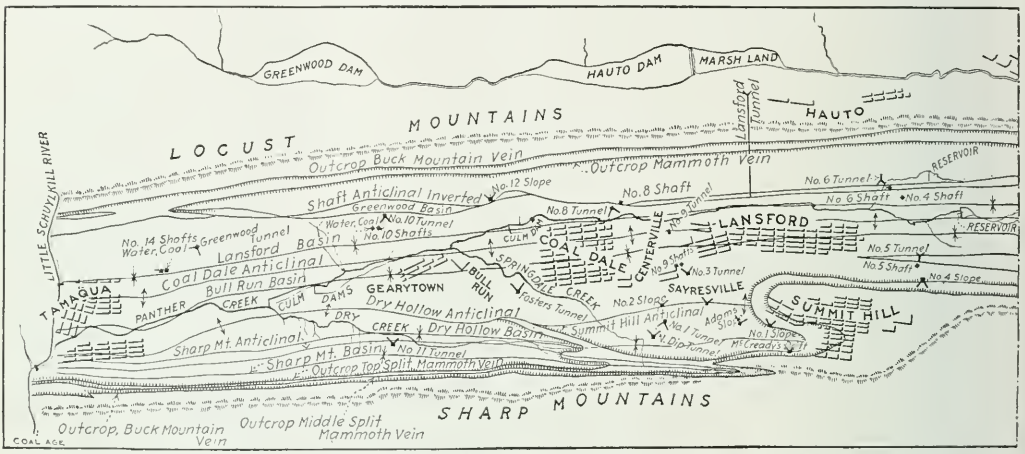
Formation No. 8-E—The Genesee slate (named after the Genesee River) outcrops in Carbon County one-half mile north of Kregesville and at Lehighton, Carbon County, just above the Lehighton Railroad station.

Formation No. 8-F—The Portage formation, named after three high falls on the Genesee River, in Western New York, is composed of shales and flaggy sandstones.

Formation No. 8-F. G.—The Girard shale of Erie County is ashen gray in color.

Formation No. 8-G—The Chemung outcrops in Erie County. It is composed of olive and green shales, sandstones and conglomerate. It also outcrops at Stroudsburg and runs from the Lehigh to the Schuylkill and Susquehanna Rivers. Oil and gas are found in this formation.

Formation No. 9—The Catskill formation is the uppermost of the Devonian. It was named after the lofty mass of mountain sandstone on the Hudson River, near Poughkeepsie, N. Y. Coal seams of from one-half to one inch are sometimes found in this formation which consists of sandstones, often passing into conglomerates, with some shale. The beds are usually red, but greenish and other shades occur. The Catskill formation is carried forward under the Broad Mountain from a point two miles below Mauch Chunk to the Little Schuylkill River. The second mountain south of Lansford carries forward the Catskill outcrop in a straight course, S. 62° W., to the Schuylkill River, three miles below Pottsville.



GEOLOGICAL MAP OF THE PANTHER CREEK VALLEY, SHOWING THE OUTCROPS

The second mountain south of Lansford carries forward the Catskill outcrop in a straight course, S. 62° W., to the Schuylkill River, three miles below Pottsville.

Formation No. 10—The Pocono formation (named after the Pocono Mountains in Monroe County) is the first or oldest subdivision of that great carboniferous system which has furnished most of the mineral coal in our day. The coal beds of the Pocono formation are thin and local, some of them mere collections of leaves and twigs floated into small lakes or ponds. A few were genuine peat bogs of limited extent, and soon buried under the inflowing sand. Even the earlier beds of the productive coal measures were irregular in size and area, by which it can be easily inferred that the great vegetation of the coal age had not yet spread itself.

Pocono coal has been found within the limits of Pennsylvania, in the Cove and Buffalo Mountains, on the Susquehanna, in Sidelong Hill, in Huntingdon County, on Tipton Run in Blair County, and in many other ravines descending the escarpment of the Allegheny Mountains; but at every attempt to work it profitably it has been a failure, except at the Tipton mines, a few miles northeast of Altoona. Here actual mining operations have been carried on. A branch road has been laid from the Pennsylvania R.R. at Tipton, and thousands of tons of good coal have been sent to the market.

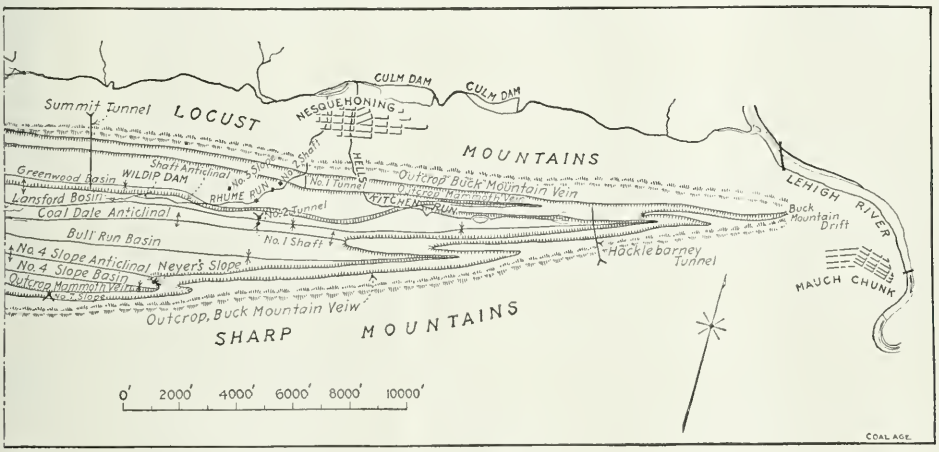
The Pocono sandstones, which rest on the Catskill formation, form the sharp crests or flat tops of most of the mountain ranges in Carbon County. The Nesquehoning, or Broad Mountain, west of the Lehigh River, is a triangular flat compound arch of Pocono, covered with a sea sand much like that spread over the Broad Mountain of the Pottsville conglomerate north of Pottsville. North of Glen Onoko it is composed of hard gray and greenish-gray sandstone and hard gray sandstone with dark gray shale. It is 1235 ft. thick north and south of Lansford, Pennsylvania.

Formation No. 11—The Mauch Chunk red shale, 2168 ft. thick at Mauch Chunk, is certainly one of the most remarkable formations in Pennsylvania, or indeed in any part of the world. Its color, its immense thickness to the southeast and its gradual thinning out to the northwest and west and the paucity of animal or vegetable life, are among its characteristics.

Beginning at Mauch Chunk the red shale valley, walled in between the straight Pocono Second Mountain and the Pottsville Sharp Mountain, runs with a depth of about 800 ft. and a width of about three-quarters of a mile, perfectly smooth and straight, from the Lehigh to the Little Schuylkill River. The red shale turns the eastern end of the basin of the Panther Creek Valley at the sharp-pointed cliff, known as Mt. Pisgah and runs west between the Locust and the Nesquehoning Mountains to the Little Schuylkill River.

The Pocono sandstone held its own against the denuding agencies but the overlying Mauch Creek red shale is a fragile rock and was nearly eroded off the Pocono floor, thus forming the Nesquehoning, Bloomingdale and Owl Creek Valleys.

Formation No. 12—The Pottsville conglomerate is the twelfth distinct formation of the Paleozoic time and forms the basal member of the true carboniferous series everywhere in Pennsylvania. Mining men frequently refer to it as the "farewell rock" because usually no true workable coal beds are found within it. The Pottsville conglomerate is so called from its magnificent and characteristic developments near the Schuylkill countyseat where it exhibits a massive structure of conglomerate and sandstone 1200 ft. thick, making a distinct break in the lithology of that locality between the underlying Mauch Chunk red shale and the overlying coal beds, sandstones, shales, etc., of the anthracite basin. The Pottsville conglomerate is 800 ft. thick through the Lansford Tunnel. By its resistance to erosion, it has been an important factor in preserving the small part of the original anthracite field which now remains. Geologists generally estimate that for every ton of coal remaining in the hard-coal region, 98 tons have been swept away by erosion, into the Atlantic Ocean. This conglomerate is the floor on which the coal measures rest and its outcrops form a protecting and inclosing mountainous rim to the softer coal measures. It is composed of beds of gray conglomerate, white-gray and brownish sandstone, usually coarse and hard, some thin beds of carbonaceous slate and generally one or more thin seams of coal, while in the southern part of the state, as at Lykens, Penn., it contains large and valuable coal seams.



OF THE PRINCIPAL SEAMS AND THE MAIN ANTICLINALS AND BASINS

Limits of the Pottsville Conglomerate—The bottom of the Buck Mountain bed, the first bed overlying the conglomerate, has been taken as the upper limit. It is, as a rule, a well defined horizon and there is rarely any difficulty in fixing its position. The placing of the bottom is much more difficult, as the transition from the red shales of No. 11 to the conglomerates of No. 12 is not often abrupt.

Thickness of the Pottsville Conglomerate—The formation shows a marked decrease in thickness and in the coarseness of the materials composing it, from the southwest to the northeast, the maximum being apparently reached in the southwestern part of this field. Measure-

ments at the Lincoln and Kalmia Collieries, where there are extensive tunnels to tap the Lykens Valley coal beds, furnish a complete section of about 1475 ft. Its thickness in the Broad Mountain is about 1200 ft., which is about the average throughout this field. In the Northern field it averages about 225 feet.

The Coal Measures (Formation No. 13)

The coal measures consist of beds of sandstone, shale, fireclay, black carbonaceous slate or shale, and beds of coal from a few inches in thickness up to the great Mammoth which, over large areas, is from 50 to 60 ft. thick. The prevailing color of the sandstone and shale is brown or gray. Beds of fine conglomerate occur within the coal measures and in some instances they are so coarse and massive as to have been mistaken for the Pottsville conglomerate. The coal seams are fairly well distributed throughout the whole of the measures, the formations separating them varying from a few feet to a couple of hundred, but it is seldom that a barren interval of more than 200 ft. occurs. The distance between the same coal beds vary somewhat, and at times decidedly, in the different basins as well as in different parts of the same basin. The lower 300 to 500 ft. of the measures, from the No. 12 to the top of the Mammoth seam, as a rule, contains the thickest coal and are more productive than those higher in the series.

Thickness of the Coal Measures—The greatest thickness is found in the deep basin of the Southern field where the total aggregates more than 2500 ft. Workable coal beds extend to the very top of the column and perhaps still others may have been originally deposited, of which every trace has been removed by erosion.

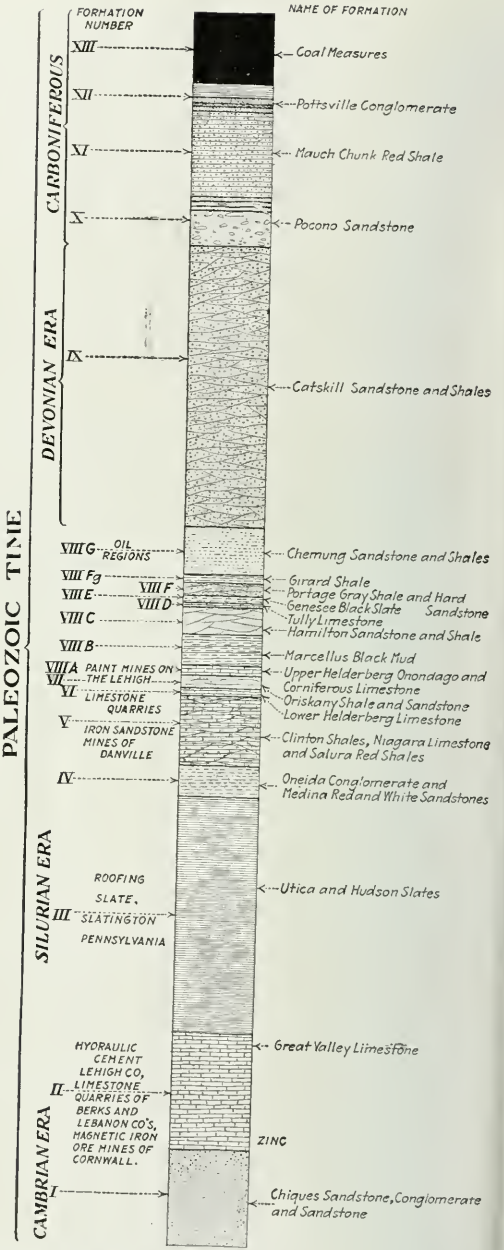
The successive deposits, from the Archean rocks to the top of the coal measures aggregate 31,500 ft., and were originally deposited in succession as shown on the accompanying columnar section, in a great water basin which, in early times, occupied the area which is now the Appalachian Mountains. Some of these measures were found in deep sea water, some in water so shallow that they exhibit mud cracks, ripple marks and foot prints and hold both shore living shells and coral reefs. These facts force us to believe that the bottom of the Pennsylvania sea continued sinking through all the ages during which these deposits were made. The rate of their deposition has been estimated at 5 ft. in a century, approximately 630,000 years to deposit the 13 formations described.

The thoughts that must be kept in mind in Pennsylvania Geology during the Paleozoic time are:

First—That which was the continental area of crystalline rocks became, by a downward movement of the earth's crust, an Appalachian sea basin of unknown depth and was in the course of the Cambrian, Silurian, Devonian and Carboniferous ages, so completely filled up as to become at last a great marsh or archipelago of marshes bearing the coal vegetation.

Secondly—That this whole area was then lifted high in the air and that a corresponding contemporaneous movement established the Atlantic Ocean, or parts of it, as the thrust that elevated the Sharp, Locust and Appalachian Mountains came from that direction.

In the accompanying illustrations there is a vertical section on line with, and through the Lansford Tunnel, showing the relative positions of the coal measures, the



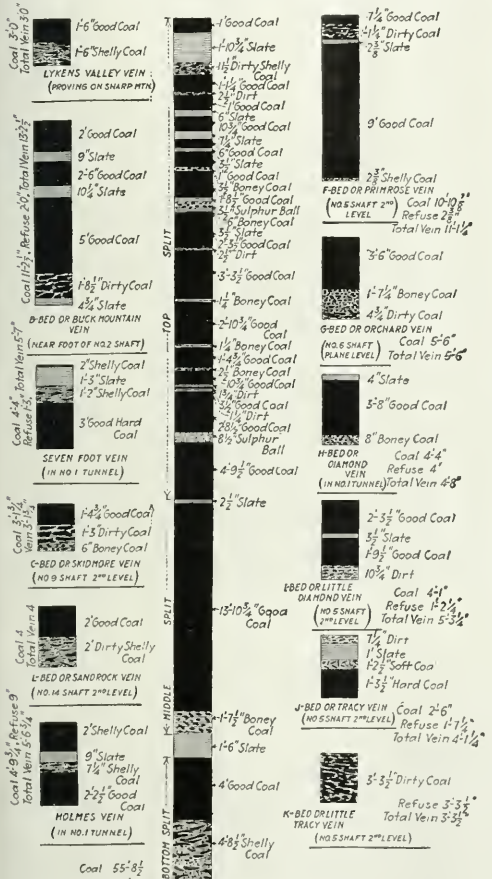
Columnar Section of the Pennsylvania Formations

Pottsville conglomerate, the Mauch Chunk red shale, and the Pocono sandstone, of the Carboniferous.

Flexures are generally parallel to the axis of the mountain range, but they are not so in this valley where they have a tendency to approach the southern rim of the valley, from the north to the south, and have the steepest

side generally facing the northwest, away from the Atlantic Ocean.

Measuring the Buck Mountain vein on this section, along its dips from outcrop to outcrop, you will find it to measure 10,400 ft., while, if we measure horizontally on the surface between the outcrops, we will find it to measure 7900 ft. This means that the vein, when horizontal, spread over the surface 2500 ft. more, or has been shortened 2500 ft. in consequence of its flexures.



SECTIONS OF THE COAL SEAMS IN THE PANTHER CREEK VALLEY

The coal measures (9 seams) as shown on the section in the Bull Run Basin are 1600 ft. thick. The lowest vein, the Lykens Valley, is in the Pottsville conglomerate and, in the Lansford Tunel, it is only a streak.

The Buck Mountain, or "B" Vein, has a specific gravity of 1.62 and is only 1.6 ft. thick in the Lansford Tunnel.

The Seven Foot Vein is 12 ft. 4 in. thick and averages 11 ft. 3 in. of coal.

The Skidmore, or *"C" Vein,* has a specific gravity of 1.64, is 3 ft. thick of good coal.

The Mammoth, or *"E" Vein,* has a specific gravity of 1.61, is 40 ft. thick and averages 30 ft. 8 in. of coal.

The Primrose, or *"F" Vein,* has a specific gravity of 1.60, is 19 ft. thick, nearly all good coal. It will be noted on the section that the Primrose Vein is shown at the mouth of the tunnel which cuts in two places. This is due to an overthrust of the strata.

The Orchard, or *"D" Vein,* has a specific gravity of 1.59, is 3 ft. 3 in. thick and contains 2 ft. 9 in. of coal.

The Diamond, or *"H" Vein,* has a specific gravity of 1.59, and was not cut in the tunnel, but is nevertheless in the Lansford and Bull Run Basins. It is about three feet thick, with 2 ft. 9 in. of good coal.

The Buck Mountain, or *"B" Vein,* is not workable at this point, but at Nesquehoning and Rahn Collieries, it it a very good seam, averaging 12 ft. thick with 10 ft. of coal.

The Holmes Vein, shown on the section, has a specific gravity of 1.58. It is only about one foot thick at this point, but is being worked at the Nesquehoning Colliery where it averages five feet thick, with four feet of coal.

The analysis of coal in this valley is as follows:

	Per Cent.
Moisture	3
Volatile	4
Fixed carbon	88
Ash	5

The total distance from the Lykens Valley to the Buck Mountain seam measured at right angles to the measures is about 515 ft., subdivided as follows:

From	To	Feet
Buck Mountain	Seven Foot Vein	90
Seven Foot	Skidmore Vein	40
Skidmore	Mammoth Vein	40
Mammoth	Holmes Vein	100
Holmes	Primrose Vein	325
Primrose	Orchard Vein	160
Orchard	Diamond Vein	75

The total thickness of the coal measures is 1600 ft. The gross thickness of the coal aggregates 71.5 ft., thus averaging 22 ft. of rock for every foot of coal. The Pottsville conglomerate is 800 ft. thick, the Mauch Chunk red shale is 2168 ft., and the Pocono sandstone is 1256 ft. thick, showing a total deposit of the Carboniferous of 5824 feet.

The Lansford Tunnel was opened originally as a mine tunnel, but in 1870 the tunnel was driven through to Hauto and the Nesquehoning Valley Railroad ran through to the Panther Creek Basin.

On the section at Summit Hill Anticlinal, I call your attention to the old quarry, which was opened in 1792. The first discovery of coal in this region was made during 1791 by the famous Phillip Ginther.

There has been sent to market and used for fuel, from the Panther Creek Valley, from 1820 to 1911 inclusive, 80,000,000 tons. The estimated life from provings so far made would indicate that the coal goes to a greater depth than has yet been reached, so that there should be a good production from this valley one hundred years hence.

The lignite beds of Alabama, Mississippi and Tennessee have been developed but slightly or not at all, while the lignites of Texas, Arkansas, the Dakotas and eastern Montana have a limited development. Lignites from Montana sometimes contain from 20 to 40 per cent. of moisture, which causes them to deteriorate rapidly on exposure to the air, thus rendering them of little value as fuel.

Phenomenal Outburst of Water at Equality.

By Lucien W. Gordon*

SYNOPSIS—The mine of the Gallatin Coal and Coke Co. was submerged and in the wreck accompanying the flow of water into the mine, the tipple and surface works were all wrecked and drawn toward a crater at the mouth of the shaft. Suddenly the mine ejected water, cars and tipple wreckage; there were several such expulsions before the phenomenon ceased.

On Sunday, Apr. 6, 1913, the 600-ton shipping mine of the Gallatin Coal & Coke Co., at Equality, Illinois, was totally destroyed in rather a unique manner, namely, by rapidly filling with back water from the Ohio River flood and by resultant outbursts of the air compressed by the inflow of water into the mine.

The entrance to the mine is an 80-ft. shaft which was sunk in 1882 by the late Broughton Temple. It was the first shipping mine developed in the southeastern Illinois field. It is located about five miles from the now well known Saline County district. The coal is extracted from seam No. 5, the number being reckoned according to the well recognized Illinois usage. Its thickness is five feet.

About 150 acres have been mined out. The main entries run to the dip and most of the rooms are driven to the rise. The roof is unusually strong and it has never broken except in about two places where the coal has been worked to the crop. The roof consists of a hard black slate with about 4 ft. of hard schist and 30 ft. of heavy bedded sandstone.

The Efforts to Protect the Mine

The mine was opened at a level above any previous high-water mark, but the exceptional flood of 1884 caused a small "cave" at the crop. Pumping was necessary while this flood continued and after this the mine mouth and buildings were raised above the flood level of that year and a large mound was built around the plant.

About the last of March in this present year, it was seen that all previous records for high-water would be broken. All mining operations were stopped, the mules brought to the surface and all available men were put to work at raising the mouth of the shaft with sandbags and clay.

About Mar. 31, it was found that the shaft cribbing had given way just above the rock and much water and débris were falling down the shaft. This was checked by placing further sandbags and clay to resist the action. Conditions seemed to improve till Apr. 5, when the caving again commenced, the backwater steadily rising.

The Second Outburst from the Gallatin Coal & Coke Co.'s Mine

The Mine of Gallatin Coal & Coke Co. before the Flood

All That Remains of What Was the Equality Mine

On the morning of Apr. 6, the tipple was found to be undermined and extensive caving commenced at the power house about 50 ft. away. For this reason, people were ordered away from the buildings. At 10 a.m., the tipple sank out of sight, without, however, toppling over. With the buildings sank mine cars, barrels of oil, the shaker and fan engines, concrete piers and tons of rubbish. The rush broke down the greater part of the

*Equality, Ill.

power house, the blacksmith shop and one of the elevated storage bins.

The Outbursts of Water

At 3:25 p.m. the mine had apparently nearly filled with water and the surface of the flood was almost quiet. The demolished plant was surrounded by sightseers, who observed the ravages of the flood from boats, the gob-pile, and high ground around. Suddenly a tremendous "explosion" occurred sending the water, dirt, rock, broken timbers and machinery about 600 ft. in the air. Twelve minutes later a second "explosion" occurred and of this I made the appended snapshot picture. Comparing the water column with known objects, I estimate its height as 260 ft. A number of gradually diminishing "explosions" took place till about 5 o'clock.

The weight of the water ejected, crushed in the roofs of the neighboring buildings; one of the cages known to have sunk in the mine was blown 300 ft. away, over the gob-pile, and the fan engine located at the foot of the tipple and known to have sunk with it, with its attached concrete base, estimated to weigh five tons, is now lying 60 ft. away. The 12-in. built-up posts of the tipple were broken into pieces and hurled hundreds of feet, and mine cars were seen at a height of 60 ft. above the shaft mouth. Draw slate, rock and fire clay were scattered over more than an acre and the 4-ft. sheaves at the top of the framework were sunk to their hubs on falling, an evidence of the height to which they were thrown.

The mine was sunk at the southern crop of the coal field and this caused the workings to be directed wholly to the north. In a measure, this probably explains the "explosions." The main entry ran N 22° W for 1200 ft. with a dip of 2 ft., then it turned to the right and went N 24° E 4600 ft. having a dip of 38 ft. in the first 1200 ft., the other 3400 ft. being flat. The east entries were driven S 66° E for 1200 ft. with a dip of 8 ft. The west entries ran N 66° W for 1600 ft. and rose 30 ft.

While some think that the compression of the air in the high levels caused the "explosions" it is more probable that previous caving had partially closed the foot of the shaft and that the rush of water completed the closure, thereby compressing the air in the main entries until the air pressure became greater than that of water. Many believe that the first water entered the shaft through rat burrows.

A group of men standing on the gob-pile at the time of the outburst was deluged with water and some were slightly bruised, but fortunately there was no loss of life. The mine mouth is now caved in, leaving an opening about 40 ft. across. The loss, including the expense of pumping is about $30,000.

The Shaft Buildings Sink As the Water Pours into the Mine

After the Tipple Had Sunk Out of Sight by Undermining

Meeting of Institute of Mining Engineers

By R. Dawson Hall

SYNOPSIS—On a per-diem basis, the coal miner is declared to have a greater death rate from accidents than the metal miner, though there is much reason to doubt the parallelism of the data on which the calculation is based. Precautions taken in aqueduct tunnels under New York City and a sizer for coal and other materials which does not depend on screenings and promises to show remarkable sizing powers and a minimum of breakage and attrition, formed the subjects of two other interesting papers.

A regular meeting of the New York Section of the American Institute of Mining Engineers was held on Friday, May 2, at the Engineering Societies' Building, 29 W. 39th St., New York City.

The chair was occupied by G. F. Kunz, retiring Chairman of the Executive Committee of the New York Section. The following officers were elected for the insuing year: Chairman, L. D. Huntoon; Vice-Chairman, A. S. Dwight; Secretary, T. T. Read; Treasurer, E. M. Shipp.

After a short discussion on ways and means, M. Below-sky, custodian of the Mineralogical and Petrographical Institute and Museum, at Berlin, made a speech in German, requesting the aid of the members in his work.

Albert H. Fay read his paper on "Metal-Mine Accidents in the United States." Mr. Fay, of course, in introducing his original remarks had to cover much of the

ground of his technical paper No. 40. In the latter part of the paper he did much to modify and correct the position which had been taken that today metal mines are more dangerous than coal mines.

He pointed out that the latter mines worked only 220 days, according to the report of the Geological Survey, whereas the mineral mines worked 300 days, according to his count.

The following table is compiled to show what the death rate would probably be per thousand men employed if the number of men killed were proportioned to the days worked and the time was in each case equated to 300 days per year.

LOSS OF LIFE PER THOUSAND EMPLOYEES BASED ON A 300-DAY YEAR IN VARIOUS MINES

Class of Mines	Actual days worked	Deaths per thousand employes	Deaths per thousand calculated on 300-day basis
Copper	308	5.33	5 19
Iron	277	4 29	4 65
Lead and zinc (Mississippi Valley)	256	3.43	4 02
Gold and miscellaneous metals	276	3.95	4 30
Non-metal except coal	258	1.73	2.01
All mines except coal	282	4.19	4 45
Coal mines	220	3 73	5.09
Quarries	228	1.69	2 22

Mr. Fay defined a quarry as a place where building material is obtained. Cement rock and broken stone, as well as dressed rock, is regarded as being the product of a quarry.

Other figures given by Mr. Fay are interesting:

LOSS OF LIFE PER MILLION TONS OF MATERIAL PRODUCED

Mines	Lives lost per million tons extracted	Lives lost per million dollars worth of product
Copper	7 96	1 74
Iron	4 29	0 60
Lead and zinc (Missippi Valley)	2 99	1.18
Miscellaneous mines (Gold and silver and others)	12 58	1 12
Other non-metal except coal	3 53	0.60
All mines except coal	6 16	0 97
Coal	5 48	4.37

Mr. Fay presented the following figures which err, we believe, in the direction of liberality. Every life lost is figured as worth $5000. The time lost is calculated on a 30-day basis and the wage of the miner at $3 per day.

LOSS IN MINING FROM ACCIDENT AND DEATH PER ANNUM

Death of metal miners	$3,000,000
Accidents of metal miners	1,000,000
Total	$4,000,000
Deaths and accidents of coal miners	$14,000,000
Deaths and accidents to quarry men	1,000,000
Grand total	$20,000,000

Taking the grand aggregate of men employed as one million, the loss is $20 per employee.

The speaker laid much stress on the number of blasting accidents and said that regulation by inspectors would largely reduce them as it had such accidents in coal mines. The blasts in metal mines are, however, much larger and more severe than in coal mines. Certainly, except where shotfirers are employed, the men who fire shots in coal mines are not superior to those who fire them in metal mines.

Moreover, even where shotfirers are engaged, the holes are usually loaded by the rank and file of operatives and not by expert men. The difference in death rate is largely due to the fact that coal-mine shots are small and single, whereas metal mines more usually explode larger shots and several at a single time.

Precautions in New York Aqueducts

John R. Healy, assistant engineer of the Board of Water Supply of the City of New York, described some precautions taken to prevent accidents in the tunnel work. All the men who load and fire shot holes have been examined and certified by the Bureau of Combustibles. All explosives used are non-freezing and the amount needed for each day's work (about half a ton)is stored underground in a magazine connected by a z-shaped passage 40 ft. long closed by a heavy door. The caps are kept apart from the explosives in a recess in the passage.

Where 20 to 25 holes are exploded in three rounds, only those holes which are exploded in one round are loaded at any one time. All firing is by electricity and the switch box controlling the ignition is kept locked, the foreman keeping the key. The field force of the Board of Water Supply examines the roof, the work not being left solely to the contractor's vigilance.

Care is taken to make the shafts larger near the surface so as to avoid material falling at the sides. Doors are placed in the shaft to prevent concrete falling down on the men below. Some contractors have put life nets below the men who were engaged in concreting. Others tried to hold them by life-lines and had a strike on their hands.

It is rumored that despite all the precautions, the death rate on the aqueduct is extremely high, but Mr. Healy gave no statistics on this subject. As usual, several men have died from shear foolishness. One man ran his motor into the shaft. The cager instead of stopping the cage jumped into the shaft to save him and was killed. Many men too eager to get home left the air locks before the required time and thus died of the "bends."

A Competitor of the Mine Screen

A paper was read by Thomas B. Stearns, of Denver, Colo., on the "McKesson-Rice Screenless Sizer. This machine operates on the following principles: (1) The largest particles roll furthest down an inclined plane; (2) if a sidewise reciprocating motion is given such a plane, the particles follow paths diverging like a fan. The smaller particles are carried further across the plane than the larger and may leave it on the side. (3) Particles on a plane broken into steps can be made to move across that plane opposite the direction of motion. (4) Particles will move with facility down a series of corrugations if the perpendiculars from their centers of gravity clear their summits. By arranging the corrugations on any one of a series of steps, it can be provided that particles of a certain size cannot travel down a plane but must travel in the direction of corrugation, whereas large particles will run quite freely, passing over the summits of the roughnesses.

As a result without the use of screens, as many as 15 different sizes have been obtained in the preparation of abrasive material for the manufacture of sand-paper, the material being taken from the bottom and side of the stepped plane. These sizings were on exhibit and photos of coal preparation were also shown. The method is of value because there are no screens to wear out, the power required is small, but little space is required, the abrasion of the material is reduced, owing to the shortness of the reciprocation of the table and to reduced travel of the coal as compared with those motions on a screen. Moreover, the coal is not in so deep a bed nor is it tossed as in a screen. Hence the abrasion is reduced to a minimum. It is hoped that the soft coal can be prepared more cheaply, less wastefully, in smaller space and more acceptably than by the present screening methods. At the same time the inventors do not wish to place the machine on the market till further experiments have been made.

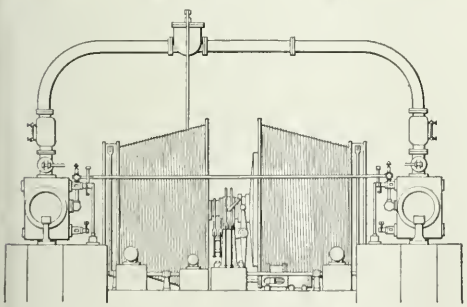
Solving the Hoisting Problem

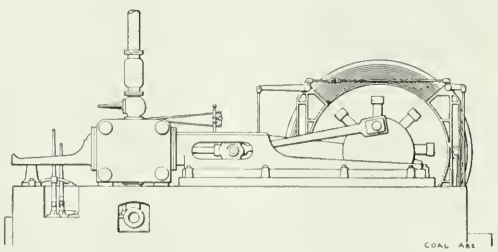
By L. F. Mitten*

SYNOPSIS—Description of a Corliss valve hoisting engine of large size. The first few revolutions are made with a late cutoff and the Corliss gear disconnected. When full speed has been attained, a complete advance of the throttle throws the trip motion into gear and steam is used expansively throughout the balance of the hoist.

One of the evidences of the changing conditions in the coal fields as regards economy and efficiency of equipment is shown by the steady increase in the demand for hoisting engines of low steam consumption. The accompanying illustration shows a 34x48-in. first-motion, link-reversing, heavy-duty, Corliss type of hoisting engine

The Conical Drums on the Erecting Floor. Note Comparative Size of Man





Rear and Side View of Corliss Hoisting Engine

built by the Vulcan Iron Works, of Wilkes-Barre, Penn., for installation by the Coal Mining Department of the Delaware, Lackawanna & Western R.R. Co.

A few years ago hoisting engines of this type were exceedingly rare in the coal regions. Fuel was, or was thought to be, cheap, ranging in estimated value from 75c. to $1 per ton, and economy of operation was therefore given practically no consideration. Operators could not see the wisdom of investing any considerable amount of money in expensive machinery merely for the sake of saving a few tons of cheap fuel when they could secure less expensive equipment that would do the work for the time being and which could be easily and cheaply replaced when necessary.

These were the conditions that manufacturers of high-grade machinery had to face, and the fact that the older types of extravagant hoisting engines are being replaced by equipment which is thoroughly modern and efficient, shows clearly the trend of the times and makes a description of the hoist mentioned above of interest to all mine owners and managers.

These engines are equipped with two conical drums, each tapering from 14 to 10 ft. in diameter and spirally grooved for 1½-in. rope. One drum is securely keyed to the engine shaft, while the other is brass bushed and driven by a toothed clutch wheel to allow for changing for different levels. The engines are reversed by an independent steam cylinder and the brakes on each drum are operated by this same means. Auxiliary hand brakes are also provided.

The engines are equipped with tail crossheads which take the weight of the pistons off from the inner surface of the cylinder and prevent the ordinary elliptical wear. Sheet steel crank and splash guards are furnished which cover entirely the crank disks. Guards are also provided for the tail crossheads.

The arrangement of throttles differs from the general practice followed in the coal regions. On top of each cylinder is mounted a vertical throttle valve. These are operated simultaneously through a crossshaft. Surmounting each throttle is a steam separator and an auxiliary throttle, which is used in case of emergency, is mounted in the overhead pipe line.

The valve motion is of the full Corliss type provided with dash pots. The cylinders are fitted with Vulcan improved releasing valve gears and the actuating catches are a combination of the hand adjusted spring and gravity types. The trip or releasing motion instead of being controlled by the ordinary type of Corliss governor is operated from the throttle lever.

The first two or three revolutions of the engine are made with a late cutoff, the throttle being only partially open. A complete advance of the hand lever after full speed has been attained throws into gear the trip motion and the engine then uses steam expansively for the balance of the hoist. The cylinders are also fitted with a by-pass arrangement allowing the engineer to lower a load

*Wilkes-Barre, Penn.

under compression, a foot pedal being conveniently located for this service.

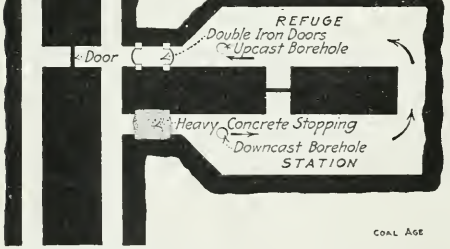
The engines are designed to handle 100 cars per hour in a vertical shaft having a present depth of 900 ft. but which will ultimately be increased to approximately 1575 ft. Cars will be hoisted from the lower level to the top of the tower in self-dumping cages. These will weigh approximately 13,000 lb. The empty cars will wiegh 5000 lb. and the coal 8000 lb.

Some idea of the size of this installation is to be gained from reference to the photograph of two of the conical drums taken while in the erecting shop. Each section of thes drums together with the drum siders weighs approximately 40 tons.

Refuge Stations in Mines

By James E. Smith*

There are too many lives destroyed in mines by explosions and otherwise and I feel satisfied that sixty per cent. of these lives could and would be saved if they only had some place of safety where they could retreat. As is well known, an explosion destroys everything in its path and its path is towards the shafts which is the only relief for the blast. Invariably there are miners who are not injured and knowing there is no escape they have to wait for the consequences, which is death from afterdamp.



Plan of Proposed Refuge Station in a Mine

I claim that these miners' lives can be saved if suitable refuge stations were installed in the mines. The nearer to the working faces these stations are located, the better chance the miners will have to reach them. These stations should be ventilated by one, or better two, boreholes, say eight, ten, or twelve inches in diameter. If but one borehole is used it will be necessary to insert a four-, five- or six-inch pipe inside of the larger casing, and connect this pipe with a small air compressor or blower on the surface to ventilate the chamber, the air returning up the larger casing.

Such safety stations may be made by driving a pair of rooms, as shown in the accompanying figure, off the inside cross entries, or at any suitable place in the mine; the width of the rooms to be determined by the character of the roof and floor. The necks of the rooms should be driven in narrow, about twenty feet, and then widened. Two boiler-iron doors are to be placed in one of the room necks, about ten feet apart, a strip of asbestos being attached to the door where it meets the frame. The other neck is closed by a heavy concrete stopping, as shown in the figure.

The door frames are to be constructed of concrete, cut in the bottom 6 in. and showing a face of 4 in. above the floor; the top frame cut in the roof 6 in. and showing a face of 4 in. below the roof; the side frames to be cut in the pillars 18 in., showing a face of 4 in. outside of the pillar; the whole frame to be at least two feet thick.

A drill hole is sunk from the surface to each of the two rooms; all surface water is shut off. A common blower placed on the surface can be attached to the pipe at a moment's notice so as to furnish sufficient air to sustain life for a large body of men, until they can be reached with safety from the surface. This pipe can also be used for the purpose of furnishing the men with food and water and sending messages back and forth. A telephone can be placed in the chamber so as to communicate with the office on the surface.

The doors of said chamber should be semi-circular in shape and open in opposite directions, one to resist pressure and the other to resist any suction that may occur and both to be air-tight. Everything being fireproof, if there is any danger of fire in the mine you may at once cover up the shafts. There is no need of men going in search of life and losing their own lives in the effort, as was done at Cherry and other places. If this device had been used in the Cherry mine before the fire, not a man of the four hundred would have been lost; or the same in the mine at Delagua, Colo., where but one man was mutilated and twenty-nine men were found dead in one chamber from the effects of afterdamp.

*Peoria, Ill.

Revision of Mining Laws in Washington State*

The legislature of 1911 provided for the appointment of a commission to revise the law regulating the operation of coal mines, the commission to consist of, one coal-mine operator, one mining engineer, two practical coal miners and the state coal-mine inspector. The first four named above were to be appointed by the governor and the fifth was a member *ex-officio*.

The following persons were appointed by Gov. M. E. Hay: Coal-mine operator, F. A. Hill, Seattle; mining engineer, J. B. Warriner, Tacoma; miners, George Temperly, Roslyn, and Peter McLean, Wilkeson; and state mine inspector, D. C. Botting, Seattle.

After the commission had held two meetings, Mr. McLean was taken seriously ill and at his request further meetings were postponed. He finally resigned and Frank Bennett, of Roslyn, was appointed to fill the vacancy. Mr. Warriner resigned, October, 1912, to accept a position with a mining company in Pennsylvania; and C. R. Claghorn, E. M., was appointed in his place.

This commission has endeavored to compile a code that will work out along practical lines, and it is to be hoped that the members of the 1913 legislature will include it among the laws passed. It has been prepared after careful study and the members of the commission are certain that in placing it on the statutes, the safety to life, limb, health and property of men engaged in this industry will be greatly enhanced.

*From the advance sheets of the Report of the State Inspector of Mines, for 1912.

EDITORIALS

The Anthracite Mining Code

Mining men throughout the State of Pennsylvania are watching with much anxiety the doings of the legislature now in session in that state. The commission to revise and codify the anthracite mining laws of Pennsylvania, appointed by Governor Tener, under the Act of June 14, 1911, which act directed the commission to report its deliberations and recommendations to the next General Assembly (session of 1913), submitted two reports, differing from each other in important points. The majority report was signed by six members of the commission; the remaining three members submitting a minority report, which was seemingly inspired, in some of its provisions at least, by influences emanating from the United Mine Workers' organization.

Both of these reports were referred promptly to the Committee on Mines and Mining. The majority report received the first attention of the committee, and after prolonged consideration was reported out, having been amended by the committee in a few unimportant matters that were agreed to by those who signed the report. Later, Apr. 22, the minority report was reported favorably to the House, by the committee. It is understood that this minority report was signed by the three members of the commission chosen from the mine workers of the anthracite region.

One of the prominent features of the minority report, in which it differs from the majority report, is the provision made in Article 15, that the mine inspectors of the anthracite region shall be elected by "the qualified electors of the several inspection districts."

The law under which the anthracite mine inspectors of Pennsylvania have been elected by popular vote in their several districts, has been clearly proven to be one of the most pernicious features of the state mining law, during the decade in which it has been in force. The majority report of the commission seeks, in Article 9, Section 6, to change this condition by providing that all anthracite mine inspectors shall be commissioned by the governor from the certified list furnished him by the examining board, in the order of the percentage mark received by the candidate in the examination. So much has been written in regard to the relative advantages of the appointed and elective systems in the choice of mine inspectors, that nothing is to be gained by further comment, but the hope is expressed that the present legislative session will mark a change in the present law, in this respect.

We will mention briefly one other feature of the minority report that in itself should be sufficient to kill the bill. We refer to the provision made in Article 15, Section 8, that "All persons holding mine foremen certificates shall be eligible to run for the office of mine inspector." According to this section, all that is required of the candidate for the office of mine inspector is that "he shall file his mine-foreman certificate with the county commissioners in the county in which he resides. After the filing of such certificate with the county commissioners, his name shall be placed on the official ballot." Such a wild and random provision as this needs no comment. Its enactment as law would overthrow the work of a quarter of a century in the effort to secure greater safety in coal mining in Pennsylvania.

Failure To Put On Breathing Apparatus

A warning example of the danger that may be present to rescue parties equipped with breathing apparatus in perfectly good condition, if the same be not properly employed, may be found in a fatal accident which occurred last November at the Möller mine in the Gladbeck inspection district, Germany. It is the subject of a leading article by Dr. Forstmann in Glückauf, April 6, 1913.

Hearing there was a fire in the mine, a party of subofficials started toward the affected region with breathing apparatus. Three of them, while passing along galleries but faintly permeated by gases from the fire, neglected to use the apparatus, and after awhile sickened, one of them collapsing so as to prevent his going farther. The other two put on breathing apparatus and proceeded. In about an hour they became exhausted and, although a retreat was attempted, they were unable to reach a place of safety.

Their death was shown to be caused by poisoning with carbon monoxide. The effect of the gas which they inhaled at first had apparently been aggravated by their subsequent exertions. It is thought also that one of them neglected to use his second oxygen flask. Neither of the victims belonged to a regular rescue team.

This accident teaches that gases of combustion which are so attenuated as to seem negligible may nevertheless be poisonous and should not be entered without wearing a breathing apparatus.

Coming Substitute for Natural Gas

Modern development of almost every type of mechanical apparatus is along lines of simplicity and economy. With proper design, simplicity means durability; durability means low maintenance and low maintenance means cheaper cost of operation.

The tendency toward simplicity in design is well illustrated in the improvement of the internal-combustion engine. Many of us can well recall the first of these machines to be placed upon the market. But our memories of these engines are that they were a mass of cams, springs, valve rods, etc.; that they were extremely heavy for their horsepower and noisy in almost a like proportion.

After a period of development that has been comparatively short, they are now one of the simplest, most elastic and most responsive machines known, as well as being the lightest of all prime movers for their power. For this reason perhaps more than any other, they have been

the most highly developed in the smaller horsepowers and have served man rather as a plaything and a toy—driving his motor boats, his automobiles and aëroplanes with equal facility—than finding any conspicuous place in industrial or manufacturing institutions.

Although at the present time stationary gas engines are made in 5000-hp. sizes, yet the development of this type of machine is still in its infancy, perhaps not so much in the mechanical construction of the mechanism itself as in the perfection of the means and methods of preparing the engine fuel.

In thermodynamic efficiency, the internal combustion engine is at least the equal, if not the superior, of steam-actuated power-generating apparatus. In the light of our present experience and achievement, it is not too much to hope that at no remote date, means will be developed for successfully producing high-grade engine fuel from inferior and inexpensive coal or lignite. When this result is commercially accomplished, we need have no fear of embarrassment or inconvenience on account of our steadily failing supply of natural gas.

The Load Factor

The paper of H. M. Warren and A. S. Biesecker before the American Institute of Electrical Engineers, published in this issue, was met with no little criticism largely because the authors defined the "load factor" for the purpose of the paper as the average load on the converter increased by the converter losses divided by the rating of the connected units whether idle or working.

The argument of the objectors was that the load factor should have no relation to the possible bad judgment which any operator had exercised in buying machinery which either he did not need or which was too powerful for his purpose.

It was pointed out that the factor, as defined by the authors, rested on the balance which machine purchase and mine development had struck between facilities needed and machinery supplied. The equipment might be excessive or might be inadequate, but the "power factor" should only express the relation between the average energy needs of the equipment with the energy needed at moments of excessive demand.

A furniture maker was instanced whose construction engineer had a contract based on the total cost of installation. In order to swell his percentage return, the consulting engineer bought equipment which greatly exceeded all the legitimate needs of a plant employing a given number of employees. Consequently had one diligently totaled the ratings on the name plates, the denominator of the ratio would have been high and the power factor correspondingly low. Such a factory would appear to be undesirable as a power customer, whereas the fact that it used almost equal quantities of power throughout the day made it a client to be sought.

The public central-station authorities favored comparing the greatest momentary demands of the station, that is the peak of the load with the average needs of the same period. This is a good method when, having built a central station of a certain size, arrangements are made to supply a number of independent concerns. But where a central station, private or public, is started to accommodate a definite number of companies, the problem is different.

It is presumable that the requirements of the various operators will be better known to them than to the power seller. On the strength of the knowledge which they should be presumed to have, they bought machinery of certain ratings. Because the central-station authorities do not know more and may actually know less than the mine-operating department regarding the mine's needs, the equipment purchased for the central station will be based inevitably on a certain function of the installed load, whether the power house is public or private.

Consequently the station equipment is bought for certain anticipated demands and the cost of construction is based on the mine machinery bought by the power-purchasing concerns, who may be independent or the owners of the station. Hence the relation of the load borne to the load expected is a ratio of no little commercial importance. A certain percentage of variation between provision and use has been expected and allowance has doubtless been made for it, but every further variation means a decrease in the expected income.

This then is the value of the Warren-Bieseker figures, They supply the basis which will make the probable factor apparent, whether it be termed load, use or service factor or what not. Clearly the operator is going to put in so many units to perform the colliery work and obviously he desires to know how large must be the units by which they are to be supplied with energy. If he does not know what the average load will be, how can he discover what is the peak load which must be met even if he has the relating factor. He might have a factor connecting average load with rating units and then a factor connecting that average with the peak load, but the Warren-Bieseker factor, to give it a title which no caviler can condemn, combines both these requirements in a single figure.

It is an uncertain factor, and to be used with caution as indeed are many others. But the authors have found it checks remarkably well in their Lackawanna practice, so closely indeed as to occasion surprise. Not how close the factor of the largest station is to the average. In fact mining practice is stereotyped, especially in any one region, and the needs are much alike. This keeps the Warren-Bieseker factors from excessive variation when taken for equal durations of time. As a rule, mine installations are rather inadequate than excessive and machinery is rarely bought before it is needed.

It would have been equally justifiable to attack the paper on the grounds that the coal mines on which the inquiry was based might be so different from others as to furnish no criterion. Clearly if the installation is not to be declared non-typical because it might be found too large or too small for the work required of it, it might also be objected to as abnormal because used in a manner not typical and then if the load factor demanded by the critics were obtained the result would not be of any value in professional practice. In short the objections to either kind of factor on the ground of uncertainty are at least equal and in addition the factor which the central-station agents demand will not serve the purpose which the authors of the paper were seeking.

The electrical experts may bicker on definitions, but the conclusions reached in the paper are valuable, despite the verbal criticisms of detractors. The authors were not trying to explain the fairest way in which to sell power from a plant already purchased in Chicago, Ill.

DISCUSSION BY READERS

Letter No. 11—The training and education of mining men for the different positions they desire to hold in the mine, must always be adapted to their particular line of work. Drivers, motormen, miners, trackmen, timbermen, electricians, firebosses, steam engineers, surveyors, mine foremen and superintendents should undoubtedly each be trained and educated in their own line of work; but the more information each is able to gain of the other man's work, the more liable he is to advance to a higher position. All mine foremen are on the lookout for bright young men, whom they are pretty sure to advance, provided the man keeps sober and is willing to study.

Training for the position a man occupies is absolutely necessary, and, in my opinion, the greater a man's theoretical knowledge, the more efficient workman he will become. I believe this is true of all grades of mining work, from driver to superintendent. Any miner who has learned to cut coal to the cleavage, one cleat at a time; the trackman who understands curves and gradients, and knows the proper radius for certain mine curves; electricians who know the value of insulation; firemen who know how to keep a thin fire; and mine foremen who can control the ventilation and drainage of a mine and adopt a successful method of working the coal, are the men who are the most valuable, because of the knowledge they possess. Although there are many good men who know little of these things and yet do good work, I am convinced they would do better work if they had a technical knowledge and training.

The position of mine foreman or underground manager requires, perhaps, the broadest information and the best skill and training of any position in the mine, because of the numerous conditions met underground and the difficult problems that must be solved. The mine foreman must understand the constitution and behavior of mine gases; nature of roofs and bottom; the peculiarity of cleavages in the roof and coal. He must possess a knowledge of the flow of fluids; steam, compressed air and electricity; and the application of each of these forms of power to pumping, drainage, ventilation and haulage. He must understand the mining of coal by hand and machine. He must be able to study carefully and successfully the problem of transporting the coal from the face to the tipple. He must be able to handle his men so as to produce dividends.

Hundreds of good men have qualified for these positions in Pennsylvania, Illinois, West Virginia and other states, thus far, without carrying textbooks to the examinations. I can see no reason why this should be done. In my opinion, it is easy to master any of the subjects in mining without the use of any difficult formula or theory. Why then "lower the bars" to admit men who will not study or try to educate themselves.

I remember when first married I could not work a long-division problem. I worked eight hours each day in the mine and studied a like time at night to pass the examination, and I feel I know the value of study. I have never since given up the study of mining subjects or laid my books aside, and I believe there are not 10 per cent. of the mine foremen in Pennsylvania and West Virginia who cannot say the same thing.

However, I do believe that mining examinations should be conducted along practical lines. I do not think it is necessary for examiners to ask how air would split itself up in five splits of given dimensions, from the same fan. In the mine, the foreman makes these splits and divides the air according to the conditions, using the anemometer for this purpose.

If a formula is needed to answer a question, in examination, I think the formula should be given with the question. I believe the introduction of textbooks in examinations would hurt the very persons they were intended to help. In any examination, there is always those who would take advantage of being allowed the use of textbooks and would pass a good examination but have little practical knowledge and less practical ability.

JOSEPH VIRGIN, Supt.

Bancroft, W. Va.

Letter No. 12—The discussion of this question by the readers of COAL AGE leads me to offer the following remarks: The most pressing need of the practical coal miner who is ambitious to acquire an education in his line, is the possession of mining books and papers that will give him the information he wants, in the plainest manner and the simplest language possible. The time a miner can devote to study is limited, and it is important that he should reap the largest returns from his reading and study.

The object of textbooks and mining journals is largely educational and while it may be necessary that in order to meet the requirements of a certain class of technical and scientific readers the writer should express himself in language suitable to that class, it is equally if not more necessary that articles written for the common reader should be expressed in words that he can understand with the least possible effort. In reading many of the articles and books on mining it is necessary for a reader of limited knowledge to refer constantly to a dictionary of scientific terms, in order to understand what he reads. Again, some sentences must be read over several times before one can fully comprehend their real meaning. The result is that the ordinary reader becomes wearied with the effort and the book or journal is thrown aside in disgust.

Without questioning the fact that the writers of most of the articles in our mining journals and of mining textbooks are practical mining men, it may be stated that the language they often use is more characteristic of their scientific than of their practical training. It is this feature that makes their writings so obscure and difficult for the average practical mining man to comprehend.

The majority of the readers of our mining journals and textbooks are men engaged in the actual operation of producing coal. Their daily labor is arduous and dangerous. The conditions under which they work are not such as to train the mind. In many cases, their early edu-

cation has been neglected. If such men can realize the need and importance of education and come to know that "knowledge is power," and that the possession of it will benefit both themselves and their fellow workers, it is only right and just to give them the fullest possible returns for the time and money they expend.

I have reached this conclusion, after conversation with miners and practical mining men in every official capacity and as a result of my own personal experience. The reason that so many mining journals and textbooks fail to interest practical men is because they fail to educate in a way that is easily understood. The principles of mining expressed in simple terms would be of untold value to practical mining men; and authors and writers should realize, when writing, that there are thousands of eager hungry minds waiting and anxious to absorb this mental food.

I. C. Parfitt.

Jerome, Penn.

Letter No. 13—The average mining man who takes up the study of coal mining today is burdened with masses of figures and formulas that look like Greek or Hebrew to his untrained mind. The course of study usually laid out for his guidance commences with the rudiments of arithmetic. If the man is possessed of extraordinary will power, he continues to study arithmetic (the hardest and driest of all studies) until he has mastered fractions, percentage, extraction of roots, the use of sines, cosines, etc., and algebraic formulas. It usually takes the average mining man from one to two years to master these rudiments, which must be done before he can take up the study of gases, pumping, track laying, haulage, ventilation, safety lamps, etc. As a result, he often becomes disgusted before completing mathematics.

I believe it is as important to make the line of study in mining interesting, as to make it instructive. To do this, it is necessary to inject into the course some elementary information on gases, air, steam, electricity, first-aid and drawing. This would rob study of much of its terror, because such information would hold the interest of the student while it broadens his conception.

I do not favor the use of textbooks in examinations. I believe in a high educational standard for mining examinations. Raise the standard of mining up to that of the most modern practice and bring the examination to that standard. Require that all applicants pass this test, but do not lower the examinations to a level where no study, sacrifice or effort is needed, except a few days' or a few weeks' study before the examination.

Much can be said, by way of criticism, of the character of the questions asked at many mining examinations. These questions often fail to state definitely the conditions, and therefore admit of different answers, according to the conditions assumed by the candidate. In such cases, the solution given by the candidate will often be different from that required by the board. If the board has the time, it may be considerate enough to give the candidate credit for his work, as far as that shows he had the right idea. The candidate may have used a different coefficient of friction, or a different constant for the flow of water through pipes, or a different rule for calculating the size of the shaft pillar at a certain depth below the surface. Again, the answer obtained will differ with the number of decimal places to which the work is carried.

Many questions asked depend solely upon the judgment of the person and, as men differ widely in their judgment, the answers to such questions will rarely prove satisfactory to the members of the board. Questions that pertain to particularly local conditions should be carefully stated; because conditions differ widely in different mining districts, and practice in one district would not be successful in another district.

I am in favor of rating each question by stating the percentage or number of points allowed for the correct answer. I believe the board ought always to state the coefficient of friction that should be used or the constant that will be accepted where different constants are used; also the number of decimal places the solution should be carried.

It is quite generally true that many successful candidates in mining examinations, lay by their studies when the examination is over, intending to renew them after a brief rest. Their inclination to study, however, grows less and less as time goes on. Such men will fall behind and give place to more ambitious men.

At the present time, there are many good schools and other means of obtaining a technical education at low cost, either by studying or reading. These give the ambitious worker every advantage and he has no excuse if he fails to avail himself of the privileges they extend. The mine worker who continues to study and read will soon be fitted for a higher position in the mining field, where many conditions will consume his attention, such as profit and loss in business, division of costs, the upkeep of property, taxes, sanitary, social and labor conditions. All of these will form an interesting study as the man advances and his fund of knowledge increases.

It is common to find many persons holding high positions, by personal favor rather than by merit. The number of these, I am glad to say, is rapidly decreasing. There is no better means for protecting these positions or preventing men who are incapable from holding them, than to require a test of competency as determined by an examination.

I believe these examinations should be periodic, and that they should be required for the renewal of certificates for mine foremen and firebosses. I also believe that all mine superintendents should undergo a more severe examination than the mine foreman and be certified by law for the position he holds.

R. Z. Virgin, Supt.,
West Virginia-Pittsburgh Coal Co.

Colliers, W. Va.

Letter No. 14—I have been much interested in reading the letters on the subject of Education In Coal Mining, particularly those portions relating to the use of textbooks in examination. I am one of the great number who did not acquire a good, common-school education, in my younger days; but have since educated myself by correspondence and now hold a fireboss certificate and a first-grade mine-foreman certificate, for the bituminous mines of Pennsylvania.

Mining is a very extensive study, which we can never hope to master completely; for there is always something new to learn in the way of improved methods, machinery, etc. The best mining men today are those who keep themselves posted by reading uptodate mining literature. It is by such constant study we become familiar with the

principles and formulas relating to the science of mining. A man's knowledge of the mine law and his practical experience in the mine should give him a good idea of the kind of questions that ought to be asked at the different examinations. This makes it possible for good mining men to qualify, in a short period of time, for any examination.

It is not necessary for a person to remember all the formulas, but he should remember the principal ones and learn how to transpose those formulas so as to find the value of any of the quantities required. In my opinion, no first-class mining man would ever require a textbook in an examination. If he has the proper qualifications for the position, he should have no trouble in passing the examination without the aid of a textbook. I cannot understand how good mining men would advocate the use of textbooks in examinations; as, in my opinion, this would tend to lower the standard of examinations. But, if we are to economize in the production of coal and reduce the number of accidents in the mine, we must increase the standard.

I think that all firebosses, mine foremen and superintendents should be examined at least every four years, in order to bring the standard up to a maximum; because the lives of the miners depend, to a large extent, upon these officials and the knowledge they possess of mining. In my opinion, it would be a good investment for every large coal-mining company, operating several mines in the same town, or a number of small companies operating mines in the same community, to open and maintain a room for the purpose of educating their employees.

It often happens that miners are more or less prejudiced in their minds against their employers and think that many things that they do are done for the sole purpose of robbing them. It is a hard matter to get men who have only a limited education to take up the study of mining, but this can be accomplished if night schools were opened and maintained by the corporations operating in a community, provided that the mine officials themselves attended the meetings and did all in their power to instruct and interest the miners. This work should be followed up by the practice of selecting the most capable men among the miners to fill the different positions.

BENJAMIN HARTILL.

Johnstown, Penn.

Note—In response to many repeated requests, we have given a few pages of purely elementary matter in the Pocket Book section. The greatest care has been devoted to the work to make it simple and clear. The purpose is to provide a handbook that will contain all and only such matter as is necessary for practical mining men to know and to use. Such elementary matter, while familiar to many, is not without value to all. In order, however, to give more advanced work, for students of higher grade, and to publish, at frequent intervals, lessons, formulas and data suitable to all, the pocketbook pages will follow no regular order at present. Later, the same pages will be arranged, and, together with many tables and other matter that obviously could not appear here, will be published as one of the most valuable mining handbooks yet produced. We cordially invite criticism and suggestions.

Study Course in Coal Mining

BY J. T. BEARD

The Coal Age Pocket Book

The order of notation is important. Beginning with units on the right the numerical value of each succeeding place to the left increases in the ratio of ten. For example, any digit, 1, 2, 3, etc., standing in the first place on the right, means 1, 2, 3, etc., units. The same digit standing in the second place means ten 10, twenty 20, thirty 30, etc., units. In other words, the value of the digit has increased ten times. If the same digit stands in the third place, counting from the right, its value is increased ten times again or one hundred times that number of units.

The order of notation is given below and should be carefully studied. In ordinary computations it is seldom necessary to go higher than millions or billions, at the most.

Hundreds of billions	Tens of billions	Billions	Hundreds of millions	Tens of millions	Millions	Hundreds of thousands	Tens of thousands	Thousands	Hundreds	Tens	Units	
1	0	0,	0	0	0,	0	0	0,	0	0	0	One hundred billion
	1	0,	0	0	0,	0	0	0,	0	0	0	Ten billion
		1,	0	0	0,	0	0	0,	0	0	0	One billion
			1	0	0,	0	0	0,	0	0	0	One hundred million
				1	0,	0	0	0,	0	0	0	Ten million
					1,	0	0	0,	0	0	0	One million
						1	0	0,	0	0	0	One hundred thousand
							1	0,	0	0	0	Ten thousand
								1,	0	0	0	One thousand
									1	0	0	One hundred
										1	0	Ten
											1	One

These four periods of three figures each are, counting from right to left, hundreds, thousands, millions, billions.

In writing large numbers composed of several figures, it is necessary to fill all void places with ciphers, as the following examples will show.

EXAMPLES TO ILLUSTRATE

1	Write twenty-five, which is two tens and five units.....	25
2	Write three hundred and twenty.....	320
3.	Write seven thousand and twenty-five.....	7,025
4	Write seven thousand and five.....	7,005
5.	Write seven thousand and fifty.....	7,050
6	Write ninty-six thousand, eight hundred and ten.....	96,810
7	Write two hundred and sixty thousand, one hundred	260,100
8	Write twenty-one million, three hundred and two	21,000,302
9.	Write four billion, sixty-one million, two thousand and nine	4,061,002,009
10.	Write one hundred and fifty billion, sixty million, and four.	150,060,000,004

The Coal Age Pocket Book

ADDITION

The operation of finding the sum of two or more numbers is called "addition," and the numbers are said to be added together. The sign of addition (+) is called "plus," and when written between two numbers indicates they are to be added together.

Sign of Equality—The sign of equality (=) written between quantities indicates that their values are equal.

To Add Numbers—Numbers are often added by counting on the ten fingers of the two hands. It was probably this early custom that originated the decimal system and gave us the ten characters—nine digits and cipher. The word "digit" means a finger; hence, the name, as applied to the nine digits, while the cipher served as a tally of the count.

To illustrate, add together two fingers and four fingers by counting as shown in Fig. 1. This is written 2 + 4 = 6

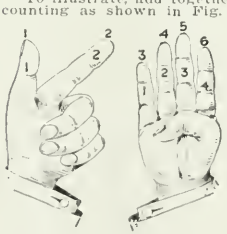


Fig. 1

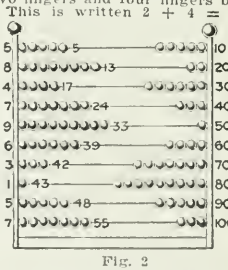

Fig. 2

fingers. When a number of figures are to be added together, a counting rack is sometimes used, similar to that shown in Fig. 2, which consists of a frame supporting ten wires on each of which are strung ten beads. The number of beads, corresponding to each figure to be added, is slid to the left side of the rack, on each wire in succession, after which the total number of beads on that side is counted. The final count gives the required sum. In Fig. 2, the figures to be added are

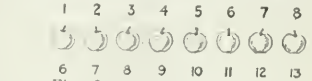

Fig. 3

written on the left and the count of each line is tallied on the wire, the final tally being 55, which is the sum required.

In the same manner, as illustrated in Fig. 3, five apples and eight apples make thirteen apples; thus, 5 + 8 = 13.

EXAMINATION QUESTIONS

Ventilation

(*Answered by Request*)

Ques.—A 7x10-ft. airway is passing 35,000 cu.ft. of air per minute, and it is desired to reduce this quantity to 21,000 cu.ft. per min., by means of a regulator. The water-gage reading taken on the regulator being three-fourths inch, what must be the area of the opening in the regulator?

Ans.—Assuming that the given water gage (0.75 in.) is obtained at the regulator, after the volume of air has been reduced to 21,000 cu.ft. per min., the area of opening in the regulator is calculated as follows:

$$a = \frac{0.0004\,q}{\sqrt{w.g.}} = \frac{0.0004 \times 21{,}000}{\sqrt{0.75}} = \frac{8.4}{0.866} = 9.7\ sq.ft.$$

Ques.—If two airways in a mine are increased to double their length, other conditions remaining the same, in what proportion must the ventilating pressure be increased to maintain the same velocity of the air current?

Ans.—The cross-section of these airways (area and perimeter) remaining unchanged, for a constant velocity, the pressure will vary as the length of the airway. Or, in this case, the pressure must be doubled to maintain the same velocity of the air current.

Ques.—If two ventilators producing the same power are used on the same airway, will they produce twice as much air as one ventilator? If not, how much more than one ventilator will the two ventilators produce?

Ans.—If the ventilators consume an equal power, and have the same efficiency, the power on the air when both are running will be double that when one ventilator is running alone. For the same conditions in the airways, the quantity of air in circulation varies as the cube root of the power; or, in this case, the quantity will vary as the cube root of two. Or, since $\sqrt[3]{2} = 1.26$, when these two ventilators are running the volume of air produced will be 1.26 times that produced by one ventilator alone. In other words, if one of the ventilators produces 10,000 cu.ft. of air, the two ventilators running together will produce 12,600 cu.ft. per minute.

Ques.—If the pressure required to pass 12,000 cu.ft. of air per min. through an open airway produces a water gage of 0.8 in., what will be the pressure required to blow 4000 cu.ft. of air per min. through a regulator fixed in what was previously the open airway?

Ans.—The first step is to find the natural water gage, or the water gage due to friction, when the air is reduced from 12,000 to 4000 cu.ft. per min. Since the pressure varies as the square of the quantity, the pressure ratio is equal to the square of the quantity ratio; hence,

$$\frac{w.g.}{0.8} = \left(\frac{4000}{12{,}000}\right)^2 = \left(\frac{1}{3}\right)^2 = \frac{1}{9}$$

$$w.g. = \frac{0.8}{9} = 0.09\ in.,\ nearly$$

The question does not state whether the pressure or the power producing circulation remains unchanged. If the pressure producing the circulation remains constant, the water gage due to the regulator, in this case, is 0.8 — 0.09 = 0.71 in. Therefore, the pressure required to blow the air through the regulator is 5.2 × 0.71 = 3.69 lb. per sq.ft.

Assuming the power remains unchanged, the pressure varies inversely as the quantity of air in circulation; and when the air is reduced from 12,000 to 4000 cu.ft. per min., the pressure, or water gage, will be increased three times, making the water gage 3 × 0.8 = 2.4 in. In that case, the water gage due to the regulator is 2.4 — 0.09 = 2.31 in. Therefore, the pressure absorbed by the regulator, when the power remains constant and 4000 cu.ft. of air is passing is 2.31 × 5.2 = say 12 lb. per sq.ft.

Ques.—The area and length of an airway remaining unchanged, in what proportion must the power be increased in order to double the quantity of air?

Ans.—The formula for power, expressed in terms of the quantity of air in circulation, is

$$u = \frac{k\,l\,o\,q^3}{a^3}$$

For the same airway, the area (a), perimeter (o) and length (l) of the airway are unchanged; and, k being constant, the power (u) varies as the cube of the quantity (q^3). Therefore, to double the quantity will require $2^3 = 8$ times the power, provided the perimeter is constant. It is possible to change the form of an airway so as to have a different perimeter but the same area.

Ques.—For the same length of airway and quantity of air in circulation, if the area of the airway is doubled, how will this affect the power on the air?

Ans.—Writing the formula for the power in terms of the quantity of air in circulation,

$$u = \frac{k\,l\,o\,q^3}{a^3}$$

In this case, the length (l) and the quantity (q) being unchanged and k being constant, the power (u) varies as the expression a^3/o.

Any change in area will generally produce a change in perimeter of the airway. It is possible to assume two separate airways having the same perimeter and different areas; as, for example, an 8x8-ft. airway, 7x9-ft. airway, or a 6x10-ft. airway—all have the same perimeter but different areas; the perimeters in each case being 32 ft. and the areas 64, 63 and 60 sq.ft., respectively. Such a change can only be accomplished, in practice, by "ripping" the roof or "lifting" bottom and building the waste material at the side of the entry. For example, if 2 ft. of roof be taken down in a 6x10-ft. entry and a 2-ft. "building" be carried on one side of the roadway, the cross-section of the entry would be changed to 8x8 ft. The entry would then have the same perimeter, but the area would change from 60 to 64 sq.ft. It would be difficult to double the area and still keep the same perimeter, in practice.

However, assuming a constant perimeter, the power varies inversely as the cube of the area. Therefore, if the area is doubled, without changing the perimeter, there will be required only $1/2^3 = \frac{1}{8}$ of the original power.

COAL AND COKE NEWS

Washington, D. C.

The Interstate Commerce Commission has just decided the case of the Sheridan Chamber of Commerce vs. the Chicago, Burlington & Quincy Ry. Co., et al. in which complaint was made of the rates on coal from Sheridan, Wyo., to points in Nebraska and South Dakota on the line of the Chicago & North Western and the Chicago, Milwaukee & St. Paul R.R., and to points east and west of Billings, Mont., on the line of the Northern Pacific.

Comparisons were made of distances and rates from Sheridan, Hudson, and from Illinois and Indiana coal fields to points of destination on the Chicago & North Western herein involved. Similar comparisons were made of distances and rates from Sheridan and Roundup, Mont., and from Illinois coal fields to points of destination on the Chicago, Milwaukee & St. Paul herein involved. Sheridan mines were found to be at a disadvantage of from 85 cents to $1 in competing at points on the Northern Pacific with the mines located on that railroad. It was held that:

1. The great screpancy between the rates from Sheridan and from Hudson to the same points of destination on the Chicago, Milwaukee & St. Paul and from Hudson to the same points of destination on the Chicago & North Western and between rates from Sheridan and Roundup to the same points of destination on the Chicago, Milwaukee & St. Paul cannot be justified on the ground that the movement from Sheridan involves a two-line haul.

2. Where the physical connection between connecting carriers is as simple as in these small western towns, involving no expensive terminal service, the additional cost due to the switching movement is small, so small in fact that it may not properly be made the basis of an additional charge for a two-line haul of substantial length.

3. The facts in these cases demonstrate the necessity of promulgating rates which will allow this coal to find a market in the territory described. In order to accomplish this result there must be a free interchange of traffic at reasonable joint rates.

4. Joint rates should be established from the mines at Sheridan to the points on the Chicago & North Western which have been specified in the complaint which should in no case exceed the rate from Hudson, Wyo., to the same points of destination, except that the rate to common points of the Chicago, Burlington & Quincy and the Chicago & North Western need not be changed.

5. A joint rate should be established from Sheridan to Chamberlain, S. D., not to exceed that from Roundup to Chamberlain and this rate should be carried back as far as Okaton, S. D.

6. A differential of 25 cents is a reasonable allowance for the difference in the distance from Sheridan and from the Northern Pacific mines to points of destination involved within 500 miles of Sheridan. As the distance to points of destination increases, the differential between the rates from Sheridan and from Red Lodge should be further contracted, so as not to exceed 15 cents to points between 500 and 600 miles distant and not to exceed 5 cents to points between 600 and 700 miles distant. To points over 700 miles distant the rate from Sheridan should be the same as the rate from Red Lodge.

Senator Kern's Resolutions

Senator Kern on April 12 offered a resolution regarding the West Virginia coal strike which has now been reported by Senator Williams from the Committee on Contingent Expenses in a completely amended form reading as follows:

Resolved, that the Senate Committee on Education and Labor is hereby authorized and directed to make a thorough and complete investigation of the conditions existing in the Paint Creek coal fields of West Virginia for the purpose of ascertaining:

First. Whether or not any system of peonage is maintained in said coal fields.

Second. Whether or not access to post offices is prevented; and if so, by whom.

Third. Whether or not the immigration laws of this country are being violated in the West Virginia coal fields; and if so, by whom.

Fourth. If any or all of those conditions exist, the causes leading up to such conditions.

Fifth. Whether or not the Commissioner of Labor or any other official or officials of the Government can be of service in adjusting such strike.

Sixth. Whether or not parties are being convicted and punished in violation of the laws of the United States.

Said committee or any subcommittee thereof is hereby empowered to sit and act during the session or recess of Congress or of either House thereof at such time and place as it may deem necessary; to require by subpoena or otherwise the attendance of witnesses and the production of papers, books, and documents; to employ stenographers, at a cost not exceeding $1 per printed page, to take and make a record of all evidence taken and received by the committee and keep a record of its proceedings; to have such evidence, record, and other matter required by the committee printed. The chairman of the committee or any member thereof may administer oaths to witnesses. Subpoenas for witnesses shall be issued under the signature of the chairman of the committee or subcommittee thereof. Every person who, having been summoned as a witness by authority of said committee or any subcommittee thereof, willfully makes default or who, having appeared, refuses to answer any questions pertinent to the investigation herein authorized shall be held to the penalties provided by section one hundred and two of the Revised Statutes of the United States.

The expenses thereof shall be paid from the contingent fund of the Senate on vouchers ordered by said committee, signed by the chairman thereof and approved by the Committee on Contingent Expenses.

Debate on Coal Tariff

During the debate on the tariff bill in the course of the past week under the five-minute rule, considerable attention was given to the section dealing with coal and an effort was made to secure the amendment of the tariff act relating to that subject. The idea of those who urged a change was expressed in the following paragraph which was offered as a substitute for the new tariff provision as contained in the Underwood bill.

Bituminous coal and shale, 40 cents per ton of 28 bushels, 80 lb. to the bushel; coal slack or culm, such as will pass through a half-inch screen, 15 cents per ton of 28 bushels, 80 lb. to the bushel: Provided, that the rate of 15 cents per ton herein designated for "coal slack or culm" shall be held to apply to importations of coal slack or culm produced and screened in the ordinary way, as such, and so shipped from the mine; coke, 20 per cent. ad valorem; compositions used for fuel in which coal or coal dust is the component material of chief value, whether in briquettes or other form, 20 per cent. ad valorem: Provided further, that on all coal imported into the United States, which is afterward used for fuel on board vessels propelled by steam and engaged in trade with foreign countries, or in trade between the Atlantic and Pacific ports of the United States, and which are registered under the laws of the United States, a drawback shall be allowed equal to the duty imposed by law upon such coal, and shall be paid under such regulations as the Secretary of the Treasury shall prescribe."

PENNSYLVANIA

Anthracite

Pottsville—Fifteen hundred men and boys struck at the Vulcan and Buck Mountain collieries of the Lehigh Valley Coal Co., Apr. 26. The cause of the strike was the refusal of the officials to grant the inside men an increase in wages for work where a safety lamp was demanded.

Wilkes-Barre—The mess house opened by the Lehigh Valley Coal Co. at its Prospect Colliery, on Jan. 16 of this year, has proved so great a success that applications have already been received by the company to establish such houses at three of its other collieries. Officials of the company report that from 75 to 100 men use the house regularly, and a number of them have formed a "Coffee Club," the members of which take turns in heating coffee for the crowd on the appliances provided for that purpose.

Shamokin—A tieup of collieries in this region, chiefly six operations controlled by the Mineral R.R. & Mining Co., laying between 7000 and 8000 men and boys idle, has been officially declared off, and the strikers are satisfied with results. The strike started on Apr. 22, at several collieries, and two days afterward all the mines along the Pennsylvania R.R., between Shamokin and Mt. Carmel, were tied up, excepting the Greenough colliery, controlled by individual operators. At that mine almost all the employees were union men with dues paid up.

Over 4 in. of rain has fallen in this section and a number of the collieries are in danger of being flooded by swollen mountain streams. It is said that if the rain continues the mules will be hoisted to the surface. All the company's pumps are in operation.

One thousand men in arrears at the collieries paid up their assessments, $1000 being collected by the secretaries of locals. The Green Ridge and Richards Collieries, owned by the Mineral Company, are now "closed shops," acording to the United Mine Workers.

Shenandoah—Seventy-five employees at strippings in this city have gone on strike because five of the employees failed to wear the union button.

The Susquehanna Coal Co. has recently equipped its William Penn colliery with the latest and most modern type of Draeger helmets and rescue apparatus.

Employees of the Sterrick Creek Colliery of the Temple Coal & Iron Co. in Jessup, are on strike because the engineers employed in and about the operation have refused to join the miners' union. Strikes of this kind are not sanctioned by the union, and the strikers do not receive union support. The agreement under which the miners are working provides that no men be forced into the union, and it provides also that all grievances between the employees and operators be adjusted by a colliery grievance committee and the colliery officials. In the event of such a conference failing to bring about an adjustment, the grievances, under the contract, go to the conciliation board for settlement.

Bituminous

Courtney—Ninety-six bodies have been taken from the Cincinnati mine of the Monongahela River Consolidated Coal & Coke Co., which was wrecked by an explosion Apr. 23. All but two have been identified. Officials of the company will make no statement. The work of cleaning up the mine and putting it in condition for reopening is progressing rapidly.

Punxsutawney—The powder house of the Rochester & Pittsburgh Coal & Iron Co., at Lucerne, narrowly escaped destruction recently as the result of a forest fire. The flames worked up within a few hundred yards of the building and it was only with the united efforts of the farmers and a few volunteers that it was saved.

Somerset—The store and a part of the tipple of the Bando Coal Co., three miles south of Somerset, were destroyed by fire recently. It is thought that the fire was caused by sparks from a passing B. & O. locomotive. The Bando mines have been idle for a year and the store building was empty. The loss is estimated at from $1800 to $2000 and is partly covered by insurance.

OHIO

Ulrichsville—The fan house at the Hiawatha Coal Co.'s mine near "52" cut, has been completely destroyed by fire. The origin is not known. The building was a frame structure, 24x14 ft., and contained valuable machinery. The mines had just resumed operations under a receiver after an idleness since Feb. 22. Forty men are out of employment. There was no insurance.

Columbus—John B. Moore, president of the United Mine Workers of the Ohio district, and Duncan McDonald, of Springfield, Ill., have been selected to represent the miners of the United States at the International congress at Karlsbad, Bohemia, July 21 to 24. The congress will be presided over by Robert Smillie, the British president.

Coal operators and jobbers throughout Ohio are very much interested in the coming appointments of Governor Cox on the commission authorized by the Ohio General Assembly to investigate the rate of payment for coal mining in the state. The authorization is contained in the Thomas resolution adopted by both houses of the legislature and was intended to forestall action on the Green antiscreen bill. While the governor has not given any intimation of the men who are to constitute the commission, he has publicly announced that that body is to have its report ready for consideration by the extraordinary session of the general assembly to be convened during the coming winter.

St. Clairsville—Two thousand five hundred miners in the various mines of the Lorain Coal & Dock Co. in Belmont County struck recently because of the refusal of the company to pay the men extra for work in cutting soapstone and slate out of the mines.

Bridgeport—Two thousand miners who went on strike May 1, still refuse to return to work. It is reported that delegations representing the men will try to induce the miners throughout eastern Ohio to enlist. The strike was caused by the refusal of the various coal companies to pay the men for roll cutting, or the removal of slate from the mine.

Logan—Work in the mines about Nelsonville and New Straightsville, is picking up rapidly. Orders from the lake ports are stimulating the shipments. The local freight crews are working full capacity to take care of the trains going north on the Hocking Valley. Pomeroy and the southern mines are not working yet. A large number of them are badly damaged by the flood.

INDIANA

Indianapolis—Indiana coal operators are not excited by the proposed abolishment, at Washington, of the tariff on coal. The state is too far inland to be more than indirectly affected. Coal men see the possibility that Welsh coal might interfere with the coast trade, say, in Pocahontas and any abbreviation in the amount of the Virginia product that goes to steamships and other consumers east might throw a larger amount into Indiana and cut down to that extent the consumption of Indiana domestic.

Indiana domestic has not been cutting a large figure, however, even though efforts have been made to make consumers better acquainted with this Indiana coal. When natural gas failed in Indiana, a board of coal dealers was created who did not know one grade of coal from another. There were operators who took advantage of this ignorance to market some inferior so called Indiana domestic coal. The result was that this low grade of fuel has given Indiana coal a blow from which it has been difficult to recover. Notwithstanding the really good domestic grades are being worked into consumers' bins again.

The executive board of the U. M. W. A. has passed a resolution endorsing the action of Senator John W. Kern, of Indiana, in trying to get a committee appointed to conduct a federal investigation into conditions in the Cabin Creek and Paint Creek fields. A copy of the resolution was mailed to all the U. S. Senators.

ILLINOIS

Royalton—The strike at the two Royalton mines still continues. It seems to be a case of where the miners insist that the new company, which bought the property of the South Mine after it had gone through the bankruptcy act, pay the miners for the labors performed under the former owners. The present operators are in no way connected with the former owners of the mine, and for that reason contend that the miners should not look to them for their wages, but should have secured same while the property was in the hands of the bankruptcy court. The miners contend differently, and won't work until they get their back wages.

KENTUCKY

Earlington—It is reported that organizers representing the United Mine Workers of America have been at work in this vicinity for some time, in an effort to unionize the mines in this section. It is asserted by some of the interested operators that the movement is due to the influence of Indiana operators, who complain because of the fact that western Kentucky mines can undersell them.

PERSONALS

W. F. Murray has been appointed assistant general superintendent of all the Colorado mines of the Victor-American Fuel Co.

Col. J. C. Maben, of New York, president of the Sloss-Sheffield Steel & Iron Co., is spending several days in Birmingham, Ala., inspecting the properties of his company in that district.

P. F. O'Neill has been appointed assistant general counsel for the Lehigh Valley Coal Co., and will have full charge of the legal affairs of Coxe Bros. & Co., Inc., operating in the Hazleton region.

R. E. Howe, former traffic manager of the Knoxville, Sevierville & Eastern Ry., has accepted a position as secretary of the Climax Coal Co., at Middleboro, Ky. Mr. Howe has been succeeded by J. M. Starrett.

P. J. Rogers, superintendent of the Tennessee Coal, Iron & R.R. Co., has been selected by Governor O'Neal, of Alabama, as the third member of a commission which will soon inspect the scales at the Banner mine.

Thomas Smith, formerly superintendent of the Consolidation Coal Co.'s mines at Two Lick and West Fork, has been transferred to Montana where he succeeds Harley W. Smith, who has asked for a leave of absence on account of illness in his family

J. Albert Cook, who for a number of years has been a member of the engineering department of the West Virginia division of the Consolidation Coal Co., has become superintendent and has been assigned to the mines at Beechwood and Murray to succeed W. H. Hess, who has been transferred to the mine at Gipsy. Mr. Hess takes the place of A. V. Morgan, who has resigned from the service.

Thomas H. Hayden, for a number of years operating superintendent of the Kentucky & Indiana Terminal R.R. Co., at Louisville, who resigned that position recently, has been appointed general manager of the Cumberland R.R., in southeastern Kentucky, with general charge of the extensive coal holdings of the company, which has five mines in active operation at this time. Mr. Hayden's experience has been entirely with railroads, having been actively engaged in almost every line of service in that connection since 1876. In his new position he succeeds E. C. Milliner, who resigned to look after private interests.

CONSTRUCTION NEWS

Natrona, Penn.—Important contracts were let at Kelly Station Saturday when officials of the Providence Coal & Coke Co. met at that company's plant. Estimates approximating $25,000 were made on a new tipple.

McDonald, Penn.—It is reported that the Peoples' Natural Gas Co. is drilling a well in this vicinity, which is already the deepest in the world. The present depth of the well is said to be over 6200 ft. and there are more than 60 tons of pipe in the hole.

Pottsville, Penn.—The extent of the Locust Mountain Coal Co.'s operations is illustrated by the recent increase in the amount of capital to $550,000. Pres. Baird Snyder states that the work of boring the tunnel through the rock and the erection of the breaker will be pushed.

Birmingham, England—A new colliery has been opened up at Birmingham and is fitted with every modern appliance to operate a coal seam 24 to 28 ft. in thickness. It is calculated that with a force of from 500 to 600 men the output will be from 300,000 to 350,000 long tons per annum.

Pittsburg, Kan.—The Central Coal & Coke Co. has started sinking a shaft one mile northwest of Edison. The top house at the mine is nearly completed. When the mine opens it will be one of the largest in the district and will employ from 200 to 300 men. It will be known as mine No. 48.

Bluefield, W. Va.—R. W. Stone, who has recently accepted the position of superintendent of construction for the Pond Creek Coal Co., states that the company is preparing to erect about 400 homes at the various operations along the new line. Several large stores will also be built. The work is to begin at an early date.

Prairie du Chieu, Wis.—The Roberts & Schaefer Co. of Chicago have been awarded the contract for a large coaling plant for the Chicago, Burlington & Quincy R.R. to be built here immediately. The same firm recently secured a contract from the Chicago & North Western Ry. for the construction of a Holman locomotive coaling plant to be erected at Green Bay, Wis.

Whitesburg, Ky.—It is reported that the work of ballasting the upper extension of the Lexington & Eastern is being rushed to completion, and two months more is expected to see the work finished. This part of the road connects Hazard and McBoberts, and will bear an important part in the freight and passenger traffic when completed. It is now handling trains, but when fully ballasted can accommodate more and heavier traffic.

Bluefield, W. Va.—The U. S. Coal & Coke Co. has conditionally awarded contracts to Rufus J. Bird & Co. for the building of 125 company houses for the concern's operations at Nos. 3 to 11, inclusive. The total cost will be approximately $130,000. A contract, involving the sum of $120,000, has also been awarded to John Doss, of Welch, W. Va. It is the intention of the company to make the appropriation and start the construction work by May 15.

Pottsville, Penn.—Large steam shovels have been shipped to Locust Mountain and it is expected that operations will soon be started to take off the entire top of the mountain to get at the coal. The seams near the surface will be stripped in time to take out the coal to operate the new breaker, now in the course of construction. Pending the construction of an extensive system of tunneling, the coal will be carried from the distant points of the strippings by a tramway.

Beaver Creek, Ky.—The construction of the new Beaver Creek branch of the Chesapeake & Ohio Ry., from the mouth of Beaver Creek to Steele's Creek, a distance of twenty miles, has recently been started, a large force of men and teams being actively engaged in the work. It is expected that the road will be completed within a year, and it is assured of heavy traffic from the start, in view of the richness of the coal and timber lands which it will open up.

Huntington, W. Va.—The Chesapeake & Ohio is opening up a vast territory rich in coal and oil in the Beaver Creek district in Kentucky. Several operations are to start there within the next four months and the railroad officials expect to handle a big output of coal. Contracts for the work of building a line to Beaver Creek from the main line have already been let. Twenty-one miles of track are now being laid, but it may be decided to extend the line later on. The spur connects with the main line of the road near Allen, Ky.

Scranton, Penn.—Contractors have broken ground for a model village that is to be built around the Underwood colliery of the Pennsylvania Coal Co. The village is to consist of 28 double houses, of timber construction, 28x40 ft. Several frame buildings are also being built for the colliery bosses and their families. The Underwood colliery is to be one of the most modern in this part of the state. It will open up large tracts of hitherto untouched coal and will give employment to a large number of men for many years. It is expected that the colliery will be ready for operation within a few weeks. Hower & Stender are in charge of the construction work.

NEW INCORPORATIONS

Pittsburgh, Penn.—The Bruin Coal Co.; capital stock, $10,000. Incorporators: A. M. Thompson, J. H. Thompson and Ray Rose.

Rock Island, Ill.—The City Coal Co.; capital stock, $5000; to deal in fuel. Incorporators: W. J. Lacey, W. F. Zibell and A. R. Gates.

Rock Island, Ill.—The Spoon River Coal Co.; capital stock, $6000; to mine coal. Incorporators: W. A. Schaeffer, C. A. Schoessel and W. D. Godfrey.

Sparta, Tenn.—The Young Coal & Coke Co.; to develop and operate a coal mine at Obey City. Incorporators: E. C. Young, W. B. Goodwin and John McDaid.

Nashville, Tenn.—The Old Virginia Coal Co.; capital stock, $25,000. Incorporators: W. F. Hutcheson, H. B. Bonney, J. R. Barnes, W. W. V. Mullan and W. B. Miller.

Sharpsville, Penn.—The Pierce Coal Co.; capital stock, $150,000; chief works in Parton County, Mo., and offices at Sharpsville. Incorporators: A. M. Imbrie, Frank Pierce, M. L. Pierce, T. A. Pierce and A. C. Andrews.

Columbus, Ohio—The Chaparal Mining Co. has been incorporated with a capital stock of $125,000 to mine and deal in coal. The incorporators are P. L. Tanzey, E. C. Paine, W. G. Bossman, C. H. Blacker and R. S. Barbee.

Dover, Del.—A certificate of increase of capital stock of the American Coal & Byproducts Coke Co. was filed at the State Department Apr. 30. The increase is from $500,000 to $5,000,000. The company was chartered in 1912.

Salem, Ohio—The Salem Mining Co. has been incorporated with a capital stock of $75,000 to mine and deal in coal and clay. The incorporators are Charles Estep, John E. Reese, J. E. Morgret, W. W. Weaver and R. D. Anderson.

Knoxville, Tenn.—The Vaspar Coal Mining Co.; capital stock, $100,000. Incorporators: G. C. Bell, E. Carson, E. C. Stookesberry, W. J. Donaldson and Robert Young. The property of the company is located at Vaspar, in Campbell County.

INDUSTRIAL NEWS

Cincinnati, Ohio—Judge A. M. J. Cochran has confirmed the sale of the Covington Coal & Sand Co. The purchaser was Theodore Kirk.

Chicago, Ill.—The Dominion Coal Co., Ltd., has given notice that $110,000 of its first mortgage 5 per cent. bonds were to be retired May 1 at 105 and interest.

Bridgeport, Tex.—Recent rains have visibly increased the city's industrial activity. The coal mines are running on full time and the working forces will be increased.

Dresden, Ohio—A recent shipment of coal to Dresden has enabled the water-works plant to resume operations. The electric lights, however, have not yet been placed in operation.

Knoxville, Iowa—Coal prospectors are now working in a newly discovered field in this vicinity. According to reports received the drillers have struck at least four workable seams of coal.

Birmingham, Ala.—At a coming meeting of the directors of the Alabama Co., formerly the Alabama Consolidated Coal & Iron Co., permanent officers will be elected. The meeting will be held in Baltimore.

Duluth, Minn.—It is estimated that over 150,000 tons of coal have reached the harbor at Duluth since the first boat arrived a little over a week ago. This has been principally in the nut and stove sizes.

Rock Island, Ill.—A theoretical merger of the Union Ice & Coal Co., the Spoon River Coal Co. and the Spoon River Colliery Co. has been effected through the efforts of Willard A. Schaeffer, president and general manager of the latter concern.

Pittsburgh, Penn.—The Pittsburgh Coal Co. has leased a strip of land from the estates of Alexander and Thomas Jones. The tract of land in question lies along the Monongahela River wharf and extends for 500 ft. above the Point bridge.

Birmingham, Ala.—A meeting of prominent Alabama citizens was held in the Morris Hotel, Birmingham, for the purpose of discussing the advisability of taking convicts out of the Alabama mines and away from the control of private corporations.

Connellsville, Penn.—The Marion plant of the Southern Connellsville Coke Co., near Cheat Haven, has been forced to bank its ovens for a week, owing to the installation of a cable across the river. Until now the plant has been making full time.

Rural, Penn.—Five diamond drills are busy testing 18,000 acres of coal lands located in Indiana County, near the Cambria County line, the holdings of the Greenwich Coal Co. It is understood that the Manor Real Estate Co., of Philadelphia, will acquire the property and commence coal operations on a large scale.

Washington, Ind.—The Riverside Coal Co.'s mine has been sold at a receiver's sale to W. B. Catching, of London, Ky. The consideration was $4000. This same property was recently appraised at $15,000. It is said that the mine will resume operations.

Johnstown, Penn.—Engineers employed by the Cambria County commissioners have just finished the task of assessing the minerals of the county at what they believe to be the full value. The coal in Cambria County is said to be valued at $25,000,000.

Denver, Colo.—The Colorado Fuel & Iron Co. has rendered 3400 acres of coal land, valued at $1,000,000, to the United States government in consideration of the dismissal of a suit involving 5800 acres owned by the company The land is located in southern Colorado.

Louisville, Ky.—It has been learned that J. C. C. Mayo, vice-president of the Elkhorn Fuel Co., has received, in consideration for the transfer of certain of his coal lands to the new corporation, $600,000 in cash, $2,000,000 in preferred stock and $2,000,000 in common stock.

Columbus, Ohio—Reports received by Columbus operators state that practically all vessels on the lake were expected to be in commission by Apr. 30. Crippled conditions of the railroads and shortage of available cars is making the movement of coal from the mines to the lake slow.

Shelburn, Ind.—The Klondyke mine, southwest of Shelburn, has been closed for some time because of burning gas in the mine. Operations will be resumed, however, as soon as the aircourses have been opened up. The work required to do this will cost in the neighborhood of $500.

Cincinnati, Ohio—On Apr. 28 the Queen & Crescent R.R. started operations with its new $15,000, 500-ton capacity coal chute at Ludlow. This is the first to be completed of the $150,000 improvements, which were authorized last Fall. The other improvements include a roundhouse and yard facilities.

Prairie Hunter, Ga.—Chauncey M. Weeks, a farmer in Prairie [illegible] Wrights, has given a two-year option to Richards & Sons, of [illegible] The tract consists of 92 acres and the option price [illegible] acre. The company may use five acres for buildings, [illegible] lines and switches; $150 an acre to be paid for the site.

Charleston, W. Va.—Clark & Krebs, civil and mining engineers of Charleston, W. Va., have recently completed a map showing the property lines, location and car allotment of the mines in the New River, Kanawha River, Coal River and Guyan River coalfields, in West Virginia. This map will be of great use for reference.

Chicago, Ill.—Officials of the Consumer's Co., which is a consolidation of the City Fuel Co. and the Knickerbocker Ice Co., report that they will soon be ready to prepare a statement of the company's financial position. This will be submitted with the applications to list the shares on the Chicago and New York stock exchanges.

Chattanooga, Tenn.—Chattanooga capitalists have recently purchased the Monarch coal mines at St. Charles, Va. Application has been made for a charter for the new company, changing the name to the Old Virginia Coal Co. The original capital stock is set at $25,000. This will probably be increased after the concern has begun operations.

New Orleans, La.—A New Orleans company has built steel barges, bought tugboats and established a depot for handling large quantities of Alabama coal for export and to supply ships' bunkers. The company will take advantage of the completion of the government locks on the Warrior and Tombigbee Rivers to barge coal past Mobile and into New Orleans.

Little Rock, Ark.—The coal tests which have been recently conducted by the Rock Island road to determine the efficiency of several grades of coal have been concluded. It is expected that a decision will be reached soon as to the grade of coal to be used on the Rock Island. Samples of Arkansas, Oklahoma and other grades of soft coal were used in these tests.

Salt Lake City, Utah—The Jesse Knight interests in Carbon County are operating a coal property located on the Denver & Rio Grande R.R. at the new town of Storrs. The machinery is up to date, and the company plans to furnish a quality of coal which is unsurpassed by any in that locality. The coal is mined from beds averaging 8 ft. in thickness, over which is 1000 ft. of solid sandstone capping. The capacity will be from 1500 to 2000 tons per day.

Brownsville, Penn.—Bids have been received for the driving of the slope entrance at the new plant of the Lilly Coal & Coke Co. This work will be hurried as much as possible. The tipple has been under construction for some time. Some alterations were made, however, due to the change of the P. V. & C. tracks in the vicinity of the new plant. It is the intention of the officials to operate the plant at the earliest possible moment. Thomas Elliott is general manager.

Pittsburgh, Penn.—A deal involving 223 acres of coal land in Allegheny Township has recently been consummated by J. F. Steele, executor of the Miriam S. Steele estate. The Lucesko Coal Co. bought the tract for a consideration of $28,500, a little more than $125 an acre. The coal is the upper and lower Freeport and Kittanning seams. The especial value of this piece of land lies in the fact that it is the key to many acres of coal behind it which cannot well be operated without the Steele holdings.

Du Bois, Penn.—Options which were recently taken on 6000 acres of coal land in Green Township by E. E. Davis, of Johnstown, were ordered lifted May 1. The land owners were notified that payment would be made within a few days. Between $50 and $70 an acre was paid for the land, and the entire deal means a transfer of about $360,000. The tract is mixed up with a field of about 15,000 acres owned by the Greenwich Coal & Coke Co., and it is the general opinion that this company is the purchaser. The field is already tapped by the Cherrytree & Dixonville R.R., which is jointly owned by the New York Central and the Pennsylvania.

Louisville, Ky.—Three Louisville coal concerns, handling Pittsburgh coal from the mines of the consolidated interests, have been combined under one management, to be known hereafter simply at the Pittsburgh Coal Co. The companies included are the O'Nell Coal & Coke Co., Joseph Walton & Co., and O'Donnell & Co. The consolidation was announced to take effect May 1. The new company is to be managed by Charles J. O'Conner, formerly president of the O'Nell Coal & Coke Co., who will be assisted by W. S. Montz, formerly of Joseph Walton & Co. Rumors of such a move have been current for some time, but it was not definitely decided upon until very recently.

Fossil, Ore.—Property owners and business men of Fossil, have organized for the purpose of developing the coal fields in this vicinity and in connection therewith the building of a railroad from Condon to Fossil and the coal deposits, about ten miles from the town. The project is headed by Joseph J. Henry, of Chicago, Anthony Mohr and J. E. Reed, of Portland, and Dr. A. Ives, of Chicago. A meeting was held this week in Fossil and committees were appointed to solicit the necessary funds for preliminary work. Vice-president J. P. O'Brien of the O.-W. R. & N. Company, which operates a branch line to Condon, has been interviewed in regard to the extension of this line from Condon to Fossil, and it is said this will be done providing evidence can be shown that the mine will have a daily output of at least 300 tons from the start. In view of the encouraging preliminary reports, it is regarded as certain that the railroad will be built as soon as the proper arrangements can be completed.

COAL TRADE REVIEWS

GENERAL REVIEW

The regular monthly advance in prices on the domestic grades of hard coal has not caused any decrease in the demand, which continues as insistent as ever. Mines are working up to full capacity and the only difficulty before the operators is providing an equable distribution of the production. In previous years at this time, the companies have usually had substantial surpluses on hand with which to meet the excessive demand, but, owing to the restricted production last year, such is not the case now and the freshly mined product has to be relied upon entirely. The loading at the New York piers for the coastwise trade is slow, and consumers are finding it difficult to obtain their required tonnages, especially when they are particular about sizes.

Now that the West Virginia labor situation has been partially cleared up for the moment at least, consumers are waiting for some response in the market before undertaking any extensive buying. The indications are that they are not without justification in their position as it is difficult to see how the new high prices at Hampton Roads can hold unless a rigid restriction is put upon the production. There is a free movement on contract in the coastwise bituminous trade, consumers taking their full allottment, and there are indications of some improvement in prices, particularly on certain grades which are developing unusual strength.

The Pittsburgh market is becoming more and more active, due to the exceedingly heavy demand in the Lake trade stocks are low at the head of the Lakes, and jobbers at that point are anxious to lay in the maximum supplies because of the possibility of labor troubles when the agreements expire next April before navigation is again open. The labor unrest, so general throughout the country, seems to indicate that there may be serious trouble between the operators and miners before the next agreement is reached. It is difficult for consumers to obtain coal at the regular Pittsburgh circular now, a contract for a million tons having been recently refused. Bituminous and anthracite operators are showing a determination to put enough coal beyond Lake Michigan to supply any reasonable demand. Both Lake and steam business in Ohio has been heavy, and the general tone is good.

There have been heavy shipments in both the foreign and coastwise trade out of Hampton Roads, but the congestion at the piers continues unrelieved; producers are showing every indication of holding firm on prices, while buyers are slow about closing, evidently believing that a sharp decline is inevitable. In the Southern pig-iron market the depression is being more keenly felt and the effects are now spreading to the coal industry; steam coals are as yet the only sufferers, but some new low prices have been touched by these.

Mines in the Middle West are working about normal, and the domestic demand is light; some summer retail prices are going into effect. Domestic consumption is much curtailed and there is a tendency on the part of dealers to reduce stocks. Contracting is more active. The customary freight discounts in the Rocky Mountain region were not made this year, and shipments are confined entirely to the current demand, with the result that operations will be somewhat restricted.

BOSTON, MASS.

Bituminous—With any possibility of serious trouble in the New River field now pretty generally minimized, buyers will wait for the market to steady up before making any comprehensive purchases. There is a good deal of opinion here that the $2.85 price on Pocahontas and New River f.o.b. Hampton Roads will be too high for summer deliveries, and that in the absence of a drastic curtailment, figures will have to be modified in order to move coal. On the other hand prices on Georges Creek and on the better Pennsylvania coals are firm in response to an improved demand. This is especially true of certain of the Cambria and Clearfield grades and quotations are from 5@10c. higher than prevailed during April. Improvement also continues in the all-rail territory and most of the shippers report a comfortable volume of business in hand.

For inland delivery, prices in general are about 15c. up from last year but orders that are competitive are also slow in being closed. Rail coals of good quality are making inroads on tonnage that is ordinarily reserved to tidewater grades. A large volume of Georges Creek is finding a ready market here. The shippers have ample business in hand and 1913 bids fair to be a record year for this popular grade. A large fleet of steamers and barges, the latter suitable for medium draft points, has an important bearing on the large tonnage placed in New England every year.

Water freights are easy at 70@75c. for large vessels, Hampton Roads to Boston, with only a moderate inquiry. The bulk of the bituminous tonnage is brought in steamers, almost all chartered on government form rather than at a rate per ton, and that has its effects on the freight market. The steamers "Kennebec" and "Kanawha" for some years in the coastwise coal trade are understood to have been sold for the lumber trade.

Anthracite—Another sign of the strong demand for hard coal appears in a disposition on the part of the companies to restrict the proportion of stove size in any one cargo. The slow loading at some of the New York piers is already causing anxiety to some of the New England dealers. Many of the latter are surprised to find that hard coal is just at this present moment rather hard to get, especially if they are fussy about the proportion of sizes.

Current bituminous quotations at wholesale are about as follows:

	Clearfields	Cambria Somersets	Georges Creek	Pocahontas New River
Mines*.....	$1 00@1.35	$1.25@1 45	$1.67@1.77	
Philadelphia*...	2.25@2 60	2.50@2.70	2.92@3.02	
New York*....	2 55@2.90	2 80@3 00	3.22@3.32	
Baltimore*.....			2.85@2.95	
Hampton Roads*				$2 75@2.85
Providence†.....				3 73@3.78
Boston†.....				3 73@3 90

*F.o.b. †On cars.

NEW YORK

Anthracite—The strong and insistent demand for hard-coal continues unabated, with no indications in sight of any immediate letup. In the steam grades, buckwheat and barley are still the easiest sizes, while rice continues as short as ever. In the domestic fuels, stove, of course, still continues to lead in demand, with egg second and also very short in supply. As a matter of fact, nearly all sizes are in heavy demand, and it is simply a question with the companies of getting a maximum production and making an equable distribution of same.

There is some uncertainty as to the amount of surplus coal in stock at the present time. Ordinarily, at this season of the year, the companies have some surplus stocks to draw upon, but such is not the case now because of the shortage in production last year. On the other hand, the exceptionally mild winter resulted in a materially reduced consumption so that, in all probability, many consumers carried over unusually large surpluses.

We quote the New York market on the following basis:

		Individual	
	Circular	Lehigh	Scranton
Broken	$4 60	$4 45	$4 60
Egg	4.85	4.70	4.85
Stove	4.85	4 70	4.85
Chestnut	5.10	4 95	5 10
Pea	3 50	3.35@3 45	3 10@3 20
Buckwheat	2.75	2 25@2.45	2 50@2 75
Rice	2 25	1.90@2.00	2 25@2.35
Barley	1.75	1.45@1 70	1 60@1.75

Bituminous—With the exception of the all-rail business, there is a noticeably better tone in the local trade. There are persistent inquiries for odd tonnages in the spot market and unexpectedly good figures are being obtained in some instances. The orders are from local brokers who are very probably acting for large producers that are falling behind on their contracts and also for water shipments into the New England trade. These conditions indicate an improved tone that is gratifying to the operators and makes the outlook for the future decidedly better.

The improved tone is naturally reflected in quotations, although the market is not quotably changed from the prices that have been prevailing over the last month and a half or two months. Quotations are being more firmly held, however, the off qualities becoming somewhat tighter and the good grades noticeably short. We continue last week's quo-

tations as follows: West Virginia steam, $2.55@2.60; fair grades, Pennsylvania, $2.65@2.70; good grades of Pennsylvanias, $2.75@2.80; best Miller, Pennsylvania. $3.05@3.15; Georges Creek, $3.25@3.30.

PHILADELPHIA, PENN.

The first week of the ten-cent increase in anthracite over April figures has passed, and the trade apparently has renewed all the unfilled orders of the previous month, as the companies still continue operating their mines to the fullest capacity and outside of some of the steam coals, there is little or none of the output going into stock. Retail dealers report that trade is fairly good ,although not as strong as it might be; the demand centering on the stove and chestnut sizes, with egg only fair. Pea coal is quiet, although some is moving into the cellars of the consumers; during the late spring and summer months this grade is not usually in particularly active demand.

Most domestic consumers of pea coal buy it from hand to mouth, and as the price does not usually vary from the basis established at the inception of the spring season, there is no particular advantage to the consumer in storing it; the stocks accumulated by the large companies finds a ready market during the winter. As a matter of fact, pea coal during the winter season is invariably short so that it is wise to provide against this call, when the demand is light.

The tidewater business continues to be heavy. Water transportation is able to find a ready market, and the current freight rates are quoted anywhere from 90c. to $1 from this port. The output at the mines was not as great as April, 1911, due in a measure to the friction between the operators and miners, and while the loss in tonnage was small, compared with the aggregate, each suspension had its effect on the total.

In regard to the bituminous market, there seems to be a tendency towards increased business, at better prices. This improvement is more in the nature of stable quotations for the present offerings, rather than in any marked increase; the numerous fluctuations in prices that have characterized this branch of the trade for many weeks past have disappeared.

PITTSBURGH, PENN.

Bituminous—It is difficult to place new business with operators at the regular season prices, so many having withdrawn. Within the past few days the leading interest here turned down an offer of a million tons of lake coal at the regular figure of $1.40. As noted last week operators controlling the major part of the production have advanced prices on all new business by 10c. and it is quite possible that the whole market may work up by this amount or even more. The demand from the Northwest is particularly heavy, both because of the short supplies at the close of last season and because of the general expectation that there will be a suspension of mining at the time of the next wage adjustment, Apr. 1, 1914, necessitating provision this season for a longer period than usual.

While it is customary to speak of the Pittsburgh district coal operators having the best season in many years, with the much higher prices ruling this year, attention should be directed to the fact that their financial results have as a rule been decidedly poor in recent years, and it is only by comparison that present results are good. The unrest among miners will undoubtedly crystallize into an unusually strong demand for advanced wages upon the expiration of the present scale. While plans are altogether inchoative at present it is well understood that this will be met by a specific demand for a reduction and a contest of no mean proportions is promised.

We quote prices at a range on some descriptions, the higher figures representing the advance asked by many operators on new business: Slack, 90c.; nut and slack, $1.05; nut, $1.25; mine-run, $1.30@1.40; ¾-in., $1.55@1.65, per ton at mine, Pittsburgh district.

Connellsville Coke—Demand for prompt furnace coke continues very light, and no interest is shown in contract coke. Furnaces are well supplied by contracts, against which full deliveries are being made, and those which must purchase for second half are biding their time, awaiting a more settled pig iron market, and seeing no occasion to ask quotations when the nominal asking price on contract is 25 to 50c. higher than prices ruling for spot. Operators generally ask $2.25 on prompt furnace coke, but odd lots are picked up without much difficulty at $2.10 to $2.20, and $2 can probably be done sometimes. On contracts $2.50 is asked but buyers do not take the figure seriously. Foundry coke is somewhat easier. We quote: Prompt furnace, $2@2.25; contract furnace (nominal) $2.25@2.50; prompt foundry, $3@3.25; contract foundry, $3@3.25 per ton at ovens.

BUFFALO, N. Y.

The bituminous market is very steady and becoming more so every week. There is a decided scarcity developing, due to a shortage of miners and to an indifferent car supply that appears steadily worse. Members of the trade are saying that they would not know which way to turn if the demand should suddenly increase. There are operators in this market who have been putting out all the coal they could for sometime and now they are not keeping up well on their contracts. There is no surplus coal whatever on track and if a jobber runs short of a certain variety he often finds it hard to buy in the open market.

The coal shortage is due to most of the mines in the Pittsburgh district declining to accept further orders from new customers at present. The Pittsburgh district used to furnish more than one-third the coal in this market, so that the mines in the Allegheny Valley had to depend on their advantage of 15c. in freight to sell their output but it is quite different now as the latter coal often has to take the leading part. The lake trade, of course, has much to do with the present situation, but it must be remembered that it was found impossible last season to satisfy the lake demand and it may turn out so again. Shippers both bituminous and anthracite are showing a determination to put coal enough beyound Lake Michigan this season to meet the demand there, for the rail lines are not able to make up much of a shortage that may exist when the lakes close.

Bituminous prices are firm at $2.80 for Pittsburgh lump, $2.65 for three-quarter, $2.55 for mine-run and $2.15 for slack. Coke continues quiet at former prices, on the basis of $5 for best Connellsville foundry. Coal now sells so readily that it is quite possible for operators to prefer that market and let coke wait till it is stronger.

The Anthracite Trade is quiet. Shippers say there is a decided hesitancy on the part of jobbers and consumers, which is quite easily explained by letters from certain dealers, declaring that their purchases are all on hand and they cannot pay their bills, all of which means that the consumers are also overstocked. Lake shipments for April foot up 505,000 tons.

BALTIMORE, MD.

There has been a slight improvement in the local spot market due apparently to some rather heavy requisitions from the large canning factories, which are making preparations to resume operations within the next few weeks. There are a great many of these plants in this vicinity, and most of them buy their supplies in the spot market. Those who do contract have not yet signed up.

Because of this improved demand quotations are somewhat firmer especially on the better grades which are in the shortest supply. The situation on the off qualities has not experienced any noticeable change. There is a free movement under contract, consumers mostly taking their maximum requirements. The labor shortage in the West Virginia fields is becoming more pronounced each week and the outlook for the future is regarded by many as rather unfavorable. This will be particularly true should the Federal Government start investigating the situation as now seems probable.

The car supply is adequate and meeting the full requirements at the moment but some believe that conditions in this respect do not look favorable for the future. The production of coke is still curtailed because of the light demand, and there are reports from the trade that prices are weak.

COLUMBUS, OHIO

Activity in the coal trade in Ohio during the past week was divided between the lake business and the steam trade. Both classes showed up well and as a result the tone of the market is very good. Operators and shippers are looking forward to a good season in both lines and preparations are being made for a heavy production.

The lake trade is opening extremely active in every respect. Chartering of vessels is going on rapidly and the movement is quite large. Since there is a good demand from the Northwest it is believed the present season will exceed that of 1912. Prices f.o.b. vessels are 10c. higher than last year, or at the same level which prevailed in 1911. The ore trade is opening actively and this means a better movement of coal.

Steam trade is strong in every way. The demand from manufacturing establishments is increasing since most of the factories put out of commission by the flood have resumed opertions. Accumulated orders has made it necessary for these factories to buy a larger tonnage of steam coal. The demand from railroads is also increasing as the freight movement is larger. Contracts which have expired recently are being renewed at higher figures than prevailed in 1912.

Considerable attention is being given to railroad contracts which will be placed soon. The one weak spot in the market is the fine coal, which is usual when the lake season is booming; but the weakness is not as marked as in former years. All other grades are holding up strong.

Some little demand is reported for domestic grades, but not sufficient to cause much stir. Most of the orders are traceable to the effects of the high waters of a month ago. Dealers, however, are preparing for the stocking season which is expected to be slightly earlier than usual.

The output in Ohio fields during the week has been good. Since the railroads are better able to handle coal, eastern Ohio and the Hocking Valley has been producing about 75 to 80 per cent. of normal. The output in the Pomeroy Bend district is not quite so large because the flood damages in that field was heavier. In the domestic fields the output is not large.

Quotations in the Ohio fields are as follows:

	Hocking	Pittsburgh	Pomeroy	Kanawha
Domestic lump	$1.50	...	$1.50	$1.50
4-inch	1.35	$1.20	1.35	1.30
Nut	1.25	...	1.25	...
Mine-run	1.15	1.10	1.15	1.10
Nut, pea and slack	0.70	...	0.90	0.80
Coarse slack	0.60	0.75	0.80	0.70

HAMPTON ROADS, VA.

The last week has brought about little change in the coal situation at Hampton Roads. While there have been some large shipments both coastwise and foreign they have not relieved the accumulation at the several piers and the railway yards are still in a badly congested condition. However, producers are not cutting prices, while buyers are holding off evidently expecting a decline, and there were few sales made during the past week.

The enormous total of more than one million tons of coal was dumped over the three Hampton Roads piers during the month of April, the exact figures being 1,054,208 tons. Of this quantity the Norfolk & Western Ry. handled at Lamberts Point 508,158, the Virginian Railway at Sewalls Point 249,225 tons and the Chesapeake & Ohio at Newport News 296,825. Work on the steel pier at Newport News which has been badly delayed is now being pushed forward as rapidly as possible day and night.

LOUISVILLE, KY.

The local situation has not changed to any material extent during the week, the domestic grades still continuing in light demand with the steam coals rather tight, although also showing a tendency to become easier. The car supply is adequate at the moment, but may become shorter with the result that operators are becoming cautious over future commitments both for this reason and because higher prices are anticipated in the near future. The improvement in the price situation will be brought about by the increased demand from the Northwest; the West Virginia producers are finding themselves less able to meet the rapidly increasing requisition from there and the result is that much of this business is being diverted into the Kentucky field in spite of the fact that the latter is under some disadvantage in freight rates. The West Virginia operators are also more handicapped as a result of the recent flood than is the case with the local producers. There is a strong demand for the Southern coals in the Northwestern market.

Prices continue around the summer level with the exception of the steam grades which as already noted, are in strong demand. The eastern Kentucky block is plentiful at $1.45 to $1.50 f.o.b. mine with lump and block at $1.25, mine-run $1.05 to $1.15, No. 2 at 85 to 95c., and domestic nut at $1.25 to $1.35. Nut and slack are firm at 85 to 95c. and western Kentucky screenings, nut and slack are quoted from 75 to 85 cents.

BIRMINGHAM, ALA.

There is little encouragement to be found in the general situation in this district, the depression being more keenly felt in the pig-iron and steel markets and the coal trade has not by any means escaped. Steam coal has suffered most and low record prices for the season have been made on what might be termed second-grade product. The lump and nut situation, while better than steam, is not showing any activity worthy of mention. The real cause of the apathy in business is somewhat difficult to place and many and varied reasons are advanced as the source of the trouble.

In contrast to other markets, the foundry coke demand is very good and is showing no signs of weakness. There is little demand for furnace coke and the surplus supply is not large. Practically all of the pig iron smelting companies in this district have sufficient coke ovens for supplying their own requirements of furnace coke. The question of securing common labor is a weighty problem with many of the large industries.

DETROIT, MICH.

Bituminous—Slack coal is somewhat more active than the larger sizes and is the strongest feature in the local market at the present moment. Consumers are showing no anxiety about closing contracts to cover their future requirements, apparently believing that the settlement of the West Virginia labor situation will react to their advantage and result in a material reduction in quotations. Rail shipments are heavy and operators maintain an optimistic view of the situation and believe that they will have no trouble in obtaining the increased circular of the year. Local prices continue on approximately the following basis:

	W. Va. Splint	Gas	Hocking	Cambridge	No. 8 Ohio	Pocahontas	Jackson Hill
Domestic lump	$1.50	...	...	...	...	$2 25	$2 00
Egg	1 50	...	$1 35	...	...	2 25	2 00
1¼-in. lump	1.25	...	...	...	...	...	...
2-in. lump	1.20	$1 20	$1 20	$1 20	$1 20	...	...
Mine-run	1.10	1.10	1.10	1.10	1 10	1 50	...
Slack	1 00	1.00	1.00	1.00	Open	Open	...

Anthracite—The hard-coal market is showing none of the activity that was anticipated for this time. Consumers generally are refusing to place orders that could be advantageously filled both for themselves and the producers; they appear to believe that there is a recession of prices in sight and it is probable that the late fall will see the usual scramble for deliveries at the last moment.

INDIANAPOLIS, IND.

Mines in this state are averaging about four days a week which is normal for the season. The demand for domestic is at a minimum, but screenings are strong. Some time back a scarcity was reported but it is said that mines are now caring for all requisitions in a very satisfactory manner.

April will be memorable as the month of the great flood; railroad communication was badly demoralized and has not yet fully recovered. Many factories were damaged and the coal industry seriously interfered with, outside the flooding of some of the mines. But much coal was needed immediately following the subsidence of the waters and the volume of business for the month was thus kept up to about normal.

Prices at the mines for standard grades, f.o.b. are:

No. 4 mine-run	$1.10@1 20	Domestic 4- and 5-in.	$1.50@1.60
No. 8 5 and 6	1.05@1.10	Screenings No. 4	0 90@1 00
Steam lump, 1¼-in.	1.15@1 35	Screenings 5 and 6	0 80@0 90
Nut and egg	1.20@1 55	Brazil block	2 00@2.10
Domestic 3-in.	1.40@1 65		

CHICAGO

As a result of an early spring, which has cut off the consumption of household coal, the domestic market is unusually quiet at the present time. There is a strong tendency to cut down storage piles and get rid of stocks as rapidly as possible.

Steam lump from Western mines is commanding prices ranging from $1 to $1.25, while mine-run coal is selling all the way from 95c. to $1.10. Western screenings are selling at from 75c. to 85c. Prices for smokeless coal remain firm and it is expected there will be a rise in quotations on this commodity within a short time; according to some, mine-run will be advanced to $1.50 and a still higher price for the prepared coal. There is a fair demand for coke in the spot market. A large number of contracts are now being made and the prices obtained vary. Contracting for coke among retailers and jobbers is especially heavy.

Prevailing prices in Chicago are:

	Springfield	Franklin Co.	Clinton	W. Va.
Domestic lump	$1 97@2 07	$2 30@2 40	$2 27	...
Egg	...	2 30@2 40	...	$3 65
Steam lump	$1 82@1 87	...	2 07	...
Mine-run	1 77	2 20@2 30	1 97	3 30
Screenings	1 57	1 95	1.57@1 62	...

Coke—Connellsville and Wise County, $6@6.25, byproduct, egg, stove and nut, $4.45@4.75, gas house, $4.60@4.70.

ST. LOUIS, MO.

Spring business is about normal in St. Louis with no demand for any size in particular. The policy of losing money on the operations still seems to continue. The lowest price quoted on Standard lump was touched the past week when it was offered at 80c. f.o.b. the mines. There are some contracts being signed up, but they do not, in a way, amount to much, and the prices are exceptionally low in view of the outlook.

Indications are that there will be a fair movement of anthracite during the present month. Coke is away off on demand but the price seems to be holding up. There is not much doing in smokeless, and it will perhaps lose in the spring tonnage this year on account of the aggressiveness of the anthracite shippers.

The prevailing circular is:

	Carterville and Franklin Co.	Big Muddy	Mt. Olive	Standard
2-in. lump				$0.90
3-in. lump			$1.20	
6-in. lump	$1.15 @ 1.20		1.25	1.05
Lump and egg		$2.25		
No. 1 nut	1.05 @ 1.15			
Screenings	0.90 @ 0.95			0.85
Mine-run	1.00 @ 1.10			0.80
No. 1 washed nut	1.35			
No. 2 washed nut	1.35			
No. 3 washed nut	1.35			
No. 4 washed nut	1.35			
No. 5 washed nut	1.10			

St. Louis prices on May anthracite are: Chestnut, $7.05; stove and egg $6.80; grate $6.55. Smokeless lump and egg is $4.45 and mine-run $4. By product coke is $5 and gas house $4.75.

MINNEAPOLIS, ST. PAUL

While there is a prevailing quietness in all the branches of the coal trade at the present writing, enough business is going on to keep all in an optimistic mood. The Northwestern states are in a very prosperous condition, and although little coal is being moved, coalmen are looking at the present situation philosophically, knowing that the trade will buy when the time comes. There does not seem to be any disposition on the part of dealers in the country to stock hard coal even at the reduced spring price, which in May is 40c. lower than September.

Immediately upon opening of navigation the head-of-the-Lakes harbors became a scene of great activity and one of the busiest shipping seasons is now in progress.

OGDEN, UTAH

April started out very good and many of the operators predicted an excellent business but about the middle of the month the dealers began to anticipate a storage period, May 1, and the operators began inquiring of the railroads concerning a reduction in freight rates during May, June and July, but nothing definite could be learned. The dealer and the consumer, especially the former, anticipated some reduction on May 1, and held off buying during the last of April in order not to have high-priced coal on hand in case of a reduction. On Apr. 29 the railroads announced there would be no reduction in freight rates this year. This caused the operators to reduce the price of coal f.o.b. mines, and while circular quotations announcing the reduction were sent out to the trade immediately, it has not increased the movement.

The Utah mines are anticipating trouble ahead this winter. Their many inducements will no doubt cause the dealers to store Utah coal, in the latter part of the season, with the idea that they will be taken care of during the winter; however, all of the Utah mines are tributary to the Denver & Rio Grande R.R. and the car supply commencing about Sept. 1 will be about 25% of requirements.

Present quotations are as follows: Lump, $2.25; nut, $1.75; mine-run, $1.75; slack, $1; on both Wyoming and Utah grades.

PORTLAND, ORE.

Cool weather has set in again in this locality and coal for domestic purposes is in demand. However in a general way there is no material change in the situation and prices remain as during the winter.

Judging from the number of steamship lines that are to operate out of Portland upon the completion of the Panama canal there will be a strong demand here for bunker coal. Several foreign lines have announced that they will send steamers to this port from various ports of Europe, on regular route, and some of them are to make Portland their Pacific coast terminus. Two lines, the Hamburg-American and the Royal Mail, have already inaugurated sailings.

PRODUCTION AND TRANSPORTATION STATISTICS

SOUTHWESTERN TONNAGE

The following is a comparative statement of the southwestern tonnage for January, 1912 and 1913:

State	1912	1913	Increase	Decrease
Missouri	281,453	305,825	24,372	
Kansas	537,928	523,605		14,323
Arkansas	155,666	183,648	27,982	
Oklahoma	348,982	366,859	17,877	
Totals	1,324,029	1,379,937	70,231	14,323

ANTHRACITE SHIPMENTS

The following is comparative statement of the anthracite shipments for April and the first four months, of the years 1912-13, in long tons:

	April		4 Months	
	1913	1912	1913	1912
Phila. & Reading	1,180,115	31,324	4,579,408	3,893,690
Lehigh Valley	1,149,896	4,840	4,216,678	3,334,231
Cent. R.R. N. J.	738,579	58	2,978,872	2,393,203
Del. Lack. & West.	861,078	112,858	3,078,995	2,604,079
Del. & Hudson	561,700	.....	2,344,688	1,718,283
Pennsylvania	585,472	49,687	2,082,297	1,653,515
Erie	672,386	67,798	2,745,928	2,222,648
Ont. & Western	216,963	60	859,199	656,927
Total	5,966,189	266,625	22,886,065	18,475,976

Stocks at Tidewater at the close of April were 546,243 tons as compared with 772,115 tons on Mar. 30.

FOREIGN MARKETS

GREAT BRITAIN

Apr. 25—The demand is quiet at present, but collieryowners are well placed as regards orders and are not willing to reduce quotations for prompt or forward loading.

Quotations are approximately as follows:

Best Welsh steam	$5.04@5.16	Best Monmouthshires	$4 56@4.68
Best seconds	4.86@4.98	Seconds	4.44@4.50
Seconds	4.68@4.80	Best Cardiff smalls	3.54@3.60
Best dry coals	4.74@4.92	Seconds	3.18@3.30

The prices for Cardiff coals are f.o.b. Cardiff, Penarth or Barry, while those for Monmouthshire descriptions are f.o.b. Newport; both exclusive of wharfage, and for cash in 30 days—less 2½%.

SPANISH IMPORTS

Spanish imports of coal for the first two months of the current year were 409,975 tons as compared 397,489 for the same period last year. Coke imports for the same periods were 59,537 tons and 78,193 tons respectively.

COAL SECURITIES

The following table gives the range of various active coal securities and dividends paid during the week ending Apr. 26:

Stocks	Week's Range High	Low	Last	Year's Range High	Low

DIVIDENDS

Mahoning Coal R.R.—Common—Dividend of $25 payable May 15 to holders of record May 1.

Lehigh Coal & Navigation (No. 138)—Regular quarterly of $1 payable May 31 to holders of record Apr. 30.

Roby Coal Co. (Cleveland)—This company is offering at par and interest, $200,000 consolidated first mortgage 6% bonds, the balance of an authorized issue of $675,000, of which $75,000 has been retired. Par value of bonds is $1000, and they are secured by a sinking fund of 5c. per ton of coal.

PRICES OF MINING SUPPLIES

THE MARKET IN GENERAL

Sentiment did not improve during April as was expected, in fact, there was more pessimism on May 1 than there was on April 1. Numerous factors combine to cause this, not the least of which was the continuation of the unrest in the far East, due to a quarrel among the allies regarding the spoils of war, which further disturbed the peace of Europe and upset the balance of powers. Monetary conditions grew slightly easier toward May 1, but it is a noticeable fact that large corporations and even municipalities were unable to secure funds on as favorable terms as heretofore.

The course of prices has been toward lower levels in the market for iron and steel, and the demand for a number of products has not been as great as was expected, save in the regions lately devastated by flood and cyclone. Metals are higher in price, while cement is in excellent demand at unchanged quotations. The steel companies have made satisfactory returns for the first quarter of the year, although the earnings of the leading manufacturer were not up to expectations, and other industrial companies are making fair profits.

The tariff bill which was introduced in Congress, and is being discussed, is not as drastic as many believed it would be, and as yet it has not had the effect of unsettling business that even the most sanguine expected.

LABOR

Strikes have been of more frequent occurrence, and labor unrest is more pronounced this spring than it was a year ago in spite of the fact that there is less demand for labor than at that time. In addition to a bitter and prolonged strike among the silk mill operators in Paterson, there is a prospect that the machinists may endeavor to force the issue for an eight-hour day, and now that the wages of the firemen have been settled, other railway employees are making demands for higher wages. This time it is the trainmen.

The strike among the operators of the twine mill of the International Harvester Co. continued during the early days of April with much bitterness, and finally the company announced that if settlement were not made by a certain date, the mills would be dismantled and the machinery shipped abroad. The company even went so far as to have machinists take apart some of the machinery preparatory to shipment abroad. Such a proceeding does not help the employer in any endeavor to gain the good will of the employees.

There is a general demand for outside labor, but it is not as urgent as last year.

IRON AND STEEL PRODUCTS

Business during April did not develop as was expected, and the total business transacted was slightly less than during March. In the line of finished steel, there were no great reductions in price, in fact there were some advances, but there was a feeling of unrest which resulted in fewer orders being placed, and less activity at the mills. The particularly unsatisfactory part of it is that the price of pig iron continued to decline.

Steel billets are $1 a ton cheaper than last month; wire products are slightly higher; there has been come uneasiness in the price of sheets with a result that quotations are $2 per ton less at certain quarters. Bars are fairly active, and, especially those for reinforcing work, are in excellent demand. Rails have been in less requisition, although somewhat over 100,000 tons were purchased during April, and a good export order received. The price of pipe was advanced, but the great falling off was in the demand for railway cars and equipment. The railways are too beset by financial troubles, and the securing of funds is too uncertain to permit them to buy more equipment than is absolutely needed.

Steel Rails—The demand for light rails has not been as large as earlier in the year, but some very fair orders for contractors' equipment were received. Early in the month the railways purchased 65,000 tons, and during the last week, a single system ordered 35,000 tons, and there were a few scattered orders aggregating 20,000 tons more. Quotations continue unchanged at 1.25c. per lb. for standard sections, weighing from 50 to 100 lb per yd.; 1.21c. for 40- to 50-lb. rails; 1.30c. for 16- to 20-lb. rails. These quotations are for carload lots f.o.b. Pittsburgh. In Chicago, 16- to 20-lb. rails, are 1.30; 12-lb., 1.35c.; 8-lb., 1.40c. Relaying rails in Chicago are $24 per gross ton and they can be had at other centers at approximately the same quotation.

Track Supplies—Due to the floods in Ohio, and the demand for an unusual number of track laborers in that section for work other than the relaying of rails, there has not been the active demand for track material that there was earlier in the season. By June, this should return, however, and at that time, business will be just as rushed as ever. Spikes are 2.10c. base for large lots; track bolts with square nuts, 2.40@2.50c. base, and tie plates $34@36 per net ton. These quotations are for Chicago delivery. In Pittsburgh angle base are 1.50@1.60c. and spikes 1.95@2.15c. These quotations are per lb. in fairly large lots.

Pipe—On Apr. 12, there was a revision of discounts for pipe, amounting to an advance of approximately $1 a ton, or a half point in the discount. Business during the month was exceptionally large, one of the leading fuel companies in Pittsburgh buying about 80 miles of pipe, and other companies inquiring for large quantities. The mills are able to make fairly prompt shipments, but the pipe business is very satisfactory. New discounts are as follows:

	Black	Galvanized
¾- to 2-in. butt welded	79½ %	70%
2½- to 6-in. lap welded	78½ %	70%

Based on these discounts, the net price of pipe per foot are as follows in carload lots f.o.b. Pittsburgh:

Size, inches	Black	Galvanized
¾	2.35	3.40
1	3.50	4.90
1¼	4.75	6.60
1½	5.55	8.00
2½	12.60	17.50
3	16.50	23.10

Sheets—There was considerable weakness in the sheet market before the floods in Ohio put a number of mills out of commission, but that strengthened the market materially. Since that time, these mills have been able to resume operations, and in consequence the market has again weakened. The mill which was the leading factor in lower prices during March, has again gone out aggressively after orders, and is cutting prices from $1 to $2 per ton. There has been no change in price by the largest manufacturers, and it is stated that this weakness is only temporary, being due to peculiar causes, and the shortness of semi-finished steel will in itself prove a barrier to any lower prices. However, this is more a matter of conjecture than anything else.

The following prices are for lots of a few bundles f.o.b. Pittsburgh and Chicago. These should not be confused with the quotations for carload lots, which is 2.30c. f.o.b. Pittsburgh for No. 28 black.

	Cents per Pound			
	Pittsburgh		Chicago	
	Black	Galv.	Black	Galv.
Nos. 22 and 24	2.75	3.55	2.70	3.50
Nos. 25 and 26	2.80	3.70	2.75	3.65
No. 27	2.85	3.95	2.80	3.90
No. 28	2.90	4.00	2.85	2.95

Structural Materials—Replacement orders by the railroads have not been as large as was expected at the time of the flood, and the only really large order placed was by the Big Four for 6000 tons of bridge material.

Fabricating shops are not nearly as busy as they were, and shops in the Middle West, as well as those in the East, are able to make contracts for fairly prompt delivery. The plate market is easier, chiefly because of the falling off in the demand for car-building materials. Shipbuilding work continues fairly active.

Quotations are without change as far as future deliveries are concerned, but for prompt shipment there has been a reduction of $1 to $2 per ton. Plates, beams and angles are 1.50c., base Pittsburgh, for future shipment, and 1.60c. for prompt shipment. In Chicago, the quotation for future ship-

ments is 1.68@1.73c., and prompt deliveries are held at $1 per ton higher. All of these prices are per 100 lb. in carload lots.

WIRE PRODUCTS

Wire—Business is fairly active as far as shipments are concerned, but few new orders are being booked on account of the advance in March. Previous to that time, most of the large consumers were fairly well informed that an advance would take place, and in consequence placed large orders, so there will be no orders for some time to come. For large lots, quotations are as follows: Painted barbed wire, $1.86; galvanized, $2.20; annealed fence wire, $1.60; galvanized, $2.05. In Chicago, annealed fence wire is $1.78 and galvanized, $2.18. Barbed-wire fencing in that market is $1.98 and galvanized, $2.38. All of these quotations are per 100 lb.; for smaller quantities bought from jobbers' stores, an advance of about 25c. per 100 lb. is named.

Wire Rope—The market is steady and prices are unchanged. Two-inch rope in Pittsburgh is held at 57c. per lin.ft.; 1¼-in., 23c.; ¾-in., 10c. These quotations are for best grades or for special grades of wire rope, but cheaper grades can be obtained at considerable concessions.

Copper Wire—The market is steady, business is active and prices are higher. There has been an unusual demand for special grades of copper during the month and quotations are high at 17c.

Telegraph Wire—Business is fairly active with quotations unchanged as follows:

Prices are as follows in cents per pound for wire measured in the Birmingham wire gage: "Extra Best Best," Nos. 6 to 9, 4¾c.; Nos. 10 and 11, 4½c.; No. 12, 4⅝c.; No. 14, 5⅛c.; "Best" Nos. 6 to 9, 3½c.; Nos. 10 and 11, 3⅝c.; No. 12, 3½c.; No. 14, 4c. Actual freight is allowed from Trenton, N. J., where it does not exceed 25c. per 100 lb.

HARDWARE

Bar Iron and Steel—Prices are steady. Stocks are well assorted, and consumers can secure supplies desired with little difficulty. Quotations from jobbers' store in New York and Chicago are as follows:

	Per lb.
Refined iron:	
1 to 1⅞ in., round and square	2.10c.
1½ to 4 in. x ⅜ to 1 in.	2.10c.
1½ to 4 in. x ¼ in. to ⅝ in.	2.30c.
Norway bars	3.60c.
Soft steel:	
¾ to 3 in., round and square	2.05c.
1 to 6 in. x ⅜ to 1 in.	2.05c.
1 to 6 in. x ¼ and ⅝ in.	2.20c.
Rods—⅝ and ½ in.	2.15c.
Bands—1½ to 6x⅜ in. to No. 8	2.35c.
Beams and channels—3 to 15 in.	2.15c.

Nails—Building all over the country is not as active as last year and in consequence the demand for nails has slumped off to quite an extent. Prices, however, are steady, large lots being held at 1.80c. Pittsburgh, 2.08c. Chicago. For small lots from jobbers' stores the price is 2c. in Pittsburgh and 2.28c. in Chicago. Quotations approximating those of Chicago are made for most Central West jobbing points.

Rivets—The demand for rivets is not as active as last month, and there is less urgency for shipments. Quotations are $2.20 for structural rivets and $2.30 for boiler rivets. These prices are per keg of 100 lb.

Chain—Prices of chain are firm, but the buying has not been especially large. Ruling quotations per 100 lb., f.o.b. Pittsburgh, are as follows:

⅜ in.	$7.50
¼ in.	4.95
⅝ in.	3.95
5/16 in.	3.40
¼ in.	3.20
7/16 in.	3.00
½ and 9/16 in.	2.90
5/8 and 11/16 in.	2.80
¾ and 13/16 in.	2.70
⅞ and 15/16 in.	2.60
1 to 1¼ in.	

Extras for BB

⅜ in.	1.50
¼ in.	1.50
⅝ and larger	1.25

Extras for triple B (BBB)

⅜ and ¼ in.	2c.
⅝ and larger	1.75c.

METALS

Copper—The excellent buying in the copper market, which was noted a month ago, has continued practically throughout the month, domestic consumers having purchased large quantities at steadily advancing quotations. In addition to this, consumers of copper abroad have made large purchases, and exports during April were large, but did not come up to the record-breaking figures of March. It is practically impossible to secure deliveries of special grades within 60 days. Electrolytic copper sells at 15¾ to 16¼c. for large lots, and Lake, 16¼ to 16¾c. from store New York.

Tin—The market is steady and higher, and tin is selling at around 50c. per pound in New York.

Lead—Prices are very firm, and the market is steady at 5.50c. New York and 5.35c. St. Louis.

Solder—Strictly half and half solder is selling in the New York market at 27½ to 28c.

MISCELLANEOUS

Castings, Gray Iron—The foundries making castings are not able to secure all the orders they desire, and have been going out after business. Rough castings in large quantities can be had at 1.75 to 2.25c. per lb.; smaller castings, such as are used for construction work, command from 2.50 to 3c. per lb.

Brattice Cloth—Conditions have not changed materially regarding brattice cloth. The demand is just as active as it was, in fact more so, and the supply continues short. Deliveries are being made with more freedom, especially by foreign manufacturers, but there are no large stocks on hand at any point. The tariff situation is not troubling dealers in brattice cloth any for the present, for the reason that there are no stocks on hand, and, according to the present schedule, it is difficult to see where there will be any material change in the price of this material.

Portland Cement—Manufacturers and dealers in cement are not as optimistic regarding the outlook as they were two months ago. There will be a large quantity of cement used in various places, but a great many of these contracts have been covered and, moreover, a good deal of this work will extend over a long period of time. Consequently, there is not the feeling at present that there will be an advance, as was so sanguinely stated about two months ago. Quotations are firm at $1.58 in both New York and Pittsburgh. This allows 40c. for bags returned.

Rope—Manufacturers of rope have never had such a season as the past one. Prices have advanced, and the best grades of Manila rope are selling at 15 to 16c., while hardware grades, which formerly sold at 6c., are now commanding 12 to 13c.

Bars, Concrete Reinforcing—Orders for bars are large, but stocks are sufficient to meet the demand. Prices are firm and for small lots from warehouse stock are as follows:

PITTSBURGH PRICES IN CENTS PER POUND

	Warehouse Stock
¾-in.	2.00@2.10
⅝-in.	2.05@2.15
½-in.	2.10@1.20
⅝-in.	2.25@2.35

Triangular Mesh—Makers of this material are able to make prompt shipments.

From mills in De Kalb, Ill., quotations are 18c. per 100 lb. higher than those quoted below, which are 100 sq.ft. f.o.b. Pittsburgh. These are for lots of less than 10,000 sq.ft.

No. 23	$1.23	No. 32	$2.62
No. 23	2.05	No. 36	1.05
No. 26	1.42	No. 40	3.25
No. 28	1.97	No. 41	2.48

Shafting—Specifications are coming in freely and although the automobile manufacturers seem to have contracted for all the material they will need this year, there is some very fair business. A slight revision has been made in the price of shafting, and new discounts are 58% from list in carload lots and 53% from list in less than carload lots. Business is fair. The following net prices per foot are based on the discount of 53%.

Diameter in inches	Cents per foot	Diameter in inches	Cents per foot
¾	4.25	2¼	31.50
1¼	10.80	2½	39.30
1½	14.05	2¾	48.00
1¾	19.20	3	56.50
2	25.00	3½	84.00

Packing—Prices vary within wide limit, according to the brands of various dealers, but in general, packing can be purchased at the following quotations: Asbestos, wick and rope, 13c. per lb.; sheet rubber, 11@13c.; pure gum rubber, 40@45c.; red sheet packing, 40@50c.; cotton packing, 16@25c.; jute, 5@6c.; Russian packing, 9@10c.

Plates—Manufacturers continue to catch up with orders and shipments are much more satisfactory. New business is coming in slowly, and there is a dearth of new orders, especially from car builders. Railroads are not buying cars in any quantity.

COAL AGE

Vol. 3 NEW YORK, MAY 17, 1913 No. 20

The Mine Telephone

By Berton Braley

Written expressly for Coal Age

"Ting-a-ling-a-ling" you can hear my noisy ring
As it echoes in the chambers of the mine,
When I clearly come across with the orders of the boss
Which are ripping in a volley down my line,
Though for miles the workings run I have hitched 'em up as one,
I have made the mine a unit by my call,
From the busy bottom pump to the breaker and the dump
I'm the blooming nervous system of it all!

"Ting-a-ling-a-ling," hear the message that I fling,
"There's a cave in Number 20, send a crew,"
So they listen to my shout and they come and dig us out
While without me 'twould be hours before they knew.
On my slender singing wire thrills the warning of the fire,
I give notice of the vapor's deadly breath,
And again and yet again I have saved the lives of men
Who would otherwise have faced a fearful death.

"Ting-a-ling-a-ling," you can hear my noisy ring
With its tintinnabulation on the ear,
I'm the terror of the shirk as I drive him on to work
But when danger comes he's thankful I am here,
I'm the foe of all delay and I help to "make her pay"
As a master of efficiency I shine,
From the collar to the sump I can keep 'em "on the hump"
I'm the blooming nervous system of the mine!

The Preparation of Coal

By Gordon Buchanan*

SYNOPSIS—In the last 35 years the preparation of coal in Illinois has experienced several revolutionary changes. Powderless extraction of coal in longwall workings, accompanied by hand screening on forks, has given place to modern methods of undercutting and shooting, with preparations on screens and rescreens and in washers. The author believes that grading will probably be carried as far as in the anthracite region and that the spiral is the best suited coal cleaner for some types of coal. He suggests that a medium size of bituminous coal may possibly soon command a premium in the market.

My experience in coal mining began some 35 years ago when, as a boy, spending my vacations at the mines, my attention was first drawn to the production and preparation of coal. It may not be amiss, to sketch briefly the changes which have come about during the elapsed period.

Reminiscences

I vividly recall the equipment at our old No. 3 shaft, which was no better, and no worse, than those of our competitors. It consisted of one old boiler, which, following its Sunday cleaning, was often the cause of much picturesque profanity on the part of our old Scotch engineer, Andy McKean. It had a practice of squirting so much water through its seams over the fire as to make it an even bet whether the coal could be made to burn or not. Usually the expansion conquered; if not, we shut down until the seams had been calked.

The hoist was a single-cylinder link-motion engine with a flywheel on the shaft, which frequently got on a dead center. Then it became necessary for Andy to walk on the flywheel spokes and "put her over," as he expressed it. There is still current among the older men in the field a tale relating to a similar installation which "ran away" one day, due to the breaking of the throttle valve, whereupon the engineer, during the ensuing excitement, was advised by a friendly Scot to "fling a prop in the wheel, Sandy." The resulting cast-iron shower forever established Sandy's reputation as an artful dodger.

Prior to my time the coal was forked in the mine before loading into pit cars, the screenings being thrown into the gob, and becoming a fruitful cause of trouble through gob fires. The gobbing of fine coal continued long after forking was abandoned. Many a day I puzzled my brain in an effort to provide means to insure the loading out of this fine coal.

During this period railway equipment consisted of ten-ton cars. Later, a certain few of our favored customers were taken over to the old Canal Street station of the Alton R.R., in Chicago, where now stands the Union Station, to see the world beater, a 12-ton coal car. Strange to say, on certain roads the spectacle of a wood-burning locomotive drawing a train consisting of cars of coal was frequently to be seen.

Mining Coal without Powder

Our longwall miners prided themselves on their skill with the pick, striving to make their cuts as narrow and as deep as possible. Explosives were practically unknown. I have known men to go home for several days on a stretch because their coal had not broken, only as a last resort using sledge and wedge to bring it down. It was nothing uncommon for a man to put in 14 hours' work daily, although the mine only hoisted during ten hours. As they expressed it, "they could take their time to it."

Under these conditions few appliances for cleaning the product were necessary. The bar screen set in the bottom of the loading chute between the tipple dump and the car was later supplemented in some few instances by a revolving screen for further sizing of fine coal, and the cleaning was provided by hand picking on the car. These simple methods constituted the sum total of preparation and continued in use for many years.

However, finally, the mine-run system was introduced into Illinois. It brought with it an increased percentage of fine coal, containing a greater proportion of impurities, due partly to the lowering of the standard of skill employed in mining. The miners now loaded out their fine coal which had formerly been thrown into the gob, and this was largely mixed with fire clay. Thus it became necessary to provide new methods of preparation in order to obtain a return from fine coal to offset the loss of revenue due to decreased percentage of lump.

Coal Passing from Tipple to Rescreener on Rubber Belt

This condition was met by the shaker screen containing various-sized perforations, which permitted a closer sizing of small coal by a single operation, with delivery direct into cars, thereby eliminating re-screening plants.

Following this a campaign was started to educate the steam consumers for the purpose of creating a demand for the smaller sizes produced. As a result various forms of stokers were introduced and perfected.

Coal Cleaning

The next problem confronting the producer was that of eliminating impurities, such as clay and pyrites con-

tained in the smaller, or steam sizes. These caused clinkers and impeded combustion through clogging of the grates, particularly in the furnaces of the traveling-chain type. Thus was introduced the coal washer in its various forms, which for a time solved the problem. Like all other appliances the washer has its limitations, and must be modified to suit the needs and peculiarities of the coal under treatment.

As perhaps is well known, it will not produce results with all coals; in fact, with some it will not produce results at all and other means must be sought. It has its drawbacks even when it does produce a clean coal. The fuel is prone to freeze in winter, thus causing increased labor and expense in unloading, while in summer disputes are frequent because of the claims for shortage at destination, which our railroad friends are prone to shift over onto the shoulders of the coal-mine operators. The shortage is invariably charged by them to evaporation of moisture and not to any other loss in transit.

Having passed through all these changes in the conduct of the industry in a period of short duration, we quickly realized, on entering the Franklin County field, that while the percentage of impurities, due to difference in mining methods, was relatively less per ton, the increase of output necessary, together with largely increased speed of handling, necessitated some method of preparation in addition to that of screening and hand picking.

In Europe, Coal Preparation is a Leading Problem

The preparation of coal is a subject on which a great deal of thought can and should be expended; yet up to the present, considering the magnitude of the bituminous industry in America, comparatively little has been done. America, unfortunately, is far behind foreign countries in this respect, and we may well take a leaf from their book of experience and profit thereby.

The European coals as a rule, compared with those of America, are poor and the beds thin, consequently, a large amount of care and labor must be expended to prepare them properly for market. In Great Britain the quality of coal is much better; nevertheless a large share of the expense involved in equipping British mines is devoted to the machinery for cleaning and sizing.

Our American coals, as a rule, are of much better average quality than the foreign coals, and have required less attention to prepare them for market. Today competition is such that the preparation often is the determining factor in retention of trade. There is a vast field for improvement in this direction.

Up to the present time, except as already briefly outlined, not much in the way of machinery to perform this work automatically has been developed for use in the bituminous field, although considerable advance in this line has taken place in the anthracite regions.

Soft Coal of Chestnut Size Should Lead in Price

One of the curious facts in the marketing of coal is that the trade pays a premium for anthracite of certain small sizes, notably chestnut, whereas in the bituminous fields the opposite is the case where at times a premium is paid for the large sizes, the small being frequently a drug on the market. The reason, undoubtedly, for this is the fact that appliances for burning domestic soft coal are not as efficient as those for the consumption of anthracite.

It would, therefore, seem as though there was a large field here for the enterprising manufacturers, who will develop and market, at reasonable cost, devices which are fitted and designed to burn the small sizes of soft coal without smoke. These are now being burned in certain types of house-heating furnaces and boilers, but as yet no practical efforts have been made to apply this principle to the ordinary heating stoves of small size, nor to the cook stoves, which make up the great bulk of the fires fed by soft coal.

Efforts to educate the consuming public to the value of the smaller sizes for domestic use would tend to make for market stability. If this campaign of education is to prove successful, it goes without saying that the fuel used must be closely sized, as clean and as free from impurities as possible. As large tonnages must be produced if operating expenses are to be maintained at a low figure, the old-fashioned methods of preparing coal are unsuccessful through their inability to take care of the volume of coal

One of the Twenty-Eight Spirals by Which Dirt and Low-Grade Coal Are Removed

at the rate of speed at which it must be handled. It is difficult, also, to obtain conscientious labor which will remove impurities by hand, also difficult to obtain labor which can stand the rate of speed necessary for this method of cleaning, and it is impossible to remove all impurities by hand methods.

The Spiral Cleaner

In searching for new ways to improve the quality of our output, our company reached the conclusion that we must look for some mechanical process which would work perfectly at high rates of speed. We, therefore, searched the anthracite field thoroughly, and also examined certain of the foreign fields. We found a number of appliances, all of which had good points, some more and some less than others. For our particular kind of coal, after careful practical tests, we concluded that one certain type of machine would do the work better than others, and we therefore installed it.

The result has more than warranted our belief in its efficiency. It is true that it is not absolutely automatic,

care being necessary to see that it is not crowded beyond its capacity. This particular device utilizes gravity, friction and centrifugal force to separate the slate and bone from the coal. When adjusted to the particular size of coal and fed within its capacity, it automatically rejects slate and bone, delivering the coal in a remarkably pure state. The coal must be first closely sized and delivered to machines built to suit the various sizes. Like all such devices, it has its limitations and probably would not work on all kinds of coal.

It must be apparent to the thoughtful producer that, given a good coal, the successful members of the industry will be those who deliver to the trade, the coals which contain the least amount of foreign matter, and which are the most uniformly sized; those which have, through close study of the needs of the consumer best fitted themselves to know and to advise which coals will give greatest economy under the consumer's peculiar conditions; not necessarily those who sell coal of the lowest price, for in the analysis the intelligent consumer is concerned less with what he pays, than with what he gets for his money.

The producer who delivers a satisfactory product exactly suited to the peculiar needs of his customer, thereby relieving him from the annoyance and loss arising from a fuel unsuited to his needs, surely should, and undoubtedly will, receive the consideration due his forethought and labor.

In conclusion, it seems apparent that more thought and care bestowed upon the preparation of our Illinois coals should result in increased returns, expansion of our selling territory and the establishment of a reputation for quality which should prove sheet anchors during a depression.

⁂ ⁂

Systematic Operation of Coal Mines

By A. J. Moorshead*

SYNOPSIS—The modern mine fails hopelessly to produce results if not planned and managed with system. But a mere assembling of physical and mental forces, even though grouped with judgment, will not create a successful operating organization without the harmony of effort resulting from the employment of men of strong character and moral force.

⁂

It is vitally important that all corporate operating bodies be efficiently organized. Every phase of the coal business is dependent for its success on the character of the organization of the body conducting it.

But no matter how elaborate may be the framework, how well it may be suited to the purpose in hand, it is valueless unless it works harmoniously. No success can be obtained without harmony and in no business is such coöperation more necessary than in the dangerous occupation of coal mining. Organization and discipline, little as we like the latter, must be linked together if we would conduct any business with success.

Forethought

The conditions of today are such that we cannot hope to succeed by merely meeting each difficulty as it arrives. Modern coal mines must develop a large tonnage and must be conducted in the most efficient manner if any return is to be obtained. Hence, the whole future of the mine must be considered before any action, however unimportant, is taken.

Complete plans must be drawn at the very outset of the enterprise, showing the fully equipped plant both below and above ground. Furthermore, the great need for enough capital to conduct the business without embarrassment, after all the expenditures of purchase and construction are completed, must never be overlooked.

Character

In selecting a working force, mere ability to design the details of operation does not constitute the sole qualification. Supervising officers should add to such ability, the force of character which will impress not only the executive, but the employees. Otherwise they will be unable to control the situation at times when danger is imminent.

Location

All shafts, slopes and drifts should be placed well above the highest flood level, and too much attention cannot well be given to drainage. Reservoirs must be established where not only good boiler water can be obtained, but of ample size to impound sufficient water to take care of the power plant and washer for a period of not less than ninety days, otherwise the colliery will be closed down in times of drought, which occur so often in the state of Illinois. Tracks for railroad cars should be on sufficient grade that both empty and loaded railroad cars may be moved by gravity and should be of such capacity that they will take care of the output of the mine for 12 hours of operating time.

All power and supply houses, machine and carpenter shops, should be ranged on definite building lines and so located that the tracks containing material will be kept out of the way of the operating tracks of the mine.

Supervision

In the arrangement of the underground working forces, the safest and most efficient practice is to have not more than three gangs for work on the roadways—one for track repairs, another for timbering, and the third for keeping the haulageways and air courses clear. To this must be added special organized gangs for any particular class of underground improvements, such as making concrete stoppings.

A gang leader or foreman should have charge of each of these separate bodies. This plan has, in actual practice, been found by far the more economical, both in point of safety as well as in service performed, than the old method of having many scattered gangs working without leaders, and subject only to the infrequent oversight of the mine manager* or his assistants.

One or two inspectors, as the size of the mine may require, should be employed on the day shift to travel the

*President and general manager, Madison Coal Corporation.

Note—Abstract of an address delivered May 9, 1913, entitled "Organization as Affecting Mining," read at the dedication of the Transportation Building and of the Locomotive and Mining Laboratories, University of Illinois, Urbana, Ill.

*The mine manager is in Illinois the certificated officer corresponding to the mine foreman in other states. He is subordinate to the superintendent.

haulageways and air courses for the purpose of inspecting all trap doors, track, switches, electrical circuits and roof. The inspectors should also test the air and locate defective stoppings, as well as watch for reckless drivers. All irregularities found should be reported to the mine manager.

Sufficient assistant managers should be employed. Their duties should require them to visit the faces of the rooms and of the entries only, to see that the ventilation is properly maintained and that all the miners are supplied with sufficient timber and that they are timbering their places adequately for their own safety. They should see that all working places are kept in good condition; also, when necessary, they should give instructions as to the manner in which the faces should be drilled to be shot with safety, and a large size of coal obtained with a minimum of shots.

It is, I believe, a fair statement to make, that in altogether too many mines, the underground managing force is totally inadequate for the number of men employed and tonnage produced, and I have, myself, known of many instances where the mine manager was without assistants, so that he became in fact a mere timekeeper. He seldom saw an air course unless a fall baffled the air and interfered with the ventilation, or visited the face except when some trouble called him there. Wherever such conditions exist, the force is seriously incomplete, and the owner of the property is permitting an unwise economy to be practiced. Leakages and mistakes must in such cases occur, and in an indirect manner the mine owner is losing a far larger sum than the yearly salaries of several assistants.

Drilling and Co-operation

It will be recognized that it is a waste of money to provide equipment without a properly organized, efficient force to handle it, and this is particularly true of fire-fighting and rescue appliances. Each and every man on the surface, and all supervising officers in the mine, as well as all employees working round about and in the vicinity of the shafts in the mine, should not only have specific duties to perform, but should, through systematic drilling, be prepared to act as a unit, because by quick, energetic action, and complete discipline alone, can even a fair degree of success be expected.

Harmony, together with firm and fair discipline, is necessary for the success of all institutions, but more particularly is it essential in coal mining, because most of the men underground are for the greater part of the working time beyond the observation of the managing forces.

❖ ❖

No. 2 Mine of the United Coal Mining Co.

By C. M. Moderwell*

SYNOPSIS—The mine at Buckner, Ill., is one of the uptodate mines of which so many are found in Franklin County. The cars are exceptionally large, the boiler equipment will make steam both economically and with minimum labor, and the rescreener makes five sizes of coal.

❖

The No. 2 mine of the United Coal Mining Co. is located about three miles east of the village of Christopher. This location was selected because, while not exactly in the center of the field which is to be developed, it is as near that point as the nature of the surface would permit.

The railroad tracks forming the working yard run in an easterly and westerly direction with the empty storage tracks on the west. The connection from the Illinois Central is made by a spur coming in from the north which forms a "Y" connecting both empty and loaded yards. The Chicago, Burlington & Quincy R.R. comes in from the south in the same manner. The mining plant is located within this double "Y," which makes a convenient arrangement for the handling of empties and loads and also for the receiving of mine supplies. The tracks are equipped with railroad track scales on the empty side and also with a scale for weighing the loads.

The Surface Plant

The mine was planned both above and below ground to produce ultimately 4000 tons of coal in an eight-hour day. The tipple loads onto four tracks and a steel rescreening plant has been built with a bin capacity of 1000 tons and a screening capacity of 1800 tons daily. The steel tipple is complete with weighing, screening and loading equipment. A combined boiler and power plant, including hoisting engines, electrical equipment and water-tube boilers; boiler-house coal conveyor, including overhead steel storage tanks for delivering coal to automatic stokers; ash-handling equipment by means of an ash tunnel under the boilers with steel ash car and hoist for delivering ashes into a hopper located outside of building: the usual repair and blacksmith shops, supply house, etc. There is also an auxiliary air shaft with a separate compartment for hoisting men and material during working hours.

Another Mine (No. 1) of the United Coal Mining Co., Urbain, near Christopher, Ill.

The ventilating plant consists of a Clifford-Capell 8x16-ft. fan housed in steel direct-connected to a Chuse four-valve engine housed in concrete. There is also a complete water system consisting of a reservoir, an electrically driven pump and an elevated steel tank with a distributing system. The entire plant is built of concrete,

*President, United Coal Mining Co., Chicago, Ill.

Note—Paper read at the meeting held May 8, 9 and 10, at the dedication of the Transportation Building and Transportation and Mining Laboratories, University of Illinois, Urbana, Ill.

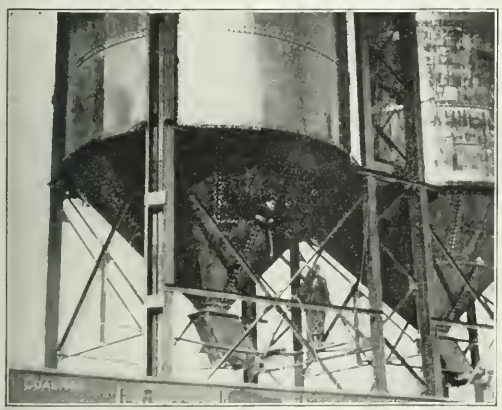
steel and brick construction and is as near fireproof and permanent as possible.

The mine is laid out underground to fit as nearly as possible the conditions found in the No. 6 seam in Franklin County. It is being worked on the panel system and it

The Buckner Rescreener in Course of Construction

is proposed to take the pillars on retreat. The seam of coal averages about 10 ft. in thickness and about 2½ ft. is left up for roof support in the first mining. This top coal is taken down when the pillars are drawn.

As the Franklin County field is comparatively new, the experience of the operators in that field does not permit of a statement as to the amount of coal recovered, but it is supposed that the total recovery will be about 80 per cent. of all the coal in the ground. If commercial conditions justify, it might be possible to recover more of the coal.



Showing Novel Arrangement for Removing Coal from Bins without Breakage

The mine at the present time is producing about 2500 tons per day, but has something like 200 rooms turned which are available for quick development.

The landing underground on the loaded side is equipped with a Jeffrey car haul which brings the trip down to an automatic car stop which releases the cars one at a time as they are caged. The main haulage roads are laid with 50-lb.; the cross entries with 30-lb. and the rooms with 20-lb. steel. A four-ton car is used and the mine is equipped with electric motors for both haulage and gathering. Overcasts are built of concrete-steel construction and permanent stoppages are built of brick.

The life of the mine is estimated at 30 years and in that time it is expected that about 1500 acres will be worked out. On the basis of 200 working days, it is expected the ultimate capacity of the mine will be 700,000 to 800,000 tons per annum.

Illinois Mining Conference at Urbana

On Friday and Saturday, May 9 and 10, an interesting conference was held at the University of Illinois, Urbana, Ill., following the dedication of the Transportation Building and the Locomotive and Mining Laboratories. During this conference, the following program was carried out. On Friday, May 9:

"Conservation and Commercialism," by Francis Peabody, president, Peabody Coal Co., Chicago, Ill.; "Organization as Affecting Mining," A. J. Moorshead, president, Madison Coal Corporation, St. Louis, Mo.; "Illinois Mineral Producers," E. W. Parker, chief statistician, U. S. Geological Survey, Washington, D. C.

Prof. H. H. Stock, acting as chairman of the conference, suggested to those attending the meeting that it might be beneficial to the coal industry of the state if more frequent meetings of this same kind were held at stated intervals. A short discussion followed this remark from the chair, and it was resolved that the chairman appoint a committee to consider ways and means for the formation of an Illinois mining institute. Prof. Stock called the newly appointed committee together in the afternoon, and the following organization was effected: J. D. Peters, general manager of the Chicago-Carterville Coal Co., Herrin, Ill., chairman; Martin Bolt, chief clerk of the State Mining Board, was elected secretary of the committee. The first regular meeting of the full committee was called for June 24, at Springfield, Ill. All suggestions concerning the formation of this proposed Illinois coal-mining institute should be forwarded to Mr. Peters at Herrin, or to Mr. Bolt at Springfield.

At 8 p.m. in the evening, the following topics were discussed:

"The Preparation of Coal," by D. W. Buchanan, president of the Bituminous Coal Washing Co., Chicago, Ill.

"Safety First." (a) From the Standpoint of the Miner, Joseph Pope, president of the United Mine Workers of America, District No. 12, Springfield, Ill. (b) From the Standpoint of the Operator, Thomas Moses, general superintendent of the Bunsen Coal Co., Westville, Ill. (c) From the Standpoint of the Mine Inspector, John Dunlop, state mine inspector, Peoria, Ill. Also a discussion of this topic led by Martin Bolt, chief clerk of the State Mining Board, Springfield, Ill.

"Modern Practice in Illinois Mines, as Illustrated by Some Recently Developed Mines." (a) The Buckner Mine, C. M. Moderwell, president United Coal Mining Co. (b) Cedar Point No. 5 Mine, C. C. Swift, general superintendent, La Salle County Carbon Coal Co., La Salle, Ill. (c) Saline No. 3 Mine, W. R. Johnson, general superintendent, Saline County Coal Co., Harrisburg, Ill.

On Saturday, May 10, the general subject of the conference was "Fireproof Mine Construction," and the various topics discussed were:

"Concrete in Mine Construction," by S. F. Allard, chief engineer of the Bunsen Coal Co., at Westville, Ill.

"Steel in Mine Construction," by Carl Scholz, president, Coal Valley Coal Co., Chicago, Ill.

"Modern Steel Tipple Design," by John A. Garcia, of Allen & Garcia, McCormick Bldg., Chicago, Ill.

"Fire Protection of Mines." (a) From the Standpoint of the Mine Operator, John P. Reese, general superintendent, Superior Coal Co., Gillespie, Ill., and Walton Rutledge, state mine inspector, Alton, Ill. (b) From the Standpoint of the Miner, Duncan McDonald, secretary of the United Mine Workers of America, District No. 12, Springfield, Ill. (c) From the Standpoint of the Mining Engineer, G. E. Lyman, mining engineer, Madison Coal Corporation, St. Louis, Mo.

The subject was then presented, "The Fireproofing of Mining Plants," by H. M. Wilson, chairman of the Mine Committee of the National Fire Protection Association.

Illinois as a Mineral Producer

By E. W. Parker*

SYNOPSIS—Illinois enjoys the unique distinction of having the center of mineral production for the United States within her boundaries, and ranks second among the producing states. Although exceeded by West Virginia in coal tonnage produced, the gross value of Illinois output is the greater.

A general but somewhat erroneous idea prevails that the Rocky Mountain and Pacific Coast States are our mining states, probably because the bulk of our supply of precious metals and the larger part of the output of copper comes from that portion. The fact of the matter is that fully two-thirds of our mineral production comes from the states east of the Mississippi River, and these Eastern States constitute only a little more than one-fourth (28.8 per cent.) of the total area of the United States, exclusive of Alaska and our insular possessions.

The center of mineral production, determined in the same manner as the Census Bureau arrives at the center of population, is located in this state of Illinois—in Cass County, about 90 miles north of St. Louis and 50 miles east of Quincy. The rank of Illinois as a mineral-producing state depends upon whether we consider iron ore or pig iron as the basis of iron production, but in either case it ranks among the first three or four. As you all well know, Illinois is not a producer of iron ore, the furnaces here obtaining their supplies of ore from the Lake Superior region, but Illinois is one of the three leading states in the manufacture of pig iron, being exceeded in this respect by Pennsylvania and Ohio, both of which produce some iron ore, but depend upon Lake Superior for by far the larger part of their supplies.

In 1911, with pig iron as the basis of production, Illinois had a total output valued at approximately $137,400,000 and was third in rank, with Pennsylvania first and Ohio second. If we substitute iron ore for pig iron in our statistical compilations, the value of Illinois' production drops to $106,230,000, but Ohio takes a bigger drop to less than $100,000,000 and Illinois comes second as a mining state and without reflected credit from the manufacture of ore mined in another state.

Illinois owes its high rank among the mineral-producing states principally to the extensive development and intelligent utilization of the coal resources with which she has been so bountifully endowed. The state has 102 counties, and coal is mined in 51 of them, which is more than in any other state in the Union, not excepting Pennsylvania. In point of coal tonnage Illinois has been exceeded in the last three years (that is 1909, 1910 and 1911, the figures for 1912 not being available) by West Virginia, but in point of value Illinois continues to lead. In 1911 West Virginia's coal production exceeded that of Illinois by over 6,000,000 short tons, whereas in value the output of Illinois was the greater by nearly as many dollars ($5,840,000). The cause usually assigned to this is that the cost of mining per unit of output in Illinois is higher than in "unorganized" West Virginia and this is doubtless true to some extent, but compensation for this condition is secured through the relatively local markets with which the operators of Illinois are blessed.

This state ranks third as a manufacturing state, with New York first and Pennsylvania second. West Virginia, her close and for the last three years her successful rival in coal production, is of relative unimportance as a manufacturing state (ranking twenty-ninth) and must seek an outlet for her coal in distant markets. All of the coal production in Illinois, on the contrary, is consumed within her boundaries or in immediate adjacent territory, and, relieved of long distance rail haul, the trade can bear within limits, a higher cost of production. No person here present, nor any one familiar with the quality of the coal produced in the United States, will claim that the average of Illinois coal is of as high quality as that of West Virginia's product and yet in 1911 the average value per ton at the mines was $1.11 for Illinois coal, and 90c. for West Virginia. In 1910 the corresponding values were $1.14 and 92c. The moral is obvious. Use your raw material at home.

In addition to consuming her own coal, Illinois uses large quantities of the West Virginia product, and some from Pennsylvania and Kentucky. Within the last two or three years, owing to the construction of large by-product coking ovens at Chicago and Joliet, Illinois has pushed to the front as a manufacturer of coke, but the greater part of the coal used (fully 80 per cent.) comes from West Virginia. Some of the Illinois coals possess coking qualities, but do not make satisfactory furnace coke. An entirely satisfactory coke is made at Joliet, using a mixture of 80 per cent. West Virginia and 20 per cent. Illinois coal.

Of the 51 counties in the state, two (St. Clair and Williamson) produce over 5,000,000 tons each; two others (Madison and Sangamon) produce over 4,000,000 tons, and several others produce from 1,000,000 to 3,000,000 tons. These are large figures, but shrink in comparison with two counties in the bituminous region of Pennsylvania, Fayette and Westmoreland, whose combined tonnage equals that of the entire state of Illinois and with two others, Luzerne and Lackawanna, in the anthracite region with about the same aggregate output. But then Pennsylvania's total production of anthracite and bituminous coal is four and a half times that of Illinois.

Second in importance among the minerals of Illinois is petroleum, the development of which in significant quantity is part of the history of the last decade. Prior to 1905 the petroleum production of Illinois was measured in hundreds of barrels; it is now reported in tens of millions. They "struck oil" in Illinois in 1905, and in the following year the wells yielded nearly 4,500,000 bbl., jumping to nearly 25,000,000 in 1907, since which time the production has been between 30,000,000 and 35,000,000 bbl. annually.

Illinois now exceeds both Pennsylvania and West Virginia in the production of petroleum and is indeed the leader in this respect among the states east of the Mississippi River. It ranks third among all of the states, be-

*Statistician, the U. S. Geol. Survey, Washington, D. C.

Note—Abstract of an address delivered at the dedication of the new buildings at the University of Illinois.

ing exceeded only by California and Oklahoma. Natural gas is produced in Illinois, but in relatively small quantities, and is used principally locally. The production of gas is valued at only approximately $600,000 per annum.

As stated earlier in this discussion, the manufacture of pig iron is not included in the mineral industries of the state, as it is not based or dependent upon the development of natural resources within the state, but it is a manufacturing industry of large proportions and deserves special mention. As a manufacturer of pig iron, Illinois ranks third among the states, the total output in 1911 (an "off" year in the iron trade) being valued at over $31,000,000. In 1910 when conditions were more nearly normal, the pig-iron product of Illinois was worth $41,500,000.

In 1910 Illinois produced 2,688,000 long tons of steel ingots and castings. In 1911 the production decreased 550,000 tons. This was due to the general falling off in iron and steel production in that year. As in the manufacture of pig iron, Illinois ranks third in the production of steel ingots and castings, although now rather closely pressed by Indiana, whose production of ingots and castings amounted in 1911 to about 1,600,000 tons.

Excluding pig iron from consideration, Illinois stands second in the 50 states and territories comprising continental United States, and contributes one-sixteenth to the annual mineral production.

Steel in Mine-Construction Work

By Carl Scholz*

SYNOPSIS—The author believes that the future will bring an increased use of steel in mine work. Steel construction, if not too heavy, is as cheap as wood and pays even where temporary. Steel tipples can be moved to new locations when the coal is exhausted. A description is given of a shaft which was cheaply lined with steel and concrete.

The tendency to secure greater safety and the development of mines, larger and of longer life, have brought about a change in the character of the material used for construction purposes, both above and below ground. Up to a comparatively short time ago, wood was used entirely for the construction of coal tipples, head frames, and buildings on the surface; the only metal used was for the screens, which were of simple design and usually only planned for a single separation. Already, however, wooden tipples are no longer built, except for small country mines, and steel and concrete are used almost exclusively for the surface plants.

No. 1 Plant Consolidated Indiana Coal Co., Dallas, Ind. An Escapeway Is Being Constructed on the Right on a 17-Deg. Slope, by Which Men Will Enter Mine. No Men Will Be Hoisted

Light Steel Tipples as Cheap as Wooden Construction

Steel tipple construction has undergone a very satisfactory change during the last ten years; prior to that time the steel tipples were clumsy imitations of the wooden structures and were built without consideration of the correct strength and location to secure the best results. The earlier tipples were much too heavy. Usually, 12-in. double-channel columns, elaborately laced, were used to take the place of 12-in. square timbers. This made a structure strong enough to raise a heavy locomotive, and the resulting cost prevented extensive adoption of steel tipples.

With modern engineering, however, a properly designed steel tipple is no more expensive than a like wooden structure of equal strength and it has so many advantages that there can be no question of the advisability of replacing wood by steel. The elimination of fire risk alone is of much importance, not only on account of the saving in insurance premiums and possible property loss, but because of the further injury to business should a fire occur in the rush season. Owing to fires for heating purposes being used during the winter months when business is most brisk, more conflagrations occur during the busiest period of the year than during the summer. The use of steel tipples enables the designer to place the supports some distance away from the shaft, and the "A" frame type has become popular and is extensively used. With a tipple of this design the wear of the shaft lining does not affect the structure because the supports are not weakened by the deterioration of the shaft. Even caving would not affect the supporting foundations.

*President, Coal Valley Mining Co., 141 Van Buren St., Chicago, Ill.

Note—Paper read on May 9, 1913, at the dedication of the Transportation Building and the Locomotive and Mining Laboratories of the University of Illinois, Urbana, Ill.

Where fireproof shafts are used, the three-leg tipple, which has been exploited by a Chicago engineering firm, can be used advantageously and at a minimum cost. The figures accompanying this article show different views of one of these tipples which is now being erected.

A Steel Tipple Can Be Re-erected in a New Location

Within the last two years I have developed two new mines, both of which will have a life of approximately ten years. One was a shaft mine and was equipped with a steel tower, bolted so that upon extraction of the coal, it can be taken down and removed to another location. In its present installation only three tracks were needed for the preparation of the coal, but the tower was built for a four-track tipple, which may be wanted at the second location.

The second mine was entered by a slope, and since it is expected to be the last slope mine which our company will develop and there would be no further use for the bents, wooden construction was adopted. Thirteen months after this mine began operation, the tipple was destroyed by fire, and the resultant losses would have paid for the steel construction even though it would have been wasted entirely upon the extraction of the coal at this locality.

The other buildings on the surface, and particularly the boiler and engine houses, must be fireproof and much steel and iron is used for this purpose, particularly siding, roofing and roof trusses. The contents of these buildings are nearly all steel and iron.

Use of Steel in Shafts

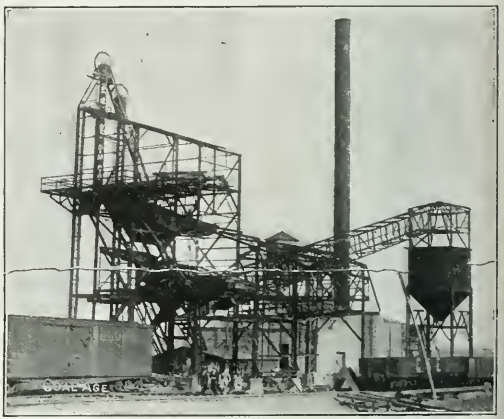
Fireproofing of shafts is regarded as important for safety, and many state laws require such construction. In large and important mines a permanent shaft lining is desirable because only by this means can delays due to frequent repairs be avoided. Steel frames similar in design to wooden sets for two- and three-compartment shafts have been installed with steel sheeting as lagging. This construction, however, is expensive and has not met with much favor.

I recently designed a modification of a steel shaft lining and it is installed at Shaft No. 1 belonging to the Consolidated Indiana Coal Co. and located at Dallas, Iowa. The arrangement of steel in this design provides for the principal members to be placed vertically instead of horizontally, as is the case when timber is prefered. Eight I-beams are used—four near the outside corners of the cages, two in the center of the cages and to these the buntons are fastened, and two on the sides to which the outside guides are attached. The shaft is of elliptic cross-section. The height of the I-beams ultimately forms the thickness of the concrete lining. In sinking, they are fastened together on the outside with curved angle irons bolted to their flanges, spaced about 5 ft. apart, and thin lumber lagging is used to prevent the caving of material.

When the bottom of the shaft is reached, the concrete is put in from the bottom to the top by clamping short form panels to the inside flange of the upright I-beams. These inside forms are made from 3 to 5 ft. in height, and ordinarily two sets are sufficient to enable concreting to progress continuously, the sets being used alternately. In the Dallas shaft this wall is made 7 in. in thickness and the outside lagging was left in place, with openings at intervals to permit the concrete to tie firmly into the rock surrounding the steel frame. The advantage of this steel and concrete combination is that the fabricated steel can be put in with very little expense and without the employment of skilled labor. Sections are bolted together with fish plates, and each section is made self-supporting by having a brace riveted to the outside of the I-beam, which rests in the rock or is supported by a shore or prop safely embedded in the shaft wall.

System which Makes Steel and Concrete Lining Cheaper than Wood

By this means not much attention need be given to the plumbing of the shaft as it is sunk, because the steel frames can be shifted into the proper position as the concrete is placed. The old method of putting in con-



Plant Being Constructed for Consolidated Indiana Coal Co., Dallas, Iowa

crete shafts by the use of wooden forms is complicated and requires much skilled labor and involves delay, because the forms must be very carefully set before the concrete is poured in order to have the required alignment for guides and buntings. In the Dallas shaft the vertical I-beams were made in 15-ft. sections, and in soft material a blind ring slightly larger than the completed shaft was used to permit lagging down to the very bottom of the excavation. Whenever the proper depth was reached and permanent steel frame was installed, the temporary rings were removed and the lagging adjusted itself to the permanent belts.

The weight of material in this construction, including 45-lb. steel rails for guides and the $\frac{1}{4}$-in. reinforcement rods six inches apart, is about 165 lb. per foot of shaft, and is less costly than the amount of lumber required for the same strength. In other words, what has been proven in tipple construction also applies to shaft lining. The method of lining a concrete shaft from the surface downward is as reasonable as would be the construction of a chimney from the top down.

The Steel Tie

In the mine workings proper, steel is used for various purposes. The oldest and most extensive application is for rails on the haulageways. Formerly wooden rails were used exclusively and on the more important roads iron

straps were placed on the upper surface. Later, 8- and 12-lb. iron rails were used, but with the increased weight of cars and motive power the important entries are now laid with 50- and 60-lb. steel rails bedded in rock ballast. Steel ties are becoming quite popular, and while at first thought, the expense seems prohibitive, considering that a steel tie for a 36-in. gage costs about 35c., whereas a wooden tie costs about 7 or 8c., the saving in wages and the reduced number of ties which are then required make steel more economical than wood under certain conditions.

Where the mine bottom is hard, steel ties can be spaced from 4 to 6 ft. apart enabling the base of the rail to rest on the floor and thus carry the load. The ties principally prevent the spreading of the track. The reduction in height required is important in low beds, and the ability to use steel ties over and over again with very little cost for recovery makes the steel ties more economical than wood.

Miscellaneous Use for Steel

Steel I-beams have been used for many years around shaft bottoms and on partings where wide entries have to be maintained, but the use of specially made steel props and cross-bars is of more recent adoption. Special H-sections have been made and found to be economical under certain conditions. The greatest strength of steel results in the use of smaller sizes which require less excavation for the same finished clearance, and the saving of wages in bolting these sets together, as compared with the costly preparation of timber, brings down the first high cost of the steel frames.

The rapidly increasing cost of timber and the damaging effect of mine air which results in dry rot warrants the investigation of these frames in many localities. Practically all of the underground equipment has been changed to steel, including mine cars, which formerly contained much wood. Locomotives have replaced animal power, and there is no part of the mine operation into which steel does not enter to a greater or lesser extent, beginning with the tools with which the coal is brought down.

Steel is now used in the cars into which the coal is loaded, in the track over which it is hauled, in the steel rope by which it is hoisted, and in the surface buildings which are used for preparing it: and yet twenty years hence we will see more new uses for it than have been found in the last twenty years.

Fire Protection Above and Below Ground

By G. E. Lyman*

SYNOPSIS—A summary of the methods used in fireproofing mines. The Illinois laws relative to the fire menace are perhaps as strict as any, but the author believes that they do not cover all the precautions which should be taken.

The broad, humanitarian features involved in fire protection will alone make the question command the earnest attention of all, and the engineer realizes that every step taken in this direction is not only in keeping with the spirit of the day, but is a policy that pays well in dollars and cents.

If there is any line of effort in which the energies of the mining engineer should be especially centered, it may be said to lie in these directions:

1. The adoption of every possible means of preventing a fire getting started, both above and below.
2. The planning and installation of the best and most complete fire-fighting equipment possible to obtain, including every available provision for rescue and escape, so frequently needed in fires below.
3. The organization of a competent fire-fighting corps, whose discipline and efficiency shall be maintained by frequent practice.

The Fireproof Plant of the Ohio Valley Mining Co., West Frankfort, Ill.

The labors of our commission for the revision of the mining law have given Illinois some advanced legislation in this direction, making compulsory many preventive measures in new developments, and the installation of certain fire-fighting equipment in old mines. The con-

*Mining engineer, Madison Coal Corporation, Glen Carbon, Ill.

Note—Paper read on May 9, at the dedication of the Transportation Building and the Locomotive and Mining Laboratories of the University of Illinois, Urbana, Ill.

scientious engineer will recognize that no statute, however broad, can take care of every detail in widely differing conditions of operation, and after satisfying himself that the law is fully complied with, he will make a further careful study of the individual conditions to be met and endeavor to provide such additional safeguards as he can devise for the better protection of life and property.

Fireproofing at the Surface

One of the first things he would consider in planning the surface plant of a new development would be the design of fireproof structures throughout, making them of brick, masonry or reinforced concrete, with modern structural-steel tipples, making the floors of these, as well as the bin linings, concrete or some equally fireproof material, so that it would be well nigh impossible for a fire to occur on the surface.

as well as an independent gravity head, so that it may be thoroughly reliable.

In certain places like wooden fan houses and tipples, means of flooding the structures through automatic sprinklers, as well as perforated pipes handled by valves outside the buildings, may save great losses. The value of steel doors to cover the shafts in case of fire is too obvious to dwell on at length.

The practice of allowing waste and other such material to accumulate is extremely dangerous, and the time required in frequent inspections with the idea of eliminating this practice is well spent. The condition of the electrical wiring, above and below, and of the cables in the shafts, is important.

Fire Protection in the Mines

Within the mine itself much can be done toward preventing fires by the elimination of everything combus-

The Buckner Plant of the United Coal Mining Co. Is Completely Fireproof above Ground and a Model of Incombustibility Underground

The fan would be housed in such a manner as to have nothing inflammable about it, outside of the oil in the journals, and would be set back a sufficient distance from the shaft to eliminate chance of injury, even though the entire shaft lining should be burned out. The boiler and power houses should be fireproof throughout, so that they could be operated if every other part of the equipment is involved in a fire.

However thoroughly fireproof the plant might be considered, it would yet be the part of wisdom to install a water system with an ample number of fire plugs at convenient points in and about the buildings, with hose connected ready for instant use. Some of the most disastrous fires have been where the contents of fireproof buildings were consumed.

In handling an old plant, the need of the water system just mentioned is doubly apparent, and altogether too obvious to require comment. Regular fire drills and the actual use of the equipment at frequent intervals are essential to its maintenance in proper condition. If possible the system should be connected to a power pump,

tible as far as possible, especially around the bottom and in the stables, oil houses, etc. The replacing of heavy lagging and timbers near the bottom, and in permanent entries, with steel and concrete, will be a matter of economy in maintenance in a property of long life, which will justify the expenditure required entirely aside from its value in eliminating the chance of fires. Such work is required by the Illinois law in new mines, within a certain area near the bottom, but its application to a modern mine can be economically extended much further.

The fireproofing of the shafts is a wise requirement, and one entirely in keeping with modern development.

The fires which cause great loss of life below generally involve the fan house, tipple, shaft linings, stables, or other like critical points. Owing to their volume and fierceness, these fires poison the entire mine atmosphere so rapidly as to render it difficult to get the men out. Here is where the value of good fire-fighting equipment, backed up by organization and discipline, becomes apparent. The first few moments are vital and in ninety-nine times out of a hundred, an organized force,

not allowed to grow stale through lack of practice, can quickly extinguish a blaze at the start. In fires of this character the value of adequate and well maintained escapement ways becomes apparent, and they should be made familiar to the men by requiring them to travel frequently through them.

The writer is a firm believer in the value of perforated sprinkling pipes in the stables and other critical points. These are operated by outside valves and are installed in addition to the automatic sprinklers required by law.

The water supply for the underground system should be not only connected to a standing head on the surface as required by law, but also to the pumps on both surface and bottom, so as to provide for all possible emergencies.

Tipple of Chicago, Wilmington & Vermilion Coal Co., Five Miles Southeast of Christopher, Ill.

Fire in the Coal

Where the coal seam itself is of such a character as to fire easily, a special study of conditions will be necessary to determine the most practicable precautions to take, and the details of such special methods of shooting, caring for machine cuttings, gob, etc., as may be determined therefrom, must be most rigidly enforced by the management. Fires on the inside, such as gob fires, both local and extended, and fires of the seam itself, generally offer less danger to life than to property, although the dangers to be encountered by the limited number who attempt to control them are often of the gravest character.

Opinions as to the proper methods of attacking such fires differ widely, and their discussion cannot properly be attempted here, but as to the necessity of the best and most complete equipment for handling them, there is no room for argument. Every mine should have available in addition to the usual small chemical extinguishers, a couple of large capacity mounted on trucks, which can be rapidly taken to the scene of action.

Iron dump cars, to be used in loading out a fire and disposing of it in that way, form useful equipment, and during ordinary operation can be used to advantage in handling dirt and refuse from roads and air courses, so as not to be idle capacity.

When pipe lines run over the mine extensively, as in cases where long-distance pumping is done from many sumps, it is an easy matter to arrange the connections so that the pump pressure can be turned into the suction lines. The writer has seen this done to most excellent advantage, and is a firm believer in its desirability. In cases of sufficient emergency, even air transmission lines may be thus pressed into service.

Oxygen helmets will often enable explorations of a fire territory to be made that could not be attempted otherwise, and may even permit of taking lines of hose or chemical extinguishers to the very seat of the trouble. It becomes necessary, therefore, for any mine desiring the most adequate fire protection to have its own equipment of helmets, pumps, supply tanks and all accessories, including pulmotors and first-aid supplies. The time lost in getting one of the state rescue cars on the ground may allow the fire to make such headway that nothing but walling off the territory can be done.

The saving to a company in a single bad fire alone could easily pay for the cost of its own rescue station and helmet equipment, while a group of mines operated by individuals could divide the expense of a common station between them and make the burden very reasonable. Their object would not be to supplant the state rescue cars in any sense, but merely to take advantage of the first vital moments, and often by such action not only avert a serious calamity, but nip in the bud what might otherwise develop into a difficult and dangerous job for the state corps. Such individual stations would, of course, be in charge of competent men who had received thorough training at the state stations.

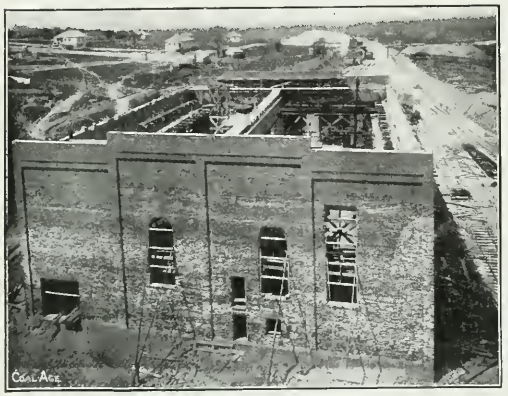
A frequent and often serious source of trouble in fighting large fires in the workings is the lack of accurate maps, and the consequent difficulty of determining the best way of walling off the territory affected. Only too often it happens that some unrecorded opening into the fire area supplies air sufficient to keep it alive, and at the same time is very difficult to locate. An accurate map would indicate at once the best way to wall off the fire and lose the least amount of territory thereby.

Where companies maintain their own engineering departments, this question of maps should, of course, give no trouble. But where it is the practice to have an outside surveyor extend the map annually to comply with the law, accuracy in details cannot be expected. Granted that the man doing the work is thoroughly competent, there will be portions of the mine inaccessible to survey. Accurate, detailed mapping requires frequent extensions, and the remedy for individual operation is for a few to

combine to secure the exclusive service of a competent engineer, and furnish him adequate help and facilities for handling their work in a manner commensurate with its importance.

Even where an adequate engineering department is maintained, and frequent map extensions made, places will frequently be found which cannot be entered for survey. The writer's experience has indicated that this situation can best be met by a system of monthly or semi-monthly reports, showing the length of every working place which has been closed since the last report was rendered, the number of cross-cuts right and left, and other pertinent information.

I do not allow these reports to be used in extending maps unless the engineers are unable to enter the place and measure it themselves. In such cases the desired information is obtained from the reports, and the place shown on the maps in dotted lines, thus differentiating it sharply from the work of the engineering department, and placing before the mine management a visible re-



THE LARGE FIREPROOF POWER HOUSE OF THE CHICAGO, WILMINGTON & VERMILION COAL CO.

minder of their responsibility for that portion of the map.

As the average number of places closed monthly in even a large mine is not great, it consumes little time to handle the report carefully, and the writer has found that it is possible to bring about a feeling of joint responsibility for this part of the work with the mine management which is helpful in many ways.

ISOLATING FIRES

There are few room-and-pillar mines which cannot be advantageously worked on the panel system, or some modification of it, which will permit the walling off of any fire territory with the least possible disturbance to the balance of the mine. The importance of having the maps show faithfully every connection between adjacent panels is obvious, and in the modern mining organization no departure in developing the mine should be permitted from the projections furnished to the mine manager for his guidance, unless the matter is properly considered and authorized by the main operating authority.

It is not uncommon to see a mine entirely, or nearly shut down on account of a fire which should ordinarily have been closely confined in its effects, and this is due to having the workings so cut up that isolation is difficult, and the ventilation hard to control. I believe that the main air courses in either direction from the shaft bottom out to the limits of the workings should be considered just as important as the shaft itself, and be just as carefully maintained. This, in connection with a powerful fan, will enable the circulation of a great volume of air at comparatively low velocity and pressure, which will permit a considerable increase in the number of splits, thus reducing the amount of territory affected by a fire in any one portion of the workings.

The maintenance of an abnormal amount of ventilation is not advocated, but the use of main air courses of more than ordinary capacity and excellence is strongly urged, so that the ventilation of the side entries can be treated as individual problems, as much air being diverted into each one from the main air courses—the arteries, so to speak, of the mine—as its individual requirements may demand.

With this method of ventilation established, there should be small necessity of ever sealing up more than one entire cross entry at the most. There are probably very few of us who have not known of instances where large mines were ventilated on two or three splits, and where a comparatively small fire caused the sealing off of perhaps half the workings.

❖

Illinois as a Coal Producer

BY A. J. MOORSHEAD*

It recently became my duty, on account of prospective legislation, to prepare statistics to show the coal tonnage produced in Illinois and the service it required from the railroads.

OUTPUT OF COAL IN ILLINOIS, 1912

For the year ending June 30, 1912, the coal mines of Illinois produced	57,514,240 tons
Of that amount, there was used for power and wasted at the mines	2,471,326 tons
Taken by railroad locomotives at mine chutes	924,854 tons
Sold to the local trade at mines	2,615,678 tons
Leaving a total to be shipped in cars	51,502,382 tons
Which, on the basis of 46 tons to the car, would require 1,120,000 cars to move the product.	

Such figures in these days, when we commonly reckon, nearly everything in millions, do not seem great or astonishing, but when we couple the 1,120,000 cars together and figure them as averaging 40 ft. in length, we have a string of loads approximately 8500 miles long, and that equals one-third of the circumference of the earth. Or, in order to describe further the length of that train of cars I might note that it would reach from New York to San Francisco and back, and there would still be enough loads left to reach from Omaha, Neb., to Chicago, Ill., and from there to New Orleans, La., via the Illinois Central R.R.

It will be furthermore interesting for you to learn that on the basis of 75 empty and 35 loaded cars to the train, carrying 40 tons each, it would require nearly 43,000 trains to market the production of the mines of Illinois for this one year only.

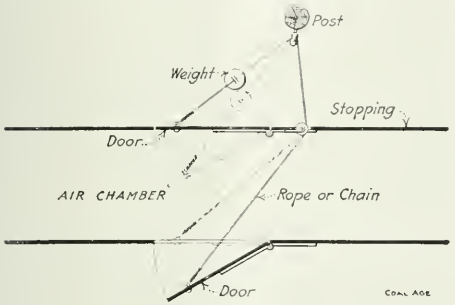
*President and general manager, Madison Coal Corporation.

Note—Preamble of an address delivered May 9, 1913, entitled "Organization as Affecting Mining," read at the dedication of the Transportation Building and the Locomotive and Mining Laboratories, University of Illinois, Urbana, Ill.

Keeping the Doors Closed

A novel method of keeping one door closed when the other is opened in an air chamber at the head of an exhaust shaft has been adopted at a mine in Roslyn, Wash.

Both of these doors, which are on opposite sides of the air chamber, swing on their hinges in the same direction. A chain or rope is fastened to the first door on the side opposite to the way in which it opens, passes around a pulley attached to a post, thence through a suitable opening in the stopping, and is attached to the second door at a point similar to its attachment to the first. Enough slack is left in the chain to allow either door to be fully opened when the other is closed.



Two Doors Closed by a Weight on a Rope or Chain

At a suitable point between the first door and the post, a weight is attached to the chain or rope. This is sufficiently heavy to pull both doors tight shut under ordinary circumstances.

The doors in question are near the fan at the top of the shaft on the return airway, which also serves as a manway. This arrangement prevents any careless person from short-circuiting the air, as only one door can be fully opened at a time.

Producing Inert Gas to Prevent Explosions

John Harger in his book on "Coal and the Prevention of Explosions and Fires in Mines," gives the following methods of producing the mixture of carbon dioxide and nitrogen whereby he proposes to make the mines free from explosions.

"An atmosphere with an abnormally low percentage of oxygen is readily produced by mixing ordinary air with the calculated amount of nitrogen and carbon dioxide, which mixture is easily obtained by the combustion of suitable fuel, but great care must be taken that it contains no carbon monoxide. The exhaust from a gas engine, with its exhaust apparatus suitably modified, will give excellent results, if the air supply is controlled and complete combustion attained. This can be assured by leading the hot gases over a catalytic surface.

"Using a 25-hp. gas engine, the exhaust gas was found to be so hot (1100° F.), that complete combustion was readily effected without the use of a strong catalyst. All that was necessary was to pass the hot gases, as they left the cylinder, over ordinary broken firebrick, which offers plenty of surface.

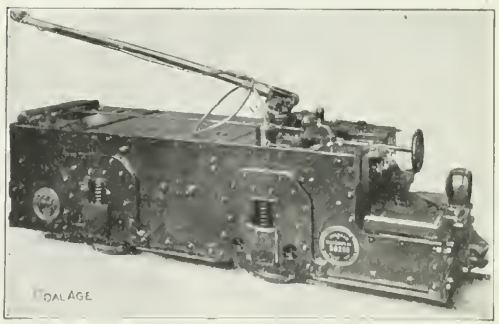
"But in many cases it would not be convenient to use such a source, and the products of combustion from a gas-fired or coal-dust-fired boiler would be preferred. The exhaust gases from these would certainly not be so hot as 1100° F., but, by the equilibriating device described below, complete combustion can be induced, without any excess of oxygen, carbon monoxide or other unburnt material being left in the gas. This device can also be used with the gases from an ordinary Lancashire boiler,* the gas being passed through the apparatus before the economizer is reached.

"The equilibriating apparatus (called an equilibriator) consists of an iron vessel divided into two parts; the front part is packed with ½x1-in. pieces of special bricks made of a mixture of clay and titaniferous bog-iron ore, or any other suitable catalyst, while the second part is packed with granulated copper or scrap copper wire. The bog-iron ore bricks have the property of causing combustible gas and oxygen to react at low temperatures, and by this means the last traces of gas are oxidized to carbon dioxide and water.

"Any carbon monoxide remaining is removed by the copper oxide, while if there is an excess of oxygen it is removed by the copper. To oxidize some of the copper a slight excess of air is introduced when the apparatus is started, but in normal working, when sufficient copper oxide has been once formed, only the exact amount of air required for complete combustion is allowed to enter."

An American Mine Locomotive in Japan

The accompanying illustration shows the construction of a Baldwin-Westinghouse electric mine locomotive at the mine of the Ishikari Coal Co. in Japan. This machine was designed for a track gage of 1 ft. 8 in., measures 8 ft. 9 in. in length, has a wheel base of 3 ft. 6 in., stands 3 ft. ½ in. above the track, has a total width of 2 ft. 11⅝ in. and weighs 6000 pounds.



General View of Locomotive

The frame of this locomotive is of plate steel. The drivers are 20 in. in diameter and are actuated by two motors hung inside the frame and wound for 500 volts. The machine is provided with sanders for all four of the wheels and two electric headlights. It is well designed, compact and well protected from dirt and dust.

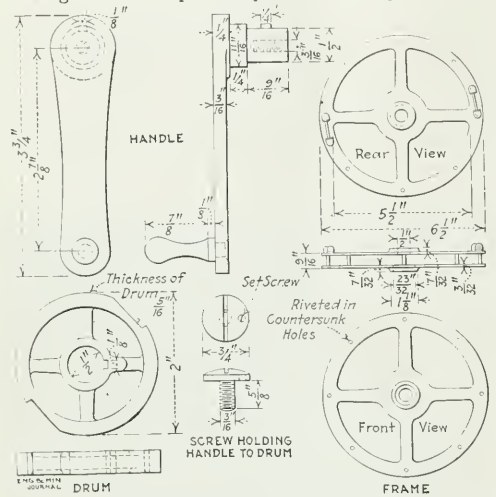
*A boiler with two large flues passing horizontally from front to back end. In these, combustion takes place. Probably any other boiler would serve as well.—Editor.

Reel for Underground Tape

By Charles H. Scheuer*

Experience with several varieties of tape reels in underground work led finally to the adoption of the Purdue model, manufactured by the Keuffel & Esser Co. It was found that considerable annoyance was experienced from the loosening of the screws, several of which entered into its construction.

To remedy this, certain improvements were described to the manufacturers and the reel shown in the detailed drawing was made up. The particular changes are: An



Reel for 100-Ft. Underground Tape

enlargement of the diameter so as to accommodate a muddy tape; the substitution of countersunk rivets for screws through the spreader washers between the two sections of the frame; the use of a countersunk riveted knob for the handle knob instead of a swiveled and screwed ring; and the fastening of the handle into the drum by a flat-headed screw, itself fastened by a setscrew. The result is a rigid and durable reel which can be taken apart as far as necessary by loosening the setscrew, removing the flat-headed screw and so releasing the handle from the drum. For a 200-ft. tape, the diameter should be increased to 7½ in. in the clear.

The Burning of Coal at Outcrops

The "Report on the Coal of Grand Mesa and West Elk Mountains, Colorado," published by the U. S. Geological Survey states that:

"The coals of Grand Mesa are burned along the outcrop in many places. Indeed where the rocks are well exposed, it is difficult to find coal at the surface. In place of it the rocks are reddened by the heat from the burning coal, and in some places they have been melted and form 'clinker.' Where the coal is protected at the outcrop by a covering of soil or slide rock, it has taken fire in fewer places.

"In the Palisades and Rollins districts, where the coals are low-grade sub-bituminous, the burning in the exposed slopes has been general. Farther east, where the coals have been hardened by the metamorphic influences of the igneous mountains, burned areas are rarely found. Because of their exposure to the hot sun, the southward-facing slopes about Grand Mesa become dry and do not support enough vegetation to hold the soil in place. The rocks consequently have become exposed, and the coal is generally burned along the outcrop.

"The northward-facing slopes are not parched so quickly by the sun and are more completely clothed with brush, the roots of which hold the soil, and this in turn protects the underlying rocks. On these slopes the coal has not been burned so generally as it has been on the southward-facing slopes.

"The belief is general that the fires were started by the spontaneous ignition of the coal. There seems to be proof that fires have been started in some coal fields in this way, and there is good evidence that some mines have taken fire in the same manner, but apparently the theory of spontaneous ignition of the coal has been too generally accepted.

"Careful observations were made in this field for evidence bearing on this question, and although coal was found in all stages of weathering, ranging from freshly exposed faces to beds of slacked coal that must have been exposed for many years, not a single place was found where the coal at a natural exposure showed any indication of heating.

"It is a well known fact that dampness favors spontaneous ignition, yet in the Grand Mesa field the coal in the southward-facing slopes, which are dry, is burned much more generally than that in the damp slopes which face northwards. The coals of the dry, exposed sidehills would be ignited by forest fires much more readily than those of the damp, soil-protected slopes, and in the writer's opinion the burning of the coal in Grand Mesa is more due to forest fires than to spontaneous ignition.

Summer Meeting of Rocky Mountain Coal Mining Institute

At a meeting of the Executive Board, held in Denver on Apr. 15, it was decided to hold the next meeting of the Rocky Mountain Coal Mining Institute in Salt Lake City. A special train, consisting of a baggage coach, dining car and Pullmans, will leave Denver at 9 p.m., June 9, arriving at Rock Springs the following morning, where the day will be spent in viewing the most important properties in this location, arriving in Salt Lake City early on the morning of the eleventh..

The Institute will convene at 10 o'clock on the morning of June 11 and hold a session for the balance of the morning. The afternoon will be devoted to a trip to the Bingham copper properties, probably the most interesting in the world. The morning of the twelfth will be devoted to Institute business, reading of papers, etc., and in the afternoon a visit to Salt Air will be made, where the rest of the day will be spent. The thirteenth will be devoted to any Institute business which may remain incomplete, to auto rides about Salt Lake City, and to a grand concert in the Tabernacle.

Note—From the "Engineering and Mining Journal," Apr. 26.
*Chief engineer, Fayal district, Oliver Iron Mining Co., Eveleth, Minn.

As at present arranged, the party will leave Salt Lake City on the return journey, by way of the Denver & Rio Grande R.R., some time during the night of the thirteenth, and will stop over at one or more important coal properties on the way back. It is proposed also to spend three or four hours in Glenwood Springs, to give the members an opportunity to indulge in bathing in one of the finest pools in the West. From this point there will be a daylight ride through the Grand River Cañon and the Grand Cañon of the Eagle River, so that the beauties of this wonderful portion of the state may be seen by those who have not yet had the opportunity of traveling over the line in daylight.

The railroad fares for the round trip will be as follows: From Trinidad, $26.15; from Walsenburg, $24.75; from Florence and Cañon City, $24.50; from Pueblo, Colorado Springs and Denver, $22.50. The Pullman charge for the entire time will be $9.10.

Please remember that the special train will be made up in Denver and will not leave until No. 3 of the Colorado & Southern arrives. Any member living in Wyoming may make arrangements to join the party when the train reaches his station.

Members returning may alight from the special train at Pueblo, Cañon City, or any point most convenient for making connections with their homes.

Several interesting papers will be presented at the convention and a good time is promised to all.

The Institute will furnish an official badge for all members and friends in attendance, and each person is urged to bring his family or any friends who he thinks would be interested in making the trip or in the proceedings of the convention.

In order that the Institute officers may make arrangements for the train, it is urgent that each member signify immediately whether or not he will be able to become one of the party. Let everyone make arrangements to attend.

E. H. Weitzel,
President.

F. W. Whiteside,
Secretary.

Miners Plan to Organize a W. Va. Field

SYNOPSIS—At a meeting of delegates in Charleston it was decided to organize a new district of the United Mine Workers of America. This will include the New River, Gauley and Winding Gulf coal fields in West Virginia.

One hundred and seventy-five members of the United Mine Workers of America, representing practically the whole of the New River, Gauley and Winding Gulf coal fields of West Virginia met in convention in Charleston, on May 10, for the purpose of forming a new district of the miners' organization.

As originally intended, the meeting was to be in the nature of a conference between the delegates and the operators. There was, however, no response when the chair asked for expressions from operators present. Vice-President Hayes then informed the delegates that, in carrying out the promise of coöperation from the national organization, the International Board had decided to form a new district in West Virginia.

The morning session, on Saturday, was addressed, in turn, by National Vice-President, Frank J. Hayes, who called the meeting to order, by District President Thomas Cairnes and International Board Member Thomas Haggerty, who had just returned from the International Board meeting at Indianapolis. National President John P. White also spoke for over an hour.

The afternoon session was addressed by Senator Wm. Green, of Ohio, who is a member of the United Mine Workers, and the International statistician of the organization, and, finally, the convention listened to an address by Governor Hatfield.

President White, in his talk, viewed the history of the organization and set forth its ideals. He spoke at length of what is expected of the future in West Virginia and pledged himself to do all in his power to assist in the work which has been so well begun.

Senator Green's address was one in which great emphasis was placed upon the benefits of organization, and, incidentally, upon the struggles that precede every achievement tending toward the welfare of humanity.

Governor Hatfield paid a fitting tribute to the men who toil—in mine, mill and shop. He wished the delegates a pleasant day in the city and assured them, unequivocally, that they had nothing to fear from him as governor of the state. "I exact but one thing," he said, "and that is respect for the law. The miners stand as high in my estimation as the mine owner. Show me and I will be your protector."

He referred, briefly, to the settlement of the Paint Creek and Cabin Creek strikes and of his part in bringing about their settlement.

"I do not question your right to organize," he said, "the physicians, lawyers and the mine owners organize, and why should I question your right to the same privilege. I am your governor, and I prefer to be the laboring man's governor to any other man's governor, and all that I ask of you, as your governor, is regard for the legislative enactments of this state and due respect to your God. Do not regard me as an oppressor. Demand your rights as men but do it in a legitimate way, and you will have me as your governor, to protect you in securing those rights.

"Do not take the law into your own hands. If you suffer from the oppressions of a stronger hand, appeal to the law. I know it has been said that the law is controlled by a certain class; but before God I tell you the interests do not control me.

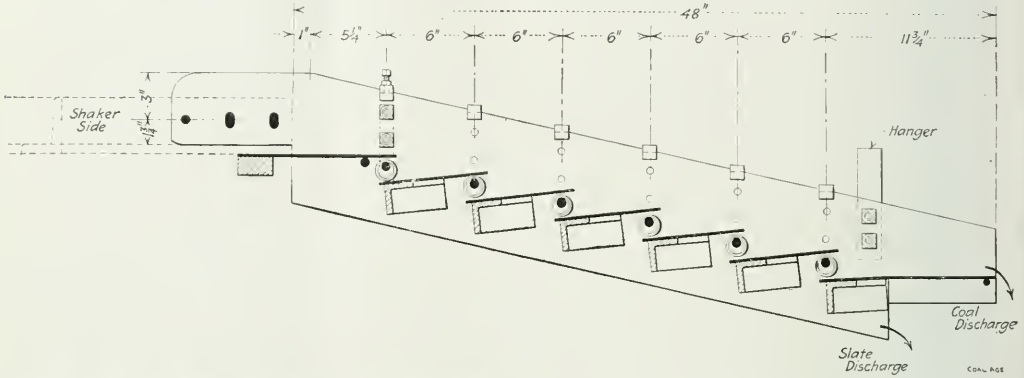
"Go about your work deliberately, lawfully, manfully. Demand your rights and you will achieve the victory. About the guard system, there is no necessity for guards in West Virginia or in any other state. The mine guard law is about to go into effect, and I promise you that I will see that the statute is absolutely and strictly adhered to and enforced.

"In conclusion, go about your deliberations like men. Do not put yourselves in the position of lawbreakers. Do the right. And, if a strike is necessary, and you act like men, you will have my protection."

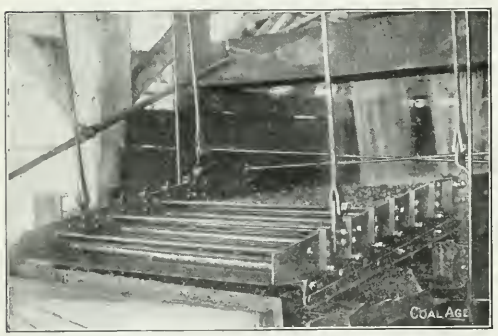
An Effective Slate Picker

The accompanying photograph shows a Mason & Allen flat slate picker in operation in a washery of the Hudson Coal Co. handling material containing 20 to 32 per cent. flat slate and throwing out 18 to 21 per cent. in the process. Tests of the droppings have never exceeded 3 per cent. coal and have been as low as 1 per cent.

The D. L. & W. R.R. is using these pickers on chestnut, pea and buckwheat coal. The machine is so constructed as to be attached readily to any standard coal shaker by means of bolts and suspension rods and is designed to separate flat slate and rock from the coal, as it passes from the shaker.



Cross-section of Picker, Showing Shelves or Steps and the Eccentric or Swinging Cylinders



The Picker at Work

This is accomplished by a series of horizontal plates rigidly fastened in a transverse position between the side plates in step fashion, so arranged as to permit a swinging cylinder, eccentrically pivoted to the side plates by means of adjustable boxes, to hang parallel with and under the front edge of each plate with an opening or space between the bottom of the cylinder and the plate below it.

This arrangement allows the flat slate and rock to pass back through the opening while the coal passes on over the plates to the chute. The cylinders swing automatically with the movement of the shaker and are controlled in the swinging movement by weighting.

The action of the machine is quick and effective, making the limit to its capacity difficult to estimate.

The simplicity of this device appeals to all coal experts. It is built to stand the severest usage, and is provided with adjustments to meet all conditions.

⁂

Rules of Thumb for Metric Conversion

Certain approximate relations between common metric units of measurement and their English equivalents exist. Albert A. Cary presents these in *Power*, Feb. 18, 1913, in the form of the following handy table:

Dimensions etc.	Unit Used	Converted to	Rule
Weight	Kilogram	Pounds	Multiply by 2 then add 10 per cent.
Length	Meter	Feet	Add 10 per cent. then multiply by 3
Surface	Square meter	Square feet	Add two 10 per cents, then multiply by 9
Volume	Cubic meter	Cubic feet	Add three 10 per cents, then multiply by 27
Capacity	Liter	Quarts	Add one-half of 10 per cent. (or 5 per cent.)
Temperature	Centigrade	Fahrenheit	Multiply by 2; subtract 10 per cent., then add 32
Heat	Calories per kilogram	B.t.u. per pound	Multiply by 2, then subtract 10 per cent.
Heat	B.t.u per pound	Calories per kilogram	Multiply by 0.556 (or divide by 6 and then by 3)
Pressure	Kilograms per square centimeter	Pounds per square inch	Multiply by 14.223 or divide by 0.07
Pressure	Pounds per square inch	Kilograms per square centimeter	Multiply by 0.07
Evaporation	Kilograms per square meter	Pounds per square foot	Divide by 5
Evaporation	Pounds per square foot	Kilograms per square meter	Multiply by 5
Distance	Kilometers	Miles	Multiply by 0.6 and add 5 per cent. of the product
Distance	Miles	Kilometers	Multiply by 1.6
Capacity	Cubic centimeters	Cubic inches	Divide by 16 (or by 4 twice)
Capacity	Cubic inches	Cubic centimeters	Multiply by 16

The rules are so simple as to be easily carried in the head, but for accurate results more complicated factors must be employed.

⁂

Substation Loads in Lackawanna Collieries

On page 713, issue of May 10, the table of Connected-Load Factor at Substations, states that the per cent. for the largest station is 32 and the per cent. for the average station is 29. These figures should be reversed. The other figures, which all show an opposite tendency, are correct.

EDITORIALS

Gasoline-Locomotive Costs

The cost of operation of the gasoline mining locomotive varies considerably with the conditions under which the machine is called upon to operate. The price of fuel and supplies, the wages of the driver and brakeman, the condition of the track, the grades to be traversed and the loads handled, all have a direct influence upon the cost per ton-mile.

With these locomotives, as with other machinery, it is but natural to expect that the cost would decrease as the amount of work done increases, and that the best results would be obtained when the locomotive is operated up to its capacity all of the time. Recent experiments in Europe appear to substantiate this idea.

The Geyser at Equality

The phenomenon at the Gallatin Coal Co.'s mine has occasioned general interest and it is differently termed by everyone according to his belief in what constituted the originating cause.

The author of the article we published last week accepts the more usual interpretation of the forcible ejection of water at Equality. The view is that taken by F. Rosbottom, the inspector of the district in which the mine is located and by several others. He regards the emission of water as resulting from the compression of the pent-up air. This action, however, would not have been violent. The air would have slowly pushed out the water, as soon as the surging flood had lost the velocity head with which it entered the mine.

If, however, a large and seemingly impossible body of air had escaped and filled the shaft for almost its full length, the downward weight of the shaft content would have been almost nil and the upward pressure would have been large. If there were another point of entry from the surface containing all water and no air, the pressure would be that of a body of water 80 ft. deep and this upward pressure would be exerted on what little water might be over the top of the shaft, which was full of air. Under those circumstances the water would have been lifted 80 ft. in the air if all resistance to its motion were removed.

Had the whole main entry and shaft become filled with escaping air, a still more unlikely supposition, the water might have belched out to a height of 120 ft. This gives the maximum elevation which the air-lift theory would permit us to expect.

The witnesses declare this elevation was exceeded. Whether their view is justified is questionable because there were few objects high enough by which momentarily to measure such extreme elevations in that flat country. The height of the second effluent column was probably estimated with more accuracy and the estimate was accordingly lower, namely, 260 ft., and even that hardly accords with the illustration we show.

Some have thought that an explosion took place, the water driving the air in old chambers on to a light left burning in some part of the mine. While the author of the article does not say whether gas is found in the workings, he does give a strong impression that the danger of flooding had caused the complete abandonment of the mine for such a length of time that there could not have been any light burning. The inspector says there was no mine fire in the workings. Hence there does not seem a leg on which this theory can stand, though unlikely solutions are permissible where there is so much uncertainty.

Another solution remains. The mine had never caved; the pressure of the water in the measures when the surface was submerged may have weakened the roof, causing it to fall later. Had the overburden to the grass roots descended slowly in the lowest part of the workings, the water might have been thrown up to a height of about 324 ft. If the roof fell where a certain amount of free fall was possible, the effect of its energy of descent would have been to make an even more violent effluence.

The mine is ruined and closed and it may be months before it is opened. Meantime the roof may fall and changes take place. The problem of the aqueous outburst may continue to be as mysterious as the violent projection of water from the West Kentucky Coal Co.'s shaft in the same section of the United States.

The Crescent, a small shipping mine, and the Sunnyside and Clover, which produce coal for local consumption were also flooded but were otherwise undamaged. No such geyser-like ejections, however, took place at these mines

Appointment Not Confirmed

The recent appointment of John Mitchell, former president of the United Mine Workers of America, by Governor Sulzer, to be the head of the state Department of Labor, in New York, marks the earnest desire of the governor to reorganize this department. A better man for the position could not have been selected than John Mitchell, who is universally conceded to be better qualified to fill this important office than any other person in the country. The fact that Mr. Mitchell has only recently removed his residence to New York State forms no adequate excuse for the rejection of his appointment by the Senate.

When that body refused to confirm the appointment of Governor Sulzer, in this instance, it placed itself in a position to antagonize the strong labor vote of the state. Mr. Mitchell has few enemies and many friends, not only among the labor classes, but among the large majority of thoughtful people, regardless of politics.

Governor Sulzer's appointment, in this case, met the general approval of the people of the state, who are well pleased with his determination not to abandon the hope of having the appointment of Mr. Mitchell eventually confirmed, at a special session of the legislature to be called June 18.

To say that we heartily indorse the appointment of John Mitchell as the head of the Department of Labor, in

New York State, would be to express mildly our appreciation of the work done by this man. Perhaps no one has ever handled more successfully than Mr. Mitchell the aggravated conditions that have existed, from time to time, between the mine workers and mine operators. No one has won so high a degree of the confidence and esteem of all classes, as this advocate of equal rights and justice.

Whatever mistake Mr. Mitchell may have made that led to the disregard, by the organization of which he was president, of a judicial mandate, it is still a matter of deep regret that recently the Court of Appeals of the District of Columbia has refused to reverse the decision of the lower court, by which Mr. Mitchell was declared in contempt. A further appeal to the United States Supreme Court is contemplated; and, although, from the nature of the case, little hope can be entertained as to the result, it can hardly be expected but that final sentence will be suspended. By this means, not only would the majesty of the law be upheld, but due respect would be paid to one whose tireless efforts have always been at the service of his fellow workers.

The Miners' Union

Unions seem necessary evils like armies, for the workman needs to defend himself as much as the nation. But against whom is his defense mostly directed?

Ostensibly every strike is a quarrel between employer and employee. Practically it is a battle between workingmen. Other operatives having received an increase in wage, the miner finds everything which he has to buy increased in price. So he strikes to make his employer charge those operatives an increased price for coal. It is a continuous struggle for life and comforts between man and man. The operator is only the go-between, the much berated middleman.

The necessity for the union might be removed if the operator would adopt a sliding scale, based on the right of the laboring man to buy so much of the other man's labor for so much of his own. Let the operators and miners form a bureau of experts to ascertain the articles purchased by miners and the amount of each type of purchase. Then let the board ascertain as nearly as possible the labor involved in the production of such articles under present-day methods of manufacture. The result would show how many hours of other men's labor were equivalent to the year's work of the miner.

This figure should be kept constant year by year, the miner's power of purchase increasing with the increased output due to improved methods of operation. The result might not be exact. There are some factors too hard to weigh with precision, but any solution seems preferable to annual or at least frequent strikes which, like wars, destroy more than they create.

The method of calculation advocated is at least as scientific as the method of hunger-strike and violence, which is a purely arbitrary attempt to adjust matters. Though our courts are not perfect, no one suggests a return to the trial by ordeal and though a bureau might be wrong in some of its conclusions, the labor struggle is still more unscientific and does not recognize the point at issue.

In fact, the strike often terminates in the defeat of one party because in the past that party has been most unjustly treated, because the laboring man has been deprived of the power of saving, or the operator prevented from securing a bank account.

It is time that it was clearly understood that any rise in wage of one class of employees must be taken out of the pockets of other operatives. There can be no federation of labor; there can only be a truce between workingmen, an arbitration of the wage war between them and the plenitude which results from the blessings of industrial peace.

Crazy Legislation

That an undue and unwise influence is being exerted by the prime movers in the United Mine Workers Organization to control legislation in Pennsylvania and force the passage of certain bills at the present session of the legislature, has been evidenced in a number of instances, by the acts of the Lower House. In no case, however, has this been made more clear than by the passage, Apr. 29, of the bill, House File, No. 1219, presented by Mr. Lenker, of Dauphin County.

The bill is an act to amend Section 7, of the act approved May 3, 1909. By this bill, which has just passed the House, the number of mine inspectors in the anthracite region of the state would be increased from 21 to 31, or nearly 50 per cent., and represent an increase of $30,000 in the annual cost of inspection of these mines. There is no question but that the number of inspectors should be increased in that district. The Anthracite Code Commission in their report recommended an increase of four inspectors for the anthracite mines, which, in their judgment, would be sufficient to meet the present needs.

It will be remembered that only recently the House passed the Schaeffer bill by a vote of 157 to 0. This bill emanates from the same source—the Mine Workers Organization—and makes all holders of mine-foreman certificates eligible to candidacy for the position of mine inspector, without further examination. The Mine Workers made an unsuccessful attempt to have this provision adopted by the Mine Code Commission, and are now endeavoring to force its passage in the legislature. It is amazing that Pennsylvania legislators would lend an attentive ear to these appeals, coming as they do from an unauthoritative source, while the recommendations of the regularly authorized Code Commission are allowed to languish.

Fires at Coal Outcrops

We quote today a statement of the Geological Survey relative to the crop fires in the Grand Mesa. The Survey follows the popular idea that water normally aids coal to burn. There is little probability that coal containing all the moisture natural to it is likely to be caused to burn spontaneously by the addition of water. The heat of hydration cannot take place without previous dessication.

On those faces of the hills where the coal is likely to be deprived of much of its natural moisture, we would naturally expect the coal to fire on being wetted if hydration is ever sufficient to account for the ignition of coal. It is in such dry and exposed places that the Survey has found the most frequent ignition and while it may be reasonably ascribed to forest fires, the cause may be due to hydration of the dried coal, despite the reasoning of the monographer.

SOCIOLOGICAL DEPARTMENT

The First-Aid Muddle

By a Physician

SYNOPSIS—The author believes that first aid should be standardized. Variation of methods confuses and disgusts the trained men. The advisory board of the American Mine Safety Association is not well chosen and the schedule of discounts recommended at last year's conference is amusing but worthless.

::

To anyone who has had much experience in first-aid work in this country, it is quite evident that something is radically wrong with the system of instruction. In studying the reports of the work already accomplished, the investigator discovers a deplorable condition of affairs, though the first glance seems to show that rapid strides are being made in the education of the men employed in hazardous occupations.

The inquirer finds that first aid is being taught in the United States by many different organizations, chief among which are the American National Red Cross, the Bureau of Mines, the Young Men's Christian Association, the many separate first-aid organizations and the various companies which have instituted the work independently. These bodies are not working in harmony. Their instructors are teaching different methods of treatment and are recommending the use of different appliances. From a purely local viewpoint, this may not seem important. To those of us who hope soon to have as efficient a first-aid organization in this country as the St. John's Ambulance Corps is in England, it is a cause of much alarm.

Variation in Training Methods

Those present at the National Mine Safety and First-Aid Exhibition, at Pittsburgh, in the summer of 1911, were struck by the many different methods by which the same injuries were treated. Teams from different companies used wholly unlike methods in dealing with their problems. This had a bad effect upon the members of the various corps. They had come to the meet representing all the teams in their section and believing that they had been trained in the best methods. They found that there were many ways of treating the same injuries and there was no way for them to discover which were best. Returning home, they reported their discovery to the other teams in that locality and each organization demanded that their instructor teach them the best methods.

Their physician found in turn that there was no way in which he could discover the best treatments and to retain the respect of his class, he was forced to teach several methods of treating the same injury. This, of course, resulted in making still more difficult a subject already too complicated for the untrained mind. As a result, many organizations disbanded and countless men discontinued the work because it was too hard. This is wrong. First aid can be made more simple and must be so rendered before we can hope to derive the benefits which it offers.

That there should be a uniform system taught is evident. What that system should be is not so clear. While it is true that there is one best way of dealing with any injury, the fact is that no one absolutely knows what that best way is. Many men think they know but they can have no legitimate assurance.

The Defects of the Conference on First Aid

Recognizing this condition, the U. S. Bureau of Mines called a conference on first aid to meet in Pittsburgh, Penn., on Sept. 25, 1912, for the purpose of standardizing the subject. The report of this conference was eagerly awaited, as it was hoped that some questions of moment would be decided. When the report was received, it was found to be merely an expression of opinion of a body of men, few of whom were known. No experiments had been performed, no opinions of men eminent in the medical profession had been secured but a lot of resolutions had been passed for our guidance, for none of which any reasons were given.

At this conference the American Mine Safety Association was formed and the recommendations that an Advisory Board be appointed to have the power to accept or reject any dressings that may be offered, was adopted. This board is to consist of two first-aid men, two operators, two physicians and a representative of the Bureau of Mines. Why operators and engineers should have a place on a board whose proceedings to be of any value must be surgically scientific, was not explained. We are sure that no surgeon would desire a place on a board, the work of which was purely engineering in character.

Some Strange Decisions

A glance at the report of this meeting will show why it has been and will be totally disregarded. The recommendation that the Sylvester method of artificial respiration be adopted was followed in a few weeks by a report of a commission of scientists of national reputation, in which the Schaeffer method was declared to be the best. As this report was substantiated by the records of many experiments, it must be believed.

The schedule of discounts, presented by the conference and intended to apply to all contests, is amusing but worthless. In it contestants are penalized ten points for failure to be aseptic in the treatment of a wound, probably already infected, when the results of such failure, in the average case, would but slightly inconvenience the patient. The team is penalized but two points for failure to perform artificial respiration properly, when upon the correct administration of this, the patient's life absolutely depends. The fact that a contestant is penalized the same two points for lack of neatness and for tying a "granny knot" adds to the humor, but not to the value, of the report.

The American Mine Safety Association announces in its circulars that in the future it "will fix the standards in rendering first-aid-to-the-injured and set the standards for the construction and use of devices and appliances

for first-aid work." Before it can do this, it must show itself to be worthy of the honor. Such proceedings as are on record from its first meeting certainly do not prove that it should be accorded so much authority.

The Need for an Authoritative Council

First aid must be standardized by a board of men of national reputation; conservative, scientific men who will prove which methods are best and recommend only the methods thus proven. These methods, supported by the records of experiments and the testimony of eminent surgeons, will be received with respect by the medical profession and will be taught as the best by them. In this way, the first-aid movement will gain the respect of the medical men, upon whom its success absolutely depends, and the methods thus proven will be taught as best by all men.

Following such standardization, let a committee of first-aid men so grade the work that all classes will be taught by the same system. The first course should consist of the best methods; in the following courses the best of the alternate methods may be taught. Let all the organizations now teaching first aid coöperate so that no effort may be wasted and no ground covered twice. Then and only then can we hope to see first aid take its rightful place and expect to reap the full benefits of the system.

⁂

Pollution of Water by Mines

By a Pennsylvania Engineer

Among the new troubles of the operators and engineers of coal mines is to find streams in which to discharge the water from the mines without injury to the public. It is generally believed that the mines and coke plants injure farms to a certain extent and kill the fish. Where the waters formerly were clear as crystal, they are now yellowish brown with iron hydrate and made acid by the hydric sulphate formed in the mines.

Vegetation is killed by the dense smoke coming from the ovens, and as a whole the villages near coke works are not a desirable place in which to live. But these mines and coke plants are as necessary to the country as a boiler to a battleship. When these industries are closed down, the country cannot thrive. They are, themselves, the occasion and support of the very people and industries which object to their presence.

Pollution of Streams Illegal

A decision has been handed down in the Westmoreland courts forbidding coal-mining companies from polluting domestic water supplies by draining their "sulphur" water therein. James McCune contended that the Pittsburgh & Baltimore Coal Co. by draining the sulphur water from its mines into a stream of water, passing through his farm, which, prior to 1908 had been pure and suitable for agricultural purposes, had made the water of the stream unfit for use. Judge Doty decided against the coal company, and in doing so said: "It is clear that the defendant has no right to pollute the stream which flows through the plaintiff's farm; and being without right in the matter, the company must cease within a reasonable time to discharge the water of its mine into the said stream." Six months was suggested as a reasonable time.

The fact that the coal company owned the coal underneath the McCune farm did not, in the opinion of the court, give it any right to pollute the water supply of the surface owners. It is clear that the company must, at great expense, pipe this water through such farms.

An Injunction Granted, Forbidding Pollution

Several weeks ago the operators who desired to open mines along Indian Creek were stopped from further development by the Pennsylvania R.R., an injunction to prevent the pollution of the streams being obtained.

The Pennsylvania railroad corporation, through its subsidiary, the Mountain Water Supply Co., secured an injunction to prevent the pollution of Indian Creek in the Monongahela watershed. This stream is the source of the water used in filling the tanks of the locomotives in that section.

Some years ago the railroad company, finding that it could not get clear water to supply its engines in Pittsburgh territory, purchased rights along the Indian Creek valley and constructed a large dam. Over $15,000,000 was expended in providing for a pure-water supply, and the water was piped to the Union station in Pittsburgh and to other points in that section.

Indian Creek is now and was at that time the largest unpolluted stream in western Pennsylvania, as the coal mines and mills on the banks of nearly all the other streams had destroyed their purity by discharging large bodies of polluted water into them. Consequently the fish were destroyed and in the large streams they are almost if not quite extinct.

Along Indian Creek there are about 75,000 acres of undeveloped coal lands. The moneyed interests controlling these lands had been making tentative plans for the opening of this potential source of fuel. News of this reached the railroad company, and, as a matter of self-protection, steps were taken to preserve the purity of the streams, for if they were polluted by the coal mines, the huge investment made by the company would become worthless.

⁂

A Model Coal Town

Contractors broke ground yesterday for a model village which is to be built for the Pennsylvania Coal Co., around the Underwood shaft now being sunk on the hills east of Throop. The village is to consist of 28 double frame houses which will be of unusually strong construction so that they may be able to withstand the settling of the mine, as the coal is removed. The houses will measure 28x40 ft.; their sills or under frames will consist of single sticks of Georgia pine 6 in. square. These will extend the full length and breadth of the houses. Several frame dwellings are also to be erected for the colliery foremen and their families.

The model village is to be plotted out in wide streets with roomy garden plots for all the houses. It will have a central plaza and part of its equipment will be two public concrete bathhouses, one for men and the other for women. Hower & Stender, contractors of Scranton, are in charge of the construction work.

The Underwood colliery is to be one of the most modern in the anthracite region. It will open up big tracts of hitherto untouched coal and will give employment to a large population for many years. It is expected that the colliery will be ready for operation in a few months.

DISCUSSION BY READERS

Education in Coal Mining

Letter No. 15—In my opinion, the use of textbooks at examinations would be a backward step. The examination of mine officials has reached a high degree of perfection in most cases where this system has been adopted. I have no desire to detract in any way from the glory of the old-time practical mine foreman. I have the greatest respect for the man who has gotten his education from the point of the pick and the ring of the shovel. These practical, hard-working fellows are surely the best men in our mines; but the mining game, like all things else, is progressive and the uneducated man who was foreman or manager in the mines a generation ago will not answer now.

I attribute this change largely to the fact that our examinations are getting more difficult each year, and they are providing more alert and better educated men to fill the positions of foreman, assistant foreman and fireboss. To uphold this standard in examinations and to advance it, if possible, let us do nothing to make the examination easier. Give a fairly well educated man a textbook in examination on mining, today, and he will pass that examination with flying colors and, perhaps, never have seen the inside of a mine. For example, give a candidate the textbook, Examination Questions and Answers, for use in the examination, and it will supply him all the information he needs to pass this part of the examination. Then, if he can show that he has had the necessary experience and has the required knowledge of the mining law, there need be no fear but that he will pass the examination.

Some writers claim, in advocating the use of textbooks at examinations, that many of the formulas are complicated and hard to remember. I have passed the examination several times, in Pennsylvania, and each year it seems to me that the desire of the examiners is to get away from complicated formulas and advanced theories, as far as is compatible with securing men who can run a mine in a scientific and uptodate manner. Permit me to add that most of the men now managing our uptodate collieries are largely those who have passed the examination without books. They had to study and study hard to remember the laws, principles of ventilataion, haulage, methods of working, etc. The result is that a man who remembers such data keeps uptodate and is proud when the inspector who made him pass the examination without the books, visits his mine.

The examinations for mine foreman and fireboss certificates, in Pennsylvania, are reasonable and fair. All questions asked are questions that relate specifically to the regular work these men must do in and about the mine, or refer to such work as may have to be done at any time.

I cannot understand how it is expected to make an efficient mine foreman out of a man, who, when an unusual condition arises in the mine that demands immediate attention, must rush to his library to look up the needed information. I believe a man should have this knowledge at his fingers' ends and understand the principles of mining, so that he can give an intelligent answer to every question liable to occur in daily work, without consulting a library or textbook.

Although many men went to work in the mine when they should have been in about the fourth room at school, there is practically little excuse today for their not being able to pass a rigid examination, because of the numerous correspondence schools, night classes, libraries and other facilities for learning open to them. I do not wish to convey the impression that, in my opinion, the best educated men are the best mine officials, as I have known many such men to make failures as mine foremen.

Some time since, I was on a train approaching Washington. The train stopped at the yards, some miles out from the city, for a second engine, when a fellow passenger inquired why they did so. The reply was: "Well, I'll tell you; it takes a mighty good pull to get into Washington." Many of us have the same view with regard to securing a position of responsibility in the mine. They think that if they can get a "pull" somewhere, they can have any position they want. I am glad to say the time when that is possible is fast going by. Mining companies today realize that efficiency rather than favor is what they require, and we must regard it in the same manner. Lawyers, doctors and men of other professions, study constantly to improve their minds and keep uptodate, and mining men must do the same or be relegated to the scrap heap. Let us make every effort possible to elevate the standard of mining; let us get the textbooks into our minds instead of taking them into the examining room.

SAMUEL M. McMAHON, Supt.
West Virginia-Pittsburgh Coal Co.
Wellsburg, W. Va.

Letter No. 16—The question of educating the miner is one that needs and should be given more than a passing thought. The nature of his occupation; the duties that are required of him; the responsibilities that rest upon him in his relations to his fellow workman; these are some of the things in which he should be educated. No man who works in the mines works to himself alone. The safety of other workers depends on his ability and knowledge, which fact requires that he should be well informed in respect to his duties to his fellow workers and to himself.

In my opinion, the one question of educating the miner has not been given the consideration and attention, in the previous letters, that it should have had. The writers have dwelt more upon the education of mine foremen and firebosses. It is of equal importance to consider the question of educating the miner in respect to his duties in mining coal. The miner, today, is not the same as the miner twenty years ago. At that time, the English-speaking miner was the most prominent, while

now the majority of our miners speak a foreign language and in a large measure are ignorant of many of the conditions that govern the mining of coal. They need to be educated in more ways than one.

Many miners, today, are unable to read or write their own names and cannot make up the time sheet that they are required to turn in to the colliery office. They cannot write a danger signal or the word "dump" on a car, if need be. It is important that all mine workers should have some knowledge of reading, writing and arithmetic.

While the efforts put forth to educate the foreign-speaking miner have met with a measure of success, a very small number of these men are being reached. Greater efforts should be made to make them more efficient in their work. They should be properly instructed in respect to the best and safest methods of mining coal and made more familiar with the nature of the explosives they use and the proper handling of the same. It is true that powder companies give rules for the use and handling of powder; but, as most of the miners cannot read the English or any other language, they cannot understand, except as they are told by some other person. They should be made to know what they are handling and how to handle it with safety to themselves and others. They should be properly instructed as to the nature of the roof and other conditions about them. They should be taught how to properly timber their place, and be made acquainted with certain conditions that present themselves, and told what to do when these conditions are known to exist.

The anthracite mine laws are made for the protection of life and limb; but probably 90 per cent. of the foreign-speaking men who work in the mines know nothing of what the law contains; and it is important that they should be made acquainted with the mine law. Again, accidents happen to many as a direct result of their ignorance of the safety appliances that are provided for their welfare; and also from their inability to properly understand the directions and warnings given to them by the foreman or his assistant.

But this education, to have proper effect, must not be given with a rod of iron or lash of the whip. Treat these men kindly; show them their duties in a brotherly spirit; let them feel that you are interested in their welfare and are doing this for their good and not for your personal benefit. If all coal companies would make an earnest effort to educate their employees they would get better results from their labors and thereby increase their earnings, and there would be less suffering and loss of time through accidents.

The reason the foreigners do not get hold of the English language sooner is that they live, work and keep among themselves all the time; they talk only their own language and are slow to learn and understand what is required of them in the mine. Educate the miner and you have solved one of the most perplexing questions in the coal fields of today.

EDWARD SANDERS.

Scranton, Penn.

Letter No. 17—I am not in favor of the use of textbooks at a mine-foreman's examination as, in my opinion, it would have a tendency to create mine foremen who are not practical mining men. I believe a man who has a college education but has never worked a day in the mine could, with the help of textbooks, solve certain kinds of questions given in the examination, especially if the proper formulas were furnished by the board; and yet if similar questions came up in actual practice in the mine, the same man would not be able to reach a practical solution because he would not have the hint how to proceed or anyone to suggest what formula he should use.

On the other hand, the practical mining man who has had a fair education and studied hard to keep up to the times should be able to pass the examination and get his certificate without the use of a textbook. In the end, such a man will make a more efficient mine foreman, as he would have a better idea of how to apply the correct formula in practice.

Examinations for mine foremen should be conducted along practical lines; that is to say, questions given and the conditions should be similar to those that are met every day in the mine. All men who are seeking certificates of proficiency that would make them eligible to the position of mine foreman or fireboss should be equipped to solve practical questions that call for good judgment in regard to safety, workmanship and economy. I do not think that they should be given the use of textbooks or formulas in examinations.

JOHN H. KELLY.

Seanor, Penn.

Two Useful Devices

I noticed a sketch for a safety block for inclines, in COAL AGE, of Mar. 29, p. 487, which was interesting, but I believe we have one in use at our mine No. 9 which is much more simple. It has been now employed for several years and has never failed. The angle of the incline to the tipple is 36 deg.

All that is necessary in making one of these stops is a piece of rail about 7 ft. 8 in. long, an old mine-car axle

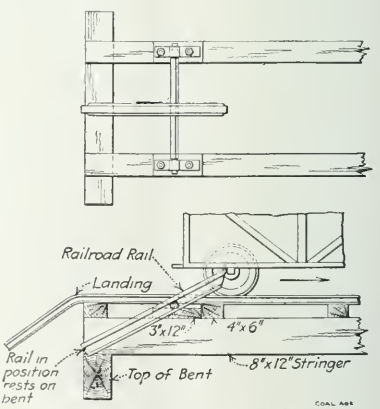


FIG. 1. CAR STOP AT HEAD

and two small clamps which any blacksmith can make. Add to this 4 long bolts to fit existing timbers and the list is complete.

I believe Fig. 1 is self-explanatory. We use the device shown, on the track for loaded cars. On the empty track we use a similar stop, but have a lever attached to the axle so that the block is lowered when cars are let down the slope. It is always best to have the lever so arranged

that the safety block is in position unless held forcibly down.

Fig. 2 is a sketch of a device for switch-backs from slopes where there is much liability to derailment. The sketch shows plan of tracks at bottom of shaft No. 8 of the Osage Coal & Mining Co.

The cast-iron plate at *A* was arranged so that no frog point would be necessary. The main rail *E* is laid exactly

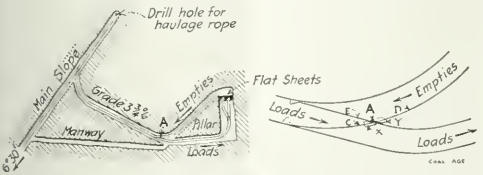

FIG. 2. FROGLESS RAIL CROSSING

flush with the part *Y* of the plate *A* and also with part *X* except that a groove is left for the wheel flanges to run in. The two rails *C* and *D* are laid just the height of the wheel flange above the plate *A*. Rail *D* is laid so that the outer rim of a passing wheel will just clear.

GEORGE M. BROWN, Engr.,
The Great Western Coal & Coke Co.

McAlister, Okla.

A Geyser from an Anthracite Mine

In the issue of May 3, page 693, you speak of the geyser-like action of the water in a flooded mine. During the recent high water in the Wyoming Valley, when the river broke into the old workings of the Enterprise Colliery, old railroad cars and baled hay were thrown in to try to fill up the opening, and when the water was forced out, evidently in the same manner as in the mine referred to, the hay was thrown high into the air. As the foreman in charge of the work expressed it: "It swallowed everything until we began to feed it baled hay, and then it threw up."

E. C. LEE.

West Pittston, Penn.

Loss of Life in Coal and Metal Mines

Referring to the article on the meeting of the Institute of Mining Engineers, May 2, line 7, top of page 730, should read 282 days instead of 300 days, that being the average time worked at all mines other than coal mines. In the accompanying table below the correct figure, 282 days is given.

Referring to the financial loss due to accidents, the totals are correct. The time loss resulting from serious accidents only is calculated on a 30-day basis at $3 per day for metal miners alone.

You do not state, however, that coal miners and quarrymen are figured on a basis of only $2 per day. The loss due to slight injuries is based not on 30, but on 5 days off duty with wages as above stated.

Taking the serious and slight injuries for the quarry and mining industry as a whole; their relative ratio is approximately 14 to 49; in other words, the slight injuries amount to about 3½ times the serious injuries as actually reported.

A. H. FAY.

Bureau of Mines, Washington, D. C.

Drawing Post Timbers

I was interested in reading the article on the Recovery of Mine Timber, by J. W. Powell, COAL AGE, Apr. 5, p. 529. I have seen a great many posts drawn with the Sylvester machine, and consider this the best way to recover timber from worked-out places. I want to make one suggestion:

It is dangerous to anchor the machine to a post, unless that post is properly set for the purpose. Mr. Powell mentions this as a precaution that should always be taken when drawing timber, but does not state how such a post should be set. It is important to set the post leaning toward the one that is to be drawn, as I have indicated in the sketch, Fig. 1. The anchor chain is fastened near the foot of this post, and the pull on the chain only tightens the post. This anchor post is moved back as the work progresses. I have often seen men spend much time in attempting to draw a post, without a machine and finally lose it under a heavy fall. A machine would have saved much time, and the post would not have been lost.

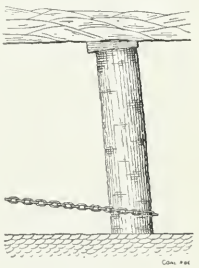

FIG. 1. ANCHOR POST SET FOR DRAWING TIMBERS

Referring to the article, Waste of Mine Timber, COAL AGE, Apr. 26, p. 853, the form of timbering described where a single stringer is used in the roof and the side struts or rafters are made to bear against this stringer is what we used to call the "herring-bone" system of timbering. It is a good system to use in certain roofs and is shown in Fig. 2, which is a cross-section of the entry.

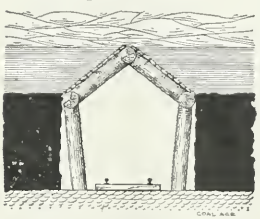

FIG. 2. A HERRING-BONE TIMBER SET

CHARLES WAINE.

Marianna, Penn.

Removing Powder Smoke from Mines

Some time ago the question of reducing ventilation at the time of firing was discussed in COAL AGE. Many of those who took part in the discussion seemed to think that to reduce the ventilation at firing time, will minimize the dangers of an explosion. The only reason given by the advocates of this practice worthy of any consideration was that the supply of oxygen being reduced combustion would cease. I consider such a theory practically impossible in mines where men must work. These advocates argue that there are more explosions in new and undeveloped mines having an abundance of air, than in old and more extensively worked mines where ventilation is not good. They point to the fact that the intake air current, in a mine, is more subject to explosion than the return; and that there is more danger of explosion in the winter than in the summer time; and they attribute these facts to the greater supply of oxygen.

While I do not wish to be understood as believing there is nothing in the arguments advanced; I must contend, nevertheless, that any results obtained by reducing the ventilation at firing time cannot be attributed to the lack of the supply of oxygen. In order to make myself clearly understood, permit me to relate the following experience of my own: Assuming the management of a new and undeveloped mine, May 1, 1910, I double-shifted all the work; and, to give the men every advantage possible, I permitted the firing of shots at midshift.

Two shafts had been sunk but were not connected below, and the only means of ventilation was through an air compartment made by carrying a brattice down the shaft. A steam jet, placed on one side of the shaft, gave sufficient ventilation to remove the powder smoke from the face of the entries in from 15 to 20 min. After a few weeks connection was made between the two shafts, the steam jet taken out and the brattice removed. While there was a great improvement in the ventilation, it still required from 15 to 20 min. to remove the powder smoke from the face of the entries. A little later I had completed the erection of a 16-ft., double-intake fan, which produced between 80,000 and 90,000 cu.ft. of air per minute, running at a speed of 80 r.p.m. With this large supply of air it still required from 15 to 20 min. to remove the powder smoke from the entries.

One afternoon in September, the temperature dropped from 90 deg. to about freezing point. On arriving at the shaft the next morning, I was informed that the night shift had to discontinue work, owing to the powder smoke, which was not removed from the face of the workings.

This experience teaches me that the rate of diffusion of the powder smoke into the air does not depend on the quantity of the air in circulation, but rather on the density of the air. I believe what is true of powder smoke is true also of marsh gas (CH_4). My conclusion is, supply enough air in the mine to render the atmosphere harmless after diffusion has taken place. This quantity of air should be sufficient to make the mine air safe. In my opinion, any excess of air will do no harm, but a deficiency of air may cause a dangerous mixture to form and result in a disastrous explosion.

I believe if it were possible to heat the intake air current so that its temperature would be the same as that of the mine workings, there would be no more danger of explosions in the intake than in the return airway; and no more danger in undeveloped than in developed mines; and no more danger in the winter than in the summer season.

Southern Coal, Coke & Mining Co.
Belleville, Ill.

Study Course in Coal Mining

By J. T. Beard

The Coal Age Pocket Book

Example—If a difference of pressure between the two ends of an airway, of 8 lb. per sq.ft., produces a velocity of 600 ft. per min., what will be the velocity in the same airway when the difference of pressure is only 2 lb. per sq.ft.?

Solution—In this case, calling the required velocity x

$$\frac{x}{600} = \sqrt{\frac{2}{8}} = \sqrt{\frac{1}{4}} = \frac{1}{2}$$

$$x = 600 \times \tfrac{1}{2} = 300 \text{ ft. per min.}$$

Pressure Producing Circulation—In mine ventilation, the word "pressure" generally refers to the pressure that moves the air. It is the difference between the intake pressure and the discharge pressure. Since the pressure of the atmosphere is equal at both ends of the airway it may be disregarded, as far as the movement of the air is concerned.

The Blowing System of Ventilation—To move the air or cause it to circulate in an airway or a mine, an extra pressure must be created at one end of the airway, so as to overcome the resistance of the mine due to friction. This is called the "blowing" system of ventilation, because the air is blown through the airway by the pressure created.

The Exhaust System of Ventilation—The same difference of pressure may be caused by decreasing the atmospheric pressure at one end of the airway, when the full pressure of the atmosphere at the other end will cause the air to move toward the point where the pressure is less. The principle is that commonly called "suction"; but this system is known as the "exhaust" system of ventilation.

How Pressure Is Produced—Various means have been used to cause a circulation of air in mine airways. The wind cowl, waterfall and steam jet are useful under favorable conditions and where a limited air supply only is needed. The mine furnace, built in the mine near the bottom of the upcast shaft, is often used in nongaseous mines, especially in deep shafts (see Furnace Ventilation). The most reliable means of creating pressure in mine ventilation, however, is the mine fan, which is generally erected at the surface, either at the top of the downcast shaft, as a blower; or at the top of the upcast, as an exhaust fan (see Fan Ventilation). The blowing fan creates a pressure above that of the atmosphere, while the exhaust fan reduces the atmospheric pressure.

How Pressure Is Estimated—In mine ventilation, the pressure producing circulation is estimated in height of air column, as in natural ventilation and often in furnace ventilation. The more common method, however, is to state the pressure in pounds per square foot or ounces per square inch. Pressure is also stated in inches of water gage.

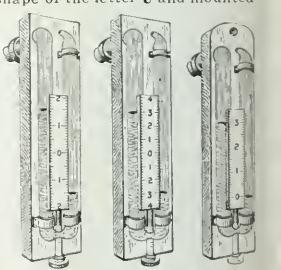
Atmospheric pressure is given in pounds per square inch, or, as barometric pressure (which is the same as atmospheric pressure), in inches of mercury

1 in. water gage = 5.2 lb. per sq.ft.
1 in. mercury = 0.491 lb. per sq.in.
1 oz. per sq.in. = 9 lb. per sq.ft.
1 in. mercury = 13.6 in. water gage

The Coal Age Pocket Book

How Pressure Is Measured—In mine ventilation, the pressure producing circulation is commonly measured by means of the water gage; or, in case of high pressures a special form of manometer is sometimes used. The manometer differs from the water gage in having one end of the bent tube closed so that the rise of the water level in that arm of the tube compresses the air above the water, which lessens the rise of water level and gives a greater range of readings.

The Mine Water Gage—This consists of a glass tube of about ¾-in. bore, bent to the shape of the letter U and mounted on a solid base. Three styles of water gage are shown in the accompanying figure. These differ only in the kind of scale. The first two on the left have the zero at the center of the scale and read up and down to the respec- water levels. The first of these scales is graduated to full-length inches, and to obtain a correct reading it is necessary to add the two readings together, or double either of them, as they are equal. To avoid this necessity the second scale is made of half-length inches, so that either the upper or the lower reading gives the full gage required, which, in this case, is 3 inches.



Three Forms of Water Gage

When the zero of the scale is at the middle and the scale reads up and down, it is evident that the scale must be adjusted so that its zero will correspond with the two water levels, before the pressure acts on the gage. When the pressure acts it depresses the water level in one arm while that in the other rises an equal amount. The difference between these two levels is the actual water column supported by the difference in the pressures acting on the water in the two arms. As will be explained later, one arm of the gage when in position is open to the intake pressure and the other to the return. The difference between these two pressures is the pressure that circulates the air between these two points.

The scale shown on the right has its zero at the bottom and reads upward. This scale must evidently be set, after the gage is in position, so that the zero will correspond with the lower water level, which is always that in the arm open to the intake pressure, as that pressure is always greater than the return pressure. The reading of the scale at the upper level is then the required gage.

The reading of each of the three gages shown in the figure is 3 in., which indicates a ventilating pressure of $3 \times 5.2 = 15.6$ lb. per sq.ft.

EXAMINATION QUESTIONS

Bituminous Mine Foremen's Examination in Pennsylvania, May 6-7, 1913

(*Selected Questions*)

Ques.—Why is it necessary to have larger pillars in some mines than in others?

Ans.—The dimensions of pillars, both length and width, are determined by such conditions as depth of cover, character of the roof, floor and coal, thickness and inclination of seam, width of opening, and the presence of gas or water in the roof or floor. All of these conditions affect the required dimensions of room pillars. As these differ in every mine, it is necessary to make the dimensions of the pillars, in every case, conform to the conditions as they exist. The size of shaft pillars depends mostly on the depth of the shaft and the inclination and character of the strata and method of working the seam.

Ques.—(a) What would be the minimum amount of air required in a split in which 70 persons were employed? (b) How would you determine the quantity of air passing, the airway being 8 ft. wide, by 5 ft. high; where would you take measurements, and how and when would you enter them in the daily report book?

Ans.—(a) The bituminous mine law (1911) specifies a minimum circulation of 150 cu.ft. of air per minute, for each person employed in nongaseous mines. This would require for 70 persons, $70 \times 150 = 10{,}500$ cu.ft. per min. If the mine generates gas in such quantity that it can be detected by an approved safety lamp, the minimum quantity of air shall be 200 cu.ft. per min. for each person employed in the mine; or, in this case, $200 \times 70 = 14{,}000$ cu.ft. per minute.

(b) To determine the quantity of air passing, select a place in the airway where the road is straight and the section uniform, and measures the velocity of the air current at this point, with a good anemometer. An average reading for the entire section of the airway should be obtained by moving the anemometer from point to point in the section, exposing the instrument to the air current an equal period of time at each point. The final reading of the anemometer divided by the time of exposure, in minutes, will give the velocity of the air in feet per minute. This velocity multiplied by the sectional area of the airway, in square feet, will give the volume of air passing, in cubic feet per minute.

The bituminous-mine law requires that the mine foreman shall measure the air once every week, at or near the main inlet and outlet airways and at the last cut-through in the last room, and in the entry beyond the last room turned, such measurements to be taken on days when the men are at work. The mine foreman must also enter plainly and sign with ink, in a book provided for that purpose, a true report of all air measurements taken, designating the place, the area of each cut-through and entry separately, the velocity of the air in each cut-through and entry and the number of men employed in each separate split of air, with the date when the measurements were taken.

Ques.—In driving entries or rooms that are approaching inaccessible old workings, known to contain a body of water, what precautions must be observed?

Ans.—When approaching old workings, a single entry only should be driven ahead, as shown in the accompanying figure. This entry should not be over 12 ft. in width, and a borehole should be kept at least 20 ft. in advance of the face of the entry, and other flank boreholes should be driven an equal distance, at an angle of 30 deg., in the rib of the entry, at intervals of 12 or 15 ft., as the face advances. This single entry should be ventilated by means of a brattice erected 2 ft. from one of the ribs of the entry, as shown in the figure. A close watch should be kept for any increase of water or gas in the strata. Plugs should be kept in readiness to stop any boreholes that may penetrate the old workings. If there is danger of gas, only safety lamps should be used.

Heading Approaching Abandoned Workings

Ques.—If a volume consisting of 100,000 cu.ft. of air per minute is passing through a mine, how will this volume divide itself between two splits of the following dimensions: Split A, 8x10 ft., 10,000 ft. long; split B, 8x10 ft., 5000 ft. long?

Ans.—The cross-section of these two airways being the same, the perimeters and areas are equal. In splitting, the quantity of air passing in each split is proportional to the split potential $a\sqrt{\frac{a}{lo}}$. In this case, the area (a) and the perimeter (o) being the same for each airway can be ignored and the expression for the potential becomes $\frac{1}{\sqrt{l}}$, which gives, using the relative values 2 and 1, for the actual lengths 10,000 and 5000 ft.,

Split A, $\quad \frac{1}{\sqrt{2}} = \frac{1}{1.411} = 0.7071$

Split B, $\quad \frac{1}{\sqrt{1}} = \frac{1}{1} = 1.0000$

Sum of potentials 1.7071

The quantity of air passing in each split is then

Split A, $\quad \frac{0.7071}{1.7071} \times 100{,}000 = 41{,}420$ cu.ft.

Split B, $\quad \frac{1.0000}{1.7071} \times 100{,}000 = 58{,}580$ cu.ft.

Total 100,000

BOOK REVIEW DEPARTMENT

COAL AND THE PREVENTION OF EXPLOSIONS AND FIRES IN MINES. By John Harger, 176 pp. with index 5½x8⅝; 4 ill.; Cloth boards. Longmans, Green & Co. 443 Fourth Ave., New York. Price, $1.25.

No book on coal mining has excited more comment in the present year than this little volume. John Harger is a man of great originality. We may not agree with him but he stimulates thought and is never dull. He introduces his volume with a fierce attack on the British equivalent of our bureau of mines which he says is conducted "mainly by amateurs." This comes with poor grace from an Englishman in view of the fact that the present safety lamp is a development of the unpractical Sir Humphry Davy, that a predominant type of fan, which revolutionized mine ventilation in its day, was introduced by a clergyman Capell, that our knowledge of mine explosives is largely the outcome of Sir Frederick Abel's investigations and that J. S. Haldane and Leonard Hill have done a great work in discovering means of reducing the unhealthiness of mines under certain untoward conditions. None of the three last-mentioned can by any stretch of a versatile imagination be regarded as practical coal-mine experts. The helmet, also, which has probably the most extensive sale in England was invented by Heinrich and Bernard Draeger neither of whom were mining men. But even more astounding is the coolness with which Doctor Harger overlooks the work of W. E. Garforth in his introduction. Surely this is not because the latter is a mere theorist.

Mr. Harger frequently surprises us with his theories. "In spite," he says, "of its attractive simplicity, we can no longer hold "the peat-to-anthracite" theory which has, in text books at any rate, held such long sway." He is even disposed to accept the bacterial theory of the formation of methane by coal.

Mr. Harger argues in favor of occasional reversals of the air current to remove such dust as is sheltered by projecting ledges of rock and would be unsheltered on reversal. Now W. E. Garforth has declared that coal dust will not rise into a ventilating current unless a velocity of 18 miles per hour is attained. If that is correct for really fine dusts, Mr. Harger's suggestion is not to be regarded seriously especially as he does not say whether he has experimented on the practice he advocates.

The reader will be anxious to see how the author proposes to fill the air of the mine with carbon dioxide and to reduce the percentage of oxygen as suggested in his celebrated address before the British Institute of Mining Engineers. It is probable, if a speedy and effectual devitalization of the atmosphere can be obtained at reasonable cost that the system will be adopted for shotfiring from the surface. Mr. Harger proposes either to use Bone's flameless surface combustion or to pass the waste gas from a boiler fire still heated over bog-iron ore so that the catalytic action will aid combustion, and then over cupric oxide and copper to effect a yet more perfect purification. He also asserts that the discharge of a gas engine can be easily freed from carbon monoxide and might be available.

The book may contain some false conclusions but it is well worth reading. A few original thinkers like Mr. Harger are needed to ferment the mass of stagnant thought.

There has been a disposition to use Mr. Harger with like impatience with that which he has exhibited toward Messrs. Dixon and Wheeler. Because G. A. Burrell and other authorities have shown that his statements relative to gas explosions need qualifications, we should not therefore assume that there is no basis of fact in his statement that under practical conditions explosions especially of coal dust, will not occur if the percentage of oxygen, is reduced to 17 per cent. Let us be reasonably sure, that he is wrong and unentitled to public recognition before we excoriate him.

BIENNIAL REPORT OF THE INSPECTOR OF COAL MINES OF THE STATE OF MONTANA FOR THE TWO YEARS ENDING OCTOBER 31, 1912. Jos. B. McDermott. 66 pp.; 6x9; paper.

The report gives the usual statistics of the production of coal and accidents in mining, together with valuable recommendations and suggestions in reference to permissible explosives, the use in mines of gasoline motors, and the smoke test as applied to illuminating oils used in the mines.

THE COAL TRADE IN 1913. Frederick E. Saward. Cloth, 6¼x8 in., 200 pp. The Coal Trade Journal, 20 Vesey St., New York City.

The fortieth consecutive issue of this bright little book, covering the trade and market statistics for the year of 1912 is again out. As in the case of the previous issues, the book is full of pertinent and useful information to those interested in the coal trade and market conditions. The data included is of a very comprehensive nature, covering temperature statistics, prices, productions, transportation, etc. The book is not, of course, of any particular originality, but it is certainly a handy and quick reference work on the subject covered. In common with previous editions, the most grievout fault to be found is the total absence of any attempt at segregating the different topics into one department. Thus selecting a page at random, say 64, at the top of the page, we find the Baltimore & Ohio R.R. freight rates on coal, which is fololwed by shipments of anthracite according to sizes, and finally the utilization of coal mined in the United States. It would be difficult to conjure up three more irrelevant subjects. Why could not the matter of freight rates all be segregated into one department or one chapter, and likewise the statistics governing the anthracite production and shipments and also that portion relating to the utilization of coal?

GEOLOGIC MAP OF ILLINOIS: Prepared by the State Geological Survey. Size, 34x56 in. Colored; Paper and mounted on cloth.

The State Geological Survey of Illinois, Frank W. DeWolf, director, has recently published a handsome provisional geologic map of Illinois. This map has been compiled from data furnished by the survey staff, and is said to vary in accuracy only with the degree of detail shown.

The map is drawn to a scale of practically eight miles per inch and the several geologic areas are marked in colors. It is stated that since practically the entire state is mantled with drift and associated deposits, the boundaries may be considerably out of place except where detailed surveys have been made, as in Jo. Daviess, La Salle, St. Clair and Monroe counties. The map shows the location of the coal mines of Illinois, and these have been revised by the state mine inspectors under the direction of the State Mining Board. Besides these, there are marked on the map the location of the fluorspar mines, the zinc mines and the petroleum and gas fields, now or formerly active.

There are marked on the map, in different places, the limits of glaciation or, the border of driftless areas. Columnar sections for northern, central and southern Illinois are given to a scale of 1 in. = 500 ft. There is also given on the map an outline of the geological history of Illinois, including a brief history of the several rock formations underlying the state. A brief résumé of the economic features of the state is given, showing the quantity and value of the mineral productions, such as coal, petroleum, clay products, pig iron, portland cement, sand, gravel, etc. It is claimed that the mineral wealth of Illinois is practically $150,000,000 annually, and that the state held the third rank among the mineral-producing states in 1911, with coal, petroleum and clay products as the chief items.

Two cross-sections, one in the northern and the other in the southern part of the state, show the general surface to be 500 ft. above sea level. In many cases the altitude above mean sea level, expressed to the nearest foot, is indicated by small figures immediately following the name of the town. These elevations are taken from the U. S. Geological Survey, the Coast and Geodetic Survey, the Army Engineers, and the Mississippi River Commission, all reduced to the 1907 adjustment. The figures refer to the permanent bench marks established by the engineers. Other figures without decimals are derived from railroad profiles and give the approximate elevation above sea level, at railroad stations.

The map is one of which the State Geological Survey can well be proud and shows great care in its compilation. A copy of this map, on heavy paper, will be sent on receipt of 15c., in stamps, to cover cost of mailing. A similar copy, mounted on cloth and sticks, will be sent if, in addition to 16c. postage, there is inclosed money order for 29c. payable to A. J. Nystrom & Co., Chicago. Remittances should be sent to the Director, State Geological Survey, Urbana, Ill.

COAL AND COKE NEWS

Washington, D. C.

Former Secretary of the Interior Walter L. Fisher has discussed with the senate committee on territories the coal question in Alaska during hearings that occurred in the course of the past week relative to the two bills now pending before the committee to authorize the construction of railroads by the Government in that territory. Mr. Fisher said in part:

Now I do not care what the views of members of Congress may be as to the proper way of handling the coal fields. I undertake to say that not one of them, if he will sit down and consider the facts, will conceive that it is possible to open them under existing law. It would be merely offering a premium to the larger financial interests to go in and absorb the existing coal fields and absolutely control them.

For instance, today we know that there are two, and only two, great coal fields in the territory—the Bering coal field and the Matanuska coal field—and we know relatively the area and extent and character of them. Suppose you should open them up to development today; what would happen? You would simply have the men who have the money, and who have the familiarity with the conditions, putting persons in the field to enter these coal lands, so far as they had not been entered, at once. There is no other possibility.

Nobody would do anything so far as the actual development of them is concerned that would be of any value to the country. If the little work which is necessary, even under instruction of the Department of the Interior and the General Land Office with regard to opening mines, were done so that the entrymen were really complying with that provision of the law, it would not put coal commercially on the market. It would merely enable the people who make the entries to acquire title, so they might sit down and wait until a sufficient time had elapsed when they would turn this property over to other people.

Mr. Fisher Favors Leasing

You may have differences of opinion about the leasing system as compared with the ownership of the coal land in fee, but you will find that in Alaska, just as in this country, the inevitable economic tendency will appear, and we will find happening there what has already happened in the rest of the country, namely, the greater portion of the coal lands operated under a leasing system.

Whether we like it or whether we do not, there is no choice between the fee and the leasing system because coal developments in the older states have demonstrated conclusively that private interests prefer to operate under the leasing system, whether the Government does it or not, and your only choice is whether the Government will lease, and lease on terms that will encourage development under effective public control or whether it will turn it over to private interests who will lease, and lease upon the purely financial considerations that will control.

This is capable of demonstration. Mr. Jones or Mr. Smith enters upon a certain tract of coal land, and he gets his title; he complies with the law and gets his patent. Now what does he do? In the great majority of cases he does not operate the coal mine. The statistics are given in the document to which I have referred, and you can have it readily brought down to date by the Bureau of Mines. What he does is to turn it over to a lessee, corporate or individual. It may be that the property will pass through a succession of transfers before the coal is finally commercially operated. If it does, each transfer means that the party who sells exacts a profit from the party who buys, and, finally, when the lease is made and the operator begins to take out coal he does so upon a royalty basis which pays the carrying charges upon the profits made in the whole series of intermediate transactions.

The result is, as has happened in the bituminous coal fields throughout the Central West that many of our coal mines are being operated upon terms that leave the operator just a chance to make a living. Many of our coal fields are being operated under existing private ownership by a private lease system, under which the operator can just work through. And what happens? The trade itself is utterly and hopelessly demoralized, because every time there is a falling off in the demand for coal, there is a decline in our general prosperity, so that there is less manufacturing and less use for coal. These coal lessees who have taken over these properties upon terms which just give them a chance to live, usually have notes at the bank, or have to meet their obligations to their lessors, and they must sell coal. They put their coal on the market. They rush in the market and the result is that there are times of plenty and times of scarcity, with the miner being thrown out of employment, and with all of the evils that associate themselves with our coal development, and to a certain very considerable extent, with our lumber development in this country.

The system does not work properly, and if men in the coal business both in Pennsylvania and in the Far West will talk to this committee as they have talked to me, there would not be any real difference of opinion as to what ought to be done.

They will all be agreed upon the proposition that the way to handle these fields is to have the Government lease them, and lease them upon terms which will encourage development, will protect the operator, and will give him a far better chance in the practical operation of the coal mines than he can possibly get under the existing system. You do not propose to throw this coal land open under the present law except in very small quantities, so small that it is not profitable, so small that certainly if there is any operation it is upon the most uneconomic basis.

The Question of Economy

We want to have our coal mined so as to prevent waste. Talk to operators as I have talked to them, and they will tell you "we would like a law of this kind to prevent waste, but here is a vein where the physical conditions are such that if we go in and take that coal out now it is going to cost us a whole lot of money. The coal market is low; there is a glut. We cannot afford to do it. It is theoretical. We ought to take out all the coal from the mine and we ought to take it out as we go, but practically we cannot do it. We could not meet commercial competition and do it."

We have already parted with the greater portion of our coal land in this country. Fortunately, we have still a considerable area in the West. Fortunately, many of the western states have considerable areas of coal land belonging to them, and it is significant that all of those states are operating under a leasing system, some of them prohibiting the disposal of their coal land under any other than the leasing system. If you will take the state laws throughout the West and examine them, and see what the states believe they ought to do with their coal land, you will observe that there is a practical unanimity of opinion that it ought to be handled under the leasing system.

Of course, the object of the whole law ought to be to get coal to the consumer as cheaply as it can consistently be done with a proper return to the people who are developing the mines and making the investment. You ought to offer to those people such a return upon their money as will be a sufficient inducement to them for the development of the property, whatever it is. If you offer them any more than that it is gratuity.

There is going to be very litle pioneering about any of this coal land, especially in Alaska, and this is true practically of all the coal land that we have left in the hands of the Government, either the Federal Government or the state governments. It is not the ordinary case of the prospector who starts out with a pick and shovel and goes out through the wilderness and finds a vein containing precious metal.

The difficulty with our coal laws is that they proceed upon the theory that coal land is just like precious-mineral land. We have tried to make the laws the same, and we have modified the mineral laws just as little as possible so as to meet conditions in the coal fields.

Concerning a Government Railroad

I think the Government can afford to build a railroad in Alaska, which perhaps private capital could not afford to construct, because of the difference between the rate of interest that private capital would have to pay and the rate of interest which the Government would have to pay. I think that is a sufficient reason for the Government building this road.

PENNSYLVANIA

Anthracite

Scranton—Two thousand mine workers at the Sterrick Creek colliery of the Temple Iron Co., in Jessup, are on strike because the hoisting engineers and a number of others have not joined the union. The union officials say that the strike is not authorized.

Shamokin—Between 7000 and 8000 men and boys, who have been idle at the collieries in this region have returned to work. The strike caused a general tie-up in the various collieries.

Bituminous

Harrisburg—Ten additional mine inspectors are provided for the anthracite field in a bill which has passed the House by a vote of 135 to 5. The bill was presented by Mr. Lenker, of Dauphin, who declared that, in view of the fact that 614 men were killed in the mines during 1911, he believed that there was a need for more inspectors.

Monongahela—The old Domestic coal tipple which has been a landmark on the East Side for a number of years has been torn down. Only a little coal has been run over the tipple during the past five years.

Washington—A large barn at the Vigilant mine of the Pittsburgh Coal Co., at Coal Center, was destroyed by fire May 6. All the mules and horses were rescued. The cause of the fire is a mystery. The loss is estimated at $5000.

Uniontown—The magazine of the Sunshine Coal and Coke Co.'s mine exploded at 1 o'clock, in the afternoon of Saturday, May 10, killing 3 persons and injuring 40, of whom 22 were seriously hurt. The plant is three miles from Masontown, Fayette County. The magazine contained 500 sticks of a dynamite powder. The general store, the home of Francis Rocks, an official of the company and 25 small dwellings were made uninhabitable. The magazine was about 25

yd. from the store and the Rocks home. Two men, both killed were in the magazine. The loss is $75,000.

Du Bois—The miners at the Buffalo & Susquehanna Coal & Coke Co.'s mines Nos. 1 and 2 are on strike to secure better wages for the firemen who work 12-hour shifts for $2.42 per day. Superintendent James Harvey has refused to accept a checkweighman as representative of the men, claiming he is not an employee. A commission composed of J. S. Forsythe for the operators and W. Broad for the miners will hear the arguments relative to the checkweighman's elegibility to the pit committee.

WEST VIRGINIA

Charleston—A special train in charge of a representative of Governor Hatfield has transported many miners from tents along Cabin and Paint Creeks to various mines throughout Kanawha County, where employment awaited them. The men and their families have been living in tents since the beginning of the strike, in April, 1912.

The Governor has announced that he would place a number of special guards in the former strike zone to do police duty, but that no mine guards would be permitted to act as police. He added, however, that he could not and would not attempt to prevent property owners from employing persons to guard their own properties.

VIRGINIA

The one most serious obstacle to the mining industry in Virginia is the difficulty experienced by the operators in getting sufficient men to work the mines. The West Virginia and Pennsylvania mines absorb nearly all the foreign-born workers, and those states give special attention to provisions for the welfare of the miners by providing hospitals for them where they may be cared for at the State's expense in case of serious accident or illness. In Virginia, while some of the mining companies are strong enough to provide and maintain hospitals for their men, many of them are not; and the lack of such, prevents many from coming to this state who would otherwise prefer to work in the thick, gasless mines of the southwest counties.

KENTUCKY

Louisville—Traffic officials of the Louisville & Nashville R.R. Co., with a number of interested business men as their guests, took an inspection trip last week over the Louisville & Eastern region. They were especially interested in the new operations of the Consolidation Coal Co. in that section. The trip was made in a special train, which left Louisville on the evening of May 9.

Hartford—Five men were killed May 6 in a deserted shaft of a coal mine belonging to the Taylor Mining Co. The men were exploring an abandoned portion of the mine, when one of their number fell into some water. The four others went to his rescue, but were overcome by blackdamp before anything could be done.

TENNESSEE

Chattanooga—The reunion of the United Confederate Veterans will be held at Chattanooga, May 27 to 29. Great preparations are being made to properly entertain the survivors of the great struggle, whose ranks are thinning so rapidly. Owing to the low railroad rates local manufacturers expect that many of their distributors and suppliers, as well as many coal operators, will pay the city a visit about that time.

OHIO

Bridgeport—The strike of 2000 miners of the Lorain Coal & Dock Co. which started two weeks ago was settled May 6. The men demanded pay for all roll cutting where the stone is more than 10 in. thick and gained their point. The strikers resumed work at once.

Martins Ferry—The fan house at the Florence mine, two miles west of this place, was burned May 9, causing a loss of $2000. Four hundred miners will be thrown out of employment for two weeks. The origin of the fire is unknown.

MISSOURI

Jefferson City—Governor Major has announced the appointment of deputy mine inspectors as follows:

For the coal mines of the state—Benjamin B. Fischer, of Lexington, and Evans Jones, of Higbee.

FOREIGN NEWS

Halifax, N. S.—The miners of the Acadia Coal Co. at Stellarton have left work to interview the management concerning the reinstatement of one of their number. They claim that he was asked to vacate one of the company's houses while sick in bed.

Vancouver, B. C.—A strike of the coal miners in the Nanaimo area has been ordered by Frank Farrington of Seattle, representative for the Pacific Northwest of the United Mine Workers of America. The collieries affected employ a total of 2500 men.

PERSONALS

C. P. Ludwig, general manager of the Alabama Iron Co., has tendered his resignation, to take effect May 31.

Willis S. Holloway, who has had 15 years' experience in designing and installing coal-handling and conveying machinery with various firms is now associated with the Roberts & Schaefer Co., of Chicago.

The Hisylvania Coal Co., which has offices in the Capitol Trust Building, announces the appointment of Thomas D. Jordan as the Western sales agent of the company, with office at 1255 Old Colony Building, Chicago.

Robert Leitch, chief chemist at the Scottdale furnace of Corrigan, McKenney & Co., has been transferred to Charlotte, N. Y., to become superintendent of the company's furnace at that place. E. Guy Wentsluer will take his place at the Scottdale plant.

E. P. Laughrey, who has been chief clerk at the Scottdale furnace of Corrigan, McKinney & Co. for the past several years, has been promoted to the position of superintendent. Mr. Laughrey succeeds W. H. Everhart, who has been made superintendent in the Cleveland works.

Paul W. Holstein has recently been appointed by the Roberts & Schaefer Co., of Chicago, to have charge of its coal tipple and washing plant construction and contracting business in the West Virginia field. He has had several years' experience along these lines for other companies.

Mine Inspector Richard Maize, Jr., of Somerset, has been appointed superintendent of all the operations of the United Coal Co. in Somerset County, including those in Boswell, Jerome and Orenda. He succeeds John Gibson, Jr., who has been made general superintendent for Pennsylvania, Maryland and West Virginia.

W. C. Redfield, formerly vice-president and director of the American Blower Co., has been appointed a member of President Wilson's cabinet. Mr. Redfield has deemed it advisable to terminate his business connections with the company and has retired from active participation in its management.

W. H. Burke, formerly purchasing agent of the Illinois Traction System, and for the past year and a half fuel agent for that system and general manager of the Kerens Donnewald Coal Co., has resigned to accept a position as secretary and treasurer of the Roberts Motor Co., at Sandusky, Ohio. He is succeeded by J. A. Jeffries, formerly of the Williamsville Coal Co., of Williamsville.

TRADE CATALOGS

Draeger Oxygen Apparatus Co., 422 First Ave., Pittsburgh, Penn. The Draeger Pulmotor. Ill., 32 p., 6x9 in

The B. F. Goodrich Co., Akron, Ohio. Pamphlet, "Longlife" conveyor belt. Ill., 5½x8½ in.

Department of Mines, British Columbia. Preliminary Review and Estimate of the Mineral Production, 1912.

Otis Elevator Co., 8th Ave. & 26th St., New York. Catalog. Incline railways and skip hoist machines. Ill., 28 p. 6x9 in.

C. W. Hunt Co., West New Brighton, S. I. Catalog No. 12-9. Hunt noiseless gravity bucket conveyor. Ill., 64 p., 7x9 in.

The C. S. Card Iron Works Co., 1601-1679 Alcott St., Denver, Colo. Catalog No. 16. Coal handling machinery and equipment. Ill., 72 p., 6x9 in.

The Electric Service Supplies Co., Philadelphia, Penn.; booklet illustrating and describing the automatic trolley guard, a new specialty which it has recently added to its broad line of electric railway equipment.

Guarantee Construction Co., 140 Cedar St., New York. Pamphlet. Economic Handling and Storage of Coal and Ashes in Power Plants. Illustrated, 40 p., 6x9 in. Pamphlet. Retail Coal Pockets and Mechanical Screening Plants. Ill., 36 p., 6x9 in.

National Tube Co., Pittsburgh, Penn. New edition, Matheson Point Pipe Booklet. 40 pp.; numerous illus. The various advantages of this pipe are enumerated as follows: Reduced weight, greater bursting strength, saving in lead per mile, adaptability to vertical curves and the advantages of National coating.

The Witherbee Igniter Co., Springfield, Mass. Booklet on Wico Safety Electric Lamps. 12 pgs., 3x6 in., illustrated.

This is an electric head lamp operated by a storage battery carried on the belt. The accumulator, it is claimed, is the lightest and most compact device of its kind and capacity known, weighing but 2 lb. 4 oz. and giving a continuous light for 12 to 14 hours at one discharge.

NEW PUBLICATIONS

U. S. Bureau of Mines. Bulletin 46. An investigation of explosion-proof motors. By H. H. Clark, 1912. 44 pp., 6 pls.

U. S. Bureau of Mines. Technical Paper 28. Ignition of gas by standard incandescent lamps. By H. H. Clark, 1912. 4 pp.

Western Society of Engineers, Journal for April, containing paper on, "The Cause of Floods and the Factors that Influence their Intensity," "Investigation of Flood Flow on the Watershed of the Wisconsin River," "The Desirability of revising the Rating and Methods of testing Electrical Apparatus," etc.

"The Electron Theory of Magnetism." by E. H. Williams, has just been issued as Bulletin 62 of the Engineering Experiment Station of the University of Illinois.

This is a mathematical discussion of the new theory of magnetism. The bulletin traces the experimental evidence leading to the development of this theory, defines its present status, and points out certain phenomena which the theory in its present form fails satisfactorily to explain.

Copies of Bulletin 62 may be obtained upon application to W. F. M. Goss, director of the Engineering Experiment Station, University of Illinois, Urbana, Ill.

CONSTRUCTION NEWS

Minneapolis, Minn.—The Sullivan Coal Co. is planning to erect a 5000-ton automatic coal elevator on the Milwaukee tracks at Lyndale Ave. and Twenty-ninth St. The cost is to be in the neighborhood of $16,000.

Gary, W. Va.—The U. S. Coal & Coke Co. has let a contract for an annex of 8 rooms to be added to the Gary clubhouse. The dining room will also be enlarged to have a seating capacity of 60 at the tables.

Bellaire, Ohio—The contract for rebuilding the power house of the plant of the Franklin Coal Co. at Stewartsville, Ohio, has been awarded and the work will be rushed to completion. The power house was destroyed by fire recently.

Lorain, Ohio—The Baltimore and Ohio Railroad Co. has started the work of rebuilding the coal docks at Lorain. The docks, especially No. 1 was badly damaged by the recent flood. Repairs will be made to dock No. 2 which was also damaged by the high waters.

Battle Creek, Mich.—Twelve new coal sheds, 200 ft. long and having a capacity of 960 tons, will be erected in the near future by the J. O. Davis & Son Coal Co. It is understood that the company will not let any contract for the work but will undertake the construction itself.

Sparrow's Point, Md.—The Maryland Steel Co. has just placed contracts for additions to its byproduct coke and gas plant. The new ovens will be of the Koppers' type and will be constructed at once. When this work is finished the company will be equipped with sufficient coke capacity to supply its needs for fuel and give it abundant byproduct gas as well.

Wyandotte, Mich.—The Eberts Bros. Co., dealers in fuel and builders' supplies, has purchased the entire block of river front property between Poplar and Walnut streets. A dock, almost a block in length, will be erected, which will be equipped with modern devices for unloading vessels, including a large steam crane. A mammoth fireproof storage building will be erected at one end of the property.

Pittsburgh, Penn.—Plans for the new cofferdam to be erected in the Ohio River at Dam No. 9 have been received at the offices of the Pittsburgh Coal Exchange. There will be 435 ft. of open channel for navigation between the outer face of the cofferdam and the river wall of the lock. For spillway purposes there will be 100 ft. opening off from the lock chamber. The contract has been awarded to the National Contracting Co. and the work will be completed by Oct. 1.

Duluth, Minn.—The new steel plant at Duluth is to build an immense storage yard for coal and limestone in the near future. The yard will be 1000 ft. long by 600 ft. wide and will have sufficient capacity to store all the necessary supplies. It has been officially announced that three additional open-hearth furnaces will be constructed at a cost of $760,000, together with another reheating furnace. There will be 90 coke ovens in the new plant with a capacity of 1000 tons of coke per day. These are now in the course of construction.

NEW INCORPORATIONS

Cheyenne, Wyo.—The Cedar Grove Coal Co. has recently filed articles of incorporation. Capital stock, $300,000.

Austin, Tex.—The Sherman Gas, Light & Fuel Co. of Maine; capital stock, $200,000. Permit granted to do a business in Texas.

Youngstown, Ohio—The Brier Hill Coal Co. has filed papers with the secretary of state increasing its capital stock from $50,000 to $500,000.

Dayton, Ohio—The Service Coal Co., of Dayton, has filed papers with the secretary of state decreasing its capital stock from $50,000 to $5000.

Brazil, Ind.—The West Side Coal Co.; capital stock, $5000; to mine coal. Incorporators: C. H. Zellar, Lena Zellar, B. F. Schrepferman and M. D. Schrepferman.

Louisville, Ky.—The White Oak Coal & Coke Co. of Kentucky; capital stock, $25,000. Incorporators: C. S. Maddis, W. H. Kurk, C. A. McKamey and H. S. Phillips.

Youngstown, Ohio—The Reserve Metal & Coal Co.; capital stock, $10,000; to deal in junk, old iron, coal, etc. Incorporators: Mary Roland, Minnie Sussman, A. B. Calvin, H. G. Bye and B. L. Smith.

Woodward, Tex.—The Farmers' Coal, Grain & Elevator Co.; capital stock, $5000. Incorporators: I. J. David, G. A. Stuart, J. I. Carpenter, D. P. Thacker, W. A. Campbell, W. R. Smith, and J. H. Hamilton.

Clinton, Ind.—The West Clinton Coal Co. has been incorporated here, with $150,000 capital stock, to mine coal. The directors are John Shirkie, Steward Shirkie, S. P. Hancock, G. H. Bridges and Henry Adamson.

INDUSTRIAL NEWS

Sullivan, Ind.—The Princeton mine, owned by the Consolidated Indiana Coal Co. is to be reopened. The machinery has been removed from the Keller mine.

Blairsville, Penn.—It is rumored that the Buffalo, Rochester & Pittsburgh R.R. is about to be extended from Josephine, through Blairsville to Latrobe and perhaps further.

Manilla, P. I.—E. Randolph Hix states that the Philippine Coal Consumers' Association has just been formed and is about to ask for bids on $1,000,000 (gold) worth of coal.

Punxsutawney, Penn.—The H. C. Frick Coke Co. has ordered the firing of more ovens at Dorothy. This will make a total of 210 ovens in operation in the Westmoreland region.

Altoona, Penn.—The Altoona Coal & Coke Co. is preparing to place in operation its coking plant of 100 ovens at Coupon, Cambria County. The plant has been out of commission for some time.

Evansville, Ind.—Fire at the Ingle coal mines, near Evansville, destroyed the boiler rooms at the power plant, with a loss of more than $15,000, and also did considerable damage to the mine shaft.

Cincinnati, Ohio—The directors of the Mahoning Coal R.R. Co. have declared a dividend of $25 a share on the common stock, payable May 15. The majority of the stock is owned by the Lake Shore R.R.

New Lexington, Ohio—The Common Pleas Court, of Perry County, has ordered the sale of the property of the Saltillo Coal Co. at auction, June 7. The property consists of several tracts of coal land in Perry County.

Connellsville, Penn.—The Indiana Coal Mining Co., whose operation is located at Lockport, on the Westmoreland County side of the Conemaugh River, is now working a new operation on the Indiana County side of the river.

Lexington, Ky.—Colonel Tierney, head of the Elkhorn Coal Co., has just purchased a large tract of coal land on Pond Creek and will soon open 15 mines there. These mines will have a capacity of about 15,000 tons a day.

Brazil, Ind.—The Indiana Clay & Coal Co. has filed a petition for a receiver in the Circuit Court. The company operates a coal- and clay-stripping pit near Patricksburgh, but this has not been in operation for two months.

Belleville, Ill.—The county mine examiner has ordered the Little Oak Mine closed because the wood work of the mine was decayed and the tipple in a dangerous condition. Three hundred miners are thrown out of employment.

Joliet, Ill.—The Joliet Coal Products Co. is considering the expansion of its operations at a cost of $375,000. The plant now consists of 35 byproduct ovens. The plan is to build an additional 36, thereby more than doubling its capacity.

Johnstown, Penn.—Negotiations have practically been closed for the purchase of about 6000 acres of virgin coal in Green and Cherryhill Townships, Indiana County. The identity of the purchasers is being kept secret. An average of $60 an acre has been offered for the coal and the deal means the transfer of $360,000.

Reading, Penn.—The Reading Coal & Iron Co. is still storing coal at Abrams and Landingville. The mines, however, are working full and are likely to continue during May. It is reported that the eastern and western states are storing large quantities of anthracite, and this accounts for the activity at the mines.

Birmingham, Ala.—The New Orleans & Northeastern R.R. and Alabama & Vicksburg R.R. have placed together with the Corona Coal & Iron Co. probably the largest individual coal order in the history of Alabama. The order calls for 600,000 tons to be shipped at the rate of 25,000 tons per month over two years, beginning July 1, 1913.

Johnstown, Penn.—It is said that the Berwind-White Coal Mining Co. is about ready to purchase the holdings of the Jed Coal & Coke Co., near Welch, W. Va., for $300,000. This property has been in the hands of a receiver for a year. Should the court confirm the sale, it is said that the Berwind company will spend $200,000 on improvements.

Lorain, Ohio—The American Ship Building Co. has arranged to launch the new freighter, "A. C. Dustin," which was built at the Lorain yards of the company in the near future. The vessel is named after A. C. Dustin, of the firm of White, Dustin & Kelly, admiralty attorneys, of Cleveland. The "A. C. Dustin" is 545 ft. long, has a beam of 58 ft., and a draft of 31 ft.

Shenandoah, Penn.—The Philadelphia & Reading Coal & Iron Co. is experimenting with a new carbide gas lamp for use in its mines. It is expected that this new lamp will do away with the old oil-burning lamp. The miners who have used the new lamp say that it is far superior to the old-style lamp. It gives a much brighter flame, in addition to being cleaner and safer.

Manhattan, Kans.—The Rocky Ford Power Co. has devised a scheme for getting its coal across the river from the Blue Valley R.R. track to its plant. Large iron pipes, supported by cables, will span the river. The coal is fine and is washed through the pipes under pressure.

The Rocky Ford company is abandoning its water-power machinery for steam power.

Pottsville, Penn.—The Philadelphia & Reading Coal & Iron Co. is preparing to reopen the old Anchor mine at Heckscherville. The mine was abandoned 40 years ago and has remained full of water since that time. It is now planned to install pumps and drain the mine. When in operation the output will be hauled by motor to the Thomaston slope and conveyed on the main line to the Pine Knot breaker.

Spottsville, Ky.—The work of pumping the water from the coal mines at Spottsville, Ky., on the Green River, which were flooded during the high water last month, has been started and it is hoped to get the workings cleared in time to resume work before long. It is said that many of the men formerly employed in the mine have left the town, being under the impression that work would not be resumed in the mine.

Scranton, Penn.—The plant and business of the Scranton Steam Pump Co. was recently purchased at a receiver's sale by a committee representing 98 per cent. of the creditors. The total price paid was in the neighborhood of $400,000. This firm was forced into receivership by a combination of financial difficulties and not by any inferiority of its product. The business will be continued and it is believed that in a short time it will again be on a paying basis.

Alliance, Ohio—Mayor B. F. Hennacy has been taking options on coal lands in this vicinity. At present he has 2000 acres in Elkrun Township and more than 3500 acres in Salineville.

Tests have shown that there are rich beds of coal underlying the land in Elkrun Township, and it will probably not be long before mining operations are begun there. It is understood that Mayor Hennacy's purchase is merely an investment.

Pineville, Ky.—The Continental Coal Corporation, operating extensive properties in southeastern Kentucky, especially in the vicinity of Pineville, has moved its Louisville offices into new and commodious downtown quarters at 217 South Fifth St., between Market and Jefferson. All of the business of the company in Louisville will henceforth be handled from the office referred to, only a yard manager being left at the yards, where the office was formerly located. The central office will be in charge of L. A. Powell, who has been local manager for some time, and the company's branch offices will remain as before.

Connellsville, Penn.—Beginning with May 1, the output of Vesta No. 5 mine of the Vesta Coal Co. is to be shipped by rail. The new arrangement has been caused by the closing for repairs of one of the locks at Lock No. 4 on the Monongahela River. The other mines of the Vesta company will ship by river as at present. A siding has been placed to hold 50 cars at the Vesta No. 5 mine.

The tipple at this mine was designed for river as well as rail shipments. For this reason the contemplated change will mean but little additional expense. The mine is turning out about 3100 tons a day.

Winchester, Ky.—Coal and timber lands in Tennessee to the extent of about 41,800 acres have been sold by H. C. Thompson, of Winchester, to J. A. Smith, Roger E. Miles and W. A. Odell, representing Cleveland and New York interests. The price paid is said to have been about $400,000. Mr. Thompson also holds an option on 50,000 acres of coal lands on the South and Middle Forks of the Kentucky River, which he may sell to the same parties. The latter will make an investigation of the property, and, if favorably impressed, will close the deal, and immediately arrange for the building of a railroad through it to open up mines.

Indianapolis, Ind.—After long working of the coal fields of Greene, Clay and Sullivan Counties, it is reported capitalists are planning to push further south into Knox, Pike, Gibson and Warrick Counties and electric roads are being promoted. The most promising looking one at present will extend from Boonville to Lynnville and thence through Petersburg and Washington to Indianapolis. It is further said the Pennsylvania and Monon contemplate building into the new fields, the American Coal Co., supposed to be closely associated with the Monon, having leased several thousand acres of coal land in Knox County, near Wheatland.

Connellsville, Penn.—Steps are being taken to wind up the affairs of the Great Lakes Coal Co., which operates in Butler and Armstrong Counties. The company went into the hands of receivers some time ago, following a strike of its miners for a union wage scale and working rules. The property is now advertised for sale at auction in the Allegheny County court house, May 29. It consists of 22,133 acres of coal in Butler and Armstrong Counties, together with 685 acres of surface land, mines, tipples, etc., and 20,000 shares of stock of the Allegheny & Western R.R., at $50 par. It is likely that some effort will be made to reorganize the property and develop it.

Birmingham, Ala.—The Maryland Coal & Coke Co., recently organized, owns 15,000 acres of coal land in the Warrior field, about 30 miles west of Birmingham, which is being developed for a daily output of 2000 tons. The Frisco system is extending its Empire branch a distance of 7 miles to reach the scene of operations. A model mining town, consisting of 250 houses, is in the course of construction. Electric locomotives and mining machines will be used.

The seam which is being developed is known to the Warrior field as the Black Creek seam. It is 3 ft. thick, and is very hard. It is expected that shipments will begin between July 15 and Aug. 1.

COAL TRADE REVIEWS

GENERAL REVIEW

A distinct feeling of uncertainty pervades the hard-coal trade. May shipments, at some points, are falling behind those for April, with the result that there is not so much free coal offered as when the spring circular went into effect; requisitions at such points and for certain grades are subject to indefinite delays. On the other hand, rumors are current that some producers are experiencing difficulty in obtaining sufficient orders to cover their production, although such rumors are indefinite and have not been established. A period of mild depression during the mid-summer seems probable, but the situation is not to be regarded as serious, providing there is no pronounced cessation of industrial activity. Troubles between operators and miners has acted as a balance and tended to keep production down to the consumption.

In the coastwise bituminous trade, the larger buyers are beginning to lose hope of compelling the operators to recede from their higher prices on contracts and a few have signed up for a short period, evidently in anticipation that there will yet be a break in the market a little later. However, the trade, generally, is in better shape in all directions; less is heard about deferred buying, and operators, as a rule, continue withdrawing their bids, probably believing that they would rather curtail production for the time being, and have some free tonnage available when the higher prices prevail.

The Pittsburgh market is becoming steadily stronger with producers asking for substantial advances over the season's prices, although the regular circular is being maintained on contracts with old customers. The car supply is good, the lake shipments are steadily increasing, while production is at the highest point of the year, and would be still greater were labor conditions more favorable. It is seldom that buyers have ever been so eager, and there is nothing to check the heavy consumption except some highly adverse legislation is enacted by the new administration.

The accumulations at Hampton Roads are still about normal, but have been considerably reduced by a heavy movement into both the foreign and coastwise trade. Steam grades in the Southern market have become still heavier, with sales of small tonnages being reported at remarkably low figures; business such as this reflects adversely on the market. The domestic trade has become a trifle more buoyant, on the strength of a stocking up movement on the part of the dealers.

The Eastern producers are moving a heavy tonnage into the Middle West, where the dealers are anxious to acquire stocks while the summer circulars are still in effect. On the local coals, there has been a slight letup on domestic, with steam grades about normal; many contracts for the latter are being renewed. Dealers are pushing business while prices are low, and consumers are responding about as usual. Chicago has experienced some price cutting, with the result that quotations have fluctuated over a large range. There has been considerable contracting for Eastern fuels.

BOSTON, MASS.

Bituminous—On the whole the market is perceptibly firmer than a week ago. All reports are that Pocahontas and New River are being firmly maintained at $2.85 f.o.b., and this notwithstanding large accumulations at the Hampton Road piers. Corporation buyers are coming into the market for a share at least of their annual purchases, and there is a tendency to buy enough now to carry over into the season when concessions will be made, if there are to be any. The market is in much better shape in all directions, and it bids fair to continue so for the present at least.

The Pennsylvania coals of the better grade are well supplied with orders, and shippers are still withdrawing quotations left out a fortnight or more ago. Georges Creek is also firm on the season-contract basis; in fact, there are few weak spots all along the line. All-rail, and for inland shipment from tidewater points there is a decidedly better tone. Less is heard about deferred buying than was current a few weeks ago.

Water Freights are also somewhat firmer than when last reported; 75c. and 80c. have been paid this week for large vessels, Hampton Roads to Boston.

Anthracite—May shipments are so far very much behind those of April, and it looks like a month of relatively small tonnages. Loading is slowing up and the companies are not as free with the various sizes as they were at the opening of the season. Stove is notably short, and schedules calling for much of this size are entered subject to indefinite delay. Pea is also hard to get and New England dealers, especially those with relatively small storage, are getting apprehensive with such reports thus early.

Current bituminous quotations at wholesale are about as follows:

	Clearfields	Cambrias Somersets	Georges Creek	Pocahontas New River
Mines*	$1.00@1.35	$1.25@1.45	$1.67@1.77	
Philadelphia*	2.25@2.60	2.50@2.70	2.92@3.02	
New York*.	2.55@2.90	2.80@3.00	3.22@3.32	
Baltimore*	..	..	2.85@2.95	
Hampton Roads*				$2.85
Providence†				$3.73@3.78
Boston†				3.78@3.90

*F.o.b. †On cars.

NEW YORK

Bituminous—The soft-coal market continues in a rather lifeless condition without, however, any appreciable loss in strength. In view of the rather unfavorable conditions, operators are maintaining prices remarkably well. There appears to be a uniform restriction in production on the part of all large producers and a firm determination to obtain profitable figures for their product; when such prices cannot be obtained the business will not be accepted. Consumers are showing a disposition to buy for their current needs in the spot market in anticipation of being able to contract at lower figures later in the season.

Production at the mines appears to have fallen off slightly during the week, but this is probably only a temporary depression. Car supply, as usual, in times of light demand, is more than sufficient to meet requirements. Stocks at tide are about normal. Some odd tonnages of low-grade coal can be picked up in the market at very low prices, but such conditions are the exception rather than the rule, being due to some unusual features, such as demurrage. The market is not quotably changed from last week, which prices we continue as follows: West Virginia steam, $2.55@2.60; fair grades, Pennsylvania, $2.65@2.70; good grades of Pennsylvanias, $2.75@2.80; best Miller, Pennsylvania, $3.05@3.15; Georges Creek, $3.25@3.30.

Anthracite—Well defined rumors are current to the effect that some of the hard-coal producers are about caught up on their orders and will have to curtail production shortly unless more business appears. These conditions have not assumed definite or tangible proportions as yet, and, as a matter of fact, most companies have sufficient business on hand to keep them going steadily at maximum capacity up into July or August. Nevertheless, it is clear to all that there is not the customary activity on the part of the buyers, and there is a distinct undertone of uncertainty over the future of the summer business, but of not sufficient proportions to create any serious alarm over the situation.

Mines continue working up to full capacity, and the "button strikes" seem for the time to be less frequent. Monday of the current week was generally acknowledged as a holiday throughout the mining regions, and another occurs on the 30th of the month, which is Friday; this virtually means two days lost time since Saturday will doubtless see a very light force out, and the consequence is that production for the month will probably fall off below that for April.

The New York hard-coal market is quotable about on the following basis:

	Circular	Individual Lehigh	Individual Scranton
Broken	$4.60	$4.45	$4.50
Egg	4.85	4.80	4.85
Stove	4.85	4.80	4.85
Chestnut	5.10	4.95	5.00@5.10
Pea	3.50	3.30@3.35	3.35@3.50
Buckwheat	2.75	2.40@2.45	2.50@2.75
Rice	2.25	1.85@1.95	2.25
Barley	1.75	1.40@1.70	1.70

PHILADELPHIA, PENN.

The coal trade in this vicinity had a slight impetus early this week because of the weather which was the coldest experienced in this vicinity and at this time during the last forty years. It caused many anxious eyes to turn toward coal bins, and resulted in the consumption of considerable coal, which was supposed to be in the nature of a nest egg for next winter. The current business, however, still continues about the same as last week. There is no unusual call for coal, and dealers are being supplied regularly with all of their requirements. From the present indications, however, May is likely to absorb all of the production of the prepared sizes; steam grades still continue to be piled up in the storage yards of the large operators, the demand having fallen off considerably.

Taking it altogether, however, the month of May thus far has been as good as anyone expected, and possibly a little better, with the prospects of continuing so for at least the balance of the month. Up to the present, there has been less reports of concessions by the individual operators than has been the case in many years. The production continues on about a parity with May, 1911, and the little difficulties occurring between the operators and miners, mostly on account of some trivial difference, has had the effect of a balance wheel, in keeping the production within the demand. Considerable coal is still being diverted from the Eastern market into the Northwest, from the Lake shipping ports, and this in measure lessens the strain on the Eastern selling forces.

The bituminous market in this vicinity does not seem to improve as rapidly as was expected. The low ebb reached some weeks ago, was not followed by any appreciable increase in prices, but the demand is good. Optimistic views are expressed that the tangled market of the last two or three months, is the precursor of summer conditions at variance with the customary market at that time. Slack coal seems to be the most erractic, declining in some cases anywhere from 15 to 25c. per ton, and the demand not particularly active at that.

PITTSBURGH, PENN.

Bituminous—The market is still stronger. While the majority of operators are asking an advance of 10c. over season prices to buyers not their regular customers, as noted a fortnight ago, prompt lots are frequently quoted at as much as 20c. advance. On regular contract trade, however, the circular prices continue to be done with favored buyers. Production is on a slightly heavier scale, and is at the best rate of the year, but would be still greater if labor were in a more equable mood. There is much unrest, which is growing and promises unusual difficulty for the next scale settlement, for the period beginning Apr. 1 next, while the occasional local outbreaks do not become less frequent. Car supply is fairly good, there being complaint in a few quarters. Lake shipments are increasing week by week. We quote: Slack, 90c.; nut and slack, $1.05; nut, $1.25; mine-run, $1.30@1.40; ¾-in., $1.40@1.50; 1¼-in., $1.55@1.65, per ton at mine, Pittsburgh district.

Connellsville Coke—The trade is remarkably steady, having shown no definite change for three or four weeks, which is quite unusual with so mercurial a market. The majority of operators have their minds set on $2.25 for prompt furnace coke and $2.50 for contract. There being light demand for prompt, this has resulted in slight shading, generally to $2.10 to $2.20, with only occasional sales at $2 and few, if any, at the regular asking price of $2.25. The contract asking price might be similarly shaded if consumers were forced to act, but they are not. No contract business needs to be placed for delivery beginning earlier than July 1, and furnaces expect more than a small concession from the asking price. Prompt foundry coke has weakened slightly by operators not usually making this grade offering limited quantities at cuts from $3, which has been the minimum asking price of regular markets, some adhering to $3.25. We quote the market: Prompt furnace, $2@2.25; contract furnace, $2.50 asked; prompt foundry, $2.85@3.25; contract foundry, $3@3.25, per ton at ovens.

BALTIMORE, MD.

There has been a great demand for gas coals in the local market, particularly the better grades and shipments to the West have also been unusually heavy with the result that a scarcity has developed in the Eastern market. Operators having loose tonnages available for this Western demand have been obtaining a much better profit and the indications are that this has become a permanent feature of the local trade. This condition has brought about a much freer buying movement which is being further stimulated by the general belief that there will be a tremendous car shortage the coming fall. Screened gas coal is quoted at $1.25@1.40, mine-run $1@1.30, with slack at 80@90c. per ton.

The lower grade gas coals are in poor demand and are as weak or weaker than the same grades of steam fuel. The better quality steam fuels are in short supply; the majority of these have been contracted for and consumers who buy in the spot market may find themselves in difficulty before long. Big Vein Georges Creek is now selling around $1.60 with the next better grades, such as Tyson and Quemahoming being quoted at $1.25 to $1.35.

Reports are generally to the effect that practically all of last year's contracts have been signed up again. Coastwise and export shipments from the local piers were unusually heavy during the week. Coke is weak and the output further reduced.

BUFFALO, N. Y.

There is a good demand for all grades and sizes of bituminous coal. Mindful of tariff agitation and the uproar of strikes, in Buffalo at least, the members of the coal trade are much pleased at the activity in the local market. Slack, which often begins to show weakness as summer approaches, is fully as strong as sizes. But for the weakness in coke there would be a uniform strength in the trade. There is a difference of opinion as to the reason for the lack of activity in coke. Some say there is an over-production and others that the iron trade is not in a satisfactory condition. There is iron enough in consumption, but the price is not satisfactory.

Another reason for a good bituminous demand is the continued shortage of miners. Scarcely a mine represented here has men enough to satisfy its needs and in some instances where an operator has a good many contracts he has difficulty in filling them.

There seems to be a general belief that politics or disturbances of any sort are not going to reduce the general consumption and so long as that remains the coal must be provided. Buffalo, for instance, is building as never before and the locomotive works at Dunkirk reports a large order of locomotives just taken and so on. The tariff bill as passed by the House is detrimental to the local trade but business goes on as before and it is seldom that buyers are so eager for shipments unless they are trying to stock up. The trade sees no likelihood of a dropping off in demand.

Bituminous prices are, therefore, strong at $2.80 for Pittsburgh lump, $2.65 for three-quarter, $2.55 for mine-run and $2.15 for slack. Coke is plentiful and weak at $5 for best Connellsville foundry. There is no change in the price of smithing or cannel.

The Anthracite Trade is still quiet. Shippers speak of it as healthy but they do not look for a brisk demand again till fall. Consumers feel easy and are mostly well supplied with coal bought late last winter. The week's shipments of anthracite from Buffalo by lake were 132,000 tons.

COLUMBUS, OHIO

With an expanding lake trade and a good demand for steam grades, the coal trade in Ohio has been firm and active during the past week. Prices with the exception of the fine grades, have been well maintained and coal men generally believe the business will continue active for some time to come. No price cutting of any consequence is reported.

One of the best features is the larger requisitions from manufacturing concerns. Business generally shows improvement and this is reflected in larger orders from many lines of manufacturing, especially iron and steel mills. Railroads are also taking a larger tonnage since the troubles resulting from the flood are passing away. Some congestion is still reported at junction points but the movement of freight is now prompt.

A number of the railroad fuel contracts were made during the past week and they were generally at a marked advance over the quotations of last year. In some cases the contracts were awarded with a provision for an increase of 5c. on the ton toward the latter part of the year. All steam contracts renewed at this time are at higher figures than last year.

The lake business is one of the most active branches of the trade. Outside of some congestion at the upper lake ports, no trouble is experienced. The congestion, which it is believed will only be temporary, was caused by the movement of dozens of boats at the opening of navigation and consequently a lack of unloading machinery at the head of the lakes. When the movement becomes more uniform the congestion will be relieved.

There is practically no demand for domestic grades, although dealers are making preparations for an active consumption somewhat earlier than usual. This is due to the

fact that the flood caused dealers to sell out stocks closer than usual.

The output in Ohio fields during the week has shown a good increase. This is especially true in Eastern Ohio where the production is up to normal and about capacity. In the Hocking Valley district it is about 90 per cent. of the average. In the Pomeroy Bend field where the greatest damage was done by the flood, the output is about 65 per cent.

Quotations in the Ohio fields are as follows:

	Hocking	Pittsburgh	Pomeroy	Kanawha
Domestic lump	$1 50	.....	$1 50	$1 50
¾-inch	1.35	$1 20	1.35	1.30
Nut	1.25	.....	1.25	.....
Mine-run	1.15	1.10	1.15	1.10
Nut, pea and slack	0.70	.....	0.70	0 70
Coarse slack	0.60	0.70	0.60	0.60

HAMPTON ROADS, VA.

The movement of coal from tidewater during the past week has been very satisfactory; there have been some large shipments both coastwise and foreign and the accumulation of cars in the railway yards has been considerably reduced, although there still remains more than the normal quantity. Quite a fleet of vessels remain at anchor off Lamberts Point and at Newport News, waiting berth, and these, together with others now due, should keep both piers working to their full capacity during the coming week. Shortage of labor has somewhat delayed loadings at Newport News and the large number of bunker steamers arriving at Lamberts Point have kept the berths occupied, coastwise tonnage suffering accordingly.

Prices for the week have remained firm with some small sales at $2.80 for prompt shipment. The Government has loaded into colliers during the past week approximately 15,000 tons from various shippers which is, of course, all contract coal. Dumpings at Sewalls Point have been good and there is no accumulation of tonnage in the stream.

BIRMINGHAM, ALA.

Not much can be added to our last week's report on conditions obtaining in the coal trade in Alabama. Steam coal business is still depressed to the extent that some extraordinarily low prices are being quoted, and while this tonnage is not large the entire steam market is suffering from the effect.

A shortage of coal cars on one of the largest railroads in the district is growing more serious daily, a number of the mines on that line having lost from 20 to 35 per cent. time during the past two weeks. This condition is not quite understood by the operators as the railroad in question is in a financial position to secure all the equipment needed. A slight improvement is apparent in the domestic coal market. Prices are firmer and dealers are taking in a normal supply of stock coal.

LOUISVILLE, KY.

Indications point to a general easing up in the situation here. Local prices have fallen off to the customary summer level with the better grades of domestic lump selling at $4, but this general reduction has failed to bring about any responsive demand. Dealers themselves are doing but little stocking. In view of the curtailed work at the mines it is rather surprising to note that the shortage of screenings has at last been overcome and this in spite of the fact that the demand continues rather brisk.

The customary summer circulars are in effect which means that consumers buy at practically their own figures. It is a notable fact, however, that prices are almost invariably held at an advance of 10c. over last year's figures; the steam grades are showing even more substantial advances than this. The better grades of eastern Kentucky block are quoted at $1.85 f.o.b. mines, although this figure would be rather high in the larger competitive centers. The poorer qualities are from 25 to 40c. below this figure. Nut and slack are heavy at 70 to 90c. for the better grades with western Kentucky selling at 75 to 85c., and pea and slack are 35 to 45.

INDIANAPOLIS, IND.

Coal operators see some slight let-up in industrial activity, apparently, but not enough to excite comment. Sales of steam grades are not materially smaller than usual in May; mines are working about half time and their shipments of the domestic grades are practically nil.

Eastern mines are moving domestic into this state, retailers wishing to take advantage of the summer schedule of prices. This is particularly true of anthracite and Pocahontas and some Virginia splits that rise in price monthly. Other Ohio and Virginia coals that hold to about one level from April to September are not moving so freely at present. Indiana domestic can be shipped to the retail points in a day from the mines, and retailers do not stock up until fall, October usually being the best month. Freight rates are a handicap to steam grades from other states, but to those points in the state where the home rate runs 60 to 80c., considerable shipments of steam grades come from nearby states.

Screenings are selling around 90c., with a range of 10c. for quality and urgency of demand. Indianapolis retailers are pushing business while prices are low and customers are responding better than usual, following their experience of the last winter when prices were at record marks. While the buying will not be large in May, which is usually a breathing spell for the consumer after the winter's drain on his finances, there are indications that the succeeding months will find the retail trade active. Mine prices are unchanged.

Local dealers came down May 1 to their summer schedule, though they would not guarantee the present level to last longer than June 1. The new prices are:

Anthracite, chestnut	$8 00	Hocking Valley lump	$4 50
Anthracite, stove and egg	7 75	Luhrig lump	4 50
Anthracite, grate	7 50	Luhrig washed egg	4 75
Pocahontas, forked lump	5 50	Cannel	6.50
Pocahontas, shoveled lump	5 00	Linton No. 4 lump	3 25
Pocahontas, mine run	4 00	Linton No. 4 egg	3 25
Pocahontas, nut and slack	3 50	Indiana washed egg	3.50
Blossburg	5.50	Brazil block	4.00
Jackson (Ohio)	5 25	Indianapolis lump coke	6 00
Kanawha lump	4 50	Indianapolis crushed coke	6.00
Kanawha egg, nut	4 50	Connellsville lump	7.00
Pittsburg lump	4 50	Citizens' egg coke	6 00
Raymond lump	4 50	Citizens' nut coke	6.00
Winifrede lump	4 50		

DETROIT, MICH.

Bituminous—The local market is rather quiet, and, while spot prices continue unchanged, the trade is undeniably weak and liable to sharp break should there be any unusual overshipments. There is no change in the contract situation, buyers still holding off in the hopes of a break in the new high prices of the year. Operators are equally determined in their position in the matter, and just what the outcome will be is difficult to anticipate at the present moment.

It is stated at some points that dealers are slow about closing for smokeless coal for domestic purposes, because of the particularly high prices demanded on contract. Some buyers, however, report that they have signed up for as much of this grade as they require.

Market quotations are as follows, f.o.b. mines:

	W. Va. Splint	Gas	Hocking	Cambridge	No. 8 Ohio	Pocahontas	Jackson Hill
Domestic lump	$1.50	....	.....	.....	.....	$2.25	$2.00
Egg	1.50	....	$1.35	.....	.....	2.25	2.00
1½-in. lump	1.25	.....	.....	.....	.....	.....	.....
¾-in. lump	1.20	$1 20	$1.20	$1 20	$1.20	.....	
Mine-run	1.10	1 10	1 10	1.10	1 10	1.50	
Slack	1.00	1.00	1.00	1.00	Open	Open	

Anthracite—The hard-coal market in this vicinity has been heavily over-shipped, and the trade is dull. The large movement in March and April, which was succeeded by an almost unprecedented spell of mild weather, restricting consumption down to the smallest minimum in all the contiguous territories, has left the dealers and consumers overstocked almost without exception. Some dealers are buying sparingly, but the tonnage is light; the stimulation which ordinarily follows the reduced circular, has not been felt at this time.

Coke—Connellsville coke is quoted at $3.10, Semet Solvay, at $3 f.o.b ovens, with the trade comparatively active and strong.

CHICAGO

There is a wide range of prices prevailing in the Chicago coal market due to a variety of reasons. One of the chief factors has been a marked increase in competition which resulted in deep cuts in selling prices by a number of operators and dealers. In the Franklin County domestic trade the larger producers are demanding $1.35 for spot shipment and from $1.35 to $2 on contracts. Other operators are offering a much lower series of prices. There are some producing companies selling Carterville coal at $1.40, the mines, for domestic lump and $1.65 for No. 1 washed coal. On the other hand, a few of the operators in this field will accept prices ranging from 25c. to 35c. a ton lower.

A large number of contracts are being let for Eastern coals. Prices, generally, are good. A comparatively small volume of smokeless is reaching the Chicago market owing to a light demand. On account of a curtailment in production, the supply of coke at present is scarce and the market for this commodity remains firm. There is a strong demand for steam coal. Announcement has been made of an advance in the price of screenings of about 5c. a ton.

Coke—Connellsville and Wise County, $5.25@5.50; byproduct, egg, stove and nut, $4.55@4.75; gas house, $4.65@4 75.

Prevailing prices in Chicago are:

	Springfield	Franklin Co.	Clinton	W. Va.
Domestic lump	$1.97@2.07	$2.30@2 40	$2 27	
Egg		2.30@2 40		$3.65
Steam lump	$1 82@1 87		2 07	
Mine-run	1 77	2.20@2 30	1 97	3.30
Screenings	1.57	1.95	1.57@1.62	

MINNEAPOLIS—ST. PAUL

The all-rail business is extremely light at this time. There is not an over amount of coal pressing the market as many mines have been closed more or less of late, owing to floods. Prices on Harrisburg are quoted at $1.30 to $1.40 for lump and egg; the price for mine-run is $1.20. Screenings are scarce, and the price now is $1 at the mines, with contract price at 80c. Other grades of Illinois screenings are hard to get and, at the docks, it will be some time before enough screenings can be worked through.

ST. LOUIS, MO.

The usual dullness in the spring trade prevails in St. Louis and adjacent territory. There are a few calls for contracts in steam lines, but other than that very little is doing, and contracts are not looked upon with favor by shipping interests.

There is a slight increase in the prospects for the anthracite movement this month, and some inquiries for smokeless. The coke market, however, is dull. Screenings, still sell for 80c. at the mines and Carterville at $1. The washed coal market seems to be holding its own, with No. 3 and No. 4 in extra good demand. There is also some call for Arkansas anthracite, but not to the extent as in former years.

The prevailing circular is:

	Carterville and Franklin Co.	Big Muddy	Mt. Olive	Standard
2-in. lump				$0.90
3-in. lump			$1.20	
6-in. lump	$1 15 @ 1.20		1.25	1.05
Lump and egg		$2 25		
No. 1 nut	1 05 @ 1 15			
Screenings	0 90 @ 0.95			0 85
Mine-run	1 00 @ 1 10			0.80
No. 1 washed nut	1 35			
No. 2 washed nut	1 35			
No. 3 washed nut	1 35			
No. 4 washed nut	1 35			
No 5 washed nut	1 10			

St. Louis prices on May anthracite are: Chestnut, $7.50; stove and egg $6.80; grate $6.55. Smokeless lump and egg is $4.45 and mine-run $4. By product coke is $5 and gas house $4.75.

OGDEN, UTAH

The Utah operators seem to have been the prime factor in reduction of price f.o.b. mines. They have either solved the secret of cheap mining and wish to give the public the benefit or are endeavoring to force their coal on the market.

No dealer cares to store coal in May for three principle reasons: First, because there is no demand while there are a lot of unpaid accounts on the books covering winter coal, which means money tied up; second, the depreciation on the coal and interest on the money invested is greater than the reduction in price f.o.b. mines; third, because there is no reason for buying coal in May when it can be obtained at the same price in July and August. Consequently, during May, about the only coal bought will be for current demand and, of course, will be sold at the storage price.

PORTLAND, ORE.

Utah mines have announced the reduction of 25c. per ton for coal during the storage season and the delivery price here in five-ton lots or over is now $9.50 per ton. Dealers expect that Wyoming mines will announce a similar reduction within the near future. There has been no change in Australian coal quotations here since last fall. This is the quietest time of the year in the coal business here and no great amount of business is anticipated for some weeks. The market is steady, however, and values fully as high as at the corresponding time a year ago.

PRODUCTION AND TRANSPORTATION STATISTICS

SOUTHWESTERN TONNAGE

The following is a comparative statement of the southwestern tonnage for February and the first two months, 1912 and 1913:

State	February 1912	February 1913	Two Months 1912	Two Months 1913
Missouri	305,759	260,586	587,212	566,411
Kansas	501,121	414,413	1,039,049	938,018
Arkansas	176,210	130,888	431,876	313,536
Oklahoma	267,731	297,004	616,713	663,863
Totals	1,250,821	1,102,891	2,574,850	2,482,82

ANACONDA COPPER MINING CO.

The following is a comparative statement of this company's coal production over the last three years:

	1912	1911	1910
Coal produced	837,815	800,073	828,531
Shipped to other departments	514,208	508,913	449,421
Sold	244,685	316,647	309,242
Used at coal mines	78,922	74,513	69,868

THE CAR SITUATION

American Ry. Association reports surpluses and shortages of coal equipment for two weeks ended May 1, as follows:

	Surplus	Shortage	Net*
New England Lines	75	150	75
N. Y., New Jersey, Del.; Maryland; Eastern Penn	4,036	451	**3,585**
Ohio; Indiana; Michigan; Western Pennsylvania	230	1,340	1,110
West Virginia, Virginia, North & South Carolina	779	1,369	590
Kentucky, Tenn.; Miss.; Alabama, Georgia, Florida	222	295	73
Iowa, Illinois, Wis., Minn ; North & South Dakota	1,519	35	**1,484**
Montana, Wyoming, Nebraska	592	0	**592**

Canadian Lines	114	0	**114**
Totals	12,243	3,733	**8,510**
Greatest surplus in 1912 (Apr. 25)	94,692	2,144	**92,548**
Greatest shortage in 1912 (Oct. 10)	6,491	14,897	8,406

*Bold face type indicate a surplus.

FOREIGN MARKETS

GREAT BRITAIN

May 2—The miners at several collieries have not yet resumed work after the May-Day labor demonstration, but the general impression is that these stoppages will not last for long. The prevailing market is as follows:

Best Welsh steam	$5.10@5.22	Best Monmouthshires	$4.56@4.68
Best seconds	4 92@5.04	Seconds	4.44@4 50
Seconds	4.74@4 86	Best Cardiff smalls	3.48@3.60
Best dry coals	4.74@4 92	Seconds	3.48

The prices for Cardiff coals are f.o.b. Cardiff, Penarth or Barry, while those for Monmouthshire descriptions are f.o.b. Newport; both exclusive of wharfage, and for cash in 30 days—less 2½%.

COAL SECURITIES

The following table gives the range of various active coal securities and dividends paid during the week ending May 10.

COAL AGE

Vol. 3 NEW YORK, MAY 24, 1913 No. 21

THE coal industry has many members with axes to grind.

Some men are flatterers by constitution. They have no real conception of the true meaning of such words as wonderful, magnificent or marvelous. Due allowance must be made for all they say, and criticism of their effulgent praise should be governed by a generous recognition of their innocent and unassumed but unfortunate fault.

There are other people interested in some phase of coal mining, however, who are not flatterers by nature, and who sweeten their tongues with a motive always in view. They are like the fox who wanted the morsel of food which was held in the crow's bill. He expressed regret that the bird should have a poor voice coupled with such beautiful plumage. The crow, intending to refute the charge, released the prize, which the fox picked up, remarking: "Your voice is all right, but your wit is wanting."

The wisest man in ancient history once remarked: "He who flattereth his neighbor spreadeth a net for his feet." When a man commences an interview with the gift of a choice cigar, or hands out a fraternal grip, you can feel fairly certain there's to be a swapping of favors, in which transaction the other fellow intends to be sole referee as to the nature of both articles exchanged in the trade.

It's more decent to present your cigar or hand out your fraternal grip at the close of a business interview. Clubs, lodges and mining institutes are essential to good fellowship, rapid progress and business convenience; but the man who joins such an organization *simply and solely* to exploit his brother man is lacking in those principles which command success through personal merit or individual worth.

Here and there we can point our finger at some man high in the councils of coal men, who gained his undeserved success through influential friends or unworthy and shameful affiliations; however, there is no doubt but that the best pull is that of our own right arm. Only when it is weak do we need a lodge grip at the end of it.

Although we live in the most commercial age history has ever recorded, and are a part of the most commercial nation the sun ever shone on, there is still room for friendships not built on a money foundation with the single idea of promoting the transaction of business.

Personal pride, if nothing more, should compel us to refrain from insincere flattery to gain a point; and natural vanity in our own strength and ability to accomplish things should cause us to refuse an advantage coming only through the avenues of pull or social affiliations.

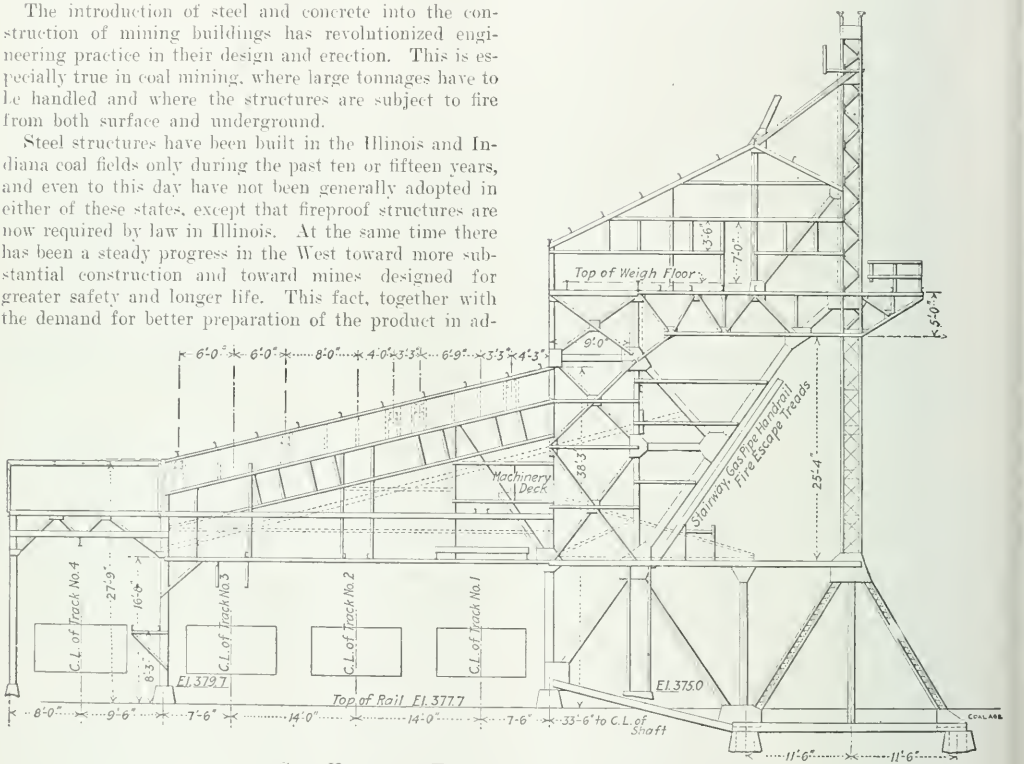
Modern Steel-Tipple Design

By John A. Garcia*

SYNOPSIS—The steps of evolution leading up to the introduction of an improved construction of headframe and screening plant are here delineated. This new design is only about one-half the weight of its predecessors and yet so rigid and firm that an independent screen-supporting framework is unnecessary.

The introduction of steel and concrete into the construction of mining buildings has revolutionized engineering practice in their design and erection. This is especially true in coal mining, where large tonnages have to be handled and where the structures are subject to fire from both surface and underground.

Steel structures have been built in the Illinois and Indiana coal fields only during the past ten or fifteen years, and even to this day have not been generally adopted in either of these states, except that fireproof structures are now required by law in Illinois. At the same time there has been a steady progress in the West toward more substantial construction and toward mines designed for greater safety and longer life. This fact, together with the demand for better preparation of the product in addition to the more recent requirement of law, has led to an interesting development in this line of engineering.



Side View of a Typical "A. & G." Steel Tipple

Importance of Shaft and Tipple

The keystone of a mining installation is the shaft and tipple. These are the connecting links between the underground workings and the commercial market, and it is natural that the best efforts of engineers have been devoted to securing permanence and safety from accident in these most important parts of a mining plant.

In the old days the shaft was put down in the cheapest possible manner, small, cramped and timber lined, and the tipple was placed immediately on the curbing or in some cases just outside of it. This structure usually consisted of six heavy, vertical timbers placed at the corners of the two hoisting compartments, braced laterally by batter braces and carrying the sheave wheel on cross timbers at the top. A heavy timber brace was then framed between the sheave deck and the engine foundations. The weighhouse was supported by similar bents placed between the tracks, and the screens were hung or supported underneath and covered by a loading shed.

When shaker screens began to come into use, it was found necessary to support them on an independent interior structure, as it proved difficult to produce and maintain a timber frame of sufficient rigidity to prevent the vibration of the screens from affecting the scales and seriously damaging the main building. On this account also, it became common practice to carry the screens on various systems of rollers, instead of hanging them as formerly, in order to avoid the great heights of the necessary overhead structure.

The first steel tipple followed almost exactly the lines of the accepted design in wood. At least six steel columns were placed on or adjacent to the curbing, the screens were carried on an independent structure and the batter braces connected as formerly, and the whole structure interwoven with a network of light angle bracing.

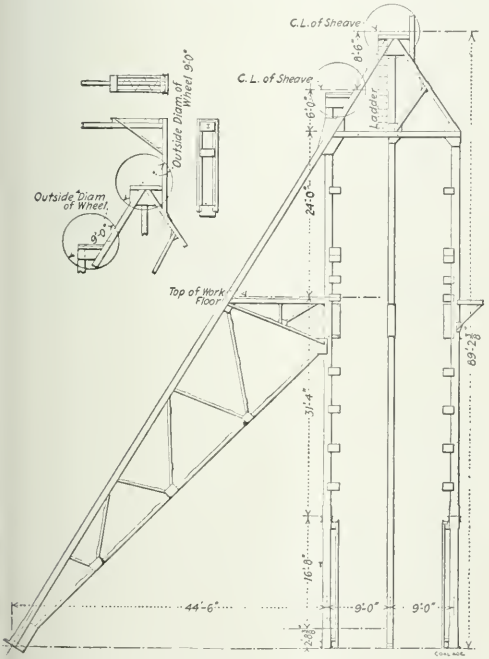
The actual working stresses in the tower were found

*Of Allen & Garcia Co., Chicago.

to be surprisingly small, and the required sections were made correspondingly light. The first designers did not realize that steel is an elastic material and that a structure of sufficient theoretical strength would lack entirely the rigidity necessary for satisfactory operation under the shock of hoisting and dumping and the constant vibration of the screens.

It is not surprising, therefore, that the first steel structures were distinctly less rigid and satisfactory than their wooden predecessors. They had just one advantage—they were fireproof. The freedom from shrinkage and rotting was offset by the rusting of the metal and the extreme liability of the light members to damage from accident.

Any damage to the shaft, any settlement around it, or fire in the curbing, had almost as destructive an effect



Front View of Hoisting Tower, Showing Simplicity of Construction

on the tipple as if it had been built of wood, and the operators rightly began to wonder whether even the small increased cost of steel over wood was worth while.

The First Superior Steel Tipple

The first step toward the construction of a steel tipple distinctly superior to wood was in the adoption of the "A-frame" design, in which the legs of the tower are carried onto firm ground well away from the shaft. Another improvement introduced about the same time consisted of crossing the tracks with a clear span and carrying the screens on a bridge so as to avoid the inconvenience and danger of columns located between the tracks.

The "A-frame" tipple, while a distinct improvement over previous designs, and greatly superior to the wooden structure in strength, permanence and rigidity, had some serious drawbacks. The guides had to be carried inside of a widely spreading tower by means of substantial horizontal frames, which, even if of sufficient strength, were particularly liable to damage and corrosion. Even at the best they added greatly to the cost of the structure. In this respect the old form of six-column tower, when the footings are carried a sufficient distance outside the shaft, still has an advantage over the "A-frame," although this advantage is entirely neutralized by the greater complexity of the structure.

In all these designs the independent screen structure was a uniform feature. The effect of the vibration of the screens was so little understood and so inadequately analyzed that none of the designers appeared to be brave enough to break away from the prevailing practice and plan a structure that should be stiff and strong and with the unavoidable vibration so localized that no damage could come to the structure or inconvenience to the operation of the scales.

In the meantime, there came a development in the direction of concrete or concrete-lined shafts. Such construction not only removes the danger of fire, but makes the shaft curbing, in most cases, the best and most substantial as well as the least expensive foundation on which to place the tower. The principal advantage of the "A-frame" structure was thus removed.

The Introduction of a New Design

About two years ago, the Allen & Garcia Co., of Chicago, took up the problem of building a tipple over a concrete shaft and decided to place the main column members directly on the curbing. A system of construction was evolved and protected by patents, which seemed to be a distinct improvement over any previous construction. So simple was it that the only wonder is that it was not devised long before; in fact, the only reason that can be assigned is found in the gradual steps outlined above, from which the steel tipple was evolved.

Instead of putting uprights at the corners of the shaft, two main columns are placed in the middle of the curbing at either end, just back of the guides, these members themselves being carried directly by, or bracketed from, these columns. The center guides are also carried by a vertical column directly between them, it being hung from the main structure so as not to rest on the buntins and bracketed at several points so as to have ample lateral and longitudinal stiffness.

When adapted to an end-hoist tower, the sheaves are carried directly on an "A-frame" of the same width as the column, the forward leg of which is carried down to the ground in a line outside of the resultant of the cable stress. All columns are made of such width as will insure sufficient lateral rigidity when unsupported throughout their length, and also carry the journal bearings of the sheaves.

The main structure carrying the weighhouse and screens is built over the tracks at right angles to the hoisting frame and designed so as to give the greatest possible rigidity to the tower and to carry the shock of dumping directly to the ground.

With this tower of extreme rigidity, it is an easy matter to design a screen structure so stiff that the vibration of the shakers will have little or no effect upon it and the screens can then be hung on properly journaled, rigid hangers so as to operate with only a small part of the friction and wear incident to roller supports. The

eccentrics or other operating mechanism for the screens may then be supported on cross members, so that any vibration arising from them will be entirely absorbed before being communicated to the main structure.

The advantages of this construction are many. In the first place, the main tower is composed of three heavy and substantial members, which can be incased in concrete, so as to protect them entirely against accident or corrosion. Second, the weight and cost of the main tower, in spite of its great strength and rigidity, is scarcely half that of a properly designed "A-frame" tower. Third, the shaft is left entirely clear at the bottom of the tower, so that rails and other material can be easily loaded on the cages. Fourth, the foundations are cheapened and cut down in number. Furthermore, a screen house of sufficient stiffness can be rigidly connected to the main structure. Fifth, the guides are attached direct to the tower columns and form a stiff, rigid slide for the cages from shaft to dumping point; all at a less cost than the former style of construction.

In working out the details of this new type of structure, which has been christened "the A. & G. Patent Tipple," it became necessary to make a careful analysis of the action and operation of the screens. The first requirement is to design the shakers so that they will be as nearly balanced as possible under the varying conditions of load. This can usually be accomplished by making the upper section of the screen which receives the coal somewhat shorter and lighter than the lower section.

In studying the forces acting upon the screen through the driving rods, it became evident that it was possible to devise a much better operating mechanism than the time-honored eccentric, which is, as all engineers know, an inefficient and troublesome appliance for transmitting power. We have, therefore, substituted a bell-crank device, operated by driving rods from two large flywheels, which have been found to perfectly balance the two sides of the screen.

The power factor is thus made so constant that the motor or engine can be direct-connected to this shaft and as the whole mechanism is self-contained, the resulting vibration is small. The driving rods have brass journal bearings of ample size, arranged for thorough lubrication, and the ratio of lever arms is such that the forces are greatly reduced before reaching the driving rods and the flywheels.

While it is admitted that these changes are somewhat revolutionary, they are based on established mechanical principles, and are only a beginning of what can be done in transforming the old-style coal-mining plant into a simple, efficient and economical machine.

Adaptation to Timber-Lined Shafts

The next step was to adapt the "A. & G." construction to a timber-lined shaft, and this has proven to be unexpectedly easy. It is only necessary to carry the two main columns on a low "A-frame," or even on steel beams to any desired distance from the shaft curbing. Next comes the adaptation of this construction to the "side hoist," which may be required under certain conditions, and here it is also possible to use two main guide columns instead of the old-style six-column construction or the "A-frame," and to obtain the same advantages with a little economy.

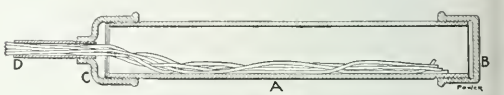
The perfect balancing of the screens and the accomplishment of proper separation for large tonnages especially, can be greatly facilitated by the introduction of an automatic feed hopper, which allows the coal to flow to the shakers at a uniform rate, thus avoiding the rush of imperfectly screened coal, so common when large amounts are dumped directly on the screen from the weigh-pan.

Space will not permit of the discussion in detail of these important questions, but the advantages of scientific designing are such that the sales department will find it increasingly difficult to market coal and show a yearly profit in competition with the operator who has taken advantage of the latest improvements in tipple construction and screening equipment.

Torch for Boiler-Inspection Work

The following description of a home-made torch, written by J. F. Mowat, of Joliet, Ill., appears in a recent issue of *Power*:

Some time ago there appeared in *Power* a description of a holder for a lamp to be used inside boilers. This ingenious arrangement brought to my mind a torch (by no means a new one) in use for the same purpose, which, possibly, does not require the care necessary with the lamp, as this torch burns equally well in any position.



Section of Home-Made Torch

One advantage of this torch, aside from the great convenience in inspecting boilers and in working in any dark restricted place, is the ease with which it may be made. Its great simplicity puts it within the reach of any handy man who has access to a hacksaw, a set of pipe dies, a vise and a few pipe fittings.

The illustration shows probably the most convenient size. A piece of 1¼-in. brass pipe *A* has a cap *B* on one end and a 1¼x⅜-in. reducing coupling *C* on the other. Into the coupling is screwed a ⅜-in. nipple *D*, about 2 in. long. A few strings of lamp wicking long enough to reach the bottom, complete the torch. Unscrew the coupling from the pipe, fill with kerosene oil, and it is ready for use.

British Coal Statistics

According to advance proof sheets of government statistics (the figures in which are subject to correction), the largest coal production of any county in England for the past year was for Yorkshire with 38,491,000 tons. Durham was second in production with 37,890,000 tons; Glamorgan was third, with 33,727,000 tons. Northumberland produced 13,381,000 tons.

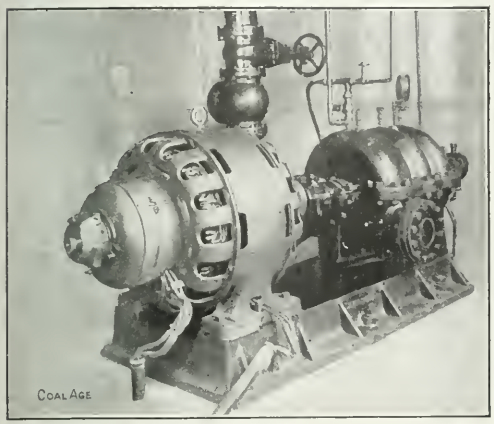
Each of these districts showed a decrease in yield from the previous year, due, of course, to the strike, but this falling off is less than might be expected when the duration of the stoppage is borne in mind.

The number of miners in Yorkshire slightly exceeds 161,700; Durham has 169,600 and Glamorgan has over 151,700 miners.

A Relay System of Pumps

The accompanying illustration shows an underground pump house of the Homestake Mining Co., at Lead, S. D. In this mine the arrangement of pumps is what might rightfully be termed a relay system, since the water is removed in a series of lifts.

The shaft is 1400 ft. deep and is supplied with pumping stations placed approximately 300 ft. apart, each station being equipped with two units, one of which is held constantly in reserve.



ONE OF THE UNITS AT ONE OF THE LOWER STATIONS

The amount of water handled by each pump is 1000 gal. per minute, and the head is approximately 325 ft. for the 1400-ft., 1100-ft., 800-ft. and 500-ft. levels, while this amount is reduced to 200 ft. for the pump placed nearest the surface. Each level is provided with a sump from which the respective pumps draw their supply.

Each of the four lower pump stations contains two Jeansville multi-stage centrifugal pumps of the double-suction type. These are direct-connected to 125-hp. Westinghouse, 3-phase, 60-cycle, 220-volt motors, operating at 1745 r.p.m., while the station at the 200-ft. level has pump units similar to the others in capacity, but with fewer stages and operating against a lower head.

Coal-Mine Accidents Report

(U. S. Bureau of Mines)

The coal-mine accidents occurring in the United States during the year 1912 have been compiled by the United States Bureau of Mines under the direction of Frederick W. Horton. The publication, which is now ready for distribution, is a résumé of the accidents from 1896 to 1912, inclusive, together with monthly statistics for the year 1912.

Mr. Horton, in reviewing the year, says: "During the calendar year 1912, there were 2360 men killed in and about the coal mines of the United States. Based on an output of 550,000,000 short tons of coal produced by 750,000 men, the death rate per 1000 employed was 3.15, and the number of men killed for every 1,000,000 tons of coal mined was 4.29. The number of men killed was the least since 1906; the death rate per 1000 employed was the smallest since 1899; the death rate per 1,000,000 tons of coal mined was the lowest, and the number of tons of coal produced in proportion to the number of men killed, the greatest on record. These facts offer indisputable evidence that conditions tending toward safety in coal mining are actually improving and that coal is now being mined with less danger to the miner than ever before.

"The general improvement in 1912, as compared with 1911, is shown by the following facts: In 1912 the number of men killed in the coal mines of the United States was 359 less than in 1911—2360 as compared with 2719—a decrease of 13.2 per cent., and this in spite of the fact that there were more men employed in the mines and more coal mined than in any previous year. The death rate per 1000 men employed in 1912, was 3.15 as against 3.73 in the previous year, a decrease of 15.5 per cent. During 1912, for every 1,000,000 tons of coal mined, 4.29 men were killed, as compared with 5.48 men in 1911, a decrease of 21.7 per cent. There were 233,000 tons of coal mined, for each man killed in 1912, as compared with 183,000 tons in 1911, an increase of 50,000 tons or 27.3 per cent.

"Although the improvement in 1912 was greater than in any previous year for which accurate statistics are available, partly due, perhaps, to the exceptionally mild weather during the last few months of the year, which decreased the likelihood of disastrous coal-dust explosions, there has been an annual improvement for a number of years, as indicated by the accompanying table:

NUMBER OF MEN KILLED IN AND ABOUT THE COAL MINES OF THE UNITED STATES, IN THE CALENDAR YEARS 1907 TO 1912, INCLUSIVE, WITH DEATH RATES

Year	Number Killed			Production per Death, Short tons
	Total	Per 1000 Employed	Per 1,000,000 Short Tons Mined	
1907	3197	4.88	6.93	144,000
1908	2449	3.64	6.05	165,000
1909	2668	4.00	5.79	173,000
1910	2840	3.92	5.66	177,000
1911	2719	3.73	5.48	183,000
1912	2360	3.15	4.29	233,000

"It will be noted from the foregoing table that the death rate per 1,000,000 tons of coal mined has decreased annually; that the production per death has increased each year since 1907, and that the death rate per 1000 men employed has steadily decreased during the last four years.

"This general improvement has been brought about by a combination of causes, the principal one of which has been more efficient and effective mine inspection on the part of the state mining departments and state mine inspectors throughout the country, supplemented by greater care on the part of both the operators and the miners. The investigative and educational work of the Bureau of Mines has kept both the operator and the miner alive to the various dangers connected with coal mining and has shown what precautions should be taken to avoid these dangers.

"Although there has been an annual improvement in mine-safety conditions since 1907, and a particularly notable one in 1912, a still greater decrease in the death rate can be effected. Whether or not such an improvement will be made in 1913 depends largely on the care exercised by the operators, superintendents, foremen, and all others in authority, and by the miners as well.

Copies of this report, Technical Paper 48, may be obtained by addressing the Director, Bureau of Mines, Washington, D. C.

"Safety First" the Slogan Cry

By J. W. Powell*

SYNOPSIS—The writer advocates the employment of a practical linguist at each mine to talk to the men and explain their work. He deprecates reliance on printed rules, and the use of the naked light. He points out that with telephones and refuge stations many lives could be saved.

The prevention of mine accidents has been the foremost thought of all conscientious mine owners and managers from the beginning of the industry to the present day; and prevention of accidents will continue to be the first aim of every careful official charged with the responsibilities of coal mines for all time to come. With this idea in view I offer the following suggestions.

A Mining Instructor in All Languages Represented.

(1) Thirty-five years ago, the mine workers in Anglo-Saxon America were mainly of English, Welsh, Scotch, Irish, French, Belgium or German extraction, while today the major portion of the laborers employed in our mines are emigrants from central and southern Europe, who are very much inferior to their predecessors.

These men are foreign to our customs, do not understand our language and the majority never saw a coal mine before coming to this continent and securing employment therein, and a large percentage of our accidents today can be attributed to these facts.

I would suggest that in every mine employing this class of labor an official who thoroughly understands the language of the men employed be appointed by the management, this official to confine his whole attention to the instruction of these men in the different methods of working, the safe handling of explosives, drilling and tamping of holes, undermining of coal, placing of timbers, etc., and all the various things having reference to their own safety and the safety of their fellowmen and of the property in general. It would not be necessary for this official to be certificated because he would be acting under the direct supervision of the certificated mine officials. Nevertheless he should be a man chosen by the management after careful consideration as to his practical knowledge, carefulness and force of character so that he might thus be enabled to command the respect of the men under his instructions.

Danger Signals and Illustrations

(2) Danger signals should be placed at several conspicuous points throughout the mine; these should be flashed by electricity where the mines are non-gaseous or painted in large letters in the different languages if gas is encountered in the mine. In addition to these there should be large finger boards pointing the direction to the surface and placed at different points throughout the mine where men are liable to become confused.

At the entrance to the workings above ground, in addition to the rules and regulations required by law, large pictures or lithographs should be tacked up, these pictures depicting the different accidents which frequently occur in the daily operation of mines, due to the carelessness of the men. For example, a miner could be shown preparing a charge of powder with a naked light on his head, undermining coal and neglecting to use sprags, working under a dangerous roof and not placing timbers, tampering with a safety lamp or using a match to light his pipe in a gaseous mine.

That day is long past when extended, heavy matter written or printed was read with avidity. Today we must reckon with the hustle which is the spirit of the age. Business and like institutions no longer call attention to their products by the use of many words. Instead of that they grip the spirit or central idea that such words would convey and depict that leading thought so that it may be apprehended at a *single glance* and leave a lasting impression on the memory.

To attempt to interest the men in safety by a system of "rules and regulations," printed in small type and carefully framed, will in my estimation fall far short of accomplishing the desired end since men by reason of deficiency in education, dullness of comprehension, or lack of knowledge of the language may not be able to understand the words at all, and those who can, have neither the time nor the inclination to do so.

The Naked Light and Its Many Crimes

(3) Naked lights should be prohibited by law in all coal mines. The lives which have been sacrificed upon the altar of the naked light have been legion, if we add to the losses due to insufficiently diluted products of combustion, the disastrous fires which have been caused by open lights and also the various other accidents which can be attributed to them. Sparks from lights have ignited kegs of powder, and boxes of detonators have been exploded by the same cause.

I would suggest the use of some form of inclosed light. Electric lamps seem to be giving satisfaction to some of the companies which have installed them. Again, nothing but the most approved type of safety lamp should be used in a mine showing the least trace of explosive gas; the use of mixed lights as is practiced today in some mines should be prohibited by law.

Telephones and Rescue Stations

(4) Telephones should be established in every mine connecting the inside workings with the office on the surface, such telephones should be placed at different points throughout the mine so as to be easily accessible in case of accident. The lines should be securely laid in conduits underneath the tracks in such a way as not to be liable to injury in case of derailment of cars or an explosion.

(5) Refuge stations should be required by law in all coal mines where the number of men employed under ground exceeds 50, so that in case of an explosion of gas, or a mine fire or any serious accident which cuts off access to the surface, the men may find refuge within its walls.

These stations should be excavated in the solid coal and surrounded by large pillars. The entrances should be through long, narrow necks which are provided with 3 or 4 sets of massive iron doors constructed in such a manner as to be explosion proof. In heavy pitching

*Mine superintendent, Mount Carbon Colliery Co., Coalmont, B. C.

seams these chambers could be excavated in solid rock on the sides of the entries.

Equipment of Refuge Chambers

To be effective such stations should be provided for each district in the mine. These stations should be connected to the surface by a compressed-air line either carried through boreholes from the surface, or through indestructible conduits along the headings. These conduits should be constructed in such a manner as to be proof against fire and explosion. Each station should be provided with a complete telephone system connected with the office on the surface, also with first-aid cabinets, stretchers, medicine chests, water for drinking and supplies of concentrated foods in dampproof cases for use by men who might be cut off from the surface for an indefinite time.

Electric lamps and an adequate supply of safety lamps of the Wolf type should be provided, with material for recharging the same, also rescue apparatus, compressed-oxygen cylinders and pulmotors for resuscitating men overcome by deadly gases. Trained men should be constantly in charge of such stations so that in case of accident they could sally forth from such places and work in conjunction with the rescue parties from the surface.

They would be far more effective in my estimation, as they would be close to the seat of the disaster, and men would be rescued and resuscitated, and restored to anxiously awaiting wives, children and friends on the surface. These men would be irretrievably lost if they had to remain in the fouled atmosphere of the mine until relief came from the outside.

There would also be a great saving of human lives among the rescuers, numbers of whom are killed in modern disasters. With independent means, by which the entombed could take care of themselves, it would not be necessary for the rescuers to act with the same haste and intrepidity, for the telephone system would apprise them of the conditions in the underground workings of the mine.

How Previous Mine Disasters Testify to the Value of Refuge Stations

Let us take a retrospective view of some of the disasters which have occurred in our mines and we will be enabled to imagine what a blessing such stations would have been to many of our poor unfortunate brothers entrapped. The Courrières mine disaster in France was the greatest in mining history. There is evidence that hundreds of the men in this mine lived for days after the explosion, some of them for two weeks, devouring the bark of mine timber and the putrid flesh of horses.

At the Monongah disaster, Dec. 6, 1907, 361 lives were lost, quite a number of which could have been saved, as was ascertained by the conditions. Some of the men were found with their heads in the ditch seeking a breath of fresh air. At the Primero explosion, Jan. 31, 1910, 11 men must have lived for hours after the disaster, for one man who was found with them was finally resuscitated. At the Fernie disaster in British Columbia, 58 men lived for 48 hours but were finally overcome by the gas which leaked through the stoppings.

A Refuge Station Would Have Saved 26 Men at Bellevue

At the Bellevue explosion in Alberta, Dec. 9, 1910, 31 were killed, including one of the rescue party. This number would have been reduced to five if there had been a refuge station in the working district of this mine. I found 21 men lying along the ditch at a compressed-air charging station near chute 84, seeking fresh air. All these men could surely have been saved, as there were 8 men rescued on the same entry 10 hr. later and these were over 2000 ft. further inby. Had the other men retreated to the face the death list would have been greatly reduced.

At the mine fire at Cherry, Ill., Nov. 13, 1909, 256 lives were lost. Written messages, several very pathetic, addressed to their families, were found with the bodies. One message showed that some of the men were conscious for 48 hr. after the fire started. Several paddle fans had been constructed from parts of drilling machinery and pieces of board. These were made, as indicated by one message, with the forlorn hope of stirring up the air while making an attempt to reach the shafts. There were, however, 21 men who saved their lives in this disaster by erecting a barricade across one of the entries, building it with powder cans, stones and mud. These men were rescued seven days after the disaster occurred.

At Delagua, Colo., Nov. 8, 1910, there was a fire and an explosion in which 33 men were killed by noxious gases and 46 by the violence of the explosion. Quite a large percentage could have been saved had rescue chambers been provided. Four men were rescued seven or eight hours after the explosion. They were found behind a brattice which they had erected to keep back the afterdamp.

In the Price-Pancoast mine fire in Pennsylvania, Apr. 7, 1911, 73 lives were lost; all of which possibly might have been saved if sufficient refuge stations had been provided.

Industrial Provisions Have Lagged behind Civic Safeguards

We have our large standing armies prepared for war in times of peace. We have our life-saving stations for the protection of lives along our seashores and at our summer resorts. We have our fire brigades in our cities ever on the alert for the protection of lives and property. In our coal mines comparatively nothing has been done in this direction for the preservation of the lives of those who work in perpetual danger and who may at any moment be imprisoned deep down in the bowels of the earth. Germany and Austria are taking up the matter of providing safety stations for the protection of their miners, and I think it is high time that their examples be followed.

(6) It is essential for the safety of our mines that there should be efficient discipline, and in order to attain this end the management of the mines should be permanent. We do not appear as yet to have learned the value of efficient, permanent management as a factor of safety and economy. Management, as a general rule, cannot be efficient unless it is continuous.

To operate mines safely and successfully there should be a mutual feeling of interest between all officials and their employers, a feeling that their association together is of a lasting character. I do not think it good practice in the interest of safety and economy to make a habit of changing officials as seems to be the policy of some companies. As a general rule accidents occur and mines are destroyed where the mine officials are continually coming and going.

The Dangers in the Mine Must Be Met by Discipline

The mine managers and subordinate officials who are successful in securing safety in a mine are men who are not afraid to stand upon their conviction and insist upon the directorate of the company furnishing them with the necessary wherewithal to protect the men under their supervision, even if it does raise the cost per ton a cent or two. If they do not have the backbone to do this, they should at least be just to their fellow men and hand in their resignations, as they are unfit for the positions with which they have been entrusted.

If they find a man violating the rules and regulations laid down for the common safety, they should not discharge him. He should be turned over to the stern hand of the law. There is no punishment which brings results as quickly as that administered by the courts. You can reprimand a man or you may discharge him and he will forget it in a short time, but arrest him and you are assured that he will not be in a hurry thereafter to violate the mining law in your mine or in that of any other company.

Meet Your Accidents Midway

When you discharge him he simply leaves you and goes to some other place and secures employment and in all probability does the same thing over again. This possibly results not only in the loss of his own life but in that of many others. All subordinate officials should be given a complete understanding of everything required for the safety of the mine and a responsibility equal to their ability for the preservation of the safety of the mines and the lives of the workmen. If any member of the official family is found to be lax in his duties or is becoming indifferent in his work, he should be immediately dealt with accordingly, as the laggard is a very dangerous official in any mine.

The philosopher who said "Forethought will often save much afterthought" expressed a great truth. Superintendents and mine managers should consider, with the officials underground and above ground, the quickest and safest method to enter the mine in case of an explosion or fire. They should have all their plans outlined and discussed and all the officials should be acquainted with the result of the deliberations.

They should imagine a fire occurring in different parts of the mine and plan their action in such cases. Remembering that an explosion may occur in certain parts of the workings or may involve all the headings and destroy their system of ventilation, they should discuss the same carefully and decide upon plans for the different cases. It is far better to prepare plans and modify them as necessity points out than to meet the catastrophe without them.

Handy Apparatus for Testing Mine Air

Special Correspondence

SYNOPSIS—The author describes two apparatus, one for the measuring of methane and the other for determining all the impurities in mine air. A knowledge of chemistry is not needed to manipulate the apparatus. Even the gas ignition is automatic, taking place only when the mercury has cut off the required body of air.

The rules and regulations of the British Coal Mines Act of 1911, which came into force on Jan. 1 of this year, provide, that a place shall not be deemed to be in a fit state for working or passing therein if the air contains either less than 19 per cent. of oxygen or more than 1¼ per cent. of carbon dioxide and an intake airway shall not be deemed to be kept normally free from inflammable gas if the average percentage of methane found in six samples of air taken by an inspector in the air current in that airway at intervals of not less than a fortnight, exceeds ¼ per cent.

No Open Lights in 0.5 per Cent. of Gas; No Electricity in 1.25 per Cent.

Moreover, no lamp or light other than a locked safety lamp can be carried or used in any seam where the air current in the return airway from any ventilating district in the seam is found normally to contain more than ½ per cent. of inflammable gas, and further provisions are that if at any time, in any place in the mine, the percentage of inflammable gas in the general body of the air in that place is found to exceed 1¼ per cent., the electric current shall be at once cut off all cables. This, of course, does not apply to telephone or signal wires and instruments, so long as safe conditions for the use of such wires are provided.

In order to provide for such tests, Leonard Levy, of the engineering firm of Alexander Wright & Co., Ltd., of Westminister, has developed the instruments shown in the accompanying figures. The first is for the estimation of methane only.

The measuring tube *A* is surrounded by a water jacket and its narrow stem is graduated so that the percentage of methane can be read directly. It is closed at the top by a cock *B* containing an "L" shaped bore so arranged that it is impossible to put the oxidation tube *C* into direct communication with the atmosphere. The plug of the cock has a screw washer fixed on the back so that it cannot be accidentally withdrawn from the barrel.

Automatic Ignition of Gas

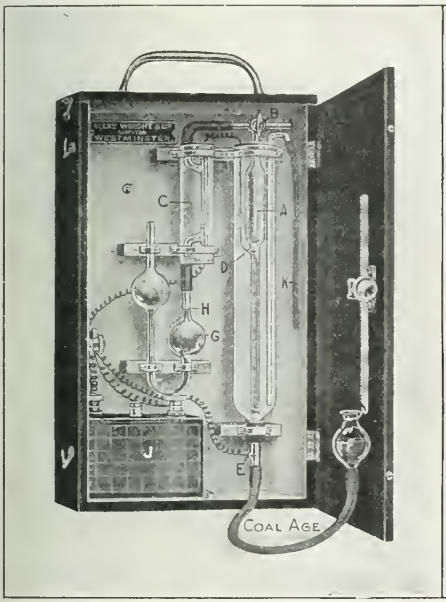
A new type of oxidation tube, *C*, has been devised by Dr. Levy. It consists of a fine quartz capillary tube through which a platinum wire runs axially. This wire is heated to whiteness by a current derived from the small storage cell *J*. The expansion of the wire on heating is taken up by a spring to which one end of the wire is attached. This oxidation tube is entirely surrounded by a water jacket.

The current passes through the platinum wire when the mercury in the measuring tube reaches the fused-in platinum contact *D*. Connection to the mercury is made through the fused-in contact at *E*. It is thus evident that the current only passes when the reservoir *F* is raised to drive the gas through the tube *C* and thus the oper-

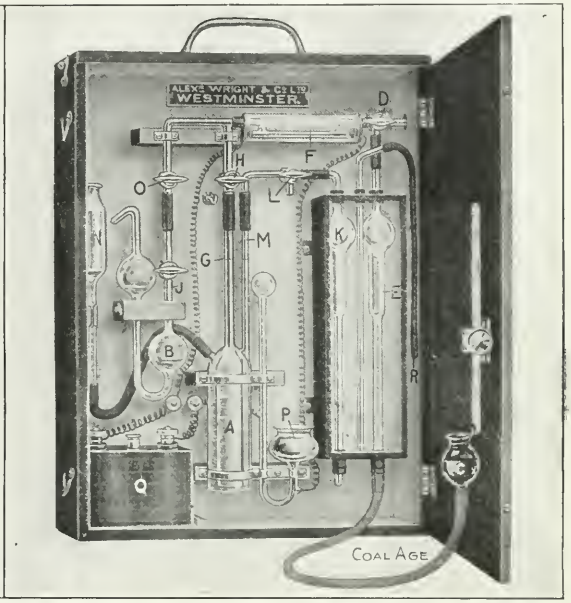
ation of passing the gas over the wire, automatically switches on the current.

During its passage through the quartz-platinum tube the methane present, no matter how small may be the percentage, is completely oxidized to carbon dioxide and water. The resultant contraction is equal to twice the volume of methane present and is observed on the fine stem of the measuring tube. The graduations at 0.25 per cent., 0.5 per cent. and 1.25 per cent., the three limits specified in the Act, are marked in red.

Two passages of the gas through the quartz-platinum tube are sufficient and an estimation can readily be effected in two minutes. An accuracy of 0.005 per cent. is readily attainable on the assumption than no combustible gases other than methane are present.



Apparatus for Determining Methane Only



Device Makes a Complete Analysis of Mine Air

Can Be Operated by Anyone Who Can Read a Scale

No caustic liquids or chemicals are employed and the necessary manipulation merely consists of drawing in a sample of the mine air by raising and lowering the reservoir *F*, and then effecting the estimation by turning the cock *B* to communicate with *C* and raising and lowering *F* twice. No knowledge of chemistry or gas analysis is required and the percentage of methane is read off directly from the position of the mercury in the graduated stem of the measuring tube.

As the make and break of the electrical circuit are entirely inclosed in the tube *A* which is surrounded by a water jacket there is no danger of any explosion being caused by the spark at the contact. The apparatus is very small and compact. The external dimensions of the base are 13½x8x3 in. and the total weight ready for use is 8 lb. A tripod is sometimes used for supporting the apparatus.

The main principles of the other apparatus which is designed for the complete examination of mine air are exactly the same as in the one first described and it contains precisely the same provisions for rapidity, accuracy and safety in use. However, in addition to affording a method for accurately estimating the methane, means are provided for the precise determination of carbon dioxide and oxygen.

A measuring tube *E* is provided into which the sample of mine air is drawn by raising and lowering the reservoir *C*. The gas is first passed into the vessel *A* which contains potash. The carbon dioxide is removed here and on drawing the gas back into the measuring tube, the percentage of carbon dioxide is observed directly on the finely divided stem. The wire in the quartz capillary tube *F* is now heated to whiteness by passing the current, supplied from a two-volt storage cell *Q*.

The circuit is completed by pressing on the leather top of the safety mercury switch *P*. This causes the mercury to rise in the tube and completes the circuit. As the make and break of this current are entirely inclosed, there is no danger of firing the atmosphere and should the apparatus be accidentally dropped, the circuit is immediately broken. The mine air is again passed through the tube *F* into the vessel *A* by raising the reservoir *C* and drawn back into the measuring tube *E* by lowering the reservoir *C*.

The percentage of methane is thus obtained by an observation of the level of the mercury in the tube *E*. The mine air is then passed into the vessel *B* where the oxygen is removed and its percentage determined by an observation of the position of the mercury when the air is passed back into the tube *E*. The complete analysis is thus effected by a simple manipulation. The apparatus requires no previous knowledge of chemistry.

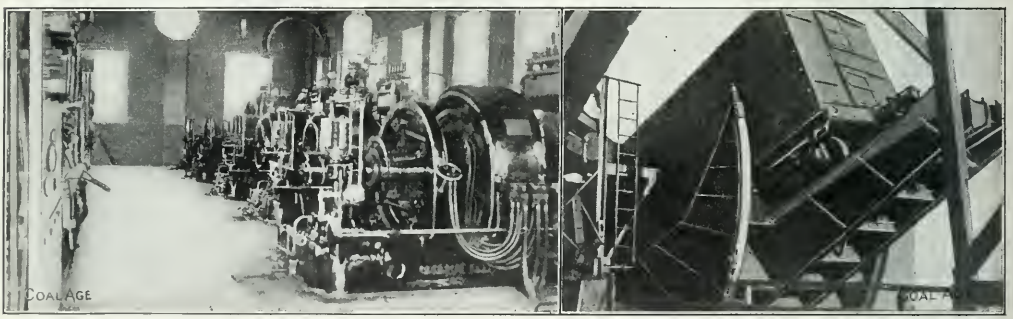
The Superior Coal Co., Wyo.

By W. D. Brennan*

The operation of the Superior Coal Co. is located among the hills of southwestern Wyoming at an altitude of 7000 ft. It is at the terminal of an eight-mile branch line, running north from Thayer Junction on the Union Pacific R.R.

The growth and advancement of this camp since its opening, less than seven years ago, has been a marvel of Western industrial development. It has now a population of about 3000 people and a daily production of 5000 tons. The coal is semi-bituminous and among the best for steam purposes, mined in the Rockies.

A Detailed and General View of the Surface Equipment at the "E" Mine



Interior View of the Turbo-Generator House and the Cradle Box-Car Loader

There are five mines in operation at present, working on three different seams, and two more are under development. The camp is electrically operated throughout, the coal being mined, drilled and hauled by electric machinery.

The main power-plant is centrally located, its equipment consisting of four 300-hp., and six 250-hp. marine boilers, and four 300-kw., 2300-volt, 60-cycle, 1800-r.p.m. turbo-alternators and two 300-kw., 250-volt direct-current turbines. Apart from this is an auxiliary gas producer plant, equipped with a No. 8 Wood Producer, an 18x24-in. tandem gas-engine, and a 150-kw. generator. The latter has proven quite successful, generating 1000 to 1100 kw.-hr. in an eight-hour run.

The "E" Mine, is a two-compartment shaft, equipped with a steel headframe, a double-drum, 200-hp. hoist, hung directly over the shaft, and self-dumping cages. There is also a steel cradle box-car loader, capable of handling 50-ton loads at an angle of 50 deg. Mine-run and lump may be loaded on two tracks at the tipple, or conveyed by belt to the adjacent rescreening bins having underneath and side chutes for loading either open or box-cars.

The modern tendency toward permanent construction is as prominently in evidence in the Rocky Mountain states as in East. Some typical examples of this are shown in the accompanying photos, the large central stack for the power plant, the steel headframe and the liberal use made of concrete. It is proposed to work out an extensive acreage with this plant, which partially accounts for the thorough equipment of the operation.

*General superintendent, Superior Coal Co., Cheyenne, Wyo.

❖

Acme Plant in Pennsylvania

The Acme Coal Mining Co.'s plant at Rimersburg, Clarion County, Penn., while not of such large capacity as compared with some other electrically operated mines, it is a particularly interesting one. Before the installation of the new electrical machinery and other improvements this mine had an output of approximately 700 tons of coal per day, but it is expected that this will be doubled within the year.

A small direct-current plant was formerly the only power used, but when the new mine was opened some distance away, it was decided to put in an alternating-current machine so that current could be economically transmitted.

The selection of an alternating current was decided upon as being best adapted to the conditions to be met.

The present site of the plant is about in the center of distribution for the mines to be supplied, and accordingly the new installation was located there. This meant that it was only necessary to remove the old direct-current generating equipment and install the new machinery. Being centrally located, accessible to water and fuel, it will be possible to supply other mines in the future, should there be occasion for such.

The Electrical Equipment

It is intended to electrify what is known as the Shannon mine and preparations have already been made for this work. Energy will be sent from this plant to a substation, located near the mine, from which direct current will be delivered to the pumps and locomotives. The generating equipment in the main power plant consists of one 400-kv.-a., 60-cycle, three-phase, 2400-volt Westinghouse alternator, direct connected to a 700-hp. Ball engine, and a three-panel marble switchboard for control of same. A voltage regulator maintains a constant voltage at the plant.

The alternating current generated here is transmitted a distance of about three miles to a substation where it is changed to direct current for operation of the mine machinery which consists of three locomotives, pumps, lights, etc. The change to direct current is affected by means of a three-bearing Westinghouse motor-generator set consisting of a 300-kw. compound-wound, 275-volt direct-current generator direct connected to and mounted on a common iron base with a 450-hp., 60-cycle, 2200-volt, three-phase, self-starting synchronous motor. The speed of the set is 900 r.p.m. The motor is started by means of a three-phase auto transformer, thus obviating the trouble of synchronizing.

The direct current is carried into the mine by means of lead-covered cables through a bore hole located near the substation, thus rendering the liability to interruption on account of grounds very remote. The lead sheathing also materially increases the safety of employees, which is always a point of particular importance, especially in mine operations. The distance from the top of the seam to the surface at this point is 246 ft. From the bottom of the bore hole, the current is distributed to the different portions of the mine by independent circuits so that in case of any trouble on one of these, no portion of the mine will be affected other than that fed by the circuit on which the trouble has occurred.

With the completion of the electric equipment, it is said that the Acme Coal Mining Co. will have expended a total of $100,000 within a year on the plants in the neighborhood of Rimersburg. All of the improvements and additional equipment were installed in the best manner possible and are of a permanent nature. The entire work has been carried on under the direct supervision of W. G. Strachan, superintendent, and the electrical work was designed and installed under the direction of the company's chief electrician, J. A. Shaw.

The entire electrical equipment of the main and substation was furnished complete by the Westinghouse Electric & Manufacturing Co., East Pittsburgh, Pennsylvania.

Coal Production in Washington

Washington's coal production decreased from 3,979,569 tons in 1910 to 3,548,322 tons in 1911, a loss of 431,247 tons, or 10.8 per cent. The production for 1912 was 3,346,946 tons, a loss of 201,376 tons or 5.6 per cent. and a combined loss of 632,623 tons for the biennial period. This decrease is not encouraging to the coal-mining industry of the state and can be assigned to no other cause than the substitution of oil as a fuel on a percentage of the steamers running out of Puget Sound ports.

Two Westinghouse Motors at the Acme Mine and a General View of the Surface Equipment

Railroads and power plants are also using a large amount of fuel oil. Just how long oil can be sold in this state, at a price that makes it more economical for steaming purposes than coal, no one seems prepared to state, but it is to be hoped for the sake of the coal-mining industry that the time is not far distant when the price of oil will advance. The value of coal per ton at the mine was $2.43 for the year 1912.

The coke production for 1910 was 57,715 tons; 1911, 40,301 tons, and 1912, 48,889 tons. The value of coke per ton at the mine, increased from $5.50 in 1910 to $5.80 in 1911, but decreased again to $5.54 in 1912.

It is gratifying to report that the number of fatal accidents reduced from 43 in 1910 to 27 in 1911, and to 14 only in 1912. But the number of nonfatal accidents increased from 108 in 1910 to 115 in 1911, and in 1912 reached the high-water mark, numbering 455. This large increase of nonfatal accidents reported for the year may be ascribed to the compensation, paid through the State Industrial Insurance Commission to employees who lost time on account of injuries received while discharging their duties. The duty of this commission is to enforce the provisions of the Workmen's Compensation Act passed by the legislature of 1911. Previous to the passage of this act and following the rule of other states, only serious accidents were reported to this department; and many of these were not reported.

The Harlan Coal Field in Kentucky

By W. R. Peck and R. J. Sampson*

SYNOPSIS—A description of one of the subdivisions of the Cumberland Gap coal field. The coal lies level generally and is a high-volatile fuel possessing excellent coking properties. This district is one of the more recent ones to be opened up.

Harlan County lies in the southeastern part of Kentucky on the state line between Virginia and Kentucky, at the head waters of the Cumberland River. It is entirely cut off from Virginia and her railroads by the Cumberland Mountains and the Little and Big Black Mountains, along the crests of which runs the state line. On the western side of the county, the Pine Mountain also cuts off the main part of the county from the waters of the Kentucky River and the railroad that follows that stream. Therefore, all freight to and from the county must follow the waters of the Cumberland River.

General View of Harlan (Formerly Mt. Pleasant), the County Seat of Harlan County

Topography and General Geology

The county is very mountainous, the valleys narrow and there is only a small area of tillable land along the streams. The mountains vary in height from the innumerable low spurs to the main ridges, which in many instances rise more than 2000 ft. above the valleys. On the accompanying map are shown several elevations which give the general height of the ridges.

This district is a part of the Cumberland Gap coal field. The geological structure is that of a flat-bottomed syncline with its axis almost parallel to the Cumberland River. From this axis the rocks rise with slow dips until they are sharply upturned in the Pine Mountain on the northwest by the Pine Mountain Fault and in the Cumberland Mountain on the southeast, by the Powell's Valley Anticline. Between these two boundaries lie the Black Mountains and Martin's Fork Ridge.

The outcropping rocks in the last named mountains are sandstones, shales and coal beds. No continuous limestone beds have been found, although a bed of fossil limestone about 12 in. thick has been reported high up in the Big Black Mountain. The shales and sandstones are about equally developed, the sandstone probably predominating. The lower part is principally sandstone and contains some fairly coarse conglomerate.

The Lee conglomerate, called here the Lee sandstone, is the lowest division of the coal measures. It does not outcrop in the Harlan field, but is seen on the north flank of the Pine Mountain, where it is brought up by the Pine Mountain Fault. Above the Lee there is about 2300 ft. of sandstone and shale in nearly equal proportions.

In the Big and Little Black Mountains and Martins Fork Ridge and their spurs, occur the workable coals. The coal in the Pine and Cumberland Mountains is so badly split up and on such a heavy pitch that it is practically worthless at the present time.

The Coals

At the foot of the crest of the Black Mountains there are a great number of coal beds outcropping, but we will only attempt to describe those, which in some part of the district are of economic value, taking them in order and beginning at the bottom.

Harlan Seam—This seam, which is the lowest that is commercially workable, is the most regular and the most valuable. It lies between massive sandstone beds, the top one of which is usually less than three feet above the coal and in many instances, rests directly on it; there is probably an average of nine inches of shale between. Underneath the coal there is usually a shale bed of varying thickness, which is too hard to be cut by chain machines.

*Fox, Peck & Sampson engineers, Harlan, Ky.

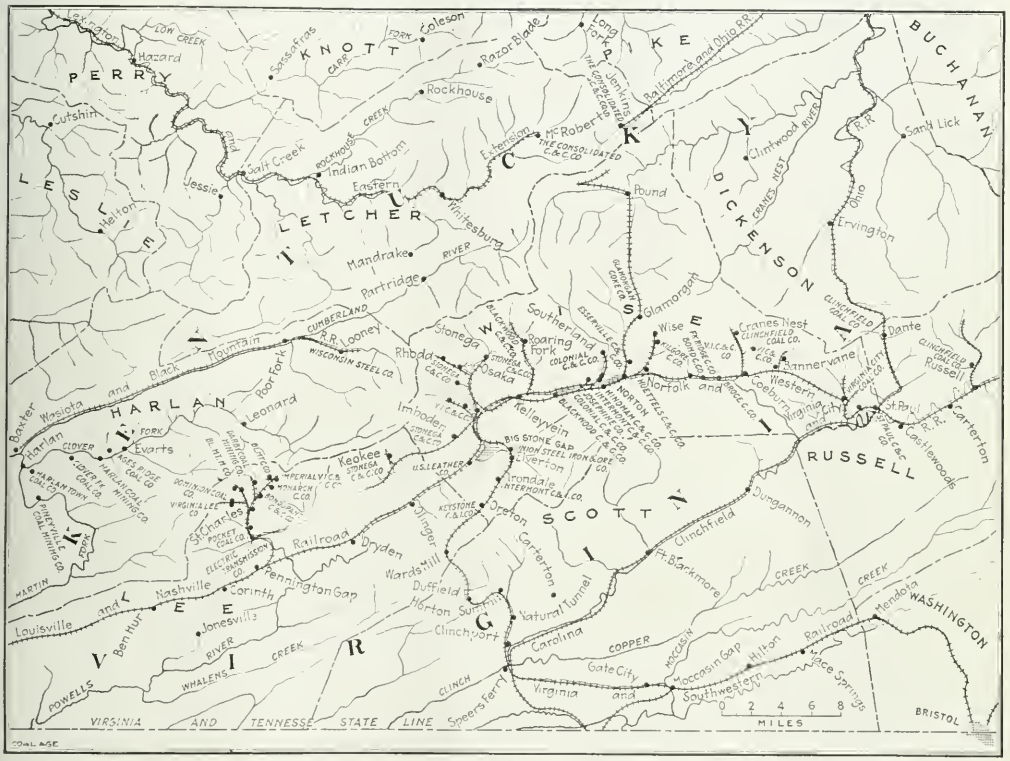
This coal is readily located by the fact that it lies 250 ft. above the Cawood sandstone, which outcrops all along the river bed, often forming prominent cliffs. It is generally known as a 4-ft. seam and has been opened in numerous places in the central, southern and western portions of the county. Eastwardly just above the mouth of Seagraves, a distance of about fourteen miles above the town of Harlan, the coal goes under the river; at this point there is 3 ft. 6 in. clean coal.

On Clover Fork, one mile above the town of Harlan, the Harlan Town Coal Co. has opened this seam. They have 50 to 56 in. of clean coal underlaid by a shale parting from 3 to 6 in. beneath which there is another 14-in. bench of coal. The seam at one place in this mine is 6 ft. 6 in. high with a 4-in. parting 14 in. from the bottom. The Clover Fork Coal Co., also operating on Clover Fork one mile above the last mentioned mine, has from 50 to 54 in. of clean coal. Between the two mines the bottom bench seems to have disappeared. Just across from the Clover Fork Coal Co., the Lynn Hollow Coal Co. has opened up this seam in the Big Black Mountain, where it shows a thickness of 48 in. of clean coal.

The Harlan Coal Mining Co. opening on Clover Fork in the Little Black Mountain, at a distance of three and one-half miles above the town of Harlan, has developed from 45 to 47 in. of clean coal, in a spur of the mountain; this is expected to be 54 to 56 in. in the main ridge, as has already been proved in an opening at the head of a hollow just west of their present operations. The Ages Ridge Coal Co. operating in the Big Black Mountain, on Clover Fork five miles east of Harlan, has found 42 to 46 in. of clean coal; this should thicken as they progress east to a maximum of 59 in. as shown in an old opening near the center of their property.

In general, the seam in the Big Black Mountain shows a uniform section of from 48 to 50 in. of clean coal on the outcrop. On the northeast side of Martins Fork there is 50 to 56 in. of coal in the upper bench with from 12 to 24 in. in a bottom bench, the two being separated by 6 to 18 in. of shale.

In the eastern part of the county this coal is under



Map of the Harlan County Coal Field, Showing Location of the Principal Mines

Bed or Seam "B" which has no importance in the western part of the county is the most persistent, though not the most valuable in the eastern portion. It lies about 140 ft. above the Harlan seam. In the extreme

The Harlan seam, in general, dips slightly in a northeasterly direction. The following is an analysis of some crop coal from the Harlan seam: Volatile matter, 38.3; fixed carbon, 55.8; moisture, 1.7; ash, 3.5; sulphur, 0.9.

drainage. On Ewings Creek, in the lower end of the county, on the property of the Wilhoit Coal Co., there is a seam from 110 to 160 ft. under the Harlan coal. This seam is 36 in. thick and usually has some partings. This is the only place in the county where it has been found with this thickness, but it has not been thoroughly prospected for yet.

RETARDING CONVEYOR OF THE HARLAN COAL MINING CO. TAKEN BEFORE COMPLETED

eastern end of the county this seam attains a thickness of 3 ft. 6 in. of clean coal.

Kellioka Seam—This seam, which occurs about 200 to 250 ft. above the Harlan coal, has not been thoroughly prospected for in the lower or western part of the county; however, where opened it shows a section of 3 ft. 6 in. to 4 ft. It is mined at Keokee, Va., as the McConnell seam and is probably the Darby or No. 5 seam mined in the Pocket district of Virginia, as well as the Taggart seam mined at Rhoda, Va.

COMPARATIVE VALUES OF VARIOUS COALS

Note:—Due recognition must be given to the fact that all Harlan samples are taken from outcrop (weathered coal)—while others are taken from active mines, far from surface.

Based on Kent's suggestion (p. 51 "Steam Boiler Economy") that a standard bituminous coal be considered as containing not over 20% volatile matter, 2% moisture and 6% ash and be rated as 100. For each per cent. of volatile matter over 25%, a reduction of 1% in value is made, and for each per cent. of moisture in excess of the standard a reduction of 2% in value is made. Also a reduction of 2% in value is made for each excessive per cent of ash. By applying this method retractively (the range from 20% to 25% in volatile matter being considered of equal value) the results above given are obtained.

*Name adopted by the state and U. S. Geol. Surveys 1902 and 1903. †Trade or geological names of various other selected coals in Pennsylvania, Ohio, West Virginia.

The Wisconsin Steel Co. is mining in this seam at Benham, Ky., 27 miles above the town of Harlan, where it has 5 ft. 6 in. of coal practically without a parting. There is also a seam in the eastern end of the county about 60 ft. above the Kellioka, which averages 3 ft. 6 in. of clean coal. The folowing is a typical analysis of the Kellioka coal: Volatile matter, 38.5; fixed carbon, 54.9; moisture, 1.8; ash, 3.8; sulphur, 0.96.

Wallins Creek Coal—This coal, named for Wallins Creek of Cumberland River, has a thickness of 9 ft. with a 6-in. parting, 18 in. from the bottom, leaving a top bench of 7 ft. of clean coal. It occurs approximately 600 ft. above the Kellioka. The Terry's Fork Coal Co., operating in this seam, on Terry's Fork of Wallins Creek, find a mining section of 7 ft. of clean coal. The following is an analysis of the Wallin coal: Volatile matter, 37.4; fixed carbon, 52.1; moisture, 2.3; ash, 7.6; sulphur, 0.88.

The Looney Seam, opened in several places in the high knobs of the Little Black Mountain, shows from 4 ft. 5 in. to 5 ft. of coal and usually has a small shale parting. The Lower High Splint coal lying from 300 to 350 ft. above the Looney seam in the Big Black Mountain, shows more than 3 ft. of minable coal. The Middle Splint averages about 3 ft. in the Big Black Mountain. The Upper High Splint occurs 400 ft. above the Looney and is the most valuable of the high seams in the Big Black Mountain; it varies from 4 to 6 ft. with practically no parting. In one place it shows 9 ft. 5 in. of coal with a 6-in. shale parting one foot from the floor.

HISTORY OF DEVELOPMENT

For several years past companies and individuals have been acquiring coal lands in this county. However, no move was made toward building a railroad until the early spring of 1907 when Mr. T. J. Asher began the construction of some thirteen miles up the Cumberland River, in Bell County, to reach the operations on his own property. This was known as the Wasioto & Black Mountain R.R. The Louisville & Nashville R.R. then acquired it and completed it to Benham some twenty-seven miles

THE CLOVER FORK COAL CO.'S MINING TOWN AND PRINCIPAL OPERATION

above the town of Harlan. When this line was completed, work began on a branch up Clover Fork to Ages Creek, a distance of five miles.

This branch was put into operation on the third of August. While the road was under construction leases were taken by mining companies and the installation of plants begun. At the present time there are six companies in the county shipping coal. These are the Terry's Fork Coal Co., operating in the Wallins coal on Terry's Fork of Wallins Creek, the Harlan Town Coal Co., operating on Clover Fork in the Harlan seam, the Clover Fork Coal Co., operating in the Harlan seam on Clover Fork, The Wisconsin Steel Co., operating in the Kellioka seam on Poor Fork at Benham, Ky., and the Stonega Coal & Coke Co., operating from the Virginia side in the Kellioka seam in the Big Black Mountain.

The Terry's Fork operation shipped their first car in the summer of 1911 and was the first to ship coal out of this district. They have recently installed an electric plant and their present output is from 600 to 700 tons per day. The total distance on the mountain side, through which they have to lower their coal, is about 6000 ft. This is divided into two parts, the lower end being an engine plane, the upper a gravity incline.

The Wilhoit Coal Co. began shipment in the early winter of 1911; their output is from 300 to 400 tons per day at the present time and is increasing. It is also very likely that they will install another plant on the opposite side of Ewings Creek from the present one. They have recently installed a Morgan-Gardner 150-kw. generator, belt-driven, and two Sullivan and one Morgan-Gardner short-wall chain coal cutters. Mules are still used for haulage but will eventually be replaced by electric locomotives.

The Harlan Town Coal Co. began shipment June 7, 1912. Their present output is from 500 to 600 tons per day, and is expected to reach 1000 tons in a few months. Their equipment consists of one Morgan-Gardner 250-kw. generator, belt driven, two 8-ton Morgan-Gardner, combination gathering and haulage motors and one Morgan-Gardner short-wall chain cutter.

The Clover Fork Coal Co. began shipment at practically the same time as the Harlan Town Co. Their machinery equipment consists of only a single engine to operate shaking screens. Their present output is about 600 tons per day.

The Wisconsin Steel Co.'s operation at Benham is at present by far the most important in the county. At present all of their coal is converted into coke for which purpose they have built 300 ovens of the beehive type, a breaker equipped with two crushers and flight conveyors driven by motors. The slack is conveyed to the ovens by electrically-driven larries. Their output is 20 cars of coke per day. A brick power house in which they have installed two 338-kw. and one 150-kw. generators, direct connected. There are two hundred modern mine houses of various designs and painted in different colors, a club house and handsome residence for the superintendent. A $20,000 Y. M. C. A. building has recently been opened and there is now under construction a large hotel.

The Stonega Coal & Coke Co.'s operation at Keokee, being really a Virginia mine, we will not attempt to describe it here.

The Lynn Hollow Coal Co. is installing a plant on Clover Fork. They will have no mechanical equipment but are developing for an output of 400 to 500 tons per day.

The Harlan Coal Mining Co. is working now on an installation on Clover Fork three and one-half miles above the town of Harlan. The equipment of this plant will be of peculiar interest in that they have departed from the customary gravity incline and will use a retarding conveyor of the rope-disk type. From center to center the length is 825 ft., the last 300 ft. across the river bending

on a curve of 600 ft. radius, 180 ft. of which is on a suspension bridge. At the foot the retarder discharges onto a belt conveyor 285 ft. long which carries the coal to the screens. The lump from these screens will be loaded by a boom loader. They have one Morgan-Gardner 250-kw. generator, directly connected to a Skinner engine, two Morgan-Gardner short-wall chain cutters, one 8-ton Jeffrey electric locomotive and motors for driving their conveyors and screens.

The Ages Ridge Coal Co. is now installing a plant at Ages, Ky. Their tipple will have shaking screens and eventually the mine will be equipped with gasoline locomotives.

It is reported that at least one operation will be started on Martins Fork in the immediate future. Whether this is true or not, it is only a matter of time until a railroad will be built up Martins Fork, which would tap what is really the best of the Harlan coal field. Also the road already started up Clover Fork will eventually be extended to a point opposite the town of Keokee, if it does not tunnel the Black Mountain and connect with the Virginia Southwestern R.R. at that point, or build into Appalachia, Va., there to connect with the Cumberland Valley division of the Louisville & Nashville R.R. itself.

Markets

All of the coke made in the county at present goes to the steel plants of the Wisconsin Steel Co., at South Chicago.

The coal from the other operations finds a ready market in the North, West and South, which it can reach over the Louisville & Nashville R.R. and its connections. The coal and coke from Keokee goes East and South over the Southern Railway. In general the fuels have an excellent reputation.

❖ ❖

Conservation and Commercial Advantage

By Francis S. Peabody*

SYNOPSIS—The pursuit of commercial advantage is opposed to conservation, and no one realizes this more than the miner who risks his life and reduces the coal bed to slack to increase his earnings and minimize his labor. On this subject legislation is silent. The waste of coal does not end in the mines. The railroads and the public generally are more wasteful than the coal operator.

❖

Conservation and commercialism are both concerned in the saving of our national resources. Where conservation would save human life, and maintain the worker in vigorous health, commercialism would save the energy of his labor by increasing its productivity. Where one would save natural resources, the other would reduce the waste of capital. It is strange that, while both seek the same end, which is the more perfect use of the endowments of nature, their work is, nevertheless, largely antagonistic.

Mine Safety

The State Legislature, in the interests of conservation, at its most recent session passed laws to promote the safety of life. No operator can deny that, on the whole, these laws are right. Criticisms may be directed at the mode of application provided for their enforcement, but not at the improvements demanded.

However, the natural attitude of the operator is to evade their operation, because they encumber him with a burden which is not imposed in other and rival coal-producing States. The new laws which were passed by the last legislature, especially those relating to the construction of shafts, tipples, surface buildings and fire appliances, have added at least 40 per cent. to the cost of developing a new mine, and these same enactments have increased by 10 per cent. the operating costs of old and new mines alike.

The operator is producing his coal as cheaply as he can. To do this he is taking the coal nearest to the shaft, that part which is most quickly reached and extracted, and which involves the least outlay of capital.

Under this method he is extracting less than 60 per cent. of the coal in the bed, leaving over 40 per cent. in the ground for the support of his roof, mine tipples, air courses, etc. He could mine the most remote coal first, but it would be years before he would receive a return from his capital. The profit of coal mining is, by my computation, less than 2c. per ton, and the operator does not feel justified in conserving the coal in the ground because such conservation would change this small gain into an absolute loss. Yet, by our mining methods, we are wasting money and making mining much more hazardous.

Although coal in place has doubled and even quadrupled in value in the last ten years, yet many of the largest operators in the State have become bankrupt. It is easy to obtain millions of dollars for the purchase of virgin coal land, but it is practically impossible to induce capital to invest in the coal-mining industry.

The Commercialism of the Workingman

Commercialism is frequently regarded as an attribute of large capitalists. But the miner has the quality as well as the operator. He tries to produce as large a number of tons of coal as possible with the least expenditure of labor. He rarely cares how much the coal is deteriorated in value by his careless methods of mining, how much he endangers his own life or that of others, and he is often regardless of the destruction of property.

The miner today, instead of mining by undercutting, shoots off the solid and shatters the coal, so that the fuel produced is almost unmerchantable. The percentage of screenings has increased from 20 to over 40 per cent. Not only does the miner thus destroy the coal, but he breaks the roof, knocks down timbers, makes windy shots probable, and thus endangers his own life and those of others, as well as destroys the mine in which he works.

The introduction of powder into coal mines has increased the dangers of mining. Despite the precautions

*President Peabody Coal Co., Chicago, Ill.
Note—Abstract of paper read May 9, 1913, at the dedication of the Transportation Building and the Locomotive and Mining Laboratories, University of Illinois, Urbana, Ill.

taken, 17 men lost their lives by its use last year, and 28 were injured. The law should require undercutting, and thus reduce the danger of coal-dust explosions.

The Miner Shoots for Maximum Product

The depth of drillholes used to depend on the depth of the undercutting, but a 5- or a 6- ft. hole would require from 20 to 24 in. of powder. A cartridge of 2-in. diameter, such as is generally used, contains a little over one pound of powder to the foot, so that miners should use at most only 2 lb. of powder to the shot. Such a conservative use of explosive would make shot firers unnecessary. But the coal is now largely neither undercut nor sheared. The miner drills what he terms a "buster" in the center of the coal face. Then he follows this with two rib shots. The holes are drilled from 5½ to 6 ft. long, and are angled so as to give the shots a chance to fire the coal out from the face. The cartridge is from 40 in. to 48 in. long, and contains 3½ to 4 lb. of powder to the shot. The result of such methods has been already described.

The law requiring payment for all the coal mined, whether pulverized to slack, or in lumps, was one of the most lamentable pieces of legislation imposed on the coal operators in the state of Illinois.

The people of this state are as much to blame as the operator or the coal miner. By permitting this shooting from the solid they have made mining dangerous and wasteful. And there has been a disposition to overlook the protection of property for political reasons. The legislature has restricted the introduction of labor from neighboring states, and when trouble has arisen between operators and miners it has been loathe to interfere and prevent the destruction of property. Nor have laws been passed requiring a proper recovery of the natural resources.

How Coal When Mined Is Wasted

But not only the mine owner and his employee are censurable for waste. It has been estimated that the railroads, the largest consumers of coal, utilize less than 50 per cent. of the heat in the coal which they burn under their locomotives. If 60 per cent. is wasted by the operator, and 50 per cent. of that is lost by the railroads, only 30 per cent. is actually utilized and 70 per cent. is wasted, and not the railroads only, but all consumers are equally wasteful.

Our state is one of the most advanced in protecting human life, but as these laws cripple the industry we should endeavor to assemble an interstate commission of operators and miners from the states of Illinois, Indiana, Ohio and Pennsylvania, appointed by the several governors of the various commonwealths. It should be the object of this body to recommend uniform laws to be enacted in the various states. Such laws would reconcile conservation and commercialism.

Alternating-Current Fan Motors

By F. B. Crosby*

SYNOPSIS—The amount of air required to properly ventilate a mine constantly increases due to the extension of the workings. To meet this condition it has been customary to install direct-current motors driving the fans. This paper describes in more or less detail the various methods that may be employed to obtain variable speed from alternating current.

❖

It is no longer necessary for the advocate of electric drive to dwell at length upon its many advantages. The superior qualities of the electric motor are thoroughly attested by its all but universal adoption. The question which confronts the engineer today is not that of relative merits of the several possible methods of transmitting energy to the point of application, but rather the intelligent selection of the most suitable electrical equipment with due consideration of all factors bearing upon the particular case in hand.

Recognizing the limitation of design and the physical impossibility of producing a universal motor, electrical manufacturers are giving more and more attention to the specific requirements of certain clearly defined classes of service. As a result of this specialization and the steadily increasing variety of forms manufactured, it is obviously of great importance that for any given duty the proper motor be selected, otherwise a motor which under conditions for which it is designed, would give entire satisfaction, may under different conditions prove an utter failure or at best needlessly expensive.

Induction motors can be readily designed to develop at reduced speeds:

a. Constant horsepower—increasing torque.
b. Constant torque—horsepower proportional to speed.
c. Torque decreasing with speed.

Moreover these motors can be given either a maximum or overload rating. The power required to drive a centrifugal mine fan varies approximately as the cube of the speed. Obviously to install for fan service a motor capable of developing constant horsepower at reduced speeds or with any considerable overload capacity, does not represent sound engineering, either from the standpoint of first cost or operating characteristics.

It is the purpose of this paper to indicate certain considerations which should govern the selection of the mine fan motor and describe briefly those types which have been adapted to this service. No attempt is made to discuss the relative merits of the several types of fan on the market or forced draft as compared with the suction draft fan. It is assumed that the type of fan and horsepower required to operate it have been determined for any given application.

Two general conditions arise requiring (1) constant speed drive, and (2) adjustable speed drive. Until recently, for adjustable speed drives, it was practically necessary to install direct-current motors. This necessity no longer exists. In laying out new installations

*A paper presented at the Pittsburgh meeting of the American Institute of Electrical Engineers, Pittsburgh, Penn., Apr. 18, 1913.

not handicapped by an existing direct-current system, alternating-current motors only need be considered.

In the following discussion the term "constant speed" implies no appreciable change of speed from no-load to full load; "variable speed" implies speeds varying with the load, but constant at constant load; "adjustable speed" implies several independent speeds, each constant under varying load. In either case the polyphase alternating current motor in some one of its several forms meets all requirements.

I. Constant-Speed Drive

This is obviously the simplest condition met with and is found chiefly in connection with long railway tunnels, subways, and old mine workings in which the volume and pressure of air handled is practically constant twenty-four hours a day and every day in the year. For such service the standard polyphase induction motor is without a competitor. Properly installed, such a motor can be stopped or started automatically in emergency by remote control and will run constantly without attention other than occasional inspection of the oiling system.

II. Adjustable Speed Drives

The great majority of mine fan installations require an adjustable speed drive and for this reason, as stated above, until comparatively recently it has been practically necessary to install direct-current motors with shunt speed characteristics.

The average fan motor operates under practically constant load throughout long periods, consequently maximum efficiency is a consideration secondary only to the reliability of operation. The direct-current shunt motor shows a fairly high efficiency throughout its range of operating speeds but its installation is subject to the inherent disadvantages of the first cost, maintenance, and attendance of a direct-current generating and distributing system. As compared with these disadvantages the many desirable characteristics of the induction motor have frequently led to its installation even at the cost of a compromise between efficiency and desirable operating speeds. Numerous schemes for obtaining speed control for polyphase induction motors have been developed. Among those of chief importance are the following:

1. Constant speed motors with changeable pulleys.
2. Variable speed motors with rheostatic control.
3. Multi-speed windings.
4. Concatenation.
5. Single cascade motors.
6. Dynamic regulation.
7. Brush shifting motors.

1. *Changing pulleys* is obviously a make-shift method subject to annoying delays and limitations such as practical ratio of pulley diameters, and distance between center lines of shafts, etc.

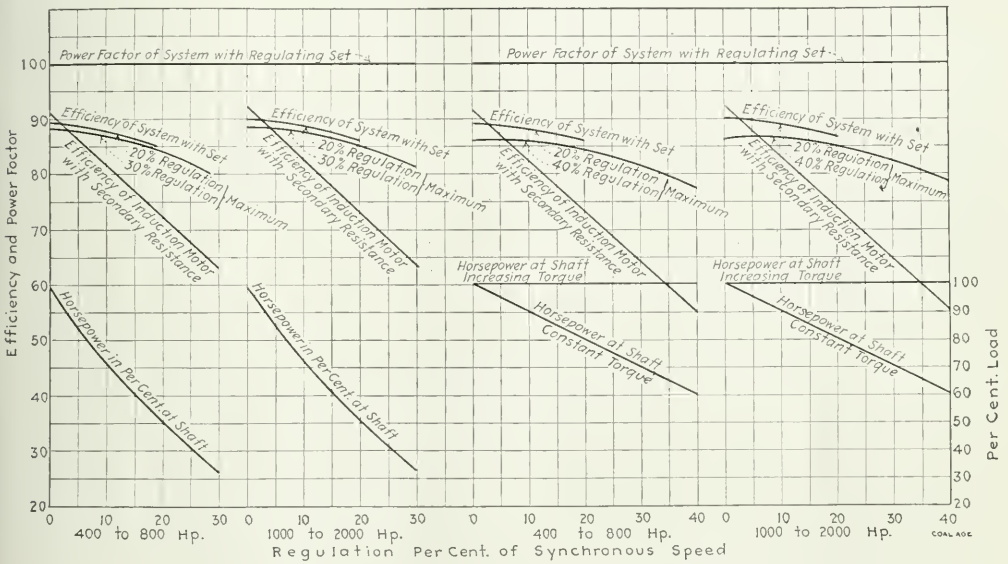

Fig. 9. Overall Efficiencies of Induction Motors

2. *Rheostatic Control.* When operating with negligible secondary resistance the polyphase induction motor is inherently a constant speed machine. Continuous speed control can be had by means of an adjustable resistance in the secondary circuit but the efficiency falls rapidly as the range of operating speeds is increased. (Fig. 4). In Fig. 1, A is the main motor and B is the external secondary resistance. Assuming that 50 per cent speed reduction by rheotatic control is required, it follows that the shaft output, with fan load must be approximately $(\frac{1}{2})^3 = 12.5$ per cent, and an equal amount of energy must be dissipated in the rheostat in addition to the losses in the motor itself. The effect on overall efficiency is obvious.

Another vital objection to rheostatic control lies in the fact that with external resistance in the secondary circuit, the speed varies with the load, accelerating under light loads and dropping again, to a value determined by the secondary resistance when the load comes on. Since at

no-load the secondary current is negligible, no amount of resistance within reasonable limits will hold down the speed of the motor.

Fig. 2 shows increase in speed of motor corresponding to several initial speeds when the load is changed from 1¼ to ¼ times full load torque.

3. *Multi-Speed Windings.* Where two definite constant speeds are sufficient the induction motor can often be supplied with external connections by means of which the polar grouping can readily be changed to give the desired synchronous speeds.. The cost of such a motor is but slightly more than that of a single-speed motor provided a 2:1 ratio is employed for the high and low speeds. Where a ratio other than 2:1, or where three or four constant speeds are required, the condition can sometimes be effectively met by two separate windings in the same slots, one or both of these windings being arranged for external multi-polar grouping. Three separate windings are not permissible in practical design. Such motors are sometimes used with or without changeable pulleys and rheostatic control for intermediate speeds but at best are a compromise, since the number of constant speed steps is limited by characteristics of design and by prohibitive costs. Rheostatic control is always objectionable for reasons noted above.

Fig. 3 shows diagrammatically the arrangement of stator and rotor windings for a two-speed changeable pole motor.

Fig. 4 shows typical efficiency and power factor curves for a two-speed motor with rheostatic control.

4. *Concatention.* Another method of obtaining three or more constant speeds, particularly where low speeds are required, has been employed abroad for mine fan service. This scheme employs segregated electrical and magnetic circuits and is known as operating in "cascade" or "concatenation."

In general two single-speed motors, one of which at least has a polar wound rotor, are mounted on the same shaft. The primary of motor *A* is connected to the secondary of motor *B*. Each of these motors may have either single or multi-speed windings and may be operated independently of the other as well as in concatenation. The second motor may have either a phase-wound or squirrelcage rotor. In case phase-wound rotors are used, speed regulations by secondary rheostatic control may be obtained in the usual manner, and with the usual objections.

Two motors are connected in direct concatenation if they show a tendency to start in the same direction and in differential concatenation if they tend to start in opposite directions. The synchronous speed of motors in concatenation may be determined as follows:

$$Speed = \frac{cycles \times 120}{P_1 \pm P_2}$$

where P_1 = number of poles of first motor and P_2 = the number of poles of the second motor, the plus sign being used for direct and the minus for differential concatenation.

With the multi-speed pole changing motors it is necessary to open the primary circuit when changing from one speed to the other, this may be avoided in concatenated sets by introducing resistance in the leads between the two motors, the resistance being cut in or out step by step when changing speeds (Fig. 5).

As noted with a polar-wound rotor, any reduction in speed by rheostatic control is accompanied by a proportionate reduction in efficiency, the power factor remaining practically constant. With concatenated motors the efficiency remains approximately constant provided there is no external resistance in the rotor circuit of the second motor, while, at the lower speed, the power factor drops, due to the fact that as compared with their normal individual ratings, the motors are underloaded when in concatenation.

5. *Single Cascade Motor.* The single cascade motor offers still another method of obtaining two or three definite fixed speeds. This motor has an internally concatenated winding. The stator windings are of the usual full- and half-speed types. The single winding of the rotor is so arranged that its magnetizing effect is the same as would be produced by two separate windings. It is, however, a decided improvement over two separate windings, since all coils which, in such cases, would neutralize each other, are omitted in the concatenated connection

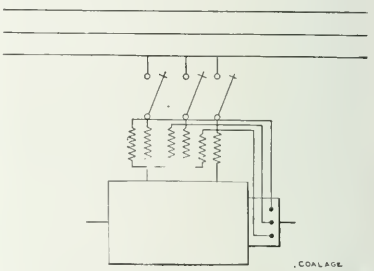

Fig. 12. Connections for Brush-Shifting Motor

and grouped together for connection to the slip rings for use only at other speeds. When the primary of the first element is properly connected with two circuits per phase in multiple corresponding to the number of poles, these circuits are in exact opposition for the number of poles in the second element and form a perfect path for short-circuiting the secondary of the second element. The stator winding, therefore, carries two currents simultaneously (1) a current from the line at full frequency and (2) induced current at a frequency corresponding to the slip. The general arrangement of windings is shown in Fig. 6.

By inserting a variable external resistance between certain points in the stator windings and open-circuiting the collector rings, variable-speed control can be obtained for the concatenated connection. Resistance across the collector rings gives ordinary variable-speed characteristics for the other two speeds.

This type of motor is particularly adapted to the three speeds corresponding to the polar ratios 1-2 and 3, for example 4-8-12, 6-12-18, etc.

6. *Dynamic Regulation.* As stated earlier in this paper, each of the foregoing schemes possesses inherent disadvantages which until recently have made it practically necessary to employ a direct-current motor with shunt characteristics whenever close regulation was required for a large number of speeds each constant under varying loads.

Recently means have been perfected whereby shunt speed characteristics can be had with the standard poly-

phase induction motor, together with high-power factor and high efficiency throughout the range of operating speeds. The method employed is susceptible of several modifications and will be referred to inclusively as dynamic regulation. With rheostatic control the secondary energy is dissipated as heat whereas with dynamic regulation the major portion of this energy is returned to the system. Referring to Fig. 7, the external resistance *B* of Fig. 1 is replaced by the compensated commutator motor *B*, which forms one element of a two unit motor-generator set, the second element of which is a standard squirrel-cage induction motor connected to the supply mains. This machine is driven slightly above synchronism by the commutator motor and operating as an induction generator returns to the system energy proportional to the slip of the main motor, less the losses in the set itself. The commutator motor receives energy from the secondary of the main motor at relatively low frequencies and in general must have a proportionately small percentage of the main motor capacity. Assuming that *A* is to drive a fan at 50 per cent. of synchronous speed the horsepower delivered to the fan will be approximately 12.5 per cent. of the rated capacity of the motor and the same amount of energy will be delivered to the regulating set.

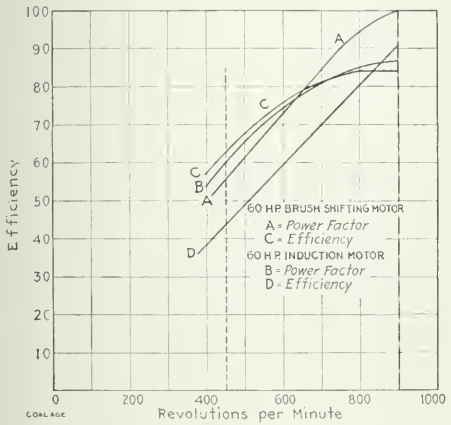

FIG. 13. POWER FACTOR AND EFFICIENCY FOR BRUSH-SHIFTING MOTOR

If the connected load required constant horsepower at the motor shaft, then neglecting losses, the motor input at 50 per cent. speed would be 200 per cent., the shaft horsepower 100 per cent. and the energy returned to the system 100 per cent.

If again the connected load required constant torque at the motor shaft, then neglecting the losses the motor input would be 100 per cent., the shaft output 50 per cent., and 50 per cent. would be returned to the system. This is shown graphically in Fig. 8. If *X* per cent. regulation is required the motor generator set must have *X* per cent. of capacity of the main motor: Fig. 9 shows typical curves of efficiency and power factor for the conditions indicated above with dynamic regulation and rheostatic control. Where standard regulating sets are employed they can be of relatively high speed and inexpensive design as compared with the slow-speed main motor.

Fig. 10 shows a modification of the above scheme in which the commutator motor *B* is direct connected to the main motor shaft. In this case the slip energy of the main motor is transformed to mechanical energy and the torque of *B* added to the torque exerted by the main motor *A*. This arrangement is especially desirable where constant horsepower must be maintained at the shaft. For fan service, however, the high-speed self-contained regulating set is usually cheaper and yields equally satisfactory results. Furthermore, the possibility of applying the standard regulating set to any standard induction motor with phase-wound rotor in event of future re-arrangement of equipment, is an important advantage.

In addition to the advantages of adjustable constant speeds under varying load and high operating efficiency the possibilities of power-factor correction are often of great importance. If desired, unity power factor can be maintained on the main motor with all the usual beneficial results in improved regulation and increased energy capacity in power-station and transmission system. Unity power factor correction naturally involves a somewhat more expensive set since the magnetizing current is supplied by the commutator motor instead of from the line. The standard sets should have sufficient capacity to raise the power factor of the main motor about 10 per cent., maintaining an average power factor of 95 per cent., or, in some cases, 100 per cent. without increased cost. In special cases it is possible to supply sufficient magnetizing current from the commutator motor to give the main motor a leading power factor, thus obtaining a certain corrective effect for low power-factor conditions on the external system. The kilovolt-ampere capacity, copper losses and first cost will be increased and the overall efficiency lower in this case.

The operation of the set with magnetic control is very simple. The induction generator is thrown across the line by means of a tandard compensator and brought up to speed as an ordinary squirrel-cage motor. The main motor is started by closing the primary oil switch and accelerated by automatic current limit control. The speed of the main motor adjusts itself to the tension determined by the setting of the exciter field rheostat. Any further speed adjustment is obtained by the manipulation of this exciter field rheostat.

The range of speed regulation obtained is limited by the maximum frequency impressed on the commutator motor. In general for good design this should not exceed approximately 20 cycles, which will give about 30 per cent. regulation on a 60-cycle motor. This limit varies somewhat with the size of the motor involved.

This system was developed in Europe and in the past four years about thirty equipments have been put in successful operation for mine fans and rolling mills. Three similar equipments have been sold in this country within the last six months.

Fig. 11 shows efficiency curves for two 400-hp motors driving a mine fan, with regulating set and with rheostatic control. Two of these motors were actually installed and operated continuously at 40 per cent. speed regulation by rheostatic control for nearly a year. Under these conditions the input to the fan would be 21.6 per cent., and the energy dissipated in the rheostat or delivered to the regulating set 14.4 per cent., of the full load rating of the motor.

From the curves the relative over-all efficiencies with

rheostatic and dynamic control are seen to be 51 per cent. and 70.5 per cent., respectively. The relative power consumption is therefore 169.5 hp. and 122.5 hp., or a net saving of 47.0 hp. per machine in favor of the regulating set. Assuming that power can be purchased for 1 cent per kw.-hr., the net saving due to the use of a regulating set with each fan 12 hr. per day, 300 days per year, would be $0.01 \times 47.0 \times 0.746 \times 12 \times 300 \times 2 = \$2525$, approximately. In many gaseous mines the fans must operate continuously 24 hours per day every day in the year, which would make the net savings $6160.

7. *Brush Shifting.* For fan installations requiring motors of 100 hp. or less capacity, in place of the regulating sets described above, the brush shifting polyphase motor can often be employed to advantage. Fig. 12 indicates the general arrangement of connections for this type of motor. The motor derives its name from the fact that it is started, stopped, reversed and controlled by merely shifting the brushes.

With a certain brush setting no torque is developed, consequently the motor will not start when the line switch is closed until the brushes are moved from this position. The speed of the motor is proportional to the brush shift. Reverse operation can be obtained by moving the brushes in the opposite direction from the zero position, but for best commutation two phases should then be reversed.

Brush shifting is accomplished by means of a suitable worm gear and handwheel conveniently located. Commutation is excellent throughout the entire speed range. Fig. 13 shows power-factor and efficiency curves for a 60-hp. brush-shifting motor and for an ordinary induction motor with rheostatic control designed for fan service. These curves were plotted from actual test data. The minimum permissible speed depends largely upon the torque requirements of the driven load. For fan service this type of motor will give stable operations at quite low speeds corresponding approximately to 70 per cent. slip below synchronism.

In conclusion it would appear to the writer that in the absence of an existing direct-current system, the advantages of the polyphase motor leave small ground for the application of direct-current motors for either constant or adjustable-speed fan drive.

Mine Inspectors' Institute, U. S. A.

The announcement has just been received of the fifth annual meeting of the Mine Inspectors' Institute of the United States of America, to be held June 10-13, 1913, at Birmingham, Ala. This is actually the sixth annual meeting, counting the conference of mine inspectors, held at Indianapolis, Ind., June 9-12, 1908. Following this first conference, annual meetings have been held at Scranton, Penn. (1909); Chicago, Ill. (1910); Charleston, W. Va. (1911); and Columbus, Ohio (1912).

All members of the Institute and all regularly commissioned inspectors of mines, in the United States and Canada, are urgently requested to attend the meeting at Birmingham. The purpose of the meeting, as stated, is to afford an opportunity to the mine inspectors of the states and provinces of North America to exchange ideas and discuss subjects relative to greater safety in mining.

All members are requested to furnish the secretary, at the earliest possible date, the title of any paper or subject they may desire to present for discussion. The following subjects are suggested as being of sufficient importance for presentation and discussion:

1. Compensation laws as they affect the miner and operator.
2. The phenomena of retarded ventilation at firing time.
3. The use of portable electric lamps by miners at the working face.
4. Need of uniformity of danger signals in mines.
5. Precautions to be observed in restoring ventilation after a mine explosion.
6. How to secure the coöperation of the miner in the reduction of accidents.
7. The use of mixed lights in mines.
8. Election versus appointment of State Mine Inspectors.
9. Ventilation in metalliferous mines.
10. Hardships imposed upon State Inspectors.

Members are earnestly requested to prepare papers on one or more of these or other subjects and to send a copy of the same to the secretary not later than June 1.

Birmingham and vicinity offers many opportunities to see coal and ore mining, blast furnaces, coke ovens, steel mills, mine sanitation, rescue stations and first-aid organizations.

If a member or a mine inspector, you are cordially invited to attend this forthcoming meeting. The State Mine Inspectors, the state and city officials, and the Chamber of Commerce of Birmingham will lend their assistance to make the meeting a success, and those who attend will have a touch of real Southern hospitality.

JAMES W. PAUL, Secretary.

A New Chapter of the Rocky Mountain Coal Mining Institute

BY F. J. MULLEN

A meeting was held at Koehler, N. M., on May 3, for the purpose of organizing a New Mexico Chapter of the Rocky Mountain Coal Mining Institute. The following members were present:

T. H. O'Brien, Allan French, Wm. McDermott, John W. Morris, Walter Kerr, J. B. Morrow, M. G. Smiglow, Frank Stafford, Frank R. Weitzel, Sebastian Frohmann, Archie French.

The following members were enrolled:

William Kilpatrick, Dawson New Mex.	H. B. Kerr, Van Houten, New Mex.
Tim Tinsley Dawson New Mex.	Alex Stewart, Van Houten, New Mex.
Wm. Hutchings Dawson New Mex.	Wm. Niel, Van Houten, New Mex.
F. J. Mullen, Dawson, New Mex.	James Stewart, Van Houten, New Mex.
Wm. Gordon, Dawson, New Mex.	T. W. Wallbank, Van Houten, New Mex
Warren Bracewell, Dawson, New Mex.	Frank A. Young, Raton, New Mex.
Moses Saul, Dawson, New Mex.	Walter Lovett, Raton, New Mex.
James Lees, Dawson, New Mex.	J. L. Caruthers, Raton, New Mex.
C. A. Mitke, Dawson, New Mex.	J. H. Willis, Gardner, New Mex.
Peter Gardner, Brilliant, New Mex.	J. Burkhalter, Gardner, New Mex.
James Bell, Brilliant, New Mex.	Adam French, Gardner, New Mex.
Joe Connor, Koehler, New Mex.	T. C. Harvey, Sugarite, New Mex.
John Evan, Koehler, New Mex.	Vincent Donati, Sugarite, New Mex.
Wm. Britton, Koehler, New Mex.	Adam Paghai, Sugarite, New Mex.
James Wallace, Koehler, New Mex.	A. H. Beamer, Sugarite, New Mex.
Menzie Wyper, Koehler, New Mex.	Wm. Langley, Sugarite, New Mex.

The following officers were elected:

President, Walter Kerr; Secretary-Treasurer, Wm. McDermott; Members Executive Board, Allan French, T. H. O'Brien, Wm. Kilpatrick, Peter Gardner.

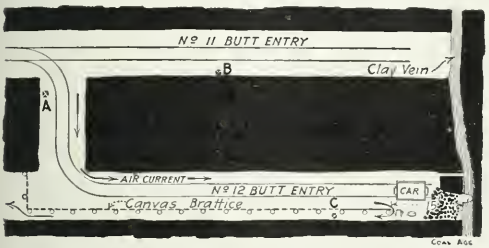
Owing to the short time at hand for the formation of the chapter, nothing else was attempted but the organization. However, at the next meeting, which will probably be held at Dawson, N. M., several excellent papers are promised for reading.

The Koehler "bunch" cannot be beaten on entertainment. A "swell" dutch lunch was provided for all those who desired to partake thereof, and added greatly to the sociability of the meeting.

The Cincinnati Mine Explosion

In addition to the meager accounts thus far obtainable in regard to the explosion that occurred in the Cincinnati mine of the Monongahela River Consolidated Coal & Coke Co., at noon, Apr. 23, 1913, in which 96 lives were lost, we have recently received a detailed sketch of the face of the heading, where the explosion is thought to have originated. This is No. 12 butt entry off No. 14 face entry.

According to the evidence given at the coroner's jury, which completed its work May 13, and whose verdict, in full, we append, the explosion was started by the ignition of a body of gas that had accumulated at the face of No. 12 butt entry. The No. 12 butt entries were being driven to open up a new portion of the mine. As shown in the sketch, one of these entries was being pushed ahead and was ventilated by a brattice, consisting of canvas nailed to a line of posts set about 2 ft. from the right-hand rib of the entry. The coal was drawn out from the face of the entry through the last cut-through, and the air current was conducted through the same cut-through to the face of that entry and returned behind the brattice.



Showing Face of No. 12 Butt Entry Where Explosion Started

The entryman had fired a shot at noon and had retired to the cut-through, where he ate his lunch at the point marked *A*. The face of the entry had struck a clay vein and the shot fired had penetrated this vein, and it is supposed had opened a feeder of gas, which is very apt to occur when an opening is driven through a fault. The gas from the feeder had accumulated in considerable volume at the face of the entry while the entryman was eating his dinner.

As no gas had been discovered in this portion of the mine since Mar. 5, 1913, according to the reports of the fireboss, the entry was being driven with open lights, no safety lamps being used. As a consequence, when the miner returned to the face of the heading, after eating his lunch, he unconsciously walked into and ignited the gas that had accumulated. The burning gas evidently developed into a violent explosion a short distance from the face, as the last 10 ft. of the brattice near the head of the entry was left intact, while the remainder was entirely destroyed, as shown by the dotted line in the sketch. The bodies of the two men who were killed in these entries were found at the points marked *B* and *C*. The miner's cap and the lamp (a common miner's torch or lamp), were found at the end of the brattice, as shown in the sketch. When the miner returned from his lunch, he had brought in with him the empty car shown at the head of this entry. The explosion that developed gained force in its passage throughout the mine, and, as a result, 96 lives were ushered into eternity with but slight warning.

Inasmuch as the verdict and recommendations of the coroner's jury are somewhat out of the ordinary, we give them in full for what they are worth. They are as follows:

The Verdict

We, the jury, find that Stephen Long and the 95 others named came to their death in the Cincinnati mine of the Monongahela River Consolidated Coal and Coke company, Washington county, Penn., on April 23, 1913, from violence and asphyxiation as a result of an explosion of gas in the said Cincinnati mine at about 12:15 p.m., while the miners were at work and the mine in operation.

We further find from the evidence given by those that worked in the mine at the time of the explosion and previously, also the state mine inspectors, experts and officials and others who made an investigation and examination of the mine after the explosion, that the cause of the said explosion of gas was as follows:

(a) That it originated in No. 12 butt entry off No. 14 face entry, as a result of the entryman, who worked in said entry, firing a butt shot which struck a clay vein exposing a feeder of gas. After firing said shot, the entryman evidently went to the break to eat his dinner and on returning with an empty car he ignited the gas with his open light with which he was permitted to work; we also find that no gas has been reported in said entry since March 5, 1913, by any of the mine officials.

(b) Further, that said explosion of gas which we find originated in said No. 12 entry reinforced itself in other entries, namely: Nos. 4 and 6 entries in which gas was generated and had been reported by the mine officials at different times and which entries were being worked with safety lamps.

(c) We further find that said explosion could have been prevented had safety lamps been used in this section of the mine.

(d) While under the law the legal responsibility for any explosion such as this would rest on the mine foreman, we say frankly that a greater responsibility rests upon the lawmakers and particularly upon those responsible for its enactment, for the reason, that it places the entire responsibility for the operation of the mine on the man granted a certificate of competency by the state but employed and paid by the owner and operator of the mine; certainly an absurdity on the face of it, and one that under human events will not successfully protect life either in theory or practice. If the present system must continue, surely the legal responsibility ought to be placed upon the owner or operator equally with the mine foreman. Guided by the testimony given, opinions expressed by those in official capacity as well as those employed in and about the mine we make the following recommendations:

Recommendations

First. To the management of the Cincinnati mine: That hereafter it be operated by safety lamps as a whole, and that no machinery be used that would make possible the emission of sparks. Surely the lesson to be learned here is the folly of working a gaseous mine with part open and part safety lamps.

Second: To the legislature and senate of this state: That if it is your desire to make safe the operation of mines that in the enactment of mining legislation you be guided more by the opinions of those intrusted with the responsibility of safe-guarding lives, namely, the state mine inspectors, the mine foreman and the miner, rather than by the opinion of the corporation, attorneys and managers of corporations, who, from a careful reading of the present law, seem to have in mind the competitive nature of business and the protection of property rather than the safe-guarding of human life.

Third: To the Department of Mines: We recommend that a more definite report be required from the firebosses and mine foremen in respect to the dangers existing in the mine, in their daily and weekly reports. For instance, if gas be discovered, that they be required to state in what part of the working place it was found, whether it be on a fall, or in a clay vein, roof, or the face of the working place and if possible in what volume.

Fourth: We call attention to this fact that while many of the mines of this district are working in whole or in part with safety lamps it is not because of any legal requirement,

but rather because of the diligence of the inspectors. Hence, until the final authority for the safe operation of the mines be vested where it should be, in the state inspectors of mines, without the right of the reverse of appeal by common pleas and supreme courts with all its delays, that the owners and operators or managers of mines cheerfully comply with the recommendations of inspectors, particularly those made for the purpose of safeguarding life and they should not be considered a business hardship.

Further, we recommend that, at any mine where gas is or has been discovered or is being generated, they be worked with safety lamps and other necessary precautions and that the use of machinery that caused emission of sparks be discontinued. We have carefully considered the evidence and law and the opinions expressed by those who testified, and feel that we have placed the responsibility for the explosion where it properly belongs, namely, on the mine foreman (legally), as we believe through an error of judgment on his part he permitted part open and part safety lamps in that part of the mine where the explosion took place; but we place a greater responsibility, morally, on those responsible for the framing and enactment of such a law.

Signed:

C. H. LANDEFELD, Foreman,
T. J. ECKBRETH,

W. F. ALTEN,
J. D. HOON,
ISAAC YOHE.

Plant of the Empire Coal & Coke Co.

Our front cover this week shows the plant of the Empire Coal & Coke Co. at Landgraff, W. Va., on the main line of the Norfolk & Western R.R., about 10 miles east of Welch. This is one of the most modern and uptodate tipples in the Pocahontas field.

The proper cleaning and sizing of the coal from this mine yields an increase in the market value approximating 15 to 20c. per ton upon the entire output. As the type of coal handled is a soft and brittle grade of Pocahontas, it has to be treated with extreme care to prevent degradation in sizes.

This tipple has a capacity of 500 tons per hour, and spans four loading tracks. It is so equipped that the coal is conveyed, sized, picked, mixed in any proportion desired, and loaded without appreciable breakage.

The mine cars are dumped at a point about 70 ft. above and 175 ft. south of the inside track. The coal is discharged from the mine cars into a 10-ton steel receiving hopper, from which it is delivered by a reciprocating plate feeder to a scraping conveyor, having steel flights 12 in. wide by 5 ft. long, placed every three feet on two 18-in. pitch sprocket chains. This conveyor is 135 ft. long between centers, and delivers the coal to shaking screens, where it is graded into slack, nut, egg and lump.

The slack coal passes by gravity to a 200-ton steel bin, from which it is carried, either by a 32-in. rubber belt conveyor to cars for shipment or by a scraper conveyor to a crusher and pulverizer, where it is reduced to uniform fineness for coking, and deposited by a 90-ft. bucket elevator in a 25-ft. diameter cylindrical steel larry bin at the end of the tipple.

The nut coal passes first to a revolving screen, where it is more thoroughly cleaned, and is then delivered to the nut picking table. This discharges either into cars direct or into a mixing conveyor. The egg and lump coal pass directly from the screen to their respective picking tables. These also deliver to cars direct or into a mixing conveyor.

The refuse is removed by hand from the picking tables, and deposited in a refuse conveyor, which runs parallel to and between the picking tables, but in the opposite direction. This discharges into a steel refuse tank located over a track at the end of the tipple.

The picking tables for lump and egg coal are each 5 ft. wide and 68 ft. long between centers, and both have hinged or adjustable loading booms, which are capable of being raised or lowered so as to discharge the coal into either the mixing conveyor or the railway cars without breakage.

The mixing conveyor runs at right angles of the picking tables, receiving coal from any or all of them simultaneously, and delivering it to the cars, mixed in any proportion desired.

All shaking screens are equipped with veils which permit of variation in the size of the product or the shipment of mine-run coal. From these screens the coal passes to the picking tables, practically without drop or breakage. The entire mechanical system consists of six units, each of which is driven by an independent motor and all operations are controlled by one man from an elevated bridge in the picking house.

The operation of this plant, which was designed and built by the Jeffrey Mfg. Co., of Columbus, Ohio, has been highly satisfactory and unattended by any serious troubles of any kind. The methods employed in the manipulation and treatment of the coal have not only eliminated the usual breakage, but have substantially increased the market value of the fuel prepared.

A Special Coke Number

The June 7 issue of COAL AGE will be devoted principally to the subject of coke manufacture. We will be pleased to receive articles and discussions dealing with some phase of the coke business from any of our readers. All matter for this particular issue of COAL AGE should be in our hands within the next week.

The Kentucky Mining Institute

The papers presented before the summer meeting of the Kentucky Mining Institute, held in Lexington, May 16-17, will be printed in our next issue of COAL AGE. A detailed account of the First-Aid Field Meet also will be published in our next number. It is safe to say that this most recent meeting of Kentucky coal men was the most enthusiastic and the best attended coal conference ever held in the State of Kentucky. The Continental Coal Corp. deserves particular mention for the vigorous support it rendered the Institute. The Continental people came to the meeting in a special train, with a brass band and all the other essentials needed to create plenty of enthusiasm.

American Coal in France

United States Consul General Frank H. Mason, stationed at Paris, says:

The year was marked by a notable advance in the prices of both coal and coke, so that some apprehension has been felt about future supplies of fuel for the iron and other industries. The price of coke for the metallurgical industries is fixed by agreement between producers in the Pas-de-Calais district and the blast furnaces in the east, and is revised every three months. The rates for the four quarterly periods of 1912 were as follows per metric ton of 2204.6 lb.: First quarter, $4.137; second; $4.194; third, $4.415; fourth, $4.697. This shows a net increase during the year of 56c. per ton.

EDITORIALS

The Miners' Opportunity

During the past few years much attention has been drawn to the various vocational mining schools being established throughout the country, and particularly in the anthracite region. Here the trapper boy, the driver, the laborer, miner and foreman meet upon a common level for mutual improvement. Nor is it uncommon to find the men in the inferior positions showing greater aptitude for, and improvement in, their studies than those higher up.

We have heard much of the hopelessness of labor and the inability of the laboring man to rise above his environment. These men should remember, however, that with the vocational schools and the mining institutes at their very doors, it is strictly "up to them" whether they shall remain in their present humble circumstances or shall succeed to positions of responsibility and profit in the mining industry. Surrounded by present-day opportunities, they and they alone are the masters of their own destinies.

Ohio's Proposed Anti-Screening Law

The determined and partially successful efforts that are being made to push through the Green "Run-of-Mine" bill in Ohio, in the face of numberless irrefutable arguments against it, furnishes conclusive evidence of another power in the political arena—the enormous and far-reaching power of organized labor. There was, of course, a time when corporations assisted in the election of men whom they could depend upon to at least protect their interests, but under pressure of public opinion they have been gradually forced to withdraw.

In the case of labor, the public is disposed to be more sympathetic and the unions are showing a prompt appreciation of the advantage and possibilities of this leniency. Class legislation is being enacted in all parts of the country, which is not only interfering with the management, but is destroying discipline and must eventually deplete the revenues of the industries affected. Labor's position differs from that of the corporation's only by delivering the votes instead of the money with which to buy them, and a candidate must declare himself or be branded as a "foe to labor" and suffer an ignominious defeat.

A brazen example of labor legislation is shown in a bill recently introduced in the New Jersey legislature, prohibiting railroads from testing their signals without first warning the locomotive engineers that such tests were to be conducted. It seems to have been the practice of the Pennsylvania R.R. to make tests of this character at intervals and of some 51,000 made in 1912 it was found that the enginemen failed to observe the signal in 510 cases.

Presumably each of these might have resulted in a fearful catastrophe and yet these men deliberately and unblushingly resent being disciplined and demand to be exempted from tests of their alertness and ability even though thousands of the traveling public are daily dependent upon these qualifications for their very lives. The "service bill" in Pennsylvania is an equally ridiculous and reprehensible measure, while the ultimatum delivered by the president of the Firemen's Brotherhood to the railroad managers that: "If we don't get it here, you can depend upon it we will get it in Washington" is particularly significant.

The Ohio screening bill is obviously a labor measure, headed by a labor leader and strongly supported by a labor party. It shows a determination on the part of the unions to gain their ends at a sacrifice of every other consideration and the people of Ohio would do well to study the effects of a like measure on the coal industry of Arkansas before idly conceding. The screening bill there went into effect in 1905. During the succeeding five years, to and including 1910 (the banner year in the coal industry for which any authentic returns are so far available), the coal production of the United States increased 28 per cent. During this same period Ohio's tonnage increased nearly 35 per cent., while that of Arkansas showed a slight *decrease*. The results are too obvious to require any comments.

The West Virginia Settlement

The Paint Creek mine-strike is settled, at least for a time, and we are not much surprised that an increase in wage is not among the provisions. The miners of West Virginia have been able to earn a fair living out of the present schedule, though it is lower on the actual tonnage basis than that obtaining in Pennsylvania and other states. This has been due to their steadier effort and to the fact that the coal is, for the most part, easier to dig.

But even if these statements were not true and the income from labor of the West Virginia miner were abnormally low, nevertheless we hardly think the Union, if firmly established, would be able to raise the wages of the miner in that state appreciably.

It has been always found that differentials were hard to correct because the interests of the operator and his employee and of the railroad transporting the coal are identical. Disturb the differential and the change in rates will reduce production in some other field; the railroad in that field as well as the operator and employee will be idle. So that real modifications of the balance are rarely effective whether decreed by courts or unions.

The Springfield, Ill., operators are raising a purse to seek lower rates from the commerce commission. If they succeed, other reductions will occur elsewhere and the differential will continue. The same condition is true of West Virginia in regard to wages. To raise the ton or day wage paid to miners and mining men will put West Virginia at a disadvantage in the market and in that misfortune, the workingman will suffer with the rest.

There was a time when wages could have been raised to a higher level in West Virginia, but that time has passed. The coal has worked its way into too closely competitive markets and the industry has grown accordingly, with the result that the lower wage is not merely needed to enter new markets but to retain those already secured.

It is foolish to believe that a Union could raise wages in a state where the ability of the operators to produce coal so largely overweighs their power to sell it. The Union and the operators have always acknowledged differentials where they existed and will be obliged to do so in the future. Labor is largely immobile and this fact prevents the actual compensation being nicely adjusted to the labor of mining. Men will not move from state to state for a trifling differential and when this difference is as much apparent as actual, the appeal is not enough to induce workingmen to migrate. So despite the lower wage the miner decides not to take "his beef and brawn" to the better market, and the price of his labor is fixed at the level which will permit the operator to conduct his business and meet the competition of all the fields into which his coal enters.

If labor was freely migratory, the lower-tonnage rate would years ago have caused the miner to move north and west. He would then have compelled the operator to raise the wage rate and the market of West Virginia would have been limited to its boundaries on three sides and to Virginia and the Atlantic Coast on the east. Labor did not migrate and West Virginia coal is found everywhere.

Nothing but a pronounced exodus can cause the operator to give higher rates than he now pays. If the miners would all have work and stay in the state, they must enable the operators to continue to ship coal to all points to which it is now being consigned by signing a wage scale like that now obtaining.

It is needless to add that the increase of wage cannot well come from the profits of the operator. West Virginia has been over-exploited like almost all of the American coal fields. Dividends in that state are hard to obtain and many are the concerns which cannot earn them or even "coax" a favorable balance on their books. The struggle between the operators of the state is now keen and profits are not made as freely as 15 years ago.

If the burden of a wage increase is to be laid anywhere, it might be placed on the royalties paid by the operators, but in any event such an increase would necessarily be small.

The Other Man's Way

The coal fields of America are operated in a number of exceedingly varied ways. It is remarkable that in a country with an active technical press, with railroads and mails highly developed, there is so much provincialism.

All our readers want a paper which will detail the plants in their own neighborhood—the mere chit-chat of local development. They do not know or care to know what is being done in remoter coal regions.

Yet the history of their own future mining methods is being written in these distant places. The State of Illinois, for instance, with increasing output and many new mines, is developing new standards—light steel headframes, fireproof yet not unreasonably expensive. It is adopting the electric hoist and largely using the recording scale. Some of its operators openly declare that the Eastern bituminous fields are effete and have set themselves largely against progress, but one can readily see where a trip East would reveal many new ideas which would revolutionize mining in the Middle West.

Our coal-mining institutes are doing valuable work in helping to bring the less modern mines of districts up to the level of the best, but these organizations are purely local. They do not broaden the minds of their members as such institutions should.

It is for this reason that we welcome the trip the Coal Mining Institute of America is about to make to Wilkes-Barre. It is well known that this body consists mainly of western Pennsylvania mining men, whose vision has been largely circumscribed by the Chestnut Ridge and the boundary lines of the western part of the state. There is a great need that all the institutions be widened by the travel of their members, and in no way could this end be obtained more successfully than by the welding of these smaller units into a common national body.

Relative Fatality Rate in Coal and Metal Mines

Albert H. Fay, at the recent meeting of the New York Section of the American Institute of Mining Engineers, declared that if the coal mines worked with the regularity of the metal mines, the fatality rate of the former would be higher than that of the latter.

But the method of calculating working days is perhaps not exactly parallel in the metal- and coal-mining industries. Mr. Fay declared that many of the companies reporting from the West, represented themselves as working 365 days, doubtless because every day some men were in the mine; the operations of timbering, laying track and repairing, proceeding briskly when the mines are idle.

The method of calculation favored by many metal-mine operators, has not found favor in the coal industry, the tendency being to record only the days when the mine is officially said to be running. In many mines when business is slack, much coal is undercut and shot down, not a little coal is hauled, and some is often actually dumped into the railroad cars on what are termed idle days; the tonnage being credited to the next official day.

Both the records of the Bureau of Mines and the Geological Survey relative to days worked are, we are assured by Mr. Fay and Jefferson Middleton, duly weighted so that the idleness of a small mine does not have appreciable effect on the estimated average, whereas the shutting down of a large mine has a much greater effect.

But the records received from the mining companies by these bureaus, while properly manipulated when presented, are not constructed by the reporting companies with due regard to scientific principles of reckoning. The results are, therefore, not entirely reliable, and if the truth could ever be known, it is probable that the small 11 per cent. margin, against the coal operator, would be shown to be the result of a variance in the method of calculation of the number of working days.

It remains a fact that the annual death rate of coal miners is 12 per cent. less than that of metal miners and, that thanks to the bureau amid many other agencies, the death rate is, at least, at present decreasing.

The Wilkes-Barre Industrial Exposition

The Greater Wilkes-Barre Industrial Exposition was held in the new Penn Tobacco Co. Building, on S. Main St., Wilkes-Barre, Penn., May 10-17, inclusive. The exhibits were displayed on the first and second floors, occupying a total space of about 24,000 sq.ft., while the third floor was used for concerts, etc. The total number of exhibitors was in the neighborhood of 112, while the materials displayed included everything from heavy mine machinery to a peanut stand.

The most interesting features of the exposition were in the display by the coal companies. To this the Lehigh Valley Coal Co., the D., L. & W. Coal Department, the D. & H., the Lehigh & Wilkes-Barre Coal and the Susquehanna Coal Co. contributed jointly. This exhibit included the demonstration of the first-aid rescue work, preparation of anthracite coal, pyramid of coal eight feet high, fossil tree weighing two tons, undercutting machine and all kinds of miner's and safety lamps, all sizes of coal and the face of a timbered gangway with a loaded car on the track.

The length of the gangway was about thirty feet and the timber was covered with tarred paper or similar black material, so that the whole room was made dark, while the face appeared to be a solid mass of coal, eight feet high, with a six-inch slate band, four feet from the bottom. It was built with lumps of coal, each about one cubic foot in size and mortared with a black cement. A dummy was placed at the face to represent a miner about to drill a hole. So realistic was this representation that a boy, after examining the face, remarked to his father: "This is really and truly a coal mine!"

Machinery Exhibits

The Vulcan Iron Works displayed a mine locomotive which was new and looked very attractive. It was so placed that a visitor could examine all its parts without bending or stooping. The Hazard Wire Rope Co. exhibited a machine drawing copper wire and insulating the same.

The Howells Mine Drill Co., of Plymouth, Penn., exhibited an electric coal drill. This outfit consisted of an electric drill, Spry type "S," and a 10,000-lb. lump of anthracite coal, obtained from one of the D., L. & W. mines, in Plymouth. This coal contained, roughly, 110 cu.ft., being a 4.8-ft. cube. The electric drill was mounted in front of the coal with a 1½-in. bit, and current was turned on. The machine actually drilled at the rate of 7 ft. per minute.

To drill a 7-ft. hole with a hand apparatus requires at least 30 min. In other words, the electric drill works thirty times faster than the ordinary hand machine. The motor requires about 15 amp. at 220 volts, direct or alternating current. The weight of the complete outfit with post is 275 lb., and the cost $275, or one dollar per pound. There are now about 300 of these electric drills used in the anthracite region. They are also being employed in salt, gypsum and talc mines.

Part of the Coal Companies' Exhibit at the Greater Wilkes-Barre Industrial Exposition

DISCUSSION BY READERS

Education in Coal Mining

Letter No. 18—Education, in its broadest sense, includes such instruction and discipline as is intended to enlighten the understanding, correct the temper, cultivate the taste, form the manners and habits, and fit persons for usefulness in their future stations. Education is as necessary in coal mining as in any other industry. Every man and youth needs all the education he can get, and the amount of good he will derive from it will depend upon himself.

A systematic study will bring good results, if properly applied to everyday conditions; but a spasmodic effort to get, in two weeks time, the knowledge that should require two years to obtain, can result only in final failure. Compulsory school laws will tend to keep many boys away from the mine; education will turn many to other occupations. As a natural result, the future of coal mining must depend on imported foreigners, who must be educated and trained how to mine coal properly, and how to protect themselves and the property of their employers.

The education that is mostly needed in coal mining is the kind that applies to the actual working conditions, and teaches the miner how to properly mine and shoot his coal, timber his working place, handle and load cars, and many other things that will insure his safety and economize time, labor and material.

My advice to every coal miner is: "Be ambitious; get all the book learning you can by reading and studying coal-mining books and journals. Do not crowd your head with formulas and neglect other things more important. Try to apply what you read to the actual conditions with which you are familiar. Make good use of your spare time and idle days. Consider the work in the mine as a course of educational training and study how the work can be done in the best, safest, cheapest and quickest manner. Observe closely all that is done in the mine, and, when possible, ask to have explained what you do not understand.

The question of deciding the character of mining examinations is a very broad one and can be looked at from many different sides. I think that only such questions should be asked as relate to the actual work and conditions that mine foremen and firebosses have to meet in the mine and the problems they must solve. Sometimes, questions are asked at examinations that are entirely out of place and, in actual practice, would be handled by one of the engineers rather than by the foreman.

Handbooks and textbooks are written by experts and authorities, and their purpose is to aid the worker and save his time. If a man understands the principles taught and has the intelligence to use a handbook correctly he will use it in actual practice; and the examination should be made to correspond to that practice, as nearly as possible. A mine worker going before an examining board is naturally anxious and excited. He fears and forgets; his hands are used to toil and it is hard for him to write fast and long. Therefore, I believe more stress should be laid on oral questions and less written work should be required of the candidate. In this way, the examiners would be able to draw out many good points that the candidate would forget to write.

Proper weight should be given to a man's experience and his personal and moral record. It frequently happens that certificates are granted to young men who are wholly incapable of running a mine and have not had the actual experience in gaseous mines; but who, by stretching the truth, are able to pass a creditable examination. A man's experience in gas should be verified. I am in favor of giving the mine worker every educational advantage possible, morally, physically, intellectually and sociologically; but, by all means, be square with him; and do not expect of him the attainments of a student or a college-trained man.

MINING ENGINEER.

Clarksburg, W. Va.

Letter No. 19—The necessity of requiring candidates for the position of mine foreman or fireboss, to undergo an examination and obtain a certificate of competency from a duly authorized examining board has been demonstrated as a wise provision. Mining today requires the services of men who have more or less technical training; but the man who blends both practical and technical experience and training is in greatest demand. The method of obtaining technical training in almost any line or industry is not denied any ambitious person today. Educational methods are made clear and concise, and the course of study much shortened by presenting only those parts of subjects that are necessary for the particular work in hand.

While there are some ambitious, energetic young men with means sufficient to obtain a thorough technical training, it cannot be denied that many of this class would have received greater benefit by going to work in the mills, mines, or on the farm than by going to college. There are, on the other hand, many thousands of men whose schooling has never gone beyond the eighth grade; and this, in many cases, has only been accomplished by the passage of the law prohibiting children under 14 years of age, in some states, and 16 years of age in Montana, from working in the mines. Few of these men realize they have much to learn until they have reached the age of 30 or 35 and sometimes 50 years.

A Chinaman in Butte City, Mont., took a course in land surveying, at 60 years of age, and successfully completed it. While men of advanced age, however, have generally lost the faculty of memorizing formulas, constants and other data, it is not difficult for them to learn to select and apply the proper formula required for the solution of any problem. The engineer, although a college-trained man, refers constantly to his handbook for such formulas, constants and data. The practical mine foreman, in the same manner, uses his handbook to work out any mathematical problem connected with his work.

Such a man is a more competent man in the mine than the college-trained man, who seldom has any practical experience.

I recently discussed the subject of examinations with a general manager of coal properties in Canada, who was himself a college-trained man but, later in life, gained considerable practical experience and understood well what was required of a good mine manager. This man remarked that, in Canada, the examinations were running more to the academic than to the practical; and that, on this account, good mine managers were becoming scarce.

When the mining law requiring the examination of mine foremen and firebosses in Montana was being drafted I asked those who had charge of the bill to incorporate a provision allowing the use of textbooks in the examinations, explaining that it would be a benefit to the practical man and that, by suitable regulations in respect to the character of the examination, it would give no advantage to the college-trained man. On the other hand, the practical man with some technical training would thus become a dangerous competitor of the technical man who had little or no practical experience.

Education is a valuable asset, more so to the man who works during the day and studies at night to acquire knowledge. Such a man is of more value to a company than any walking encyclopedia who can reel off formulas, constants and other data, without reference to textbooks. In the performance of difficult mining work, I very much prefer to employ the engineer who refers to his textbook in preference to the wiseacre who quotes from memory.

The use of textbooks, in examinations before county boards in Montana, is safeguarded, as the books are only allowed for certain purposes, and this law is working satisfactorily. I believe less harm will result in allowing the use of textbooks to enable the practical miner to pass an examination for mine foreman or mine inspector than would result if many of these men were debarred on account of their inability to memorize formulas. In such an examination the college-trained man certainly has an advantage, because he can more easily remember the data and formulas he needs in the examination.

It is my experience that the use of textbooks, in this manner in examination, does the technical man no harm, while it places the practical man of limited technical training on the same basis on which he is accustomed to work in the office or at home. In other words, it gives the practical man an opportunity to show his ability to handle this class of work in connection with his other duties. It would not make him a better man if he could remember the data and formulas he is accustomed to find in the textbook.

JOSEPH B. MCDERMOTT,
Chief Mine Inspector.

Helena, Mont.

A Suggestion

The practical man has a hard road to travel; and there should be some means adopted that would require him to increase his education along certain lines. It might be that an examination at certain periods would solve this question. Mining journals should give this matter careful consideration.

A MINE SUPERINTENDENT.

Johnstown, Penn.

Carelessness the Cause of Many Mine Explosions

Since I have been a reader of COAL AGE, many articles have appealed very strongly to me, especially those treating on explosions of gas or dust.

In the year 1888, Jan. 24, I was in an explosion at No. 5 mine, Wellington, B. C., Canada, where 97 men lost their lives. Eight months previous to this No. 1 mine at Nanaimo had exploded, causing the loss of 137 men. I was a witness of the terrible effects of these explosions, both of which were ascribed to coal dust ignited by blownout shots. I know gas was often found in each of these mines and I believe that in the explosion gas was disturbed and brought down on the naked lights by the blownout shots. I believe also the explosion was augmented by the coal dust blown into the air by the force of the blast. However, comparatively little was known then of the danger of coal dust in respect to mine explosions. In these cases the coal seam was irregular, measuring in some cases 16 and 20 ft. in thickness, while in other cases the coal would run out to 2 and 3 ft. in thickness. This condition interfered considerably with the proper ventilation of the mine.

I feel the coal industry deserves greater consideration by scientific men than it has received in the past; and I am glad to see that such men are applying themselves to a careful study of this subject. I believe that greater care should be taken by mine managers generally in the selection of workmen in mines where gas is encountered, and coal dust is known to be a source of danger.

I recall an instance that occurred when I was employed in an entry where several stalls were turned off and the only means used to conduct the air past these stalls into my place was a brattice cloth. I found gas in my place and went out to ascertain the cause, when I discovered a man with a curtain propped up while he was loading a car. I pushed the car ahead and dropped the curtain. Going back to my place, it was not long before the condition was as bad as ever. Going out again, I found the man working as before with the curtain up. It is true he was rather cramped for room to fill the car with the curtain down, and sooner than put up with that inconvenience he was willing to run the risk, and endanger the lives of every man in the mine.

I reported this incident to the firebos, but it did not seem to impress him as a matter of importance, and I left the mine at once. I could not leave the camp, since a washout had occurred on the railroad, and while I was waiting for transportation, the most disastrous explosion ever experienced in British Columbia occurred at No. 2 mine, Fernie, May 22, 1902. I was at Michel. The superintendent there called for volunteers to go to Fernie. With others I answered the call and worked four days in the efforts to rescue the men in that mine.

I think this and similar accidents, which are of everyday occurrence show that it is of the utmost importance in coal mining that careless workmen should be eliminated and kept away from the mines. I admit there are difficulties in accomplishing this, but claim it should be the constant effort of mine managers to secure a force of careful workmen.

AMOS GODFREY, MGR.,
B. C. Anthracite Coal, Ltd.

Vancouver, B. C., Canada.

Appointment vs. Election of Mine Inspectors

Referring to the editorial on "The Anthracite Mining Code, COAL AGE, May 10, p. 733, permit me to add that the chief objection urged against the appointive system, in the selection of mine inspectors, is that this system places in the hands of a single person, generally the governor of the state, the power to appoint any person he may choose who fills the requirements of the law in this respect. If this were true, and it is in some states, the objection would be an important one, since it would inaugurate the "spoils system," which is opposed to civil-service practice, which should always control the selection of mine inspectors. All will agree that the office of inspector of any nature, mine inspector, boiler inspector, building inspector, etc., should be entirely disassociated from the spoils system, in order that the work of the inspector may be efficient, and that he may be untrammeled as an officer of the law, in the difficult work he has to perform.

Referring to the appointment of mine inspectors, the law recommended by the majority of the anthracite-code commission (Art. 9, Sec. 1), provides that the governor shall appoint a mine inspectors' examining board, consisting of four mining engineers and five miners, whose qualifications are specified in the law. The law further specifies the time and character of the examination and the qualifications of the applicant, and requires that the successful candidate must obtain at least 90 per cent. in the examination. The law provides that at least six of the nine members of the board shall certify to the governor and also to the chief of the Department of Mines the names and percentages of the candidates who passed a successful examination.

Then follows Sec. 6, which reads:

The governor shall, from the names certified to him by the examining board, commission a person or persons having the highest percentage in the examination, to be inspector for each district where a vacancy exists.

The advocates of this provision of the law claim that, since the governor must appoint the candidate or candidates receiving the highest percentage in the examination, he is not free to appoint the man of his choice. It must be remembered, however, that, in accordance with Sec. 1, the governor appoints also the examining board, which lays the law open to the previous criticism, giving the governor the supreme power that is always objectionable. To avoid this difficulty, the district court should be made to appoint the examining board, while the governor is authorized to appoint, as inspectors, and commission those candidates receiving the highest percentages in the examination.

Study Course in Coal Mining

BY J. T. BEARD

The Coal Age Pocket Book

MECHANICS

Mechanics is that branch of science which treats of the action of force on matter.

Force—Force is an indescribable agency that acts on matter and changes or tends to change its condition or state with respect to rest or motion.

Statics, Dynamics—There are two general divisions of the subject, which may be defined as follows: 1. Statics includes all cases in which force acts on a rigid body and no motion results. 2. Dynamics relates to the action of force on bodies free to move and motion is produced.

Measure of Force—A force is measured in either one of two ways, according to the conditions under which it acts or the results produced. In statics, the action of the force produces pressure only, and this pressure is the measure of the force expressed in ounces, pounds, hundredweight, or tons.

In dynamics, the unit of measure is a force capable of producing a unit velocity in a unit of mass. The moving force, in any given case, therefore, is expressed by the product of the mass (m) of the body and the velocity (v) produced. This moving force is sometimes regarded as imparted to the body when it is called the "momentum" of the body.

Gravity—The force of gravity is the most universal force in its manifestation and, for this reason, its effect is made the basis for the measurement of all forces both in statics and dynamics. Gravity is the attraction that every particle of the mass of the earth exerts on each particle of the mass of a body. This attraction is greatest at the surface of the earth and decreases above or below sea level.

Weight—The action of gravity on bodies produces weight. The generally accepted unit of weight is the pound. Since gravity acts equally on each particle of the mass of a body, the weight (W) of the body is proportional to its mass (m) and the force of gravity (g), as expressed by the formula

$$W = mg$$

The pound is the static unit of measure. It is the amount of the force of gravitation that acts on a certain prescribed mass, at sea level.

Mass—The mass of a body is expressed by the quotient obtained by dividing its weight, in pounds, by the value of the force of gravity at sea level, as expressed by the formula

$$m = \frac{W}{g}$$

Value of Gravity—The value of gravity is determined by the gain, each second, in the velocity of a body falling in a vacuum. This value varies with the latitude of the place and the elevation, and is expressed in feet per second. It has been carefully determined by a number of experiments.

The Coal Age Pocket Book

Theoretical Velocity—When a body falls freely in a vacuum there is no resistance to its fall; and the force of gravity (considered as constant for the distance of fall) acts on each unit of the mass of the body to increase the velocity of its fall. At sea level, New York, lat. 40°, the force of gravity produces an increase in the velocity of a body falling in a vacuum, of 32.16 ft. each second. This is called the "theoretical velocity" of a falling body; because, in practice, the resistance of the air is always present and reduces the gain or increase per second.

Body Falling from Rest, in a Vacuum—If the body falls from rest, in a vacuum, its velocity is zero at the beginning of fall and 32.16 ft. per sec., at end of 1 sec. The average velocity for the first second is therefore ½ (32.16) = 16.08 ft.; and the distance of fall in the first second is also 16.08 ft.

For two seconds, the gain in velocity is 2 × 32.16 = 64.32 ft. Falling from rest, the velocity at end of 2 sec. is 64.32 ft. per sec. The average velocity for the 2 sec. is ½ (64.32) = 32.16 ft. per sec.; and the distance of fall for two seconds is therefore 2 × 32.16 = 64.32 ft.

For three seconds, falling from rest:

Gain in velocity	= 3 × 32.16	= 96.48 ft. per sec.
Velocity at end of 3 sec.	= 0 + 96.48	= 96.48 ft. per sec.
Average velocity for 3 sec.	= ½ (96.48)	= 48.24 ft. per sec.
Distance of fall in 3 sec.	= 3 × 48.24	= 144.72 ft.

In like manner, for a body falling from rest, in a vacuum, the total gain in velocity is the final velocity at end of fall; the average velocity is one-half the final velocity; and the distance of fall is the average velocity multiplied by the number of seconds of fall; thus,

Time of Fall, in Seconds	Gain in Velocity Each Sec.	Total Gain or Final Velocity	Average Velocity in Ft. per Sec.	Distance of Fall, in Feet
0	.....	.....	.....	.....
1	32.16	32.16	16.08	16.08
2	32.16	64.32	32.16	64.32
3	32.16	96.48	48.24	144.72
4	32.16	128.64	64.32	257.28
5	32.16	160.80	80.40	402.00
10	32.16	321.60	160.80	1608.00

Formulas for Theoretical Velocity—The formulas expressing the final velocity (v), of a body falling from rest, in a vacuum, under the influence of gravity (g = 32.16 ft. per sec.); and the height of fall (h); for a number of seconds (t) are as follows:

Final velocity, $v = gt$ (1)

Average velocity, $\frac{v}{2} = \frac{gt}{2}$ (2)

Height of fall, $h = \frac{gt}{2} \times t = \frac{gt^2}{2}$ (3)

Time of fall, $t = \sqrt{\frac{2h}{g}}$ (4)

INQUIRIES OF GENERAL INTEREST

Removing Gas by Boreholes

A difference of opinion existing, we desire to submit the following question relating to the drainage of gas accumulated in abandoned workings that have been sealed off with air-tight stoppings:

The surface is of a hilly nature; a 6-in. borehole 900 ft. in depth has been drilled from the surface to tap a body of pure marsh gas accumulated in an abandoned section of a mine. The gas is dormant, by which is meant there are no feeders producing a fresh supply of gas. The abandoned section is entirely isolated from any other part of the mine and does not get any air from the mine workings. Owing to the depth of the workings below the surface, the difference between the atmospheric pressure at the surface and that in the mine is 1 in.; or, say the pressure on the surface is 23 in. of mercury when the pressure at the bottom of the shaft is 24 in. Will this borehole remove the accumulation of gas in the abandoned area under these conditions? The only vent is through the drillhole to the surface.

JAMES W. GRAHAM,
Deputy Mine Inspector.

Lafayette, Colo.

The question states that the place is sealed off with air-tight stoppings, and the only vent is through the drillhole to the surface. Therefore, no air can enter or leave this section except through the drillhole.

There are two conditions that would give rise to a slight or gradual interchange of the gas below and the atmospheric air at the surface: (1) The atmospheric air is generally cooler and therefore heavier than the mine atmosphere. (2) The "pure marsh gas" (CH_4), being much lighter than air, will tend to rise as fast as it is replaced by the heavier air at the surface.

The interchange of the gas below and the air at the surface will be very gradual at the best, owing to the great depth of the hole. There would probably be no perceptible current, either up or down, in the drillhole. The conditions named, however, would operate slowly to change the gaseous condition in the abandoned section, but the change would be too slow to be of any practical benefit in draining off the gas.

In order to drain the gas from the abandoned section, in this case, it would be advisable to insert a pipe provided with a stop-cock, in one of the sealed stoppings. Observations should be taken, from time to time, to ascertain any movement of air or gas through this pipe. If the blowing system of ventilation is used in the mine, the mine air will always escape through the pipe into the abandoned section and drive out the gas, which would then pass up through the drillhole to the surface. If, on the other hand, the exhaust system of ventilation is employed, the gas accumulated in the abandoned section will be forced by the pressure of the atmosphere exerted through the drillhole, into the mine workings whenever the stop-cock is open in the pipe.

Hoisting from Two Seams

What kind of an engine must we install to hoist coal from two veins in the same shaft? The first vein is 70 ft. below the surface and the second vein is 105 ft. lower, making the total depth of the shaft 175 ft. Should we use a friction clutch on the drum, or should the drum be keyed to the shaft?

ENGINEER.

Calvert, Texas.

For this depth of shaft (175 ft.), a geared engine, sometimes called a second-motion engine, should be used. In deep shafts, say where the depth exceeds 75 or 80 yds., a higher speed of winding must generally be used; and for that purpose a direct-connected or first-motion engine is generally preferred. In shallow shafts, the geared engine gives a better control of the hoisting operations and permits a heavier load being hoisted.

In order to hoist from two separate seams, a double drum must be used, one portion of which is movable on the shaft and supplied with a friction clutch by which it can be made fast to the other drum or to the drum shaft. This arrangement will permit the relative position of the cages in the shaft to be changed when it is desired to hoist from another seam.

For example, suppose it is desired to stop hoisting from the lower seam and start to hoist from the upper seam. When hoisting from the lower seam, one of the cages is at the landing in that seam when the other cage is at the tipple landing. Now, to change the relative position of these cages, it is only necessary to apply the brake firmly to the movable drum, thus securing the cage at the upper landing, and, having loosened the friction clutch holding that drum to the drum shaft, hoist the other cage to the landing at the upper seam, and again apply the friction clutch. The cages are now in position to hoist from the upper seam.

Percentage of Gas in Air Splits

If an air current containing 9.5 per cent. of gas and measuring 30,000 cu.ft. of air per minute, is divided at the regulator so that one split passes 10,000 cu.ft. per min., and the other split 20,000 cu.ft. per min., what percentage of gas is there in each of these splits, and what quantity of gas is passing in each split per minute?

STEPHEN STRANCH.

Helen, Penn.

Assuming the gas is evenly distributed in the air current, it will be divided in the same proportion in which the air is divided and there will be the same percentage of gas (9.5 per cent.), in each of the splits, as was found in the main air current before it was divided.

The quantity of gas in the first split is $0.095 \times 10{,}000 = 950$ cu.ft. per min.

The quantity of gas in the second split is $0.095 \times 20{,}000 = 1900$ cu.ft. per min.

EXAMINATION QUESTIONS

Bituminous Firebosses' Examination in Pennsylvania, May 8, 1913

Ques.—On entering a mine as fireboss, how would you discharge your duties as such, and what information should you obtain before beginning the examination in the mine?

Ans.—Assuming that the fireboss has properly cleaned, filled, trimmed and tested his lamp before entering the mine, his first duty is to proceed at once to the main intake airway in order to ascertain whether the usual amount of air is passing into the mine. Before entering the mine, the fireboss should always ascertain that the fan is running at the usual speed and that the proper danger signals are set at the mine entrance to prevent anyone from entering the mine while he is making his examination. The fireboss then proceeds to the intake of the section of the mine in his charge and examines, in regular order, the working places in that section.

Ques.—What are the legal duties of a fireboss? State briefly.

Ans.—The bituminous mine law of Pennsylvania requires the fireboss to examine carefully, within three hours before the appointed time for the men to enter the mine, every working place without exception; all places adjacent to live workings; every roadway and every unfenced road leading to abandoned workings and falls in the mine; and to examine for all dangers in all portions of the mine in his charge; and to mark the date at the face and side of every place examined, as evidence that he has performed this duty. He must examine the entrance or entrances to all worked out and abandoned portions adjacent to the roadways and working places, where explosive gas is liable to accumulate; and place a danger signal across the entrance to every place where explosive gas is discovered or danger is found to exist. In making his examination, he must use no other light than that of an approved safety lamp. It is the duty of the fireboss to explain all danger signals to the non-English-speaking employees of the mine, through an interpreter, in their own language.

The law requires the fireboss to enter in a book kept at the mine for that purpose, a record of his examination, in ink, and sign the same immediately after the examination is made. This record must show the time taken in making the examination and state the nature and location of any danger found, which danger must be then immediately reported to the mine foreman. He must notify the mine foreman, or assistant mine foreman, by telephone, or otherwise, that the mine is in safe condition for the men to enter. Where the record book is kept at a station in the mine, the fireboss must also sign the report made in the book kept in the office on the surface. The law requires that a second examination shall be made by the same or other firebosses during the hours when the men are at work. The mine foreman and the fireboss must provide a permanent station with a proper danger signal designated by suitable letters and colors, at or near the main entrance or entrances to the mine.

Ques.—Give six essential features of a safety lamp for testing purposes.

Ans.—A good lamp for the purpose of testing for gas and examining the mine for other dangers must not only be (1) simple in construction and sensitive to gas, but must be (2) capable of giving a good light when required. In order that the lamp shall be sensitive to gas, (3) the air should enter the lamp at a point below the flame and circulate upward through the combustion chamber. The lamp should be (4) provided with a double-gauze chimney that will permit of a free circulation of the air in the lamp while, at the same time, giving the needed protection in the upper part of the lamp. The lamp should be (5) provided with a suitable bonnet or shield, such as to protect the lamp against strong air currents or blasts of air, without unduly restricting the circulation in the lamp. The oil burned in the lamp should be such as (6) to give a constant flame that does not incrust the wick or cause the lamp to heat rapidly in gas. A pure sperm, or cottonseed oil, is better adapted for testing than a volatile oil, because the latter volatilizes more rapidly as the lamp heats in gas and gives unreliable results in testing.

Ques.—Who should be intrusted with a safety lamp, and when and where should you use safety lamps in bituminous coal mines?

Ans.—A safety lamp should only be intrusted to a competent person—one who has shown that he understands its use and can be relied on to exercise proper judgment and discretion in its handling and use. A safety lamp is never safe except when properly handled by a competent person.

Safety lamps should be used exclusively, in mines generating gas in sufficient quantity to be detected on the flame of a common Davy lamp, or where the condition at the working face, with respect to the generation of gas and the circulation of air, is such that gas can be readily fired at the roof or at the immediate face of the coal. In the present status of coal mining operations, it is not safe to work, with open lights, such places where the lamps must be kept at a safe distance below the roof and away from the face of the coal. The only exception to this rule may be at the anthracite mines, where coal dust is not as dangerous a factor in the production of an explosion.

It is not safe to work any bituminous coal mine with mixed lights, since any unforeseen occurrence in the safety-lamp section, such as a fall of roof or a slight derangement of the ventilating system, may precipitate a dangerous condition in the open-light section of the mine.

Ques.—Where should safety lamps be filled and trimmed before being given to the workmen?

Ans.—All safety lamps should be properly cleaned, examined, filled and trimmed in the lamp house before they are delivered to workmen.

COAL AND COKE NEWS

Washington, D. C.

T. P. MacDonald has filed with the Senate Committee on Territories a recommendation for dealing with the coal situation in Alaska which embodies the following suggested propositions:

First. Limit the ownership or control of any coal company to 4 or 6 sq.mi., or such acreage as may be deemed sufficient.

Second. Fix adequate penalties to prevent combinations to control output or prices.

Third. Empower the Interstate Commerce Commission or some other competent court to make thorough investigation and fix minimum and maximum prices upon a proper showing by either a coal producer or a coal consumer and thus prevent the crushing of independent operators by their more powerful rivals on the one hand or the charging of extortionate prices on the other.

Fourth. Fix a permanent tax of a few cents per ton to be paid into a territorial fund to defray the expenses of proper supervision of mining methods under laws to be enacted by the territorial legislature, to protect the lives and health of the miners, and to provide a laborers' compensation fund.

Such a law would preserve the principles necessary to secure competition, a wide distribution of ownership, and enable the operator of moderate means to finance his enterprise, and provide for the welfare of the miners.

Fifth. The coal-land law of May 28, 1908, was intended to restrict the amount of coal land any company might own or control and to prevent monopoly, but that law is only applicable to such lands as were located prior to the withdrawal. That act has been nullified to all intents and purposes by construction and such drastic rulings by the Land Department that no titles can be issued under it.

Opinion on an Alaskan Railway

Falcom Joslin, of Fairbanks, Alaska, in discussing before the committee the question whether a government line should be built in Alaska for the purpose of opening up the country and developing coal mining, said:

I think the coal fields should be opened without a moment's delay. Then I believe there is no better way of getting these trunk lines built than the way proposed in the bill. You might provide that the government shall guarantee 75 per cent. of the cost of those lines by guaranteeing the bonds of a company to build them, the company to supply 25 per cent. of the cost, as was done in the western half of the Canadian line.

This is a good system. It results in the economy of private enterprise both in construction and in operation; but if the government guaranteed 75 per cent. of the cost of the lines, I would certainly put in the contract that the government should have at least 50 per cent. of the net earnings when those roads become profitable. I cannot see any reason in the world why, if the government guarantees the cost of the lines, or 75 per cent. of the cost of the lines, the government should not have a percentage of the net earnings, exactly as a banker would require for supplying the money to build them on a straight business proposition.

If I sought the money to build that line across from Seward or Cordova from a banker in New York, and he supplied the money secured by bonds to build the line, he would unquestionably require at least half of the equity or half of the stock of such company. I cannot see why, if the government is going to do such a thing, it should not have an equal privilege.

Instead of giving the government stock for its interest the government would retain a certain percentage of the net earnings when there are net earnings. As these roads could not become profitable for five, or maybe ten, years after they are built, the government would be obliged probably to pay the interest on the cost of the lines for that period. Whatever they paid on such a guarantee should be added to the cost of the roads, as the Canadians do, after seven years.

Trouble with the Coal Roads

Further progress has been made by the Department of Justice with reference to the plan for the prosecution of the coal roads along new lines as was announced by Attorney-General McReynolds some time ago. It has not, however, been positively indicated precisely how the plan will be put into effect nor does it appear that details have been fully worked out in the department.

What is evident is that the work done under the Taft administration is not considered final or conclusive. It is intended to go further and get some more effective application of the commodities clause than has yet been considered feasible. It is probable that a suit will be started against some one road rather than against several at the same time in order to make a test of the method that has been developed by Mr. McReynolds.

According to apparently trustworthy information, legislation regarding the price of coal or legislation intended to affect that price directly is not likely to be attempted during this session of Congress, but there is a disposition to await the experience of the coming fall before acting definitely upon any proposition, however limited or ineffective it may be. Neither does it appear as yet that any very good prospect exists for the adoption of an extended form of the Erdman Act intended to apply to controversies involving the transportation of coal in interstate trade.

PENNSYLVANIA

Anthracite

Hazleton—As the result of a recent decision rendered by Charles P. Neill, commissioner of labor, who has been umpire on questions submitted to him by the Conciliation Board, $500,000 in back pay will be awarded the anthracite miners who have won a victory in three or four cases

Pottsville—Five-hundred employees of the Oak Hill Colliery at Duncott, are on trike in support of eleven firemen who have struck because their demands were flatly refused by Superintendent Jeffreys.

Plymouth—Of the 49 candidates who took the mine foremen's examination in the Ninth Anthracite District, held in Plymouth, four passed successfully for mine foremen's certificates, and 14 for assistant foremen's certificates.

Bituminous

Masontown—The explosion of 500 sticks of dynamite in the magazine of the Sunshine Coal & Coke Co.'s mine No. 1, three miles from Masontown, May 10, virtually wiped out the little mining settlement, killing three men and injuring forty more. The cause of the explosion is unknown.

Monongahela—The coroner's jury which has been hearing the testimony regarding the cause of the death of 96 men in the Cincinnati mine of the Monongahela River Consolidated Coal & Coke Co., Apr. 23, has returned their verdict placing legal responsibility for the disaster upon the mine foreman, and the moral responsibility upon the mining laws of the state. Throughout the verdict blames ineffective and defective laws for the disaster, and recommends to the coal company that it operate the Cincinnati mine hereafter with safety lamps and that no machinery be used which will cause sparks. The legislature is asked to pass remedial statutes.

Uniontown—The boiler house at the Colonial No. 4 mine of the H. C. Frick Coke Co., was destroyed by fire May 10. The loss is estimated at $15,000, and 350 men will be thrown out of employment for a week. Four boilers of the structure were damaged beyond repair, and it was necessary to hire traction engines from nearby farmers to keep the mine fans running. The origin of the blaze is unknown.

MARYLAND

Cumberland—Early on the morning of May 14, 1700 lb. of dynamite and 70 kegs of powder, stored in the magazine of the Consolidation Coal Co., at Eckhart, exploded, killing three men. Every house in the town was more or less seriously damaged. The shock of the explosion was felt distinctly a distance of 60 miles.

WEST VIRGINIA

Fairmont—John Hoffer, a blacksmith by occupation, claims to have invented a mine-cage safety device which will absolutely prevent an accidental drop. He states that in a short time he is going to make a demonstration of its merits by getting into a mine cage and cutting the cable when 279 ft. from the bottom of the shaft. This demonstration, Hoffer says, will be made at the shaft of the Jamison Coal Co., at its No. 7 mine, near Barracksville. The Jamison people will be the first to equip a mine cage with this invention. If this device is what Hoffer claims, a company will be formed by local business men and it will be put upon the market.

Morgantown—Delegates to the West Virginia State Mining Institute, which meets June 24 to 26, will go to Connellsville for a trip of inspection through the H. C. Frick and Oliver & Snyder Coke Works. Mining men from all over the state will attend the institute.

Charleston—Officials of the United Mine Workers of America and the Peytona Block Coal Co. have made arrangements whereby the men working in the mines will get an advance of 7c. per ton for mining coal. This company has plenty of orders and needs 35 families at once to do work in the mines. The same arrangements have been made with the Hickory Ash Coal Co.

After more than a week of strenuous debate the Senate has referred to the education and labor committee, Senator Kern's resolution for a federal investigation of the conditions in the West Virginia coal fields. It is understood that the committee will report favorably within a few days and that the senate will adopt it.

It is understood that charges of peonage and oppression of workers in the Paint and Cabin Creek coal fields in West Virginia have been laid before Senator Kern by representatives of the State Federation of Labor and Miners Union.

OHIO

Belle Valley—The bodies of fifteen miners who lost their lives, May 17, in an explosion of firedamp at the Imperial mine have been brought to the surface by rescuers. An investigation into the cause of the explosion was begun, May 19, by officials of the State Mining Department. The Imperial mine is owned by the O'Gara Mining Co., composed principally of Cleveland stockholders.

Dilles Bottom—Three-hundred miners employed by the Rail & River Coal Co., have gone on strike, asserting that they were not getting their full weight. They claim that the screens used by the company are fitted with meshes which are too large.

Columbus—Considerable discussion is heard among coal men of the action of the Hocking Valley Ry. Co. officials in selling three thousand 30-ton coal cars to a Northwestern railroad and only securing 500 of the 60-ton cars to replace the equipment so sold. It is believed the curtailment of the railroad equipment will work a hardship on the coal trade in the summer and fall.

KENTUCKY

Louisville—One of the most interesting and practical first-aid devices seen at the first-aid meet held under the auspices of the Kentucky Mining Institute at Lexington, Ky., on May 16 and 17, was the first-aid box used by the team representing the St. Bernard Coal Mining Co., whose general offices and mines are located at Earlington, Ky. The box itself contains bandages for every possible injury, from the finger to the head and the various parts of the body, as well as safety-pins, scissors, antiseptics, aromatic spirits, distilled water, and the like. Besides the box, however, the outfit consists of adjustable splints, which can be used in the shorter lengths or bolted together for the purpose of serving in case of compound fractures. A take-down stretcher frame is also included, consisting of four sections of pipe which screw together, forming the sides, with two wooden cross pieces which complete the framework.

Spottsville—The work of pumping the water from the coal mines on Green River, which were filled during the recent flood, will start in a few days. About one-half of the men who worked at the mines previous to the flood have left the town, fearing that the mine owners could not resume work.

INDIANA

Brazil—During a severe electric storm, May 15, a coal mine belonging to Geo. Wiederoder, was struck by lightning and the tipple and sawmill near-by were burned. The total loss was $1500.

Wheatland—The mines in this vicinity are temporarily shut down because of the recent high waters.

ILLINOIS

East St. Louis—Indictments against the Vandalia, the Big Four, and the Grand Trunk Ry. of Canada and the O'Gara Coal Co., of Chicago, were returned by the United States Grand Jury for the eastern division of Illinois, is session in this city.

The five indictments include 71 counts. In the last indictments the four corporations are named as defendents, charged with conspiracy, and the maximum fine is $10,000 each on seven counts, and no minimum is named. On the remaining sixty-four counts, the maximum is $20,000 on each count, with a minimum of $1000.

MONTANA

Butte—The one hundred and fifth meeting of the American Institute of Mining Engineers will be held at Butte, Mont., from Aug. 18 to Aug. 21, 1913. Tours have been carefully arranged for members of the Institute.

UTAH

Salt Lake City—The semi-annual convention of the Rocky Mountain Coal Mining Institute will be held in Salt Lake City, June 11-13. Excursions will be made to the celebrated copper mines at Bingham. The meetings will be held in Barratt Hall and will be open to the public. It is expected that 500 delegates will be present.

FOREIGN NEWS

Benthen, Germany—The strike of 60,000 coal miners in this district which began Apr. 21, has been called off by the Men's Trade Union, owing to the apparent hopelessness of attaining success. The employers have refused to grant the concessions which were demanded.

PERSONALS

John Gibson, formerly superintendent of the Boswell mine of the United Coal Co., has been appointed general superintendent of a mine of that company.

William Warner, for some years secretary-treasurer of the Pittsburgh District Mine Workers organization, has recently been appointed superintendent of the mines of the United Coal Co., at Thayer, W. Va.

William H. Weller, secretary and treasurer of the Munro-Warrior Coal & Coke Co., has resigned his position with that company, effective June 1. Mr. Weller has held the above mentioned position for several years.

Governor Major, of Missouri, has appointed J. P. Hawkins, of Kennett, secretary of the State Bureau of Mines and Mining, to succeed George Bartholemeus, whose term has expired. The appointment is for a period of four years, at a salary of $1800.

George Watkin Evans, consulting coal-mining engineer, of Seattle, has been selected to make an examination as to the commercial possibilities of the Matanuska coal field of Alaska, for the United States Bureau of Mines. Mr. Evans left Seattle on a preliminary trip May 18.

Word has been received of the selection of U. S. Morris, formerly commercial agent for the Clinchfield Coal Corporation, as vice-president and general manager of the Superior Colliery Co., which operates mines in the Jackson field. The general offices of the concern have been removed rfom Wellston, Ohio, to 418 Hammond Bldg, Detroit. The operating offices are still located at Wellston.

NEW PUBLICATIONS

Department of the Interior—Bureau of Mines, Bulletin 62, "National Mine Rescue and First Aid Conference, Pittsburgh, Penn., Sept. 23 to 26, 1912," by Herbert N. Wilson, 74 pages.

University of Illinois—Bulletin No. 64, "Test of Reinforced Concrete Buildings under Load," by Arthur N. Talbot, and Willis A. Slater, 104 pages, 6x9 in., with 75 diagrams, figures and illustrations.

Department of the Interior—Bureau of Mines, technical paper 38, "Waste in the Production and Utiliaztion of Natural Gas and Means for their Prevention," by Ralph Arnold and Frederick G. Clapp, 29 pages.

Department of the Interior—Bureau of Mines, "Monthly statements of coal-mining accidents in the United States for January and February, 1912," compiled by Frederick W. Horton, contains 12 pages and numerous tables.

Department of the Interior—Bureau of Mines, Bulletin 55, "The Commercial Trend of the Producer Gas Power Plant in the United States," by R. H. Fernald, 92 pages, with numerous tables and diagrams and an insert map of the United States, showing a distribution of gas-producer power plants using anthracite, bituminous and lignite fuel.

CONSTRUCTION NEWS

Sheboygan, Wis.—The C. Reiss Coal Co. will complete its new coal dock with a capacity of 250,000 tons at Green Bay before the end of the year.

Wilkes-Barre, Penn.—Bore holes are being drilled on North River St., for the foundations for the new $100,000 office building for the Lehigh Valley Coal Co.

Whitesburg, Ky.—The Lexington & Eastern is to build a branch line up Rockhouse Creek and into Knott County. It is planned to open up rich coal and timber districts.

Huntington, W. Va.—A new extension of the Baltimore & Ohio R.R., running 28 miles from Huntington, W. Va., up the left fork of Beaver Creek, is soon to tap the eastern Kentucky coal fields.

Windber, Penn.—Extensive improvements have been made by Lochrie Brothers Coal Co. at their Argentine, Butler County, plant. The daily output has been increased nearly 150 tons, and the capacity now reaches about 600 tons.

Coshocton, Ohio—Active development of the holdings of the Ohio Cannel Coal Co. in Bedford Township between Warsaw and Tunnel Hill is to be started within the next few weeks. A contract for the building of a tipple with a capacity for 5000 tons daily has been let.

Martins Ferry, Ohio—The Big Five Coal Co. has under construction eight new houses for the use of its men, employed in its Stewartsville mine. The capacity of this mine is about 1200 tons a day, and this tonnage is increasing steadily as the supply of cars is augmented.

Racine, Wis.—The Bauman & Murphy Coal Co. has decided to equip its coal-hoisting machinery with modern clamshell grabs, which will be put in operation within a week. This type of equipment lessens the time required to unload a coal barge, and reduces the number of men needed in the work.

Johnstown, Penn.—The Cambria Steel Co. has awarded contracts for 28 byproduct coke ovens, to be located at its works near Johnstown. The company proposes ultimately to increase the plant to 500 ovens, and will replace the present ovens with new ones of the byproducts type. Work on the new plant has already been commenced.

Knoxville, Iowa—Actual work of developing the New Ramsey coal shaft has been in progress since May 5, and at the present time the excavators are working in blue shale at a depth of 41 ft. The steam-hoisting apparatus is being put in place and will be in working order in a short time. The coal lies at a depth of 161 ft. and is 6 ft. 5 in. thick.

Youngstown, Ohio—Actual construction work has begun on the first ovens of the byproduct coke plant of the Republic Iron & Steel Co., at Youngstown, and it is hoped to have them completed and in operation by the end of the year. The plant will be of the Koppers' type, and is the first installation of this kind for the Republic company.

Milwaukee, Wis.—A $100,000 steel derrick is to be constructed by the Milwaukee Western Fuel Co. at 16th and Canal Sts. The derrick will form a span of 300 ft. and will be a twin to the coal hoist which was destroyed two years ago by the McNamara dynamiters. It will be equipped with clamshell grab, capable of carrying five tons of coal to each load.

Lebanon, Penn.—The Philadelphia & Reading Coal & Iron Co. has recently awarded a large contract for stripping a large tract of virgin anthracite at a point between St. Clair and Wadesville. The coal will be prepared for the market at the Wadesville breaker. The largest steam shovel employed in the anthracite region will be used in the stripping work.

Clarksburg, W. Va.—A new mine is being opened on the Stout Farm by the Francois Coal & Coke Co. It will be one of the largest and most modern plants in this region. Two of the four openings have already been made as far as the coal. The remaining two will be started at once. The work of constructing the tipple and power house will begin at an early date.

Indianapolis, Ind.—The Indianapolis Mortar & Fuel Co. is planning to enlarge its yardage and equipment and install modern coal-handling equipment. It has issued $50,000 in bonds, the money from which will pay for elevated coal pockets and apparatus for dumping cars and for dumping direct from the bins into wagons. A. E. Bradshaw is president of the company.

Whitesburg, Ky.—It is rumored from Wise County, Va., that the Wise Terminal R.R. is to be extended into the coal and Timber fields of Dickinson County, and that a right-of-way is now being secured. It is said that the road will make a connection with the Carolina, Clinchfield & Ohio, which is now constructing a branch to Elkhorn City. The work of construction will begin within the next two months.

Grafton, W. Va.—It is rumored that the Wionna Coal & Coke Co. intends to erect 16 new two-story residences at Coffman, and that the contracts will be let in a few days. During the early work at Coffman, about 25 houses were built along the hill east of the coal plant, and a few years ago several houses were built below the railroad west of the plant. The new buildings will be built north of the railroad, just west of the present location of the tipple and power house, and will be of frame construction.

Punxsutawney, Penn.—The Lindsey Coal Mining Co., which is opening a new operation at Ross Run, has awarded a contract to Patrick E. McGovern for the construction of a spur at a point three miles below this place to the new mine. The railroad track is to be completed during July, and the company expects to begin shipping coal before Aug. 1. It is estimated that the output will be between 500 and 600 tons a day when the mine is running full, and between 100 and 125 men will be employed. The new mine will be known as the Lindsey No. 8.

Pittsburgh, Penn.—More than 1000 new merchant coke ovens are being built by small independent companies in this region. Among them is the plant of the Poland Coke Co., which recently began to ship coke from its ovens at Dunkard Creek, Green County. This company is building 100 ovens. The Reliance Coal & Coke Co. is building 400 ovens at Denbo, Fayette County, and other small companies have 500 additional ovens under way. The majority of the new operations are located in Green County, which is rapidly developing as a coking center.

Pittsburgh, Penn.—Half a dozen working camps have already been established on the Montour R.R., which will extend from Homestead to North Star, where connections will be made with the old Montour R.R., a branch of the Pittsburgh & Lake Erie. A bridge to cross the Chartiers Creek near the Bell Tunnel is under way, and it is expected that the road will be completed in about 18 months. The road is owned by the Pittsburgh Coal Co. and will be used mainly as a coal and coke road. Passenger trains will be run, however, to meet the requirements of the State Railroad Commission.

NEW INCORPORATIONS

Little Rock, Ark.—The Sterling Anthracite Coal Co., of Clarksville; capital stock, $50,000. Sam Laser, president.

Chicago, Ill.—The Pilsen Coal Co.; capital stock, $10,000. Incorporators: G. H. Ruble, M. A. Bitullo, B. B. Collins.

McAlester, Okla.—The Pascoe Coal Co.; capital stock, $2000. Incorporators, W. M. Pascoe, S. Pascoe and August Bernhardt.

Dover, Del.—The American Mining & Power Co., Inc.; capital stock, $6,000,000. Incorporators: W. B. Jones and M. M. Mays.

Covington, Ky.—The Consumers Coal & Supply Co.; capital stock, $50,000. Incorporators: Louis Fritz, S. D. Rouse and D. C. Lee.

Hazard, Ky.—The Northfork Coal Co.; capital stock, $10,000. Incorporators: C. G. Bowman, E. L. Speaks, D. G. Speaks and J. W. Speaks.

Clinton, Ind.—The West Clinton Coal Co.; capital stock, $150,000; to mine coal and other minerals, and sell the same. Directors: J. Shirkie, S. Shirkie, F. P. Hancock.

Knoxville, Tenn.—The Catrons Creek Coal Co.; capital stock, $40,000. Incorporators: J. K. Grillin, L. M. G. Baker, C. H. Baker, G. H. Gallagher and B. A. Morton.

Evansville, Ind.—The Warrick Coal Mining Co.; capital stock, $5,000,000; mining. Directors: Robert R. Hammond, L. E. Fischer, H. C. Hays, W. H. Hays and A. C. Owens.

Huntington, W. Va.—The Blackburn-Thacker Coal Co.; capital stock, $100,000; coal development. Incorporators: J. C. Miller, J. E. Biscoe, F. W. Riggs, G. F. Wallace and M. E. Brown.

Birmingham, Ala.—The Fuel Economy Co.; capital stock, $25,000; headquarters, Birmingham. W. L. Rosamond, president; C. R. Waid, vice-president; W. L. Kirkland, secretary and treasurer.

Williamson, W. Va.—The Tug Valley Coal & Land Co.; capital stock, $500,000; real estate and mineral developments. Incorporators: B. C. Goings, A. Goings, W. Bronson, S. D. Stokes and F. Meeks.

Charleston, W. Va.—The Buffalo Creek Coal & Coke Co., of Atlanta, Ga., has been admitted to do business in West Virginia and hold property in that state. The company is capitalized at $800,000.

Kingwood, W. Va.—The Cleveland-Kingwood Coal & Coke Co.; capital stock, $250,000; to develop coal lands in Preston County, W. Va. Incorporators: John Orgill, S. M. Brady, Carl Huett, T. A. Fleming and W. B. White.

INDUSTRIAL NEWS

Galesburg, Ill.—A contract for 24,000 tons of soft coal has been landed by the Spoon River Coal Co. The coal will be used in federal service.

Poteet, Tex.—The Poteet Sand & Coal Co. has recently struck a new seam of very fine coal. The discovery is said to be 6 ft. 6 in. thick.

Pittsburgh, Penn.—The Cambria Steel Co. has recently purchased the Robert H. Love tract of 324 acres of coal land in Loyalhanna Township for $50,000.

Washington, Penn.—Sixty-three acres of coal land in Snowden Township, have been sold by H. J. Davis to Chas. Braznell, of Pittsburgh, at a price of $700 an acre.

Shenandoah, Penn.—The Locust Mountain Coal Co., which is opening a new colliery at Raven Run, has received two new locomotives and a number of mine cars to start work at their new operations.

Greensburg, Penn.—The Greensburg Coal Co. has placed a contract with William B Scaife & Sons Co., Pittsburgh, Penn., for a structural steel headframe, together with a number of plate steel bins.

Montreal, Can.—The Montreal office of the Sullivan Machinery Co., hitherto located at 403 Lagauchetiere St., West, is now situated at Room 806, Shaughnessy Bldg., corner St. Paul and McGill Sts.

North Sydney, N. S.—During 1912, the Nova Scotia Steel & Coal Co. mined 841,000 tons of coal. Of this amount 256,000 tons were used by the company itself. A new seam of high quality coal has been discovered and 1500 more men will be employed to work it.

Leslie, Ark.—A 14-in. seam has been discovered in this vicinity, and it is claimed that the surface is underlaid for miles around by a solid bed of coal. A company has been organized, known as the Red River Coal & Mining Co., with a capital stock of $100,000.

Toledo, Ohio—Nine-day tests of three qualities of coal to determine which variety is most suitable for locomotives, are being conducted by the Toledo & Ohio Central and the Lake Erie & Western. The same engine crews are retained without layoffs as long as the tests continue.

Columbus, Ohio—E. W. Clark & Co. have leased about 90,000 acres of land which they owned in West Virginia, to the Huntington Development & Gas Co. It is said that a bond issue of about $2,000,000 will be made for the purpose of developing the lands and putting in pipe lines for the transmission of gas.

Montgomery, Ala.—The Blount Mountain Coal & Lime Co. will, it is reported, develop mineral lands owned by them in Blount, St. Clare and Jefferson Counties, Alabama. The company is capitalized at $2,000,000. J. C. McGinnis is general manager and Carl F. Wittichen assistant general manager.

Pittsburgh, Penn.—When the Rice's Landing Coal & Coke Co. has taken out its charter of incorporation, it will take over the Dillworth Coal Co.'s plant, which went into bankruptcy about 18 months ago. This plant is located near Brownsville, on the Monongahela River, and its mine and shipping facilities will be developed more fully.

Lexington, Ky.—During the past week 41,800 acres of Tennessee coal and timber land were sold to Messrs. J. A. Smith, Roger E. Miles and W. A. Odell, of Cleveland and New York. The consideration is said to have been $400,000. It is said that the Cleveland people are looking out for coal and timber lands in both Kentucky and Tennessee, and claim to have large sums of money to invest.

Sergent, Ky.—The H. Hardaway interests of Wise County, Va., have just transferred their 300 acres of coal and timber land holdings on Pine Creek, near the new extension of the L. & E. R.R. to the Heuser Coal Co., of Roanoke. It is said that it is the purpose of the company to start the work of development within the next few months. It is rumored that the amount of the consideration is unusually large.

Tamaqua, Penn.—The East Lehigh Colliery has recently established a record for pumping water from its mine. Several days ago a tap was made to a large body of water in an abandoned working, with the intention of pumping out the water so that the mammoth seam could be worked in the mine. Three pumps were kept continuously at work, and 1,750,000 gal. of water were hoisted out of the mines within 36 hr.

Tracy City, Tenn.—The Tennessee Consolidated Coal Co., is reported to have purchased the property of the Fren Hill Coal Co. near Fern Hill, Ky., including 600 acres of land, with the complete equipment for the operation of the mine. The output will be increased by the purchasers to 350 tons a day. The price, it is said, was in the neighborhood of $75,000. This sale was rumored some time ago, but the identity of the purchasers was not known.

Pottsville, Penn.—The Otto colliery, at Branchdale, one of the Reading's most valuable operations, recently handled a total of 703 mine cars on a single tipple at the breaker. This colliery has been in continuous operation for about 70 years. One of its main feeders is the White Ash slope, which was sunk in the year 1859, and bids fair to keep up its shipments for many years to come. The Otto colliery is one of the most modern in equipment in the anthracite region.

Shadyside, Ohio—Work is progressing rapidly at the new mine of the Geo. M. Jones Coal Co., at Wegee. Contractors, who are doing the concrete work, have been making rapid strides, and, while other mines were out of commission during the flood, either on their own account or because of scarcity of cars, work was continued in preparing this large operation. It is rumored that the concrete work is to be completed next week. Already, a number of new houses have been erected.

Pontiac, Ill.—The property of the Brady Coal Co. has been sold to Murphy, Linskey & Cashier for $4825. It is proposed to begin work immediately in overhauling the mine and to have a large force of men engaged in mining coal by next fall The mine will be equipped in accordance with all the requirements of the state mining laws so that a large force of men may be put to work. The coal is of excellent steaming quality and there has always been a ready sale for it in this vicinity.

Marquette, Mich.—The City Fuel Co., recently organized at Manistique, at a capitalization of $10,000, has taken over the coal business of the Chicago Lumber Co., leasing the warehouse, coal bins, etc., and the building known as the Ann Arbor.

The company has procured the agency for the high-grade coals that have been handled in the past by the Chicago Lumber Co. and arrangements are being made to procure the supply for the coming year.

Lisbon, Ohio—All the metal which has been used in the operation of the mining plant of the Duquesne Coal Co., at Newhouse, has been sold as junk. This includes all the iron rails, copper, brass, machinery, and everything composed of metal about the power house and mine. The Duquesne mines were abandoned by the company following the fire, which destroyed the power house several weeks ago, and the probability is that they will never again be operated. The price paid for the metal was $4000.

Fayetteville, W. Va.—It is rumored that 5361 acres of valuable coal land belonging to the Wm. Hill estate has been optioned to Chicago capitalists. The ultimate consideration is said to be in the neighborhood of $250,000. The option is for a period of 90 days, but it is expected that the Chicago men will close it before the expiration of that time. The new owners will operate the mine already under development, and will also open up other extensive mines. It is said that they now handle over 500 cars of coal per day.

Zanesville, Ohio—The Pan-American Coal Co., which is owned principally by Newark men, has taken over the properties of five large coal mines in Ohio and West Virginia. It is said that the Pan-American company will apply for a new state charter, increasing its capital stock to $500,000. It is said that the average ouput of the five or six mines will reach 8000 tons per day. The company already has contracts for furnishing coal to the Michigan Central, Père Marquette, Ann Arbor and other large railroads, besides having a large market for domestic consumption. All of the mines own and operate individual electrical equipment, and the coal is mined with the latest improved electric mining machinery.

COAL TRADE REVIEWS

GENERAL REVIEW

Business in hard coal for the current month is exceeding expectations, which were pessimistic because of the lack of snap during April. As a result there is a better feeling in the trade, but receipts continue rather small, and dealers claim they are unable to get sufficient business ahead to justify any heavy buying. However, companies are having difficulty in meeting orders on certain grades, while promises for May shipments are now difficult to obtain, and many orders for June delivery are already coming in.

In the Eastern coastwise bituminous trade the better grades are becoming steadily stronger and predictions are freely made that there will be a general shortage in these the coming fall and winter. Some large consumers are in the market, but bids for their business are scarce. Supplies in the spot market are short, due to the slow loading in Hampton Roads, and consignment coal is scarce. The labor shortage is also becoming a feature in the market. There is a better consumption, and, as a rule, a generally better tone pervades the trade, particularly on the more desirable qualities.

The Pittsburgh market continues to show increased strength with operators asking a substantial advance on new business. There are, however, rumors to the effect that this firmer tone is an artificial condition brought about by a restriction in production, so that the situation is subject to reversal should the companies open up full blast. The mines are running short of men and the car supply is a trifle tight. It is obvious that there is not sufficient coal to go around, and producers have ceased to ask for further orders. There is considerable activity in the steam grades in Ohio, due to a heavier railroad movement and an increased demand from manufacturers. The congestion at the head of the lakes has been removed, and the lake shipments are heavy. Quotations are firmer than for several months, with production steadily increasing.

A very heavy dumping, mostly on contract, occurred at Hampton Roads during the week, with the result that the congestion there has been relieved, and there is a scarcity of coal for the remaining vessels. The Southern market is weak, but would be much more so were it not for a car shortage which has had a steadying influence on the situation. This shortage of equipment seems to be general on all roads touching the coal fields, and there are no indications of any immediate improvement.

In the Middle Western market the consumers are becoming anxious to close contracts in order to protect themselves over a possible suspension in mining next April. The market remains moderately firm, particularly on the steam grades, and Eastern coals. The possibility of an acute shortage the coming fall is also a condition which is to be considered. Prices here, as in the Eastern coastwise markets, are holding unexpectedly firm.

BOSTON, MASS.

Bituminous—The market continues to improve, both on spot business and contract. Two large corporations have been in the market here this week, and there have been surprisingly few competitors for the business. Several of the larger agencies sent in regrets that they were not in a position to submit any quotations. The tonnage has not yet been awarded and it will be interesting to see to what quarter it goes. The $2.85 price for Pocahontas and New River f.o.b. Hampton Roads is firm, and there are those now who freely predict a shortage of high-grade coal next fall and winter.

Georges Creek is also in strong position. Shipments are regular and orders plentiful for that grade as well as for the better qualities from the Pennsylvania districts. Prices are hardening on all the desirable coals and the prospect is good for an even market during the summer months.

For inland shipment quotations are somewhat up from a week ago. The slower loading at Norfolk has shortened up the volume of consignment coal for sale, and there is a disposition to go slow for the present on commitments. All-rail shippers are getting coal forward rather slowly for the season, due, in part, to good business and parly to the shortage of labor in the various districts.

Anthracite receipts in May continue to be rather small, as compared with other normal years. Several of the anthracite companies have difficulty in working out the sizes the trade calls for, and the succession of miners' holidays, and all manner of interruptions to mining, have seriously cut down the supply available for New England. It is now practically impossible to secure from any of the larger companies a promise of May shipment and orders are already being set forward into June. The cool weather is creating a demand on retailers, especially for domestic coal, and with the fill-up orders that are usual in the spring there is a rather brisk trade.

Reports are that the companies shipping West have so much business in view that they will have little coal this summer and fall for delivery in this market. Tide-water New England is so largely dependent on the companies that are suitably equipped with transportation, and now that these are practically confining their output to the line and Western trade, the choice of coals is pretty well narrowed down from what it was two years ago.

Current wholesale quotations on bituminous are about as follows:

	Clearfields	Cambrias Somersets	Georges Creek	Pocahontas New River
Mines*	$1.05@1.40	$1.25@1.45	$1 67@1 77	
Philadelphia*	2.30@2.65	2 50@2.70	2.92@3.02	
New York*	2 60@2 95	2 80@3 00	3.22@3.32	
Baltimore*			2.85@2.95	
Hampton Roads*				$2.85
Providence†				$3.73@3 78
Boston†				3.78@3.90

*F.o.b. †On cars.

NEW YORK

Bituminous—The local soft-coal market continues to show a better tone. There is less coal on demurrage than is customary at this period of the year, and consumers are buying more freely because of the scare last winter. A great many of the new contracts are for much heavier tonnages, buyers frequently signing up for more than their actual requirements, in order to guarantee an adequate supply. Last year many of the operators failed to fulfill their contract obligations during the period high prices were in effect, and consumers are endeavoring to protect themselves against this contingency over the coming season; the possibility of a strike next April is also having an effect upon the situation. Quotations are becoming still stronger, but actual prices have not advanced and we continue those of last week as follows: West Virginia steam, $2.55@2.60; fair grades, Pennsylvania, $2.65@2.70; good grades of Pennsylvanias, $2.75@2.80; best Miller, Pennsylvania, $3.05@3.15; Georges Creek, $3.25@3.30.

Anthracite—The local hard-coal market is featureless. Business is continuing without any let up, but there is an entire absence of any snap to the trade. Indications are that May business will fall behind April, and, in fact, no great activity is anticipated until about the middle of August, when the demand will rapidly become insistent. The mines are working good at the present time, there being no further reports of "button strikes," and with the car supply good, the shipments are quite heavy.

Some companies report that they are ready to furnish any size in any quantity demanded, while others state that they are unable to meet requisitions for certain grades; it is clear in any event that nothing is going into storage. Rice and stove continue in the shorest supply, with pea and buckwheat the easiest. The water trade out of New York up into New England is quite heavy.

The local hard-coal market has not shown any material variation during the week, and is now quotable on approximately the following basis:

	Circular	Individual—Lehigh	Individual—Scranton
Broken	$4 60	$4.45	$4 50
Egg	4 85	4.80	4 85
Stove	4 85	4 80	4 85
Chestnut	5 10	4.95	5 00@5 10
Pea	3 50	3 30@3 35	3 35@3.50
Buckwheat	2 75	2 10@2 45	2 50@2 75
Rice	2 25	1 85@1.95	2 25
Barley	1.75	1 40@1 70	1.70

PHILADELPHIA, PENN.

Judging from the expressions heard, the current month thus far has exceeded the expectations. April did not start with the usual whirl and snap to business that characterizes that period, and rather pessimistic utterances were heard regarding business for May; now that the month is almost gone, there is a better feeling regarding June business. One large operating company states that their tidewater business already in hand is likely to carry them over during the month of June, but the business locally is not much to brag about. This is not meant to convey the idea that no coal is being sold, as there is a large tonnage moving, especially of the domestic sizes, with a fairly good demand for pea, but the dealers state that they do not seem to be able to accumulate sufficient ahead to warrant them in placing any extensive orders; one day's business almost cleans up what orders they have in hand.

This is the kind of business prevailing at present. Orders given in the morning are quite frequently filled in the afternoon, but at that, the dealers as a whole, characterize the situation as fairly satisfactory. The mines are all working full and the entire production of the prepared sizes is being absorbed. The independent operators are still on their good behavior, little or no reports of concessions being made. This is really one of the features of the market, and speaks well for prevailing conditions. Quotations of the individual producers heretofore have almost been a perfect index of trade conditions.

The bituminous market is still holding its own. The slack coal seems to be the only bad feature; outside of this, quotations are not reported as fluctuating, and in some coals, there is a better price being realized. As far as the demand is concerned, coal on cars seems to be as active as it has been, with a fair movement on contracts, although there is a host of the latter that have not been signed up as yet, for next year's business. The 10c. or 15c. advance is meeting with opposition, and with coal on the market at this much less, current requirements are being filled from spot offerings.

PITTSBURGH, PENN.

Bituminous—The local coal market continues strong, with operators continuing to ask an advance over the season prices on new business, though the standard market is still represented by the prices put out some time ago. The Pittsburgh district trade is undoubtedly stronger than the market in some of the more Western districts, and while superficially the demand is active and not easily satisfied, there is a theory in some quarters that this condition is due in considerable part to some of the larger operators having held back part of their tonnage in anticipation of better prices. If this is the case, there may not be as plain sailing as now presaged, as difficulty may occur in marketing the additional tonnages.

The advance in railroad fuel is being maintained by a number of interests, the advance being 5c. to 85c. for slack, $1.20 for mine-run and $1.30 for ¾-in. Shipments are increasing slightly from week to week. On new business the majority of operators are usually asking 5c. to 10c. over the regular prices on mine-run, ¾-in. and 1¼-in., but on the other hand the regular price of 90c. on slack is sometimes shaded 5c. We quote regular prices unchanged as follows: Slack, 90c.; nut and slack, $1.05; nut, $1.25; mine-run, $1.30; ¾-in., $1.40; 1¼ in., $1.55, per ton at mine, Pittsburgh district.

Connellsville Coke—Shading of the $2.25 asking price on prompt furnace coke has been less pronounced in the past ten days. The Bethlehem Steel Co. purchased about 15,000 tons, and paid $2.15 or $2.20 for the bulk of the tonnage, purchasing a little at $2.25. A 10c. cut is about the most to be expected now from $2.25. As to contract coke, there is more dickering. The New Jersey Zinc Co. has inquired for about 10,000 tons a month over the latter half of the year, and it is rumored in several quarters that the Pittsburgh Steel Co. has closed for its requirements against two blast furnaces now being completed and involving a possible consumption of about 25,000 tons a month. The rumor mentions 15,000 tons as having been covered, but this cannot be confirmed. While $2.50 is frequently mentioned on contract coke, no specific quotation is known to have been made on a bona fide inquiry, the $2.50 price merely representing the idea of a group of operators. We quote: Prompt furnace, $2.15@2.25; contract furnace (nominal) $2.50; prompt foundry, $2.75@3.25; contract foundry, $3@3.25 per ton at ovens.

BALTIMORE, MD.

The demand for the better grades of fuel continues good and prices remain firm. The output of most of the mines is going on contracts, and operators say that the supply for the spot market is short. In some instances, the best free steaming coal is difficult to obtain, especially Quemahoning. Some operators are not disposed to sell more than one car to spot purchasers. There is about 10c. difference in the price of spot and contract business, better grades of Georges Creek coal under contract bringing $1.60, while spot delivery is around $1.50. Georges Creek and Quemahoning coals are practically out of the spot market being contracted up for about as much as the mines are producing. Spot prices for the last-named fuels were quoted at $1.15, while contract prices ranged from $1.25 to $1.35, the same as last week. Gas coals are in good demand, and the shipments to the Lakes are heavy; there was no material change in prices for these grades during the week.

A reduction in the coal tonnage of the Baltimore & Ohio R.R. occurred in March, on account of the floods in Ohio and adjoining states. The total tonnage of the road for the month was 2,538,039 as against 3,173,168 tons for the same month of 1912.

BUFFALO, N. Y.

In spite of all sorts of discouraging conditions the bituminous market is good. There is not enough coal to go around and it appears to be growing scarcer daily. The price of slack which is usually the gage of the market, is much above what it was a year ago. Jobbers say that it went begging then at 65c. net, while it sells easily now on contract as high as 90c. The increase in the price of sizes is not so great, but there is no discount on the trade so long as slack sells at a good figure.

At the same time mine-run and three-quarter are at least 10c. higher than they were a year ago. There are also a good many shippers who are not asking for any more business at present. Especially is this true with Pittsburgh coal, which is going into the lake trade so freely and is so tied up in contracts, that shippers are pulling their salesmen off the road and letting the trade take care of itself. One reason for the strong market is that the mines are all short of men. The drain caused by so many men going home to the Turkish war has not been made up yet and it is not going to be right away. Cars are none too plenty also and a good many delays are caused in that way.

At the same time the condition of the coke trade is not reassuring. It has been weak for quite a long time and now the most optimistic of jobbers advise a quotation decidedly down from former figures, in fact to a basis of $4.75 for best Connellsville foundry. It is not very easy to say why the weakness exists, except that iron is not high and is crowding coke down to its level.

Bituminous quotations are strong at former figures, $2.80 for Pittsburgh lump, $2.65 for three-quarter, and $2.15 for slack. There is no consignment coal on track anywhere and everything is healthy. The anthracite trade is quiet, but very steady. Shipments by lake for the week were heavy, being 164,500 tons.

COLUMBUS, OHIO

Coal men in Ohio are having a good run of business in steam grades. This is due to increased activity among manufacturing establishments and a larger tonnage required for railroad fuel. In fact, every branch of the trade shows activity with the possible exception of the domestic sizes. Generally speaking, the market shows a good tone, and it is the belief that the year 1913 will be a prosperous one in coal circles.

One of the features of the trade is the good demand for lake tonnage. Since the boat congestion at the upper lake ports is over the vessels are running much more smoothly. The docks on the lower lakes are busy loading a heavy tonnage. The Northwest is demanding a large amount of fuel and Ohio operators are trying to supply the demand. Lake prices are 10c. higher than last year, and this aids in the lake movement; the ore trade is also good, and boats are active in both directions.

Steam tonnage is wanted by manufacturers in this territory in larger quantities than for some time. The bad effects of the flood are now passed and practically all factories are again in operation. Railroads are taking a larger tonnage since the freight movement has increased. No trouble has yet been experienced from a car shortage, but operators are looking forward to a lack of equipment in a few months.

Preparations are being made for an active domestic demand in about a month when the stocking period starts. The fact that dealers stocks are unusually low, is taken as an indication of a larger domestic movement than in years. Sales agents are busy making their connections for the domestic business.

Increases in production from all Ohio producing districts are reported during the past week. In the Pomeroy Bend district, which is waiting for the domestic trade, the output is estimated at 55 per cent. of the average and the same percentage prevails in the other domestic fields. In the Hocking

Valley the output is practically normal and the same is true of the Eastern Ohio field.

Quotations are rather firm and there is less price cutting now than for several months.

	Hocking	Pittsburgh	Pomeroy	Kanawha
Domestic lump	$1 50		$1 50	$1 50
2-inch	1 35	$1 25	1 35	1.30
Nut	1.15		1 25	
Mine-run	1.15	1.15	1 15	1 10
Nut, pea and slack	0.70		0 70	0 70
Coarse slack	0 60	0 65	0 60	0 60

HAMPTON ROADS, VA.

The beginning of the past week saw some large shipments, both foreign and coastwise, over all the local piers, but tonnage to move coal has gradually decreased, and there is at the end of the week very few vessels waiting cargo. Such vessels as are now in the stream are not loaded on account of suppliers being short of coal due to the heavy loadings at the beginning of the week. Bonker business for the week has been exceptionally good at all piers. The greater portion of the cargo shipments have been on contract business, although there have been a few sales of spot cargoes. The New England market has taken practically all of the coastwise business.

To date the dumpings for the Sewalls Point piers alone will amount to over 150,000 tons, and unless tonnage now bound for this pier is delayed, it is hoped that the dumpings for the month of May will amount to considerably over 275,000 tons. Lamberts Point and Newport News are also well ahead in tonnage dumped, and it is expected that these piers also will run considerably over past records.

BIRMINGHAM, ALA.

The shortage of coal equipment in this district takes on a more serious aspect from week to week. Practically every railroad touching the coal fields is short of cars and there are no indications that any of them will be able to relieve the situation at any time in the near future.

Labor conditions are also gradually becoming more acute. A number of the smaller mines have suffered from shortage of labor during the past week and it is possible that had an ample supply of cars been furnished their outputs would not have been materially increased. A lack of equipment always causes unrest among the labor which has a habit of roaming from mine to mine when regular work is not obtainable.

LOUISVILLE, KY.

There is a noticeable shortness in the supply of cars at the present time and although not sufficient to restrict operations at the moment it is threatening to develop to larger proportions at any time. The probabilities are, however, that this feature will be eliminated by June when operations should be open in full swing and a heavy movement of domestic coal on into the northwest. The recent elimination of the 10c. differential in freights against the eastern Kentucky field as compared with the Jellico district is of course, having a stimulating effect on the movement from the former field into the North and Northwest.

Prices on the steam grades are weak, the off-qualities of pea and slack being quoted at as low as 20 and 25c. Western Kentucky nut and slack are selling at 40c., with the second-grade eastern Kentucky qualities at 50 and 55c., f.o.b. mines. The better grades from this district are not in very heavy demand, because of the plentiful supply of cheap coal and can be had at 85 to 90c. Block coal is also rather low, at $1.50 to $1.65, with block and nut at $1.45 to $1.50, depending largely upon the conditions of the sale. Indications point to still lower prices when consignment coal begins to come in and demurrage charges start accruing.

INDIANAPOLIS

There is little change in the mine situation in Indiana. Some mines are operating only two days a week but the average for all seems to be three or four. Prices hold steady. Practically no domestic coal is moving, but there is a normal demand for steam grades from the local mines.

Jobbers say they are not able to place all the orders they wish to for Eastern coals, the mines there reporting they are sold far ahead and that prices will be advanced 15c. a ton in June. That is probably the reason the wholesalers are anxious to get their orders in this month. Another reason is that the new interstate agreement will be made next spring and buyers are willing to make contracts to carry them over this uncertain period.

Retailers in the city report a satisfactory opening summer trade. More consumers than usual seem to be ready to put Eastern coal in their cellars while the price is at the low point. It is noted that some of the small coal yards that sprang up in the winter are for sale. This occurred when it was seen the weather was apparently going to continue mild and there was a chance to get coal at lower figures than had been paid when the fall trade opener at high figures, forcing a continuation of the high prices throughout the winter by the large yards.

DETROIT, MICH.

Bituminous—There seems to be a diminishing activity in the local market, notwithstanding the fact that industrial concerns are operating up to full capacity. However, there is no excess coal being shipped in. Quotations remain unchanged, and the strongest demand is for the finer sizes. The situation will probably become somewhat easier as the summer advances, but indications are that it will remain stronger than ordinarily.

The local market is quotable on about the following basis, f.o.b. mines:

	W. Va. Splint	Gas	Hocking	Cambridge	No. 8 Ohio	Pocahontas	Jackson Hill
Domestic lump	$1.50	....	$1.40	....	..	$1 70	$1 90
Egg	1 50	....	1.40	....	..	1.70	1 90
1¼-in. lump	1 25	....	....	....	..	....	....
¾-in. lump	1.15	$1 15	1 10	$1 10	$1 10		
Mine-run	1.05	1 05	1 00	1 00	1.00	1 25	
Slack	0 85	0 90	0.80	0 80	0.80	Open	

Anthracite—The movement of hard coal so far this month shows some little improvement over that of last month. The unusually cold spring has tended to stimulate the consumption. While there is no particularly active demand, the circular seems to be well maintained and there are no surplus tonnages in evidence. Some coal ordered as far back as February is only now coming in.

CHICAGO

There continues to be a strong demand for steam coal, the prevailing prices for the steam lump and mine-run being $1 and $1.15 at the mines. Screenings are selling at 80c. to 85c. for the lower grades and 85c. to 90c. for the better qualities.

Conditions in the coke trade are satisfactory, the supply of this commodity not being fully up to demand. A fair amount of smokeless coal is being received. Mine-run, chiefly, is in demand, the circular price being $1.25. An increase in orders for anthracite is being noted and the volume of business for the year is expected to be fully up to normal.

The car shortage question is again agitating dealers and operators. With the assurance that bountiful crops will be harvested this year, the opinion prevails that the railroads will not have a sufficient supply of equipment to handle an unusually large volume of business next fall. On this account many dealers are now purchasing coal for storage purposes.

Prevailing prices in Chicago are:

	Springfield	Franklin Co.	Clinton	W. Va.
Domestic lump	$1.97@2 07	$2 30@2 40	$2 27	
Egg		2.30@2 40		$3 65
Steam lump	$1 82@1.87		2 07	
Mine-run	1 77	2 20@2.30	1 97	3 30
Screenings	1.57	1.95	1 57@1 62	

Coke—Connellsville and Wise County, $5.25@5.50; by-product, egg, stove and nut, $4.55@4.75; gas house, $4.65@4.75.

MINNEAPOLIS—ST. PAUL

Business in the coal line has only been a repetition of the past two preceeding weeks. The trade has been slow and were it not for the fact that the time for writing contracts was here, very little activity would have been experienced. Prices are being maintained, far beyond expectations, even in the face of the existing sluggishness of the market. Very little all-rail coal is moving and the market during the past week has been practically free from demurrage coal. The steam trade is holding off expecting prices to weaken along about June 1 as was the case last year.

The hard-coal business is reported to be unusually quiet so far this year, with a tendency to hold off on the part of the country dealer. This is contrary to last year at this time, and it would seem that with the empty bins in the country and the advancing price of 10c. per month, the dealer is playing his hand very poorly. Conditions will not favor him any more by waiting. Prices on all grades of Illinois coals are holding steady with not much change from two weeks ago. Various grades of screenings are still in demand and the price is ranging from 80c. to $1 at the mines.

ST. LOUIS, MO.

There is absolutely no change in local conditions, and country business, instead of picking up, seems to be dropping off. There is a fair movement of anthracite under way, and during the past week a small tonnage of Arkansas has been placed. There is nothing doing in coke, and it is al-

most a drug on account of a few speculators bringing it in unsold.

Among the washed coals No. 2 is just a trifle too plentiful, and Nos. 3 and 4, which have been bringing an exceptionally good price, are expected to drop. The circular of last week still prevails.

OGDEN, UTAH

The coal market throughout the entire Western territory is in a bad condition, with mines only working one or two days per week, due to the small demand for lump coal. This has caused quite a shortage of slack. The demand for nut coal has decreased, and with the mines working short time, the market is able to take care of the production. At this time last year there was quite an over-production of this grade, due to the brisk demand for lump coal.

The reduction in price on May 1 has not stimulated shipments or caused anyone to commence storing coal. This has been somewhat of a disappointment to the operators, who cannot get away from the idea that lowering the price or cutting quotations will increase shipments. At this time of the year the consumption of coal is at its lowest point, and at the same time the operator, whose output is large enough to dictate prices, sees fit to sell his coal at the lowest price.

SPOKANE, WASH.

A coal war has been precipitated here because mining companies are selling direct to large business blocks, hospitals and other large consumers at jobbing prices, which is lowering materially the price of the product to these buyers. Whether it will become so general as to effect the buyer of one- and two-ton lots is not known at present. The trouble has grown out of the charge that the Crows Nest Pass Co. is owned largely by the same stockholders as the Great Northern Railroad and this company is chiefly responsible for the trouble. Responsibility is also laid at the doors of the McGillvary Co. and the Corbin Coal & Coke Co. The local men have appealed to officials of the Great Northern both at Seattle and St. Paul asking that the coal company be forced to change its methods, and adding the threat that they might not receive any more shipments over their lines. This threat has been carried out after learning that the railroad will not enter into the controversy, and nearly all local dealers have refused to accept coal shipped over this line.

PORTLAND, ORE.

Newcastle (Wash.) and South Prairie coals are selling here at $9 and $7 per ton, retail, respectively. They have been shipped in to replace the Black Diamond coal of which there has been very little in the local market for some time. Lignite coals retail here at from $6.50 to $8 per ton, the wholesale price to dealers being $5.25 per ton sacked and in three-ton lots. Wyoming coal is retailing for $10 per ton, and Utah brings $9.50@10 according to haul. Stocks are light for the present but receipts are quite liberal and there will be enough to fill all requirements. Although practically no Australian coal was imported here during the past year there is still some in stock. High freight rates prohibit importations for the present. Very little Wellington coal is being sold owing to its high price, and little has been shipped in since the strike at the mines.

PRODUCTION AND TRANSPORTATION STATISTICS

CHESAPEAKE & OHIO RY.

The following is a comparative statement of the coal and coke traffic over the lines of the C. & O. Ry., for March, and the nine months ending Mar. 31, 1912-13, in short tons:

	March			Nine Months		
Destination	1913	1912		1913	%	1912	%
Tidewater	328,442	487,236		2,720,022	23	3,092,449	23
East	292,410	198,472		2,032,099	15	1,671,276	13
West	700,150	805,017		6,809,347	56	8,261,891	62
Total	1,321,002	1,160,725		11,561,468		13,025,616	
Coke	32,207	22,932		227,550		170,548	
From connections							
Bituminous	71,588	20,060		494,699	4	173,950	1
Anthracite	309	3,330		9,138	1	29,976	1
Grand total	1,353,209	1,513,657		11,789,018	100	13,195,164	100

NORFOLK & WESTERN RY.

The following is a statement of tonnages shipped over this road from mines in West Virginia and the commercial and company coal, for the month of March, in short tons:

Field	Shipped	Tipple	Total	Commercial	Company
Pocahontas	1,003,352	16,363	1,019,715	981,120	120,031
Tug River	184,658	3,169	187,827	153,430	34,397
Thacker	238,340	8,978	247,318	177,358	69,960
Kenova	59,345	7,470	66,815	57,108	9,707
Clinch Valley	.....	....	.....	139,426	8,621
	1,485,695	35,980	1,521,675	1,508,442	242,716

Shipments of coke entirely from the Pocahontas field, were 116,219.

BALTIMORE & OHIO R.R.

The following is a comparative statement of the coal and coke movement over this road for March and the first three months of this year and last year:

	March		3 Months	
	1913	1912	1913	1912
Coal	2,538,039	3,173,168	8,091,860	8,312,570
Coke	405,220	384,094	1,215,753	1,080,427
Total	2,943,259	3,557,262	9,307,613	9,392,997

FOREIGN MARKETS

GREAT BRITAIN

The market remains firm, but quiet, there being little inquiry. Buyers are disposed to wait until after the holidays, in the hope of easier conditions. With supplies so limited after the recent stoppages, sellers show no signs of relaxing quotations either for large or small coals. The very best Cardiff large steams are now unobtainable for May loading.

Quotations are approximately as follow:

Best Welsh steam	$5.40@5.52	Best Monmouthshires	$4.80@4.92
Best seconds	5.28@5.40	Seconds	4.68@4.80
Seconds	5.04@5.28	Best Cardiff smalls	3.60@3.72
Best dry coals	5.04@5.28	Seconds	3.36@3.48

The prices for Cardiff coals are f.o.b. Cardiff, Penarth or Barry, while those for Monmouthshire descriptions are f.o.b. Newport; both exclusive of wharfage, and for cash in 30 days—less 2½%.

COAL SECURITIES

The following table gives the range of various active coal securities and dividends paid during the week ending May 17:

Stocks	Week's Range High	Low	Last	Year's Range High	Low

DIVIDENDS

Delaware & Hudson—Regular quarterly of 2¼% payable June 20, to holders of record May 28.

Hocking Valley—Regular quarterly of 1% and an extra of 4½%, payable June 28 to holders of June 6.

INDEX OF COAL LITERATURE

We will furnish a copy of any article (if in print) in the original language for the price quoted. Where no price is quoted, the cost is unknown. Inasmuch as the papers must be ordered from the publishers, there will be some delay for foreign papers. Remittance must be sent with order.

BLASTING, EXPLOSIVES

Development in Explosives in the United States During the Last Three Years. Chas. E. Munroe. Eighth Internat. Cong. of App. Chem., Vol. XXV, 1912, 9⅓ pp.

Methods for the Determination of the Effective Strength of High Explosives. A. M. Coney and F. B. Holmes. Eighth Internat. Cong. of App. Chem., Vol. XXV, 1912, 16¼ pp.; illus.

Electric Dynamite Thawer. Sigurn Nauckhoff. Jernkontorets Annaler, January, 1913, 9 pp.; illus.

The Selection of Explosives Used in Engineering and Mining Operations. C. Hall and S. P. Howell. Bureau of Mines, Bull. 48, 45 pp.; illus.

Explosives in Coal Mines. (The new "permitted" list issued by the Home Office.) Coll. Guard., Apr. 18, 1913, 1½ pp. 40c.

What Dynamite Grade Markings Express. F. H. Gunsolus. Coal Age, Apr. 26, 1913, 1¼ pp. 10c.

Squibs in Mines. (Report of Departmental Committee Appointed in Nov., 1912.) Iron & Coal Trades Rev., Apr. 11, 1913, ¾ p. 40c.

The Testing of Safety Explosives. Prof. V. B. Lewis. (Abstract of paper read Apr. 2 before the Royal Soc. of Arts.) Iron Coal Trades Rev., Apr. 4, 1913, 2 pp. 40c.

Explosives and Electrical Ignition. (Sprengstoffe und elektrische Zündung.) Wichert. "Bergbau," Jan. 30, Feb. 6 and 13, 1913, 6 pp. 80c.

BORING, SHAFT-SINKING AND TUNNELING

Rand Practice in Deep Shaft-Sinking. Chas. B. Brodigan. Min. & Sci. Press, Apr. 26, May 3, 1913, 7½ pp.; illus. 40c.

BRIQUETTES

Briquette Making at Polmaise Colliery. Iron Coal Trades Rev. Apr. 4, 1913, 1⅓ pp.; illus. 40c.

The Briquetting Industry at the Head of the Lakes. Chas. T. Malcomson. The Coal Dealer, April, 1912, 3¾ pp.; illus. 20c.

Commercial Aspects of the Coal-Briquetting Industry. Chas. T. Malcolmson. Eighth Internat. Con. of App. Chem., Vol. XXV, 1912, 12½ pp..

COAL DUST

The New Coal Dust Experiments. Third report of the Explosions in Mines Committee. Iron & Coal Trades Rev., Apr. 18, 1913, 2 pp. 40c.

Small Coal and Dust; Its Production, Prevention, Treatment and Utilization (Dry Mines). J. Drummond Paton Paper read Apr. 8 before the Manchester Geol. & Min. Soc.). Iron & Coal Trades Rev., Apr. 11, 1913, ¾ p. 40c.

The Combustion of Oxygen and Coal Dust in Mines. (Paper read Apr. 12 before North of England Inst. of Min. & Mech. Engrs.) W. C. Blackett. Iron & Coal Trades Rev., Apr. 18, 1913. ¾ p. 40c.

The Experimental Gallery Station in Derne. A detailed description of the new Westphalian outfit for explosion tests. (Die Versuchsstreckenanlage in Derne.) Beyling and Zix. Glückauf, Mar. 22, 1913, 9½ pp.; illus. 40c.

COKE

Production of Ammonium Sulphate by Means of the Sulphur in Coke Oven Gases. Coke Works Commission Report. Ueber die Gewinnung von Ammoniumsulfat mit Hilfe des in den Kokereigasen enthaltenen Schwefels.) J. Reichel. Glückauf, Apr. 12 and 19, 1913, 7½ pp.; illus. 80c.

Types of Coke Oven Plants as Seen in Operation—II. The Gas World. Apr. 5, 1913, 5 pp.; illus. 40c.

Influence of Coke Sales on the Fuel Market. Black Diamond, Apr. 19, 1913, 1 p. 20c.

The Rise and Development of By-Product Coking—II. The Gas World. Apr. 5, 1913, 1⅓ pp. 40c.

The Advantages of the Direct Ammonia Production Process as Against the Old Indirect One. (Die Vorzüge des direkten Ammoniak-Gewinnungsverfahrens gegenüber dem alten indirekten Verfahren.) C. Heck. Glückauf, Mar. 22 and 29, 1913, 10 pp.; illus. 80c.

Latest Things in Coke Works Practice. (Die letzten Erscheinungen auf dem Gebiete des Kokereiwesens.) K. Ellingen. Feuerungstechnik, Apr. 15, 1913, 2 pp.; illus. 40c.

Carbonization in Bulk in Horizontal Chambers. G. S. Cooper. Gas World, Apr. 26, 1913, 2¼ pp.; illus. 40c.

Notes on the Recent Reconstruction of a Retort House at Deckton, Eng. (Abstract of paper by T. Goulden, read at meeting of Eastern Counties Gas Managers' Assn., Apr. 24.) Gas World, Apr. 26, 1913, 2¾ pp.; illus. 40c.

DRAINAGE, PUMPING, ETC.

A Pump Designed for Acid Water. Coal Age, Apr. 5, 1913, 1½ pp.; illus. 10c.

The Advantages of Electric Pumps. J. M. Matthews. Coal Age, Apr. 5, 1913, 2½ pp.; illus. 10c.

The Evolution of the Mine Pump. F. H. Kneeland. Coal Age, Apr. 5, 1913, 1 p. 10c.

ELECTRICITY

Hydro-Electric Power for West Virginia Industries. Mfrs. Rec., Apr. 17, 1913, 1 p.; illus. 25c.

Safeguarding the Use of Electricity in Mines. H. H. Clark. Proc. Amer. Inst. Elec. Engrs., April, 1913, 7 pp.

Purchased Power in Coal Mines. H. C. Eddy. Proc. Amer. Inst. Elec. Engrs., April, 1913, 6 pp.

Parallel Operation of Alternators. C. A. Tupper. Coal Age, Apr. 26, 1913, 1¾ pp.; illus. 10c.

The Electrification of Cannock Chase Colliery. S. P. Sopwith. Coll. Guard., Apr. 25, 1913, 1½ pp.; illus. 40c.

Central Station Power for Coal Mines. C. W. Beers. Proc. Amer. Inst. Elec. Engrs., April, 1913, 10 pp.

Characteristics of Substation Loads at the Collieries of the Lackawanna R.R. Co. H. M. Warren & A. S. Biesecker. Proc. Amer. Inst. Elec. Engrs., April, 1913, 7 pp.; illus.

EXPLOSIONS

The Bellevue Explosions, Alberta, Canada. (An account of and subsequent investigation concerning three explosions produced by sparks from falls of roofs.) J. T. Stirling and J. Cadman. Trans. Inst. Inst. of M. E., Vol. XLIV, Part 4, 16 pp.; illus.

Forecasting Barometric Changes. Coll. Engr. April, 1913, 1½ pp. 40c.

FUEL TESTING

Standardization of Coal Sampling. Iron & Coal Trades Rev., Apr. 11, 1913, 1⅓ pp. 40c.

Standardization of Coal Analysis and Sizes. Iron & Coal Trades Rev., Apr. 18, 1913, ¾ p. 40c.

Proximate Coal Analysis and Its Value in Power Plant Economy. A. R. Maujer. (Abstract of lecture before Ill. N. A. S. E. at Chicago, Jan. 15, 1913.) Coal & Coke Op., Apr. 17, 1913, 1⅓ pp. 20c.

The Rapid Determination of Ash in Coal. H. M. Ullmann and N. W. Buch. Eighth Internat. Cong. of App. Chem., Vol. XXV, 1912, 3 pp.

Report of the Sub-Committee on Standardization of Methods on Determining Water in Coals and Other Fuels and in Minerals of the International Committee on Analyses. R. Lessing. Eighth Internat. Cong. of App. Chem., Vol. XXV, 1912, 50 pp.; illus.

GENERAL

From Alabama Coal Fields to Tidewater by Barges. Mfrs. Rec., May 1, 1913, 2 pp.; illus. 25c.

Coal-Mine Accidents in the United States, 1896-1912. F. W. Horton. Bureau of Mines, Tech. Paper 18, 66 pp.

The Ethics of Organized Labor. Coal Age, Apr. 5, 1913, 1½ p. 10c.

The French Coal Market and Supply. Coal & Coke Op., Apr. 24, 1913, ¾ p. 20c.

Coal Industry of the British Empire. Iron Coal Trades Rev., Apr. 25, 1913. ½ p. 40c.

Interesting Reminiscences About British Mines and Miners. Wm. Clifford. Coal & Coke Op., Apr. 24, 1913, 1½ pp. 20c.

Mine Accidents and the Remedy. John I. Pratt. Coal & Coke Op., Apr. 3, 1913, 2½ pp. 20c.

Properties of the Four States Coal & Coke Co. (Tells how by planning ahead the Jones' interests have made ample provision for a continuous supply of their coal for more than 100 years.) Black Diamond, Apr. 19, 1913, 2 pp.; illus. 20c.

Conservation as Applied to Bituminous Coal Industry. S. A. Taylor. Eighth Internat. Cong. of App. Chem., Vol. XXVI, 1912, 6 pp.

The Economic Utilization of Natural Fuels in Austria. (Ueber die wirtschaftlichere Ausnützung der natürlichen Brennstoffe in Oesterreich.) E. Donath. Oest. Zeit. f. B. u. H., Mar. 29 and Apr. 5, 1913, 9 pp. 80c.

Mining in the Belgian Congo in 1912. Sydney H. Ball. Min. & Sci. Press, Apr. 19, 1913, 6 pp.; illus. 20c.

Entropy-Temperature and Transmission Diagrams for Air. C. R. Richards. Univ. of Ill., Bull. 63, 15 pp.; illus.

The Illinois Coal Fields. A. Bement. Coal Age, Apr. 12, 1913, 5 pp.; illus. 10c.

Standard Colors for Designating Pipes in Industrial Works. With colored plate. (Einheitsfarben zur Kennzeichnung von Rohrleitungen in industriellen Betrieben.) Glückauf, Mar. 22, 1913, 1 p. 40c.

COAL AGE

Vol. 3 NEW YORK, MAY 31, 1913 No. 22

The Best Time

By Berton Braley

Written expressly for Coal Age

I

I'll tell yuh somethin', neighbor,
Which same I will expound
—Uv all the hours uv labor
I puts in underground,
The one that's most appealin'
(An' that's no idle hunch)
Comes with that hungry feelin'
When it is time fer lunch!

II

My ratchet drill—I chucks it
An' lays my shovel by,
An' opens up my bucket
An' eats my bread an' pie,
There's fun an' talk an' jokin'
Among the dusty bunch
That's eatin', laughin', smokin',
When it is time fer lunch.

III

The mule he champs his bridle,
The trapper gulps his scoff,
The bloomin' mine is idle
An' everybody's off,
The pipe smoke's curlin' hazy,
You hear the miners munch
—Gee, life is good an' lazy
When it is time fer lunch!

IV

There ain't no need to hurry,
There ain't no need to sweat,
Yuh murmurs, "I should worry,"
An "wot's the use to fret,"
Yer eyes they halfway closes,
Yuh nods among the bunch,
An' then—an' then yuh dozes
When it is time fer lunch

V

An' so I'm sayin', neighbor,
Which same I will attest,
Uv all the hours of labor
The lunchin' hour's the best,
At minin' I'm no slow one
But—listen to my hunch,
I make my biggest showin'
When it is time fer lunch!

Flood Protection at the Illinois Mines

Special Correspondence

SYNOPSIS—A brief description of the methods employed in protecting the shafts of the O'Gara Coal Co. during the recent floods. One of the chief troubles encountered was in obtaining clay for filling in the bulwarks; as the surrounding country was completely inundated, this material had to be carried in by hand. The water stage exceeded the previous high record of 1884 by 3 ft. but the O'Gara Co. was uniformly successful in protecting its mines.

The rich coal field of Saline County, Ill., lies in the low valley of the Saline River, a tributary of the Ohio, with its mouth near Shawneetown, Ill. The Middle Fork of the Saline River flows within two miles of Harrisburg, the county seat of Saline County. The drainage area at this point approximates 200 square miles of low land of which 25 square miles are subject to overflow. At the time of the recent flood, back water from the

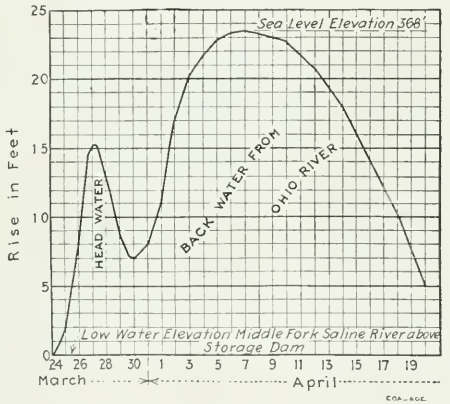

Fig. 1. Profile Showing Rise and Fall of the Flood

Ohio River extended 30 miles inland with a varying width of from 2 to 10 miles.

No definite record of the precipitation was kept at Harrisburg during the storm period of Mar. 22 to 26, but approximately 6 in. of rain fell. The effect was plainly visible in the rapid rise of all streams, which reached a flood stage filling all the low lands on Mar. 27. On Apr. 1 the head water had almost disappeared. At 1 p.m. on this date a reversal of the current in the Saline River was noted and a rapid rise of back water at the rate of 3 in. per hr. was registered. Reports of flood conditions in other states had been received, but owing to the rapid fall of the local headwater no one feared extensive damage from the incoming flood. The overflow from the Ohio continued until Apr. 8, when observations showed the water to be stationary. The previous high-water mark of 1884 was passed and a new record 3 ft. higher has been duly recorded. A large territory in Harrisburg Township was submerged, including a portion of the city of Harrisburg. Fig. 1 shows the rise and fall of the water, while Fig. 2 shows the submerged area.

Five mines of the O'Gara Coal Co. were within the flooded district. These have a daily output of 10,400 tons of coal when operated to capacity. The shafts are all sunk in low ground but were considered above high water. Mines Nos. 2, 3, 4 and 9 are all connected, forming a chain of underground workings more than three miles in length. The average depth is 230 ft. The soil depth in the shafts ranges near 40 ft., which includes 10 to 15 ft. of loose rock fill around the timber casing.

After observing the rapidity of the rise of the water on Apr. 2, the management of the O'Gara Coal Co. began the fight to keep the water from the threatened mines. Work continued for five days and nights before the mines were considered safe; subsequently all company men reported at the mines as a reserve until the water subsided.

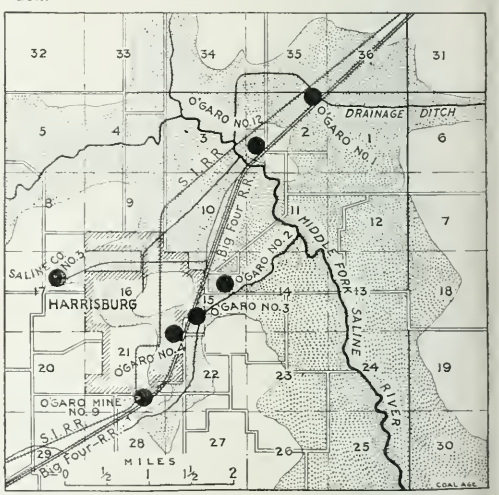

Fig. 2. Map Showing Area Inundated

Methods of Protection

Mine No. 1—The air shaft and fan house at this mine are located 300 ft. distant from the hoisting shaft; they were threatened on Apr. 4. A protecting wall of puddled clay was immediately started around the entire fan house. The clay was held in place by a substantial form built of car lumber. In order to make the wall as water-tight as possible, the top soil was removed and a stiff clay substituted. This wall proved effectual against a head of 2 ft. of water. The hoisting shaft was never reached by the flood, although the same protection was provided as at the air shaft.

Mine No. 2—The hoisting shaft at Mine No. 2 was first surrounded by a wall 6 ft. distant from the casing, 3 ft. high and 2 ft. thick, formed of puddled clay supported by timber forms. As the water approached the bulkhead, leaks from underneath became so numerous that it was found necessary to increase the height of the shaft casing at least five feet. This was done and a wall formed of clay was thrown around the added casing, the clay being protected from the waves by lumber forms

well braced (see Fig. 3). The air and escapement shaft was provided with a clay and timber bulkhead carried to a height of 5 ft.

At all of the mines the greatest problem was to obtain the clay, as the territory surrounding the mines had be-

FIG. 3. HOISTING SHAFT AT THE O'GARA CO.'S NO. 3 MINE

Mine No. 3—O'Gara Mine No. 3 is located within the corporate limits of Harrisburg. The underground works are connected with O'Gara Mines Nos. 2, 4 and 9, so that the failure to save any one would have flooded all four mines. The air and escapement shaft at Mine No. 3 received the first attention. The wood casing around the shaft appeared to be weakening under the pressure of the saturated soil. Immediately men were placed in the shaft and the portion subject to the direct soil pressure was heavily reinforced.

Bulkheads made of puddled clay, supported by forms, were started around the entire fan house. As soon as the water reached these walls, leaks through the loose rock fill under the bulkheads developed to such an extent as to prove dangerous. All efforts to stop these from the outside were in vain until clay was filled in between the bulkheads and the fan house and its height kept above that of the surrounding water. When observations showed the flood at a standstill, five feet of water was found around the protecting wall as shown in Fig. 4.

More than 300 cu.yd. of clay had been used in the protection of this shaft alone, 75 per cent. of which had been carried to place in cement sacks over a trestle man-

FIGS. 4 AND 5. VIEWS AT THE O'GARA CO.'S NO. 3 MINE, SHOWING PROTECTION AT AIR SHAFT

FIGS. 6 AND 7. METHOD OF PROTECTING THE AIR SHAFT AT O'GARA MINE NO. 4

come flooded before the work of protection began. Dump wagons drawn by company mules were abandoned after the first day's work. Railway flat cars were then loaded along the right-of-way of the Big Four Railroad two miles from the mine and placed at the mines by switch engines as long as these were able to run. Later cars were pulled in to the low mine tracks by means of block and tackle, the power being furnished by mules working from small elevated areas.

way 200 ft. long. The work at night was aided by means of strings of incandescent lights, the current being supplied from the central power station at Mine No. 3. In order to do this, two boilers were surrounded by dikes and fired when the water level stood several inches above the top of the fire box. Hand pumps and jets took care of all leakage.

At the time everything seemed safe a strong wind sprang up from the east, causing waves to run 3 ft. high.

These waves soon softened the clay in the bulkhead to such an extent as to render it almost fluid. Cement sacks were immediattely filled with sand, some being rammed into the softened clay while others were placed outside the walls until the exposed side was protected, as shown in Fig. 5.

The hoisting shaft at Mine No. 3 is 6 ft. higher than the air shaft and therefore requires less attention. The clay wall was thrown around it and all leaks in the casing calked. No difficulties developed at this point.

Mine No. 4—The hoisting shaft at Mine No. 4 was quite high, compared with the air shaft which required immediate attention. Owing to a peculiar location of the air shaft, it was uncertain just how soon the water would break across the railway embankment which had temporarily held it. For this reason the fan house was partially removed and the shaft sealed. (See Fig. 6.) The

FIG. 8. FLOOD AT THE O'GARA CO.'S WAREHOUSE

bulkheads with the filling of clay were also added, 200 cu.yd. of clay being used. This clay was hauled to a convenient point on flat cars, sacked and carried to place over a trestled manway, as at Mine No. 3.

RESULTS OF THE FLOOD

Some water seeped in around the casing at all the shafts. This could have been easily handled by the bottom pumps had the boilers remained in service. Two days' pumping prepared each mine for hoisting coal. The O'Gara Coal Co. sustained considerable loss, additional to the expense incidental to the actual protection of the mines. Seventy-five company houses were submerged and damaged by waves and floating débris. The company warehouse, machine shop, electric shop, foundry and corn crib were all damaged, including various supplies and machinery located at this center of distribution. Two weeks of running time were also lost, due to the railroads being unable to handle the traffic.

The work of protection was directly in charge of Harry Thomas, general superintendent of mines of the O'Gara Coal Company.

All predictions of past years that coal could not be worked at a greater depth than 1500 ft. no longer hold water. At the present day, according to W. E. Garforth, president of the British Institute of Mining Engineers, coal is being mined at depths exceeding 3000 ft. The adoption of a system of long-wall working has solved the question of superincumbent weight. The coal is exposed to this weight for a very short time and places are closed up rapidly.

A New Safety Lamp and a Blasting Machine

Schaffler & Co., of Vienna, Austria, are the manufacturers, and Peter A. Frass & Co., Inc., of 417 Canal St., New York City, are the American agents of the new mining apparatus illustrated herewith. Fig. 1 shows an electric blasting machine with a capacity of six detonators fired simultaneously. It is not a magneto but a miniature dynamo-electric generator, operated through a ratchet by a detachable T-handle.

This device measures 3⅞ in. long, 3⅛ in. wide over the strap buttons—being but 2¼ in. wide over the case—and 5¼ in. high to top of handle connection. The weight is 4½ lb. As may readily be seen, the whole machine

FIG. 1. SHOTFIRING MACHINE

is small, compact and durable, being thoroughly protected by a seamless drawn-metal case.

The magneto machines, as ordinarily constructed, are heavy for their capacity, and the magnets are certain to deteriorate or lose their strength, correspondingly weakening the current generated. This device is free from this inherent defect, as it is furnished with electro instead of permanent magnets. This greatly increases the life of the machine.

Fig. 2 shows an electric safety lamp of remarkable simplicity. The three principle exterior parts, base, housing and cover, are each a single casting of magnalium metal, which has the strength of cast brass and about the same weight as aluminum.

The battery is of the lead-plate, non-spilling, celluloid-incased type. A lug placed upon the side of the case fits into a mortise in the housing and renders it impossible to get the connections to the lamp reversed. The one- or two-candlepower tungsten filament light bulb (this lamp is made in both powers) is incased between two convex reflectors in a heavy glass cylinder, which is rendered air-tight by means of a gasket upon either end. The outer or protecting glass is shielded from external injury by four heavy columns cast integral with the main body of the housing.

The cover to which the suspension hook is attached is screwed into place and automatically locked by the insertion of the battery. A small thumb-screw upon the side

of the housing and plainly visible in the illustration serves as a switch for turning the current on or off from the lamp.

The bottom or base of the housing screws to place and is locked securely by means of a small winged socket-wrench. The locking bolt can not be readily withdrawn by any other means than this key.

As may be seen from Fig. 2, this lamp is extremely

FIG. 2. LAMP ASSEMBLED AND TAKEN DOWN

simple yet carefully made and amply strong. It weighs, dry, 4 lb. 3 oz. The addition of the electrolite would probably increase this weight a few ounces more.

An Indiana Mining Bill

The following bill introduced by Senator Kolsem, president of the Indiana Bituminous Coal Operator's Association, was passed by the last legislature, and signed by Gov. Ralston. It is felt that this law, in time will prove to be of great benefit to both the mine employee and employer.

A bill for an act to amend Section 3 of an act entitled "An act to revise the laws in relation to coal mines and subjects relating thereto, and providing for the health and safety of persons employed therein," approved Feb. 28, 1905.

Section 1. Be it enacted by the General Assembly of the State of Indiana that Section 3 of the above entitled act be amended to read as follows:

Section 3. It shall be unlawful for any operator to allow more than ten (10) persons to work in any mine at any one time after five thousand (5000) square yards have been excavated until a second outlet shall have been made; provided, that all air and escape shafts sunk hereafter shall be separated from the hoisting shaft by at least two hundred (200) feet of natural strata and shall be provided with stairways not less than two (2) feet in width, at an angle of not more than fifty (50) degrees, with landings at easy and convenient distances and with guard rails attached to each set of stairs from the top to the bottom of the same, and shall be available at all times to all employees engaged in such mines.

Also provided, that the stairways, landings and guard rails shall be of suitable design and strength to accomplish the purpose for which they are intended, and shall be kept free from obstructions. And that when the escape and air shafts are combined, the escape shaft and air shaft shall be separated by a good substantial partition from top to bottom.

Provided, further, where the approach or approaches to the escape shaft crosses an air course, entry or other passageway used as an air course, either as an intake or return, the air current shall be conducted by an overcast or undercast, over or under the point where such approaches shall be kept free from falling slate, mine tracks, mine cars and other débris, and shall be used only as a means of ingress or egress to or from the escape shaft. All water coming from the surface or out of any strata in such shaft shall be conducted by rings or otherwise to prevent it from falling down the shaft and wetting persons who are descending or ascending the shaft. The operator may provide at such outlet or escape shaft hoisting apparatus, which shall be at all times available to all persons in the mine, the same signals to be used as provided by law for use at hoisting shafts. The traveling roads or gangways to said outlet shall be separated from the hoisting shaft by at least two hundred (200) feet of natural strata and not less than four (4) feet in height and four (4) feet wide and shall be kept as free from water as the average haulage roads in such mines. At all points where the passageway to the escapement shaft, or other place of exit, is intersected by other roadways or entries conspicuous boards shall be placed indicating the direction it is necessary to take in order to reach such place of exit. It shall be unlawful to erect any inflammable structure or building or powder magazine on the surface so near to the escapeway as to jeopardize the safety of the workmen in case of fire. And no boiler house shall be erected nearer than thirty-five (35) feet of the mine opening. All explosive materials shall be stored in fireproof buildings on the surface located not less than three hundred (300) feet from any other building.

Fans shall be located and maintained at such place as not to be directly over the opening of an air shaft or escapement shaft, and all fans hereafter installed shall be arranged so as to enable the operator, when desirable, to reverse the air current.

Provided, further, that escape shafts already constructed under the provisions of the law herein amended shall not be affected by this act except they shall be maintained according to the provisions herein.

New Development Work in Illinois

The Consolidated Coal Co., of St. Louis, with offices in the Syndicate Trust Building, have completed arrangements for the greatest development made in the coal mining fields of Illinois for many years. A huge central power house is being erected, about a mile and a half north of Staunton, which will supply all the power required at four new mines that this company will open. Mines Nos. 14 and 15 will be midway between Benld and Staunton to the west, and connected up by spurs from the C. & N. W., which is now building down to connect with either the Wabash or Litchfield & Madison. Mines Nos. 16 and 17 are two and four miles respectively southwest of Staunton on a proposed spur from the C. & N. W. The four mines will have a daily capacity of from 4000 to 6000 tons each.

No information is available as to what this tonnage is intended for, but it is presumably a part of the original Gould scheme to furnish fuel from central Illinois for all of the Gould lines, including the Wabash, Cotton Belt, Iron Mountain, and Missouri Pacific, and possibly a portion of the Texas & Pacific and International & Great Northern. Excluding the T. & P. and I. & G. N., the Gould roads at the present time are estimated to use about 10,000 tons of coal per day.

At the present time the Consolidated Coal Co. has several mines in the field east of St. Louis and has recently taken over a big operation at Johnson City in Williamson County. They, with the Western Coal & Mining Co., which has a mine in Williamson County and several mines in Missouri, Kansas and Arkansas, are furnishing fuel for part of the Gould system at this time.

The Origin and Deposition of Coal

By W. B. Richards*

SYNOPSIS—A rather detailed summary of the modern theories of the formation of coal. Types of coal measure flora are described together with the different agencies which determined the varying qualities of the fuels. Particular attention is devoted to anthracite coal.

Plants are the source of coal beds. Their stems, leaves and tissues have gathered in places and beds like peat bogs and after long burial have been converted into coal. The formation of the coal from the beds of vegetable *debris* probably only made a beginning while these lay as open beds of peat. The same process is carried forward in the modern peat beds but result only in poor coal, which contains 25 per cent. or more of oxygen. Peat is a woody material passing part way to coal and sometimes wholly so in places; it is an accumulation of half decomposed vegetable matter in wet or swampy depressions.

In the temperate climate it is due to the growth mainly of spongy masses of the genera of sphagnum which are very absorbent of water. Besides spreading over many swampy places they extend in a floating layer from the borders of shallow ponds, dropping portions to the bottom from their lower roots, as they die above. They thus gradually take possession of the pond and may form beds of great thickness. The leaves, stems, branches of trees and shrubs, growing over the marshy region or in shallow water also contribute to the accumulating bed. This dead and wet vegetable mass slowly undergoes a change in its lower part, becoming brownish-black, loose in texture and often friable, although commonly penetrated with rootlets. This change is sometimes continued until coal is formed, but unlike good coal, it still contains 25 to 33 per cent. of oxygen.†

The rate of growth varies with the amount of vegetation, moisture and other conditions. A foot of depth may form in from five to ten years. Over many parts of New England, there are extensive beds; the amount in Massachussets has been estimated to exceed 130,000,000 cords. Peat waters have an antiseptic power and, consequently, tend to prevent complete decay of the vegetable matter. The deposits of clay or sand over the peat accumulations of the Carboniferous prevented the atmospheric oxygen from participating in the change and to this is due the better product.

The Carboniferous period, or that of the coal measures, was a period of large marshes. The clay beneath the coal, often called the underclay, generally contains fossil plants and especially the roots of underwater stems of the Lepidodendrons and Sigillaria, called Stigmaria. It is often the old dirt beds of earth over which the earth's plants grow that commence to form the coal beds. It was either those or the clayey bottoms of the plant bearing marshes or basins which accounts for the slate bottom in the anthracite seams.

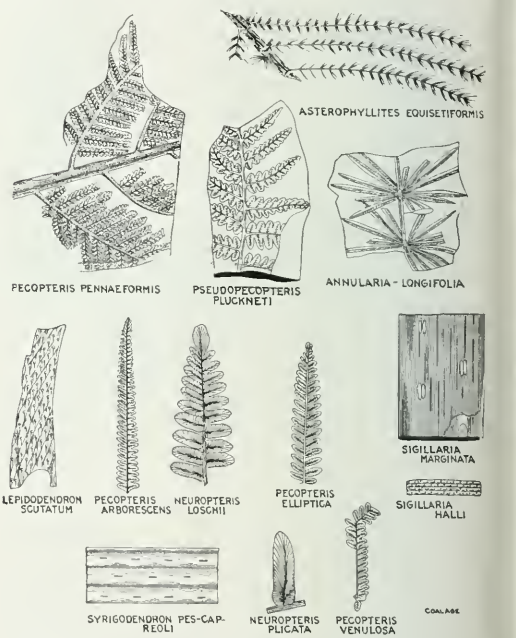
*Engineer, Lehigh Coal & Navigation Co., Lansford, Penn.

Note—Abstract of paper read before the Panther Valley Mining Institute.

†A more technical and detailed discussion of this interesting phenomenon will be found in "Coal Age," Vol. 1, page 712.—Editor.

Plant Life of the Carboniferous Period

The Nova Scotia coal fields abound in erect stumps of trees, standing in the old dirt beds. The rocks capping the coal may be slate, sandstone or conglomerate, depending on whatever circumstances succeeded. The shaly beds often contain the ancient ferns spread out between the layers and so abundant that however thin the shale may be split, it opens to view new impressions of plants. In the sandstone, broken trunks of trees sometimes lay scattered through the beds. Some of the logs of the Ohio coal measures are 50 to 60 ft. long and 3 ft. in diameter.



Typical Coal-Measure Fossils Found in the Panther Creek Valley

At Carbondale, Penn., there was found an impression of the bark of a Lepidodendron 2 ft. wide and 75 ft. long.

At Breckenbridge, Ky., the coal is marked through its whole mass by stems and leaves of the Stigmaria and Lepidodendrons, rendered distinct by the infiltration of sulphuret of iron. The coal is often penetrated with the tissues and spores of plants; even the solid anthracite has been found to contain vegetable tissues.

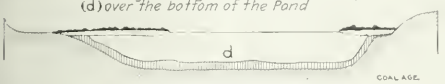
Animal material has also contributed to the coal, though sparingly, for animal decomposition always yields carbonaceous material and animal life, particularly fishes, were so abundant that the contribution in some cases may have been important. The mineral charcoal differs very little in composition from the ordinary bituminous coal. It must be kept in mind that all the agencies which contributed to the formation of coal beds worked on a prodigiously larger scale than those which are now in activ-

ity for the formation of peat. Then the deposits of vegetable remains were from an exceptionally exuberant vegetation, favored by the greatest possible humidity of the air and a superabundance of carbonic acid in the atmosphere. During that period the amount of carbon in the atmosphere was at least 3 in 1000 parts as compared with 3 in 10,000 parts today.

Deposition of the Coal Materials

The flora consisted of acrogenous plants, ferns, lycopods and equiseta (horsetail) covering nearly the whole area of the coal region. All the plants of these orders, represented by the numerous genera, were then large trees, their trunks measuring from 1 to 3 ft. in diameter and from 10 to 100 ft. high or even more, growing close together and forming an impenetrable forest of stems, branches and leaves, whereas at the present time plants are represented by mere herbage of small size with stems and branches scarcely as thick as a goose quill.

The first growth was generally floating or creeping plants and was essentially composed of a peculiar species, the Stigmaria, whose unusually long stems and branches from 4 to 6 ft. thick, were woven together into a mat or thick carpet over which the luxuriant land vegetation



Sketch Showing Deposition of Peat

spread itself. Such a mass of vegetation naturally sank of its own weight at times and places, until wholly submerged. This hypothesis is proved by the superposition of the beds of sandstone, shale, clay, ironstone and limestone upon the old coal beds.

The measures containing the coal seams were laid in salt, brackish or fresh water and vary accordingly. If the salt water had found its way into the life of the jungles and forests they would have been destroyed. At that time the encroaching water occasionally flowed with great and plunging waves, as is shown, not only by the coarse gravel beds of conglomerate, but also by the erosion of rock deposits, and in some cases the vegetable *débris* was washed away making what we call faults. Geologists admit that in some regions the coal plants may have been drifted to their place of deposit.

Subsidence and Compression of the Coal Measures

To account for the succession of coal beds separated from each other by many feet of strata, constituting a mass of coal measures several thousand feet in total thickness, it is necessary to take into consideration the slow subsidence of large areas of the earth's surface; these have taken place in all geological ages and were nearly continuous on a grand scale during the whole time in which the numerous formations of middle and western Pennsylvania were being deposited, ending with the rise of the whole region to its present height, at the end of the coal periods. During the last part of the downward movement the coal vegetation flourished magnificently but was interrupted by inroads of the sea on an equally grand scale, which explains the intermediate sandstones, shales, limestones, and iron-ore beds. The plant life was precisely similar but vastly greater and perhaps more long-lived than the plants composing the peat bogs of our day.

From all that has been said, it plainly appears that in the growth of the peat, we have microcosmic, but true, representation of the formation of coal. A coal bed itself bears evidence of alterations of conditions in its own lamination, and even in the alteration in shades and colors. A layer of one-eighth of an inch in thickness corresponds to an inch, at least, of the accumulating vegetable remains and, hence, the regularity and delicacy of structure is not surprising.

There may have been great variations in the length of time before the peat-like vegetation, after forming, was covered with water, which would cause a varied quality of coal due to the pressure of the beds of clay and sand. The decomposition of the vegetation depended on the amount of water, the composition of that water, and the length of time exposed. In some parts of the marsh, there were pools where the vegetation was long steeping and so became reduced to pulp, thus obliterating all bedding planes. The coal period was a time of increasing change, eras of verdure, alternating with those of widespread inundation destructive to all the vegetation and terrestrial life, except that which covered the region beyond the coal measures. Yet it was an era in which the changes went forward for the most part with such extreme slowness and with such prevailing quiet, that if a man had been living at that time, he would not have suspected the change.

The Change of Wood into Coal

All organic materials tend to decay and in this the chief process is oxidation; oxides are the largest part or all of the final result. Wood, when thoroughly dried, consists approximately of the following percentages: Carbon, 49.66; hydrogen, 6.21; oxygen, 43.03; nitrogen, 1.10 and traces of sulphur and phosphorus; animal fat contains the same elements. In smothered combustion, as in making charcoal by burning wood under a cover of earth, nearly all of the hydrogen and oxygen disappear in carbon monoxide, carbon dioxide and water, without the consumption of all the carbon. This also occurs when the plants decompose under a complete covering of water or earth, because this excludes the air and confines the change to the elements of the plant and the more complete the protection the greater will be the proportion of carbon and hydrogen saved. In the change of ordinary bituminous coal, the loss in the hydrogen in wood as compared with carbon is about 2 to 5 and to that of oxygen about 4 to 5. About 5.5 per cent. of such coal (ash excluded) is hydrogen and 12 to 15 per cent. oxygen, with 80 to 81 per cent. carbon. Mineral coal consists chiefly of carbon. Anthracite contains, usually, 2 to 5 per cent. of oxygen and hydrogen, and bituminous often 12 per cent., by weight, of oxygen and 4 to 6 per cent of hydrogen, while brown coal contains 20 per cent. or more of oxygen, with 5 to 6 per cent. of hydrogen.

The process of conversion of woody material into coal is shown in the following table:

	C.	H.	O.	N.
Wood	49.66	6.21	43.03	1.10
Peat	59.5	5.5	33.00	2.0
Bituminous	81.2	5.5	12.5	0.06
Anthracite	95.0	2.5	2.5	0.00

It is probable that in the formation of bituminous coal, at least three-fifths of the ingredients of the original

wood was lost, and in anthracite about three-fourths. Besides this reduction of two-fifths and one-fourth by decomposition there is a reduction of bulk by compression, which, if only one-half, would bring the total up to one-fifth or one-eighth. On this estimate it would take 5 ft. in depth of compact vegetable *débris* to make one foot of bituminous coal, and 8 ft. to make one foot of anthracite. For a bed containing 55 ft. of pure coal, like that at our Greenwood Colliery, the bed of vegetation should have been at least 440 ft. thick.

Anthracite coal is a result of the action of heat on bituminous coal under the pressure which accompanied the upturning of the rocks, the heat driving off nearly all the volatile matter, and leaving the anthracite behind. Anthracite in eastern Pennsylvania is due to the action of heat on ordinary bituminous coal, caused by the upturned and flexed condition of the rocks in that part of the state. The upturning fades out to the north westward and the Wilkes Barre anthracite region is on its outskirts. The conversion of bituminous to anthracite coal would not require any great amount of heat nor heat of prolonged duration. Moreover, it would have spread laterally from the area of greatest disturbance, as is well exemplified in the various metamorphic regions.

The following are the facts governing the origin of coal:

First—The coal of the upturned and more or less metamorphic coal measures of Rhode Island is the hardest of anthracite.

Secondly—The coal of the Carboniferous coal measures of western Pennsylvania and that of the states farther west, where beds are nearly horizontal, is uniformly bituminous and not anthracite.

Thirdly—Variations in the condition of the coal making eras over the whole globe have led to various kinds of coal without making anthracite. Brown coal, or that containing a large percentage of oxygen, is known to form where there is much excess of air. Cannel coal, a kind rich in oil producing hydrocarbons and little oxygen, was formed by prolonged steeping beneath a deep cover of sediments. Graphite, a grade beyond anthracite, is formed from the excessive heating of mineral coal, as is proved in the metamorphic regions of Rhode Island and Worcester.

❖ ❖

An Improved Steel Mine Car

By Alfred C. Fickes*

SYNOPSIS—These cars have a capacity of nearly three tons run-of-mine coal and weigh over 5200 lb., yet they are so constructed that one man can easily push them about upon a level track or even a slight grade.

❖

As the use of steel mine-cars is becoming more general every day, a description of an advanced type recently put in service by the Lehigh Coal and Navigation Co., will be, perhaps, not altogether inappropriate.

The Car Is Practically All Steel

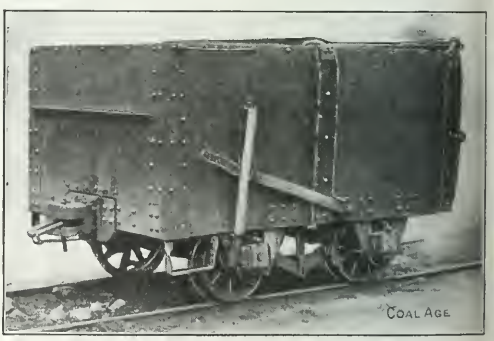
The car weighs 5204 lb. and is composed almost entirely of steel and wrought iron. The wheels, brake-shoes and pedestal-box lids are the only parts constructed of cast iron. The pedestal boxes and bearings are made of malleable iron, while the pedestals, couplers, door-brackets, etc., are made of cast steel, there being eleven various parts composed of this material.

The car is constructed for a gage of 3 ft. 6 in., the general dimensions being shown on the accompanying drawing. The capacity is 115.43 cubic feet, top-level full, or about 2⅞ tons of run-of-mine coal.

The L. C. & N. Co. has been experimenting with part steel and all-steel mine-cars for some years with various degrees of success, having made up cars ranging in weight from 4150 to 5530 lb. The new car was designed at the Lansford shops, under the supervision of Robert E. Hobart, master mechanic, who has had much experience along these lines and who has endeavored to embody all the good features of former cars without their disadvantages, at the same time introducing improvements wherever possible. The present car contains the latest features of car design.

The sides and bottom are made of ¼-in. steel, strongly reinforced with heavy angles and channels. A heavy strap-brace of 1x4-in. iron is placed across the top of the car at the center. With the exception of the slightly protruding brake, there are no projections on the outside of the body, while on the inside, all the rivets are flattened.

One of the improved features is the brake, which is operated on the rachet principle from either side of the



General View of the Car

car. A workman can easily operate this mechanism by running alongside, lifting the brake-lever and engaging it in the rachet, thereby setting in motion the levers and operating the brake-shoes. As these latter wear, an adjustment is easily made by means of shifting holes on the brake-arms. In localities where steep pitches are common, it is easy to discern the advantages of the brake over spragging.

The 20-in. wheels are spoked and can be spragged if necessary. They weigh 177 lb. each.

Another notable improvement has been made in the

*Lansford, Penn.

couplers. They are equipped with 1-in. round steel spiral springs and have been found to decrease considerably the strain on the locomotives hauling the trips, especially in starting. The compression and pull on these cars are both on center. The impact being deadened greatly reduces the wear on couplers, which in the old-style cars ran into a considerable sum of money annually for repairs and replacements. Instead of the usual three-link coupling but one link is used.

The axles are made from 3⅜-in. stock, turned down to 3¼ in. in the center and 3 in. at the wheels and journals. The ends of the axles project beyond the wheels as shown and are inclosed by the bearings and pedestal-boxes. Ordinary car-oil is used for lubrication and the boxes are packed with waste to keep out dust and dirt and prevent leakage of the oil. The pedestal-box lids are fastened to the boxes by ¼-in. round iron chain to prevent being lost.

Journal Boxes Are Carried on Springs

The shock on the bearings is reduced to a minimum by the use of ⅞-in. square steel spiral springs, each

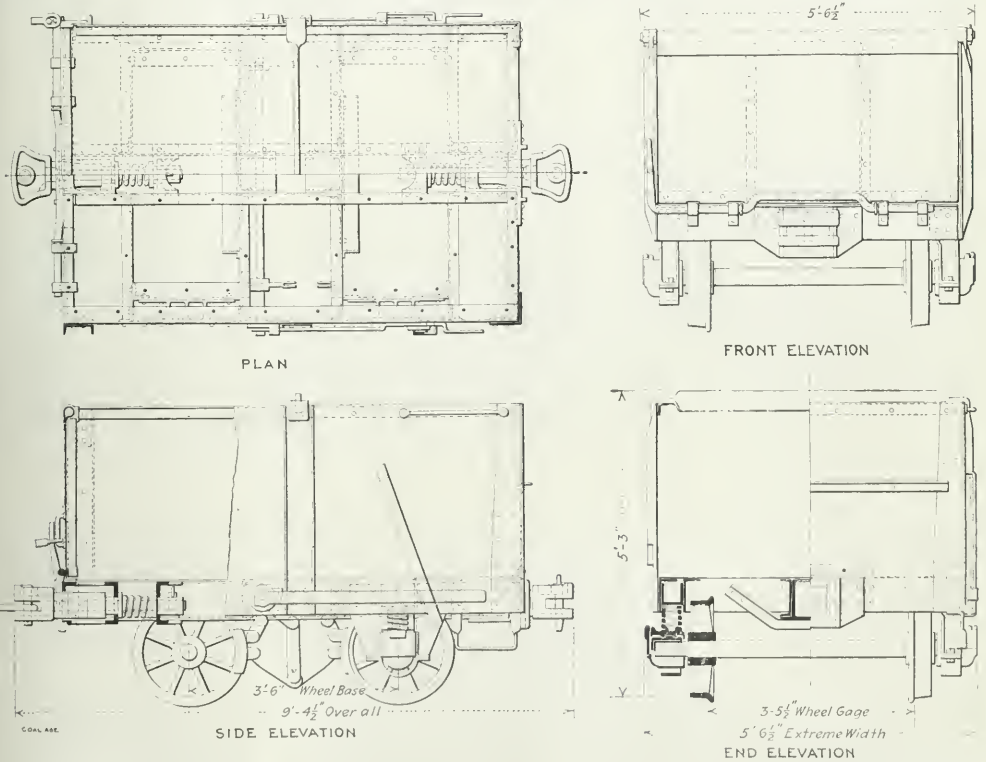
Last February, 175 of these cars were placed in service on the Springdale run at Coaldale Colliery and are doing good work. These were fabricated by the American Car & Foundry Co. Orders have been placed for 400 additional cars and the Lansford shops are now building them in large numbers.

This type of car costs approximately 40% more than the style formerly used by this company. It is the intention however to replace the old ones as fast as possible and manufacture the new style exclusively in the future, modified, of course, or improved wherever conditions warrant.

Last Year's Anthracite Production

According to the figures of the United States Geological Survey, the production of anthracite coal in Pennsylvania during the year 1912, amounted to 75,310,049 long tons. The value of this coal at the mines was $177,167,054, or an average price of $2.36 per ton.

The year's production was smaller than that of 1911



Details of Construction, Note Spring Dr awheads, Spring-Supported Journal Boxes, and Ratchet Brake

figured for 5800-lb. safe load. Every effort has been made to produce an easy-running car in spite of the great weight and as one man can readily push a car about on the level, or even on a slight grade, it would indicate that these efforts have been successful.

by approximately five and one-half million tons; but its value was greater by over $2,800,000.

The present average price at the mine is greater than at any previous time, the highest price charged before being $2.28 per ton in the year 1903.

Non-Fatal Injuries in Anthracite Mines

By F. L. Hoffman*

SYNOPSIS—The author points out that workmen's compensation is about to become universal without any data being available in the United States from which the probable rate of injury per 1000 men employed can be determined. The records covering only serious injuries are inadequate, as comparisons with British statistics amply prove.

The increasing extent to which employers' liability laws are being replaced by workmen's compensation statutes makes it important that the nature of industrial accidents should be much better understood than they are at present. In a few of the annual reports of state mine inspectors, the information is given in sufficient detail to disclose the nature of the injuries, as well as their causes, and the resulting degree of incapacity for work. It would serve a most useful public purpose if mine inspectors were to present the facts in a more convenient form, and, as a suggestion towards a feasible method of statistical research, the following tables and observations are presented as a first contribution towards a subject which has heretofore been much neglected.

The Pennsylvania Records

As a rule, the information concerning mine accidents is limited to a statement of the number of fatal and non-fatal injuries and their causes. But fortunately, in the reports of the Pennsylvania Department of Mines, additional information is supplied as regards the nature of the injuries sustained, but the data are not presented in the form of a convenient summary or made the subject of critical analysis. The total number of such accidents during 1907-11 was 5745, equivalent to a non-fatal accident rate of 6.7 per 1000 employed.

Since the fatality rate for the same period was 3.8 per 1000, it requires no extended analysis to sustain the conclusion that the non-fatal accidents are far from being fully reported, and that a thorough revision of the methods by which records of such accidents are obtained is urgently needed. Granting that the most serious accidents are of most importance from a medical, legal, social or economic point of view, it is nevertheless true that a large number and proportion of less serious non-fatal injuries occur, for which compensation would be required under the operation of more or less drastic compensation laws.

In Great Britain 105 Are Injured to One Killed

As perhaps the best illustration of existing defects in the reporting of non-fatal mine injuries, attention may be directed to the British experiences for 1911, as reported in the statistics of compensation and of proceedings under the Workmen's Compensation Act of 1906, and the Employers' Liability Act of 1880. According to this return, the number of persons employed in mines was 1,059,612, and among this number there occurred 1711 fatal accidents and 178,166 non-fatal accidents. The fatality rate was, therefore, 1.6 per 1000, and the non-fatal accident rate was 168.1 per 1000. The ratio of fatal to non-fatal accidents was, therefore, as 1 to 105.

If the ratio of non-fatal to fatal accidents for British mines is applied to the Pennsylvania anthracite collieries, the resulting number of non-fatal accidents during the five-year period ending with 1911 would be 114,348 against 5745 as actually reported. Granting that possibly the non-fatal accident rate is much less in the Pennsylvania anthracite mines than in British coal and metalliferous mines combined, the fact remains that the returns of non-fatal injuries, as at present made, are unquestionably untrustworthy and a serious understatement of the facts.

To secure more trustworthy and complete returns it is essential that the term "accident" should be defined in the law and general usage, and that uniform rules of statistical practice should be agreed upon by the mine inspectors of the several coal-producing states. Such a definition, to be trustworthy, should provide for information regarding the resulting duration of incapacity for work, and the importance of such a requirement is best illustrated in the British statistics, according to which, of the non-fatal accidents reported during 1911, 60.6 per cent. caused a work incapacity of less than four weeks.

TABLE I DURATION OF INCAPACITY FOR WORK, OR PERIOD FOR WHICH COMPENSATION WAS PAID

Compensation Paid (weeks)	Mining	Quarrying	Railroad Employees*	Dock Laborers	Shipping Steam	Shipping Sailing
Under 2	6 1	7 9	16 0	9 7	6 3	2 5
2—3	35 1	30 2	28 9	23 1	20 4	12 2
3—4	19 4	18 2	17 4	18 1	15 4	15 7
4—13	34 3	38 4	31 8	41 9	45 3	52 8
13—26	3 5	4 0	4 0	5 0	8 4	12 5
26+	1 6	1 3	1 9	2 2	4 2	4.3
	100 0	100 0	100 0	100 0	100 0	100 0

* Excepting clerical staff

According to this table, of the mine accidents, 5.1 per cent. required compensation for 13 weeks or more as against 16.8 per cent. for men employed on sailing vessels, and 12.6 per cent. for men employed in steam navigation. The table emphasizes the wide divergence in the economic consequences of non-fatal injuries, which by modern conceptions of legal responsibility will probably require to be provided for by the compensation of the injured employee by the employer, who, as far as practicable, will shift the expense upon the cost of production.

Are Returns Less Accurate or Mines More Safe?

As stated at the outset, the non-fatal accident returns for the anthracite coal mines of Pennsylvania are without doubt seriously defective. Since the returns do not show the duration of resulting incapacity for work, it is impossible to say whether the defect in the returns is limited to accidents of comparatively small economic importance, or to all classes, excepting, perhaps, the most serious. The table which follows seems to show that the tendency is rather towards diminished accuracy or completeness, for against a rate of 8.11 in 1907 the reported rate for 1911 was only 6.18 per 1000 employed.

TABLE II NON-FATAL ACCIDENTS IN PENNSYLVANIA ANTHRACITE COAL MINES, 1907-1911

Year	Employees	Accidents	Rate per 1000 Employed
1907	168,774	1369	8 11
1908	174,503	1170	6 70
1909	171,195	1034	6 04
1910	168,175	1048	6 23
1911	173,338	1124	6.48
Total	855,985	5745	6 71

*Statistician, Prudential Insurance Co., Newark, N. J.

The analysis which follows is for a five-year period, since a study of the facts by single years would have required much more space than is available for a discussion of this kind.

Considering first the age distribution of the injured, the table below gives the required information by divisional periods of life. It has not seemed necessary to extend the analysis to single years of life, since the frequency distribution is quite well emphasized by the less elaborate and more convenient method.

TABLE III. AGE DISTRIBUTION OF PERSONS INJURED IN NON-FATAL ACCIDENTS IN PENNSYLVANIA ANTHRACITE COAL MINES, 1907–1911

Ages	Number Injured	Per cent. of Total	Ages	Number Injured	Per cent of Total
12—14	18	0 3	45—49	418	7 3
15—19	825	14 4	50—54	251	4 4
20—24	1000	17 4	55—59	135	2 3
25—29	949	16 5	60—64	60	1 0
30—34	809	14 1	65+	49	0 9
35—39	686	11 9	Unknown	2	
40—44	543	9 5			
			Total:	5745	100.0

The value of the foregoing table is materially impaired by the fact that the age distribution of the men employed in anthracite mines is at present not known. It is possible that the forthcoming results of the Twelfth Census may give the required information, but in view of the curtailment of census appropriations, it is doubtful whether the analysis was extended, as indeed is desirable, to the age distribution of occupations by divisional periods of life.

The Relation of Place of Birth to the Accident Rate

The same conclusion, in part, applies to the factors of race and nativity, which also have an important bearing upon the frequency of accident occurrence. As shown by the table, which follows, the proportion of Polish mine workers injured during the five-year period was 25.1 per cent, or not much less than the proportion of native-born Americans, returned as 26.6 per cent. A serious question may be raised, however, as regards the accuracy of the nativity returns, since it is difficult to believe, for illustration, that the number of Magyars and Greeks, as well as Austrians, was not larger than actually reported. Apparently, many men of these nativities were returned as Slavs, which is a rather indefinite term in popular usage, although ethnologically well defined and understood.

TABLE IV. NATIVITY OF PERSONS INJURED IN NON-FATAL ACCIDENTS IN PENNSYLVANIA ANTHRACITE COAL MINES, 1907–1911

Nativity	Number Injured	Per cent. of Total	Nativity	Number Injured	Per cent. of Total
American	1530	26.6	Lithuanian	529	9.2
Arabian	2	0.0	Magyar	3	0.1
Austrian	161	2.8	Mexican	1	0.0
Bohemian	2	0.0	Montenegrin	2	0.0
English	157	2.7	Norwegian	1	0.0
Finnish	7	0.1	Polish	1442	25.1
French	6	0.1	Russian	261	4.5
German	147	2.6	Scotch	19	0.3
Greek	12	0.2	Slavish	379	6.6
Horvat (Croatian)	3	0.1	Swedish	11	0.2
Hungarian	141	2.5	Syrian	3	0.1
Irish	308	5.4	Tyrolean	18	0.3
Italian	391	6.8	Welsh	209	3.6
			Total:	5745	100.0

Conjugal Condition

The same conclusion as to inherent inaccuracy would seem to apply to the returns as to conjugal condition. Out of 5745 injured mine employees, 56.1 per cent. were returned as married, 43.6 per cent. as single, but only 0.1 per cent. as widowers. It is practically certain that the widowers were returned as married, in conformity to local usage. From a legal point of view, in connection with workmen's compensation legislation, it is of considerable importance that returns of this kind should be accurate and conclusive, since the compensation rates vary according to the relationship of dependent survivors.

The causes of injuries have been classified in reasonable detail in the table which follows, and the minor occupations have been grouped on account of the required limitation of space. For scientific purposes the occupations in detail would be of considerable importance, but the value of the analysis diminishes on account of decreasing numbers by minute classification, which can only be made to advantage for a much longer period of time or upon the basis of much more complete returns than are at present available.

Table V is self-explanatory and requires no extended discussion. It is shown that of the accidents reported, 25.9 per cent. were due to mine cars, 22.4 per cent. to falls of rock or slate, 14.4 per cent. to falls of coal, and 10.3 per cent. to gas or dust explosions. These four principal groups of causes, therefore, accounted for 73 per cent. of the non-fatal accidents from all causes.

Nature of Injuries

The foregoing discussion has been with reference to the general facts of non-fatal injuries in anthracite mines, which it is necessary to take into consideration in a subsequent discussion of the nature of the injuries sustained.

It is much to be regretted that the reports do not state the duration of the injuries, since the total amount of compensation is naturally conditioned by the length of time for which the compensation is paid. To a certain extent, of course, the probable duration of injury is indicated by the nature of the injury sustained, and the following table gives in detail the single injuries as well as the complicated injuries where more than one part of the body was affected.

Considering the large number of complications possible, it has been necessary to combine some of the injuries, which, however, are not of sufficient numerical importance to affect the results. The proportion of not specified injuries was 7.5 per cent. of the whole, and of injuries combined but not available for tabular analysis, 6.5 per cent. The table exhibits the principal groups of occupations, together with the estimated number of employees for the five-year period, the percentage distribution of single and combined causes in detail, and the non-fatal accident rate per 1000 employed for each specified group.

The foregoing results have been summarized in the next and concluding table, in which the bodily injuries have been arranged somewhat in conformity to the human anatomy. This table is of unusual interest and is the first statement of its kind exhibiting with approximate accuracy, the nature of the injuries sustained in anthracite mining, with a due regard, however, to the necessity of combinations, and returns too indefinite for scientific classification. The proportion of

such returns and the data not available for analysis was 14 per cent. and to that extent the table is open to criticism, although there are no reasons for believing that any one class of minor injuries is more affected by this degree of uncertainty than another.

Most Accidents Are to Lower Extremities

The foregoing table exhibits the rate of non-fatal injuries according to their nature per 1000 employed, together with the percentage distribution of the injuries according to the part of the body affected. It is shown that the lower extremities, including the hips, represent the largest group, or 11.5 per cent. of the whole, followed by the upper extremities, including the shoulders, which account for 21.1 per cent. Injuries to the head, including the eyes and nose, account for 12.1 per cent., or about the same as injuries to the trunk, including the collar bones and internal injuries not otherwise specified, which account for 11.3 per cent.

TABLE VII. PARTS OF BODY INJURED IN NON-FATAL ACCIDENTS IN THE ANTHRACITE MINES OF PENNSYLVANIA, 1907–1911

In more detail, the most important cause of injuries was to the legs, or 31.7 per cent., followed by injuries to the hands, or 9.0 per cent., and to the arms, or 7.9 per cent. The analysis proves the economic importance of compensation, in that evidently a considerable amount of prolonged incapacity for work resulted from the injuries sustained. If the returns were more complete, it is safe to assume that the number of minor injuries would be largely of a nature not involving continued absence from work, or chiefly to the fingers, hands, wrists and feet, including ankles and toes. Eye injuries have been comparatively infrequent, at least of the most serious kind, for, according to the table, there were only 56 such injuries, equivalent to 1 per cent. of all injuries, or 0.07 per 1000 employed.

Internal Injuries Are Rare

Internal injuries also appear to have been comparatively rare, the actual number having been 47, and the proportion 0.8 per cent. of the whole, or 0.05 per 1000 employed. The relatively small number and proportion of internal injuries, however, is accounted for by the fact that most of such injuries in mine labor are followed by fatal results.

The foregoing discussion is merely intended as a brief contribution towards a better understanding of the accident problem in anthracite mining. The discussion suggests the economic importance of non-fatal mine injuries and the imperative necessity for more complete and, as far as practicable, uniform returns, to provide a better basis than is at present available for discussions of workmen's compensation problems in coal-producing states, with special reference to the needs of mine workers.

Definitions of Fatalities and Injuries

It may be suggested that every accident involving an absence from work of more than one day should be reported, and that accidents which do not result in death within seven days should be listed not as fatalities but as injuries. At present the definitions vary and accidents reported in one state as non-fatal would be reported in another as fatal. In order to avoid a subsequent correction of the record, after several months have intervened, most of the states class fatalities which occur long after the accident as merely injuries.

As a final illustration of the economic importance of the non-fatal accident problem, it may be pointed out that if the non-fatal accident rate experienced in the British mines is assumed to prevail in the Pennsylvania anthracite mines, the amount of compensation required on the British basis of $24.70 per accident, would have been $3,560,456. The amount requires only to be stated to emphasize the great practical importance to the employer, the employee and the state, of trustworthy accident statistics on the one hand, and of a thorough understanding of the facts on the other.

View of Kentucky First-Aid Meet

Showing the Teams Standing at Attention Ready to Commence Work

Meeting of Kentucky Mining Institute

SYNOPSIS—The spring meeting of the Kentucky Mining Institute was held in Lexington, Ky., May 16 and 17. In addition to several interesting papers which were read, there was a state-wide first-aid meet, with 24 teams competing.

The first-aid field meet held in connection with the spring meeting of the Kentucky Mining Institute at Lexington on May 16, took place on the athletic field of the State University.

An address of welcome was delivered by President Barker of the Kentucky College, after which there was a short drill by the cadets of the state school. Following this the first-aid teams lined up preparatory to commencing the contest. The events were as follows:

First Event—Lacerated wound in palm of left hand. Right-thigh compound fracture, bleeding; patient carried 50 ft. on an improvised stretcher. Full-team event.

Second Event—Treat burns of face, neck, ears and hands. Two men carry patient without stretcher. Two-man event.

Third Event—Dislocated shoulder left side; right foot mashed, bleeding. Full-team event.

Fourth Event—Man overcome by gas; one man shoulder, lift and carry to place of safety. Perform standard form of respiration. One-man event.

Fifth Event—Man to fall on electric wire; back down, unsconcious. Rescue, give artificial respiration, one minute; treat burns on back and right upper arm. Improvise stretchers; carry 50 ft.

LIST OF TEAMS

No. 1—Wallsend: James Dixon, captain; Robert Coswell, Thomas McDonald, James McGleneroy, James Wicks.

No. 2—Stearns Coal Co.: Earl Mallcy, captain; Brier Donaldson, Harry Donaldson, Sam McMurry, Clabe Brier, Elmer Chitwood.

No. 3—Rim No. 1: Anderson Manon, Harry W. Fritts, J. Grayson Ponder, Charles McPherson, John Shelton, Jim Stone, Captain. Instructed by Dr. E. M. Howard.

No. 4—Stearns, No. 2: Nels Robbins, captain; Will Taylor, Alec Taylor, Ben Sweet, Jacob Reeves, Louis Burnet.

No. 5—Barker, No. 1: J. W. Dean, captain; J. I. Stone, E. G. Moore, Henry Hubbard, James Hampton, Chas. Mailer, Joe Cox, Dr. B. E. Giannini.

No. 6—Luzerne.

No. 7—Arjay: Sid Ingram, captain; R. A. Billings, L. M. Disney, R. F. Frye, Walter Fortner, Joe C. Cobb, Dr. Fred D. Haston.

No. 8—St. Bernard Coal Co.: Tom Peyton, captain; Wads Cole, F. Griffin, Chas. Ray, James Cloren, Will Donnelly.

No. 9—Barker No. 2: William Taulbee, captain; Charles Pressnell, John Sutton, J. S. Dozier, Perry Lone, Chas. Moore, Dr. B. E. Giannini.

No. 10—Jenkins No. 1: Lester Shrum, captain; Louis Biggs, James Walker, G. W. Rucker, Forest Bice, Thad Shunk.

No. 11—Rim No. 2: John Clark, captain, Ben Stone, Halsey Johnstone, William Anderson, James Phillips, Charles Rollins; instructed by Dr. E. M. Howard.

No. 12—Stearns Coal Co., No. 3: Joe Henry, captain; Lee Tourds, Sid King, Oscar Ross, Jim Strunk, Silas Jones.

No. 13—Glendon: John Onks, captain; Frank Bowman, John T. Lackard, Jim Lay, Bentley Messer, Dr. Fred D. Haston.

No. 14—Van Lear: J. P. Jennings, captain; Noah Henson, William Joushon, J. M. Stambaugh, Grover Wolf, Carl Picklesiner.

No. 15—Castro: James Hyatt, captain; Wilson Spivy, Walter Lock, Walter Green, Elijah Burke, Tip Jackson.

No. 16—Graham: W. B. Hager, captain; S. E. Hite, W. L. Cash, P. H. Morgan, T. J. Vinson, J. H. Spencer, W. D. Duncan Coal Co., of Greenville, Ky.

No. 17: Geraldine: Smith Snow, captain; William J. Black, Ed. Whittaker, Ballard Mattimgly, Harvey Markham, Floyd Mills, Dr. F. D. Haston.

No. 18—Stearns No. 4—Reason Cecil, captain; Ed. Winchester, John Smith, John Hiffdon, Jim De Prossett, Bill Bowman.

No. 19—Cary: Ed. Duncan, captain; John Stillings, Frank Bradshaw, Francis Dunn, Thad Idol, Will France.

No. 20—Stearns, No. 5: Noble Stevens, captain; Dault Boyce, Edgar Phillips, Carl Fleming, Homer Stevens, George Smith.

No. 21—Auxier: John Ward, captain; M. L. Cornutte, John Coyer, Dave Corder, A. M. Alley, Ancil Rogers, Northeast Coal Co.

No. 22—Benham: L. D. Smith, Verner Luigart, J. R. Foster, Orby Hall, Orion Kelly. Wisconsin Steel Co.

The colored teams, Barker No. 3 and Rim No. 3, from the Continental Coal Corporation competed for Events 3, 4 and 5.

PRIZES

First prize, a silver loving cup, donated by the Goodman Manufacturing Co., of Chicago, and $60 in cash donated by the Jeffrey Manufacturing Co., of Columbus, was tied for by the following teams:

Team No. 9, Barker No. 2, Continental Corporation, 99 1/8 per cent.; team No. 22, Benham, Wisconsin Steel Co., 99 1/8. By agreement the money was divided and the cup was given to the Benham team to keep for six months, when it will be sent to the Pineville team and at the meeting in October it will be contested for as a side event between these two teams.

Second prize, a Johnson & Johnson first-aid cabinet, one Woods emergency case, five copies of Johnson's First-Aid Manual, and one-half dozen rubber-cloth covered first-aid packets. Won by team No. 10, Jenkins, Consolidation Coal Co., 98 1/8.

Third prize, an electric-lamp outfit and a safety lamp. Won by team No. 8, St. Bernard Mining Co., Earlington, Ky., 98 1/8.

Fourth prize, clock mounted in cannel coal. Was won by team No. 3, Rim No. 1, Continental Coal Corporation, 98.

Colored teams, Barker No. 3, 91⅜, Rim No. 3, 95.

RATINGS

No. 1, 92; No. 2, 97 1/8; No. 3, 98; No. 4, 95 3/8; No. 5, 97 3/8; No. 6, 75 1/8; No. 7, 97; No. 8, 98 1/8; No. 10, 98 4/8; No. 11 96 1/8; No. 12, 97 1/8; No. 13, 94 3/8; No. 14, 96; No. 15, 93 3/8; No. 16, 95 3/8; No. 17, 96; No. 18, 96 2/8; No. 19, 97 4/8; No. 20 95 1/8; No. 21, 97 4/8; No. 22, 99 1/8.

The prizes were awarded by Prof. Norwood, chief state mine inspector. President Barker of the University also presented each team with a banner, and Mr. Wilson, Chief Engineer of the U. S. Bureau of Mines, presented a dozen medals to the teams, giving one medal to each of the twelve teams scoring the highest number of points.

In the evening, at 7:30, a banquet was held at the Phoenix Hotel. Short addresses were delivered by E. W. Parker, Floyd W. Parsons, Pres. Rash, James W. Paul, J. E. Beebe, J. B. Johnston, E. B. Wilson, C. J. Norwood, W. A. Miller and W. L. Moss.

THE MEETING SATURDAY MORNING

On Saturday morning the convention of the Kentucky Mining Institute convened in the Civil Engineering Building of the State University. The meeting was called to order by President Rash. The convention then adopted a memorial to C. F. Frazier, mining engineer, Taylor Coal Co., Beaver Dam, Ky. Next was the reading of a paper by Dr. A. M. Peter on "Calorimeter Tests Made on Kentucky Coal." Then followed a paper on "Workmen's Compensation," by K. W. Meguire, president of the Snead & Meguire Coal Co., Louisville, Ky. Following this was another paper by W. C. Tucker, general superintendent of the Wisconsin Steel Co., Denham Ky. Mr. Tucker discussed "welfare work." After Mr. Tucker came David Victor, chief mine inspector of the Consolidation Coal Co., Fairmont, W. Va., who read a paper on "How Best to Handle the Dry or Dusty Mine."

Because of trouble to the electrical apparatus of the University, it was found impossible to use the stereop-

ticon slides that were necessary to illustrate Mr. Wilbert A. Miller's paper on "Shortwall Mining." Pres. Rash announced, however, that this paper will appear in the proceedings of the Institute.

Next was a discussion on Mine Ventilation by Mr. Weinshank, after which President Rash made a short talk thanking the members of the Institute for the hearty coöperation they had rendered him during his term of office. He then called for nominations for a new president and Mr. Davies presented the name of White L. Moss. The nomination of Mr. Moss was made unanimous, and he was elected president of the Institute for the ensuing year.

The committee on nominations reported further elections as follows: For secretary and treasurer, T. J. Barr; for vice-presidents from the following districts of Kentucky: For the central district, B. R. Hutchcraft; for the western district, T. E. Jenkins of Sturgis, Ky., and C. W. Taylor of the W. P. Duncan Coal Co.; for southeastern Kentucky, James Butler of Stearns, and W. C. Tucker of the Wisconsin Steel Co., Benham; for the northeastern district, L. G. Abbott and H. LaViers. There being no further nominations, the foregoing were duly elected to the offices suggested.

The meeting closed after a further discussion on ventilation by Messrs. Victor Weinshank and Paul.

Heat in the Volatile Matter of Coal

By Alfred M. Peter*

SYNOPSIS—The author endeavors to separate the heat of combustion of the volatile combustible matter in coal from that of the fixed carbon. He uses several analyses of coals from the Kentucky field and concludes that the bituminous matter from the Eastern field is more heat-giving than that from the Western. The heat from the volatile combustible matter is much greater than that from fixed carbon and appears to reach 17,412 B.t.u., whereas carbon on burning only generates 14,500.

During the years when the Kentucky Geological Survey was being conducted under the able and efficient directorship of Charles J. Norwood, with headquarters at State University, a number of calorimeter determinations were made upon samples of coal obtained from different mines in the state. For this work Prof. Norwood provided, first a Parr fuel calorimeter and later one of the Emerson design, the latter being a new form of the bomb type of calorimeter and capable of giving results as accurate as those obtainable with the other standard instruments of this type but much easier to manipulate and more rapid in action.

The determinations were made at different times by Prof. Norwood's assistants, Messrs. Quickel, McHargue and Calloway. Some of these results have been published in the report of progress of the survey for the years 1908 and 1909; some are to be found in the bulletins of the survey, part of which, however, are still in the hands of the public printer, and I believe some have never been published.

Is the Volatile Combustible in the Kentucky Coals All Equally Heat-Giving?

I intend to take only a few of the determinations, those which are most representative of the more important coal beds in the state, and I shall endeavor to ascertain whether that part of the coal which is both volatile and combustible is of equal heating value in all the coals presented, considering, of course, the quantity of such matter in the coal.

Where coal has a large amount of volatile combustible matter, we naturally expect it to have a high heating value because of the large amount of hydrocarbons which are contained in such matter. Hydrogen, on burning, produces 62,000 B.t.u. per pound, whereas carbon develops only 14,500 B.t.u., and for this reason we would expect matter containing hydrocarbons to give more heat than fixed carbon when burned.

On the other hand, volatile combustible matter contains more or less oxygen, and its presence indicates that the coal is more or less an oxidized product and, therefore, less capable on combustion of giving out all the heat which a completely unoxidized body would emit on burning. Moreover, in this volatile combustible part of coal, sulphur and nitrogen are included, the former having a low heat value, about 4000 B.t.u. per pound when burning, and the latter oxidizing with the emission of but little heat. In the incombustible volatile matter, more or less water is found. This is derived from the clay which forms after burning a part of the ash constituent. Thus, if the volatile matter has a varying composition, it may have a variant ability to emit heat when burned.

I propose to estimate the heat in this volatile part of the coal by deducting the heat generated by burning fixed carbon or coke from that which is obtained when the original sample is burned. This deduction for the heat of the fixed carbon will not be taken from coke prepared in the laboratory, nor from the same sample of coal of which the heat of combustion is determined but will be derived as an average from 7 commercial cokes made from coal mined in Kentucky and consumed in a Parr calorimeter.

Had this investigation been kept in view at the time the survey made the tests on Kentucky coals, the goal would have been more certainly attained by actually determining the heat of combustion of the coke from a sample of coal which was a duplicate of the fuel tested in the calorimeter.

AVERAGE ANALYSIS AND HEAT OF COMBUSTION OF 7 COMMERCIAL COKES FROM KENTUCKY COAL

	Highest Value	Lowest Value	Average Value
Moisture	0.77	0.02	0.35
Volatile combustible matter	1.62	0.19	0.89
Fixed carbon	90.61	79.23	84.63
Ash	19.16	9.07	14.13
Total			100.00
Sulphur	2.01	0.45	1.01
B.t.u. per lb. of coke	12,717	10,283	11,703
Total combustible matter (100 − moisture − ash)			85.52
B.t.u. per lb. of same	14,491	12,842	13,684

*Chief chemist, Agricultural Experiment Station, Kentucky State University, Lexington, Ky.

Abstract of paper entitled "Some Calorimeter Determinations of Kentucky Coals," read at the Kentucky Mining Institute, Kentucky State University, Lexington, Ky., May 17, 1913.

From this table it appears that the average heat value of the combustible matter in these samples of coke was 13,680 B.t.u. per pound, and, in the absence of better data, I propose to use this figure in the calculations which are to follow.

Why Coke Burns with Less Heat than Amorphous Carbon

The range of variation in the analysis of these samples and in their heat values as thus determined, is quite large and the figure for the average heat value is considerably lower than that usually accepted for carbon. There are, however, certain reasons why the heating value of the combustible matter in coke should not be as great as that of pure carbon. Coke always contains more or less sulphur as well as small percentages of nitrogen and hydrogen.

Hydrogen, of course, would tend to bring up the value a little, whereas, sulphur and nitrogen would reduce it. Besides this, according to the statements of the textbooks, Favre and Silbermann, whose work was published in 1852, declare that the heat value for graphitic carbon is decidedly lower than that for the amorphous form of that element, and it is probable that a part, at least, of the carbon in coke is graphitic in character. The value, 13,680 B.t.u., therefore, does not seem unreasonably low.

In recent literature there seems to be little which bears upon the subject of this investigation. One chemist, however, seems to have made some careful inquiries along much the same lines, but unfortunately I have the account of his work only in the form of the brief summary which appeared in the Abstract Journal of the American Chemical Society.[1] The work is a thesis by Herman Streit, entitled "Studies on the Chemical Composition and Heat of Combustion of Cokes Prepared by Different Methods, and on the Determination of the Heat of Combustion of Coals by Calculation."[2]

STREIT'S AVERAGES FOR HEAT OF COMBUSTION OF COKE

For oven coke	14,310 B.t.u.
For gas coke	14,400 B.t.u.
For crucible coke made by the American method of analysis	14,580 B.t.u.

These averages are close to the commonly accepted value for carbon and much higher than the one derived above from Kentucky cokes. Indeed they seem too high.

One of the author's conclusions is that, with few exceptions, due to abnormal composition, as high sulphur, the heat of combustion of cokes can be calculated within about 1 per cent. by multiplying the per cent. of combustible matter by the appropriate factor corresponding to these findings. Thus, for an analysis by the American method, the factor would be 115.8. Another conclusion is that the heat of combustion of the total combustible matter of coke obtained by the same method from different coals is the same, but differs if different methods are employed. The author also concludes that the chemical composition and hence the heat of combustion of the combustible matter of a coal depends on the method of coking.

A paper by H. Bunte, entitled "Notes on the Byproducts of the Gas Industry,"[1] an abstract of which was seen in the Journal of the Society of Chemical Industry,[2] contains data of interest in this connection. The author reports the chemical analysis and heat of combustion of 12 gas cokes, mostly German.

LABORATORY DETERMINATION OF 12 GAS COKES

Ultimate analysis combustible part of cokes	
Carbon	94.18 per cent.
Hydrogen	0 90
Oxygen and nitrogen	3 77
Sulphur	1 13
	99 98
Proximate of analysis of original coal	
Total combustible matter	89 11
Water and ash	10 89
	100 00
Actual and theoretical determinations of heat values	
B.t.u. per lb. of total combustible matter, from the calorimeter determinations	14,101
Calculated from the analysis by Dulong's method	14,006

This value, also, is higher than that obtained from the Kentucky cokes, but tends to confirm it because gas cokes are presumably less thoroughly carbonized than are oven cokes and would be expected to have a somewhat higher heat of combustion on account of their containing more hydrocarbons.

Having decided upon a value for the heat of combustion of the combustible matter in coke, we may determine, by difference, what the heat of combustion of the volatile combustible matter in a coal should be, if we have the proximate analysis of the coal and its heating value as determined by the calorimeter.

Allowance Is Made for Water of Constitution in Clay

In order to get the total combustible matter in applying this method, I have decided to subtract not only the ash and moisture but in addition a further 10 per cent. of the ash, which is an allowance made for the combined water contained in the ash constituents before heating.

The ash of coals is composed largely of clay and it is evident that this clay must have contained its proper amount of combined water before the coal was burned. This water would be driven off with the volatile combustible matter and be counted with it in the analysis. Kaolin contains about 13 per cent. of combined water, but as the ash is not all clay I have assumed 10 per cent of the weight of the ash as approximately representing the original amount of water in combination.

Accordingly, in the following calculations, one-tenth of the ash has been, in each case, deducted from the amount of volatile combustible matter shown in the analysis of the coal. The percentage of fixed carbon multiplied by 136.8 gives the heat of combustion of the fixed carbon. This deducted from the heat of combustion of the original coal gives the heat of combustion of the volatile combustible matter, which, divided by the weight of that matter, corrected as already explained for combined water, gives the heat of combustion per pound of the volatile combustible matter.

These calculations have been made upon the analyses representing coal from five of the important beds of ordinary bituminous coal and also upon a number of cannel coals, as shown in the following tables, which give the data for the calculations and the results. In the last table the final results are brought together and a comparison of them is interesting. As was to be expected, the cannel coals show considerably the highest heat of combustion, both for the total and for the volatile combustible matter.

The Volatile Matter of the East Kentucky Field Has More Heat Units Than That of the West

The most important point brought out in this table is that the coals of two important beds, Nos. 9 and 11, in the Western field, agree pretty closely in the heats of combustion of their total combustible matter and of their volatile combustible matter, but differ materially in these respects from the coals of three important beds in eastern Kentucky. It is seen that the heat of combustion of the volatile combustible matter from the Eastern Kentucky coals approximates more nearly that of cannel coal than that of the western Kentucky coals. I believe this observation is a new one and while I do not know that it has any practical application, it seems to me to be worth recording. It would be interesting to extend this study to coals of other important beds, but the time at my disposal did not permit this in the present communication.

In conclusion I desire to thank Mr. J. S. McHargue for assistance in looking up the literature. It is proper also to say that he made nearly all the chemical analyses used in this paper.

CALCULATION OF HEATS OF COMBUSTION OF TOTAL COMBUSTIBLE MATTER AND VOLATILE COMBUSTIBLE MATTER

Coal No. 11. Western Coal Field. Average of 12 samples from Muhlenberg, Union and Webster Counties.

	Highest Value	Lowest Value	Average Value
Moisture	5 87	1 16	4 11
Volatile combustible matter	41 78	37 55	39 67
Fixed carbon	51 11	41 58	47 63
Ash	15 52	5 62	8 59
Total			100 00
Sulphur	4 69	2 64	3 59
B.t.u. per lb. of coal	13,450	10,722	12,833
B.t.u. of 0.4763 fixed carbon @ 13,680 per lb.			6,516
B.t.u. of 0.3967 volatile combustible matter			6,317
B.t.u. per lb. of same after deducting 1 10 of the ash			16,277
Total combustible matter (100 less moisture, ash and 1 10 of the ash)			86 44
B.t.u. per lb. of same $\left(\frac{12,833}{0\ 8644}\right)$			14,846

Coal No. 9. Western Coal Field. Average of 16 samples from Daviess, Henderson, Hopkins and Webster Counties.

	Highest Value	Lowest Value	Average Value
Moisture	7 32	2 41	4 17
Volatile combustible matter	38 47	34 24	37 19
Fixed carbon	54 34	46 03	49 62

The Kentucky Coal Mining Industry and Workmen's Compensation

An interesting paper with the title given above was read before the Kentucky Mining Institute by K. U. Meguire. We hope to publish the principal part of this article in our next issue.

A European method of disposing of a large gob fire is to first locate the area by testing the temperature of the goaf with metallic rods. The limits of the spontaneous combustion being defined, roads are opened to it through the goaf and the fire or heated material dug out, the space being filled in with sand or flue dust.

Welfare Work at Benham, Kentucky

By W. C. Tucker*

SYNOPSIS—A detailed discussion of the sociological work being carried on by a subsidiary of the International Harvester Co. in its coal mines. The article includes some interesting remarks on Workmen's Compensation Laws, and suggests a basis for the enactment of such legislation.

In building the town of Benham we built neat comfortable houses of two, three, four and five rooms. These houses are on stone foundations, have novelty siding or weather-boarding and are plastered throughout with one coat of wood-fibre plaster. We have found that plaster is more cleanly and sanitary, makes a warmer, cleaner house, and is at the same time cheaper than good ceiling.

There are chimneys with grates in every room except the kitchen, which is provided with a brick flue. The town is cut up into blocks by regularly laid out streets, each house is fenced separately with a neat picket fence in front, and the back yard has either a board or woven wire fence, and there are alleys through center of blocks in rear of lots for convenience in removing refuse, delivering coal, etc.

Water is piped to the back yard of every house from a dam built across a small mountain stream and impounding about one-half million gallons of water suitable for all domestic uses. Electric lights are furnished at the rate of 25c. per room per month, the tenant supplying the lamps after the initial installation. The houses are painted and trimmed in different colors and are of different designs, the idea being to give the appearance of a village where the individual dwellers are owners and have expressed their different ideas in building and painting.

All Yards Must Be Kept Clean

We insist that all tenants keep their yards clean, and we haul away all trash and refuse and furnish lime for the closets, which, by the way, are the ordinary outside type as we have no general sewage system—a vault is dug in the ground, cased with lumber, and the closet set over this and filled around with earth to exclude light and flies.

Under the plan followed by all mines our employees contribute a fixed sum toward a medical fund, which, is used to pay our physician a fixed salary and to pay for all drugs; this also provides a visiting nurse, an experienced trained graduate nurse who visits the homes, attends the sick and instructs the mothers in the care of their babies and helps the physician in operations or accidents.

We have three churches, one for the colored population, also one for the catholics, and another for the use of all protestant denominations. The company does not support these churches so far as pastors or visiting preachers are concerned, but does provide the buildings, furnish same, and gives free electric light. The protestant church is supported financially by a league organized for that purpose, and a regular Sunday school is carried on by all the denominations together and is self supporting.

The School System

In order to give our people a full term school we tax our men $1 for families with children of school age, 50c. for those children under school age or none, and 25c. for single men. This charge is monthly and when added to the public funds enables us to have a good school the full term, and we have three teachers and an enrollment of about 140 pupils. In this case we are acting on the idea of enlisting the employees' interest and aid and insuring the attendance of the children through their contributions.

Realizing that amusement is a necessity, it was planned to erect our amusement hall, but through the efforts and solicitations of the State Y. M. C. A. Secretary, this was abandoned and a Y. M. C. A. building erected and equipped at a total cost of about $15,000. This building is steam heated, electrically lighted, and is equipped with tub baths, shower baths, hot and cold water, lavatories, closets, etc. It contains three pool tables, one table for either pool or billiards, a double bowling alley and a moving picture machine. Shows are given three times a week for which a charge is made and on Sunday afternoon a free show of appropriate pictures is given. A handsome soda fountain is in operation, cigars, candies, etc., are sold. A neat barber shop is included in the equipment and is kept busy. The moving picture hall is used for a number of purposes as well as shows.

The Y. M. C. A. Is Self-Supporting

The Company contributes $100 per month to the operation of the Y. M. C. A., but its accounts show that the Association is paying all expenses and a little more, not including the $100 donation, though its object is not to make money, but to afford a place for harmless amusement for our men under the supervision of a regular Y. M. C. A. Secretary and to reduce drinking and rowdyism. This plan certainly adds something to life in isolated places such as most mining camps are.

Now gentlemen, all this is not done for profit. Neither is it done in order that we may say: "I am more righteous than thou," but because the Company takes a personal interest in the welfare of its employees individually and collectively and believes that it is good business policy to get in close touch with the employee, give him comfortable quarters, living wages, and show him that we realize and know he is a human being and not merely a machine performing so many hours' labor.

We intend to build a Y. M. C. A. for our colored population also, and it is hoped that it will have an influence for good among them, and tend to reduce drunkenness, gambling, etc.

We have also planned to build a miners' wash house but have not yet reached the point of actual construction; a small park to be used as a general recreation ground is under consideration. We have now under construction a hotel to be steam heated, electrically lighted

*General superintendent, Wisconsin Steel Co., Benham, Ky.
Note—Abstract of paper read before Kentucky Mining Institute, May 17, 1913.

and equipped with modern comforts in the way of hot and cold water, baths, etc.

Industrial Accident Insurance

The Company has an Industrial Accident Department which provides the payment of one-half wages for not more than two years on account of accident. This plan also provides for three years' wages in case of death from accident and a specific amount for other serious accidents, such as loss of eye, loss of foot, etc.

All the benefits provided by this plan and all expenses of its administration are paid by the Company, except one-half of the disability benefits during the first 30 days, which is paid out of a fund to which the employee contributes the nominal sum of from six to ten cents per month according to his wages.

Since the inauguration of this plan by the International Harvester Company, of which the Wisconsin Steel Company is a constituent part, several states have enacted compensation laws, and in the states of Illinois and Wisconsin, where such laws have been enacted and where the Harvester Company has industrial plants, the Company has filed its acceptance of these laws and is now operating under same.

I think I have said enough of Benham, but in closing I would like to get before this body a statement concerning this workingmen's compensation legislation, which is now attracting so much attention.

Compensation Laws Promote Harmony

The experience of our Company has demonstrated that operation under carefully prepared Compensation Laws has a decided tendency to promote more harmonious relations between the employer and the employee, reduce personal injury litigation to a minimum, and increase efficiency to a noticeable extent, as one indirect effect of compensating for all accidents is an increased effort on the part of employers to reduce accidents. These advantages are, of course, aside from the distress and suffering of the injured employee of the dependants of those who are fatally injured, which are to some extent relieved by the compensation, including necessary medical, surgical and hospital service provided for under Compensation Laws.

The object of so called Workmen's Compensation Laws is to provide adequate and definite compensation to employees who become disabled as a result of accidental injuries received in the course of their employment, also to the dependants of employees who meet with fatal accidents while on duty. The underlying principle for legislation of this kind is that an industry should bear the burden of its industrial accidents in the same way as it bears the burden of fire insurance and replacement of machinery and equipment. This compensation should be provided regardless of who is to blame for the accident, and practically all the compensation laws abolish the usual common law defenses, namely:

1. That the employee assumed the risk of his employment.
2. That the accident was due to the negligence of a fellow servant, or
3. That the accident was due to the contributory negligence of the injured employee.

Prior to this year, fourteen states enacted Workingmen's Compensation Laws, including, Illinois, Michigan, Massachusetts, New Jersey, Ohio and Wisconsin. In addition to these laws, the legislatures of fifteen other states are considering bills providing for similar laws, a number of which have passed both houses. Among these states are Minnesota, Missouri, New York and Pennsylvania.

The Compensation Laws which have stood the tests of the highest courts and in practical operation, include several important provisions, namely:

1. Employers and employees are given the option of electing to accept or reject the provisions of the law; if rejected, the employer is not permitted to plead the common-law defenses.
2. A definite and fair schedule of compensation for certain serious injuries other than death.
3. The creation of an Industrial Commission or Industrial Accident Board to administer the law and to settle all disputes.
4. Payment of compensation to be assured by requiring the employer to furnish evidence of his financial ability to meet the obligations of the law, or on the other hand to require the employer to insure his liability in some mutual or other insurance company authorized to do business in the state.

Favorable Aspect of Such Laws

With a law of this kind you as operators would know that you would have to pay in case of certain accidents, no lawsuits to defend, no liability insurance to carry and at the same time the welfare, or humanitarian idea, if you will, is there just the same because the injured party would get his benefits and in case of death of husband and father the wife and children would get their benefits, without litigation and long delay, but promptly and at the time when it is most needed and will be of greatest benefit; further it will deprive the so called ambulance chaser, both legal and medical, of his job and his parasitic livelihood.

I also wish to call the attention of the operators present to our plan of safety committees. We have a committee of three men on each entry who serve without pay and whose duties are to observe any and all things which may be dangerous, contrary to the rules of the company or the mining laws of the state. These committees are provided with suitable badges and these are worn all the time. Each committee of three men is changed by retiring one man every month and putting in a new man. We feel that in this way we can ultimately interest all our men in preventing accidents.

The Coal Deposits of Holland

A coal seam 6 ft. 3 in. thick has been discovered at the Beringer Veld, near Helden (Limburg), at a depth of 3280 ft. Boring operations are now in progress near Mill and Aploo (Limburg) and in the Zeeland province, and further discoveries are expected shortly.

At present the Dutch coal basin covers an area of 205.8 square miles, including 85.5 square miles in southern Limburg, and 53.2 square miles in the Peel. In addition to this there are 63.9 square miles of coal, which is too deep to be worked. Recent discoveries have been made in the Overyssel province, under an important bed of salt. In the eastern part of this province it is estimated that the coal area, consisting mainly of gas coal, extends over 7.6 square miles.

Thanks to the reduced railway tariffs and to the low rates of freight by the Rhine, German coal practically commands the home market. The total coal consumption by the Dutch industries varies between 10 and 12 million tons annually.

WHO'S WHO—IN COAL MINING

There are few instances in which the careers of ambitious hard-working men of limited means and education stand out as strongly for the uplift of their fellow workers as does that of John Mitchell. The plain unvarnished tale of his forty odd years of life is an inspiration to loyalty and devotion to a noble cause.

John Mitchell was born, of Irish parentage, in Braidwood, Ill., Feb. 4, 1870. He was left an orphan at an early age, and when ten years old went to work on a farm; at thirteen he entered the mines at Braidwood, and from that time until his twenty-sixth year he was employed in the coal mines of Illinois and in those of several of the Western states, which his desire to see something of the world led him to visit. In 1892, Mr. Mitchell returned to Illinois and was married to Miss Catherine O'Rourke, of Spring Valley.

JOHN MITCHELL

As early as 1885, he had joined a Local Assembly of the Knights of Labor, and from that time on his entire sympathies were enlisted in behalf of organized labor. John Mitchell's education, in so far as it can be measured by actual school attendance, was meager; he read with interest, however, many of the standard works on sociological questions, and by study at night endeavored to overcome the handicap which his lack of opportunities produced. He became president of the Local Assembly of the Knights of Labor; and upon the formation, in 1890, of the organization known as the United Mine Workers of America, he identified himself with that body.

Mr. Mitchell was, successively, secretary-treasurer of the Northern Illinois subdistrict of the United Mine Workers of America; member of the legislative committee of the Illinois miners' organization, member of the state executive board of that organization, and finally was appointed national organizer for the United Mine Workers of America. In 1898, he was elected national vice-president, and that same year, upon the resignation of the president of that organization, he was appointed acting president, being later elected to that position, in 1899. He was unanimously reëlected each year until 1908 when, on account of seriously impaired health, he declined to again become a candidate for the office. Mr. Mitchell's first official connection with the American Federation of Labor was in 1898, when he was elected fourth vice-president; he was unanimously reëlected to that position the following year, and in 1900 was elected second vice-president, to which position he has been reëlected each year since that time.

When Mr. Mitchell was made president of the United Mine Workers of America, that organization consisted of 43,000 members; and when he retired from the presidency, it had a membership of more than 300,000 mine workers. Aside from its enormous increase in membership, the achievements of the organization regarded by Mr. Mitchell as of the greatest moment are the great advance secured by joint conference with the coal operators, in 1900, when wages of bituminous-mine workers were increased 21 per cent.; the increase of 24 per cent. in the wages of the anthracite-mine workers, secured as a result of the successful strikes of 1900 and 1902; the establishment of the eight-hour workday in central and western Pennsylvania, Ohio, Indiana, Illinois, Michigan, Iowa, Kentucky, Alabama, Missouri, Kansas, Arkansas, Oklahoma and portions of Tennessee and West Virginia.

At present Mr. Mitchell is a member of various nonlabor organizations for the study of social and industrial conditions and for their betterment, namely, the National Child Labor Committee; the American Academy of Political and Social Science; and the American Association for Labor Legislation. He was a member of the New York Commission on Workmen's Compensation, and is the Trustee representing Labor on the Nobel Peace Prize Fund—the Foundation for the Promotion of Industrial Peace, which Theodore Roosevelt gave to be devoted to the promotion of industrial peace.

In the summer of 1908, Mr. Mitchell was strongly urged to become the democratic candidate for governor of Illinois, as well as to be a candidate on the same ticket for vice-president of the United States. Politics has never attracted Mr. Mitchell, however, and he declined, in both of these instances, to become a candidate. He then moved to New York, and became actively identified with the National Civic Federation, as Chairman of the Trade Agreement Department of that organization. Mr. Mitchell terminated his connection with the National

Civic Federation in March, 1911, because of an unfounded prejudice of the United Mine Workers organization in respect to the work undertaken by the National Civic Federation; thereby proving his great loyalty to the rank and file of the order with which he was still identified. Mr. Mitchell has maintained his membership in the United Mine Workers of America, and has never lost his keen interest in the mining industry, in its affairs, and the men engaged in it, whether as miners, operators or otherwise. For the past two years, Mr. Mitchell has been on the lecture platform; he has spoken in practically all the large cities of the country, and in a large number of the smaller cities, and has addressed many Chautauqua assemblies.

How Best to Handle the Dry or Dusty Mine

By David Victor*

I believe with Frank Haas, consulting engineer of the Consolidation Coal Co., that an explosion may be largely propagated by the gas distilled from the coal in the ribs of the mine during an explosion. Moreover, seeing that it is impossible to get the large quantity of air necessary for combustion in immediate contact with the coal, I feel confident that the explosion is not a true combustion of the coal dust but of the gas distilled from the coal when it is heated.

It is easy to show, without taking any extreme figures, that it is not possible to make a mine free of dry dust by the use of water cars or sprays from water pipes even if these devices are competent to wet dust and not merely create pools of standing water, surrounded by undampened coal powder.

Suppose a mine circulates 100,000 cu.ft. of air per minute and that the intake current shows a dry-bulb temperature of 32 deg. F. and a wet-bulb reading of 29 deg. F.; this shows that the moisture content is only 69 per cent. of capacity. The space occupied by the intake air passing into the mine every minute holds 2.496 gallons.

When the air leaves the mine we will suppose that the wet and dry bulb both read 60 deg. F. This shows that saturation has been reached. The 100,000 cu.ft. of space contains 9.813 gal. of water and the water removed from the mine must be 9.813 — 2.496 = 7.347 gal. per min. = 10,579 gal. per day.

Boilers for Moistening Air

The Consolidation Coal Co. is using exhaust steam from the fan engine and other engines near the drift mouth. Where this is not sufficient, live steam is taken from the boilers, and in a few cases boiler plants are being installed solely to complete the humidification of the air. Every operator should provide each of his foremen with a thermometer, barometer, psychrometer, anemometer and water gage, and see that he understands how to use them.

I believe a charge limit of 2.5 lb. should be fixed for blasting powder and of permissibles no more should be used than will produce a result equal to that of 2.5 lb. of black powder. When the coal is too thick to be broken with the prescribed charge, it should be shot in two benches, the lower bench being shot and loaded out before the holes in upper bench are fired.

All heavy rock shooting or work requiring dynamite should be done when the miners are out of the mine and when only enough men are underground to do work of that kind.

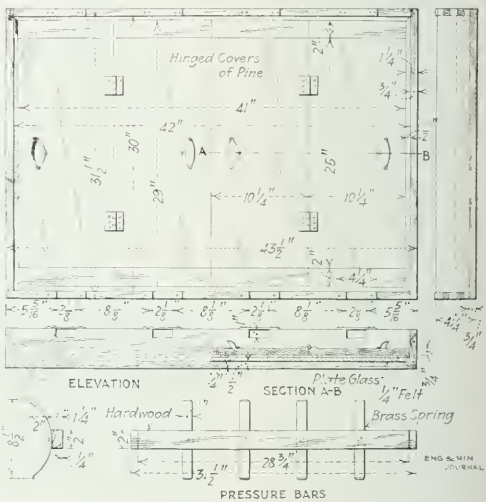
*Chief mine inspector Consolidation Coal Co., Fairmont, W. Va.

Abstract of paper read at meeting of Kentucky Mining Institute, Kentucky State University, Lexington, Ky., May 16 and 17

Blueprint Frame

The accompanying illustration is a working drawing of a blueprint frame for prints up to 29x41 in. in size. "This is a standard type of commercial frame," says the *Engineering and Mining Journal*, of May 24, "but circumstances may arise where it becomes necessary or desirable to make such a frame at the mine."

The most important and expensive single item entering into the construction is the plate glass. This is



Working Drawing of Standard Blueprinting Frame

usually of a gage approximating ¼ in., but should be heavier rather than lighter for a frame of this size. The frame proper should preferably be made of hard wood, which should be as thoroughly seasoned as possible. If even a small amount of warping takes place, the glass will be cracked. The same consideration makes it imperative to protect the wood from the absorption of moisture, which is also capable of distorting the frame and breaking the glass.

To avoid accident and save time, it is advisable to have large frames mounted so as to run either on tracks or on a floor and to revolve upon a horizontal axis, and if possible, upon a vertical one, thus obtaining the full value of the sun's light at any time. Such a mounting can usually be constructed out of scrap iron or a good carpenter can make one of wood. A small unmounted frame, similar to the one here illustrated, will, however, be found extremely convenient for handling small tracings.

EDITORIALS

A Generous Public

Sometime ago we read with some surprise that Congress had on the advice of the director of the Bureau of Mines voted Mrs. Cora K. Evans $1320 compensation for the loss of her husband who died performing valiant service for the country in the mines of the Price-Pancoast Coal Co. where, with other members of the Bureau of Mines, he had gone to rescue the unfortunates who were trapped in that mine.

How Congress expects the rescue men of the Bureau to disregard their lives, the happiness of their wives and families and plunge into places of extreme danger with with such a paltry compensation as a reward for heroism in case of death, we cannot tell. Congress and the people are alike niggards when the private purse is concerned, and it is little creditable that the widow had to wait two years for a moiety or less of her just claim.

We are not surprised seeing that the public will not have to pay the bill that the people of Pennsylvania are arranging that wives like Mrs. Evans shall be compensated with $1904 if their husbands die in the coal mines without any of the accompaniments of heroism or that in the state of Washington a compensation of $20 for life has been awarded in a recent act, the limit being placed at $1000.

We do not wonder seeing the subtle distinction between "ours and yours" which the people are making, that the Bureau of Mines which pays compensations of $1320 reckons each life lost as worth $5000. We do indeed somewhat question its estimate of the annual death loss especially in the case of single men.

Most men have so regulated their affairs, that when they die no anticipated gain is lost to the state. They have spent all they made and if they continue to live the outcome will be the same; their consumption and their production will balance so that if they are single the world is hardly the loser when the passing bell is tolled as far, at least, as things of sense are concerned.

We turn with pleasure from the unkind views of the public taken hitherto in this editorial to view the generosity of those same people in gently emptying the pockets of the cruel operator when an accident occurs. We note that the St. Paul Coal Co. of Chicago wound up the last claim against it for $6900. This was not paid without reason. The company knew it was safer to pay Andrino Muzzarelli than to contest the suit. The Cherry mine disaster had already cost that corporation $500,000 for the 256 miners who lost their lives—far more being paid to the wives of men who accepted an ordinary risk than the nation paid to appease the sorrows and remove the want of the widow of a hero who had gone bravely to his duty where death seemed certain.

We would not shame the people by holding up before them a trust—above all the United States Corporation and its subsidiary coal companies. But the temptation is too strong. The wife of a common miner, not a hero, but a woman married to just a plain coal hewer or loader, fresh perhaps from a land where wages are far lower, would get 18 months pay or one half more than Mrs. Cora Evans received and in addition funeral expenses not to exceed $100 from that industrial organization without even filing a claim. The company would not be as good to her as to some others as she had no children and her husband had not worked five years for the trust but still it would be much more liberal than the representatives of the people.

We hope we may escape a charge of *lese majesty* to our sovereigns, the electorate, if we point out that John Hays Hammond who is not even a coal magnate or expert gave $250 to Evans' widow as part of the contribution of the Pittsburgh Coal Operators Association which totaled $375.

In conclusion we may be pardoned if in a table we record the compensation to which Mrs. Evans would be entitled under the compensation acts of several of the states assuming, so as to be well within the mark, that the Bureau employees are paid for 52 "weeks" in the year.

COMPENSATION SET BY STATE LAWS

State	Compensation	State	Compensation
Arizona	$4,000	Massachusetts	$3000
California	3,960	Michigan	3000
Indiana under	10,000	Nevada	3000
Kansas not more than	3,600	New Hampshire	3000
Maryland	3,960	New Jersey	1904

Judging by recent legislation, we conclude that while it may be true that corporations have no souls, it seems generally understood that they possess pocketbooks. The people reluctantly and adequately pay their dues to the dead but in righteous indignation they are now determined that the corporations shall not be equally penurious. Of course, they are right; who is it that shall rise and condemn the common people?

Spontaneous Combustion of Coal

A careful investigation shows that in a single recent year, there were 103 cases reported in Lloyd's list of vessels with bunkers on fire, and also 24 cases of vessels with cargoes on fire. The investigators concluded that the occasional spontaneous development of heat is due to chemical changes, which iron pyrites and some carbohydrogen compounds occurring in coal undergo through the agency of atmospheric oxygen.

There is no doubt but that oxidation of pyrites is accompanied by the development of heat, which may increase to such an extent as to lead to the ignition of the coal. It is also a fact that carbon itself, in a finely divided condition, has the property of condensing within its pores large volumes of certain gases, including oxygen. Wood charcoal, for instance, will absorb from the air nine times its volume of oxygen and seven times its volume of nitrogen, which condensation of gas is attended by the development of heat. In such cases, if the heat is allowed

to accumulate, chemical action may be promoted and the carbon be heated to the igniting point.

It is certain, therefore, that the presence of water would diminish the power of coal to absorb oxygen, and, as a consequence, be antagonistic to the oxidation of the carbon of the coal, although it would accelerate the oxidation of the iron pyrites present. Another precaution in the matter of safeguarding stored coal is to have efficient surface ventilation to remove into the open air the gases rising from the coal; however, any attempt to ventilate the bulk of coal by drawing air through it would favor the production of a violently explosive mixture of gas and air.

When coal is being carried on long sea voyages, the temperature in the various portions of the cargo should be tested periodically by a thermometer and registered in the ship's log. In order to guard against an explosion, free and continuous egress to the open air, independently of the hatchways, should be provided for the explosive gases by means of a system of surface ventilation which would be effective in all circumstances of weather.

Some years ago, interested parties conducted an inquiry into a casualty sustained by a sailing ship, through the spontaneous ignition of her cargo of coal and coke. They reported:

1. Artificially dried coal absorbs oxygen with great avidity.

2. Ordinary air-dry coal absorbs oxygen, though less rapidly.

3. Damp coal absorbs oxygen less rapidly, and when piled in heaps does not rise in temperature any faster than dry coal.

4. Thoroughly wet coal is practically protected against the action of the air insofar as the production of spontaneous heating is concerned.

One authority has said that "the heat given off by the oxidation of pyrites is only one-fourth of that evolved by the oxidation of the same weight of coal." Moreover, the oxidation of coal goes on more rapidly than that of pyrites so that it would be expected that the cause of heating in any particular case is the oxidation of the coal rather than that of the pyrites.

It is significant that both Richter and Fayol established the fact that dry coal oxidizes more readily than wet coal, whereas the reverse is the case with pyrites, and yet numerous cases of spontaneous heating occur with dry coal. For all practical purposes, therefore, pyrites is not an agent in the spontaneous heating of coal. In ship's cargoes of large coal the only danger is in the heap of small coal under the hatchways.

The explanation of this is that the rise of temperature in a heap depends upon two factors: The heat must, in the first place, be generated, and in the second, it must not be allowed to escape. Amongst large coal, with much interstitial space, the circulation will be too great to allow of overheating.

If there are any parts of bunkers in which, owing to the proximity of boilers, uptakes, or recesses through which steam pipes, etc., are carried, there is likely to be a higher normal temperature, these parts should, if possible, be stowed with large lump coal and should be worked out as soon as possible. The shoots should be arranged not to deliver small coal into these places. Small coal which accumulates under shoots, etc., should be worked out as soon as possible and not left till the last.

If any coal is left in a bunker when a fresh charge has to be taken in, it should be trimmed into a position to insure its being used on the next voyage. It cannot be too strongly impressed upon those responsible that danger of overheating and spontaneous combustion increases with the length of time the coal remains in a ship.

There is no risk entailed by the coal being wet when put on board. In fact, in cases where coal is known to be of a fiery nature, it is of advantage for the small coal to be dampened when charging the bunkers.

In conclusion, it is well to remember that although some kinds of coal have proved to be more liable to spontaneous heating and combustion than others, it should be realized that all coal, even anthracite, is liable to these occurrences.

The Uninstructed Foreigner

We shall not repeat the time-honored story that the foreigner who now enters our mines is an agricultural laborer and not a miner, and that he cannot be taught by the foreman because he cannot be instructed by the latter in his own language. We leave these banalities of the office and the institute, and ask instead what can be done about it.

Much can be effected we think by the Bureau of Mines. An opportunity is given that organization, it seems, to put the industry still further in its debt for coöperation and assistance. We believe it could engage men who have a good working knowledge of foreign tongues to travel from mine to mine with vitagraphs, stereopticans and models showing how mining work should be performed. Any one who had attended the course could be given a certificate. Such a man would not necessarily be made thereby a miner, but he would be better fitted to be so regarded than a man who had not received such instruction.

Some of these teachers would, of course, talk English, and these could hold day sessions in the schools educating the scholars in the work of safe mining wherever the sons and daughters of miners were to be found.

At the several stations of the bureau, teachers could be kept who would teach elementary mining to all comers. In time, it would probably come about that no man would be allowed by state law to enter the mines without such training and certificates. Moreover, when the compensation law gets fully into operation, the mine owner himself may demand "papers" before admitting the raw product of European farms to the imminent dangers of his mine. It is a wonder that some of the larger companies have not taken that stand already. It would be a hardship to the miner, but its very requirement would make him realize the importance of taking care of his safety.

We are aware that such learning will be condemned as being unequal to that afforded by experience, but to learn by maiming is expensive, and training which results in death is unavailable to the person who suffers it. So it may be conceded that perhaps the inferior training of a school is more to be sought than the rougher education of the mine.

The presence of blackdamp, a mixture of carbon dioxide and nitrogen, will often neutralize the effect of firedamp on a flame. Analyses of mine gas, which gave only a faint cap when tested with a safety lamp, have shown 4 per cent. of methane mixed with blackdamp.

SOCIOLOGICAL DEPARTMENT

Concrete Houses at Lackawanna Mine

SYNOPSIS—The Coal Department of the Delaware, Lackawanna and Western R.R. Co. has constructed twenty double houses of poured concrete for its miners. These houses are perfectly fireproof, the floors, roof and staircases being of concrete. They have 6 rooms and rent at $8 per month.

At Nanticoke, Penn., the Delaware, Lackawanna and Western R.R. Co.'s Coal Department has built twenty concrete double houses by a new and interesting process. It has long been anticipated that before many years, houses would be built by pouring concrete into forms, and perhaps Thomas A. Edison was the first person of record to make this suggestion.

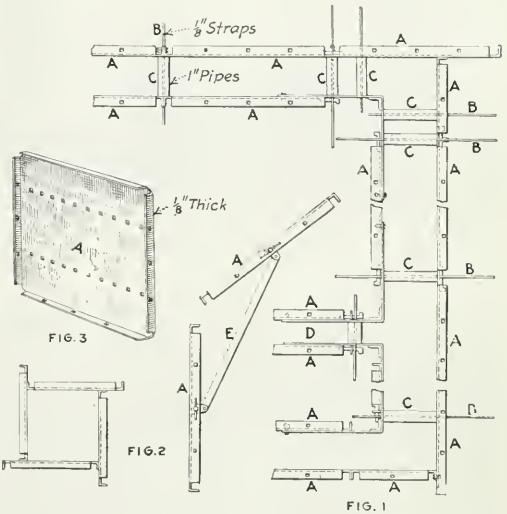
The Edison Plan

That inventor estimated that an equipment of heavy cast-iron molds would be necessary, costing $30,000 for each design. His suggestion could hardly have commended itself to those who are interested in the improvement of dwellings, because a distressing uniformity would inevitably have resulted, and the designs would in many cases have been entirely unsuited for the tenants of the houses thus built. Moreover, so heavy would the molds have been that it is probable that it would not have been possible to have shipped them from place to place economically where only a few buildings were to be constructed.

Contrast this heavy expenditure for molds, the inflexibility of design and the weight of material to be transported, with the simplicity, tightness and portability of the Morrill molds which are illustrated in this article.

Steel-Plate Molds

The plates used are 2 ft. square and are made of ¼-in. cold-rolled steel, all four edges of these plates being slightly flanged as shown. Two horizontal rows of square holes are punched in each plate, and three square holes are punched in each of the small flanges. These plates are arranged around the building with their flat sides back to back and set at a distance equal to the width of the wall which it is desired to construct.



Figs. 1, 2 and 3. Showing How Parts Are Assembled

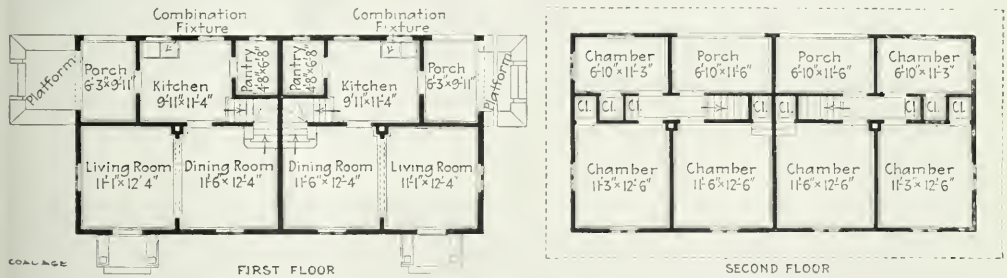


Fig. 4. Plans of the Double Six-Room Dwellings at Concrete City

In order to maintain a uniform width of wall, straps of ⅛-in. cold-rolled steel punctured with square holes are passed through the opposing belts of plates and through a pipe distance piece. The straps are secured in places by wedge pins which are lightly driven into position. Thus the walls are prevented by the pins and straps from becoming too large, and by the pipes provision is made that they are not less than the required width. In Fig. 1 is shown the method of constructing the outside wall of a house. Fig. 2 shows a plan of the forms arranged for a post, and a side view of a plate being lifted from the inferior to the superior belt. Fig. 3

shows a unit plate. The binding strips are marked *B* and the pipes for regulating the width of the wall *C*. The space *D* forms, when filled with concrete, a narrow partition wall.

How the Sizes of the Houses Can Be Varied

It will be seen that it is possible, when turning an angle, to connect the plates to one another at any point desired. Consequently, it is not necessary that the dimensions of the building shall be any even multiple of the width of the plates. For all kinds of houses the same molds will do, the only variation consisting in the variant use of the same plates. As will be seen in the figure which shows the plates in detail, they can be used for the construction of a small concrete post, as well as for molding the lines of the building proper.

Where several houses have to be constructed at one time, it is usual not to use more than two belts of plates around the building. The lower belt serves to protect the concrete which has already been placed, and the upper is used for the molding of the new concrete which is poured in. Where, however, only one house is to be built and consequently a delay of this kind would be expensive, sufficient plates are obtained so that the building can be constructed wholly in one day. Such a building needs to be covered, as shown, with plates from the ground to the roof.

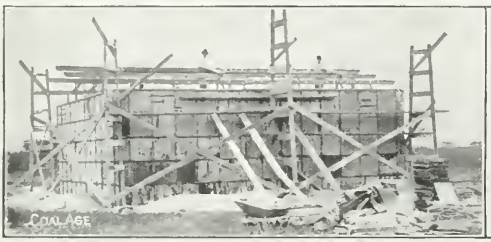

Fig. 5. Plan Adopted Where Rapid Construction Is Desired

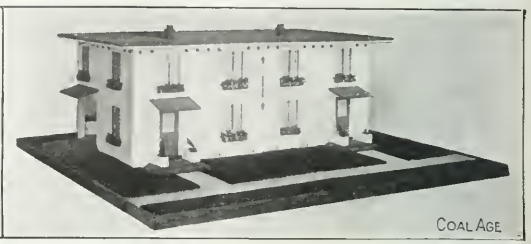

Fig. 6. House Model Showing Cheerful Yet Simple Effect

Fig. 7. Raising a Belt. Note Window and Door Frames

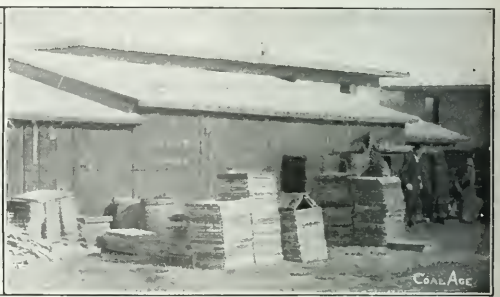

Fig. 8. Piling Frames for Trans-Shipment

Fig 9. Pouring Concrete Into the Forms

Fig. 10. The Architect's Building Scheme

A most important feature in the method of construction is that the belts of plates which surround the building do not need to be entirely separated by the withdrawing of all connecting wedge pins when it is purposed to raise a belt to a higher elevation. Each series of belts is connected with the belt below it by cross-arms connected to the square perforations in the flanges of the plates.

Thus, as will be seen in one of the illustrations, several

of the plates in a single belt can be lifted with ease at one time. It will be noted that the inner belt in this particular illustration has already been lifted into position, and the outer belt is being placed ready for the pouring of the mixture, which will raise the wall another stage.

The arrangement for openings is extremely simple. As soon as the mixture is at the right level for the casings to be inserted they are placed in position and the filling with concrete continues as before.

Provisions for Warmth and Dryness

In most climates it is not necessary to leave any air space in the wall. It is well, however, to make the concrete as porous as possible. In this way the interstitial spaces serve to make the concrete a good nonconducting material. Such a wall would, however, be extremely damp and cold unless coated with a good coat of paint inside and out. To this end it is the practice of the patentees of this system of building to use two coats of paint, one a primer which will not be affected by the alkali in the cement, and the other coat, one which will improve the appearance of the building.

Resistance to Fire

There are many advantages in connection with these houses. They are entirely incombustible except insofar as the window frames, doors and any moldings which may be inserted are concerned. A fire would not in any way destroy the building, though, of course, as a result, it would be somewhat disfigured by smoke. In fact, in a suburb near Washington, it has been the habit of a concern which is engaged in exploiting a piece of available suburban land, to start a fire in a house of this construction, having previously announced that this experiment would be made and thus gathered a crowd to attest the fire resistance of the structure. Another advantage is that the house is entirely sanitary, and should an undesirable tenant occupy the building, it is extremely easy to clean it out with a water hose when vacated.

Income Derivable

Accustomed as we are to wooden floors in all our dwellings, it is perhaps necessary to point out that some of the finest hotels in New York City have concrete floors in their lobbies, which are covered with rugs.

Fig. 11. Living and Dining Rooms

Fig. 12. Kitchen and Pantry

In order to insure further the dryness of the structure, the mixture of cement and cinders is made nonabsorbent by the use of hydraulic lime, the proportions of the ingredients being as follows: One-half part of lime; one part of cement; six or seven parts of cinders. In order to prevent water from rising from the foundations upward into the building, the lowest course is mixed with crude oil.

The Concreting Train

It will be seen that the houses are arranged around a park or playground which measures 300x600 ft. A railroad track was laid around the entire group, and a mixing plant was mounted upon a flat car with an elevator for hoisting concrete attached. Cars of sand, cement and cinders were attached to the mixing car, and the concrete was hoisted from the mixer to an elevated hopper, from which spouts conducted the mixture into steel forms at various parts of the building. As soon as the concrete was placed so as to complete one belt around the building, then the mixing train was moved to the next house and a belt of concrete was placed there.

Each side of the houses which the Delaware, Lackawanna & Western R.R. have built, contains 7 rooms including the pantry, and rents at $8 a month, and we are informed by the company that there is no difficulty in filling these dwellings. The cost of construction has been from $1800 to $2000 for each side of the house.

The profits, therefore, of the investment will probably not exceed 5 per cent. under the most favorable circumstances. It certainly would not pay in direct material dividends to build such houses, if it were not for the fact that they need no repairs and are not subject to fire losses. In order to meet the objections raised to the concrete floors, wooden strips were laid so that carpets could be attached to them. This has removed all difficulties.

It is worth noting that a combination fixture is placed in the kitchen. This serves the duplicate duty of a wash tub and sink.

The introduction of these houses is due to desire of E. E. Loomis, President of the Delaware, Lackawanna and Western R.R., to furnish model buildings for the workers of the coal department. The intention is also

to arrange, not only for uptodate dwellings, but for model surroundings. Much loss of life has occurred from non-fireproof buildings in the mines, but it may be safely said that still more lives are being lost annually by the lack of fireproof buildings. This loss will be entirely removed when the walls, floors, partitions, roofs and stairways of dwellings are constructed of concrete as are those in these buildings.

The patentees of this system of construction are Reed & Morrill, Inc., of 179 Joralemon St., Brooklyn, N. Y. They are providing the molds for several workingmen's dwellings, which are about to be erected near Budapest, Hungary.

We are indebted to them for some of the illustrations to this article but also to C. E. Tobey, Vice-President and General Manager of the D., L. & W. R.R., who kindly had several photographs taken for this issue of COAL AGE. That company has long been most energetic in promoting safety in mines and is about to be equally active in devising new plans for promoting the health and comfort of its employees above ground.

Sincerity and Safety

By THOMAS MOSES*

Before the motto "Safety First" can have any real meaning, the employer must sincerely and honestly believe in it. If he, as many do, paints it on his property in big signs, places it on his stationery in bright letters, speaks of it in public gatherings, and does nothing more, the words are meaningless, and rather oppose than advance the cause which he should desire to be aiding by their use, but if he sincerely believes in the maxim, makes it his religion, and under no circumstances deviates from its meaning, he will obtain more profit from its preaching than from any other device.

It is important that the employees realize the sincerity of the superintendent in promoting safety. I am informed that only the old men in the industry can recall the times when profits could be made. But when markets are good, and there *is* a profit in the coal business, if you go into your mine and discover some broken bars, loose rock, an accumulation of gas, bad tracks, or any one of the numerous dangers to which a coal mine is heir, it seems a hardship to be obliged to stop operations until the dangerous condition is removed.

THE ADVANTAGES OF THE COMPENSATION LAW

When an accident happens the conditions must be studied with an open mind free from selfish desires. You must find out exactly what caused it, and then make sure that similar conditions are removed from all parts of your mine, if indeed such a provision is possible.

No man can urge safety on his men, if he speeds up the fan or sends special men into the mine to shut doors or to operate his regulators so as the deceive the mine inspector when he makes his visits of inspection. If you would discipline your men, you must first of all discipline yourself. You, yourself, must obey without question the instructions of the mine inspector.

The compensation law is doing a great deal in Illinois to reduce accidents. When the operator knows that he must pay for every accident, he is indisposed to misrepresent the causes of its occurrence in order to make a good defence against liability, and the injured man is equally free from a desire to misrepresent the manner in which he was injured.

THE COST OF SAFETY

It is hard to discover just how much it takes to promote safety in a mine. All the men who are employed to make inspections, serve not only to make the mine safe, but also to make its operation efficient. Good tracks and safe timbering are needed as much to maintain the output of a mine and to save repairs as to protect the miner. Safety and efficiency run so completely hand in hand that it is impossible to classify duties exclusively under either of those heads.

In the nine years previous to the inauguration of "Safety First" as a motto at the mines of the Bunsen Coal Co., there was one fatal accident to every 135,827 tons of coal mined. In the best year of those nine years, there was one fatal accident to every 188,387 tons of coal. During that year very little coal was mined, less than one quarter of the amount now produced.

During the first year of the "Safety First" campaign, one fatal accident occurred to each 132,452 tons of coal mined. During the second year, we had one fatal accident to every 329,474 tons of coal, showing an increase of 192,022 tons of coal mined per fatal accident.

THE "SAFETY FIRST" CAMPAIGN DID NOT INCREASE COSTS

Notwithstanding the fact that an increase of 10.8 per cent. in wages took place during this time, the coal cost less per ton for labor at these mines than it did the year previous to the inauguration of the new slogan. The cost to this company for safety during the period it has been operated under the compensation law of Illinois has been approximately 1½c. per ton, which charge covers all money spent in first-aid instruction to employees, ambulance and hospital service to all who need it, medicine and doctors' services, and the salaries of persons in charge of the compensation department and compensation for all injuries received.

Mine Rescue Work in the State of Washington

By D. C. BOTTING*

Up to Jan. 1 1911, 46 men had taken helmet training in the state of Washington and received certificates of competency. This number has been considerably increased for we now have 304 men trained as follows: In the use of the helmet only, 64, in both helmet and first-aid work, 146, in first-aid work only, 94. The Bureau of Mines issues no certificates for first aid only but men who take this training are qualified to receive a certificate from the Industrial Branch of the American Red Cross Society.

It is the intention of the Department of Mines to arrange for the organization of Red Cross Societies in as many of the mining towns as possible, during this year and we also hope to have sufficient men trained in both helmet and first-aid work, in every coal-mine town in the State, to enable us at all times to make up a team of at least 6 men who could render efficient service in case of need.

*General superintendent, Bunsen Coal Co., Westville, Ill. Abstract of paper entitled "Safety First from the Standpoint of the Operator," read at a mining conference, State University of Illinois, Urbana, Ill., May 9, at the dedication of the Transportation Building and the Locomotive and Mining Laboratories.

*Chief mine inspector, Seattle, Wash.

DISCUSSION BY READERS

Conditions in the Cincinnati Mine

The recent disaster in the Cincinnati mine calls to mind some recollections in my own experience in the mines in that vicinity, where I worked nearly forty years ago. The mining methods at that time were generally crude; butt entries, in many instances, were driven single and draft facilities (ventilation) were of a low order. Fans were almost an unknown feature of the equipment of the mines located along the west bank of the Monongahela River, and small furnaces and natural draft were almost the sole dependencies for ventilation. There was gas in the mines, but the quantity was small, and the air current, though feeble, was sufficient to dilute the gas below the danger point. Occasionally, explosions occurred, but they were of comparatively little force and mostly local.

With the inauguration of the inspection service in Western Pennsylvania, a general and steady improvement in mining and ventilating methods began; and, apparently, from the mine inspectors' reports, the Cincinnati mine has kept abreast with the progressive movement. The report for 1907 shows 186 men employed in the mine, which is about the same number that was in the mine on the day of the recent explosion. A ventilating fan produced a current of 42,000 cu.ft. of air per minute against a 2-in. water gage. The report states "The ventilation has been improved and is well conducted to the face of the workings." The report adds that the "8-ft. Stine fan driven by a 40-hp motor was installed to be used temporarily, until a shaft could be put down near the face of the workings, when it is the intention of the management to place a more powerful ventilator at the shaft." The report of 1911 shows that these improvements were made, and that the mine at that time was ventilated by an electrically driven Capell fan, which, running at 150 r.p.m., produced 129,000 cu.ft. of air against a 3-in. water gage.

In my opinion, it is worthy of note that under the primitive methods of working and ventilating this mine and the subsequent gradually improved methods no explosions involving great loss of life occurred; but, after the draft facilities had been improved to an unusual extent, producing a greater air volume than ever before in the history of the mine and when the mine appeared to be better and safer in every way, a great disaster has occurred. The situation suggests the question: Did the effects of these commendable and desirable improvements contribute, in any manner, to the occurrence and magnitude of the explosion? I believe they did.

Some time since, experiments were made by T. E. Richards, Aberdare, South Wales, to ascertain what effect, if any, the speed of the ventilating fan had upon the flow of gas from more or less constant feeders in the mine. While the experiment showed that the effect of reducing the speed of the ventilator on a number of such feeders was to almost invariably lower the level of the igniting line of the gas; there were, however, two blowers that acted otherwise, a feature that could not be explained, but was thought to be the result of opposing factors.

In a recent paper on Analysis of Mine Air, Mr. J. W. Hutchinson states that the slowing down or stopping of the fan when exhausting resulted in an increase of pressure throughout the mine; and, as a result, the outflow of gas from the strata was materially checked for a time; and the fan was again started the outflow of gas increased at once, owing to the decrease of pressure caused by the action of the fan.

Now, applying these facts to the ventilation of the Cincinnati mine, the water gage produced by the old fan was 2 in., which the new fan increased to 3 in. The increased depression in the mine favored a larger emission of gas from the strata.

I have repeatedly called attention to the fact that the most disastrous explosions have occurred in mines with ventilating arrangements of a superior order, where large air currents were produced by powerful fans. I believe that explosions of great force and magnitude are of much less frequent occurrence in mines having less facilities for producing draft. In my opinion a review of the conditions and events in the Cincinnati mine during the many years of its existence presents a striking illustration of this fact

I am impressed with the thought that the great improvements made in recent years, in the methods of mine ventilation, have created a danger that could be readily minimized or eliminated entirely, if the existence of such danger were generally appreciated and its nature better understood. I believe the danger is greater because its presence is generally unsuspected, under the improved conditions of ventilation in mines. In order that the commendable work done by mine operators and owners, who have provided more than sufficient means for producing ample and efficient ventilation in mines, may have its due reward and that these efforts to secure greater protection to health, life and property may bring, in the fullest measure, the desired beneficial results, a better understanding of the existing danger and how it may be overcome is necessary.

The alarming frequency of great explosions in well arranged mines where the ventilating facilities are far above the average, and the apparent immunity from such explosions in mines working the same seam of coal under practically identical natural conditions but having greatly inferior ventilating arrangements, in my opinion, cannot be reasonably regarded as a matter of mere chance. There must be a general and fundamental cause to account for their persistent occurrence under conditions generally considered as acting to prevent such occurrences; and it seems decidedly worth while to discover this cause, if possible.

JOHN VERNER.

Chariton, Iowa.

Danger in Rapid Firing

Some time since my attention was drawn to a statement in COAL AGE, referring to the rapid manner in which shotfirers must perform their work. In most cases, these men must fire from 150 to 300 shots a piece. They go into the mine at 3:30 and start firing, often finishing their work by 5 o'clock but seldom later than 6:30 p.m., no matter what the size of the mine may be or the number of shots to be fired. I believe this rapid work is too often the cause of local explosions, which at times result in loss of life.

If shotfirers would take into consideration the dangers to which they are subject, I believe they would, in most cases, change their method of working. Instead of doing this work in 3 or 3½ hr., if shotfirers would allow themselves a longer time, say 5 hr., to do the same work there would be less danger of trouble.

Many explosions have originated in the firing of shots in quick succession, or in the firing of two or more shots in a close working place or heading. The firing of such shots is, in many instances, absolutely unsafe and, rather than perform the work in this manner, shotfirers should make a second trip to such places.

JOHN SUTTON, Fireboss,
Wizard Mine.

West Terre Haute, Ind.

The Geyser at Equality

I note in the editorial of your paper reference to the accident to the mine of the Gallatin Coal company. I once experienced a phenomenon somewhat similar. About 1900 or 1911, No. 1 mine belonging to what was then the James W. Ellsworth & Company, Ellsworth, Penn., took fire and to put it out the mine was flooded. The fire destroyed the tipple and timbering in the shaft.

Mine No. 1 was connected with mine No. 2 by two entries, 1800 ft. in length. The average depth of each shaft was about 215 ft. The water entered at mine No. 2. Above the highest point in the mine, a bore-hole was drilled to act as a vent.

To unwater the two mines, buckets were swung in the No. 2 shaft. After the work of unwatering had been in progress a short time, a stream of water was noticed to shoot up out of the bore-hole driven for a vent. At times it would rise fully fifty feet in the air. This action continued at least two days and then gradually ceased.

My theory is that the borehole acted as a steam ejector, compressed air being the power in place of steam, the air being compressed by the water used to flood the mine. I believe the Equality outburst has a similar cause.

General Manager, Virginia-Lee Co., Inc.

St. Charles, Va.

Study Course in Coal Mining

BY J. T. BEARD

The Coal Age Pocket Book

Combining equations (1) and (4), we have

Velocity due to fall through height h.

$$v = g\sqrt{\frac{2h}{g}} = \sqrt{2gh} \qquad (5)$$

Height to produce a given velocity.

$$h = \frac{v^2}{2g} \qquad (6)$$

EXAMPLES TO ILLUSTRATE

1. What is the theoretical velocity that a freely falling body will attain in eight seconds?

Solution—$v = gt = 32.16 \times 8 = 257.28$ ft. per sec.

2. What is the theoretical velocity a freely falling body will attain and what is the time required in falling through a height of 2000 feet?

Solution—The final velocity or the theoretical velocity due to this height is

$$v = \sqrt{2gh} = \sqrt{2 \times 32.16 \times 2000} = \sqrt{128{,}640} = 358.66 \text{ ft. per sec.}$$

The time required for this fall is

$$t = \sqrt{\frac{2h}{g}} = \sqrt{\frac{2 \times 2000}{32.16}} = \sqrt{124.37} = 11.15 \text{ sec}$$

3. What height of fall is required to produce a theoretical velocity of 500 ft. per sec.?

Solution—

$$h = \frac{v^2}{2g} = \frac{500 \times 500}{2 \times 32.16} = 3886.8 \text{ ft.}$$

4. Through what height will a body fall from rest in 30 seconds?

Solution—

$$h = \frac{gt^2}{2} = \frac{32.16 \times 30 \times 30}{2} = 14{,}472 \text{ ft.}$$

Velocity Due to Any Given Height—Since a body falling under the influence of gravity attains a certain velocity and falls through a certain height, in a given time, the velocity attained is said to be due to the height through which the body has fallen. Roughly, the velocity attained by a falling body, disregarding the resistance of the air, is eight times the square root of the height from which the body falls; the body falling from rest, and the height being expressed in feet and the velocity found in feet per second. This relation is expressed by the formula

$$v = 8\sqrt{h}$$

For example, disregarding the resistance of the air, which acts to retard the fall, a leaden bullet dropped from the top of a tower 100 feet in height would strike the ground with a velocity of $8\sqrt{100} = 80$ ft. per sec.

The Coal Age Pocket Book

The following are the values of the force of gravity at sea level, for different latitudes, as determined by experiment and subsequent calculation:

By experiment,	New York,	lat. 40° 30′;	g = 32.160 ft. per sec.
	Paris,	lat. 48° 50′;	g = 32.183 ft. per sec.
	Greenwich,	lat. 51° 29′;	g = 32.191 ft. per sec.
By calculation,	Equator,	lat. 0° 00′;	g = 32.091 ft. per sec.
	Parallel 45,	lat. 45° 00′;	g = 32.173 ft. per sec.
	Poles,	lat. 90° 00′;	g = 32.255 ft. per sec.

For the purposes of general calculation, the value first given above, being the value for New York at sea level and a fairly average value, is commonly used. But where greater accuracy is desired, this value must be corrected for latitude and for elevation above sea level.

Calculation of Gravity—The calculation of the force of gravity for any latitude (L) and any elevation (h) above sea level, is based on the value determined for the 45th parallel; namely, $g = 32.173$ ft. per sec. The formula used for making this calculation is

$$g = 32.173 - 0.082 \cos 2L - 0.000003h$$

Example—Calculate the value of gravity at Mexico City, latitude 19° 26′ N.; elevation 7600 ft. above sea level.

Solution—

$$g = 32.173 - 0.082 \cos 2(19° 26') - 0.000003 \times 7600$$
$$= 32.173 - 0.082 \times 0.7786 - 0.0228 = 32.086 \text{ ft. per sec.}$$

Effect of Change in Gravity On Weight of Bodies—Since the action of gravity on bodies at or near the earth's surface gives to them weight, any change in the force of gravity produces a like change in the weight of bodies. For this reason, a body weighs slightly more in the higher latitudes at sea level than on a lofty mountain near the equator. The difference, however, is very slight, and, in the use of balances, is wholly eliminated, because both the body and the balancing weights are affected alike.

Gravitation of Bodies—All bodies free to move fall, under the influence of gravity, and are then said to "gravitate." The movement is always downward. The force of gravity acts, in this case, to create a certain velocity each second or unit of time. The same increase of velocity is imparted to each particle of mass so that if there is no resistance to the fall, a small body will drop as fast as a large body.

In a vacuum, a feather is found to fall with the same speed as a lead bullet, because there is no air present to resist the fall. Resistance decreases the velocity of fall.

Acceleration Due to Gravity—The gain per second, in the velocity of a falling body, is called the "acceleration due to gravity." It is the velocity imparted to the body by gravity, each second or each unit of time and is estimated in feet per second. In like manner any force acting on a body free to move produces acceleration. A constant force produces a constant acceleration.

INQUIRIES OF GENERAL INTEREST

Calculating Electrical Currents

The power supplied to an electric motor is 35 kw., the pressure, 250 volts; find the current in amperes; also the horsepower of the current. Kindly give the formulas for these calculations.

ELECTRICIAN.

Michel, B. C., Canada.

In electricity, the power, in watts, divided by the pressure of the current, in volts, gives the strength of the current, in amperes. Therefore, since 1 kw. = 1000 watts and 35 kw. = 35,000 watts, the strength of the current is, in this case

$$amperes = \frac{watts}{volts} = \frac{35,000}{250} = 140 \; amperes$$

Since 746 watts are equivalent to 1 hp., the power of this current is

$$horsepower = \frac{watts}{746} = \frac{35,000}{746} = 46.9, \; say, \; 47 \; hp.$$

Coal Underlying an Acre

Being interested in lignite coal land in this state, I want to learn the method of calculating the number of tons of coal underlying an acre of land. I have seen, recently, a chart published by COAL AGE, giving the weight of coal underlying an acre of land, for different thicknesses of the seam; but I think this table applies only to hard or anthracite coal and bituminous coal. Can the same table be used for lignite coal?

WILLIAM HENDERSON.

Cameron, Texas.

We reproduce in the figure below, a portion of the chart to which correspondent refers. As explained in

TABLE I - TONS OF COAL UNDER ONE ACRE OF SURFACE
Calculated for a Specific Gravity of 1.50 or 93.7 lb. per cubic foot

INCHES	LONG TONS	ONE FT.	TWO FT.	THREE FT.	FOUR FT.	FIVE FT.	SIX FT.	SEVEN FT.	EIGHT FT.	NINE FT.	TEN FT.

The top horizontal column of TABLE I, gives the thickness of coal seam up to ten feet. The extreme left-hand column shows inches. For example: to find the number of tons of coal in a 10-acre tract, where the seam has a thickness of 2 ft. 6 in. run down the 2 ft. column until opposite 6 in. and you will find 4557.46. Multiply by 10 and the result is 45,574.60 long tons

To find the weight in long tons for a coal of any specific gravity other than 1.5 it is only necessary to multiply the figures shown in these tables by the ratio of the given specific gravity to 1.50

For Example: The weight of coal underlying a 10-acre tract, when the seam is flat, 2 ft. 6 in. thick, and the specific gravity of the coal 1.30 (Bituminous) is
$\frac{1.30}{1.50} \times 45,574.6 = 39,498$ *lg. tons*

On a pitch of 60 deg. this seam would contain double this amount or practically 79,000 long tons.

Expressed in short tons, these amounts should be $\frac{2240}{2000} = 1.12$, *or say* $\frac{1}{8}$ *greater.*

COAL AGE

CHART SHOWING WEIGHT OF COAL UNDERLYING AN ACRE, FOR A LEVEL SEAM

the note accompanying this chart, the weight of coal is given in long tons, for each inch of thickness of a level seam, from 1 in. to 10 ft. 11 in. in thickness and underlying one acre of surface. The figures on the chart refer to a coal having a specific gravity of 1.5, which is the average specific gravity of anthracite coal.

The figures of this table may be made to apply to coal of any other specific gravity, by dividing the weight given in the table by 1.5 and multiplying that result by the specific gravity of the coal in question. This will give the weight of such coal in long tons per acre for a level seam, and to find the weight in short tons (2000 lb.) it is necessary to multiply by 1.12 or, say add one-eighth to the weight given in the table.

When the seam has a considerable inclination it is necessary, in order to obtain the quantity of coal underlying an acre on the surface, to divide the weight given in the table for the given thickness of seam, by the cosine of the angle of inclination. For example, a level seam of coal 5 ft. 6 in. thick contains 10,026.46 long tons of coal having a specific gravity of 1.5. If the specific gravity of the lignite coal, in question, is 1.2, the weight in short tons, of this lignite underlying an acre is

$$10,026.46 \left(\frac{1.2}{1.5} \times \frac{2240}{2000} \right) = 8983.7 \; tons$$

If this seam of lignite coal had an inclination of 26 deg. from the horizontal, it would contain

$$\frac{8983.7}{\cos 26^\circ} = \frac{8983.7}{0.89879} = say \;\; 10,000 \; tons \; per \; acre$$

When great accuracy is desired, it is always necessary to ascertain the exact average specific gravity of the coal in question, since this varies for different qualities of all grades of coal.

A Suggestive Inquiry

I want to make a suggestion that may help to save lives, and would be glad to see the same discussed in COAL AGE. The question is as follows:

Would there be any benefit derived by connecting the two shafts of a mine (upcast and downcast) by means of a heavy masonry air course built on the surface and provided with iron doors in such a manner that the air current in the fan drift could be conducted to either shaft? It frequently happens that the air shaft with which the fan is connected, is damaged in an explosion and choked with débris to such an extent as to practically incapacitate the fan, although this may not have been injured by the blast. In such a case, would not the proposed arrangement enable the ventilation to be restored in the mine more quickly and expedite the work of rescue?

GEORGE DAVIS

Shenandoah, Penn.

[We give space to this suggestion, which no doubt has some value in its relation to gaseous mines or dusty mines, liable to explosion. We shall be glad to have the question discussed further by practical mining men.

There are many questions similar to this one, asked by correspondents, from time to time, that are deserving of the most careful consideration on the part of mine officials. It often happens that what seems a good scheme is proved by the discussion of practical men to be unsafe. Hence the value of a thorough discussion.—ED.]

EXAMINATION QUESTIONS

Examination for Mine Managers, Mine Examiners and Hoisting Engineers Held at Springfield, Ill., April 14, 1913

(*Selected Questions*)

Ques.—To light a mine with 200 lamps of 16 cp. each, what amount of mechanical energy would have to be available for conversion into electricity?

Ans.—A 16-cp. lamp may be assumed to consume from 50 to 56 watts of energy. Estimating on the maximum amount, the total electrical energy required would be $200 \times 56 = 11{,}200$ watts. The efficiency of the dynamo may be taken as 90 per cent. and, since 1 hp. is equivalent to 746 watts, the power transmitted by the belt running the dynamo is

$$H = \frac{11{,}200}{0.90 \times 746} = 16.68\ hp.$$

Now, assuming the efficiency of the engine driving the dynamo as 85 per cent., the total indicated horsepower (i.hp.) is

$$i.hp. = \frac{16.68}{0.85} = 19.62,\ say\ 20\ hp.$$

Ques.—A siphon has its short leg, 10 ft. vertical, and long leg, 20 ft. vertical, and is 6 in. in diameter, with a total length of 100 yd. Find the flow, in gallons per hour, allowing for frictional resistance.

Ans.—It is never safe to calculate the discharge of a siphon without first ascertaining whether this siphon will run dry or, in other words, tend to empty itself, which will always be the case if the flow of water in the short leg, under atmospheric pressure, is less than the discharge in the long leg, under gravity. At sea level, the water column supported by the atmospheric pressure is practically 34 ft.; and, assuming that the short leg, in this case, is 100 ft. long and the long leg, 200 ft. long, while the uniform diameter of the pipe is 6 in., the relative flow in each leg of the siphon, calculated independently, is as follows:

$$\text{Short leg,}\quad \frac{34 - 10}{2.08 \times 6 + 100} = \frac{24}{112.48} = 0.213$$

$$\text{Long leg,}\quad \frac{20 - 10}{2.08 \times 6 + 200} = \frac{10}{212.48} = 0.047$$

There is, therefore, no danger of the siphon running dry, in this case.

The discharge of a 6-in. siphon 300 ft. long, having a rise of 10 ft. and a fall of 20 ft., is calculated thus:

$$G = 6^2 \sqrt{\frac{800 \times 6\ (20 - 10)}{2.08 \times 6 + 300}} = 36 \sqrt{\frac{48{,}000}{312.48}}$$

$$= 446.18\ gal.\ per\ min.$$

The discharge of this siphon per hour is, therefore, $60 \times 446.18 = 26{,}770$ gal. per hr. It is important that both ends of the siphon be submerged and that an air trap be provided at the crown or summit to collect the air given up by the water.

Ques.—If water weighs 62.5 lb. per cu.ft., and steam at atmospheric pressure has 1640 times the volume of the water from which it was generated, what weight of steam would be used per hour by a pair of engines, 30-in. cylinders and 5-ft. stroke, making 30 r.p.m. and discharging steam at atmospheric pressure?

Ans.—In general steam practice, the terminal pressure in the cylinder, at the moment of release when the exhaust valve opens, is considerably above the atmospheric pressure, for noncondensing engines, which is the usual type of hoisting engines at mines. For this reason, the only assumption that will make possible an intelligent answer to this question is that the steam in the cylinder expands down to atmospheric presure at the moment of release. Even on this assumption, the calculation would be practically worthless since no allowance is made for condensation and clearances, which always form a very considerable percentage of the total quantity of steam consumed.

However, ignoring these two factors, condensation and clearances, and assuming there are four compressions in the steam in the cylinder previous to cutoff, if the engine cuts off at ¼ stroke, the steam will have expanded down to atmospheric pressure, at the moment of release, very nearly. Under this assumption, the cylinder displacement, in cubic feet per minute, or per hour, will give approximately the volume of steam consumed in that time, measured at atmospheric pressure; and if this is 1640 times the volume of the water from which it is generated, the weight of steam is found by dividing the cylinder displacement, in cubic feet, by 1640 and multiplying that result by 62.5.

In the present case, the area of each 30-in. cylinder is $0.7854 \times 30^2 = 706.86$ sq.in. The piston displacement per stroke for the two cylinders is then $2 \times 5 \times 706.86 \div 144 = 49.09$, say, 50 cu.ft. An engine running at 30 r.p.m. makes 60 strokes per min., which gives for the total piston displacement per hour, in this case, $50 \times 60 \times 60 = 180{,}000$ cu.ft. On the assumed basis, the weight of steam consumed per hour is, then, $180{,}000 \div 1640 \times 62.5 =$ say, 6860 lb.

Ques.—How would you open and close the valves to start and stop an engine, as quickly or as slowly as possible? Give reasons.

Ans.—Steam is compressible, and the effect of the sudden arrest of the flow of steam is not like that when a flow of water is suddenly arrested by the closing of a valve. The sudden opening or closing of the steam valve or throttle will produce no other effect than a possible derangement of the rope connections on the cage or the position of the rope on the sheave or drum, provided the momentum of the cage is such as to produce a slack rope when the winding drum is arrested too suddenly by shutting off the steam and applying the brake. It is important, however, in hoisting, to start the engine slowly, so as to overcome the inertia of the cage gradually and not produce an undue strain on the rope connections and other parts of the winding gear.

COAL AND COKE NEWS

Washington, D. C.

According to information made public by the Department of Justice a modified final decree of the Supreme Court in the Government's case against the Philadelphia & Reading Coal & Iron Co. has been filed in Philadelphia. The so called 65 per cent. contracts made by the defendants severally with other named producers before the court for the purchase of anthracite coal mined or owned by the producers, as set forth in the pleadings and evidence, "from the times they were entered into have restrained and monopolized trade and commerce among states."

The exceptions already referred to were a contract dated Mar. 1, 1902, between the Pennsylvania Coal Co. and the Elk Hill Coal Co.; a contract dated Nov. 1, 1900, between the New York, Susquehanna & Western Coal Co. and John Jermyn and Joseph J. Jermyn; a contract dated Oct. 21, 1903, between the Hillside Coal & Iron Co. and the Lackawanna Coal Co., Ltd.; a contract dated Oct. 26, 1899, between the Lackawanna R.R. and the People's Coal Co., and a contract dated May 1, 1907, between the Lackawanna and the George F. Lee Coal Co.

The so called 65 per cent. contracts, therefore, with the exceptions stated, are canceled by the decree of the court, and the defendants who are or were parties thereto, including their officers, directors or other agents or assignees are "perpetually enjoined and prohibited from further executing them directly or indirectly, and from entering into any like agreements or arrangements restraining or monopolizing interstate commerce in anthracite coal."

The decree of Dec. 20, 1910, is modified, so as to dismiss the petition as to the alleged acquisition and holding by the Erie of a majority of the capital stock of the Susquehanna R.R. This is done, however, without prejudice to the right of the United States to institute any other suit or proceedings.

The same dismissal of petitions, but without prejudice to the United States government, is made in respect to the charge based on the alleged acquisition and holding by the Reading company of a majority of the capital stock of the Central R.R. of New Jersey.

Reduction Ordered in Freight Rates

In a decision handed down on May 23, the Interstate Commerce Commission, upon the complaint of Wayne R. Brown, orders the Boston & Maine, Delaware & Hudson, Lehigh Valley, New York Central, New York, Ontario & Western and West Shore R.R., to reduce the rates on anthracite coal from points in Pennsylvania to Scotia, New York. The roads have been charging $2.15 per ton on prepared sizes, which rate was ordered to be reduced to $2 from Packerton, Peckville and Scranton, Penn., to Scotia, by July 15.

Rates on coal of other sizes were ordered reduced proportionately. In this instance it was found that rates were so arranged as to permit merchants in Schenectady to deliver coal in Scotia. The commission held that both points were in the same traffic area, and that Scotia should be placed upon the same rate basis as Schenectady.

Coal Will Probably Be on Free List

Thus far efforts in the Senate Finance Committee to secure the elimination of the item coal from the free list have entirely failed. Coal men and various others have lately seen members of the committee for the purpose of securing some duty if possible upon the item. There appears, however, to be a strong disposition to avoid the odium which would, it is supposed, come from a restoration of coal to a dutiable status.

The argument has been made that in order to have a good basis for reciprocity negotiations with Canada it would be only fair to arrange matters, so that coal could be used as makeweight in the negotiations. This argument has not had much effect, so far as can be learned, and it now seems probable that the item will remain on the free list throughout the history of the tariff bill not only in the committee itself, but probably also in the later discussion on the floor of the Senate.

WILKES-BARRE, PENN.

Plans for the new office building which the Lehigh Valley Coal Co. several months ago decided to erect, have been completed by D. H. Burnham and Co. of New York, and the contract in all probability will be awarded by June 1. The structure will be six stories in height, and will be built on North River St., north of the Laurel Line tracks. It will be a handsome edifice of white granite and terra cotta, and will probably mark the beginning of a group of modern buildings in the neighborhood of the Luzerne County court house. It is hoped to have the building ready for occupancy by April 1, 1914.

It will be built upon specifications providing absolute safety from fire. The skeleton structure will be of steel, the interior walls of tiling and the floors of concrete. It will be lighted by electricity and heated by steam, both the power and the heat are to be obtained from the Dorrance Colliery, about 3000 feet away. A conduit along the Lehigh Valley Railroad tracks will carry the necessary conductors.

he outside measurement of the structure is 60x125 ft., over 40,000 sq.ft. of floor space being available. The offices will be of varying size, to suit the requirements of over two hundred employees.

The offices of the vice-president and general manager, the mining superintendent, and the mining engineer, will be on the sixth floor. In the basement there will be, in addition to the storage and stationary rooms, a large dressing room with showers, baths, lockers, etc., for such employees of the office whose work takes them into the mines.

The first floor will be occupied by the paymaster's office, the chemist's office and laboratory, the office of the retail coal shipper, the telephone exchange and information booth, and a large room to be used for conference of officials, or if desired, for employees as a reading room. The second floor will contain the two division offices, that of the Wyoming and that of the Lackawanna. The latter is now located at Pittston, but will be moved to Wilkes-Barre when the change is made. The fourth floor will remain unoccupied for some time, being reserved for future needs. The offices on the fifth floor will consist of those of the mechanical and electrical engineers, of the inspector of equipment, of the legal department, and of the real estate department.

PENNSYLVANIA

Anthracite

Wilkes-Barre—The concrete wall constructed last December to seal off a mine fire in the Kidney Vein of the Buttonwood Colliery, was recently broken down and the fire found to have been smothered by the gases generated by combustion. The work of unsealing the fire area was done by Mine Inspector D. T. Davis, of the Ninth Anthracite District, Superintendent Lewis J. Davis, Mine Foreman William Powell, and five firebosses. This fire had burned for several weeks before the plan of bulkheading it was decided upon, and about 300 acres of coal land were in danger. The colliery is now operated by the Lehigh & Wilkes-Barre Coal Co.

Bituminous

Somerset—The big power plant and tipple owned by the Consolidation Coal Co. at Houghton, near Ralphton, have been destroyed by fire.

VIRGINIA

St. Charles—Plans for the extensive development of the Monarch coal mines near St. Charles, Va., have been completed by the Old Virginia Coal Co., which was formed recently at Chattanooga, Tenn. W. F. Hutcheson is at the head of the company. H. B. Bonney, J. R. Barnes, W. W. Mullen and W. B. Miller are other Tennessee mining men who are identified with the new company.

ALABAMA

Montgomery—Chief Mine Inspector C. H. Nesbitt has asked Governor O'Neal to add another man to the present force of mine inspectors. The term of W. R. Ray, district mine inspector at Blocton, expired Apr. 30. It is believed he will be reappointed.

TENNESSEE

Obey City—Work of opening the large coal seam near Obey City, Tenn., has been begun. The operations are being conducted by the Young Coal & Coke Co. This is the most pretentious effort that has ever been made to develop the coal deposits in Overton County. E. C. Young is at the head of the company, and John McDaid has charge of the mine.

KENTUCKY

Louisville—By a recent ruling of the Interstate Commerce Commission the Louisville & Nashville R.R. Co. was given authority to establish rates on coke in carloads from Benham, Ky., at which point the great coking plant of the Wisconsin Steel Co. is located, to various other points the same as rates concurrently in effect from Appalachia, Va.

Shafer—The East Jellico Coal Co., of Shafer, Ky., which was recently in effect deprived of the possession of its mines by a decision of the Kentucky Court of Appeals in favor of the Bennett-Jellico Coal Co., a suit involving the title to the property upon which the mines were located being sent back to the lower court for a new trial, has opened new entries on a part of its property regarding which there is no dispute, and expects to be able to get out coal by June 1 or thereabout.

Elkhorn—The Elkhorn Fuel Co., in accordance with its plan for the acquirement and development of coal lands on a large scale, has recently purchased of the Long Fork Coal Co. several thousand acres of coal property in Letcher County. Development work will begin at once, and it is believed that coal will be shipped within the next 12 months.

McRoberts—A full recovery from the scarcity of labor which resulted from the shutdowns necessitated by the April floods at McRoberts, Ky., is indicated by the report from that point that the Consolidation Coal Co. is getting out an average of about 54 cars a day.

Middlesboro—A meeting of Harlan County operators was held recently at Middlesboro, Ky., for the purpose of taking steps to present to the Louisville & Nashville R.R. Co. the request of the operators in that field for the same rates on coal to all points as are given the Bell County operators. The removal of the 10c. differential as to all points north of the Ohio River was recently announced, but it is reported that the operators have not had like success with reference to points within the State.

OHIO

Columbus—Both Ohio mine inspectors and the Federal Government investigated the cause of the explosion at the Imperial mine at Belle Valley, Noble County, recently. Two inspectors representing the National Government came from Pittsburgh. After a thorough investigation it was announced by John C. Davies, state mine inspector of Ohio, that insufficient ventilation was the cause. This permitted firedamp to accumulate and this was ignited by a spark.

A number of coal operators met at the Neil House in Columbus, May 23, and discussed the antiscreen bill, which is expected to come up at the extraordinary meeting of the Ohio General Assembly, to be convened some time in the winter. The operators will make a determined effort to prevent the passage of the bill and plans are being laid to bring this about. At the last session of the General Assembly the bill was side-tracked by the adoption of the Thomas resolution, providing for a commission to investigate all the conditions surrounding wages for mining coal in Ohio.

Coshocton—Miners employed at the Morgan Run mine in Coshocton County again went out on a strike because of a controversy over the prices to be paid for driving entries. There was a difference between the men and the operator, according to the miners, of 68c. per yard. An effort is being made to settle the trouble.

Lorain—In the presence of over 200 out-of-town operators the new freighter, "Arnold C. Dustin," built at the Lorain yards of the American Ship Building Co., for John Mitchell, of Cleveland, was recently launched. The vessel is 545 ft. long, and will be used in the coal and ore trade.

McArthur—The fire which destroyed the tipple, engine house and plant of the Starr-Hocking Coal Co., at Coonville, Vinton County, Ohio, caused a loss of $100,000. The fire was discovered in the yard office at 7 p.m. in the evening, and every effort made to stop the flames proved fruitless. Charles Hargray, who controls the mine ownership, announced that the tipple and engine house would be rebuilt at once.

INDIANA

Indianapolis—Attorney-General Honan, of Indiana, has given an option to Frank J. Pearce, state mine inspector, interpreting the law of 1905 to mean that firebosses in Indiana mines are compelled to examine mines for firedamp that are known to contain, or are supposed to contain that gas, but are not required to examine all working places in mines for firedamp.

Miners employed at the Washington-Wheatland mine near Washington, Ind., have returned to work after being out several days, contending that the mineboss did not make careful examination for firedamp, and they feared accidents. They returned to work after the state mine inspector and deputies had made careful investigation.

Petersburg—The S. W. Little Coal Co. officers were surprised, after pumping out the Blackburn mines, three miles north of this city, to find the motors dry and in usual condition. Before deserting the motors during the recent rush of water into the mines, the drivers took them to the highest point in the mines. It is believed the water forced the air in the mines to the top of the slope and so compressed it as to keep the water back from the motors. It was expected the machines would be ruined by long immersion, and the company was glad to escape a loss of several thousand dollars.

Boonville—The Warrick County Coal Co., recently organized, has bought the Polk Patch mine properties in this country from the J. Wooley Coal Co., and will introduce the strip mining process. The properties have a daily output of 1000 tons. The deal carries with it the conveyance of 5000 acres of coal lands east of Boonville. W. H. Hays, L. E. Fischer and R. R. Hammond are the directors. The capital stock of the new company is $350,000, all from Chicago.

ILLINOIS

Marion—A fire, which started about six o'clock on the evening of May 22, at the mine of the Illinois Hocking Washed Coal Co. at Marion, continued until about three o'clock on the afternoon of the following day. Two supply men, who were distributing powder in the mine at the time of the fire, were taken from the mine on the afternoon of the 23d. They were Ed and John Duncan, brothers, 19 and 30 years old, respectively. John was dead when found and Ed was unconscious, was able to tell of his experience the next morning. One mule of the 17 owned by the mine was saved, the other 16 having perished in the fire. The air shaft, the fan and fan house were also destroyed. It is not known how the fire originated, but is supposed to have started in an old tool house, which was being used as a wash room.

Springfield—Fire destroyed the plant of the Royal Collieries Co., at Virden. The loss is estimated at $125,000.

OKLAHOMA

McAlester—After a three months' shutdown the Adamson mine of the Union Coal Mining Co., of McAlester, Okla., has been reopened. Orders from the district tributary to this mine are expected to be heavy enough to keep the property in operation without interruption until February or March. W. E. Beaty is president of the company.

TEXAS

Palestine—Anderson County, Texas, coal deposits are being examined by New York engineers. Prospect holes are being sunk on several of the outcrops and diamond drilling is being done. Considerable secrecy surrounds the operations, but it is understood that Palestine interests have an option on a considerable acreage of coal lands.

Loving—The Sallie-Alice Mining Co. has opened a coal shaft on the W. S. Purselley lease and has installed its machinery. The firm is working night and day shifts to get the entries sufficiently advanced to enable it to begin filling a large contract at an early date. The coal is considered as good as any in the state, being a 5-ft. bed of bituminous found at a depth of 100 ft. under a rock roof and carrying just enough water to keep down the dust.

WYOMING

Lander—The Gebo coal lands, near Hudson, in Fremont County, amounting to 2200 acres, were formally restored to public entry on May 12. These lands are regarded as some of the most valuable in the district and already a number of filings have been made. This tract has been classified by the Government and entrymen will have to pay from $30 to $50 an acre to secure their claims.

MONTANA

Glendive—R. W. Snyder Coal Mine has been purchased by C. J. Bohannon and Geo. B. Williams, the consideration has not been made known. Experts have been employed and after a brief examination they state that the public has no idea of the tremendous amounts of coal in this mine. The Northern Pacific Ry. will build a spur leading to the mine from Stipek, a distance of two miles and will carry 100 tons of coal per day for the first year.

WASHINGTON

Astoria—J. C. Brooks, representing a big coal company, located in the Middle West, was in Astoria last week for the purpose of investigating conditions relative to the establishment there of a big coal dock to provide coal for steamships coming to the Columbia River. Astoria is at the mouth of the river and bunkers there would be in good position to furnish

coal for outbound vessels which, as a rule, now proceed to British Columbia to fill their bunkers for long voyages.

Chehalis—J. E. Leonard has found a vein of coal 250 ft. west of Coal Creek. The height is 8 ft. and the quality is superior to most coals that have been uncovered in the vicinity.

PERSONALS

E. F. Mullin, for many years engineer for the Jeffrey Manufacturing Co., and previously with the Heyl & Patterson Co., has severed his connection with the former concern to join the engineering staff of the Link-Belt Co., Philadelphia.

Mr. Mullin has had extensive experience in the design and construction of tipple equipment and general coal handling machinery, particularly in the West Virginia and Pennsylvania coalfields.

J. F. Healey has resigned his position as general manager of the operating department, Davis Colliery Co., Elkins, W. Va., effective May 31. Mr Healy is considering several offers of similar positions, but may open a consulting office in Charleston, W. Va.

A. M. Campbell, formerly of Louisa, Ky., and recently engaged in mining and development work in eastern Kentucky, has been made general manager of the Elkhorn Fuel Co.'s operations, and is at present in the Boone's Fork district looking over the ground for the purpose of planning for the beginning of active work.

The announcement is made that W. H. Warner will be in charge of the offices of the Pan-American Coal Co., of Newark, Ohio, which will be moved to the Schultz Building, Columbus, about June 1. The Pan-American Coal Co. recently took over a large number of mining properties in Ohio and West Virginia, making it one of the largest operating concerns in the Buckeye state. W. M. Fulton will be president of the company which will have an authorized capital stock of $500,000.

PUBLICATIONS RECEIVED

Cornell University, Ithaca, N. Y. The Sibley Journal of Engineering; vol. XXVII, No. 8, May, 1913. 30 pp.; 6⅞x9⅜ in. Annual subscription, $2.50; single copies, 25c.

West Virginia Geological Survey, Coal, Oil, Gas, Limestone and Iron Ore Map. This new edition is the joint publication of the State Geological Survey and the State Semi-Centennial Commission. It contains all the special features of previous editions brought up to date and shows the approximate areas of the several coal series, operating mines and their post-office addresses, as well as the oil and gas pools. Size, 35x44 in. Price, 50c, postpaid.

CONSTRUCTION NEWS

Latrobe, Penn.—Tony Colangelo had been awarded the contract to build 80 ovens for the Marietta company, at its plant, near Wilpen, in the Ligonier Valley.

Youngstown, Ohio—Julian Kennedy is at the head of the Poland Coke Co., which is building a plant of 100 ovens on its 1100-acre coal tract on Dunkard Creek, near the Monongahela River in Greene County, Pennsylvania.

Coshocton, Ohio—William Powers, who operates a mine five miles southeast of Coshocton, is contemplating opening up a new mine near Kimbolton Guernsey County, on 140 acres which he has under lease.

Athens, Ohio—A force of men is now at work in mine No. 210 on Sugar Creek, making ready to put that shaft in operation as soon as possible. This mine has been idle for the past six years, although in all that time its owners, the Sunday Creek Co., has at all times kept it pumped out

Bicknell, Ind.—The American Coal & Mining Co., recently organized, has purchased a large acreage of coal land near here, and is preparing to sink two mines. The first vein is 7½ ft. thick. Hal R. McClelland, of Clinton, Ind., is vice-president and manager of the company.

Buffalo, N. Y.—The Cascade Coal & Coke Co., an adjunct of the Rogers-Brown Iron Co., of Buffalo, has awarded the contract for an increase of its coal-mining plant at Sykesville, Penn., which will include two 300-hp. boilers and engines, and which is a practical duplication of the present equipment. The addition is to be finished by July 1.

Moundsville, W. Va.—Contractor R. J. McFadden announces that he will start the work of the new shaft on the Ball property back of Glendale, for the Hitchman Coal Co., to be used in connection with the Glendale mine now in operation.

Ragland, Ala.—The Ragland Coal Co. is preparing to open new mines on their property at Coal City in the near future.

Lexington, Ky.—It is reported that on account of the great increase in coal operations along the lines of the Lexington & Eastern, the Louisville & Nashville R.R., which controls that road, is preparing to spend $1,000,000 in improving the property, cutting down heavy grades, shortening the curves, and the substitution of wooden trestles and bridges with steel work, covering the entire distance of 95 miles between Lexington and Jackson, Ky. These improvements are considered necessary in order to handle the traffic which is expected, heavier engines and longer trains being planned.

Altoona, Penn.—Vast coalfields, containing deposits estimated at 475,000,000 tons situate in northern Blair and Cambria Counties, and traversed by the Altoona Northern R.R., now in a state of construction, will soon be tapped. Expert mining engineers declare that the deposits of the new field are sufficient to keep 10,000 men constantly engaged during the next ten years.

The branch of the New York Central into the Cambria fields and at Frugality, and further construction of ten miles of trackage will be necessary to tap into the Gougherty-Patton field.

NEW INCORPORATIONS

Nashville, Tenn.—The Fern Hill Mining Co., Grundy County, capital stock, $25,000. Incorporators: H. L. Gregg, W. G. Dillon, E. W. Patterson, W. P. Stone and W. E. Robertson.

Cleveland, Ohio—The Tice Coal Co., of Cleveland, Ohio has filed papers with the secretary of state changing its name to the Kirk-Dunn Coal Co. and at the same time increasing its capital stock from $10,000 to $300,000.

Columbus, Ohio—The Stalter & Essex Coal Co. of Columbus, Ohio has been incorporated with a capital stock of $25,000 to mine and deal in coal. The incorporators are Calvin Essex, James R. Stalter, Fred Essex, Robert R. Stalter and Charles Essex.

Huntington, W. Va.—The Sharon Coal & Coke Co., of Newton, Penn., chief works to be located in Pike County, Kentucky; to engage in the mining of coal and the manufacture of coke, authorized capital stock, $100,000. Incorporators: Z. T. Vinson, W. R. Thompson, T. J. Bryan, E. M. Watts and A. E. Bush, all of Huntington, W. Va.

INDUSTRIAL NEWS

Scranton, Penn.—New mining is to be done by the Scranton Coal Co. in the hill section between Irving Ave. and Nay Aug Park and Vine and Myrtle Sts

Pittsburgh, Penn.—Charles T. Topping has been appointed agent for the Phœnix boilers and engines in the Pittsburgh district. His office is room 816 Bessemere Building

Windber, Penn.—M. C. Yoder, Chas. Estep and John Reese have taken over the property of the Salem Coal Co., near Salem, Ohio. The mine is being equipped with modern machinery

Pottsville, Penn.—The Philadelphia & Reading Coal & Iron Co. will soon place in operation in its Suffolk Colliery an 8-ton electric mining locomotive ordered from the General Electric Co.

Moundsville, W. Va.—A big coal deal was consumated here May 10, when the tract lying in Cameron and Liberty districts, comprising a total of 556 acres, was sold to S. W. Booher for $40,600.

Sullivan, Ind.—The Rood mine, near Farmersburg, has been sold by Receiver J. T. Akin to Ralph Sharp, trustee, for

$2035, which will pay the preferred claims. There is due miners for wages $6000.

Bollvar, Penn.—J. W. Miller, representing the company which recently acquired the coal underlying about a thousand acres south of here, has also purchased the John A. Campbell farm, near West Fairfield.

Birmingham, Ala.—The Alabama Mineral Land Co. announces the purchase of 12,000 acres of coal land situated in Walker County, near Jasper, the county seat. C. C. Huckabee, of the Alabama Mineral Map Co., states that the purchase was made from J. F. Andrews, of New York City.

New Orleans, La.—Contracts have been signed in New Orleans for a year's supply of Alabama coal for the vessels of the United Fruit Co., which ply between Mobile and Central America. The vessels landing cargoes at New Orleans will use Pitsburgh coal.

Columbus, Ohio—Application has been made by the Middleport & Northeastern Ry. Co. before the Ohio Public Utilities Commission for permission to issue secureties for the extension of the railroad line through the southeastern part of Athens County to open a rich coal area.

Tamaqua, Penn.—Baird Snyder, of Pottsville, former head of the Lehigh Coal & Navigation Co., is to be president of the corporation that will reopen Silver Brook in a few months. C. M. Dodson Coal Co. is to back Mr. Snyder, and will own a good part of the stock of the new concern.

Pottsville, Penn.—New York City capitalists, who have organized the Bloomingdale Valley Coal Co. have just bought the individual coal operation known as the Phillips Colliery, in the southern part of Middleport, in the Schuylkill Valley. The new owners will develop it to its fullest capacity.

Welch, W. Va.—Jairus Collins, of Bramwell, has purchased the holdings of the Kimbal-Pocahontas Coal Co., for the sum of $35,000. The property is unimproved. At this time we have been unalbe to learn whether Mr. Collins bought the property for the Pocahontas Consolidated Co. or not, although it is supposed he did.

Washington, Penn.—Several coal tracts in the neighborhood of Old Concord, Morris Township, and East Finley Township, have been optioned at a uniform consideration of $200 per acre. Persons taking the options represent that they are agents of Waynesburg people, who are able to finance the deals should they decide to accept the coal.

Birmingham, Ala.—The interests of P. B. Thomas in the Montevallo Mining Co. were acquired May 19 by Henry L. Badham and W. S. Lovell, following the purchase of the Thomas stock by two well known industrial men. Robert J. Badham was elected vice-president, and D. A. Thomas, a son of the retiring president, was elected secretary.

Fostoria, Ohio—The Seneca Coal Co. has brought suit against the Ohio Coal & Coke Co., of Cleveland in the courts at New Philadelphia, Ohio, claiming that a contract for the purchase of certain coal lands in Warwick and Mill Townships in Tuscarawas County has not been carried out. The plaintiff asks for immediate possession of the property.

Wilkes-Barre, Penn.—The Delaware & Hudson Co., will place in operation a new 300-kw. motor-generator set and switchboard in its Baltimore Tunnel Mine. This company will also install a motor-generator set with switchboard of the same capacity in its Pine Ridge Mine at Parsons, Penn. Both machines and apparatus will be furnished by the General Electric Co.

Uniontown, Penn.—A large coal deal involving more than $150,000 and conveying 757 acres of Gilmore Township coal from the Enterprise Realty Co. to Judge R. E. Umbel, Hon. B. F. Sterling, et al, is about to be consummated. The deal was engineered by Kobert & Bradley, J. H. Zimmerman, representing the Realty company and Carter Bros., representing the purchasers of the property.

Chicago, Ill.—The Cleveland, Cincinnati, Chicago & St. Louis Ry. (Big Four Route), through their chief engineer, G. P. Smith, awarded a contract to the Roberts and Schaefer Co. this week, for five large Holmen coaling plants to be built immediately at Paris, Ill., Lynn, Ind., Anderson, Ind., Lilly, Ill., and Dayton, Ohio. This company has also secured a contract for two large 400 ton capacity, reinforced concrete, fireproof Holmen coaling plants which are to be built immediately at Chicago.

Columbus, Ohio—Columbus will be the headquarters of a new coal company, which is expected eventually to rank in size with the Sunday Creek Co. and the Lorain Coal & Dock Co. The new organization is being formed by the merger of the Pan-American Coal Co., the Granger Coal Co. and the Buckeye Coal Co., of Murray County, the Sedalia company, of Jacksonville, Athens County, and others. The new company will control 12,000 acres, employ over 900 men, and have a daily capacity in the start of 8000 tons.

Tiffin, Ohio—The Seneca Coal Co., a company composed of local capitalists, organized a number of years ago to operate coal mines and leases in Tuscarawas County, has brought suit in New Philadelphia, claiming that the Ohio Coal & Coke Co., of Cleveland, has failed to carry out its contract to purchase the property, which is located principally in Warwick and Mill townships, Tuscarawas County, for $50,000. The terms of the sale were $6000 down and $2000 the first of each month until the balance was paid. The Seneca company claims that $35,000 is still unpaid.

Washington, Penn.—During the past two weeks coal tracts in the neighborhood of Old Concord, Morris Township and East Finley Township have been optioned at $200 an acre. The options are being taken by parties who claim to be acting as agents of Waynesburg interests. More than a dozen bore holes are being drilled at various points in the tract known as the Dawson block and should the coal seams prove to be of uniform thickness and the coal of good quality it is believed the options will be taken up. The Dawson block extends over a large portion of Morris and East Finley Townships, a portion reaching across the line in Morris Township. This tract surrounds most of those recently optioned and it is announced that should the Dawson block which is optioned at $240 an acre be accepted the smaller tracts will be sold at the consideration previously named of $200 an acre.

Columbus, Ohio—The international officers of the United Mine Workers of America have given a decision on the strike of the Hisylvania Coal Co. at the Trimble mine at Glouster, Ohio. The men after being out for four months went back Apr. 22 pending an adjustment of the trouble. The original cause of the strike was the discharge of three men, for failing to set posts while driving entries. After an investigation by a representative of the international officers of the organization, during which evidence from the company was admitted tending to show that the posts were on the ground and had been buried by the men, the three men were reinstated at their old positions. Both the men and the company were held equally guilty in violating the state laws relative to safety. J. W. Blower, general manager of the company is trying to have the case re-opened in order to show that the company was blameless in the matter.

Butler, Penn.—W. S. Wagner who has been in the cement business for several years past but who formerly had worked a quarter of a century as a coal miner recently purchased the coal rights on the Redick farm in the Bonnie Brook district. He has recently completed his explorations for coal in that vicinity and has taken up options for the coal rights on several farms adjoining. One of the seams found is 3 ft. 2 in. thick and is pronounced the best coal that has been discovered in this country for some years past. Chemists who have examined the coal declare that it is entirely free from sulphur and superior to the Pittsburgh coal which is extensively used in the Butler district. The old mine taken over by Mr. Wagner is being rapidly developed the new workings having been already extended several hundred feet. There is a nice grade on the roadways that favors the movement of the loaded cars. This is a rare occurrence in mines in this section. It is stated that arrangements have been made and work will be commenced at an early date by the Rochester company for the building of a switch from their main line to the mouth of the mine, a distance of about 500 feet.

Galveston, Tex.—It is confidently expected that this city will be the Texas gateway to South America for both Atlantic and Pacific ports when the Panama Canal is opened for traffic. The outlook is promising for the establishment here of many new lines of business. Inquiries are being received daily and merchants and manufacturers are visiting the city with a view to securing locations. One of the latest evidences in this line concerns coal interests operating in Illinois, Arkansas, Kansas, Oklahoma, Missouri and Colorado. S. W. Sorat, president of the Star Coal Co., and E. R. Dusky, general sales agent for that concern, have been recently looking over the ground relative to the establishment of a mammoth marine coaling station. It is thought to make Galveston a base for supplying bunker coal to ships of all nations. With favorable freight rates the way will be clear for bringing additional industries into the entire Trans-Mississippi territory through the port of Galveston.

The daily production of the mines operated by the Star Coal Co. is 110,400 tons. This company can bring coal to Galveston to supply every ship that floats in the Gulf of Mexico, engaging in the coastwise and foreign commerce.

COAL TRADE REVIEWS

GENERAL REVIEW

The month of May has closed with the hard-coal business in a fairly satisfactory condition. Shipments are coming forward slowly, but small dealers have a liberal supply and a normal amount of orders are on hand for June. The main demand continues to center on stove, egg and nut being comparatively easy and some of the steam sizes now going into storage.

The strong tone still continues in the Eastern coastwise bituminous market, with buyers unusually anxious for tonnage, even at the new high level established for this year; prospects are excellent for a profitable season. All Hampton Roads coal not required in the coastwise trade is being readily absorbed in the export business and on Government colliers. Shipments, all-rail, are barely up to requirements and mining is much below capacity in some districts. Many of the large agencies are declining further orders except when same are from old customers, and the increased buoyancy in the market is being felt even on the lower grades.

New business in the Pittsburgh district is light, but that being done is invariably at an advance on the season circular. The market undoubtedly occupies a strong position with the producers in full control of prices, and will in all probability continue so as long as present conditions prevail. But should the car and labor shortage be relieved, the increased production would probably bring about a rapid reversal in conditions as noted in these columns last week. Indications are, however, that the situation will continue indefinitely, or, at any rate, until the winter trade opens up. The railroads are moving heavy tonnages with good dispatch, but it is becoming apparent that they are up to about full capacity.

Railroad equipment is also becoming scarcer in Ohio, and it is believed that the customary fall car shortage will develop much earlier than usual this season. The Lake trade continues the main feature in the local market, while steam coal is also active and some stir is evident in domestic, although dealers are not as yet beginning to stock. The tonnage handled at Hampton Roads fell below that of the previous week, but was, nevertheless, heavy. There is a strong demand in the spot market, but producers are inclined to hold any surplus tonnages for the purpose of applying these on contracts which soon become effective. Alarm is still felt over the car situation in the Southern markets and fears are expressed that this will not be cleared up before the usual fall shortage develops.

The situation in the Middle Western market remains unchanged, with prices at a low level and likely to continue so. There was, however, some slight stiffening on the steam grades, due probably to the advance in Eastern coals. In the Rocky Mountain region there are rumors that some of the oil-burning railroads and manufacturing industries will again resume coal burning. No authentic information is available regarding this point, but the effect on the coal business there, would be quite material.

BOSTON, MASS.

Bituminous—There is almost no news beyond the general firmness reported last week. Some of the large buyers are engaged in a still hunt for some shipper with a volume of Pocahontas and New River to sell, even at the $2.85 price, but by far the most of the agencies are out of the market, at least for the time being. What coal at Hampton Roads is not being moved coastwise is readily absorbed for export or by government colliers. The tone is strong and the prospect excellent for the whole season.

For Georges Creek and the better grades from Pennsylvania there is steady request and no accumulation is heard. Practically every anthracite cargo from Philadelphia includes at least a bin-load of bituminous. Stocks at this end are small rather than large. All-rail supplies are barely keeping up to requirements. Mining is less than normal for most of the districts and operations in most cases are becoming infrequent. The loading continues slow and with vessels arriving here already on the point of demurrage there is small encouragement for dividing up cargoes.

Water Freights share the generally firm tone of coal prices; 75c. is the prevailing figure on large vessels, Hampton Roads to Boston, with 5@10c. advance on smaller tonnage.

Anthracite is coming forward very slowly, and with many restrictions on the proportion of sizes. There is practically nothing being shipped to the storage depots in New England and dealers are most urgent in their calls for coal. The smaller retailers have had a liberal proportion of their season's supply in April and May, but large distributors in the cities are still anxious over their smal receipts. To still others it is embarrassing not to be able to take the apportionment of egg and nut they are asked to absorb in order to get stove. All told, however, there is a reasonably good amount of anthracite business in hand for June.

Current bituminous quotations are about as follows:

	Clearfields	Cambrias Somersets	Georges Creek	Pocahontas New River
Mines*	$1.05@1.40	$1.25@1.50	$1.67@1.77	
Philadelphia*	2.30@2.65	2.50@2.75	2.92@3.02	
New York*	2.60@2.95	2.80@3.00	3.22@3.32	
Baltimore*			2.85@2.95	
Hampton Roads*				$2.85
rovidence†				$3.73@3.78
oston†				3.78@3.90

*F.o.b. †On cars.

NEW YORK

Bituminous—Local conditions in the bituminous trade continue about the same as the previous week. No further recessions in prices have occurred except in few instances where demurrage coal, particularly in the cheaper grades, were offered at $2.45 and $2.50. The market prices on various grades were as follows: West Virginia steam, $2.50@2.60; fair grades, Pennsylvania, $2.65@2.70; good grades of Pennsylvanias, $2.75@2.80; best Miller, Pennsylvania, $3@3.10; Georges Creek, $3.25@3.30.

Contract tonnage still continues in demand, although the majority of large consumers have already arranged for their yearly requirements. The present situation from all ponits of view indicate a fairly healthy condition, which is probably accounted for by the limited car supply and shortage of labor in some of the Pennsylvania and West Virginia fields. Operators, on the other hand, avoid sending surplus tonnage to tidewater in fear of a repetition of past occurrences when they received ruinous prices for their product. The general trade opinion, notwithstanding the anxiety experienced by certain manufacturers over the tariff question, seems to indicate a decided expectation among operators that there is going to be a lively and active fall and winter season.

Anthracite—From all indications the hard-coal trade is in splendid shape, especially on prepared sizes. The demand for egg and stove coal has created a shortage with most of the operators on these particular sizes, and nut, which up to this writing was hard to dispose of, is beginning to move more rapidly. Local dealers are busy delivering their spring orders, but most of them express a certainty that summer conditions this year will not be different from previous years.

Heavy shipments are being forwarded to the Lakes and Western markets. The individuals are finding difficulty in disposing of pea coal with their line trade, which accounts for the cut price on this size at tidewater. Buckwheat still continues to be a drug and hard to dispose of, in many instances it is offered by the individuals at low prices. Barley and rice coal in the better grades are decidedly short, due, no doubt, to the heavy contract demand on this quality, but the Schuylkill grades of rice size are beginning to get long, although no real difficulty is experienced in making dispositions where a slight cut in price is offered. The Schuylkill grades of barley are not as freely offered as in the past month, but what tonnages happen to be available are still offered at cut prices.

The following is the local market on hard coal:

		—Individual—	
	Circular	Lehigh	Scranton
Broken	$4.60	$4.45@4.55	$4.50@4.60
Egg	4.85	4.70@4.80	4.85
Stove	4.85	4.80	4.85
Chestnut	5.10	4.95@5.05	5.00@5.10
Pea	3.50	3.20@3.45	3.25@3.50
Buckwheat	2.75	2.15@2.45	2.50@2.75
Rice	2.25	1.85@1.95	1.75@2.25
Barley	1.75	1.40@1.70	

PHILADELPHIA, PENN.

The month of May closes with the anthracite trade in a comparatively satisfactory condition. Most of the large companies will have considerable business go over into the month

of June at the advance of 10c per ton; they claim that the prospects look as favorable as May, when the mines were worked to their full capacity, and little or no coal went into stock, outside of the small or steam sizes. Broken, egg, stove and nut are still holding their own, as far as demand is concerned. There has been a trifle less demand for pea, which is essentially a domestic size in this market, while buckwheat and rice show little or no improvement. A large proportion of the three last sizes are going into stock.

The retail business is fairly good, although still in the hand-to-mouth state as far as orders are concerned. The demand here is in marked contrast to some of the large Eastern cities. Prompt shipments are demanded, the claim being made that coal is going out faster than received, which seems to be an indication that the lesson learned last fall and winter has had its effect. In this market, the experience of last year has had exactly the opposite effect. It is almost safe to say that the business now being done by the retailers is the same that they have been doing from year to year in the early spring months. There is comparatively little new business from householders anticipating a possible shortage in the fall and winter, and the consequence is, that there is no particular snap or activity to the trade. Most of the dealer's solicitations are along the lines of trying to prevail upon the consumers to take advantage of the present, when coal is comparatively easy, but the results are not as satisfactory as they would like. They will all wait until the last moment, and then it will be again the same committees, investigations, etc., that characterized the business during the last year.

The bituminous market still remains about the same as last reported.

PITTSBURGH, PENN.

Bituminous—While new transactions are relatively light, the major portion of current sales seems to be at an advance of 5c. over the regular season prices, with some large operators refusing to sell except at a 10c. advance. There has been a moderate amount of lake coal sold to the smaller shippers at $1.47½, or a 5c. advance. As noted before, the local coal market appears to be very strong, but there is question how much allowance must be made for the definite policy of many operators not to sell up to the full productive limit except at an advance. The labor and car supply will determine how close to capacity the mines will be able to operate, and these factors are largely indeterminate at this time. With the supply scant the present market position can easily be held, but a fairly full supply of cars and labor might put more pressure upon sellers than is now in evidence. We quote regular season prices as follows, subject to frequent premiums, particularly for ⅜-in.: Slack, 90c.: nut and slack, $1.05; nut, $1.25; mine-run, $1.30; ¾-in., $1.42½; 1¼-in., $1.52½, per ton at mine, Pittsburgh district.

Connellsville Coke—The market continues relatively inactive, but with still greater evidence of underlying strength. With a limited demand for prompt furnace, the market has been held at close to the asking price, $2.25, of several weeks, indicating that operators as a whole are closely regulating their output to contract requirements. Foundry coke has sold quite well on contract, being more active than for some time, and $3 does not seem to have been shaded in any instance, sales at slightly under this figure being only of odd prompt lots. While details are lacking, it is understood that the Pittsburgh Steel Co. has closed for at least the major portion of its requirements against the two blast furnaces it is completing at Monessen, the first to be blown in about the end of June and the second about the end of July, shipments to start about a fortnight earlier. It is assumed that the contract was placed at a concession from the usual asking price of $2.50, which price the furnaces thus far have shown no inclination to pay. We quote: Prompt furnace, $2.15@2.25; contract furnace (nominal asking) $2.50; prompt foundry, $2.85@3.25; contract foundry, $3@3.25, per ton at ovens.

BALTIMORE, MD.

There is every indication that the local trade has entered into a period of activity which will continue indefinitely. The demand is becoming more insistent, with the result that prices are stiffening, and many companies are finding it necessary to refuse further orders, except to oldest customers. Spot coals in the line trade are particularly strong, especially the better grades, while the off qualities are bringing higher average prices than for some time past. Coal which has been selling at 70c per ton has now advanced to 80c., and tonnages are scarce even at this new high level.

The labor situation is one of the principal features in the market at the present time. The scarcity of miners has caused the general impression that the market may advance rapidly until even the high level prevailing during the strike in Great Britain is reached. Many large consumers who have kept out of the market are now buying readily for stocking-up purposes, and indications are that they will continue doing so until substantial surpluses have been accumulated. Operators seem to be in good cheer and say they expect a very satisfactory year. They are busy now making or renewing contracts for steam grades.

The unusually cool weather has had a tendency to create some activity in anthracite, although not of any great extent. Coke operators claim that production has been restricted recently, and is now just about equal to the demand, with no surplus in the market.

BUFFALO, N. Y.

There is all of the former firmness in the bituminous trade and operators are expecting to maintain this position through the season. All the reasons for a continuation of the demand are still in full force and the output cannot well be increased under present conditions. The chief efforts are directed toward increasing production, but that is difficult to accomplish and about the best possible now is to make sure it does not fall off. In some districts there is a growing scarcity of cars which is decreasing the tonnage of the mines. The scarcity of men is also becoming more acute; it extends into all branches of the trade. Anthracite shippers find country jobbers and retailers complaining that they cannot unload their consignments, for it appears that men are harder to get in small towns than anywhere else.

The only weak spot is still coke, which is none too strong at $4.75 for best Connellsville foundry. Quotations of bituminous coal continue on the basis of $2.80 for Pittsburgh lump, $2.65 for three quarter, $2.55 for mine-run and $2.15 for slack, with Allegheny Valley about 25c. less. It is often hard to get Pittsburgh coal at all, as so much of it is tied up in contracts and the lake trade. There is no coal on track unsold and it looks as if the utmost service is being obtained of the cars where the roads are moving them with good dispatch. Consumers are buying promptly and not haggling about the price if they know the quality of the coal. Control of prices seems to have gone entirely over to the seller.

It is now believed that conditions are such in the bituminous trade that nothing short of a general break-down or other business can injure it very much. While iron is not at its best the crop situation is so good that it will counteract almost any bad feature. If labor difficulties fail of an early settlement they will reduce the demand for coal, but they ought to subside before long. The demand for anthracite is still light, with not much promise of early improvement. Lake shipments for the week were 147,000 tons.

HAMPTON ROADS, VA.

While the dumping at tidewater has not been so heavy the past week as the previous one at the same time there has been a good supply of vessels and all piers have been working constantly. Some few of the suppliers are short of coal which has held up a number of vessels a few days but the beginning of next week should see these all loaded and away. There has been a heavy demand for spot coal during the entire week, a number of inquiries coming from the foreign buyers but few sales have been made owing to the fact that suppliers having coal on hand are holding same for contract tonnage about due.

On account of the unrest in the New River field suppliers from that district are making few contracts prefering to hold off until matters are more settled.

Prices offered by buyers have ranged from $2.80 to $2.85 for June cargoes but the latter figure has been refused by the operators as it is expected quotations will go higher during the coming week. Prices for high volatile coals have been quoted from $2.40 to $2.50 but only one or two small sales have been made, there being little inquiry for this grade.

COLUMBUS, OHIO

Despite a growing car shortage which is affecting a number of mining districts in Ohio, the trade has been fairly active during the past week. Reports from Eastern Ohio show a scarcity of cars and this is having an effect on the production from that region. There is also some car shortage reported from other mining districts in the state. Coal men are predicting an acute shortage later on and it is believed it will develope earlier than last year.

The lake trade is active in every way and the demand from the Northwest is strong. Dock prices are 10c. higher than last year and that fact is stimulating the trade. The congestion caused by the ice and scarcity of unloading machines in the upper lake ports is passing away. Toledo docks of the Hocking Valley company loaded 113,000 tons for the week ending May 23 and since the opening of navigation the docks have handled 504,000 tons. Another strong point in the market is the demand for steam tonnage. Factories engaged in making iron and steel products are busy and their fuel

requirements are large. The railroads are also taking a large tonnage since the freight movement is increasing. Most of the railroad contracts have been made and many of the steam contracts with manufacturing establishments have been closed.

Some stir is being felt in domestic sizes. While the stocking season has not opened, retailers are placing small orders. Preparations are being made to take care of the stocking demand earlier than usual. Most of the dealers in this section have very light stocks and they are placing their orders now.

Quotations have been well maintained in every mining district and on all grades with the possible exception of fine coal, on which there is a slight weakness. This is due to the larger tonnage of nut, pea and slack and coarse slack resulting from the Lake trade. Mine-run and three-quarter inch are the strongest sizes in the market.

The output in Ohio fields has been fairly large during the week although the car shortage has decreased it in certain localities. In the Pomeroy Bend district where the operators are slowly recovering from the effects of the flood the production is gradually increasing. In Eastern Ohio it is estimated at about 65 per cent. of normal while in the Hocking Valley it is about 85 to 90 per cent.

Quotations in the Ohio fields are as follows:

	Hocking	Pittsburgh	Pomeroy	Kanawha
Domestic lump	$1 50		$1 50	$1 50
4-inch	1 35	$1 25	1 35	1 30
Nut	1 15	.....	1 25	...
Mine-run	1 15	1 10	1 15	1 10

Coarse slack	0 60	0 65	0 60	0 60

LOUISVILLE, KY.

A between-seasons lull seems to be prevailing over the local market. This is due probably to the reluctance on the part of the dealers to begin laying in their winter stock.

The local market has undergone a direct reversal of form within the last ten days, particularly in the steam-coal branch. The scanty supply has been abruptly relieved and there are plenty of tonnages available now. With railroad conditions again practically restored to normal, there is a good, strong movement; dealers are stocking quite heavily, and there appears to be plenty of slack coal available.

The Illinois Central R.R. is taking a very heavy tonnage, a great deal more than normal, at any rate, probably for the purpose of accumulating some surplus supplies in case of an emergency. Because of this condition, mines along this line are finding themselves with more slack on hand than they are able to market and as a consequence quotations have fallen off to ridiculously low points.

BIRMINGHAM, ALA.

Considerable alarm is felt among the local operators lest the car shortage, which has gradually grown worse for the past few weeks, will not be remedied before fall. The labor situation is also apparently growing more serious from week to week. The domestic coal market is possessed of a little more interest than during the few weeks preceding, owing principally to the fact that many of the mines have not been furnished with sufficient equipment to keep up with monthly specifications on contracts with dealers.

The market for steam coal is quiet, but quotations have not changed materially during the past three weeks. A good deal of interest is added to the steam market, as this is the season of the year when most annual contracts are being closed for shipments to begin July 1.

Foundry coke maintains a stiffness decidedly above other kindred markets on which it so often depends. Record high prices are now being obtained and the market has been extended over the entire Western States. The demand for furnace and smelter coke is well balanced with the production.

INDIANAPOLIS

The mine situation here is about what it usually is in June and July. While there is fair demand for steam grades, there is nothing doing in domestic. Prices are at the bottom and no prospect for an advance. Some buyers, however, say they note a stiffening in the price of steam grades, probably due to the higher tendency in Eastern coals, which throws more inquiries to Indiana operators. Wholesalers in this city say there is not as much free coal in the market as there was a year ago and they are having continued trouble to place orders for their requirements. The largest consumers of steam grades have placed their orders for next season, and contracts are being made quite liberally with those that take wagon delivery. A slight advance is looked for the first of June in eastern coals. Retailers say deliveries to householders for next winter's consumption, is up to the average for May, if not somewhat above that. The experience of these domestic consumers the past seson was such as to make them more eager to buy earlier than usual.

DETROIT, MICH.

Bituminous—The contract market in this vicinity is showing increased strength, but spot sales are somewhat off. An embargo against lake coal, which was established by two of the large carriers has diverted a great deal of fuel here on consignment, with the result that this had been forced on the market and a reduction in prices has consequently followed; however, the indications are that the slump is only temporary. Buyers are also showing only a slight inclination to purchase believing apparently that a decided slump is in prospect.

The following is approximately the Detroit market:

	W. Va. Splint	Gas	Hocking	Cambridge	No. 8 Ohio	Pocahontas	Jackson Hill
Domestic lump	$1.50		$1.40			$2 00	$1 90
Egg	1 50		1.40			2 00	1 90
1½-in. lump	1 25						
3-in. lump	1 10	$1 10	1 10	$1.10	$1 10		
Mine-run	1 00	1 00	1 00	1 00	1 00	1 25	
Slack	1.00	0 75	0 75	0 75	0.75		

Anthracite—Buying of hard coal in the local market has been gradually improving, due, of course, to the demand for storage coal. The demand for this purpose customarily starts somewhat earlier than this, but has been delayed this season by the late shipments. The local dealers are reporting a good business for the current month.

Coke—The demand for this commodity is strong and the market firm in every respect, with local ovens working to their maximum capacity and behind on shipments. Connellsville is quoted at $2.80; Semet Solvay, $3; gas house, $2.75, all f.o.b. ovens.

ST. LOUIS, MO.

Conditions are about normal as they have been for the past few weeks, with perhaps a similar demand for bituminous coals. In connection with this, the price has also gone down. Standard 6-in. lump has gone down to 85c. and 87½c. at the mines, while 2-in. lump is at from 80c. to 85c.

These prices not only prevail in the city, but also in the country to some extent, on demurrage coal. In the Carterville sizes the lump and egg are being sacrificed at $1, both in the city and outside, while screenings have not increased any in value. Some of the washed sizes are a drug on the market, and are being sold at the same price as unwashed coals.

The prevailing circular is:

	Carterville and Franklin Co.	Big Muddy	Mt. Olive	Standard
2-in. lump	.....	.....	.....	$0.90
3-in. lump	.....	.....	$1.20	.....
6-in. lump	$1 15 @ 1 20		1 25	1 05
Lump and egg		$2 25	.....	.....
No. 1 nut	1.05 @ 1 15		.....	.....
Screenings	0.90 @ 0 95		.....	0.85
Mine-run	1 00 @ 1 10		.....	0.80
No. 1 washed nut	1 35		.....	.....
No. 2 washed nut	1 20		.....	.....
No. 3 washed nut	1 25		.....	
No. 4 washed nut	1 25		.....	.....
No. 5 washed nut	1 00		.....	.....

St. Louis prices on May anthracite are: Chestnut, $7.50; stove and egg $6.80; grate $655. Smokeless lump and egg is $4.45 and mine-run $4. Byproduct coke is $5 and gas house $4.75.

OGDEN, UTAH

There are probably instances where a low price would be an inducement to a large consumer to place an order, and this would offer temporary relief, but the bulk of the coal goes to dealers who at present are only buying single cars, and then only when absolutely necessary. In other words, the mines are working short time, which increases the cost.

Reports indicate that some coal will be stored during June and that July will probably be up to standard; however, this will be caused by the season of the year, and not by the low price. Present quotations for the entire territory are: Lump, $2.25; nut, $1.75; mine-run, $1.75, and slack, $1.

PORTLAND, ORE.

The mines in the Centralia district are all preparing to increase their output for which there is a good demand both in the Puget Sound cities and in Portland. One company is now putting out about 1500 tons daily and another has an output of 500 tons. The Rainer company's mine has an output of about 100 tons daily but this will be increased as rapidly as possible. Development work is now under way.

The coal market here is unchanged and as we now have

summer we be there is little probability of any great volume of business until consumers begin putting in coal for next winter under the storage rates, which are about 50c. per ton lower.

PRODUCTION AND TRANSPORTATION STATISTICS

NORFOLK & WESTERN RY.

The following is a comparative statement of the coal and coke shipments over the lines of the N. & W. Ry. for the month of April and the first four months of 1912 and 1913 in short tons:

	April		4 Months	
Destination	1912	1913	1912	1913
Coal				
Tidewater, foreign	223,220	147,917	589,202	535,211
Tidewater, coastwise	315,076	326,920	1,137,359	1,300,671
Domestic	1,325,259	1,068,383	5,395,002	5,401,914
Coke				
Tidewater, foreign	7,744	6,950	25,147	16,984
Domestic	108,601	122,675	509,919	561,469
Total	1,979,900	1,672,845	7,656,629	7,816,249

COAL MOVEMENT

The following is a summary of the fuel movement over the principal roads during March and the first three months of this year and last:

	1913			Three Months	
Anthracite	January	February	March	1913	1912
B. & O. (a)	195,667	161,676	77,049	434,392	571,754

*Bold face type indicate a surplus

NORFOLK & WESTERN RY.

The following is a statement of tonnages shipped over this road from mines in West Virginia and the commercial and company coal, for the month of April, in short tons:

Field	Shipped	Tipple	Total	Commercial	Company
Pocahontas	861,724	13,947	875,671	865,154	95,271
Tug River	183,995	2,498	186,493	156,336	30,157
Thacker	189,004	10,359	199,363	142,167	57,196
Kenova	48,839	5,042	53,881	45,713	8,168
Clinch Valley				130,565	12,493
	1,283,562	31,846	1,315,408	1,339,935	203,285

Shipments of coke entirely from the Pocahontas field, were 96,659.

BALTIMORE & OHIO R.R.

The following is a comparative statement of the coal and coke movement over this road or April and the first four months of this year and last year:

	April		4 Months	
	1913	1912	1913	1912
Coal	2,516,367	2,122,285	10,638,227	10,434,855
Coke	400,317	390,228	1,616,070	1,470,655
Total	2,916,684	2,512,513	12,224,297	11,905,510

FOREIGN MARKETS

GREAT BRITAIN

May 16—The market is somewhat unsettled owing to the uncertain position after the holidays. Business is quiet, but there is no alteration in values—which are approximately as follows:

Best Welsh steam	$5.40@5.52	Best Monmouthshires	$4.74@4.86
Best seconds	5.28@5.40	Seconds	4.62@4.74
Seconds	5.04@5.28	Best Cardiff smalls	3.60@3.72
Best dry coals	5.04@5.28	Seconds	3.36@3.48

The prices for Cardiff coals are f.o.b. Cardiff, Penarth or Barry, while those for Monmouthshire descriptions are f.o.b. Newport; both exclusive of wharfage, and for cash in 30 days—less 2½%.

PENNSYLVANIA RAILROAD

The following is a statement of shipments over the P. R.R. Co.'s lines east of Pittsburgh and Erie for April, and first four months of this year and last year in short tons:

	April		Four Months	
	1913	1912	1913	1912
Anthracite	930,592	990,865	3,674,096	3,579,602
Bituminous	3,796,432	3,291,985	15,914,179	15,461,920
Coke	1,230,979	1,079,046	4,987,304	4,190,832
	5,958,003	4,661,896	24,575,579	23,232,354

No Important Dividends were announced during the week.

COAL AGE

Vol. 3 NEW YORK, JUNE 7, 1913 No. 23

A time keeper who had been in the employ of a coal-mining company for three years, remarked on quitting his job that of the 400 men then enrolled on the company's pay sheet there were only 10 who were on the roll when he first entered service at that mine, although during all that time the average number of employees had been nearly constant.

Time keepers at most of our camps would have to make a similar statement if asked to investigate.

Coal miners are in demand everywhere; wages, living conditions and surroundings in general are pretty much alike at all mining camps, so why should a man remain at a place if he becomes dissatisfied? Of course it takes money to move, but if one's household possessions are few the money involved is a small consideration, especially to the average miner whose ability to value small sums of money hasn't been developed.

A little thought and investigation will convince most any one that the average miner could buy a cosy cottage with the money he wastes in moving, added to the loss of time incident to moving, during a period of 20 years.

What is being done to change these conditions? Much by the few, little by the many.

The few are beginning to realize that if a man's family can be induced to take an interest in a garden, a school, a church or a community, they will take enough interest in the man to see to it that he becomes satisfied with the community in which they live. Some have gone a step farther and arranged to reward a man for each additional year's residence in the camp; this appeals to the man as well as to the family and the interest aroused is spontaneous.

The most satisfactory system so far developed for accomplishing this, is to inaugurate old-age pensions with benefits directly proportional to the years of service preceding the arrival at the age limit. Upon the same principle, sick and accident benefits may be established whose benefits are governed by the years of service of the injured man. When interest is once aroused and the workers realize the benefits of such a system, it takes more than a misunderstanding with a driver or a drunken brawl with a "buddie" or a row with a check clerk to make a man pack up bag and baggage that he may try his luck in a new town.

To this plan of pensions one dissenting voice has been raised: John A. Fitch of "The Survey" objects to them on the ground that it gives the employer an unfair advantage over the employee in compelling him to remain at work *continuously* or lose the benefits of his years of service. To quote him: "This effectively prevents any stoppage of work as a protest against anything considered unjust by the workmen."

In trivial disputes, undoubtedly the pension would make itself felt, and its restraining influence would be beneficial to both employer and employee. In serious misunderstandings, however, its influence would probably be nil. "Give me liberty or give me death" is woven into the creed of too large a portion of Americans from all walks of life, to leave room for doubt as to what would occur if an unscrupulous employer attempted to ride roughshod over his employees.

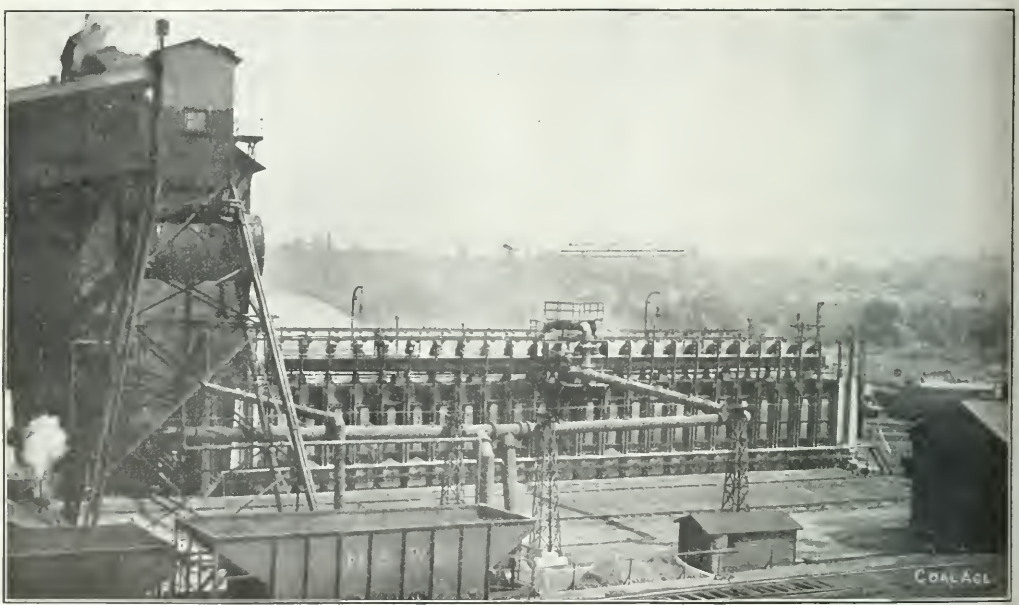
Semet-Solvay Coke Plant at Cleveland

By T. E. Pierce*

SYNOPSIS—A description of the plant and methods employed for the production of a metallurgical coke with the recovery of such byproducts as gas, tar, ammonia and benzol.

The Semet-Solvay Co., in April, 1909, entered into a contract with the Cleveland Furnace Co. to rebuild the coke-oven plant, which had been constructed about 1903 by Wilcox and Wagner, known at that time as the Retort Coke Oven Co. This plant had a series of irregular operations, which were never successful and in the fall of 1904, Dr. Rothberg rebuilt the ovens and the plant was run until about March, 1907, when it was shut down, as it was considered a failure.

The plant as rebuilt has 49 Semet-Solvay, silica-lined, recuperative ovens, known as the five-high, with necessary machinery for handling coal and coke, and apparatus for the recovery of tar, crude ammonia, gas and benzol. The capacity of the plant is about 600 tons of dry coal per day, producing approximately 430 tons of coke. This latter is used for metallurgical fuel by the Cleveland Furnace Co.



A Block of Byproduct Ovens

How the Coal Is Handled

All the coal comes in by rail and is unloaded at the track hoppers, from whence it flows to be crushed in a Williams hammer pulverizer and elevated by belt conveyors to the charging bin over the ovens. Due to a fire on Dec. 21, 1911, the coal-preparation plant is at present only temporary. The present practice is to mix approximately 70 per cent. high-volatile coal and 30 per cent. of low-volatile Pocahontas. To insure against shortage in coal deliveries the Cleveland Furnace Co. carries a stock of from 20,000 to 35,000 tons, which is handled by their ore bridge.

The ovens are of the well known Semet-Solvay type, the most characteristic feature of which is the system of horizontal heating flues in the oven linings which constitute the retorts. These are so constructed that they are entirely independent of the main structure of brick work and carry no load except their own weight. They can thus contract and expand independently of their surroundings and a single oven can be completely repaired while those adjacent to it are in full operation.

The ovens are heated by gas admitted to each of the top four flues through external pipes. The air for combustion is preheated by the recuperation system underneath each oven. The waste gas, after preheating the air, passes to waste-heat boilers and generates some of the steam for the operation of the plant. The gas and air entering each flue are easily regulated, as is the chimney suction on each tier of flues.

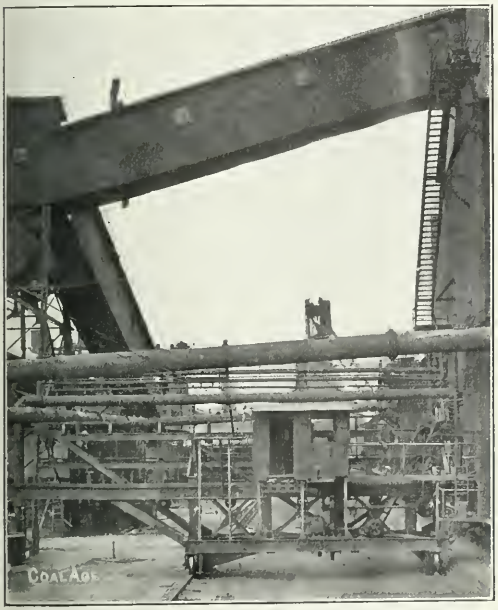
Coal from the larries is charged through the holes in the top of the ovens and leveled by an electrically driven leveler carried on the pusher. The oven is sealed and the coking process proceeds undisturbed for from 18 to 20 hr., the gases passing to the collector main on top of the ovens. When this process is finished, the coke is discharged in a single operation by the pusher, and distributed in the sloping-bottom quenching car where it is quenched.

*General superintendent, Semet-Solvay Coke Plant, Cleveland, Ohio.

The temperature of the oven flues is easily controlled at every point, thus insuring uniformity of product, which is essential in metallurgical fuel.

The easy control of the flue temperatures makes it possible to vary the daily production of coke and gas, excellent results being possible whether the coking time be shortened to 17 hr. or lengthened to 26 hr. or 28 hr. This flexibility of output is obtained without interfering with the uniformity of the product.

The horizontal-flue system makes it possible to maintain any desired temperature in the gas space above the coke without interfering with the complete coking of the coal. This is a matter of great importance, as the temperature to which the gas is exposed, after being driven



Coal Conveyor, Gas Mains and Coke-Pusher with Leveler Attached

out of the coal, controls the secondary reaction, upon which, to a great extent, depend the quantity and quality of the gas and tar as well as the quantity of ammonia and benzol which may be recovered.

Semet-Solvay ovens are described as 4-high, 5-high and 6-high, depending upon the number of superimposed horizontal flues upon either side. The 5-high ovens at this plant hold nine tons of dry coal to a charge.

The Manipulation of the Gas

The gas coming off in the early stages of the coking process is higher in both illuminating and heating power than that evolved later. At some plants there are two independent gas condensers and scrubbing systems, the one for rich and the other for lean gas. Double hydraulic mains are used, so arranged that the products of distillation from any oven may be turned at will into the rich or lean system. This makes it possible to keep the calorific power of the surplus gas very close to any standard which may reasonably be required. At this particular plant however there is but a single main with no arrangement for separating the gas.

The gas from the hydraulic mains is first conducted to air-cooled condensers, thence to water-tube condensers and finally through an intermediate water-tube condenser. The exhausters are placed immediately after the primary gas condensers. From the exhauster the gas goes to the ammonia washer and from thence to the oil washer. This is a tower about 60 ft. high, with wooden grids, onto which oil is fed at the top. The gas, passing up through a shower of oil, is brought into intimate contact with this absorbent, which removes any naphthalene or other condensible hydrocarbons.

The benzolized oil is pumped to the light-oil plant where the benzol and heavier volatile oils are distilled off. The absorbing oil, after being debenzolized, is cooled and returned to the benzol washer.

The debenzolated gas is piped direct to the gas holder, and from thence to the fuel-gas distributing mains for heating at the ovens. The fuel gas going to each block of ovens passes through a Venturi meter, equipped with a recording device, which gives a continuous record of consumption.

Coal Trestle and Track Hoppers

About 425 tons of coke are delivered daily in quenching cars to the Cleveland Furnace Co.'s bins; the cars being hauled direct from the ovens to the bins by a steam locomotive. The quenching apparatus spreads the coke in a thin layer, where it is quickly and thoroughly quenched by means of a large stream of water; this enables the production of a coke containing a low percentage of moisture. The quality of coke produced in these ovens is suitable for blast furnace and foundry purposes, whereas that obtained from the same coal in a gas retort is not adapted to these uses.

The byproducts, ammonia and tar, are recovered in the same way as from coal gas made in ordinary retorts. The quantity of gas and ammonia obtained from a ton of any given coal carbonized in Semet-Solvay ovens is somewhat higher than the quantity obtainable from the same coal when it is carbonized in horizontal or inclined retorts. The quality of tar is slightly different, as it carries less lampblack.

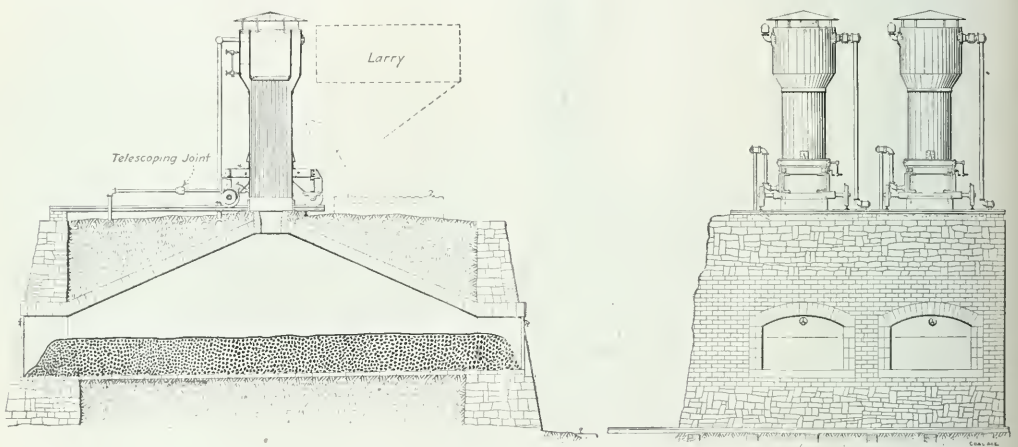
As the conditions of carbonization in a coke oven having horizontal heating flues are quite similar to those existing in a vertical retort, the results obtained with respect to byproducts closely resemble those secured with vertical receptacles of this kind.

A New Device for Waste-Heat Recovery

By A. T. Shurick

SYNOPSIS—It is estimated that the annual loss sustained through waste heat from coke ovens is approximately 30 million dollars. This is undoubtedly one of the gravest menaces to the basic principles of true conservation there is. The apparatus here described introduces a novel innovation by bringing the boiler to the heat instead of the reverse, along which lines all previous attempts at solving this problem have been conducted.

Many different plans have been evolved for the utilization of the waste heat from coke ovens with varying degrees of success. One of the chief disadvantages has been the heavy first cost and the excessive cost of maintenance. Furthermore, most installations of this character have been found notoriously uneconomical, due to the excessive radiation in the flues, it being safe to say that not to exceed 40 per cent. of the gross latent power available being realized.



Longitudinal Section and End Elevation, Showing Application of Apparatus to the Mitchell Oven

The Titlow Apparatus

In the apparatus described herewith, the inventors have ingeniously overcome many of these difficulties by taking the boiler to the heat instead of *vice versa*. The illustrations shown herewith will give a very clear idea of the construction and method of operation. It will be noted that the generators are quite simple, being similar to the ordinary vertical boiler, less the usual equipment of stack, firing door, grate bars, etc.

The generators are mounted on trucks carrying a framework adapted to hold them in an upright position over the trunnel heads of the coke ovens. Ordinary T-rails are laid at right angles to the larry track, one on each side of the trunnel head, and are supported at one end on the foundation wall and at the other by the pillars or wall between each oven, thus avoiding any possibility of any weight resting on the oven itself. These rails act as a track on which the truck or frame work supporting the generators travels. Each truck is equipped with sprockets, chain and crank so that the generators can be quickly and easily moved from their position over the trunnel head and permit the charging of the ovens in the regular manner.

The question of maintaining an approximately constant water level in the large number of small boilers units is, of course, one of prime importance. E. C. Morgan, of Chicago, has proposed a method which consists of placing a feed water main, without static head, located on a level with the proper water level in the boilers and connected to each through pipe with swinging joints. The principle is that the pressure being equal in the boiler and feed-water main the water level will be the same.

It is believed that pre-heating the feed water can be accomplished by a direct-acting heater of special design on the principle of the economizer, permanently locating these heaters at fixed intervals, mounting and regulating them in the same manner as for the boilers. These heaters would be of the closed type, all being served by a common feed-water pump. If super-heated steam is required the boiler design may be easily modified to meet this demand.

One main steam pipe and one main feed-water pipe are suspended under the rails which carry the generator, and flexible connections are made between each generator and the main pipelines. Automatic feed-water regulators are provided with each generator and also non-return valves on the steam and water connections, so that when a generator is moved off the opening over the oven, it does not in any way affect the operation of the balance of the generators on that bank of ovens.

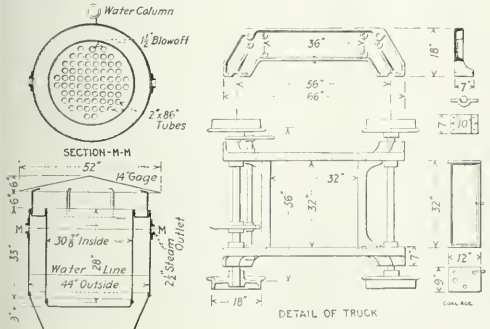
The steam pipe may be suspended outside of the foundation wall of the oven, if desired, but from actual tests it has been found advantageous to place both the main

water and steam pipes in the filling of the oven as it acts as a feed-water heater and also has a tendency to superheat the steam and prevent condensation in the pipes. When desired, a superheater for drying the steam may be placed in the top of each generator.

Operating Expenses and Results Obtained

Large batteries made up of these units can be taken care of by one man. With the arrangement outlined any number of generators may be connected to one feed-water supply pipe without regard to the variation in height of the different ovens. Also one steam pipe will carry all of the steam from a battery of generators direct to the power house.

As regards the efficiency of the apparatus, under practical working conditions, a thorough test of this was conducted at a coke-oven plant at New Salem, Penn. This test showed that each unit is capable of developing about 25-boiler horsepower, which in a modern turbine



Details of Boiler and Truck

would be the equivalent of approximately 50 i.hp. per oven. The inventors contemplate the construction of apparatus having 20 per cent. greater capacity than this.

As compared with the ordinary oven, it was found that the increased draft obtained by the Titlow process accelerated the burning time by 9½ hr. on 18-hr. coke. The yield in coke also showed a slight increase, and the ash was somewhat less. In a test conducted at the Shamrock Works of the Fayette Coke Co., near Uniontown, Penn., it was found that 40-lb. pressure was obtained in the boiler at the end of 30 min., after which it increased at a nearly uniform rate of 5 lb. per min., reaching 90 lb. at the end of 40 min.

Comparison with Byproduct Ovens

It is believed that this apparatus will effect a recovery of 17 per cent. of the heating value of the coal charged into the ovens during the year, and it cannot but compare favorably with the savings of the byproduct oven. In addition to this the comparative cost of the latter and standard rectangular or beehive type of oven must be taken into consideration, as well as the value or quality of the coke produced.

The largest saving from byproduct ovens is in the gas, which amounts to considerable in some territories where a reasonable price can be secured for it and sufficient demand exists. However, in the Connellsville region where the natural-gas resources are so great, it is doubtful if the gas produced from byproduct ovens could be sold except at a loss.

The tests already made have also demonstrated that these generators do not in any way affect the quality of the coke, but on the other hand it was found that an increase in coke yield was given, due to the perfect coking of the coal clear to the bottom of the oven, practically eliminating "soft ends."

Regulation of Power and Cost of Installation

The amount of heat utilized or power generated can be regulated by the number of steam generators placed in position for operation over the ovens. As it is the usual practice to charge one-half the battery of ovens on alternate days there is little variation in the total amount of steam generated per hour or day.

From equipment already purchased and quotations from various manufacturers, the inventors state that it will cost no more to install Titlow Waste Heat Generators and equipment than to construct and equip a regular generating plant of equal capacity. It is at least clear that with this apparatus there will be no boiler house, with its expensive equipment, to construct and maintain.

The cost for labor to operate the plants should be less than that of the regular generating plants, as there are no firemen to employ; one attendant should take care of from 50 to 60 generators; no ashes or cinders to handle, no expense for loading or unloading coal and no fuel to purchase.

The Effect of Knots on Timber

The accompanying table sums up the results of a series of tests made by the U. S. Forest Service, and published by them in *Bull.* No. 108. The tests were made to determine the effect of knots of different classifications on the crushing strength of certain varieties of timber. It will be noticed that in some cases the presence of knots seems actually to increase the strength.

RATIO OF RESULTS OF STRENGTH TESTS ON KNOTTY TIMBER TO RESULTS ON CLEAR TIMBER, STRENGTH OF CLEAR TIMBER TAKEN AS UNITY

	Compressive Strength at Elastic Limit per Sq.In.	Crushing Strength at Maximum Load per Sq.In.	Modulus of Elasticity per Sq.In.
Douglas fir:			
Pin knots	0.95	0 94	1 06
Standard knots	0 87	0 86	0 90
Large knots	0 78	0.78	0 71
Western larch:			
Pin knots	1 12	1 01	1 19
Standard knots	0 98	0 89	1.00
Large knots	0.98	0 85	
Western hemlock:			
Pin knots	0 96	0.97	1.00
Standard knots	0 94	0.91	0.97
Large knots	0 86	0.83	0.81

Pin knots are defined as sound knots ½ in. or less in diameter. Standard knots are defined as sound knots ranging from ½ to 1½ in. in diameter. Large knots are also sound knots from 1½ in. in diameter up.

Connellsville Coke Selling Problems

By W. L. Byers*

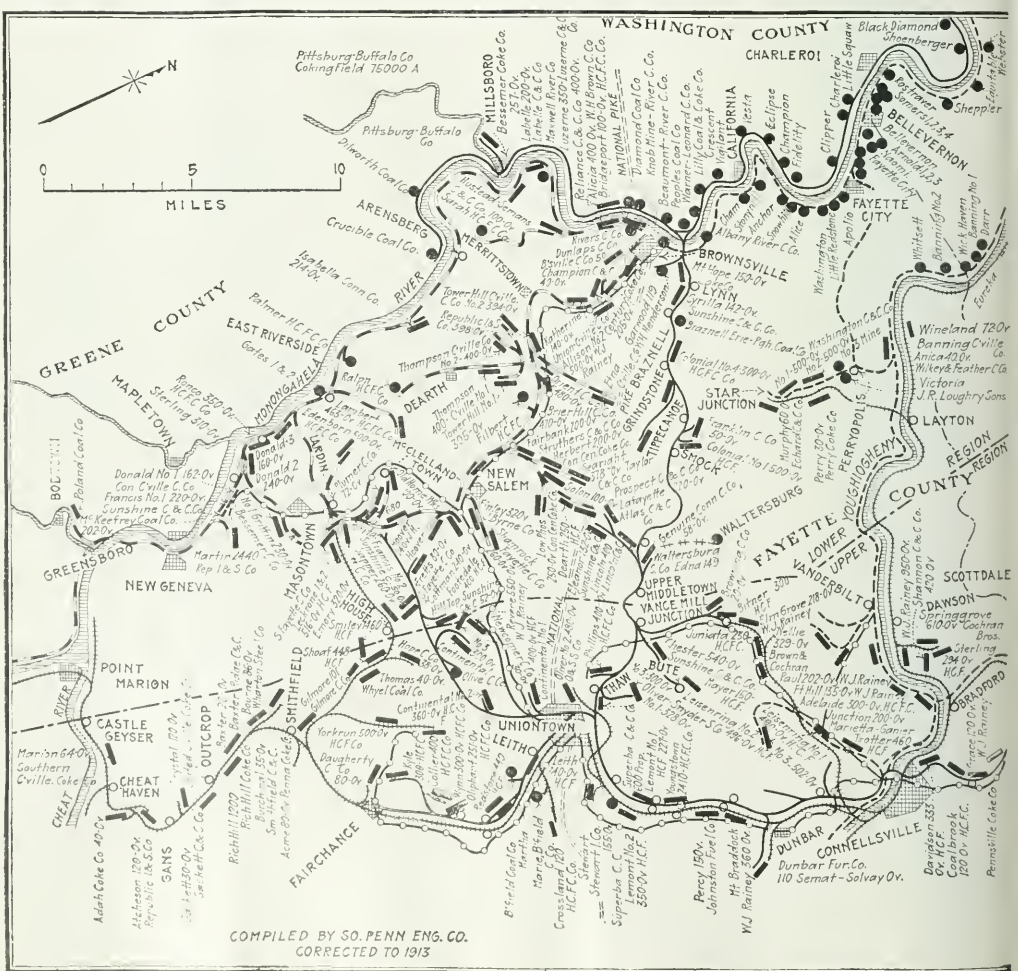
SYNOPSIS—There is probably no other article of the industrial importance of coke that fluctuates in price over such a wide range. The variations in a year have been as much as 200 per cent. Investments in the Connellsville regions have reached an enormous figure and costs of production are advancing rapidly. The demand for the product is erratic and herein lies the advantage of the large sales agency.

The independent or merchant ovens (those not allied with some consuming interest) of the Connellsville, Latrobe, Greensburg and Washington County Regions, can produce approximately ten million tons of coke annually. About eight millions tons of this is ordinarily sold for blast furnace purposes and the remainder for foundry, heating and smelting purposes.

*Sales manager, Producers' Coke Co., Uniontown ,Penn.

Distinguishing Features between the Upper and Lower Regions

By far the largest tonnage of blast furnace coke is supplied by the Connellsville Region which is divided into two divisions known as the Old Basin and the Lower Connellsville Region. The Old Basin Coal Fields are largely owned and operated by the United States Steel Corporation and the most of the merchant coke is supplied by the Lower Connellsville Region. The principal difference in the cokes is that Old Basin product is larger in size and higher in phosphorus than the Lower Connellsville Region, while the better grade of the latter



A Detailed Map of the Connellsville Coke Regions, Showing Location of Railroads,

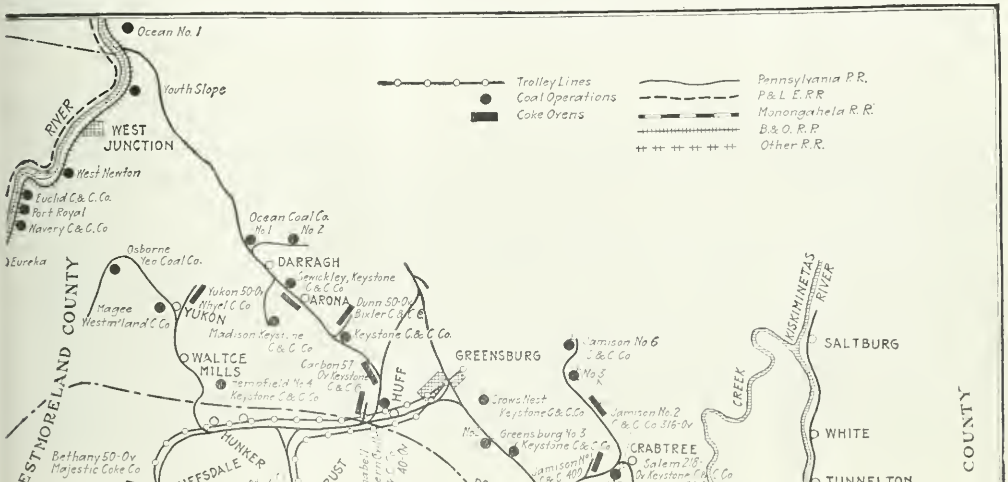
is lower in phosphorus, ash and sulphur. The Lower Connellsville Coke is smaller in size but has equally good burden-bearing qualities or structure.

The terms size and structure are often erroneously confused and it should be understood that they are entirely different. Upon the cell structure of coke depends its qualification for bearing the burden in the furnace, but this has nothing to do with the size of the pieces. Uniform small-size pieces of strong cell structure give the best results in the furnace if thoroughly cleaned of ashes and breeze. Some concerns are now crushing coke to standard size for blast furnace use. The chemical specifications mentioned in sales of blast furnace coke are usually the Bessemer Limits of not over 12% ash, 1% sulphur and 0.02% phosphorus.

The largest tonnage of blast furnace coke is sold through sales agencies. Sales direct from producer to consumer would seem to be the logical method, but unless the producer has a large output, the sales agency gets the better results. First, because the risk of shipment being suspended can be distributed over a greater number of furnaces with a large tonnage. A great many sales contracts are made subject to the operation of the furnaces; on account of accidents at the furnaces, the uncertainty of the life of linings, conditions of the iron market and many other unusual circumstances, the consumption of coke at the stack is more uncertain than the work at the ovens. Therefore, if a coke plant has a contract with one or two furnaces alone and they hold up shipment, the operations are either compelled to shut down temporarily at a heavy expense or go into the spot market. Whereas, if a sales agency has contracts with a number of furnaces, well scattered in different iron markets, it is improbable that they will all suspend operations simultaneously.

The Advantages of Large Sales Agencies

Sales agencies to be successful must be well financed



Mines and Coke Plants with the Number of Ovens, Corrected to the Current Year

so that they can pay the operation promptly on the twentieth to the twenty-fifth of the month following shipment. The furnaces do not always pay promptly but as a rule the credits in the furnace coke business are good and the losses small compared to the volume of business. It often takes the output of two small operations to supply one large furnace with fuel while the furnaces usually want their contracts placed, for at least the entire requirements of one stack, with one source of supply.

Furnaces require heavier shipments in the fall and winter than in the spring and summer largely because of the slowing up of the movement of cars due to the advent of bad weather, and a consequent greater number needed *en route*, especially on long hauls. When the furnaces are not getting delivery, no matter how many cars they have *en route*, they order more coke and then hold up shipment when the weather becomes better and the railroads begin to gather up the stretch. A sudden change in the weather may make a difference of fifty to one hundred cars needed in transit for one concern to furnish a supply or avoid car service.

Foundry, heating and smelting coke is generally sold through local wholesalers near the point of consumption. The most insistent complaints come from these men. They apparently take the stand that for 35c. above the price of run-of-oven furnace coke, in open-top cars, they should receive the heart of the oven, on 72-hr. charges, carefully wrapped in tissue paper and loaded in box cars. They want it to look good enough to eat, no matter how it works in the cupola. Some will insist on the coke being 1 ft. long and 6 in. thick and then pay a man two dollars a day to break it up with a sledge. Others want it small but thoroughly polished. It not infrequently happens that one car is refused at a foundry and another accepted when both have been loaded at the same ovens the same day, side by side. Some of the big foundries now have solved the problem of costs and quality and buy high-grade run-of-oven 72-hr. coke loaded in open top cars and gondolas if they do not have trestles for unloading. It is a wonder to the coke man they do not all do this.

The best furnace ovens do not make a practice of loading foundry coke. The foundries require selected 72-hr. coke, that is, the fronts and jambs taken out of ovens which have burned over from Friday until Monday, or, over an extra day during the week. This selection makes considerable coke which is not quite as hard and bright as the best and must either be sold as heating coke or put into the furnace grade, which is not fair to the latter, and the well posted furnace men will not buy what is left if they know it.

Smelters usually buy good structure coke, low in ash but not limited as to sulphur or phosphorus, although some smelting processes require regular blast furnace coke. Considerable smelting coke is shipped to the piers for vessels loading for points in Mexico and South America. A large trade in Pennsylvania and West Virginia coke is anticipated for smelting purposes on the western coast when the Panama Canal is opened. It is thought the freight rate will be lowered by $4 per ton under the present all-rail rate.

THE WASHINGTON MINE, AT STAR JUNCTION, A TYPICAL CONNELLSVILLE SURFACE PLANT

COSTS OF PRODUCTION

The cost of making coke has been advancing constantly in labor supplies, coal land and plant construction. Although not generally known there has been an advance in wages in the Connellsville Region since the first of the year. Pit timber is becoming more scarce while oil, wire rope and all supplies are showing substantial advances. Good coal land is also becoming more scarce each year, and as most of the new development is now at considerable depth, expensive shafts and power equipment for handling the coal and water are necessary. Washers are being installed as the lower grades of coal are developed.

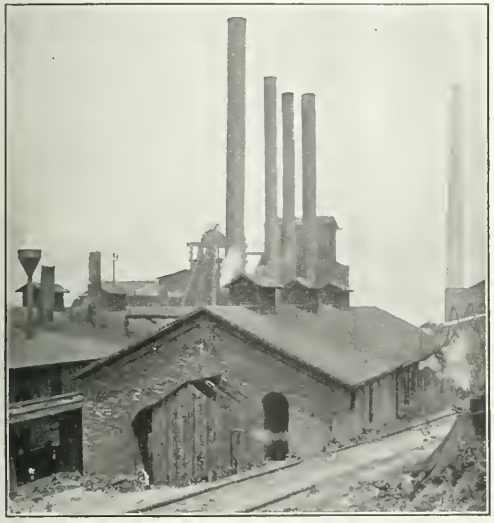
It now costs some modern plants 80c. per ton of coke in fixed charges for depletion of coal land, sinking fund for plant and equipment, interest, replacement and general expense which with a labor cost of $1.20 and 20c.

for supplies makes the total $2.20 net ton at the ovens.

The employers liability act now before the Pennsylvania Legislature, if passed, will add considerable to the present cost. One large mine explosion will put most of the present operators out of business. It is, however, excellent for the insurance people, who, it is understood, are pushing the bill.

In general it might be said that the capital invested in local coal land and equipment is enormous, and out of all proportion to the stability of the business. Plants with a fair coal acreage and oven capacity sufficient to supply one furnace frequently stand one million dollars and good-sized operations involve as high as seven million dollars capital. Sometimes they yield high returns but over a period of years the profits are not great.

The tricks of a trade are always interesting and the



Boiler Plant at the H. C. Frick Coke Co.'s Leisenring No. 2

coke business has a brand of its own. The oven owners say the coke brokers are all rascals, while the brokers retaliate by saying that the owners are farmers (*some* farmers, surely, as far as the capital is concerned). The brokerage business has in the past been profitable but with easy profit came also the greed which tempts men to overstep the bounds of honesty and fair dealing. Brokers at one time used to speculate on the producers coke under the conditions that if the spot price went above contract quotations, then the producer is compelled to ship the full tonnage, but when the reverse occurred only part of the tonnage would be taken. This has, however, about been discontinued and the producer now wants the profit if he takes the risk.

Brokers have frequently sold a brand of coke without either having the agency or any of the brand bought, expecting to get the order first and cover with the producer afterwards. Not infrequently they were caught and made to pay dearly for the coke or else they shipped other brands under the name of the one sold. Misbranding coke has frequently been practiced by the brokers on the furnace men and they are sometimes detected, which would be easily done if the furnace men would have their freight bills checkd with their notice cards. By buying one good brand of coke and two or more inferior brands the brokers can often "sweeten up" and get business by being able to quote a lower price than first-class coke brings and hence furnaces frequently buy some inferior coke in order to establish a low price.

Speculation in the coke market is very hazardous. In an active market it has been known to advance 75c. a ton in one day and a fluctuation of 200 per cent. in a year is certainly greater than occurs in any commodity of like industrial importance. In a general way it follows the demand for steel but labor conditions plays a most important part since it constitutes about 55 to 65 per cent. of the gross cost of coke on board the cars.

Susquehanna Relief Funds

A new kind of benefit fund, in which the mine workers themselves contribute a percentage of their wages for one day and the operators the rest, is being successfully tried at three of the subsidiary collieries of the Susquehanna Coal Co. in the anthracite region of Pennsylvania. Usually the miners remain idle on the day of a funeral. At these collieries the custom has been instituted of having the men work and contribute 20 per cent. of that day's wages to a fund for the family of the deceased while the company contributes $200.

The Susquehanna Coal Co. has had a relief fund in its main collieries at Mineral and Nanticoke ever since 1887, under which it pays out about $20,000 a year. This fund, which is managed by the company free of charge, consists of a graduated scale of assessments on the wages of the mine workers who are members, the company contributing an equal amount.

Membership is open to all employees, inside and outside, and the members are divided into four classes: Those receiving between $2 and $2.50 a day, those receiving between $1.50 and $2 a day, those receiving between $1 and $1.50 a day, and those receiving less than $1 a day. Members of the first class contribute $2.25, those of the second $1.75, those of the third class $1.25 and those of the fourth $0.75. The contributions are assessed as needed.

In case of accidental death $50 is paid from the fund for funeral expenses, $3 a week to the widow for one year and $1 a week for each orphan under twelve years of age for a like period. In case of accidental injuries, not fatal, $6 a week is paid to members of the first class, $4.60 a week to members of the second class, $3.30 a week to members of the third class, and $2 a week to members of the fourth class for a period of three months. No payment is made for injuries which do not incapacitate the member for a longer period than two weeks.

The existence of this relief fund for over two score years is the best recommendation of its value. The anthracite mine workers of Pennsylvania have a keen sense of perception and do not perpetuate any plan which does not work to their manifest benefit.

What is claimed to be the largest steam turbine in existence today is being constructed by Messrs. Brown, Boveri & Co., of Mannheim. It is a 35,000-hp. unit and will be coupled to a generator. It is intended for the extension of the municipal central electric-lighting station in the town of Hagen.

Coke-Crushing and Screening Plants

By F. W. Hetzel*

SYNOPSIS—Typical coke-crushing and screening plant used in western Pennsylvania. It is designed for a capacity of 300 tons in 10 hr. and costs about $3500 in place. Among the special features is feeding the elevator buckets directly, instead of into an elevator boot, which latter causes excessive wear.

Within the past five years a number of cheap and efficient coke-crushing and screening plants have been built for various coal and coke companies in western Pennsylvania. These have usually been placed between the ovens and the shipping track, so that the coke can be wheeled to the plant with a minimum of labor. These plants take the cleanup of the coke yard, or coke which is not salable for furnace or foundry use, and reduce it to the various sizes for domestic trade; or in case of delay in getting cars a portion of the total output can be crushed and elevated to the bins for storage. Fig. 1 shows such a plant and Fig. 4 gives a good idea of its construction. The crusher is usually set a little below the yard level for convenience in dumping in the coke. The crushing rolls are not large, 20 in. in diameter by 24 in. face being a common size and running at about 100 r.p.m. One of the rolls is fixed and the other backed up by springs. They are provided with teeth, which, to resist the abrasion of the coke, are cast in chills.

Fig. 1. General View of a Typical Western Pennsylvania Coke-Crushing and Sizing Plant

Mechanical Details

The crushed material falls down into a collecting hopper, which, for greater durability, is sometimes lined with hard cast-iron plates. A chute or nozzle on this hopper directs the flow of coke into the buckets of a vertical elevator, care being taken in the design to deliver the material directly into the buckets and not into the elevator boot; this saves wear on the buckets, which would otherwise have to dig the coke out of the boot, and at the same time it avoids unnecessary crushing of the coke and the production of too much "breeze."

The elevators designed for this service must be simple and durable. The steel buckets are of the continuous type fastened to a strong chain which has hardened steel renewable pins and bushings. As a further precaution against wear and to insure long life to the elevator, the sprocket wheels are of the flint-rim type manufactured by the Link Belt Co., with rims and teeth cast in chills. In order to avoid making "breeze" the buckets are shaped so as to pour the coke out instead of throwing it. A steel chute leads the coke from the head of the elevator into the rotary screen; sometimes this chute is

*Chief engineer, Link Belt Co., Nicetown, Penn.

made with a perforated bottom to take out part of the "breeze," but as the perforations are apt to clog with small bits of coke, it is better practice to leave all the sizing to the rotary screen.

To stand up to the work of sizing coke, a rotary screen must be properly designed and well built. The coke must be kept from contact with the working parts and from the parts which give strength to the screen. The perforated plates are made in sections and these are so arranged that they can be renewed without trouble by taking out a few bolts. The usual practice is to take dust or "breeze" out through 5/8-in. square holes, nut through 1¼-in. square, small stove through 1¾-in. square, stove through 2½-in. square and egg over the end of the screen.

The frame of the screen carries two steel tire rings, which run on chilled rollers, these rollers being mounted on pedestals and base plates to hold them in proper alignment. If these are not properly held, there is unnecessary wear on the rollers and tires and it takes more power

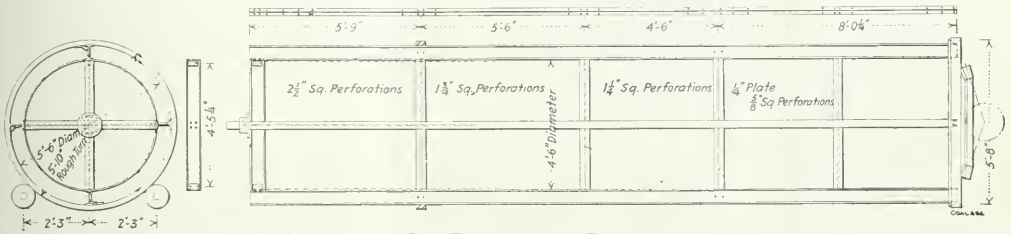


Fig. 2. Detail of 24-Ft., Four-Section, Rotary Coke Screen

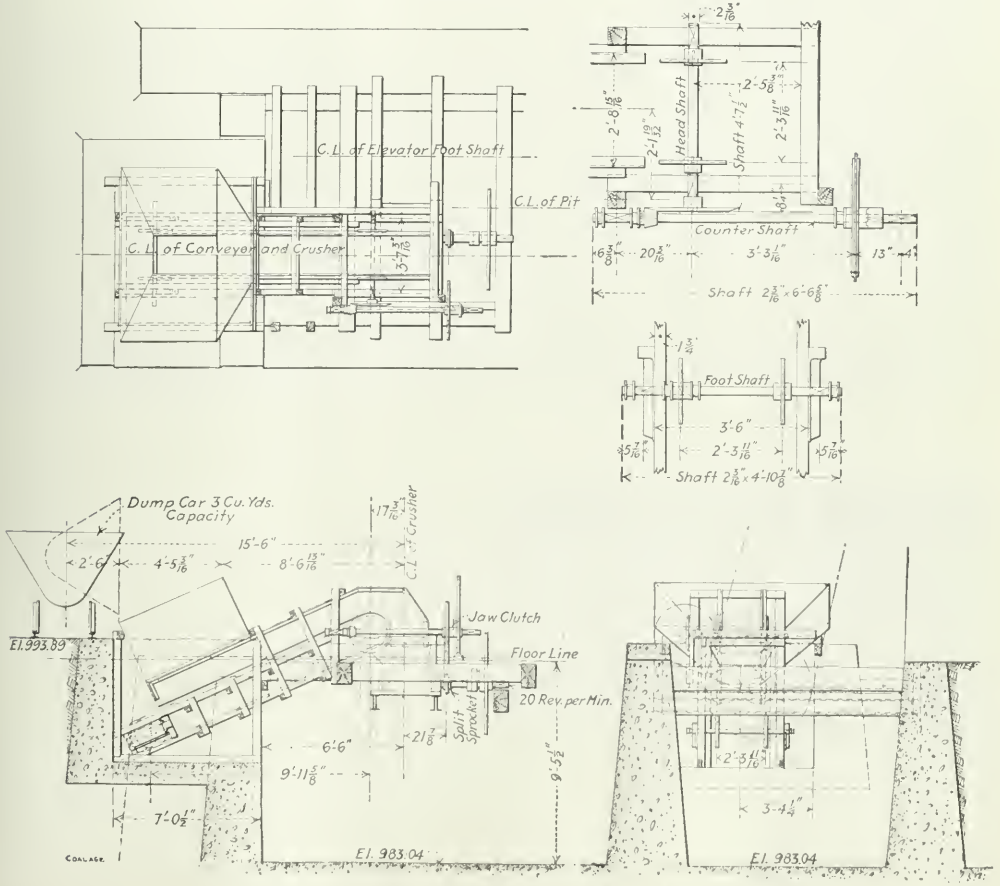

Fig. 3. Detail of Dump Hopper and 24-In. Apron Feeder

to drive the screen. The drive is usually by bevel gearing, the large gear being cast on one head of the screen; at the other end a thrust pin on the axis of the screen works in a fixed bearing and keeps the screen from running down hill. Fig. 2 shows such a screen 4 ft. 6 in. in

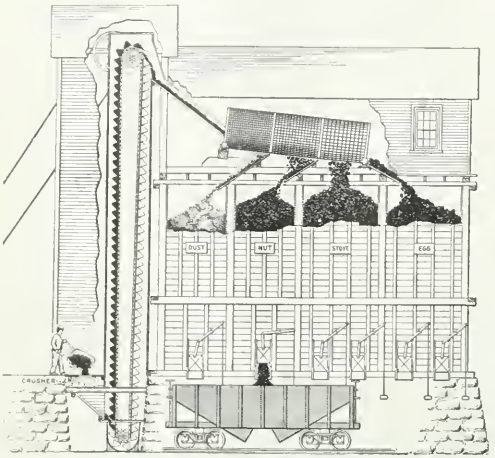

FIG. 4. SIDE ELEVATION, SHOWING METHOD OF SIZING AND LOADING

diameter by 24 ft. long adapted to make five sizes of coke and Fig. 5 shows a similar screen at work.

METHOD OF DRIVING

Referring again to Fig. 4 it will be seen that a single manila rope from the engine drives the whole plant, the rope running from the engine sheave to the top of the elevator, thence to the crusher and back to the engine through a tension carriage or slack adjuster. The screen is driven from the head of the elevator. This plan makes the driving simple and keeps the engine on the ground where it can be easily attended to.

In some plants the coke is received in side-dump cars, and to control the delivery from these cars to the crusher feeding conveyors are used. These consist of steel pans

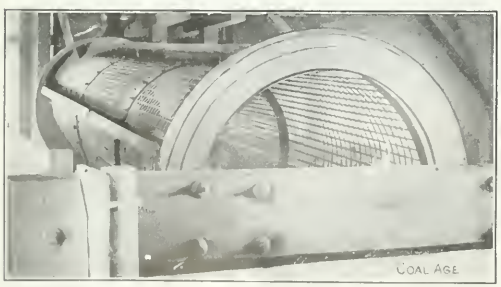

FIG. 5. VIEW OF THE REVOLVING SCREEN IN PLACE

attached to two steel roller chains running at slow speed. Fig. 3 illustrates such a machine. It is of advantage in permitting the cars to be dumped quickly and taken away and at the same time the regular delivery of coke prevents the crusher from being overloaded. If the feeder is not used a jam of coke in the crusher may cause the spring relief roll to yield and this may pass coke uncrushed, hence the advantage of the feeder in getting a better crushing and sizing of the coke.

The feeding, crushing, elevating and screening machinery of such a plant has a capacity of about 30 tons per hour and costs about $3500; when it is erected on a wooden structure with wooden bin it forms a low-cost, compact and efficient means of producing sized coke.

Permissible Explosives in Washington

Considerable progress has been made in the use of permissible explosives in this state, during the past year (1912).

In July, 1911, I took up with Doctor Holmes, director of the Bureau of Mines, the question of securing the assistance of the bureau in the effort to introduce permissible explosives into the mines of this state. Doctor Holmes detailed H. M. Wolfin, division engineer for the bureau in the northwest, instructing him to make a series of tests in several of the mines of the state. Much time and patience was expended in this work. As a result, the Roslyn Fuel Co. is today using permissible explosives exclusively, at their mines at Beekman. The Pacific Coast Coal Co.'s Coal Creek mine, at New Castle, and the Fairfax mine, at Fairfax, also use permissible powders almost exclusively.

Several other companies have used them at different times, but find it difficult to get the miners to adopt them. The miners claim that the use of these powders reduces their earnings. In the majority of cases, however, I do not think the miner has used the permissible powders long enough to thoroughly understand them. Another reason for their dissatisfaction is that a permissible explosive must be given a little more chance than the miner usually gives high explosives.

I sincerely hope that before long, nothing but permissible explosives will be used in the mines of this state; or, at any rate, that their use will be adopted in all gaseous or dusty mines. The following law, relating to powder and other explosives, was passed by the 1911 legislature:

EXTRACT OF WASHINGTON STATE MINING LAW

Be it enacted by the legislature of the state of Washington:

Section 1. Each person, firm, or corporation engaged in coal mining, requiring the use of powder or other explosives, shall provide (subject to the approval of the state mine inspector), at or near the entrance of each coal mine operated or at some suitable place near such work, a suitable distributing magazine for the storage of such powder or other explosives. There shall be posted upon such magazine a notice, printed in letters not less than 3 in. in height, that such magazine contains explosives. No person shall store or keep in any magazine mentioned in this section, any powder or other explosive in excess of one ton. In the case of coal mines, such powder or other explosive shall be issued daily, in quantities not to exceed the average used by each workman in one day, in proper receptacles. Any person or corporation violating or failing to comply with the provisions of this section shall be guilty of a gross misdemeanor.

Section 2. Any person who shall store or keep any powder or other explosive, in a quantity greater than 1 lb., in any occupied dwelling house or residence, or in any outhouse appertaining thereto within 300 ft. of any dwelling shall be guilty of a misdemeanor.

Note—From the advance sheets of the Report of the State Inspector of Mines, for 1912.

Beehive and Byproduct Coke in Alabama

By H. S. Geismer* and David Hancock†

SYNOPSIS—A statement of the quality and quantity of coke produced in Alabama and the coal from which it is made, together with a discussion of the washing of coal for the purpose of reducing the ash in the coke and the necessity for using dry coal for coking.

In 1880 there were 316 coke ovens in Alabama and these ovens produced 60,781 tons of coke, which was consumed in the four coke blast furnaces then in blast in the state.

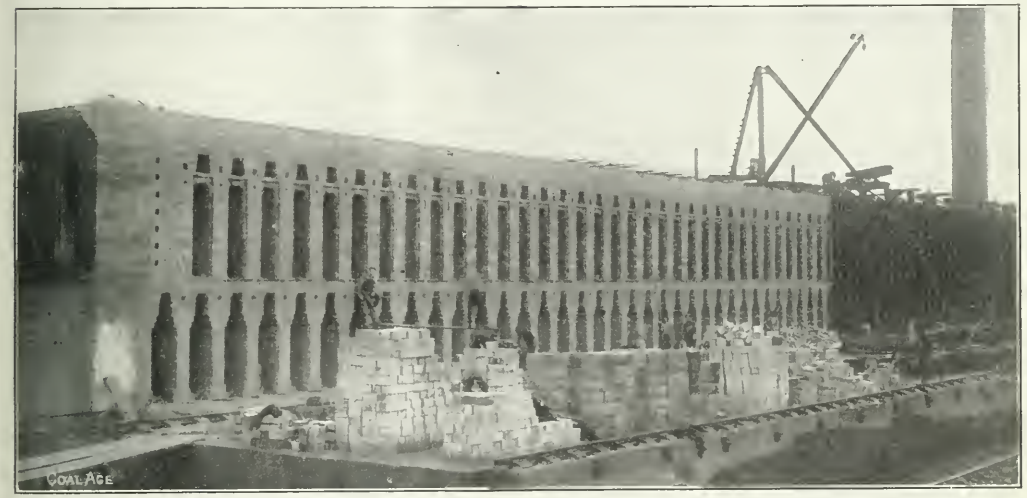
At the present time there are nearly 10,000 ovens of the beehive type in the state and 700 byproduct ovens, 420 of the latter being of the Koppers type and 280 of the Semet-Solvay type. In 1911, the last year for which statistics are available, the total coke production was 2,761,521 tons and by far the larger portion of this coke was consumed by the blast furnaces of the state, a comparatively small portion going to foundries and to markets outside of the state. All but about 1000 beehive ovens are owned by companies operating iron blast furnaces.

The annual capacity of the 10,000 beehive ovens is about 5,000,000 tons, if all were continuously in operation, and the annual capacity of the 700 byproduct ovens is about 2,000,000 tons under the same conditions.

The completion of byproduct plants has put thousands of beehive ovens on the idle list and while no separate statistics are available at the present time there is no doubt that over 50 per cent. of the present coke production of the state is from byproduct ovens. There have been no beehive ovens built in the state since 1907, while 460 byproduct ovens have been built since 1907, and two additional byproduct plants are projected.

Since almost the entire coke product of the state, now, as in the past, goes to local blast furnaces, the annual production follows closely the annual production of pig iron and incidentally follows the fluctuations in the pig-iron market, therefore, no great increase in coke production is to be looked for, but the rapid change from beehive to byproduct coke shows that the Alabama coke manufacturers are in the front rank of progress.

The coal used for coke making comes almost entirely from the Warrior coal field and from two principal seams of coal in that field. The Pratt seam was the first to be extensively developed in the state. This is a seam about 4 ft. thick, ordinarily, with one principal slate parting. It can be mined in a comparatively clean state and for many years mine-run coal from this seam was made into an excellent grade of coke. With the advent of coal washers it has become the general practice to crush and wash this coal, preparatory to coke making with the result that there is now made from this coal a quality of coke probably not surpassed by any blast-furnace coke in the world.



Eighty New Koppers Ovens Being Built at Woodward, Ala., by the Woodward Iron Co.

Seams of Coal Being Mined

The Big seam of coal, locally known as the Newcastle, Horse Creek, Blue Creek, Mary Lee, Jagger, etc., all belonging to the same geological horizon, is now extensively mined and the coal made into coke. It is a dirty seam carrying numerous slate partings as well as irregular lenses of slate and requires washing to make a satisfactory grade of coke. With the improved coal-washing machinery now in use a good quality of coke is made from it, the coke being in many cases but slightly inferior to the Pratt. The Big seam is generally from 6 to 12 ft. thick, and, although the loss in washing is large, the washed product is produced at less cost than Pratt washed.

The necessity of washing the Big seam coal has led to a close study of the washing problem and to extensive ex-

*Consulting engineer, Birmingham, Ala.
†Consulting engineer and chemist, Birmingham, Ala.

Byproduct Coke-Oven Plant, Koppers System, Near Corey, Jefferson Co., Ala.

perimenting. Three important washing machines, the Robinson-Ramsay, the Stewart, and the Montgomery were first tried out on a large scale in this state. Other types of coal washers have also been tried and are in successful operation.

As illustrating the extent to which coal washing has been introduced into the state it is interesting to note the character of coal used for making coke in 1911:

15.7 per cent. was mine run coal unwashed.
29.2 per cent. was mine coal crushed and washed.
0.1 per cent. was slack unwashed.
55.0 per cent. was slack washed.

Slack is usually understood as comprising all coal smaller than 2½ in., though the practice is quite varied at different mines. Slack screens as small as ¾ in. are frequently employed, as well as bar screens of 1½-in. opening, which will pass a certain amount of material that will not go through a 2½-in. round perforation. The coal over the slack screen is either crushed and mixed with the slack or else sold for fuel coal.

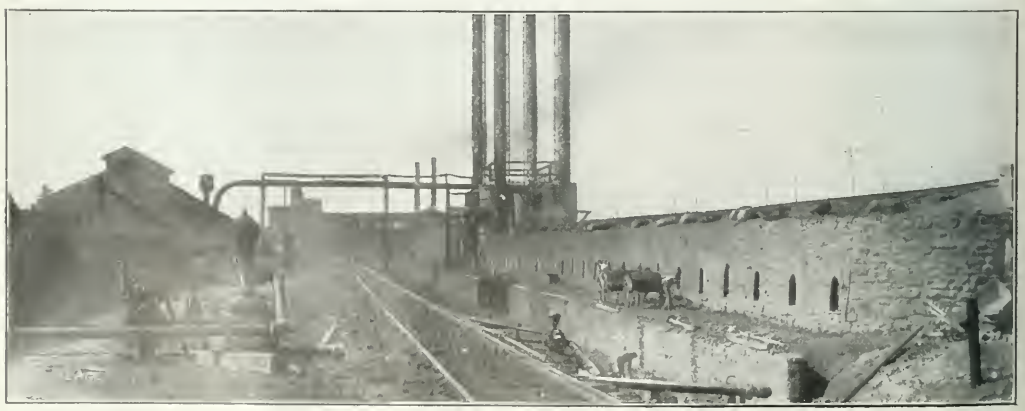
The location of coal washers in close proximity to the coking plant has brought forth a peculiar problem, viz., that of reducing the amount of water in the washed coal to a constant and satisfactory figure.

Necessity for Drying the Coal

The wet coal will contain from 1 per cent. to 13 per cent. of water and for some time after charging one can notice a considerable stream of water running out of the oven door. The oven is thereby chilled and often the yield of coke as well as the quality is affected. Also, the variable quantity of water makes it impossible to keep accurate records of the tonnage of coal charged and consequently no reliable figures as to yield of coke can be compiled. This trouble has been obviated to some extent by allowing the coal to stand in cars or in large storage bins for 24 to 36 hr. before charging into the ovens; in this way a fairly constant though still somewhat uncertain quantity of water is retained in the coal. Experiments on an extensive scale have shown that on an average about 5 per cent. of water is retained in the coal after standing for about 36 hr. This percentage is influenced to some extent by size of the coal, but is fairly constant for coal coming from the same washer.

Recently a centrifugal dryer has been placed on the market by the American Concentrator Co., that will handle 50 tons of washed coal per hour containing 13 per cent. of water and reduce this uniformly to 5 per cent. These machines will be given a try out in the Birmingham district in the next few months.

The average yield of coke from Alabama coal in 1911 was 62.6 per cent., recent years having shown an increase from about 59 per cent. The increase is due largely to the increased percentage of byproduct coke, the yield



Utilization of Waste Heat from Beehive Ovens

Showing Property of the Tennessee Coal, Iron & Railroad Company

from Pratt and Big Seam coal in beehive ovens being still about 59 per cent. Yields lower than this are found on individual plants and are generally the result of inefficient supervision of the coke-oven operation, variations in the size of the charges, poor drafting and daubing, leaky oven doors, imperfect or slow sealing of the ovens after burning in, etc.

Systematic records so placed that they are available and intelligible to the foremen in charge generally result in noticeable improvement both in quality and yield.

The yield on byproduct plants is much higher, averaging around 70 per cent., though the screening operations which are necessary for preparing a suitable coke for blast-furnace use, by removal of a large amount of small coke, reduce this figure somewhat. Probably 66 per cent. would be a fair average for the yield of screened coke at the byproduct ovens of the state.

It is often erroneously assumed that the analysis of a coking coal will give exactly the yield which may be expected from it, by simply computing the total of ash and fixed carbon; a corollary to this fallacy is often worked out by which the ash of coke is computed by dividing the ash of coal by the known per cent. of yield. Such calculations neglect entirely the variable production of ashes and breeze at the ovens.

A test made at one of the Alabama coke plants shows a very peculiar condition, as well as the danger of making such assumptions as those mentioned. At this plant a very regular coke product was being made and analyses of the coke over a long period showed an average of 14.50 per cent. ash, and a yield of about 60 per cent. The coal used was Big seam washed and ran regularly 12 per cent. ash. This coal theoretically would produce coke running 20 per cent. ash instead of 14.50 per cent. It was decided to investigate this, so two ovens were selected for the test and a tight floor built in front of them so as to retain all ashes and breeze. The coal charged into the ovens was weighed and analyzed and everything from the oven after a 72-hr. coking period was also weighed and analyzed.

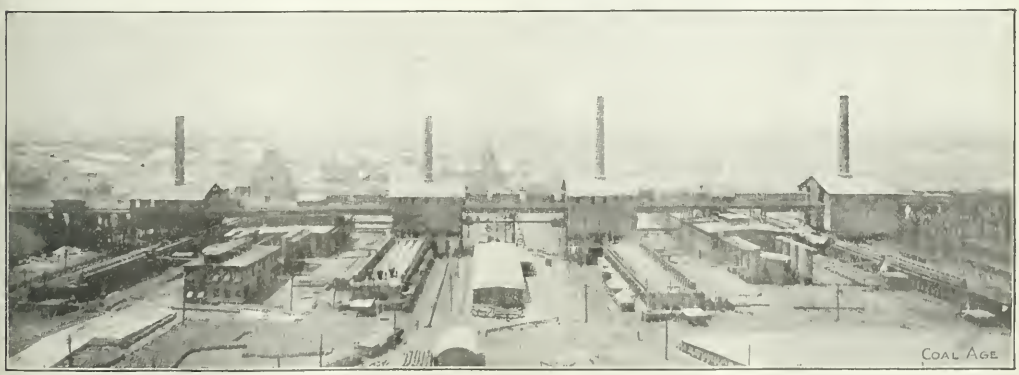
Ash Content of the Coke

The following results were obtained (per cent. of original dry coal):

60.6 per cent. screened coke, ash contents	14.56 per cent.
2.6 per cent. dry breeze, ash contents	31.56 per cent.
4.1 per cent. dry ashes, ash contents	49.34 per cent.

The amount of ash represented by these products was then calculated to be 11.72 per cent. of the original weight of coal (dry basis), while the analysis of the coal before charging showed 11.90 per cent. ash.

The explanation of this is that with this particular coal, the ash-forming impurities are to a great extent noncoking, and in some peculiar way are segregated from the coke during the coking operation and appear in the

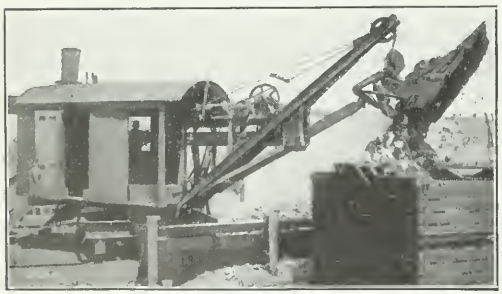


Semet-Solvay Byproduct Coke-Oven Plant, Ensley, Jefferson County, Ala.

910 Beehive Coke Ovens at Thomas, Ala., Largest Group of Ovens in the South. Owned by the Republic Iron & Steel Co.

form of an unusual amount of ashes at the oven instead of going into the body of the coke. This action probably takes place to a greater or less extent with all coking coals, and, unfortunately, makes it impossible to determine in advance of actual trial to what extent reduction of ash by improved coal washing would be reflected in the reduction of ash in the coke.

For instance, in this case improvements in the coal-washing plant were contemplated, amounting to about $60,000, by which it was expected to reduce the ash of this coal to about 8.5 per cent., but in view of the results shown by the test it was concluded that no lowering of the ash of coke would be effected thereby, but only a diminution of the amount of ashes made at the coke-



Steam Shovel Loading Coke

oven plant, and the only saving would be the saving in expense of disposing of the ashes.

Many analyses and physical tests of Alabama coke have been published from time to time, some of these were of special samples, some others from locations not typical of the district. The writers believe that the following analyses and physical tests represent a fair average of the quality of the coke produced by the principal operations on the Pratt and Big Seam:

(Dry basis)	Pratt Coke	Big Seam Coke
Volatile matter	0 96	1.27
Fixed carbon	91 34	84 64
Ash	7 70	14.09
Sulphur	1 33	0.73
Physical tests:		
Apparent specific gravity	1.30	1 00
True specific gravity	1.92	1 63
Per cent. of cells by Vol.	36.0	43.0
Ultimate strength per sq.in.	1600	1400
Load strength (factor of safety 4)	450	425

The above are representative figures from the records of operating companies and are averages of many separate results. All are on coke produced from washed coal in beehive ovens. Byproduct coke is usually superior to beehive in density, but does not have the silvery bright appearance characteristic of good beehive coke.

The products obtained from the byproduct ovens of the state with Pratt coal will run on an average about as follows:

Screened coke	66 to 70 per cent.
Breeze and small coke	6 to 4 per cent.
Ammonium sulphate	20 to 25 lb. per ton of dry coal
	to 9 gal. per ton of dry coal
Gas	9000 to 10,000 cu.ft. per ton dry coal

About one-half of the gas is needed for heating the ovens and the balance is either wasted or used outside of

Thomas Type of Coke Ovens at Coalburg, Ala. Probably First Mechanically Drawn Ovens in United States

the coke plant. The saving, which can be accomplished by coking in the byproduct oven in this state, depends very largely upon the use which can be made of the surplus gas.

Erratum

On p. 766 of our issue of May 17, in the first paragraph of the article entitled "An Effective Slate Picker," the following statement is made: "The accompanying photograph shows a Mason & Allen flat slate picker handling material containing 20 to 32 per cent. flat slate, etc." This should read "handling material containing 20 to 22 per cent. flat slate, and rejecting 18 to 21 per cent. in the process."

Improving Coke from Beehive Ovens

By Newell G. Alford*

SYNOPSIS—An article suggesting lines for the practical investigation of the causes for the variation in the quality of the product produced in beehive coke ovens, and the means for maintaining a uniform product.

To standardize operating methods about a beehive coke-oven plant is a problem which superintendents and managers find themselves periodically facing. Of course, this applies best to operations where a "coke inspector" is not overseeing the work and consulting with the coke boss. This overhauling of operating methods is apt to involve the personal supervision of an engineer or one higher up, and offers material for a lengthy article. Therefore, only the more common difficulties are dealt with in this short article.

To begin with, the distress is likely to start with some sultry letter addressed to the general superintendent in somewhat this tone.

Dear Sir:

We beg to advise that the last two consignments of coke received from your ovens are far from satisfactory. Our laboratory analyses show that the fixed carbon for the past week has been averaging 78% instead of the 84%, which you guaranteed in our contract. Unless your coke is brought up to this latter figure at once, we shall be forced to make other arrangements for our furnaces.

The general superintendent, of course, gets the gist of the letter in one reading and summary action follows. Needless to say, an interesting bit of dialogue ensues between the superintendent and the coke boss. For the sake of discussion let it be assumed that the letter to the superintendent was a true statement of facts.

Inspection reveals that the moisture in the coke may be noticed in touching it, an inch or more of "black butts" marking the ends of the lower sections, while the color is a dirty gray and the cell structure spongy.

If the coal used in charging the ovens analyzes the same as it did when better coke was produced, it is safe to lay the cause of the trouble to the oven operation. Under these conditions the coke described above is usually the result of cool ovens, together with insufficient combustion. The analysis of the coke will, therefore, show high moisture and volatile matter with a low fixed carbon.

It is understood that a cool oven will produce a slow ignition and feeble combustion of the coal with which it is charged, and that it will require a longer time to complete the burning than an oven which was hotter at the start.

Overquenching the coke not only injures the coke but destroys a certain amount of the heat that would be available in the bottom tile of the oven, in order to start the combustion of the next charge of coal. The heat destroyed varies with the temperature of the bottom tile before the coke is quenched and the amount of excess quenching.

Increasing Heat of Oven

After the coke has been drawn the first step is to raise the heat in the oven preparatory to charging the coal. Radiation and reflection of heat from the dome and floor are contributary elements for regaining heat. Following the drawing of coke from an oven, pieces of coke varying in size from chunks to breeze may be seen on the oven floor where they have been left by the puller. Good practice has shown that sweeping the oven floor clean with a steel broom will aid in the radiation and increase of heat.

To increase the heat the oven must be closed by placing a sheet of iron snugly in the oven doorway and the lid on the trunnel head. This not only excludes the outside air but hastens the rise in temperature, so that after standing an hour and a half or two hours in this state before charging, the inner temperature will have risen from approximately 150 deg. F. to 600 deg. or thereabouts.

With the oven ready for charging, further features of interest are brought to notice. When the sheet iron and lid are removed, the dazzling of heat can be seen within, while, perhaps, the bricks in the dome may be tinged with an orange glow. If dry coal is charged, gas may be generated so readily that a slight explosion may take place, and a streak of flame be emitted from the top of the oven door. This is a good indication, as it signifies quick combustion, the very result desired.

However, if washed coal is being used in the ovens, another difficulty is likely to arise. The benefits derived from sealing an oven and letting it stand over between charges can be entirely effaced by charging coal which is too wet. Unless dried after washing, coal is scarcely ever fit for charging into the ovens the same day that it comes from the washer. If there is more water present in the coal than the heat of the oven will evaporate before the coal ignites, the same result will be obtained as in the case where the oven was too cool before charging.

Size of Charges

Another feature well worth considering is the size of the charges. There are two or three gauging devices for sale which measure the discharge from the slack bin into the larry, which insure a standard charge for all ovens burning the same length of time. One of these devices, known as the Hughes Patent Charge Cutter, can be set to gage correctly for any charge varying from 48 to 96 hours per oven. This charge-measuring machine is in successful operation at the plants of the Wise Coal & Coke Co. and the Colonial Coal & Coke Co., both of Dorchester, Va.

Tests should be made upon the ovens to determine the exact size of the charge which burns off best in a given period, the determination to be governed by analyses. By coupling the results of such tests with the use of a charge gager, underburning and overburning of the coal may be avoided.

Underburning, on the one hand, produces coke such as that described in the hypothetical case at the beginning of this article. Overburning, on the other hand, results in the waste of fixed carbon, and yields as well a brittle coke.

*Assistant chief engineer, St. Bernard Mining Co., Earlington, Ky.

Quenching the Coke

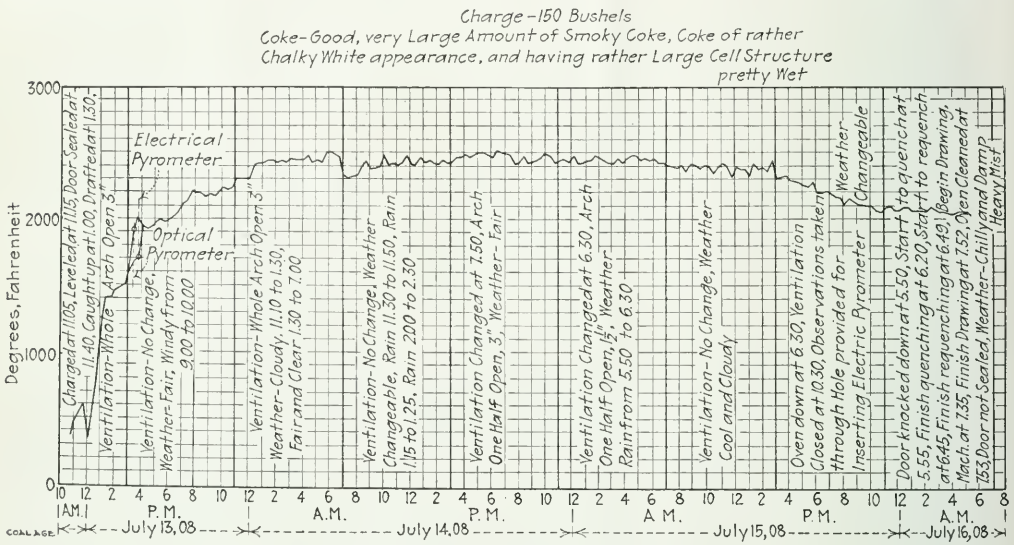
The quenching of coke is an important department of the process. Where coke is drawn with electric-pulling machines, quenching is usually done by one or two men. But where this is not the practice, the watering is done by the pullers, and, consequently, a variety of quenching methods are apt to be in vogue.

Coke otherwise perfect may be spoiled by watering it after it has been drawn from the oven. The man quenching the oven should make a careful distribution of the water over the incandescent coke, and the quenching should only go to the point of extinguishing the fire, when the pipe should be pulled from the oven. If the water is thrown on the coke for a longer period than this, saturation will follow with the consequent cooling of the oven.

If the fire in the coke is not put out with the first application of water, the coke should be requenched while air must enter at the door of the oven to permit a brisk combustion until the active generation of gases has subsided. Following this the air space at the top of the door is to be gradually decreased until the flaming on the surface of the incandescent coke ceases. The oven door should then be tightly sealed with the lid placed on the trunnel head until the coke is quenched.

Failing to put the lid on the trunnel head, neglecting to repair chinks that occur between the jamb bricks, or not sealing the oven door thoroughly, result in the burning and consequent waste of fixed carbon.

Coke, which shows upon analysis a high per cent. of volatile matter, may also be the result of uneven leveling of the coal. The process of fusing and coking begins with the surface of the coal and continues downward through the mass to the bottom. If the charge of coal has been unevenly leveled, the vertical sections of the charge being of varying thicknesses, will not all burn off



Temperature Curve of an Oven

inside the oven. If watered on the ground after being drawn from the oven, the moisture does not evaporate from the coke. An analysis of such coke may show the moisture varying from 2 to 5 per cent., or, perhaps, even more.

In the very nature of things, air is necessary in the beehive process to furnish the requisite heat for the coking of the coal by the combustion of the volatile matter. Air is, therefore, admitted through the door of the oven to supply the necessary oxygen to secure complete combustion of the gases thrown off by the coal while coking.

Experience has proved that the key to the ventilating problem is this: The supply of air entering the oven must be adjusted so as to give a complete combustion or as nearly so as is possible in practical work. Observation shows that the largest volumes of gas are liberated by the coal in the early stages of the process, varying with the amount of volatile matter in the coal. Enough in the same length of time. Thus there will be patches in the oven, which will be underburned coke, with "black butts" and dark-colored masses running high in volatile matter.

A good grade of coke may be readily identified by the presence of silvery globules on the upper half of the section, which, when held in the sunlight, often have a tendency toward iridescence. The silvery globules are the deposits formed by the gases from the volatile hydrocarbons in the coal during their upward passage through the fissures of the incandescent mass which has been already coked.

A high per cent. of ash in coke may be caused by a poor interior condition of the oven. The intense heat sometimes breaks the silica brick in the crown of the oven, bits of brick and brick dust falling upon the coke. The very best grade of silica brick should always be used in oven crowns, as these will stand the amount of heat with which they are likely to come in contact.

Variation in Coke

The records of two differing conditions, under which the same coal was coked, follow, the marked contrast in the coke produced being shown in each case by the analyses.

Test No. 1

Conditions: Oven was not sealed and was allowed to stand over prior to charging. The bottom was not swept out. An hour elapsed before the coal ignited. There was insufficient ventilation at top of door in the beginning, which was not altered throughout the process. The charge was burned off long before door was sealed. The lid was not used at all. The coke was overquenched. Brick dust was present on the top of the coke. Black Butts occurred on the coke near the door jamb. The coke was too dark in color and the cell structure spongy.

ANALYSIS

	Per cent.
Moisture	2.71
Volatile matter	3.91
Fixed carbon	78.62
Ash	14.76
	100.00

Test No. 2

Conditions: Oven was in good repair. Hot ovens were on both sides. The bottom of the oven was cleaned out. Oven was sealed, standing idle 2½ hours prior to charging. Oven dazzling hot. Leveling very even. Coal ignited 4 min. after charging. Whole arch of door given 3 in. draft in the beginning. Combustion decidedly more brisk than in test No. 1. Draft was diminished gradually until charge ceased flaming. Carefully quenched. No black butts. Color-metallic gray with luster. Coke bore silvery globular deposits on upper half of section.

ANALYSIS

	Per cent.
Moisture	0.61
Volatile matter	1.92
Fixed carbon	85.17
Ash	12.30
	100.00

With the preceding data in mind, the following nine questions will give the investigator a clue to his beehive-oven trouble, if the cause lies in the operation of the oven:

1. Are the ovens sufficiently hot when charged?
2. Are proper steps taken to regain heat between charges?
3. Are charges of uniform size?
4. Are charges too large or too small for the length of time that the ovens burn?
5. Does the ventilator attend to his duties?
6. Is the proper amount of air admitted to the ovens?
7. Is the coke properly quenched?
8. Are the ovens in good repair?
9. Are the charges evenly leveled?

A few years ago one of the large West Virginia coke-producing companies made a thorough investigation of the conditions which tend to produce the best coke, the research including pyrometer readings on the temperatures of the ovens, readings being taken every half hour and the temperatures plotted to show the variations graphically.

From the accompanying figure, an idea can be had of the rise and fall in temperatures throughout the coking process. The electrical pyrometer was used until the heat became strong enough to effect the optical pyrometer. The readings were taken by three men, each working an eight-hour shift.

The maximum temperature in the curve shown is 2520 deg., while in some instances where ovens are hotter before charging they frequently reach 2800 degrees.

Machinery for Beehive Coke Ovens

By E. C. Ricks*

SYNOPSIS—The three coke-drawing machines at present on the market are briefly described and their principal advantages and shortcomings set forth. A few short paragraphs are also devoted to a successful leveling machine.

The purpose of this article is not to enumerate the various machines (almost a score of them) which have been designed for drawing coke from beehive ovens, but to outline briefly the operation of the three types at present in everyday operation.

The Hebb machine is one of the "over-drawing" type, operated by electricity, and pulls the coke from the oven onto a chain and slat conveyor, which deposits it in railroad cars. The machine is a very heavy affair, but performs its work fairly well although it has attained comparatively no commercial success. This has been due partly to "squabbling" among the stockholders, but mainly on account of the cost of the machine, which is necessarily much greater than that of the other machines mentioned below, while it, seemingly, has no advantages worth mentioning, to offset the additional expenditure. To the best of the writer's knowledge, there are five of these machines in use today; one at Jones & Laughlin's plant in Pittsburgh, and four at the plants of the Thompson Connellsville Coke Co., at Republic, Penn.

The Stauft machine—At present, there is only one of these in operation, it being located at the plant of the Taylor Coal & Coke Co., near Uniontown, Penn., of which plant, the inventor, D. B. Stauft, is general superintendent. This is also of the "over-drawing" type, similar to the Hebb machine. The conveyor part of this apparatus works on the same principle as the Hebb and Covington machines and is operated by electricity; however, air is used on the extractor part, not only to draw the coke, but to propel the device along the track in front of the ovens.

The Stauft machine, while yet in its infancy, is doing good work and attracting some attention. As to how well this machine will continue to stand up to everyday work, drawing its capacity of ovens, remains to be

*Uniontown, Penn.

seen; however, the machine at Taylor works has been drawing 46 ovens per working day, for the past several months. The supreme test of time and operation under varied conditions, through which this machine will have to pass, before it can be considered a commercial success will be watched closely, and with interest by all coke operators.

The Pioneer Machine Has Attained Success

The Covington was the pioneer machine to attain commercial success and is, today, the only one for drawing and loading coke from bee-hive ovens, which has been extensively adopted, there being approximately two hundred of them in operation throughout various sections of the United States and Canada, representing an investment of more than a million dollars.

From the crude machine operated by steam, shown in Fig. 1, the Covington has had its ups and downs, working under all imaginable conditions; being redesigned

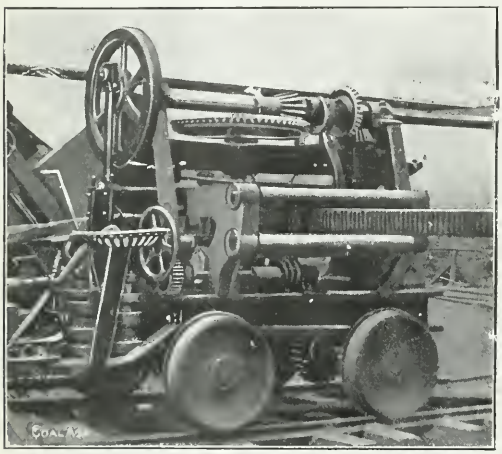


Fig. 1. The First Successful Covington Coke-Drawing Machine

from time to time, better material being used in its construction, whenever experience proved a change necessary for its betterment. So well have coke operators taken to this machine, that it has been necessary for the makers to build large additions to their plant twice within the past few years. Now they have a capacity of one coke machine every two days.

The Covington Machine Co., of Covington, Va., are the manufacturers of the Covington machine. This company reports that its entire output has been sold from three to four months ahead, for the past year. Although there are about fifty concerns using these machines, one of the best evidences of their utility is the fact that the H. C. Frick Coke Co. has given repeat orders five or six times. At present their total investment in these machines is close to a half-million of dollars.

The Covington machines are of the "under-drawing" type and are operated by electricity; every mechanical movement of the latest model being power driven.

The capacity of all three makes of machines above mentioned is from four to six ovens per hour. The coke being drawn, screened and loaded into cars, including shifting of the machine, etc., within the period mentioned.

The total labor cost for drawing an oven in the Connellsville region, where most of these machines are in use, is 31c. per oven as against $1.10 to $1.15 per oven, for the same work done by hand. Adding to the labor cost, repairs to machine and ovens, power, oil, waste, interest on investment, etc., the machines effect a net saving of from 50 to 60c. per oven drawn, to say nothing of the increased production from the ovens, due to the short time required for drawing by machinery, allowing a longer burning period, which permits heavier charges of coal.

Fig. 2 shows one of the later model Covington drawers, a number of which have been installed in Pennsylvania and West Virginia, within the past four months. Twenty more of these machines are now on order for the same section, and will be installed within the next 60 to 90 days.

The Covington Leveler

In Fig. 2 is also shown a Covington leveler, a number of which are in operation in the Connellsville region.

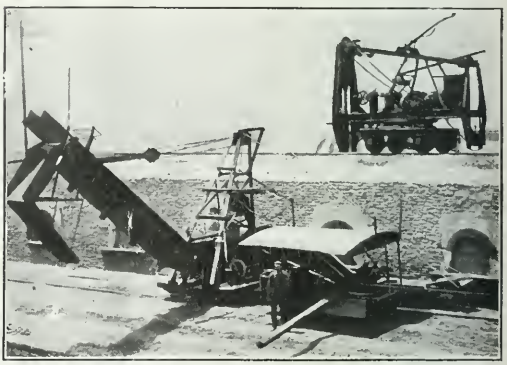

Fig. 2. A Modern Machine, also a Leveler on Larry Track

The machine shown in the picture was put in service at the Continental No. 1 works, of the H. C. Frick Coke Co., Uniontown, Penn., June 4, 1909, and so far has leveled more than 150,000 ovens. At this plant there are 400 ovens, comprising two blocks and one bank, and this one leveling machine takes care of the entire installation, keeping ahead of three larries charging. The machine levels from 30 to 40 ovens per hour, including shifting, and requires only one man for its operation.

Where this leveling machine is used, as soon as the coke is drawn, the door is immediately bricked completely, and daubed, regardless of when the oven is to be re-charged. This, of course, conserves heat and makes the new charge ignite much sooner than is the case where it is necessary to leave the door partly open until the leveling is done by hand.

This machine, also, makes it possible to burn heavier charges, besides, being a great labor-saver. It has been conservatively estimated that 5 per cent. additional coal can be coked, in a given time, where the machine is used, owing to the conservation of heat, above mentioned, and the good leveling done.

EDITORIALS

Evolution in Coking Practcie

Coke manufacturers have been slow to give up the old beehive type of oven. There has probably never been an example of more tenacious adhering to acknowledged uneconomical methods than is exemplified in this case That a change must eventually take place is obvious, but it is equally clear that it will not be an abrupt change such as is frequently witnessed in metallurgical engineering. In this latter profession, when new and more effective methods of ore treatment are devised, the engineers are prompt to take advantage of them and there are innumerable examples of elaborate and expensive plants being dismantled before they were scarcely in operation.

The evolution of the beehive oven, while less rapid, and along more conservative lines is, however, none the less sure. Thus we find that a radical modification of it is now being generally accepted in the Connellsville region, the Mitchell type of rectangular oven having definately superseded it there. It is estimated that less than two per cent. of the ovens constructed in that district during the last year have been of the beehive type. In its present accepted form the Mitchell is not a byproduct oven, but the inventors have devised certain alterations by which they expect to be able to effect a saving of these, and without any depreciation in the quality of the product.

The principal advantage of the Mitchell oven lies in the rapidity with which it can be discharged. To "pull" the old beehive type requires from 3½ to 4 hr., while the mechanical pusher and loader used with the Mitchell oven reduces this time to as many minutes. By the former method the oven becomes cooled to such an extent during the time the coke is being extracted that there is also a loss of about two hours more before the coal starts burning properly, so that the total time lost amounts to between 5½ and 6 hr. In addition to this the charging capacity of the Mitchell type is between 8 and 9 tons per oven, or from 35 to 50 per cent. greater than the standard Connellsville beehive oven.

Mother Jones

Mother Jones came to New York and addressed a meeting of 1500 enthusiasts and left the following morning for Washington. The yellow journals gave her three inches of insignificant type with a one-column headline. So despite the cheering and waving of banners, Mother Jones did not score any marked triumph.

She had been brought to the city for the purpose of setting a new monthly periodical on its feet and perhaps she was successful in this endeavor, but she did not bring the sober elements of society to a decision favoring her cause, for her supporters on the platform were Socialists and Industrial Workers of the World, and in Carnegie Hall were few if any labor unionists and none of the philanthropic multitude who frequently make labor troubles their hobby.

Mrs. Jones is a venerable old woman, 81 years of age. For the most part, one is disposed to believe she does not purposely palter with the truth. Perhaps she knew well the temper of her audience, knew that it was not ill-disposed toward violence, for she did not hesitate to admit that the large following she took to Charleston to demand the dismissal of the guards provided themselves with guns before their return to their homes.

She detailed the evidence against her at the court martial and related that a mine superintendent and a bookkeeper complained that she had incited them to violence by calling them individually, and we may add not very brilliantly, "two by fours." A major in uniform complained that he had been incited by being told that, one of these days, his epaulets would be removed and swords would be transformed into pruning hooks.

These are mild ways of creating a disturbance, but Mother Jones showed that she is not a child at the art, and has not served her apprenticeship for nothing, for at the hall she declared that Morgan's fingers had dripped with the blood of women and children and that a certain senator had murdered 700 men in his mine by an explosion. We could not help wondering whether Mother Jones had not uttered in the hill country of West Virginia, language at least as inciting as she used in Carnegie Hall.

She had nothing to say about wages or company-store prices. It is true that she did open her discourse by saying that the Cabin Creek miners had never had a good meal and that their toes protruded from their worn-out shoes. But she made it clear that the fight was primarily for the establishment of a union in some places and for its effectual recognition in others.

We are not sure that unions can ever greatly benefit the working classes but nevertheless we cannot feel that the operator does well to attempt in any way to prevent their formation, unreasonably harassing though they often are. Interference with the liberty of the individual does but exasperate him and breed violence such as West Virginia has just seen and will see again shortly if the signs do not fail.

The Industrial Workers of the World think they note in West Virginia a fit place for their lawless attacks on society and though now they are cumbered with the barbers' strike, and the frenzied attempt to wipe Paterson, N. J., from the map, they may at any time descend on the coal fields of West Virginia.

They frankly confess that they have no ultimate program. The present evil to be overborne, they declare, is capitalism; that being overthrown, the work of reconstruction will be commenced. But the manner of structure to be selected, they do not know. They in very truth "don't know where they are going but they're on their way."

The impression is abroad that the Industrial Workers of the World are the very off-scouring of the people.

Those who have such an idea would be disabused by a visit to their well attended meetings. They are fanatics of the type of the English suffragettes. The frenzy of modern life is in their veins, a wild craving for excitement, to leave the beaten path, to plunge headlong with their fellows, whether friendly or resisting. This spirit of unrest has seized all the overstrung, brilliant and weak-willed alike, and among their leaders are many men of ability and character.

The only way to meet the evil propaganda which have created them is by mending what is now unjust and by commencing a campaign of education which will sweep away the tissue of lies that magazines and newspapers prepare for the pleasure of their subscribers. What object can there be to a publisher to tell the truth when the sale of a newspaper depends on the number of readers? Most of these are not wealthy and the journalist must condemn the "haves" and commiserate the "have-nots," right or wrong.

If every government bureau must publish bulletins, engage press agents, and send trained speakers, north, south, east and west, how are the coal operators going to succeed if they sit passively through it all and do not defend their positions? The world is very equal, very human; the high places and the low are filled with men, good and evil. They who would maintain those economic principles which they believe will promote human happiness, must urge them at some expense of time and money on their less enlightened fellows and give the world a glimpse, we think it will be a gladdening glimpse, of the real brotherhood and true socialism of our modern coal operators.

Coal Storage under Water

Some of the larger industrial companies, as well as many of the railroads, habitually store coal in the open air upon vacant property. This method is, however, open to two serious objections. Soft coal, when subjected to the action of the atmosphere, is certain to oxidize to a greater or less extent, and thus depreciate in heat value. Furthermore, the action of frost tends to disintegrate the individual pieces of coal, thus increasing the losses in burning. Second, particularly if the coal contains a large percentage of sulphur and is stored to considerable depth, there exists a strong liability to spontaneous combustion, and considerable losses occur annually from this cause.

To overcome both of these difficulties, coal is sometimes stored under water in concrete tanks or vats of considerable size and capacity. It is claimed by those who employ this method of storage that the practically negligible loss in heat qualities vastly more than offsets the increased amount of moisture in the coal as it goes to the boiler furnaces. Furthermore, the subaqueous storage of the fuel renders spontaneous combustion impossible, and there is therefore no danger of loss from this source. This result, too, is accomplished regardless of the size or quality of the coal stored.

A large Chicago manufacturing firm is at present employing this method at one of its suburban plants, with results which are averred to be entirely satisfactory. The fuel handled is No. 1 screenings, Illinois coal, which ranges in size from dust up to approximately 1¼-in. lumps. This fuel, after being loaded out from storage, is allowed to drain for a few hours before passing to the chain-grate stokers with which the boiler furnaces are fed.

Although the expense of building a storage plant of this kind is great, it would appear that in many instances at least the advantages gained, namely, small loss from oxidation, immunity from spontaneous ignition, and the fact that the smallest sizes and poorest grades of coal may be thus safely stored throughout indefinite periods, are commensurate with the expense. The cost of handling coal in a storage scheme of this kind should not be higher and may be decidedly less than when it is piled upon the ground in the usual manner.

John Fulton

A number such as this would be incomplete did it not reflect some opinions and views of the leading spirits in the coke industry. Fulton and coke are two such entirely synonymous words that each immediately recalls the other. John Fulton occupied a unique position in the coke industry of the past—a position which no one may ever attain to in the history to come. He stood preëminently at the head of the profession in all its ramifications, whether of the beehive oven, the retort oven or any of the intricate regenerative or byproduct recovery processes. As he now frankly concedes, the industry has become too complicated for one brain to grasp in its entirety; in common with other engineering professions, new branches and subdivisions have developed, each requiring the attention of a specialist so that it is quite probable no one man will ever again predominate the profession as John Fulton has in the past.

Mr. Fulton thinks the country is facing a great problem when the Connellsville region is exhausted. The life of these fields is quite definitely defined now, and when the end comes, the retort oven must be resorted to. This he thinks will also witness the final demise of the beehive oven. But so long as there is a supply of these coals, he predicts that the old-fashioned beehive will continue to thrive, as no retort oven has yet been devised that will displace them with the world's two standard coking coals—the Connellsville and the Durham, England. And it is incidentally interesting to note that Mr. Fulton puts the Connellsville product ahead of Great Britain's, the slightly higher ash content of the former producing somewhat better slag in the blast furnace.

Conservation is also a favorite topic with Mr. Fulton. While both coal and iron are being exhausted at an alarming rate, he thinks that the real conservation will be effected by greater economies in the methods of using, particularly in the case of coal. He also views the growing scarcity of water with some alarm.

Of the foreign coal-mining methods, Mr. Fulton has the greatest disdain. He spoke of one German installation he visited which was constructed along the most elaborate and permanent lines. Steel and concrete were used throughout and the whole represented an almost awe-inspiring edifice. The cages had many compartments for cars, but these were only of a quarter-ton capacity, while the production of the plant was only between 200 and 300 tons per day. The local superintendent also explained that they were most careful to ship only sufficient coal to just meet the market requirements. Evidently a Sherman anti-trust law is unknown in Germany.

A Model Coal-Preparation Plant

By Milton J. Williams*

During the past few years, although much has been written about the subject of coal mining and coke manufacture in both beehive and byproduct ovens, only a comparatively meager amount has appeared concerning the pulverization or other preparation which the coal should receive if a fine grained and superior grade of coke is to be anticipated.

In this matter of preparation before coking, the plant of the Byproduct Coke Corporation at Solvay, Ill., just south of South Chicago, may be well considered as an example of the best practice in this country. Unfortunately, it is impossible to show photographs illustrating the various machines and processes.

The preparation plant consists of three distinct sets of units, each consisting of a Bradford breaker, a coal hopper, a magnetic separator and feeding belt, and a No. 6 Williams crusher. The coal handled is smokeless and Boomer West Virginia bituminous. It is first passed through a Bradford breaker provided with perforations 1½ in. square. Here a large percentage of the foreign matter is removed and no coal passes on until it has been reduced to the size of the perforations above mentioned.

Of this 1½-in. product and smaller, 80 to 85 per cent. is ½ in. and under. When the moisture content of the coal reaches 3½ to 5 per cent., the material becomes difficult to handle in hoppers and chutes, as it is an inert or slow-moving body; consequently, special chutes are employed to handle this coal.

The Bradford Breakers

The Bradford breakers above mentioned are of Heyl and Patterson design and are regulation size. Each has a capacity of 125 to 150 tons per hour, and the succeeding machinery over or through which the coal travels is arranged for a similar capacity. From the breakers the material falls into large steel bins or hoppers, from whence it passes to magnetic separators in the form of short belt conveyors. These are approximately 5 ft. wide, and 8 or 10 ft. long.

The coal upon these belts varies from 3 to 3½ in. deep throughout the full width of the conveyor. The head or driving pulley is magnetized and consequently catches and discharges into a special chute a considerable percentage of the iron or foreign metallic material which has found its way from one source or other into the coal. These separators also furnish an automatic, uniform feed to the crushers.

From these belts the coal passes directly to No. 6 Williams Jumbo crushers and is pulverized or ground to a product ranging from 80 to 90 per cent. through a ⅛-in. opening. These machines are direct connected to 150-hp. alternating-current motors by means of a Muir friction clutch. Such clutches are employed to pick up the load gradually in starting the crushers as the hammer type of pulverizer requires more power to start than to operate empty at full speed. In many similar installations flexible couplings are used to direct-connect crushers to motors, but in such cases it is advisable to have special motors with high starting torque.

These particular crushers are 48 in. in diameter and 36 in. wide. They weigh approximately 25,000 lb. each, and operate at 750 r.p.m. Their durability, accessibility, and efficiency are too well known to require further comment.

After being crushed and pulverized, the coal is carried by an inclined belt conveyor to a storage bin, from which it may be drawn off from time to time and carried to the ovens as the operation of the latter may require.

From the foregoing it will be seen that the preparation of the coal for coking at this plant is continuous and entirely mechanical, and can therefore be accomplished with a minimum of labor and superintendence. A failure or breakdown of any one piece of the apparatus can only decrease the output of the preparation plant by one-third, for should the failure of the particular unit be sufficiently serious to stop operations in that part of the equipment, there are, as mentioned above, three separate and distinct routes by which the coal travels from the original dumping or storage point to the bins serving the coke ovens.

*Old Colony Building, Chicago, Ill.

A New Method of Boiler Cleaning

A new type of boiler-tube cleaner, or, more strictly speaking, a new method of boiler-scale removal, has been recently invented and placed upon the market in England

The Oxyacetylene Scale-Removing Apparatus after a Trial Test

by Adolph Schror. This method is radically different from those common in this country, which are strictly mechanical in their action.

The principle of the new apparatus is simple. It consists in the employment of an oxyacetylene flame of high temperature but of moderate pressure, which is rapidly played upon the scale. The effect is to disintegrate and break down the deposits, and, notwithstanding the high temperature of the flame, the makers claim that there is no cause for anxiety on the score of undue heating in the boiler tubes, and that the apparatus may be used to remove the thinnest scale.

Contracts under this system are undertaken on the "no cure, no pay" principle, by the Pyro Boiler Cleaning Co., of London, and we understand that thus far, at least, the results obtained have been entirely satisfactory.

Coke Works of the Entire Connellsville Region

Revised and Corrected to Apr. 1, 1913. Published through Courtesy of "Connellsville Courier."

DISCUSSION BY READERS

Carbon Monoxide a Supporter of Combustion

In the present June issue of a contemporary, in answer to the question as to the correctness of two contradictory statements in reference to carbon monoxide supporting combustion, the editor states:

The statement quoted from the I. C. S. Instruction Paper that carbon monoxide does not support combustion is correct.

The contradictory statement was made in the first 1000 copies of "Examination Questions and Answers," but was corrected in all subsequent issues. A similar incorrect statement was made in some editions of "The Coal and Metal Miners' Pocketbook." Previous editions of the pocketbook stated that carbon monoxide is not a supporter of combustion. The statements that it is a supporter of combustion were made by a writer formerly in the employ of the publishers of "The Colliery Engineer," who, while an able mining writer, and as a rule accurate, in this instance expressed an opinion of his own, which is in direct opposition to the actual experience of chemical authorities whose works are regarded as standards all over the world.—EDITOR.

It is clear the above statement refers to me as being the author of the offending statement, viz., "carbon monoxide will support combustion," and the reference justifies a reply.

The quotations referred to are as follows:

It (carbon monoxide) is combustible, burning with a pale blue flame; but, by itself, does not support combustion.

I. C. S. Reference Library, Vol. 145, § 6, p. 2.

It (carbon monoxide) is also a supporter of combustion, being the only mine gas that burns and also supports combustion.

Coal and Metal Miners' Pocket Book, Tenth edition (1911), p. 350.

It (carbon monoxide) is combustible, burning with a pale-blue flame. This gas also supports combustion . . . .

Examination Questions and Answers, First edition (1907), Ques. 312, p. 53.

The statement is not one of "opinion," but on the contrary one of *fact;* although it were better that, for mining students, it should be further explained. While carbon monoxide has no available oxygen and therefore cannot support the combustion of carbon, the gas (CO) will support an oxygen flame, which will burn in an atmosphere of pure carbon monoxide, although it would not burn in air. The statement, although correct, was modified later, at my own suggestion, in the I. C. S. coal-mining textbooks.

As I have often explained, the reason mine lamps burn even more brightly when in the presence of carbon monoxide (CO) is because the gas adds to the combustion going on in the flame of the lamp by adding a gaseous fuel to the hydrocarbons of the flame. The air, and not the gas, in that case, supports the combustion.

Any gas or substance that, through its own agency by virtue of its composition, renders the combustion of other matter possible is a "supporter" of that combustion. By combustion we understand any destructive chemical reaction between the constituent elements of two substances, and resulting in the formation of new products or compounds.

New York City.

A Valuable Suggestion to Buyers of Mining Machinery

I was much interested in the Foreword of Feb. 15. I believe that the writer of that article had, unquestionably, the right idea. From the manufacturer's standpoint, all the plans and estimates made and engineering work done for various prospective customers, as well as for those who make inquiries from curiosity, must be charged to some account. In some factories, this becomes a serious consideration in the matter of costs, which must be added proportionately to the price of machinery. Considering now that six or seven manufacturers have all prepared plans and specifications for one inquiry, and, out of all these, only one can receive the contract, the balance must figure to recover on future sales what they have spent on these estimates.

Another matter of great difficulty is, as suggested in the article, that no competent engineer is employed by the purchaser of machinery, in a vast number of cases, the purchaser considering that by requesting bids and specifications for machinery he gets his engineering done for nothing. The variation in specifications on machinery by different manufacturers for the same installation is often startling. Equipment that will not stand long enough to warrant its being considered even a fair investment, is very frequently sold at a much higher price than high-class machinery that someone else has offered at a comparatively low figure.

Most purchasers will say that they want a plant to give lasting, uniform service, and, when the specifications arrive, they are incapable of judging what machinery will give them such service. They usually form their judgment largely by the little item at the end of the proposal, which states the price, and they purchase on this basis frequently to their own detriment.

Our universities are every year turning out young engineers in large numbers. The majority of these young men have a natural leaning and aptitude for this line of work, but, as the Foreword suggests, they become timekeepers, clerks or hold other similar positions in which their knowledge of engineering is not properly broadened, nor is their opinion, from an engineering standpoint, often requested by their employers. Many of these young men would have been as well off if they had taken a business course for $60, instead of having spent several thousand dollars and four years of their time training for engineering and never having an opportunity to use the knowledge acquired. These young men should be given positions in which they can prepare drawings and specifications, after having investigated the conditions and ascertaining the requirements. In this manner, it would be possible to receive from manufacturers a uniform line of bids, and then prices would become a true comparison as to the quality of the machinery offered.

I believe it is the custom in Europe that when a buyer asks a manufacturer to prepare plans and specifications,

he agrees to pay for these on a basis of 2½ per cent. of the total estimate, irrespective of whether the bid is accepted or rejected. This places the various bids received on a more equal basis of comparison. In this country, the purchaser does not pay the 2½ per cent. for the plans and specifications submitted; but, in reality, he unconsciously pays six or seven times that amount.

I believe that if some system of this kind were adopted in this country, both the manufacturer and the buyer of machinery would be saved many thousands of dollars a year; and it would certainly eliminate the person who sends in inquiries merely as a matter of curiosity or for the purpose of ascertaining if he has been duped in some recent purchase of machinery. I would like to see this matter further discussed by those who are interested, and I believe much good would result from such a discussion.

American Contractor Co.

Joplin, Mo.

Systematic Timbering

Systematic timbering may be practicable where the conditions with respect to the roof and floor are regular; but, in many coal seams, the roof is fractured and there are fault lines and cross-slips in the roof that make it seem more advisable to set a post where it is needed, regardless of the regular distance apart. In this locality, the heavy pitching seams have been fractured by the very forces that disturbed the strata. The system of timbering employed here is irregular, being adapted to the varying conditions of the roof. In some cases, posts are set to prevent the bottom from sliding as much as to secure the roof.

The care of mine timber is a question of growing importance. Statistics show that three times as much timber is being consumed as is being produced by the forest growth. According to the U. S. Forest Service Bulletin No. 78, 1909, there are approximately 500,000,000 cu.ft. of mine timber in use in the United States, about 40 per cent., or 200,000,000 cu.ft. of which, it is claimed, can be advantageously treated, which would reduce this portion of the timber in use, to one-thirteenth of the quantity required, or say, 15,000,000 cu.ft. These figures are based on the estimated life of an untreated mine prop as being approximately three years; while, with proper treatment, it is claimed the life of mine timber may be increased to 13 years. The cost of mine timber per ton of coal mined makes the question of the preservation of timber an important factor. This cost, in 1905, in the anthracite region of Pennsylvania, was 8c. per ton of coal mined.

Coalmont, B. C., Canada. J. W. Powell.

Study Course in Coal Mining

By J. T. Beard

The Coal Age Pocket Book

Height Due to Any Given Velocity—Reversing the conditions of falling bodies and assuming a body is projected vertically upward with a given initial velocity (v), it will rise to the same height (h) from which it must fall to gain the given velocity. The same formulas are used in each case.

This is well illustrated by a simple experiment. The small tank of water shown in Fig. 1 is placed under a bell jar from which the air is then exhausted. The water was previously boiled to drive out the air, which otherwise would escape into the vacuum formed in the jar and destroy the accuracy of the experiment. As shown in the figure, there is provided at the bottom of the tank a spout turned vertically upward. When every provision is made to reduce the friction, the column of water that spouts from the tank will rise to practically the level of the water in the tank. As shown by the dotted lines, the height to which the water spouts decreases as the level of the water falls in the tank.

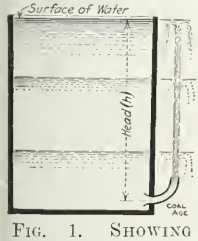

Fig. 1. Showing Height of Rise Equal to Fall

Velocity of Efflux—By means of the above experiment or a similar one, it is found that water or any fluid flows out through an opening in a tank (Fig. 2) with the same theoretical velocity that a body would attain falling through a height equal to the distance of the point of discharge below the free surface of the water in the vessel or tank. This is called the "velocity of efflux" or the "velocity of discharge."

Head-Producing Velocity—The vertical distance of the point of discharge below the free surface of the liquid is the "head" producing the velocity of the discharge. Hence, the theoretical velocity of discharge for any given head is the same as the velocity due to an equal height, in the case of a body falling in a vacuum. This is one of the most important principles in the study of hydraulics.

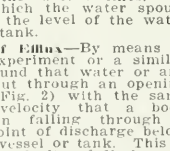

Fig. 2. Head (h) Produces Velocity (v)

Pressure Head—The pressure at the point of discharge is caused by the weight of water above that point. It is this pressure that produces the velocity of discharge. The head corresponding to a given pressure is called the "pressure head."

1.0 ft. water column = 0.434 lb. per sq.in. pressure;
2.3 ft. water column = 1.000 lb. per sq.in. pressure.

The Coal Age Pocket Book

Flow of Air and Water Compared—Air and water are both fluids and as such the flow (theoretical velocity) in each case, is calculated from the head, by the law of falling bodies. The same head will produce the same velocity in air as in water, but the pressures are very different.

Water, at maximum density is about 815 times as heavy as the same volume of air, at normal temperature and pressure (60° F., 30-in. bar.). A given head of water column, therefore, weighs about 815 times as heavy as the same head of air column, and produces a pressure as many times as great.

Disregarding friction, the pressure required to produce any given velocity in a flow of water is practically 815 times as great as that necessary to produce an equal velocity in air. For example, a head of 400 ft. gives a velocity of $v = 8\sqrt{400} = 160$ ft. per sec., which is the same for air as for water. The corresponding pressures, in each case, are

Water pressure, $400 \times 0.434 = 173.6$ *lb. per sq.in.*

Air pressure, $\frac{400 \times 0.434}{815} = 0.213$ *lb. per sq.in.*

It is important to note that the head must always be estimated as of the same density as that of the flowing medium.

EXAMPLES TO ILLUSTRATE

1. To what height will a stone rise if thrown vertically upward with an initial velocity of 90 ft. a second, disregarding the resistance of the air; and what time will elapse before it again reaches the ground?

Solution—The height to which the stone will rise is the height due to its initial velocity, which is

$$h = \frac{v^2}{2g} = \frac{90 \times 90}{2 \times 32.16} = \frac{8100}{64.32} = \textit{say } 126 \textit{ ft.}$$

The total time of flight is double the time required to fall from this height, the time of rise and the time of fall being equal; therefore,

$$t = 2\sqrt{\frac{2h}{g}} = 2\sqrt{\frac{2 \times 126}{32.16}} = 5.6 \textit{ sec., nearly}$$

Or, the time can be calculated from the initial velocity; thus

$$t = 2\left(\frac{v}{g}\right) = \frac{2 \times 90}{32.16} = 5.6 \textit{ sec., nearly}$$

2. With what theoretical velocity will water be discharged from a hole in the side of a tank, at a depth of 10 ft. below the surface?

Solution—The velocity of discharge disregarding friction, is the same as the theoretical velocity due to that height; and is

$$v = \sqrt{2gh} = \sqrt{2 \times 32.16 \times 10} = 25.3 \textit{ ft per sec.}$$

INQUIRIES OF GENERAL INTEREST

Foundation for New Headframe

A shaft 225 ft. deep is lined for the first 75 ft. from the surface with timber. The present headframe or derrick rests on sills above this timber lining. It is desired to erect a new steel headframe. The timber lining is not durable or substantial enough to support the new construction: neither would it support the surrounding ground, should the new headframe be built on foundations on either side of the shaft. It has been suggested that the new headframe must rest on concrete foundations set a considerable distance back from the shaft to afford a firm bearing. The size of the shaft is 8x18 ft., in the clear. The ground is soft and inclined to slip.

SUPERINTENDENT.

Steubenville, Ohio.

In reply to this inquiry, we cannot do better than to refer our correspondent to two articles, recently published in COAL AGE, one entitled "Steel in Mine-Construction Work," May 17, p. 757; the other "Modern Steel-Tipple Design," May 24, p. 786. Both of these articles explain in detail the great advance made in tipple construction since the introduction of steel for this purpose.

In the most recent designs in steel-tipple construction, the vertical columns have been replaced by inclined or spreading legs, forming a very substantial frame and making it possible to set the foundations at a considerable distance back from the shaft, so that the vibrations incident to the handling of the coal on the tipple are not transmitted to the shaft lining. This form of construction is known as the "A-frame" and very much reduces the vibration in the structure, which formerly interfered with the weighing of the coal on the tipple. This special form of construction is the result of a careful study and investigation of the requirements in coal-tipple design, by the manufacturers. Since its introduction, in the Middle West, this type of tipple has attracted considerable attention and, it is stated, continues to give satisfaction.

⁂

Tension of Water Vapor

Referring to the answer to the first question, under the heading "Air and Mine Gases," COAL AGE, Feb. 15, p. 275, I want to ask what is meant by the "tension of water vapor." Also, in the answer to this question, what does the number 0.3765, represent; and, in answer to the third question on the same page, what do the numbers, 0.6235 and 0.37 represent?

H. E. URSHINE.

Monongahela, Penn.

By the tension of water vapor is meant its elasticity; or, in other words, the effort exerted by the water vapor to expand. This expansive effort of a vapor or gas is always equal to the pressure that it supports. Some authorities use the word "pressure," instead of tension; but, correctly speaking, the tension of a gas or vapor is the effort it exerts to resist the pressure it supports.

In the calculation of the weight of 1 cu.ft. of saturated air, it is necessary to calculate, first, the weight of 1 cu.ft. of dry air, under a pressure diminished by the tension of the vapor, and add to this the weight of moisture in 1 cu.ft. of the air when saturated. In making this calculation for saturated air, the weight of the air, disregarding the moisture it contains, depends on the atmospheric pressure (p) minus the tension (t) of the water vapor; while the weight of the water vapor depends on the tension (t) of the vapor, multiplied by its specific gravity (0.6235). The combined weight (w) of the air and the water vapor it contains, therefore, is proportional to the expression $(p - t) + (0.6235\ t)$, which can be written $p - (1 - 0.6235)t$, or $p - 0.3765\ t$.

As just explained, the number 0.6235 is the specific gravity of water vapor, referred to air of the same temperature and pressure, as unity.

The number, 0.37, is the reciprocal of the weight of 1 cu.ft. of dry air at absolute zero (460° F.) and a pressure of 1 lb. per sq.in. This number corresponds to the number, 1.3273, which is the weight of 1 cu.ft. of dry air at absolute zero and a pressure corresponding to 1 in. of mercury. The weight of 1 cu.in. of mercury (32 deg. F.) is 0.4911 lb., and $0.4911 \div 1.3273 = 0.37$, which shows that these two constants correspond and will give the same result in calculation.

⁂

Calculation of the Specific Gravity of Gases

Kindly explain the method of calculating the specific gravity of gas, and why this does not correspond exactly with the actual specific gravity.

ROBERT SMITH.

Federal, Penn.

The specific gravity of any gas, referred to air of the same temperature and pressure, as unity, is calculated by first finding the molecular weight of the gas, which is the sum of the atomic weights of its elements. Thus, for marsh gas (CH_4), $C = 12$; $H_4 = 4 \times 1 = 4$; and the molecular weight of this gas is $12 + 4 = 16$. Then, since the molecule of a gas is assumed to have twice the volume of an atom of hydrogen, at the same temperature and pressure, the density of the gas referred to hydrogen is one-half its molecular weight; or, in this case, the density of marsh gas is 8.

Air is 14.4 times as heavy as hydrogen, at the same temperature and pressure, and the specific gravity of a gas referred to air as unity, may, therefore, be calculated from its density referred to hydrogen, by dividing the density by 14.4. Thus, for marsh gas, $8 \div 14.4 = 0.556$, nearly.

The actual specific gravity of a gas, as determined by experiment, varies more or less from the calculated specific gravity, owing to inaccuracies of determination and impurities in the gas, but the difference is slight.

EXAMINATION QUESTIONS

Bituminous Firebosses' Examination in Pennsylvania, May 8, 1913

Ques.—If, while making an examination, you discovered explosive gas in the intake current of one of the splits in which 60 persons are at work, explain your method of proceedure to protect the men.

Ans.—Assuming that the intake current contains a dangerous percentage of gas and that it is impossible to restrict the inflow of gas into the current, and, further, that to short-circuit the air current in an endeavor to prevent the gas from reaching the working face would create a dangerous condition where the men were at work, the only means left to prevent disaster would be to increase the circulation of air in the section affected, if this is possible. In the meantime, prompt notice should be sent in for the men to extinguish their lights and withdraw from that section of the mine. By sufficiently increasing the volume of the air current in that section of the mine, the percentage of gas would be reduced below the danger point.

Ques.—What provision does the act of June 9, 1911, make in regard to firebosses who neglect to comply with their duties, or who shall make false reports?

Ans.—The law specifies (Art. 5, Sec. 6) that for such neglect of duty or false report, the fireboss "shall be deemed guilty of a misdemeanor and shall be suspended by the mine foreman, and his name shall be given to the inspector for prosecution. If found guilty, he shall return his certificate of qualification as fireboss to the Department of Mines; provided, however, that he may again be an applicant for a certificate as fireboss, at any regular examination, after the expiration of six months; but if found guilty of a second offense, he shall return his certificate to the Department of Mines and cannot then be an applicant for reëxamination."

Ques.—If a feeder of gas fills a large cavity in the roof of a heading, how would you keep the cavity clear?

Ans.—A special brattice should be erected so as to deflect the air current into the cavity in the roof. Such a brattice is generally arranged by stretching a piece of canvas across the heading a sufficient distance above the floor and inclined at a suitable angle to carry a portion of the air up into the cavity of the roof, so that it will sweep out the gas.

Ques.—If, while making an examination on a fall, your lamp became extinguished, how would you determine what gas or gases were present?

Ans.—It is difficult to answer this question without more exact information. The gas above the fall may be a body of pure marsh gas, the gas being given off in the roof and accumulating in the cavity as fast as it is carried off by the air current. In this case, the action of the flame in the lamp should betray the fact that it is undiluted marsh gas. On the other hand, this body of gas may be a mixture of carbon dioxide and marsh gas, formed under conditions that permitted these gases to mix together without the addition of air. Such a mixture will extinguish the flame of a lamp, in a brief time. The mixture has been styled "flashdamp," because, when the lamp is first introduced into the gas, a cap is formed on the flame but almost immediately disappears, owing to the fresh air in the combustion chamber of the lamp being exhausted. The flame then dims and is extinguished by the gas, which enters and fills the combustion chamber of the lamp. The mixture of carbon dioxide and marsh gas is lighter than air and collects at the roof.

Ques.—How would you proceed to enter and examine a place supposed to contain firedamp?

Ans.—Proceed with caution, moving quietly and making frequent tests for gas at the roof. Care should be taken not to allow a thin layer of gas at the roof to escape notice. The gas should be slightly disturbed by blowing the breath against the roof, so that the gas will come down and reach the lamp. Every precaution should be taken to avoid walking into a body of gas, or passing under a layer of gas at the roof, without this being observed, until it is too late to retreat safely.

Ques.—Where are the gases that are generated in bituminous coal mines generally found?

Ans.—Gas is found, in all mines, in greatest quantity, either where it accumulates or in poorly ventilated places where it is generated. The accumulation of gas depends on the character of the gas and the strength of the air current circulating through the place. The tendency of marsh gas (CH_4) is to accumulate at the face of rise headings, or at the roof, or on the "falls." The tendency of carbon dioxide (CO_2) is to accumulate in swamps, or at the foot of dip workings, or at the floor or other low places and in poorly ventilated abandoned workings.

Ques.—Under what conditions would it be unsafe to fire shots in bituminous coal mines?

Ans.—It is always unsafe to fire a shot in a working place generating gas before carefully testing that and the adjoining places for gas. If the mine is dusty, the working face and the road, ribs and gob should be sprinkled thoroughly before a shot is fired. It is unsafe to fire a shot when the brattice has not been properly arranged or there is any derangement of the circulation by which an unusual condition is produced. It is generally unsafe to fire more than a single shot in a close working place of contracted area, since the heat, gas and dust generated by the first shot may be ignited by the flame of the second shot. It is always dangerous to fire shots facing each other, or to fire a shot depending on another shot that is expected to explode first. An entry shot, in blowing roof or bottom, should never be laid to face a strong air current.

Ques.—What is meant by the "head" in reference to air, water, or other fluids?

Ans.—The term head, as then used, is the vertical distance between the surface of the fluid and any given point below the surface. Whether the fluid is air, water or other liquid, the pressure, at any point below the surface, is equal to the weight of a column of that fluid extending from the given point to the surface.

COAL AND COKE NEWS

Washington D. C.

A revised form of the resolution for the investigation of the coal controversy in the West Virginia fields has been reported in the Senate within the past few days as follows:

Resolved, that the Senate Committee on Education and Labor is hereby authorized and directed to make a thorough and complete investigation of the conditions existing in the Paint Creek coal fields of West Virginia for the purpose of ascertaining:

First. Whether or not any system of peonage has been or is maintained in said coal fields.

Second. Whether or not postal services and facilities have been or are interfered with or obstructed in said coal fields; and if so, by whom.

Third. Whether or not the immigration laws of this country have been or are being violated in said coal fields; and if so, by whom; and whether or not there have been discriminations against said coal fields in the administration of the immigration laws at ports of entry.

Fourth. Investigate and report all facts and circumstances relating to the charge that citizens of the United States have been arrested, tried, and convicted contrary to or in violation of the Constitution or the laws of the United States.

Fifth. Investigate and report to what extent the conditions existing in said coal fields in West Virginia have been caused by agreements and combinations entered into contrary to the laws of the United States for the purpose of controlling the production, sale, and transportation of the coal of these fields.

Sixth. Investigate and report whether or not firearms, ammunition and explosives have been shipped into the said coal fields with the purpose to exclude the products of said coal fields from competitive markets in interstate trade; and if so, by whom, and by whom paid for.

Seventh. If any or all of these conditions exist, the causes leading up to such conditions.

Said committee, or any subcommittee thereof, is hereby empowered to sit and act during the session or recess of Congress, or of either house thereof, at such time and place as it may deem necessary; to require by subpœna or otherwise the attendance of witnesses and the production of papers, books, and documents; to employ stenographers, at a cost not exceeding $1 per printed page, to take and make a record of all evidence taken and received by the committee and keep a record of its proceedings; to have such evidence, record, and other matter required by the committee printed; and to employ such other clerical assistance as may be necessary. The chairman of the committee or any member thereof may administer oaths to witnesses.

Subpœnas for witnesses shall be issued under the signature of the chairman of the committee or subcommittee thereof. Every person who, having been summoned as a witness by authority of said committee or any subcommittee thereof, willfully makes default, or who having appeared refuses to answer any questions pertinent to the investigation herein authorized, shall be held to the penalties provided by section one hundred and two of the Revised Statutes of the United States.

The expenses thereof shall be paid from the contingent fund of the Senate on vouchers ordered by said committee, signed by the chairman thereof, and approved by the committee on contingent expenses.

Divergent Opinions of the Supreme Court of Appeals

In the furtherance of its study of the West Virginia coal situation, the Senate has had printed two recent decisions by the Supreme Court of Appeals of West Virginia in the cases of State ex rel. Mays vs. Brown and others, in which careful attention is given to the action taken by the governor of West Virginia in establishing martial law in that state. According to the majority opinion in these cases:

As a result of these principles, views and conclusions, we have two areas or sections in the state, by virtue of the declaration of a state of war in the district, in which the powers of government and the rights of citizens differ most radically. The tremendous power of the governor in the military district does not extend beyond the limits thereof. Nevertheless, he is the governor of the peaceable territory of the state, and has such powers as are normally vested in him by the constitution and the laws, and any additional authority the legislature may have conferred upon him in pacific territory in the event of such exigencies, not violative of constitutional provisions. In the language of John Adams, the state has a peace power and a war power, both of which are now active.

We construe the returns of the respondents as asserting, for the purposes of this case, the power of detention of the petitioners, not a right to try them by a military commission. Having shown the existence of a state of war in the area covered by the governor's proclamation, and the steps taken to suppress the insurrection and lawlessness in that territory, the returns say the petitioners have been largely instrumental in causing and encouraging the lawlessness, riot and insurrection, and that their detention is, in the judgment of the executive, necessary in order to effectually suppress the same.

This sufficiently charges them with having willfully given aid, support, and information to the insurgents, the enemy, in a time of war, insurrection, and public danger, and Section 6 of Chapter 14 of the code confers upon the governor power to apprehend and imprison all such persons.

Such acts may be done either inside or outside of the military district. Nothing in the terms of the statute limits the exercise of this executive power of apprehension and imprisonment to persons within the military district, and it is obvious that persons outside of such district may do as much or more than persons inside of it to defeat executive action looking to the suppression of the insurrection or rebellion. Hence there is no reason for such a limitation. On the contrary, there is good reason against it, wherefore we must say the legislature intended no such a limitation, and the statute contemplates such arrests and imprisonment of persons committing these acts outside of the military district.

The minority opinion in the same case as now issued by the Senate takes practically the reverse point of view, saying:

A clash between mine owners and miners cannot be considered public war, and the participants dealt with as enemies of the state. True, it is that in war the enemy, whether a foreign one or a rebel to whom the status of belligerent has been given, has no legal rights which those opposed to him must respect. But have either the mine owners and their guards on the one side, or the miners on the other assumed the status of belligerency against the state?

Because of warfare between themselves and violations of the law in relation thereto, has neither side any constitutional rights which the state is bound to respect? Nothing in the record justifies the conclusion that either the mine owners and their guards on the one hand, or the miners on the other, have lost their allegiance of the state by the unfortunate clash between them or by any other act.

Neither faction has made war against the state. Each time the militia has been sent to the district, all has remained quiet. Chief Justice Marshall early defined what it is to make war:

To constitute a levying of war, there must be an assemblage of persons for the purpose of effecting by force a treasonable purpose. (Ex parte Bollman, 4 Cranch, 75.)

Nothing even reminding one of treasonable purpose is involved in these cases. Yet the majority opinion deals with the citizens of the district as rebels. It deals with a part of Kanawha County as enemy's country. In this it cannot be sustained by reason of authority. Cabin Creek district has not seceded! The residents of that district are citizens of the state under its civil protection, though they may have violated the law. Because one violates the law, does he lose his legal rights? The guiltiest man, if he is not an enemy in public warfare directly against the state, is entitled to all rights as a citizen.

PENNSYLVANIA

Anthracite

Philadelphia—G. C. Todd, special assistant to Attorney-General McReynolds, has presented to Judges Gray, Buffington and McPherson, in the Federal District Court, a decree to enforce the mandate of the highest court, cancelling the so called 65 per cent. contracts under which the large coal-carrying railroads purchase the product of small companies. This decree will not prevent coal companies, individually, from entering into the 65 per cent. contract arrangement with railroads, so long as they are not the result of a concerted plan or plot or in restraint of trade.

Wilkes-Barre—About 700 employees at the Westmoreland Colliery of the Lehigh Valley Coal Co. and 1000 employees at the Taylor Colliery of the Lackawanna Coal Co. are on strike because of the failure of some of their number to wear the union working button. It is reported that agents of the I. W. W. have been at work at Westmoreland, influencing the men to drop their allegiance to the United Mine Workers and ally themselves with the Industrial Workers of the World.

The 1500 employees in the coal-stripping operations of Contractor David Benjamin, in the Hazleton section, have been granted a substantial increase in wages under a three-year agreement, secured by the officers of the United Mine Workers of the Seventh District.

Scranton—The climax of this city's fight for surface protection comes with the march of citizens on the State Capitol in Harrisburg, to demand that the Senate pass the Davis Mine Cave bill and the Roney coal tonnage tax measure. Special rates have been obtained, and it is expected that more than 200 men will form the delegation. This demonstration promises to surpass any that has ever been made in this section of the state.

Bituminous

Monongahela—Over 600 men employed at the Gallatin and Manown mines of the River Coal Co. struck, May 26, because the company officials demanded that they work in entries with white powder and safety lamps. It is reported that the men have stated that they would not work with safety lamps and white powder in any entry as long as electricity is used in the mines. They claim that electricity is as dangerous as open lights.

WEST VIRGINIA

Charleston—Governor Hatfield, of West Virginia, is exonerated on a number of charges circulated against him in connection with the West Virginia coal strike, in a report to the national commiteee of the Socialist party made June 3 by Victor L. Berger, Adolph Germer and Eugene V. Debs, who conducted a personal investigation.

Sagamore—The large and costly plant of the Buffalo & Susquehanna Coal Co., at Sagamore, was put out of commission and a loss of about $15,000 was entailed by an accident, May 30, that has all of the earmarks of being the handiwork of vandals.

The coal train that visits the town daily had taken out all but eight loaded coal cars and put 30 "empties" in on the grade above the tipple. About two hours after the train had left there was a heavy crash of girders, and every one of the 38 cars was smashed up badly and piled under and about the tipple. The bottom pans, girders and much other skeleton work of the tipple being torn out.

Investigation showed that the cars had had their brakes properly set when they were put in. It is evident that some one opened the brakes and the cars started by their own weight. There is no clue as to the perpetrators of the deed. A wrecking crew from Galeton was called and has been at work clearing the tracks, but it will be some time before the tipple is put into shape to permit the resumption of work at the big operation.

Wheeling—Five hundred miners went on strike May 24 at the Loraine Coal & Dock Co.'s mine at Crescent, Ohio. In addition to this 400 workmen employed at the Enterprise Enamel Works, at Bellaire, Ohio, are also on strike.

Morgantown—The summer meeting of the West Virginia Coal Mining Institute will be held in Morgantown, June 24, 25 and 26. There is a desire on the part of the officials of the Institute that the coal men of the state get acquainted with the State University. It is believed that when the interests become aware of the excellent equipment of the school, so far as the college of mines is concerned, that they will take more interest in it and will begin the ground work of an important school of the state.

OHIO

Columbus—The Ohio representative of the annual mining congress to be held at Karlsbad, Bohemia in July will ask for a six-hour day and a five-day week for all work connected with coal-mining industries. He will also ask for a uniform inside day wage scale, and proportionate advances for machine mining and also for a substantial advance on pick-mined coal.

It is said that Ohio coal operators will be drawn into the investigation to be made by the United States Senate Committee on Education by the labor people in West Virginia fields. Allegations have been made by the members of the committee that the operators in Ohio are interested in fomenting trouble in the West Virginia field.

Governor Cox, of Ohio, will soon take up the matter of naming the commission provided for in the Thomas resolution adopted by the Ohio General Assembly. This commission is to investigate the rate of wages being paid for coal mining in Ohio. The resolution was adopted to sidetrack the Green antiscreen bill, which had passed the Ohio Senate and was pending in the House of Representatives. Judge M. N. Donahue, of the Ohio Supreme Court, who was offered a place on the commission, refused to serve.

INDIANA

Indianapolis—The Indiana wide entry law of 1907 is held to be constitutional by the Supreme Court of the United States. It provides that there shall be at least 2 ft. of space between track and wall, either on one or both sides, as a means of escape for miners in case of threatened collision or other accident to the cars. Veins 3 and 4 in the block field are exempt from the law. The penalty for violation is a fine not to exceed $200, to which imprisonment may be added. The Vandalia Coal Co., in a test case, which it carried through the courts of the state, took it in final appeal to the highest court of the land, the judges of which decided unanimously that the law is constitutional. The company alleged it was discriminative and class legislation.

ILLINOIS

Springfield—If the mine inspectors' bill, which is now in the State Legislature, becomes a law, the miners of Illinois will soon vote on each inspector by districts. Notices are to be posted at each mine, giving the date of the proposed convention to which each mine shall send a delegate. The delegate has a vote for every miner represented, so that two or three large mines in a district may by combination agree on a choice and force it on the others.

Jacksonville—A fire which started from spontaneous combustion of coal dust recently destroyed $125,000 worth of property of the Royal Colliery Co., 1½ miles west of Virden. The upper works of the mine, with the exception of a one-story brick engine house, and the tipple and washery containing 100,000 tons of coal were consumed. Machinery in the tipple valued at $17,000 was ruined. The fire started in the upper part of the washer building and had gained considerable headway before employees of the company on their way to start the night shift had discovered the blaze. None of the company's men were in the mine at the time. The upper works were recently improved at a cost of $20,000, and the tipple, when constructed a few years ago, was valued at $15,000. The cost of the washery was placed at $50,000, and this spring new shaker screens were installed at a cost of $10,000. The loss is covered by insurance. Six hundred men will be thrown out of work temporarily.

Herrin—One life was lost and another saved only by the use of an oxygen machine as the result of a fire which broke out May 22 in the mine of the Illinois Hocking Valley Washed Coal Co. The fire is still raging and the state rescue car has been called from Benton to aid in fighting the flames. The fire is believed to have started in the mule stable, where 17 animals were burned to death.

COLORADO

Denver—The new coal mine inspection bill of Colorado has now become a law. Each coal operator is compelled to pay the coal mine inspection department ½c. for every ton mined. It is expected that this will bring in a revenue of approximately $24,000 a year. The expenses of the department will be in the neighborhood of $15,000 to $18,000, and the balance will go into the general fund of the state.

IDAHO

Kellogg—The miners employed on Big Creek, at the Sidney Shonts lease went on strike May 19, demanding $4 per day. They claim this is a scale that should be paid at all properties located on isolated spots such as the one at which they are working.

MONTANA

Lewistown—Judge R. E. Ayers has named the following men to constitute the Board of Coal Mine Inspectors for Fergus County: P. H. Gilkerson, mine operator; A. H. Brew, coal miner; J. B. McDermott, state inspector.

PERSONALS

R. M. Waugh, of Calvert, Tex., has been appointed general superintendent of the Southwestern Fuel Co.'s mines, located three miles north of that city. Mr. Waugh succeeds T. M. Reaverly.

J. W. Bishoff, chief engineer of the Davis Colliery Co., has been appointed acting general superintendent, in the place of J. F. Healy, general manager of mines, who has resigned. This appointment was to take effect June 2.

Martin Garvey, superintendent of the operations of the Davis Coal & Coke Co., at Thomas, Tucker County, W. Va., has resigned his position, to take affect June 1. It is expected that he will travel for eight months. After that time has elapsed, he will have charge of the coal properties in the state of Kentucky.

OBITUARY

James E. Reese, foreman of Mine No. 6, at Albia, Iowa, was instantly killed while on duty May 28. Mr. Reese was using the telephone at the foot of a hill, when the tailrope on the ingoing trip broke, letting the cars run wild. Mr. Reese was struck and sustained a broken neck. He is survived by a wife and child.

T. S. Elwell, general manager of the Pittsburgh Coal Co., of Wisconsin, died May 21 at St. Mary's Hospital, in Duluth, following an operation for acute appendicitis. Mr. Elwell is a graduate of the University of Wisconsin Law School, and, for a number of years practiced that profession. The body has been taken to Minneapolis. Mr. Elwell is survived by a widow, a daughter and a sister.

RECENT COAL AND COKE PATENTS

Coal Drill—J. G. Huntley, Pittston, Penn., 1,055,464, March 11, 1913. Filed Sept. 3, 1912. Serial No. 718,303.

Coal Separator—S. T. Pratt, Nanticoke, Penn. 1,058,259, Apr. 8, 1913. Filed Aug. 21, 1912. Serial No. 716,265.

Improvements in Charging Gas Retorts—Riter-Conley Mfg. Co., 15 Exchange Pl., Jersey City. Filed in London. 6898 of 1912.

Crusher Roller for Coal Breakers—E. L. Clark, Scranton, Penn. 1,058,948, Apr. 15, 1913. Filed Aug. 5, 1912. Serial No. 713,210.

Dump Car Device—C. H. Doty, W. L. Burner and J. M. Wilcox, assignors to Kilbourne & Jacobs Mfg. Co., Columbus, Ohio. 1,057,413, Apr. 1, 1913. Filed Apr. 14, 1910. Serial No. 555,541.

CONSTRUCTION NEWS

Red Lodge, Mont.—It is reported that the Northern Pacific R.R. is securing right of way for lines from Bridger to the Bear Creek coalfield.

Seattle, Wash.—The new coking plant, which is to be established at Seattle, is to cost in the neighborhood of $3,000,000. The plant will employ from 300 to 600 men and will be a large consumer of Alaska coal.

Catasauqua, Penn.—The Lehigh Coal & Navigation Co. contemplates the erection of coal docks near Catasauqua for emergency use during flood periods. At present, anthracite is handled by docks at Mauch Chunk.

Hazard, Ky.—The Hazard Coal Co., has just contracted with the Roberts & Schaefer Co. to design and build a coal mining plant at Hazard, Ky. The new Marcus combination screen and picking conveyor equipment will be used.

Birmingham, Ala.—George B. McCormack and Erskine Ramsey and associates are planning to construct a byproduct coke-oven plant with a daily capacity of 1000 tons. It is estimated that the cost will be in the neighborhood of $1,500,000.

Astoria, Ore.—J. C. Brooks, representing a large coal company in the Middle West, is investigating local conditions relative to establishing a large coal dock at this place. The purpose is to provide coal for steamships coming to the Columbia River.

Birmingham, Ala.—The Sloss-Sheffield Steel & Iron Co. has awarded contracts for the construction of large concrete and steel coal washers at Flat Top and one at Brookside. The company will also build two washers at Russellville and four coal openings in the Brookside district. Altogether, about $750,000 will be spent in the improvements.

Wilkes-Barre, Penn.—The Wilkes-Barre Colliery Co. has just begun operations at its electrically driven plant at Hudson. This is the only complete colliery so driven in the anthracite region. The apparatus was furnished by the Westinghouse Electric & Mfg. Co. Power is purchased from the Lackawanna & Wyoming Valley R.R. Co.

Hazleton, Penn.—The C. M. Dodson Coal Co. is installing at the Beaver Brook Colliery an electric hoist driven by a 300-hp. Westinghouse slip ring motor with magnetic control. The source of current supply is the Harwood Electric Co.'s plant at Harwood, Penn.

The Lehigh Valley Coal Co. is changing the Spring Brook Slope hoist from steam to electric drive. A 250-hp. Westinghouse alternating-current motor with liquid conroller is being used to replace the hoisting engine.

Whitesburg, Ky.—A location for one of the many mining plants to be constructed by the Elkhorn Fuel Co., recently organized at Baltimore, has been selected at Kona, on the main line of the Lexington & Eastern R.R., at the mouth of Boone's Fork. Engineers are now starting on the preliminary surveys. Actual construction work will be started within a few days. Two other industrial cities will be built in the immediate vicinity. This development is expected to eclipse the large operations and developments of the Consolidation Coal Co.

Portland, Ore.—The Portland Council this week granted a franchise to the Northwestern Electric Co. to install a steam heating plant in the city and according to an announcement of General Manager W. E. Coman the pipes will have been laid and the steam turned on in the business district of the city by the end of the present summer. The company will use fuel oil in its furnaces and hence the installation of the plant will probably to some extent affect the local coal consumption, although a good many of the buildings that are counted on as customers are now using this fuel.

Chattanooga, Tenn.—The Cumberland Land Syndicate is planning the erection of a 60-oven byproduct coking plant in Chattanooga, at a cost of $1,500,000. This plant will produce approximately 275,000 tons of coke annually, besides an immense quantity of gas for industrial, domestic and illuminating purposes. As yet no site has been decided upon, but it is rumored that the Cumberland Syndicate expects to use the 22,000 acres of coal land near Tracey City, recently purchased, for this purpose. Construction work will require approximately 15 months, and it is said that it will be at least 60 days before this can be started.

NEW INCORPORATIONS

Birmingham, Ala.—The White Cross Coal Co.; capital stock, $5000. Incorporators: John Kerr, T. H. Kerr, Lee Stone.

Peoria, Ill.—The Logan Coal Co.; capital stock, $2500; to mine coal. Incorporators: J. M. Tyson, R. W. Peters, J. H. Kingsbury.

Chicago, Ill.—The American Fuel Co.; capital stock, $10,000; mining coal. Incorporators: Frank Hajek, Frank Radons and Walter Baldwin.

Chicago, Ill.—The Eastman Coal Co.; capital stock, $20,000; coal, coke, kindling wood, etc. Incorporators: C. W. Mogg Freda Spears, T. H. Miller.

Buffalo, N. Y.—The Stickney-Price Coal Co.; capital stock, $30,000; to deal in coal, wood, etc. Incorporators: S. W. Stickney, R. S. Price, G. A. Hughes.

Scottdale, Penn.—The Round Bottom Coal Co.; capital stock, $200,000; to purchase and operate 2000 areas of coal land in Marshall County, W. Va. J. W. Wiley, president.

Louisville, Ky.—The Big Four Magnolia Coal Co.; capital stock, $20,000; to deal in coal and land. Incorporators: R. F. Harrison, E. J. Harrison and Paul Blackwood.

Lex, W. Va.—The Lex-Pocahontas Coal Co.; capital stock, $2500; sale of coal and merchandise. Incorporators: J. H. Norman, Russell Mott, W. C. Haight, Paul Cortell and E. Landstrom.

Logansport, Ind.—The Citizens Coal & Gas Co. has been incorporated here, with $10,000 capital stock, to deal in coal. The directors are, G. A. Linton, H. G. Williamson and W. L. Morris.

Newton, Penn.—The Saron Coal & Coke Co.; capital stock, $100,000; to engage in the mining of coal and manufacture of coke. Incorporators: D. T. Vinton, W. R. Thompson, T. J. Bryant, E. Watts and A. E. Bush. Chief works to be located at White County, Ky.

Buffalo, N. Y.—The Commercial Coal & Supply Co., capital $2500; directors, William A. Adolf, Henry C. Stone, a former coal dealer, and Peter Englehardt. The coal business of the late James Ash is incorporated under the name of James Ash, Inc., the directors being John G. Cloak and Charles F. Houck, executors of the estate, and Daniel C. Shearer.

INDUSTRIAL NEWS

Wellsburg, W. Va.—T. C. Bane, of Short Creek, has sold half of his farm, 175 acres, to the McKinley Coal Co.

Punxsutawney, Penn.—W. J. McAninch, Joseph Knabb and others, have secured options on a large tract of land fronting the Sandy Lick, where they have secured siding privileges. They are now test drilling and expect to develop a deep seam of coal which has been found constant throughout the numerous drillings for gas.

Connellsville, Penn.—A seam of coal has been discovered at Rockwood recently, and preparations are being made to develop it and erect coke ovens.

Pottsville, Penn.—The actual work of stripping Broad Mountain for coal by the P. & R. has been started by Dick and Co., contractors of Hazleton.

Shady Side, Ohio—The shaft at the new Webb mine, of the Jones Coal Co., has been completed, and work on the inside of the mine is to be started at once.

Minot, N. D.—The site for a briquetting plant has been bought for some time and the machinery has recently been arranged for. This makes the plant practically an assured reality.

Spokane, Wash.—The International Coal & Coke Co., whose mines and offices are located at Coleman, Alberta, will distribute $30,000 in profits, among its stockholders who were registered on May 20.

Albia, Iowa—The Harris Bros. are arranging to open their new mine on the Spencer farm, south of Hilton. They have a large tract of land to work and the enterprise will represent an investment of $300,000.

Connellsville, Penn.—The Pittsburgh Coal Co. has purchased 300 acres of the Caldwell tract in Washington County. The consideration was $82,500. The tract of land in question lies in Mt. Pleasant Township.

Waynesburg, Penn.—W. H. Brown, who recently bought 1344 acres of Greene County coal at Grays Landing, is expecting to develop his property during the fall. His Alida plant of 400 ovens, on the river near Brownsdale, is in active operation.

Detroit, Mich.—The Solvay Process Co., of Detroit has bought the Spring Coal Co.'s property in the Pocahontas smokeless district of West Virginia, as an addition to its list of ten mines. The output is to be increased to 500,000 tons annually.

Wichita, Kan.—It is rumored that S. B. McClaren, a coal and lumber dealer, will establish two coal yards in Wichita this fall. Men are now at work erecting the sheds, the first of which is to be 14x130 ft., and the second, 20x58 ft. The buildings will be finished early in June.

Coffeyville, Kan.—A 6-ft. bed of coal is said to have been found at a depth of 292 ft. on the Sullivan farm, four miles south of Parsons. The coal was so finely ground that it is impossible to determine its quality, but there is talk of organizing a company to make a thorough test.

Columbus, Ohio—The Hocking Valley R.R. Co. has placed an order with the Ralston Steel Car Co., of Columbus, for 1000 gondola steel coal cars, to be delivered some time in the fall. These cars are to take the place of the 3000 30-ton cars sold by the road to a Northwestern railroad company.

Windber, Penn.—It is reported that the first coal has been extracted from the Loyalhanna new mine at Cairnbrook. This coal is being taken out through the tunnels put in for taking in empty mine cars when the mine is in complete operation. Scheesley & Sons, contractors, finished their work and left the job May 30.

Hickman, Ky.—Saad Salaamy, who has been in the coal business in this region for the past two years, has gone into business with J. T. Dillon. The firm will be known as the Independent Coal Co. They will install a large electric crane, with two 100-ft. towers, for conveying coal from barges on the river to their yards.

Pittsburgh, Penn.—The new coke-drawing machinery has been delivered at the Marianna plant of the Pittsburgh-Buffalo Co., on the Ellsworth branch of the Monongahela division of the Pennsylvania R.R. One thousand men are employed at present, but additional miners are being employed each day, and 200 more men can be given work.

Coshocton, Ohio—Members of the Ohio Coal Co., whose mines are located in the Tunnel Hill neighborhood on the C., A. & G. lines, held a business meeting in Coshocton recently. Extensive improvements have been made about the mines the last several months. The shipping facilities and output have been increased, houses built and other improvements made.

Moundsville, W. Va.—Attorney I. N. Kuhn, of Waynesburg, and J. W. Iams, of East Waynesburg, have just closed a deal by which Mr. Kuhn secures from Mr. Iams 521 acres of coal land located in Marshall County, W. Va. The coal is in two tracts, one lying near Limestone, and the other near the Panama mines on the B. & O. R.R. In partial payment, Mr. Kuhn has given a business property in Washington.

Eldora, Ill.—Mr. Reece, of Gillespie, Ill., has been in Eldora for considerable time investigating the coal fields in that region. His object was to become acquainted with owners of property where coal prospects exist. Later he will return and endeavor to secure option on the coal-bearing lands for the purpose of drilling. If successful, he will install machinery and at once begin mining operations.

Los Angeles, Calif.—It is rumored that the Standard Oil Co. of California is behind individual land seekers who are buying or leasing extensive properties in the Kern River district. It is pointed out that the company is already in the fuel, oil and asphalt business on an extensive scale, and the heavy variety of petroleum found in the Kern River field is needed by the concern's refinery in that section.

Birmingham, Ala.—Contracts have been closed with the Central Coal Co. to supply electric power for the production of coal at Kimberly No. 3, and Kimberly No. 4, which are located about 19 miles north of Birmingham, on the Louisville & Nashville R.R. The power will be furnished by the Birmingham Railway Light & Power Co., at a cost of $50,000, approximately half of what it will cost the coal company to manufacture it itself.

Battle Creek, Mich.—For nearly six weeks the Grand Trunk R.R. has been unable to get coal from the mines in Indiana, and it has been necessary to use the largest part in the reserve dock in the Nichols yards. In view of the fact that the flooded mines are now dried out, the road intends to replenish this reserve coal supply which it has drawn upon. For this purpose 50 men are at work in the local yards unloading coal, and it is expected that several hundred tons will be required to refill the bins.

Cleveland, Ohio—The Kirk-Dunn Coal Co., with $300,000 capital stock, contemplates developing 2000 acres of Ohio coal land on the Youngstown & Ohio River R.R., according to an announcement made recently. Interested in the new company are F. M. Kirk, Cleveland coal man, and W. H. Dunn, Salem coal man. The land lies in the neighborhood of East Liverpool and Lisbon, Ohio. The company expects to be operating extensively by autumn of this year. Its Cleveland office will be in the Williamson Building.

Philadelphia, Penn.—At a meeting of the directors of the George B. Newton Coal Co., the report of the president for the first six months showed earnings in excess of the amount necessary to pay a dividend on the first and second preferred stock, as well as a sufficient amount to take care of the sinking fund. In view of betterments and improvements to be made this summer, it was felt that the consideration of the dividend on the second preferred stock should be postponed until the end of the company's first year, in November.

Colon, Panama—The discovery of a high-grade anthracite coal has been made within 18 miles of deep-water transportation, in the Colon region. The discovery was made on the Rio Indio, which flows into the Caribbean, not far from the mouth of the canal. An area of 25 miles was surveyed and was found to be underlaid uniformly by a seam of coal from 2 to 4 ft. thick, running 85 per cent. carbon. Surveys, preliminary to the construction of a railroad, 80 miles in length, are to be started at once. This will bring the coal region into direct communication with the canal, where it can be loaded aboard ship.

COAL TRADE REVIEWS

GENERAL REVIEW

The demand for hard coal keeps up in all sections of the country, and the current month is expected to be an active one in the anthracite business. The loading out of New York harbor is notably slow, and stove still continues to be the shortest in supply. Naturally some of the sizes are beginning to drag with the approach of midsummer but as compared with previous years the situation is satisfactory in every respect.

The coastwise bituminous trade is showing an increase in strength as the season advances. Most agencies seem to be liberally supplied with orders, and the small buyers have now definitely abandoned hopes of lower prices. The market is firm all along the line, and in much better condition than ordinarily at this period of the year. The labor supply in the mining regions is short, and a slight curtailment in production on the part of a large number of operators would create an interesting situation to say the least. Loose tonnages are becoming more infrequent, due to a broadening in the market and a restriction in production, and this is, of course, creating a freer buying movement in the spot market.

In the Pittsburgh district indications point to a record-breaking business in the lake trade, while the market still continues strong in all branches; in the spot market most operators are demanding a premium over the season's circular for whatever free coal they have. Most shipments on contracts are being well kept up but there are occasional reports of an insufficient labor supply; were this condition remedied the movement would immediately become so heavy that a car shortage would develop. In adjacent territories practically no one is filling orders promptly, because there is insufficient coal to go around; reports are current that a number of large wholesalers have contracted for some tonnages that they are now unable to deliver.

There is an increasing demand for domestic grades in Ohio, which, together with the good steam trade, and a heavy lake business, has stiffened the market in every respect; every effort is being made to rush as large a tonnage as possible into the Northwest, and prices are being well maintained. Dumping at the Hampton Roads piers during the week has not been as heavy as was expected; producers, however, are holding their surpluses in a number of instances to apply on contracts which shortly become operative. The Southern market is as active as could be expected at this time, with a car shortage in some districts, as a result of which a number of mines are falling behind on their contracts.

Buyers generally in the Middle Western market still appear to be holding off in anticipation of a uniform break in prices, but indications in most districts are that the coming winter will see some new high records in quotations. The heavy shipments in the lake trade are reducing consignments on certain grades, with the result that a scarcity is developing in some few districts. The strong position of the Eastern fuels continues to be the main feature in the market.

BOSTON, MASS.

Bituminous—Very little new business is heard from. All the agencies appear to be comfortably supplied with orders, especially on Pocahontas and New River. The smaller buyers are falling into line from week to week, having practically abandoned any hope of lower prices. The market is very firm and there is an entire absence of "cut" rumors. The first of June finds the situation in decidedly better shape than for many years at this season. Receipts at Hampton Roads are rather smaller than a month or two ago. The accumulation has all been moved and on account of short labor supply the daily output is somewhat diminished.

Georges Creek is slowing up on deliveries. Some of the transportation operated by Georges Creek interests has been diverted to loading other coals, in only a small way, to be sure, but yet it seems to signify a reduced output. A small decrease in each of a large number of operations will be sufficient to make things interesting again this fall and winter. Even at the high prices ruling it is no effort to place all the Georges Creek that comes down. The same is true of the better known grades from Pennsylvania districts. All-rail and up the line from the tidewater distributing points there is no perceptible change from a week ago.

Current quotations on bituminous at wholesale are about as follows:

	Clearfields	Cambrias Somersets	Georges Creek	Pocahontas New River
Mines*	$1 05@1 40	$1 25@1.50	$1.67@1.77	
Philadelphia*	2 30@2 65	2 50@2 75	2 92@3.02	
New York*	2 60@2 95	2 80@3.00	3.22@3.32	
Baltimore*			2 85@2.95	
Hampton Roads*				$2 85
Providence†				$3.73@3.78
Boston†				3.78@3.90

*F.o.b. †On cars.

Anthracite is coming forward steadily on spring orders. The demand keeps up from all sections and June is expected to be an active month for hard coal. Stove is the size most in request although the demand for other grades is really more even than was expected. It is understood that a liberal share of the anthracite mined is being sent to other markets and if that condition holds for a few weeks the demand will continue to be somewhat ahead of the supply. Loading with most of the New York companies is notably slow, except on pea and buckwheat.

NEW YORK

Anthracite—The hard coal business during May was just about equal to that of 1911, and, of course, far ahead of the trade during the same month in 1912, conditions then, being abnormal, due to the suspension in mining. The outlook for the summer is doubtful. Some companies are inclined to regard the situation rather optimistically, while others anticipate an abnormally dull market over the midsummer period. In general it appears that the trade is easing off slightly, although not more than what is normally expected at this time of the year.

Stove coal continues to be the shortest in supply, with Lehigh egg a close second; in fact most companies report all the prepared sizes to be in good demand. Pea and buckwheat in the steam grades are still the heaviest, some operators reporting that they are now putting these into storage, although others state that they have not yet found this necessary. While labor is short in the mining districts, the effects are not apparent on the shipments coming in, which are fully up to the usual amount for this time of the year. Car supply is excellent.

A further increase in the standard anthracite circular of 10c. per ton is now in effect, and we quote the New York market on hard coal as follows:

		Individual	
	Circular	Lehigh	Scranton
Broken	$4.70	$4.45@4.65	$4.50@4 70
Egg	4.95	4.90	4 95
Stove	4.95	4 90	4 95
Chestnut	5.15	5 15	5.20
Pea	3.50	3 30@3.45	3.35@3.50
Buckwheat	2 75	2 15@2 45	2 50@2 75
Rice	2.25	1 70@1.95	2 25
Barley	1.75	1.35@1.70	1.60@1 75

Bituminous—A strong insistent demand for soft coal still continues at tidewater. There are no large stocks on hand, and requisitions on contracts are much heavier than usual at this period, with the result that there is a large tonnage moving.

The feature of the local market is the exceedingly heavy demand for gas coal. This is so far in excess of the supply that considerable of the business has been diverted to other grades, resulting in a material stiffening in the market all along the line. Another unusual condition is the lack of any reasonable explanation for the unusually large demand at this period of the year. It is obvious that there is a heavy consumption, but it is equally clear that this is not confined to any one particular industry, and seems to be entirely due to general industrial activity.

Companies are refusing to take any further new business, except at fancy prices, and spot business in the line trade is also much improved. Some contract buyers, accustomed to holding out for low prices, are beginning to find out that they are in a difficult position now. We continue last week's quotations with prices firm, and tonnages rather difficult to obtain on the following basis: West Virginia steam, $2.55@2.60; fair grades, Pennsylvania, $2.65@2.70; good grades of Pennsylvanias, $2.75@2.80; best Miller, Pennsylvania, $3.05@3.15; Georges Creek, $3.25@3.30.

PITTSBURGH, PENN.

Bituminous—The market continues strong throughout, but as operators are well able to ship there is not much prompt business being placed. There is no uniform prompt market, some producers being willing to sell such free coal as they have at regular circular prices, while others demand a premium, and occasionally secure it. We note a sale today of 1500 tons of prompt at 10c. above circular prices. The supply of labor is somewhat scant, according to the opinion of some, but it remains a fact that necessary shipments are being made. The car supply is short only occasionally, but with a larger labor supply operators would probably try to get out more coal than they could secure cars for, and then the situation would be definitely called one of car shortage.

Lake shipments are heavy with all signs pointing to a record breaking tonnage this year. This does not mean that the Pittsburgh district is doing more than its share, but that there is general pressure for heavy Lake shipments. The slack market is quite irregular, as usual at this time, many operators selling for what they can secure, while others hold to the circular price of 90c. and store what cannot be sold. The lowest price done on slack this season is understood to have been 55c., and in extreme cases in the past week 60c. has been done, though 75c. would probably represent the average market for prompt slack. Operators are now quoting two prices on 1¼-in. screened coal, $1.55, the regular circular price put out months ago, for 1¼-in. domestic, and $1.50 for 1¼-in. steam coal. Noting that prompt coal, except slack, frequently commands a premium of 5@10c., we quote regular circular prices as follows: Slack, 90c.; nut and slack, $1.05; nut, $1.25; mine-run, $1.30; ¾-in., $1.40; 1¼-in. steam, $1.50; 1¼-in. domestic, $1.55, per ton at mine, Pittsburgh district.

Connellsville Coke—The market remains quite strong in the face of a very decided lack of activity as regards new business, and it is quite evident that the operators are holding together on prices through faith, stimulated by the strong influence of banking interests, rather than through actual market conditions. Shipments against contracts are heavy, but have undergone a slight decrease in the past fortnight, due to the blowing out of a few blast furnaces. Prompt demand is extremely light, and is generally filled at concessions of 5@10c. from the usual asking price of $2.25 for furnace coke. Negotiations for contracts for furnace coke are light, and some inquiries recently out have been withdrawn. Demand for foundry coke is only moderate, but prices continue to be held at a good premium over furnace coke, on account of the shortage of labor, which particularly affects the forking of cars. We quote prices unchanged: Prompt furnace, $2.15@2.25; contract furnace (nominal asking) $2.50; prompt foundry $2.85@3.25; contract foundry, $3@3.25, per ton at ovens.

BALTIMORE, MD.

The improved condition in the local market was maintained during the week, the demand for all grades continuing brisk and the price list firm; spot business was the feature of the market, especially in the line trade. Consumers depending on prompt delivery are buying more freely, while loose tonnages are becoming more infrequent, due to a broadening of the market and some restrictions in production at the mines.

The movement under contract continues large, with prices unchanged. In fact, a good healthy tone pervades the coal industry in this vicinity due to an unusual industrial activity, and operators are having difficulty in meeting the increased demand because of the labor shortage.

Shipments of gas coal to the Lakes have reached the highest point of the year, and this has tended to create a shortage of railroad equipment in the Eastern markets. As yet, this has not seriously interfered with operations, but indications are that it will gradually become worse and be even more acute than usual the coming fall.

PHILADELPHIA, PENN.

The anthracite trade is now past the first week in June, and comparing with the business during this month last year, which was the first full month that the mines worked after the suspension, the situation is said to look fairly good. Of course, some of the sizes are beginning to drag, notably the small ones, and egg and chestnut, but stove coal will carry the others along. All orders for this last size must be accompanied by some for the other sizes as well.

The market so far has shown almost a reversal of conditions, as regards the demand for stove and chestnut. It was the unprecedented call for the latter size some two years ago, which doubtless impelled the operators to advance the price to 25c. over stove, and the effect has been to drive some of the business that formerly was on chestnut, back to the stove size. At any rate, the market is hungry for stove, and the proportion of the orders is entirely at variance with the percentage of this size mined.

Tidewater business from this port seems to be the strongest feature of the market. The local trade is still going along at a jog trot, with nothing to boast of in either the demand, or the outlook for future business. As a matter of fact, the market is gradually approaching the season when conditions are generally sluggish. Of course, a comparison with last year during the summer months, cannot be considered, but as general rule curtailed work at the mines, and a stagnant condition of the market, usually prevails during the season now approaching.

The bituminous market has still to redeem itself. While there seems to be a slightly better feeling, its growth is slow, and action feeble, although the feeling seems to be general that, taking all in all, it is gradually growing better.

BUFFALO, N. Y.

The bituminous market is as strong as ever and bear members of the trade now content themselves by predicting that it will all go flat next fall. At present they need most of their time for hunting up coal enough to meet their demand. Practically nobody is filling orders promptly, for the reason that there is not bituminous enough to go around. There were long faces when the Decoration Day reports came in with notice of next to nothing done in the mines. Every effort was made to keep the miners at work, but with only partial success.

There are still a good many minor contracts making, all of which are quite satisfactory to the seller; one operator claims to be getting fully 15c. more than a year ago. There is much report of jobbers eastward who have taken big selling contracts without fortifying themselves at the mines and now they are begging for coal. One of them who used to buy all he could sell, and getting it at his own prices, is now paying as much for slack as he contracted to furnish mine-run for.

There is, therefore, no slackness in prices. Pittsburg select lump is quoted at $2.80, three-quarter at $2.65, mine-run at $2.55 and slack at $2.15. Coke is less firm than coal and is quotable on the basis of $4.75 for best Connellsville furnace.

The anthracite trade is steady, but consumers are well enough supplied to keep them quiet for sometime yet. Report has it that the Eastern coast trade is good enough to make it undesirable to crowd coal Westward just now except for storage against winter. Shipments of anthracite by lake for May, were 628,650 tons and for the season, 1,133,364 tons. For the same time last season the shipments were only 40,250 tons, owing to mining suspension.

COLUMBUS, OHIO

Activity still characterizes the coal trade in all the mining districts of Ohio. There is a slightly increasing demand for domestic grades, which coupled with a good steam trade and a heavy Lake business has the effect of making the market stiff in every particular. The tone is good and practically every one connected with the trade anticipates a good year. Prices are well maintained at the same level which has prevailed for the past few weeks.

The lake trade is still active, every effort being made to rush a large tonnage to the Northwest. The docks are taking care of the shipments in good shape and the congestion among the lake vessels is about over. Dock prices are well maintained and shippers in both the Hocking Valley and eastern Ohio fields are working as fast as possible. Some trouble over a car shortage is reported from eastern Ohio and as a result production in that district has been curtailed.

Railroads are taking a large tonnage, because of the increasing freight movement; many of the railroad contracts have been renewed although a few are still hanging fire. Steam contracts have been mostly renewed at higher figures than prevailed in 1912.

Quotations in the Ohio fields are as follows:

	Hocking	Pittsburgh	Pomeroy	Kanawha
Domestic lump	$1 50	.....	$1.50	$1.50
1-inch	1 35	$1 25	1.35	1.30
Nut	1 20	.....	1.25	....
Mine-run	1 15	1.10	1.15	1 10
Nut, pea and slack	0 70	....	0.70	0.70
Coarse slack	0 60	0.70	0 60	0.60

Practically no labor troubles are reported from any of the Ohio fields; most of the strikes have been unimportant although a few have lasted for some time. As a result production has held up well with the exception of districts where the car shortage has affected the output. In Eastern Ohio it is reported at about 75 per cent. because of the car shortage. In the Hocking Valley it is about 90 per cent. and in the Pomeroy Bend field it is 60 per cent. of capacity.

HAMPTON ROADS, VA.

While dumpings at the tidewater piers have been good they have not been as heavy as was expected at the beginning of the week when there was a large fleet at all piers. Buyers have been offering $2.85 to $2.90 for spot or prompt coal during the week and while there have been some few sales, suppliers are not negotiating, preferring to hold coal now at tidewater for contract vessels about due. One of the large shippers over Lamberts Point has 19 vessels due during the month of June for foreign cargoes in addition to Coastwise contract business and it now looks as though the coal shortage will continue on into June unless the unrest at the mines is straightened out and the collieries worked to their full capacity.

Total dumpings for the month of May are not yet in but at Sewalls Point it will be around 280,000 tons, at Newport News about 295,000 tons, while Lamberts Point figures should run considerably over 330,000.

LOUISVILLE, KY.

The abnormal supplies of slack which have been offered during the past few weeks appear to have been absorbed, and the market for this grade is again in an approximately normal condition. As noted in a previous issue, this condition was due to a large railroad consumption, particularly in the Southern market. It now seems that these roads have acquired good surpluses, with the result that their demand has been materially reduced, and the supply of fine coal is again approximately normal. As a result of the excessive demand for the small grades, there was naturally an overproduction of lump coal, and a consequent falling off in prices. This, however, tended to stimulate the stocking-up so that no unusual surpluses accumulated.

As a result of the falling off in domestic consumption, due to the arrival of summer, eastern Kentucky producers generally find it difficult to obtain orders, and the trade is dull. Operators are now looking forward to the time when consumers will begin to stock up, with which business they will have to be content until the real winter demand opens up in the fall. It is not unlikely also that the labor situation in West Virginia may have a stimulating effect upon the local market; car supply in those fields is also reported as inadequate, and the combination of these conditions may prove to the advantage of the local market. There is some inquiry from Chicago and the Northwest, but this has not as yet resulted in a sufficient volume of business to materially affect the field as a whole.

The second-grade eastern Kentucky screenings are in light demand at 50 to 60c. f.o.b. mines, with the better qualities at 75 to 85c., and little moving. Western Kentucky fuels range about the same as the second-grade eastern Kentucky products, with 30c. being a fair average on pea and slack. Eastern Kentucky block is $1.60 to $1.70, block and lump $1.50 to $1.55, and round $1.25 to $1.35.

DETROIT, MICH.

Bituminous—The market generally is slightly duller than last week, due probably to the firm stand which the operators are taking in the matter of prices. Some buyers are undoubtedly holding off in anticipation of a decided slump before very long, while on the other hand one of the largest local wholesalers is credited with the statement that he expects to see the highest price level the coming winter this district has ever witnessed. It is generally conceded that many of the Ohio operators are already sold up to December and are now refusing to accept any further business at the prevailing circular.

The following is approximately the local market on soft coal:

	W. Va. Splint	Gas	Hocking	Cambridge	No. 8 Ohio	Pocahontas	Jackson Hill
Domestic lump	$1 50		$1 50			$1 90	$1 90
Egg	1 50		1 50			1 90	1 90
1½-in. lump	1 25						
¾-in. lump	1 15	$1 15	1 15	$1 15	$1 15		
Mine-run	1 05	1 05	1 05	1 05	1 05	1 25	
Slack	0 80	0 85		0 50	0 85		

Anthracite—The demand for hard coal in the local market is holding up well, and jobbers seem to have a better volume of business than they had anticipated. There has been no difficulty in disposing of all the coal coming in, and a number of orders for May delivery have been carried over into the current month.

BIRMINGHAM, ALA.

A canvass of the local situation shows that most of the producers consider the general coal market as active as could be expected for this season of the year. It is only in rare cases that orders are seriously needed and in almost every instance the mine that is short on orders has a poor grade of coal to offer. Where the coal is properly prepared there is not much worry about disposition at a remunerative figure. In many instances, on the railroads where the car shortage is most acute, the mines are not keeping up with their contracts.

Regardless of how favorable other conditions may be, it is not believed that the outputs in Alabama can be largely increased until the labor situation is materialy improved. Prices seem to have struck a level properly justified by consumption and production as there is little variation from week to week.

INDIANAPOLIS

The coal trade continues in about normal condition, with little to change the situation from week to week. There is a fair amount of the steam grades moving, all the factories continuing on a steady, if somewhat limited schedule. The delivery of domestic coal from the retail yards increased as the month of May advanced, consumers apparently having the idea that prices may increase. If no lift is given prices for June, that month is likely to see more than the average quantity of coal put in house cellars.

The following prices prevail:

Anthracite, chestnut	$8 00	Hocking Valley lump	$4 50
Anthracite, stove and egg	7 75	Luhrig lump	4 55
Anthracite, grate	7 50	Luhrig washed egg	4 75
Pocahontas, forked lump	5 50	Cannel	6 55
Pocahontas, shoveled lump	5 00	Linton No. 4 lump	3 20
Pocahontas, mine run	4 00	Linton No. 4 egg	3 20
Pocahontas, nut and sack	3 50	Indiana washed egg	3 50
Blossburg	5 50	Brazil block	4 00
Jackson (Ohio)	5 25	Indianapolis lump coke	6 00
Kanawha lump	4 50	Indianapolis crushed coke	6 00
Kanawha egg, nut	4 50	Connellsville lump	7 00
Pittsburg lump	4 50	Citizens' egg coke	6 00
Raymond lump	4 50	Citizens' nut coke	6 00
Winifrede lump	4 50		

CHICAGO

There is an exceptionally strong demand for smokeless coal in the Chicago market. A number of the larger buyers who have not obtained a sufficient supply on contract are buying freely in the spot market. A large amount of tonnage is being absorbed by the lake trade and, as a result, rail shipments to Chicago are light. A large supply of eastern Kentucky coal is being shipped here and sales are brisk. Hocking Valley prices continue to be strong, but comparatively little of this coal is being received here.

Dullness prevails in the spot market for Western domestic fuel. In anticipation of the harvesting season, a few orders have been sent for Brazil block and southern Illinois coal. A substantial increase in the number of orders for anthracite has been noted, although the general volume of business is far from heavy. As a result of the small production of lump, there is a strong demand for Western screenings. Low grade screenings command 80 to 85c., while the price for the high grades ranges from 85 to 90c.

Prevailing prices in Chicago are:

	Springfield	Franklin Co.	Clinton	W. Va.
Domestic lump	$1.97@2.07	$2.30@2.40	$2.27	
Egg		2.30@2.40		$3.75
Steam lump	$1 82@1 87		2.07	
Mine-run	1.77@1 82	2.20@2.30	1 97	3 30
Screenings	1 62@1 67	1 95	1.57@1 62	

Coke—Connellsville and Wise County, $5.25@5.50; byproduct, egg, stove and nut, $4.55@4.75; gas house, $4.65@4.75.

MINNEAPOLIS-ST. PAUL

The coal business continues on the same slow and steady basis as heretofore this coal year. May was a sample of two extremes in weather. The forepart of the month was cold and rainy, and the retail trade was stimulated by small ordering of coal with which to keep heating plants agoing. The last week was the other extreme, with the thermometer registering as high as 90 degrees. A smaller amount of hard coal was placed with the consumer at the spring prices than usual, and it seems the early summer storage has become almost a negligible quantity in the Twin Cities and the Northwest. Dock prices have been adhered to at circular very closely and the senseless cutting in vogue last year, has not been in evidence except in a few cases.

ST. LOUIS, MO.

The past week saw some new records for low prices made, in both high-grade and cheaper coals. Standard mine-run sold down to 72½c., 2-in. lump 77½c., and 6-in. lump 85c. It is generally conceded that the cost of producing Standard coal is above 85c., on a mine-run basis, so if they continue to produce large enough tonnages, it is only a matter of time. On Carterville and Franklin County the low market was 95c. for lump and egg. Even in anthracite, on a jobbing basis it is being handled in St. Louis on a 5c. margin.

There is a scarcity of smokeless and very little moving in; the strike in the New River field threatens to cut off the local

supply, as St. Louis draws largest from that particular district.

The prevailing circular is:

	Carterville and Franklin Co.	Big Muddy	Mt. Olive	Standard
2-in. lump				$0.90
3-in. lump			$1.20	
6-in. lump	$1.15 @ 1 20		1 25	1.05
Lump and egg		$2.25		
No. 1 nut	1.05 @ 1 15			0.85
Screenings	0.90 @ 0 95			0.80
Mine-run	1.00 @ 1 10			
No. 1 washed nut	1 35			
No. 2 washed nut	1 20			
No. 3 washed nut	1 25			
No. 4 washed nut	1 25			
No. 5 washed nut	1 00			

St. Louis prices on June anthracite are: Chestnut, $7.15; stove and egg $6.90; grate $6.65. Smokeless lump and egg is $4.45 and mine-run $4. Byproduct coke is $5 and gas house $4.75.

SPOKANE, WASH.

It is said that a big profit is made by the retailers in Spokane, and that the domestic trade could be served with Roslyn and Crows Nest Pass coals at about $6.75 to $7.25 a ton, according to the haul, and at about $8 to $8.25 for the Wyoming product, the difference in freight rates making the latter coal higher. There is said to be about $1 difference in the cost of slack and mine-run and there is 25c. more duty on lump coal for family use from Canada than on slack, or steam. Prices at which steam coal is sold to business blocks are: $5.25 for mine-run or $5.75 to $6.25 delivered. This coal costs at the mine in the Crows Nest district: Slack, $2; mine-run, $2.85@2.35 and lump, $3@3.25 a ton. The latter retails at $8.75@9.25 f.o.b. Spokane. The freight rate on coal from the Crows Nest Pass district ranges from $2.15 to $2.25 a ton and the duty is 15c. on slack and 40c. on mine-run and lump. On this basis the lump coal costs from $5.65 to $5.80 laid down in Spokane, and as it is claimed that this must be screened, and the screenings sold at a low rate, this loss is estimated at about 25c. a ton.

Taking the benefit of this, the highest rate for Canadian coal is $6.05 a ton. Owl Creek coal comes from the Northern Wyoming field and the freight rate is $4.25 a ton to Spokane, but the Carney and Roundup coals draw a lower rate, the latter coming from Montana. The cost of Owl Creek at the mine for lump is $2.75 and for nut $2.25. Taking the highest rate, it costs $7.20 laid down in Spokane. Southern Wyoming coal including the Rock Springs district costs $4.80 freight and the mine cost is the same as Owl Creek, making it cost $7.55 here.

PRODUCTION AND TRANSPORTATION STATISTICS

IMPORTS AND EXPORTS

The following is a comparative statement of imports and exports in the United States for March, 1912-13, and for the nine months ending March, 1911-12-13, in long tons:

	9 Months			March	
Imports from:	1911	1912	1913	1912	1913
United Kingdom	13,067	5,911	7,451	50	96
Canada	1,240,937	729,583	1,361,379	104,346	107,016
Japan	7,474	15,886	42,657	5,578	440
Australia & Tasmania	228,003	159,720	105,158	10,324	10,141
Other countries	4,717	1,501	3,289	57	32
Total	1,494,198	909,601	1,231,934	120,355	117,725
Exports:					
Anthracite	2,048,535	2,578,400	3,383,126	277,283	158,522
Bituminous,					
Canada	5,996,537	7,987,237	8,295,614	511,616	736,549
Panama	396,367	330,433	340,259	27,414	32,500
Mexico	491,490	235,493	264,537	24,119	57,629
Cuba	705,478	804,094	915,889	91,643	110,727
West Indies	385,708	503,769	456,013	63,075	53,308

VIRGINIAN RAILWAY

Total shipments of coal over this road for April of the current year were 345,939 tons as compared with 280,995 tons for the same month last year. Shipments for the first four months of the year were: 1,578,283 tons for the current period and 1,195,600 tons in last year.

FOREIGN MARKETS

GREAT BRITAIN

May 23—Prices continue to show irregularity for prompt shipment. Smalls, particularly, are more abundant, with prices on the downgrade. Colliery owners are holding firmly for high figures for forward delivery, but buyers are unwilling to operate at the prices asked.

Quotations are approximately as follows:

Best Welsh steam	$5 28@5 42	Best Monmouthshires	$4.74@4.86
Best seconds	5 10@5 22	Seconds	4.56@4.68
Seconds	4 92@5.04	Best Cardiff smalls	3 48@3.54
Best dry coals	5 04@5 28	Seconds	3.36@3.48

The prices for Cardiff coals are f.o.b. Cardiff, Penarth or Barry, while those for Monmouthshire descriptions are f.o.b. Newport; both exclusive of wharfage, and for cash in 30 days—less 2½%.

British Exports—The following is a comparative statement of British exports for April, and the first four months of the last three years, in long tons:

	April		4 Months		
	1912	1913	1911	1912	1913
Anthracite	29,793	235,650	766,219	587,797	937,166
Steam	1,986,312	4,708,475	14,631,510	10,132,535	17,317,543
Gas	256,486	983,697	3,203,899	2,205,484	3,503,943
Household	45,654	146,273	474,255	344,888	581,727
Other sorts	66,326	276,774	973,356	696,939	1,159,199
Total	1,494,571	6,350,869	20,049,239	13,967,643	23,580,878
Coke	11,081	70,200	319,909	288,204	352,396
Manufactured fuel	21,856	184,145	548,697	395,188	492,541
Grand total	1,527,508	6,605,214	20,998,859	14,651,535	24,633,615

GERMANY

Germany's coal production, imports and exports, for March and first three months of the current year were as follows:

	March		Three Months	
	1912	1913	1912	1913
Coal	12,811,823	15,413,278	42,021,733	47,558,449
Lignite	7,041,990	6,706,221	20,413,947	20,917,977
Coke	2,159,905	2,744,350	6,742,553	7,991,860
Coal briquettes	356,336	462,014	1,222,190	1,436,225

DIVIDENDS

Lehigh & Wilkes-Barre Coal—Dividend of $3.25, payable June 17 to holders of record June 10.

FINANCIAL DEPARTMENT

Consolidation Coal Co.

President J. H. Wheelwright of this company reports under date of Mar. 19, for the fiscal year ended Dec. 31 as follows:

Bonds—The following 5% 1st Ms. have been released of record and bonds canceled. Consolidation Coal Co. Kentucky Div., $3,000,000; Somerset Coal Co., $4,000,000; Clarksburg Fuel Co., $2,500,000; Pittsburgh & Fairmont Fuel Co., $1,300,000.

Bonds in Sinking Funds and Pledged under First and Refunding Mortgage.

	Pledged	In S.F.
Consolida—4½% 1st M		$444,000
tion —4½% ref. M	$322,000	446,000
Coal Co.—5% 1st and ref	.....	95,000
Cumb. & Penn. RR. 1st 5%		x
Fairmont Coal Co. 1st 5%	189,000	694,000
So. Coal & Trans. Co. 1st M. 5%	486,000	14,000
Briar Hill Coal & Coke Co. 1st M. 5%		
Somerset Coal Co. 1st M. 5% of 1910	3,585,000	

x Sinking fund holds $678,000 bonds of other companies.

Of the auth. issue of $40,000,000 1st & ref. 5s, $10,495,000 are held to retire underlying bonds, $95,000 are in sinking fund, $14,956,000 are held for future additions, improvements, etc., $1,479,000 are in treasury and $12,975,000 are held by public. [Compare convertible bonds below].

Tonnage—The tonnage produced by all mines of the company from 1912 was 10,347,100 net tons, compared with 9,219,731 net tons in 1911.

	Maryland	*W. Va.*	*Penn.*	*Mis.Cr.*	*Elkhorn*	*Tot.Gross.*	*Tot. Net.*
1912	2,162,996	4,576,484	1,748,091	522,900	228,011	9,238,482	10,347,100
1911	2,178,391	3,925,329	1,671,639	456,544	.....	8,231,903	9,219,731

Elkhorn Field—The development work of the company in its 100,000-acre Elkhorn Field in Eastern Kentucky has progressed most satisfactorily. The town of Jenkins, on the eastern or Sandy Valley & Elkhorn Ry. side of the field now has a population of over 5000 people. The central power plant is now supplying all the power for the mines in the entire field, and these mines have been equipped with electrical haulage locomotives and electrical mining machines designed to cut this Elkhorn seam of coal.

Owing to the unusually high waters last spring, the construction of both railroads into this field was seriously delayed, and it was Oct. 1 before the Sandy Valley & Elkhorn Ry. was taken over for operation by the Baltimore & Ohio R.R. On the western side, the L. & N. R.R. was not completed until several months later, and the buildings are not so far advanced as at Jenkins, but some have been completed and a large number are under construction. The Louisville & Nashville R. R. Co. has ordered 3000 all-steel cars to take care of our output and they are now being delivered. The Baltimore & Ohio R.R. Co., for the Sandy Valley & Elkhorn Ry., has had built and delivered to that road 2000 all-steel cars, and we understand have an order for an additional 1000 all-steed cars in the process of being placed. Considering that the construction of neither railroad was commenced until April 1911, and the fact that their construction and equipment expenditures made and to be made are estimated at $10,000,000 shows the desire of the railroad companies to reach this field as quickly as possible and the value placed by them upon the traffic originating therefrom.

It is our belief that the production this year from the Elkhorn field will be at least 1,750,000 tons. During 1913 miners' houses and other necessary buildings will be constructed so as to provide homes for the miners required to produce the increasing output of these mines.

All the important steel producers have built, or are building, by-product plants, and have, therefore, adopted this method of making coke. Several hundred thousand tons of our Elkhorn Coal have been used in the largest by-product plants and gas works in this country, and the coal has been found to be uniform in quality and analyses show only ½ of 1% in sulphur, 3% or under in ash, with only a trace of phosphorus. This is run-of-mine coal as it reaches the consumer and not an analysis of picked samples. By practical use, therefore, it has been proven an ideal fuel for by-product purposes, yielding a pure metallurgical coke, a large and rich yield of illuminating gas, together with the other resultant by-products, tar, etc.

Outlook—The conditions show an improvement over last year and it is believed that the production of 1913 will greatly exceed the tonnage of 1912.

[The stockholders on Feb. 18, 1913 authorized the issuance of $6,500,000 6% 10-year bonds convertible into stock at 105 prior to Feb. 1, 1922, and also an increase of $6,190,500 stock, to take care of the convertible feature of the bonds. A public offering of the bonds was made in March. Pres. Wheelwright on Feb. 27, 1913, reported the company's total bonded debt as $28,613,000, including $11,645,000 "1st & ref. M" 5s, $10,468,000 underlying issues and the $6,500,000 new convertible bonds. He also reported the collateral for the new bonds as $1,800,000 Northwestern Fuel Co. com. stock; $500,000 Metropolitan Coal Co. stock, and $6,500,000 Consol. Coal Co 1st & ref. M. 5s, or their equivalent in cash, pending deposit of bonds. There are now listed on the N. Y. Stock Exch. $16,345,000 1st & ref. M. 5s, which amount, we learn, includes $4,605,000 of the $6,500,000 which are to be pledged for the convertible issue.]

RESULTS FOR YEAR ENDING DEC. 31, INCLUDING SUBSIDIARIES

COAL AGE

Vol. 3 NEW YORK, JUNE 14, 1913 No. 24

True Success

By Berton Braley

Written expressly for Coal Age

Though Dividends come rolling in
Beyond the dreams of avarice,
The measure of success you win
Is not determined just by this;
For it is Failure, not success,
(However great the golden spoil)
To profit by the harsh distress
Of those who serve you by their toil.

Your house of pride and lordly show
Is only proof of gold and greed
If in the miners' huts below
Are famine, misery and need;
If those who mine your good black coal
Have had no share in all your gain
But labor for a grudging dole,
Then your "Success" is false and vain.

If you are playing fair and square
And giving those who toil their due,
Taking for yours, your honest share
Of what the mine has yielded you,
If no man justly owes you hate
If you have kept your tenderness,
You may not gain a vast estate
But—you will find the true success!

Coking the Semibituminous Johnstown Coals

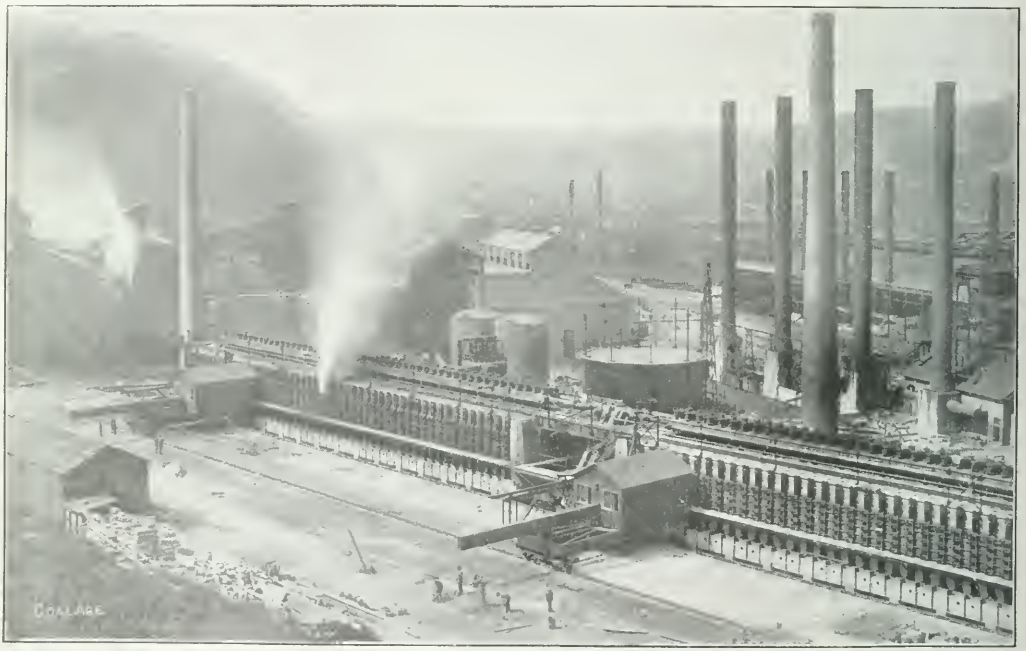
By John W. Gocher*

SYNOPSIS—The Johnstown coals will not coke in beehive ovens unless part of the fixed carbon is burned to make heat. They give much trouble because they swell so freely on coking. It has been noted that the coals which expand least are those which are highest above sea level. These also contain the highest volatile content but the indications do not afford sufficient basis for a conclusion as to the cause of the excessive expansion.

Although classed as a semibituminous fuel, the workable seams of coal in the Johnstown basin may be said to be among the dryest of the so called dry bituminous coals.

ning, or Cement, bed, with a few openings tapping the Upper Freeport, or Lemon seam. The topography of this region is so badly broken up that within a comparatively short radius from the center of the city, coal is mined from the same seam in openings varying 200 ft. or more in elevation, and this coal shows markedly different characteristics, with a more or less definite relation between the elevation of the coal and its proximate analysis.

A reference to the Johnstown folio of the Geological Survey will show that the bottom of the basin lies immediately north of the city and for convenience, in the table which is given later in this paper, the elevation of the various workings from which samples were taken is



Batteries 5 and 6, Otto-Hoffman Byproduct Ovens, Johnstown, Penn., Fifty Ovens to a Block

The Johnstown syncline crosses the lower end of the city in a northeasterly direction, and lies between the Laurel Ridge anticline on the northwest and the Ebensburg anticline on the southeast. In the hills surrounding the valley of the Stony Creek, on which the city is located, the workable seams of coal outcrop at numerous points.

Apparent Relation between Elevation and Coking Action

Most of the workings are to be found in two seams, the Lower Kittanning, or Miller, and the Upper Kittanning, or Cement, bed, with a few openings tapping the Upper Freeport, or Lemon seam. The topography of this region is so badly broken up that within a comparatively short radius from the center of the city, coal is mined from the same seam in openings varying 200 ft. or more in elevation, and this coal shows markedly different characteristics, with a more or less definite relation between the elevation of the coal and its proximate analysis.

A reference to the Johnstown folio of the Geological Survey will show that the bottom of the basin lies immediately north of the city and for convenience, in the table which is given later in this paper, the elevation of the various workings from which samples were taken is given as above sea level, the lower Kittanning bed in the bottom of the basin being approximately 950 ft. above that datum.

The Early Coking Methods

In the early days of the iron industry at Johnstown, the Upper Freeport coal was coked in heaps or mounds and the resulting product used in the local blast furnaces. The coke is said to have been of fair quality and well suited for use in the small blast furnaces of the time, which were used for smelting the local low-grade self-fluxing ore. More recently various attempts have been made to coke the local coals in ordinary beehive ovens, but with indifferent success, the coking time being 72

*Consulting engineer, Cambria Steel Co., Johnstown, Penn.

to 96 hr. and great difficulty being experienced in maintaining the oven heats.

At the present time, however, in West Virginia, similar coals are being coked in beehive ovens, but with low yield, a fair percentage of the carbon being used in addition to the volatile matter, to maintain the heat.

The method of coking in heaps at the Cambria plant was followed sometime in the seventies, by a plant of so called "Belgian" ovens, which were operated for several years and abandoned about 1880, when the company acquired coal lands and built beehive ovens in the Connellsville region. No definite records of these Belgium ovens are now in existance.

Coppee Nonrecovery Retort Ovens

The first retort ovens in which Johnstown coal was used were located at Conemaugh and worked in connection with the Cambria Iron Co.'s blast furnace at that point. The plant consisted of 60 Coppee nonrecovery retort ovens and was built in 1886-1887, and operated until the furnace plant was destroyed by the Johnstown flood in 1889, after which it was not rebuilt.

The coal used was the Upper Freeport, containing about 17½ per cent. of volatile matter, and it was crushed before charging, but was not washed. The ovens were 16 in. wide at one end and 20 in. at the other, 5 ft. high and 22 ft. long, and the coal charge weighed three tons. The coking time was 18 hr. and the coke yield 68.7 per cent.

At the outset the usual Coppee practice of working the ovens in pairs was followed, a fresh oven being charged alongside a partly coked one, in order to maintain the battery heat. This did not work satisfactorily and continual trouble was experienced in pushing the ovens.

Afterward the practice was changed, so that the ovens were charged and pushed in rotation, the oven heats probably being maintained by combustion of some of the carbon in the retort, the yield, as noted above, being 68.7 per cent. Efforts made from time to time to reduce the coking time below 18 hr. were unsuccessful, and were finally abandoned.

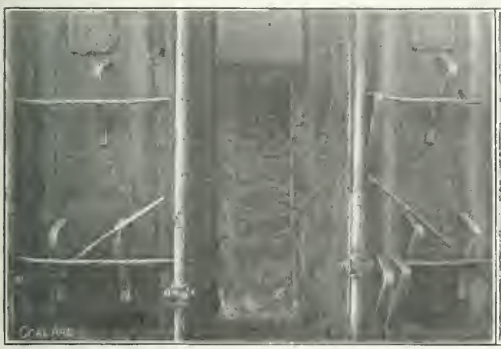
The operation of this plant gave constant trouble. The coal in coking swelled to such a degree that when the coke was pushed, unless extreme care was used, or the cake of coke had burned itself loose, damage to the oven walls resulted.

The Introduction of Otto Ovens

The gradual exhaustion of the Cambria Iron Co.'s holdings of first-class coking coal in the Connellsville region led, soon after the flood of 1889, to further investigation of possible methods for coking the local coal, and in 1893 and '94 representatives were sent to Germany to study the various systems of retort ovens. Coal was shipped to some of the German plants and coke made from it.

As a result, a contract was made with the Otto Coke & Chemical Co., the American representatives of Dr. C. Otto & Co., and 60 retort ovens with a plant for the recovery of tar and ammonia, were built at Johnstown in 1894.

This was the first byproduct-coke plant in this country to be built in conjunction with a steel plant and making its principal product for use in a blast furnace. This initial plant is still in service. Additions were made to it from time to time, until at present the installation consists of 372 ovens, all of them practically the same size, with a capacity of 4½ net tons of coke per charge.



Appearance of Red-Hot Coke in Retort before Pushing. Note How Tightly It Fills the Oven

Coke after Being Pushed from the Oven. It Is Not Large and Columnar like Beehive Coke

As compared with the large units now being constructed, these may seem small, but, until recently, the advisability of adopting larger ovens has been a matter of doubt. It has been questionable whether the "structure" of the coke would be sufficiently strong to withstand the pressures resulting from the swelling of the coal on coking, if that operation were conducted in larger ovens.

Small Variations in Analysis with Wide Variation in Expansion on Coking

The first plant was built with the intention of using mountain coal from points east of Johnstown, containing a higher percentage of volatile matter and for a time this coal was used.

The possibilities of the local coals were always kept in mind, however, and the practice gradually modified until, at present, only local coal is used, the mixture consisting of half from the Lower Kittanning and half from the Upper Kittanning seams.

This is true, however, of the coal from two openings

only, known locally as Franklin mines Nos. 1 and 2, efforts to use the coal from other mines in the same seams giving trouble.

This fact led, recently, to a systematic investigation of the characteristics of the coal as mined at different points, the results of which are given in Table I.

The results given are fair averages, and if any deduction can be made, it is that the highest volatile content is found in the coal at the highest level in the basin, and also that the degree to which the coal will swell in coking varies considerably with only slight differences in analysis.

An effort was made to trace some analogy between the average analysis of mixed coal, washed mixture and sludge. The average loss in crushing and washing is about 12 per cent. by weight.

After draining for an average period of 72 hr. the coal is removed, in successive layers of about 6 in. thick, from the top of the piles in the storage pits, by means of a traveling excavator which places it on belt conveyors, which, in turn, deliver it to the oven bins.

The average moisture content in the coal as delivered to the ovens is about 8.5 per cent. With fair oven heats the coking time is about 21 hr., and the coke yield about 80 per cent. of the coal charged, or the yield from coal as mined will average 68 to 70 per cent. of dry coke.

RESULTS OF COKING TESTS

Mine No. 1—Swelled badly—could not push when ovens were "down."
Mine No. 2—Swelled badly—could not push when ovens were "down."
Mine No. 3—Swelled considerably—pushed, but with difficulty.
Mine No. 4—Swelled somewhat less than No. 3—pushed hard.
Mine No. 5—Same conditions as No. 3.
Mine No. 6—Swelled badly—could not push.
Mine No. 7—Average working conditions.
Mine No. 8—Swelled considerably—pushed with difficulty.
Mine No. 9—Average working conditions.
Nos. 7 and 9 are the mines from which the coal is being coked.
Mine No. 8 is the famous Rolling Mill mine, from which 3000 tons of steam coal are taken daily.

behavior of the coal and its ultimate analysis, but the laboratory results varied so widely that no definite basis for such comparison could be fixed.

Present Practice in Preparation

The coal as mined from Mines 7 and 9, given above, is delivered in approximately equal quantities from the tipple bins onto a conveyor belt leading to Bradford breakers, where the lumps are broken and some of the bone, sulphur balls, etc., removed. The coal then passes to the crushing rolls, and is crushed to the following sizes:

Sizes	Percentage
On ½-inch mesh	3 78
Through ½-inch mesh	95 4
Through ¼-inch mesh	78 5
Through ½-inch mesh	66 2
Through ⅛-inch mesh	57.5

Leaving the crushing rolls, it is conveyed on belt conveyors to a storage bin in the highest part of the washery building. Thence it is delivered through spouts to the feed screws of two rows of improved Campbell washing tables.

From the tables the washed coal is sluiced, using the same water with which it was washed, into nine concrete drainage pits, each holding 1500 tons. The refuse is also sluiced into two smaller pits and allowed to drain, afterward being loaded onto cars for removal.

The water from the drainage pits finds its way into sewers under the pits, is collected in a sump and pumped back to an elevated tank for re-use. Table II shows an

TABLE II. AVERAGE ANALYSIS OF MIXED COAL, WASHED COAL AND REFUSE

	Mixed Coal	Washed Coal	Refuse
Volatile matter	17 09	18 00	13 30
Fixed carbon	69 50	73 95	20 56
Ash	13 20	8 05	66.14
Phosphorus	0 012	0.011	0.046
Sulphur	2 25	1 17	11 51
Silica	5 61	3 50	28 60
Lime	0 14	0 10	0.25
Magnesia	0 32	0 06	0 34
Alumina	3 52	2 73	16 42
Ferric Oxide	3 02	1 28	20 38

The product is regarded as a good metallurgical coke. It breaks with a good deal of cross fracture, into rather small rectangular blocks instead of fingers.

In appearance it is quite dense, with a large number of extremely small cells, and with the following physical characteristics: Apparent specific gravity, 1.005; true specific gravity, 1.847; porosity, 45.72 per cent.

After the shatter test of four drops from a height of 6 ft., 20.51 per cent. passes through a 2-in. mesh.

TABLE III. ANALYSIS OF COKE

Volatile matter	0.81%
Fixed carbon	89.28%
Ash	9.90%
Phosphorus	0.014%
Sulphur	0.94%
Silica	4.46%
Lime	0.13%
Magnesia	0.21%
Alumina	3.18%
Ferric Oxide	1.84%

Moisture in Coke High, Byproduct Yield 67 per Cent. of Normal Yield

The moisture in the coke varies. With the small-cell structure mentioned above, it is difficult, in the first place, to quench the coke properly, and when so quenched that danger of fire in the cars is eliminated, the small cells retain a large percentage of water, with not enough heat in the cell walls to drive it off. Since the coke is used in the company's furnaces and the charges are measured, not weighed, the variable moisture is not so serious a feature as it might be under other conditions.

The byproduct yield is a disappointing feature in coking this coal. It will be readily understood that constant use of a more or less swelling coal in a brick oven will inevitably result in the distortion of that structure, with resultant cracks and unavoidable leakage of the products of distillation. In consequence, the amount of ammonia and tar recovered is about two-thirds of the possible yield and the surplus gas is not enough to justify plans for its use elsewhere.

The average life of the coking chambers up to the time when the walls become so crooked as to prevent pushing the charge, is about two and one-half years. Renewal of individual retorts or of a group, with the remainder of the battery in service, is not good practice, as the local expansion of the new brickwork tends to increase any cracks which may exist in the working portions of the battery. It is now believed that the best procedure is to work the battery as a unit as long as practicable, allowing ovens which become too bad for service to remain banked. When the number of idle ovens becomes excessive, the battery should be rebuilt as a whole.

Effect of Moisture in the Coal

With oven chambers constructed altogether of silica brick, the question of what effect charging the wet coal into the hot chambers will have on the brickwork has repeatedly been asked. The face of the brickwork, after extended use, shows a slight checking or spawling, but in certain particularly good ovens, which have been in constant use six years, this checking is not enough to interfere with pushing the coke.

Coke Pusher Working at Battery No. 8

It is a question whether the moisture contained in the coal as charged may not be beneficial in coking a swelling coal. While wet coal weighs about 14 lb. per cu.ft. more than the crushed dry coal, the mixture as charged occupies considerably more space in the coking chamber than the same weight of dry fuel, due probably to the tendency of the moist particles of coal to stick together in irregular masses, thus forming interstices, which, when the coal later commences to swell in coking, provide room for a portion of the increased volume.

Tests have been made with dry coal and the coke apparently pushed about as easily as the usual charge. As the unwashed coal does not make satisfactory coke this practice could not be continued long enough to obtain definite information along this line.

The water vapor driven off during the process of coking, however, adds considerably to the volume of gases to be handled through certain parts of the byproduct apparatus.

From the foregoing it will be apparent that coking a lean semibituminous coal while practically impossible in beehive ovens, in retort ovens presents a variety of complex and interesting problems, such as do not fall to the lot of oven operators who can select their coal.

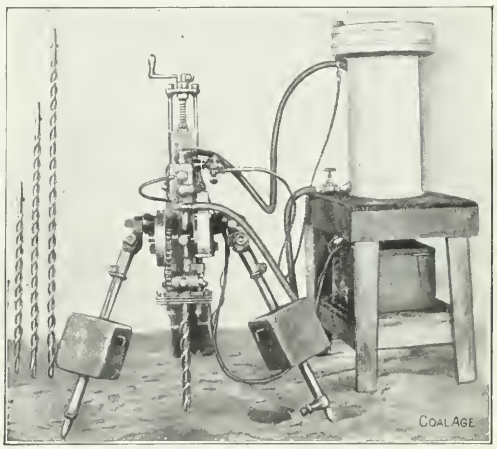
A Gasoline Rock Drill

A new and interesting gasoline rock drill has been recently developed in St. Louis, Mo. This has been built in four sizes, ranging from the hand drill weighing 35 lb. to the largest size which weighs 265 lb. and which will drill holes up to 20 ft. or more in depth.

The gasoline drilling engines are built to operate upon the two-cycle principle. They are free from gears, cams and pushrods. Backfiring is said to be impossible and speeds up to 3000 r.p.m. can be attained if desired.

The piston is moved rearwardly by energy stored in the flywheel and is picked up or cushioned on the return stroke by the compression of air. The drill steels are automatically rotated by means of a chain and sprocket which connects the crank to the rotator shaft.

Two types of drill steels may be used, one the common hollow steel through which water can be forced together



The Gasoline Rock Drill Upon Its Tripod

with a small amount of explosive pressure for the purpose of removing the rock cuttings from the drill holes. The other type is solid but is formed with a spiral conveyor which works the rock cuttings out of the hole, in the same manner as a wood augur does its chips. This type of steel does away with the water connections which sometimes cause trouble.

It is claimed that this machine is fool proof and simple and light for its capacity; that it will drill rock at the rate of from three to 15 in. per minute and the largest machine uses only two gallons of gasoline per ten-hour day.

The roller bearings with which this machine is supplied are packed with grease and require attention only about once a month. The exhaust may be either cooled by being piped into water, or led to the mouth of the shaft or tunnel through pipe lines. In either case, provided the ventilation is reasonably efficient, the exhaust does not vitiate the mine air to any extent.

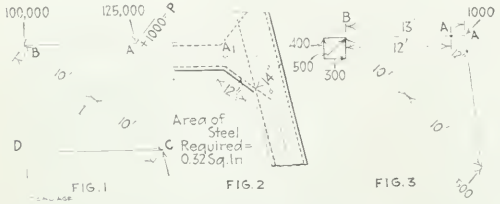
Experience has shown that with the most careful of packing the surface subsidence will equal from one-third to one-half the thickness of a seam. Even where hydraulic packing is used the subsidence may be anywhere from 0 to 10 per cent. Allowance should always be made for this shrinkage.

Colliery Practice in Concreting

By Elwyn E. Seelye* and A. T. Shurick

SYNOPSIS—This is the third installment on this subject. In this issue the advantages of concrete are discussed, together with costs and methods of designing a number of different types of structures. A number of construction details, and few remarks on forms are also given.

In our previous issues of Dec. 14 and 28, we have described the processes involved in concreting operations, the general rules which should be followed to safeguard the execution of the work, the commonest types of reinforcement in use, and proposed formulas for the design of reinforced-concrete beams, slabs and struts. It is proposed in this article to take up the practical design of some of the ordinary structures which may be built in reinforced concrete.



Figs. 1, 2 and 3. Stresses in Knee Bracing

Reinforced Concrete versus Other Materials—The first problem which will present itself will be the expediency of using reinforced concrete in place of steel or timber for a certain structure. Factors determining this are as follows: The occurrence of a suitable aggregate near the site, such as a gravel bed, slag or facilities for crushing rock, and availability of a suitable sand. Questions of life and durability of the structure will generally militate in favor of reinforced concrete.

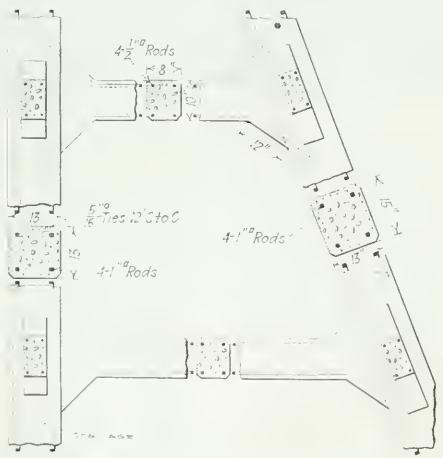


Fig. 4. Complete Details of Bent Panel

Cost of Reinforced-Concrete Structures

A rough idea of what a reinforced-concrete structure should cost may be obtained by using the figures given below. These price must be considered as basic inasmuch as they will vary greatly with location and conditions:

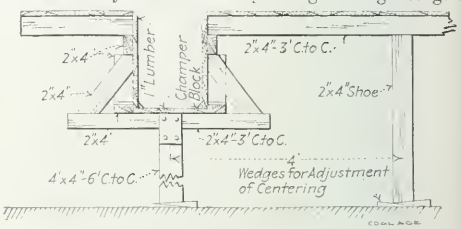

Fig. 5. Form Details

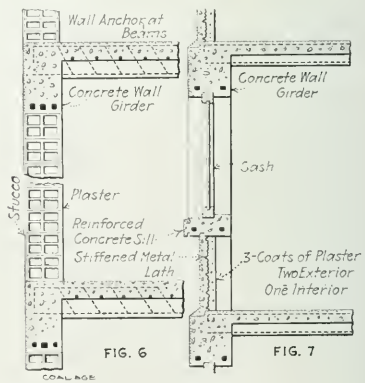
Column centering of concrete surface[1]	80.10
Centering for solid slabs[1]	0.11
Centering for tile and joist slabs including shoring for ordinary story heights[1]	0.10
Beam and slab centering and shoring[1]	0.08
Concrete in place[2]	6.00
Steel reinforcement in place[2,3]	0.025
Stiffened-wire lath in place[1]	0.06
Plastering three coats on stiffened wire lath[1]	0.07
Cement tile for roofs in place[1]	0.18

[1] Per square foot. [2] Per cubic yard. [3] Per pound.
[3] A rough idea of the weight of the reinforcement in a structure may be obtained by the formula weight of steel in pounds equals cubic feet of concrete times five.

Reinforced-Concrete Framing

The frames of such structures as headframes, tipples, breakers, washeries, buildings and trestles may be readily constructed of reinforced concrete. The main difference between the steel and reinforced-concrete frame is that in the concrete structure knee-bracing is generally resorted to in lieu of diagonal bracing. This is because diagonal-brace centering is uneconomical.



Figs. 6 and 7. Sidewall Construction

Let us assume a stress diagram for a unit of a frame and design the members and the knee bracing, see Fig. 1. The main stresses are assumed to be acting along the axis of the main members, but the wind load and vertical panel load will be resisted by the knee bracing and flexural

*Consulting engineer in reinforced concrete, 38 W. 32d St., New York City.

strength of the main members. This knee-brace design will be taken up first.

This problem is really statically indeterminate and susceptible of solution only by an excursion into the complication of the elastic theory. But, if we assume that B and C are pin connections, we shall have a higher bending moment in the angular beams $B\,A\,C$ than if B and C are rigid joints, and hence, be on the side of safety. Accord-

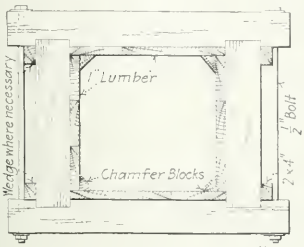


FIG. 8. COLUMN FORMS

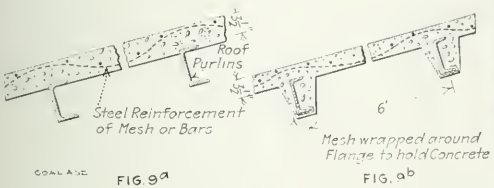

FIGS. 9A AND B. STEEL AND CONCRETE ROOFS

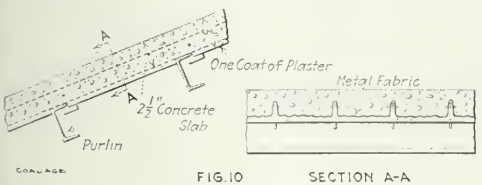

FIG. 10. THE APPLICATION OF STIFFENED-WIRE LATH

ing to this assumption, if the 1000-lb. wind load is normal to $B\,C$, we have a bending moment at A equal to

$$\tfrac{1}{4}\,Pl = \frac{1000 \times 20}{4} = 5000 = \text{ft.-lb.} = 60{,}000 \text{ in.-lb.}$$

Now recalling the flexural formula for reinforced concrete (see our previous issue of Dec. 28, 1912, p. 901), $M = 108\ bd^2$, where

M = Moment in inch-pounds
b = Width of strut
d = Effective depth of strut

We have $60{,}000 = 108\ bd^2$. Assuming effective depth of joint = 14, see Fig. 2, and we have:

$$b = \frac{60{,}000}{108 \times 14 \times 14} = 2.8$$

Area of steel = $0.008 \times 2.8 \times 14 = 0.32$ sq.in. in strut. Next the bending moment at A should be calculated. This is done by determining the resultant at B or C normal to AB. See Fig. 3. We then have $300 \times 12 \times 12 = 43{,}200$ in.-lb., and by the formula for reinforced concrete in flexure gives us:

$$bd^2 = \frac{43{,}200}{108} = 400$$

Assume d = 8 then w $= \frac{400}{64} = 6\tfrac{1}{4}$ in.

Steel = $8 \times 6\tfrac{1}{4} \times 0.008 = 0.42$ sq.in.

Hence, we will make the horizontal strut 8 × 10 in. with four ½-in. square rods, as shown in Fig. 4. The rods are placed in both top and bottom to provide reverse flexural strength which might be induced from the panel above.

The direct compressive stress in AC was assumed at 125,000 lb., and the axial component of the wind load is 400, making a total 125,400 lb., see Fig. 3. The formula

FIG. 11. CONCRETING A HY-RIB ROOF

for direct compression in a concrete strut is $W = (A_c + 15\,A_s)\ 600$ in which

W = The load on the strut
Ac = Area of concrete
As = Area of steel.

Hence, we have (see our previous issue of Dec. 28, 1912)

$125{,}400 = 600\,(A_c + 15\,A_s)$ hence $A_c + 15\,A_s = 209$

Assume the steel reinforcement to consist of four 1-in.sq. rods, then:

$$A_s = 4\ sq.in.$$

and we have:

$$A_c + 60 = 209$$

$$A_c = 149$$

So that the strut should be 12x13 in., but in addition we have the flexural stress of 43,200 in.-lb. to take care of just as in AB above. As before, $bd^2 = \frac{43{,}200}{108} = 400$, and the effective depth of the strut 12x13 in. will be 11.5 in., hence $b = 3$. So that the strut should be 15x13 in. with four 1-sq.in. rods. A similar design for BD gives us a 13x13-in. strut.

There is also an additional compressive stress in the cross struts, due to the moment of wind load. This would be found for AB by taking moments around C, Fig. 1. The moment due to the force P must be resisted by a compressive stress in AB. However, for ordinary structures this stress is comaratively small and we will not consider it in our design.

The complete design of the unit is shown in Fig. 4. Attention is called to the fact that the actual flexural stresses, induced by wind load or other conditions, will be much lower than those obtained by the assumption of

pin connections at *B* and *C*. This is a good thing in a design where the nature of side stresses are indeterminate and where safety factors should be increased for impact.

Certain features of design common to tipples, washeries, power houses, breakers and miscellaneous buildings will now be discussed. These include roof, floor and sidewall construction and may be divided into two groups, namely, those where the skeleton frame is steel and where it is reinforced concrete.

Roof Construction

Under the first group for roofs, we have the solid reinforced slab, and the concrete slab on stiffened-wire lath, as shown in Figs. 9, *a* and *b* and 10.

On steep-roof work it may be found advisable to run the ribs of the stiffened-wire lath horizontal in order to retain the concrete while pouring. This is opposite to that shown in Figs. 10 and 11. Stiffened-wire lath for this purpose is manufactured by the Trussed Concrete Steel Co., of Detroit, Mich., the Corrugated Bar Co., of Buffalo, and the Northwestern Expanded Metal Co., of Chicago. An illustration of such a roof in process of concreting is given, Fig. 11.

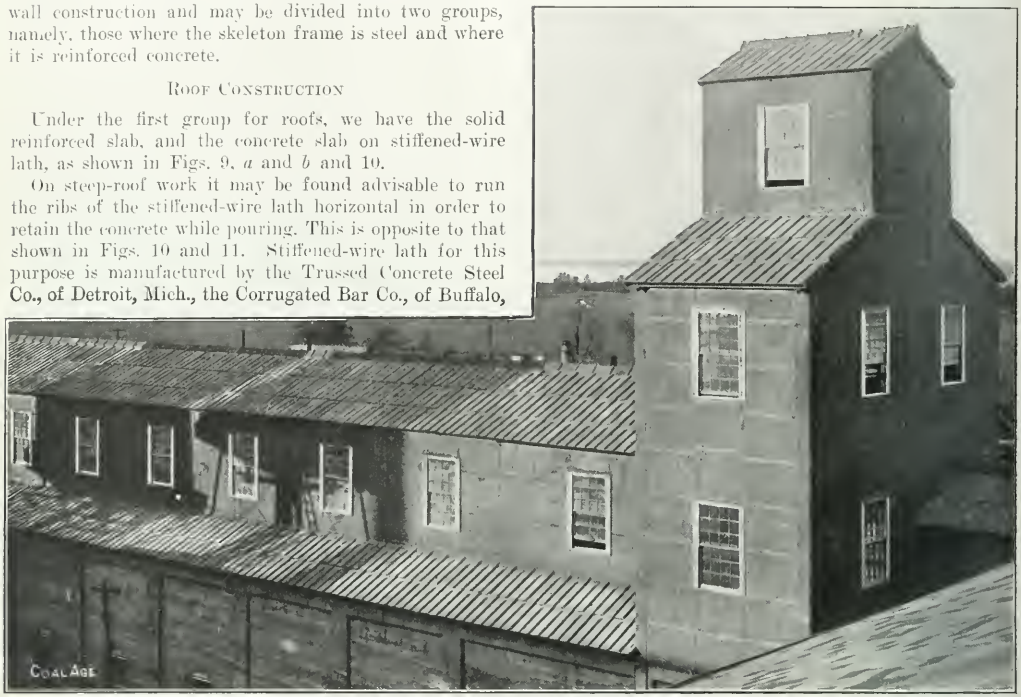

Fig. 12. A Practical Application of American Cement-Tile Roofs

Concrete Purlins—Under this heading we have the beam and slab type, the tile and joist, and the stiffened-wire lath construction shown in Figs. 13, 14 and 15, respectively.

Roof Design

These roofs are designed by computing the flexure on the girders, purlins and slabs by means of the formulas given on p. 901, of our issue of Dec. 28, 1912. Wind stresses are taken care of by knee bracing between the main girders and columns as discussed in this article for the unit frame. Roof live loads should be assumed at 50 lb. per sq.ft. for flat roof and 30 lb. for pitched roofs. Attention is called to the method of forming the T-flange in Fig. 11 by the reduction of the size of the block.

Cement-Tile Roofs—Another economical type of concrete roof is the cement tile. This tile is really a reinforced-concrete slab. It is about ⅞ in. thick and reinforced with expanded-metal lath. It weighs 13 to 15 lb. per sq.ft. The slabs are made to span between purlins on 4-ft. centers. The top surface is treated so that it is impervious to moisture. It will be seen from the illustration in Fig. 12 that the tiles lap and interlock. They should not be used on a flatter pitch than one-quarter rise to one horizontal. This tile is manufactured by the American Cement Tile Co., of Wampum, Penn., and includes a complete line of special shapes such as gutter, ridge tiles, etc.

Floor Construction—The types of construction, shown in Fig. 9 *a* and *b*, 13 and 14, are commonly used in floors.

Sidewall Construction—The commonest forms of concrete sidewall construction are the concrete blocks, terra cotta tile, bricks, reinforced-concrete slab, and hydraulic plaster slab, used in connection with the stiffened-metal lath. The brick, concrete blocks or tile blocks may be used either as bearing walls or in skeleton construction, see Figs. 6 and 7. The formula for stucco is five parts portland cement, 12 parts sand and 1 part hydrated lime; to this may be added the coloring matter and an integral waterproofing compound, such as described in our previous article of Dec. 28, 1912.

Forms or Centers

The appearance of the finished structure will largely depend upon the quality of the forms, so that not only must we build true workmanlike forms, but they must be so stayed that they will not become deformed under the severe strains due to the heavy hydraulic pressure caused by ramming and the weight of the concrete mass.

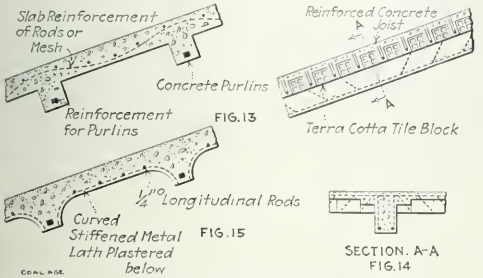
Class of Wood—In selecting a lumber, choose one which will not warp too readily, is not too hard to be easily workable, will not split when the forms are removed and which is also cheap. Spruce is an ideal lumber, and hemlock is coming into use because of its cheapness, but the

latter splits too readily to be a good material for forms. Cypress and yellow pine are suitable materials, but the latter is rather expensive.

Slab and Beam Centering—For forms supported on structural steel, ⅝-in. lumber may be used. Various methods for carrying the centering on the steel are in vogue, the commonest being to carry slab forms on beam boxes and suspend same with wire ties.

For the beam and slab construction, such as is shown in Fig. 13, one-inch material with 2x4-in. framing and 4x4-in. shores is suggested, as shown, Fig. 5.

A typical section of forms for a column is shown in Fig. 8. For octagonal columns the same forms are used



FIGS. 13, 14 AND 15. REINFORCED-CONCRETE ROOFS

with triangular blocks between the frames and the planking.

New Coal Fields in Western Canada

BY PHILLIPS THOMPSON*

D. B. Dowling, of the Canadian Geological Survey, recently visited some new coal fields concerning which the survey had previously but little information. Among these were three small areas on Flathead River, B. C., a newly opened field on Saskatchewan River, east of the Brazeau coal field; and the Coteau in southern Saskatchewan.

One of the Flathead areas which is near the boundary appears to be the most important of these fields. It is a basin of rocks similar to the Crows Nest, but restricted in area to a few square miles. In this basin, seams of 20, 30 and 50 ft. are exposed by opencuts and prospecting tunnels and a very large tonnage can be safely expected. The seams dip at angles of about 20 deg. and are easily mineable. In the center of the valley, 20 miles north of the boundary, a block of these rocks on edge was also found, and the 50-ft. seam has been traced for two miles in a north and south direction. This is probably the extent of those measures. The third locality being prospected is near the North Kootenay pass and is a block recorded by Doctor Dawson, but is probably not so extensive as he supposed. Seams of 6, 12 and 18 ft. are exposed by tunnels. A mass of coal near the fault line is claimed to be the 50-ft. seam.

The coal field on the Saskatchewan is on the line of the Canadian Northern Ry. that is being built west from Stettler. Outside the break marked by the Brazeau hills, the Edmonton formation is brought to the surface and a 10-ft. seam of domestic coal is exposed beneath the railway grade, near the mouth of Shunda Creek. Inside the Brazeau hills, Kootanie rocks are exposed, dipping west at about 20 deg. and four coal seams of 7, 14, 7 and 4 ft., respectively, are being opened for mining at the railway grade. A vast quantity of coal lies above this level, and it is believed that at one place between Shunda Creek and the Saskatchewan, the uprises from the main entry will measure 6000 ft. at right angles to the entry.

The fuels of southern Saskatchewan are found south of the main line of the Canadian Pacific Ry. The nearest coal supply to Moose Jaw, at present known, is south of Lake Johnston, and outcrops on the banks of the Lake of Rivers. This is a seam of about 8 ft. of lignite, which appears to be a good fuel.

G. S. Malloch continued his examination of the Groundhog coal basin, in British Columbia, and determined the southern, eastern and northern boundaries of the area in which coal-bearing strata occur. The southern boundary is situated near latitude 56 deg. 50 min.; the eastern follows the Dooti fork of the Skeena to Shawnee Lake, thence to the valley of the Chatakutahn, from which it passes over a flat divide to the Chuayetz fork of the Stikine and thence over another divide to the east fork of Clappan River. The northern boundary is, approximately, latitude 57 deg. 30 min. Information given by prospectors leads to the belief that the western boundary runs up the east fork of the Nass River and over a divide to the main fork of the Clappan. The dimensions of the field are, therefore, roughly 30 by 45 miles; but in parts of this area the coal-bearing rocks have been removed by erosion.

While many new outcrops were discovered last season, no marked improvement in quality was noted, quartz or calcite veinlets being present in nearly all the seams and niggerheads and numerous thin beds of bone occurring in many of them. Proximate analyses of nine samples, from different localities in Groundhog basin, made in the laboratory of the mines branch, showed great variations in quality, the percentage of fixed carbon ranging from 40.81 to 80.25, the majority of samples, however, carrying upward of 60 per cent.

J. D. Mackenzie examined about 250 square miles in southwest Alberta, including most of the foothills area between the valleys of the South Fork River and Pincher Creek. The well known coal measures of Blairmore and Coleman, in the eastern part of the Crows Nest Pass, extend in part southward into this district, and an investigation into their extent and structure shows that there is a considerable amount of coal in this area that can be worked when railway transportation becomes available.

W. W. Leach made a detailed examination of the country covered by the Blairmore map sheet, an area of about 12 to 17 miles, including practically all the producing mines of the bituminous coal fields on the Alberta side of the Crows Nest Pass. Sufficient information was obtained to map closely the outcrops of the coal-bearing beds and the position of the major faults, rendering it possible to represent accurately the location of the coal measures and the quantity of coal available.

Nothing tends to shorten the life of a rope so much as bending and unbending on drums and pulleys which are too small. This fault is more often encountered in haulage drums and pulleys than in hoisting arrangements. The drums of hoisting engines and the head gear-pulleys are generally more than 100 times the diameter of the rope, which, according to many rope experts, is the minimum size of pulley for six-stranded seven-wire ropes. Head-gear pulleys should not exceed 18 ft. in diameter. If over this dimension they become unnecessarily heavy and lead to trouble and excessive local wear.

Kentucky Mines and Workmen's Compensation

By K. U. Meguire*

SYNOPSIS—The author describes the advantages of that form of compensation which divides the losses evenly among the operators of the state, regardless of the mine at which the accident took place. He compares this with the employers' liability decisions, which are satisfactory to no one but the lawyer who, as a result of the present jury system, is the principal person to be compensated.

In at least 37 of the states of this country there have been adopted or are now under consideration, laws providing workmen's compensation and practically abolishing the old common-law defences, with which the employer could frequently meet suits for personal injuries which arose from accidents to men at work. In 15 of these states, the new system is now in operation; in the other 22, the subject is being considered with a view to legislation. But in Kentucky as yet, personal-injury suits still multiply; courts are clogged; all the other evils of the old era flourish mightily, and no official notice has been taken of what is an epoch-making change all over the civilized world.

Compensation Is Greatest Factor in Social Evolution Since Civil War

The principle of workmen's compensation is declared to be the greatest factor in social evolution since the Civil War; its embodiment in modern law is declared to mark an important step in industrial evolution. Certainly it has been the most prominent feature of labor legislation all over the world for several years. Patterning to a degree after the European nations, the United States Government first adopted this principle for compensating accidents at the naval stations, arsenals and in the limited sphere of federal jurisdiction. Later, one by one, the various states, led by Maryland, have adopted laws, extending this protection to the more numerous individual corporations.

I shall not discuss the abstract principle at length. Its essential value rests in the distribution of the economic loss arising from an accident by removing this loss from one or several employers and employees and dividing it among all the persons engaged in the industry in question, thereby placing that loss finally on the consumer in the form of a slight increase in price on every unit of manufacture which he buys.

The Evils of Employers' Liability

The benefits of workmen's compensation are not yet as certain as are the evils of employers' liability, which it practically supersedes. The old scheme of law devised in England at a time when materials were manufactured by small groups of workmen under the personal direction of the employer, relieved the latter of liability for damage arising from an accident, where the negligence of the injured workman or that of a fellow-employee contributed toward the injury. With the radical change in industrial conditions due to the introduction of modern machinery, the division of labor, and the grouping together of large armies of workers, there came greater danger of accident and greater difficulty in placing responsibility therefor, and it has gradually dawned on the minds of men that negligence is an unavoidable factor in modern industry, and that there will be less disturbance of business and less hardship on human beings when its consequences are borne by the entire industry and not by one or several individuals.

By abolishing the old defences of the employer, the new order of things seeks also to do away with personal-injury suits altogether, to relieve the state of expensive litigation, which now congests the courts, to ease the employer and employee alike of the uncertainty and inconsistency of jury verdicts, to save the employee heavy court costs and lawyers' fees; to exempt the employer from loss of time in court attendance, and, finally, to clear the whole industrial horizon of the ill-feeling invariably attendant on personal-injury actions.

The Uncertainties in Workmen's Compensation

In escaping these known evils, we may expose ourselves to others, which are yet unforeseen. The experience of the 15 states which have compensation or state insurance laws is as yet too brief to have bared all the weaknesses of the new system. In Germany, we are told, the costs of administering the state's industrial insurance are so great as to be burdensome to the industries it was established to protect. In this country, from the mass of data and argument collected by the Bureau of Labor and by private interests, such as the casualty companies, it is impossible as yet to form even an approximate estimate of the cost of compensation.

Nor is the time yet ripe to appreciate the full effect which the system will have on the relations between labor and capital. Even the legality of the various state laws or vital parts thereof is still in question, numerous cases instituted to attack these laws in a number of states being still pending.

It seems to me that the disposition of the large sums of money collected from the various industries to compensate their injured employees must be safeguarded with the utmost care to prevent widespread fraud and graft. That, in addition to the danger of waste and corruption, there is likely to be a continual struggle between labor and capital as to the amounts to be fixed for compensating the several classes of accident, the former seeking to increase and the latter to decrease these amounts unduly, and bringing into play to accomplish these ends all the disorganizing methods of political chicanery.

Whatever be the ultimate cost in money, strife and corruption, the ills of the employers' liability system seem to me so great and the relief promised by workmen's compensation so tangible and attractive that I look for the automatic compensation method to prevail in every state in which the so called hazardous occupations are carried on.

The loss of the entire United States through work accidents is now estimated at about $250,000,000 annually. The figures would convince *economists* that a deficit

*President, Harlan Coal Mining Co., Coxton, Ky.

Note—Abstract of paper read before the Kentucky Mining Institute, Lexington, Ky., May 17.

of such magnitude should be distributed with care, so that individual employers or employees be not swamped by an accident, while their fellows enjoy temporary immunity.

The Employers' Liability Is to the Lawyer Rather Than to the Employee

But economists cannot do much to enact or defeat compensation. For the employer, the strong argument for compensatory laws is furnished by the inconsistency and injustice of many jury verdicts. And on the other hand, the injured employee or his dependents, while they may usually rely on sympathy from a jury, receive little or none from damage-suit lawyers; so that after they have collected a judgment—probably excessively large—against an employer, and after they have paid their 50 per cent. contingent fee, they may have a net balance to their credit amounting to much less than the fair compensation given for injuries by the new system. Indeed it may be said with almost entire truth that under the past laws the principal liability of both employer and employee was the lawyer, rather than the accident.

The coal-mining business of Kentucky is now the second largest of the state's productive occupations, exclusive of agriculture. The gross value of output is more than $16,000,000 per annum, and its importance as an industry in Kentucky ranks next to that of the distilling of whiskey. In addition thereto, it yields to the transportation companies a revenue in freight somewhere between $12,000,000 and $15,000,000 within the boundaries of Kentucky alone, and further revenue to connecting lines serving a territory extending from the far Northwest to Florida and the Gulf of Mexico. Its aggregate payroll, amounting to about $13,000,000, maintains nearly 25,000 employees and their families, and spreads through channels of trade in a hundred different directions.

Not only has the coal industry already assumed this magnitude, but it will soon outstrip all other productive industries of Kentucky, barring agriculture alone. Present mining developments along Kentucky River, the upper Cumberland and Big Sandy Rivers assure that the 20,000,000-ton mark will soon be reached.

The Low Mining-Accident Death Rate in Kentucky

But there is another side to this picture of prosperity and growth, and the more sensitive public conscience of this day will not allow this unattractive side of the picture to escape scrutiny, or its meaning to remain uninterpreted. This side of the picture is an exhibit of the toll of human life and the destruction of health and efficiency, with a consequent loss of money to employers and employees alike, and an added burden imposed on the state by an increase in the ranks of paupers and other public charges.

It is true in Kentucky we may console ourselves that our record of mine fatalities compares favorably with the averages for industry through the entire United States and even bears comparison with the figures from states in which the mining industry has been for some years the subject of much remedial legislation.

The latest publication of the United States Bureau of Mines, shows that in all the mines of the United States the total deaths in 1912 were fewer than in any year since 1906, and conspicuously fewer per 1,000,000 tons of output or per 1000 men employed. But while all the mines of the country killed 4.29 employees per 1,000,000 tons, Kentucky during the same year killed only 3.25. And while the nation's mines killed 3.15 employees per 1000 on the payrolls, Kentucky's mines killed only 2.08 per 1000.

Amount and Manner of Compensation

The laws of the 15 states in which compensation is already required by law, and also the act of our neighboring state, West Virginia, effective May 22, impress us, on examination, with the simplicity of the problem of compensation for fatal accidents. The range of the compensation fixed by the various states is not wide, extending from a minimum of three years' average earnings, or $2000, to a maximum of six years' average earnings, or $6000.

In nearly all states, the commission is instructed to disburse the compensation in weekly or monthly payments, as in the discretion of the commission may best suit the particular case. I cannot overlook an opportunity here to emphasize the merit of this method of payment over the system that now results. After several years of controversy, the dependent family secures by jury verdict a lump sum of money, which is shared with their attorney. They do not have the proper knowledge or experience to handle it, and so it is with them, in most cases, for only too brief and fleeting a period.

The Compensation for Partial Disability Is the Uncertain Factor

A compensation of $3000 as the average economic loss of a death in Kentucky mines would have cost the industry as follows under a State Compensation Law:

1910, 84 lives	$252,000
1911, 44 lives	132,000
1912, 52 lives	156,000

and considering the present premiums on casualty insurance, the industry could well afford to meet the bill. I will say, however, that attractive as the new system appears to me in general, I think we will have to jump in the dark in regard to nonfatal accidents, for I see no means of ascertaining, within any bounds of reasonable certainty, what the bill for minor accidents will be. While several of the annual reports from the state mining inspector give the number and classification of nonfatal accidents, it is certain that under the system of compensation for all injuries, the list of such injuries may soon become appallingly lengthy and the amounts demanded for these accidents will exceed those claimed for deaths and total disabilities.

Though the operator will, under the proposed legislation, eliminate excessive jury verdicts, he need not be too confident that workmen's compensation will necessarily afford less expensive insurance than he is now able to purchase from the companies that are embraced in the so called Conference, much less that it will be cheaper than that furnished by several outside companies, which now make rates as low as 90c. per $100 of annual payroll, and did until the last year or two, write policies for as low as 7 mills on the dollar.

Not cheaper insurance, but more complete protection is due the operator, for the policies now written by the companies to indemnify operators for damages recovered under their present employers' liability, indemnify only within certain limits, and when a jury verdict is rendered against the operator, assessing damages greater than the

maximum fixed in the policy, either due to the loss of one life or the results of one accident, the operator is left to pay a sum which may be greatly in excess of his stipulated maximum.

But this danger is not the only serious objection to the present indemnity policies, as the loss of time and money due to court attendance is expensive alike to the defendant employer and to the commonwealth, and friction between employer and employee is continually aggravated by the personal negotiation of claims for damages arising from a death or from the breaking of a finger. The employee is prone to feel that if he does not take the claim to court, he will be a recipient of charity, and not justice.

A State Commission To Administer Insurance Funds

Therefore, when we come to consider the advantages of the compensation system, let us assure ourselves at the outset that to achieve satisfaction for either employer or employee, it must be reasonably fair to both; that it is not merely a device by which the former may escape being "soaked," nor a scheme of graft by which the latter may recover money for accidents numerous and trivial. Let us bear in mind that the ideal condition is one whereunder all accidents will be fairly compensated, with the least possible interruption to business, by the payment of fixed sums of money in such manner as is best suited to the beneficiary. This should be paid promptly, but with due care, by a state commission, which body should be free of the influence of party politics. Payments should be made out of general funds collected from the several hazardous industries and carefully guarded.

I strongly recommend that the Kentucky Mine Owners' Association, either alone or in conjunction with the body representing the southern Appalachian coal operators, constitute a committee to advise with the framers of a compensation act. If this be done, Kentucky will be as conspicuous in her success in compensating mine accidents, as she now is in reducing their frequency.

::

The Belle Valley Mine Explosion

The following letter from J. C. Davies, the state mine inspector of Ohio to the governor, James M. Cox, relative to the Belle Valley mine explosion, needs no further comment:

On the evening of May 17, at 11 p.m., the State Mining Department was notified that an explosion had occurred in the Imperial Mining Co.'s Imperial No. 3 mine at Belle Valley, and that a number of men were entombed as a result of the explosion, the news having been brought to the surface by four of the men who though employed in the mine at the time had escaped the force of the explosion.

Upon arriving at the mine, I ascertained that the bodies of the entombed men had already been reached. Immediately following the explosion, District Mine Inspector Abel Ellwood of the fifth inspection district, in conjunction with General Superintendent Thos. Matthews of the Imperial Mining Co., made arrangements with the Pennsylvania R.R. Co., to run a special train from Cambridge to Belle Valley, carrying rescue equipment and medical aid.

District Mine Inspectors Hill, Grogan, Morrison, Devore, Werker and Wheatley, were also notified of the explosion, and with myself went to the mine to render such assistance as was possible. Upon the arrival of the special train, rescue parties were organized to enter the mine. The ventilating appliances were not deranged, and this led us to hope that at least some of the entombed might be still alive.

Previous to the arrival of the rescue equipment, Henry Fairhurst, of Belle Valley, and several others entered the mine to attempt to rescue the injured. They succeeded in saving J. R. Yeager, who was badly hurt, but Fairhurst died from the effects of breathing the afterdamp.

Superintendent J. B. Morris of the Caldwell mine, John Smolley of the Laura mine, and others, formed a rescue party and penetrated the mine to the seat of the explosion, where they encountered the bodies of several of the victims.

Upon the arrival of myself and the other inspectors, we found the work of the recovery of the bodies well under way, several of them having been brought to the surface. We entered the mine, made our way to the vicinity of the trouble, and rendered what assistance we could, and continued at the work until the last body was recovered, which was about 11:30 Sunday morning.

Upon our arrival at the mine early on Monday, we found Jas. W. Paul, the engineer who is in charge of the federal station at Pittsburgh, and two of his assistants, had arrived for the purpose of making an investigation for the federal government, and to render all assistance.

In company with the above and John Moore, state president of the United Mine Workers of America, Lee Hall and William Thompson, vice-presidents of the same organization, we entered the mine and proceeded to obtain evidence that would enable us to determine as nearly as possible where and what caused the explosion. Returning to the mine on Tuesday, we completed our investigation. A report of this party of inquiry is herewith attached to this report.

* * * * *

Mine Inspector's Report

We have today completed an examination of the O'Gara Coal Co.'s Imperial No. 3 mine., Noble County, O, with a view of determining the cause of the explosion in that mine on the evening of May 17, 1913

This explosion occurred between six and seven, p.m., at which time twenty men were in the mine. Of this number 14 were killed, and several others injured. The number of fatalities was later increased to 15 by the death of Henry Fairhurst, who was overcome while attempting to rescue one of the injured men.

As a result of our investigation, it is our opinion that the explosion originated in the vicinity of No. 5 room, off No. 7 south entry, and that it was produced by the ignition of a body of firedamp in or near this room. The force of the explosion seems to have radiated from this point.

The direction of greatest force was from the vicinity of No. 5 room, in No. 7 entry outward through No. 7 entry and through the crosscuts into No. 8 entry. In the latter heading opposite No. 4 and No. 5 rooms, a number of men were engaged in laying a side track and two machinemen were cutting a skip from the east rib of No. 8 south entry. Ten of the victims were found along No. 8 entry; one in No. 1 east entry, just west of No. 8 south; one in No. 1 room in No. 1 east entry, one in No. 7 south entry between No. 4 and No. 5 rooms; and one in No. 1 room in No. 4 east entry. None of them were mutilated to any considerable extent, but all except the one in No. 1 room in No. 4 east entry were severely burned.

Considerable marsh gas is generated in this section of the mine, and an examination of the workings in the vicinity of the scene of the explosion on May 19, and 20, showed traces of firedamp in most of them.

In our investigation we found no dates marked in the working places later than May 16, indicating that these places had not been examined by the fireboss on the date of the explosion. Evidently, the ventilation had been cut off this section of the mine for a considerable time, thus permitting a body of firedamp to accumulate, and some of the workmen, presumably the one found between No. 4 and No. 5 rooms, in No. 7 entry had entered No. 5 room wth a naked light, igniting the gas.

APPROVED

J. C. DAVIES,
Chief Inspector of Mines.

THOS. MORRISON,
Inspector 9th District.
L. D. DEVORE,
Inspector 10th District.
R. S. WHEATLEY,
Inspector 12th District.
W. H. WERKER,
Inspector 8th District.
THOS. F. GROGAN,
Inspector 11th District.

When testing for gas with a safety lamp, remember that (1) The height of the cap depends not only on the amount of gas present, but also upon the size of the testing flame. (2) That a 1½ to 2 per cent. mixture produces quite a large, though very delicate cap, with a testing flame having a small white apex. (3) That density is a better indication of percentage than height.

Concrete in Mine Construction

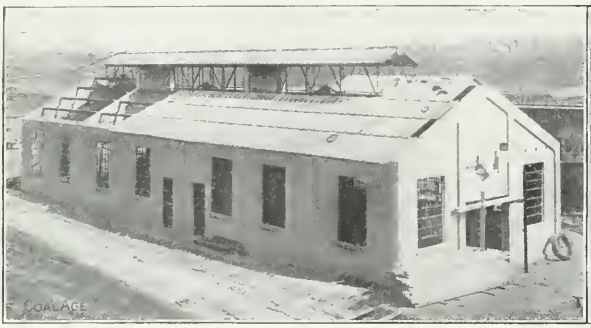
By A. S. Allard*

SYNOPSIS—The modern coal-mining plant uses a large amount of concrete above and below ground to assure permanence and safety from fire. A concrete shaft costs only about one-third more than one cased in wood. The author describes three kinds of concrete shaft-bottom linings and details the appropriate places for their respective use.

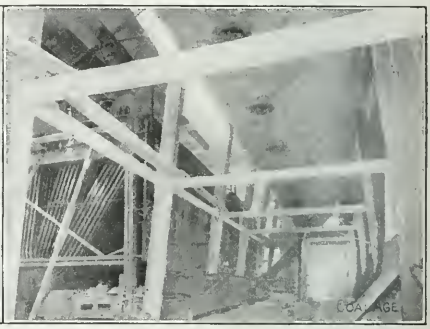
Within the last few years, a great many important advances have been made at the modern coal plant in the use of concrete for buildings, shaft-lining walls and construction inside the mine. The appearance of the up-to-date plant is wonderfully improved with its concrete mine buildings, consisting of the power plant, hoist house, repair shop, miners' bath house, fan house, supply house, powder house and outside stable. These fireproof structures with reinforced-concrete walls, concrete floors and cement roof covering are permanent and involve little or no expense for upkeep during the life of the plant.

The boiler house, with its reinforced-concrete chimney towering to a great height, is substantial and attractive in appearance as compared with an installation of steel stacks which are subject to deterioration from rust and require frequent painting and attention; while no expense for maintenance after first cost is necessary on a concrete stack. Coal-storage bins and water-supply tanks are now erected of reinforced concrete, instead of wood or steel.

This material now replaces the wooden walks and platforms of the steel tipple and the members themselves are protected from rust and mine gases with a covering of the same material. Swimming tanks built of concrete prove a source of amusement and recreation for the employees at a coal-mining plant.



View of Concrete Machine-, Blacksmith- and Carpenter-Shop Building



Reinforced-Concrete Bunker; Capacity, 250 Tons

Granary

Mule Stable

Shaft Walls

As a fireproof and permanent material for the lining of shaft walls, concrete is without a rival. From comparative cost data, I find that the price per vertical foot of a completed concrete-lined shaft is about one-third more than for one encased in wood. As timbers have to be renewed after a short period of time, this additional cost in first construction is soon absorbed by the savings in repair bills. Of all the numerous designs for concrete shafts, rectangular, circular, elliptical, etc., the shaft with straight sides and circular end walls is the most economical. The end space is utilized for pipeways

*Chief engineer, Bunsen Coal Co., Adams Building, Danville, Ill.

Abstract from a paper read at the Mining Conference in connection with the dedication of the Transportation Building and of the Locomotive and Mining Laboratories, University of Illinois, May 10, 1913.

or stairways, and excavation and concrete yardage is reduced to a minimum. The circular end walls adequately resist the pressure of the strata and of the water, forming as they do a concrete arch from the surface to the shaft bottom. However, the sidewall pressures have to be resisted by the thickness of the concrete lining, and this must depend upon the nature and depth of the strata penetrated. Self-sustaining measures, such as rock, sandstone, slate or good shale, generally require a wall of from 6 to 9 in. in thickness. This is sufficient for the anchorage of the buntons. A heavy fireclay or wet sand would require a much thicker wall.

Shaft-Bottom Linings

Shaft-bottom linings can be constructed in one of three ways: First: A wall of rectangular section can be built along either side supporting I-beams. These can be covered with reinforced-concrete slabs having a thickness of three or four inches. The depth of the beam is usually 6 or 8 in. for a single-track span, and from 12 to 18 in. for that of double track, but the size and weight of the beam selected depends upon the nature and condition of the room. My practice has been to place the beams on 4-ft. centers, covered with slabs 2 ft. in width.

Second: A poured-concrete arch with concrete sidewalls. Third: The concrete-block arch, which is composed of plain concrete blocks molded in steel forms with joints disposed on two radial planes. Blocks are laid up in the arch crown from each side wall with cemented joints, supported on a light framework until the key piece is placed and one section of the arch is thus completed.

Provision is made in molding to provide blocks of different lengths so that joints are broken on alternate courses. Blocks 6 in. thick for single- and 8 in. for double-track spans, and about 18 in. long make a convenient size for men to handle. This method of arch construction is much cheaper than that of the solid-poured sections, for it eliminates the cost of expensive forms and the time necessary for the transporting and placing of the wet mixture.

The first system is preferable at the back of the shaft where it is necessary to provide clearance room for the empty-car lifts and where cutting into the roof with an arch of large span would prove expensive.

The second, or poured-arch section, is generally adopted for a distance of from 10 to 15 ft. on each side of the shaft, the work being connected to and supporting the shaft walls. By continuing the arch with concrete-block construction for the main landing and empty runarounds, an ideal and fireproof shaft bottom is made.

COMING SOCIETY MEETINGS

Mine Inspector's Institute of the U. S. A.—J. W. Paul, secretary, Pittsburgh, Penn. Annual meeting at Birmingham, Ala., June 10, 11, 12 and 13.

Coal Mining Institute of America—C. L. Fay, Wilkes-Barre, Penn., secretary. This institute holds its annual meeting at Pittsburgh, Penn., on June 17 and 18.

Michigan-Ohio-Indiana Coal Dealers Association—G. F. Nigh, secretary, Columbus, Ohio. This association holds a joint annual meeting with the order of Kokoal at Cedar Point, Ohio, June 17, 18 and 19.

Order of Kokoal—C. E. Lester, secretary, No. 1 Broadway, New York City. This society holds a joint annual meeting with the Michigan-Ohio-Indiana Coal Dealers Association at Cedar Point, Ohio, on June 17, 18 and 19.

West Virginia Coal Mining Institute—Prof. E. N. Zern, secretary and treasurer, Morgantown, W. Va. This institute holds its annual meeting at Morgantown, W. Va., on June 24, 25 and 26.

American Institute of Mining Engineers—This institute holds its next annual meeting at Butte, Mont., on Aug. 18 to 21 inclusive. Bradley Stoughton, 29 W. 39th St., New York City is secretary.

The Situation in West Virginia

The West Virginia Mining Association, W. N. Page, Pres., has issued the following statement regarding the labor situation there:

"The United Mine Workers of America are making capital out of the forthcoming investigation by the Senate subcommittee of conditions in the coal mines of West Virginia. Thomas Haggerty, the international board member, who has headquarters in this city, issues frequent bulletins recounting the success of his efforts to 'settle the strike on New River,' and of his trips into that region 'to bring the miners and operators together,' when, as a matter of fact, no strike exists on New River, and Mr. Haggerty has never left Charleston. Nor have the miners on New River any desire to strike.

"The most convincing evidence that a strike exists is the fact that the production of the mines on New River for the six working days ending Friday, May 30, was 123,120 tons shipped by the C. & O. alone, which is about the average for the last six months.

"The miners are being told that the Senate subcommittee is coming to put all the forces of the United States Government to work to insure them the full enjoyment of their rights to join the Union, the inference being that they had better join at once and so avoid future trouble at the hands of that organization.

"The Union is also making a play to the galleries by ostentatiously manufacturing tents in a conspicuous place here to 'shelter the strikers on New River.'

"Incendiary articles abusing Governor Hatfield for his efforts to restore normal conditions are being sent to daily papers in the state by ex-Senator Sam B. Montgomery in behalf of the Union, accompanied by letters offering to pay advertising rates for their publication. The Union has ample funds, for the assessment of 50c. a month on all members for use in West Virginia is still in force. This alone yields at least $2,250,000 a year. In addition the United Mine Workers of Illinois in the last week in February voted to give $900,000.

"As the Union has but 3200 members in a total of 79,781 mine workers in the state, it is essential that this should be one of the cases in which 'money talks.'

"These activities have two objects: First, to make the miners believe the Union is carrying everything before it in the state, and that if they do not join at once they may find themselves out of a job; the second is to impress the Senate subcommittee with the importance of the Union and its magnanimous attitude toward the operators in offering its good offices to 'settle' a 'strike' that never existed."

Coal Mining Institute of America

The meeting of the Coal Mining Institute of America is to be held in the Assembly Hall of the Engineers' Society of Western Pennsylvania, 25th floor of the Oliver Building, Pittsburgh, June 17 and 18.

The following is the program beginning on Tuesday afternoon:

"A Pictorial Survey of the Pennsylvania Bituminous Coal Field." Introduced by John Boileau and illustrated by private maps and numerous lantern slides showing distinctive operating and transportation developments of principal mining companies.

Inspection of offices and appliances of the U. S. Weather Bureau by invitation of Henry Pennywitt, Local Forecaster.

H. C. Frick Coke Co.'s "Safety First" show, demonstrating methods of safety instruction used by this company. Stereopticon and motion pictures, combining instruction and entertainment in a novel and interesting manner.

In the evening there will be a banquet.

On Wednesday in the forenoon a visit will be made to the Carnegie Museum, by invitation and under direction of Dr. W. J. Holland, Curator.

In the afternoon, the Bureau of Mines will either arrange a demonstration at the Arsenal Grounds, or a trip to the experimental mine operated by the Bureau

The meeting was to have been held at Wilkes-Barre, Penn., but the place was changed because so many of the operators and other mine officials were too busily engaged to permit of their attending.

A Government-Approved Mine Lamp

The Ceag* portable electric mine lamp has the distinction of being the first to be approved by the United States Bureau of Mines. The approval was granted on June 3 and carries with it the permission to attach a plate to each lamp, reading as follows:

"Permissible electric hand lamp, United States Bureau of Mines, Approval No. 1."

The approval is given under the restriction that any modifications the manufacturers may desire to make at any future date shall first be submitted to the Bureau, in order that they may be subjected to the necessary tests. The Bureau also reserves the right, should occasion demand, to rescind its approval at any time. The use of unapproved changes in the design and construction of the lamp will be considered as sufficient reason for withdrawing the approval, as will also any developments which may appear in practical use that prove it to be unreliable, unsafe, or easily made so.

The Harlan Coal Field in Kentucky

We are informed by Frank A. Carr, of Hendersonville, N. C., that two of the photos used in our article under the above title (See COAL AGE, Vol. 3, No. 21, p. 796) were copyrighted by him. A notice to this effect was unfortunately overlooked.

*For detailed description of this lamp see "Coal Age," Vol. 2, p. 393.

Gates for Run-of-Mine Coal

By F. V. Hetzel*

SYNOPSIS—The disadvantages and inconvenience of the slide gate are well known to mining men. Various types of undercut gates are here described and illustrated.

Most men in the soft-coal business know that it is almost impossible to control the flow of run-of-mine coal by an ordinary slide gate. There are several reasons for this.

First: A gate opening which will pass run-of-mine coal without choking is necessarily large and the weight of the gate plate makes it hard and slow to handle.

Second: If the gate in closing comes down on a lump, the small coal and slack continue to flow under the edge

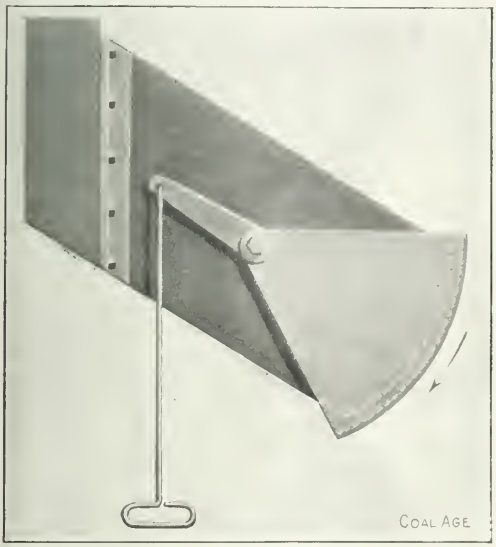

Fig. 1. Pivoted Undercut Gate in Its Simplest Form

of the plate; to stop this the gate must be repeatedly lifted and dropped until it happens to miss all large pieces. Slide gates with rack-and-pinion movement have been used to give the operator a better control of the gate and large plates are sometimes fitted with steam or air cylinders to force the gate down in spite of large or hard lumps.

In principle, however, all such gates are inferior to those of the undercut type and particularly to those which work on a pivot. In its simplest form such a gate is shown in Fig. 1. In opening, the curved plate drops as is shown by the arrow and the coal flows over the top edge. In closing the gate rises and either cuts off the flow partially at an intermediate point or completely when in the position shown in the figure. It is evident that no lump can ever stick this device, because it would be lifted by the upward movement of the curved plate and either stay in the chute or else fall over the edge of the gate.

Tipple Gates Are Usually Counterbalanced

For tipple work the undercut gate is usually counterbalanced to make the movements easier and more rapid,

Fig. 2. "Local Coal" Chute Fitted with Geared Gate

Fig. 3. Run-of-Mine Loading Bin Fitted with Two Large Chutes

*Philadelphia, Penn.

and for large gates the motion is geared for operation by hand chain or handwheel.

Fig. 2 shows a "local coal" chute fitted with a geared gate, and Fig. 3 shows a run-of-mine loading bin fitted with two large chutes. Here the lowering of the chute aprons and the opening and closing of the gates are all under the control of an operator on the elevated platform. This control is so accurate that the loader can deliver the coal at the rate of 20 tons a minute, or he can load the car to its limit by dropping the coal a bushel at a time if he pleases.

Fig. 4 shows the assembly of such a gate with its chute apron, and Fig. 5 illustrates a geared undercut gate set up on the front of a tipple. The cover plate over the chute is hinged and loose; it serves to keep the coal from becoming wet and frozen in cold weather, but it does not prevent the gate from pushing lumps upward in the act of closing.

At some mines the disposal of rock is a serious problem. If it is put into a bin it is quite a job to get it out again. A large gate is a necessity in such a case.

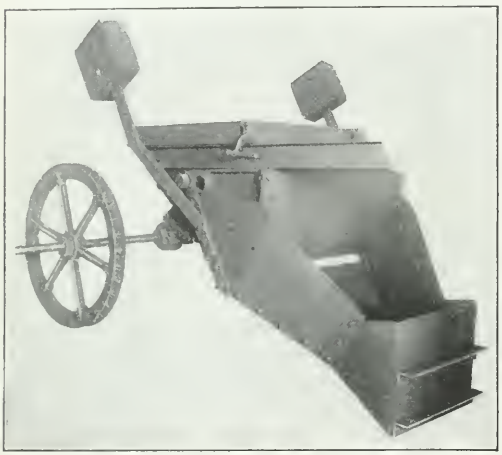

Fig. 4. Assembly of Gate and Chute Apron

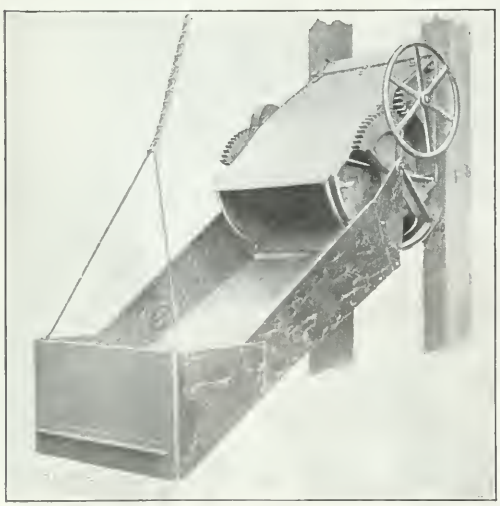

Fig. 5. Geared Undercut Gate for the Front of a Bin or Tipple

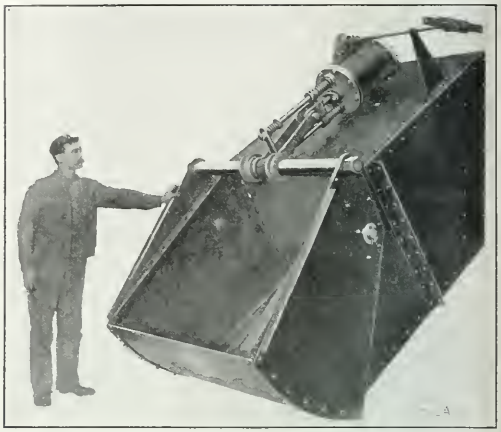

Fig. 6. A Heavy Steam-Actuated Rock Gate

Fig. 6 shows a rock chute 54 in. square in cross-section with a steam-operated undercut gate attached. This is extra heavy in construction and will handle rock as big as a man's body. The gate is controlled by a small hand lever on a four-way valve and is quick and certain in operation.

Mine-Inspection Service in Illinois

During the year 1883, a law was passed creating the office of state inspector of mines. Candidates for this office were required to furnish evidence satisfactory to the state mining board that they were citizens of the state, at least thirty years of age, and that they had a practical mining experience of ten years. All candidates were required to pass an examination to show what practical and technical knowledge they possessed of mine surveying; mining machinery and appliances; the proper development and operation of coal mines; ventilation in mines; the nature and properties of mine gases; the geology of the coal measures in this state; and the laws of this state relating to coal mines.

During the year 1911, the subjects of first aid to the injured and mine rescue methods and appliances were incorporated in the law; but this was the only change made in the law in twenty-eight years. During the same session of the legislature, a law was passed placing all state employees under the civil service rules. This included the state inspectors of mines. Although Illinois is not in the lead in coal production, it has taken an advance step in legislation over all other states in matters pertaining to mining and particularly to the method of appointing mine inspectors. Prior to this time, the inspectors were subject to the changes incident to a change of administration.

The inspectors are required to send to the Civil Service Commission monthly reports stating the number of

mines examined; and also to the state mining board a report of the mines examined during the month. I submit herewith a copy which the inspectors are required to fill out, after making an examination of a mine.

Shipping or Local

ILLINOIS COAL MINE INSPECTION SERVICE

Report of **State Inspector of Mines**
For the **District**
To the Chief Clerk of the State Mining Board,
Springfield, Ill.

Sir: I have this day of .191 inspected mine operated by located at County of State of Illinois, and find its conditions as follows: (If mine has changed hands since last inspection, give old name here)

1. BOILERS AT PLANT:
   (a) Condition
   (b) Date of last inspection
2. HOISTING APPARATUS:
   (a) Condition of engine
   (b) Condition of fans
   (c) Condition of cages
   (d) Condition of ropes
   (e) Condition of safety catches
   (f) Checking system
3. FIRE-FIGHTING APPLIANCES:
   (a) Is the water supply for fighting fire underground provided as required by law?
   (b) Where is it located?
   (c) Is the quantity sufficient?
   (d) Is it conducted into the mine by proper sized pipes and are all required hose connections provided?
   (e) Are they extended to cover the fire-protected area?
   (f) Are they properly installed?
   (g) Is the mine supplied with the necessary hose and is it ready for immediate use?
   (h) Are automatic sprinklers properly located and connected
   (i) What is the distance of the nearest underground stable from the hoisting shaft? feet; from the escapement shaft? feet; if the distance is within 1000 feet, are automatic sprinklers properly placed and connected in the stable?
   (j) If the stable is otherwise located, are extinguishers and hand pump buckets kept therein, including entries and passageways into which stable opens, and are they ready for use?
   (k) Give the number of extinguishers Hand pump buckets
   (l) Are barrels of water and pails properly located in each entry or passageway leading to the stable?
   Give number
4. NUMBER OF MEN AND ANIMALS EMPLOYED:
   (a) Men underground (b) Total employees
   (c) Animals
5. VENTILATION:
   (a) Quantity of air in cubic feet at bottom of downcast
   (b) Quantity of air in cubic feet at bottom of upcast
   (c) Quantity of air in cubic feet at last open crosscut of each division or split of the air current
   1st 2nd 3rd 4th
   5th 6th 7th 8th
   (d) Number of employees supplied in each division
   (e) Is sufficient air supplied in every working place throughout the mine?
   (f) Does the mine generate explosive gas in dangerous quantities?
   (g) Did you discover the presence of gas in the main return airway?
6. ESCAPEMENTS:
   (a) How many roads leading to the escapement shaft?
   (b) Are signboards placed indicating the direction thereto at each intersection?
   (c) Are men hoisted from the escapement shaft, or is it equipped with stairs, or both?
   (d) If hoisted, what time would be required to get men out?
   (e) Area of escapement shaft?
   (f) Width and general condition of stairs
   (g) Distance to each landing
   (h) Are there any obstructions in the escapement shaft?
   (i) Is it wet or dry?
   Conditions as follows:
7. TELEPHONES:
   (a) Are they supplied as required by law?
   (b) Number (c) Conditions
8. RECORDS:
   (a) Are the records required to be kept by the Mine Manager, Mine Examiner and Shotfirers in accordance with the law?
   (b) Are maps made and recorded according to law?
   (c) Give date of last extension
9. DOORS:
   Are doors used for directing the ventilating current constructed so as to close automatically?
10. CROSSCUTS.
   (a) Are crosscuts made within sixty feet?
   (b) Are any rooms opened in advance of last open crosscut?
11. EXPLOSIVES:
   Is the law relating to the storing of explosives and the opening of powder kegs observed?
12. TRAVELING AND HAULING WAYS.
   Condition
13. AIRWAYS.
   What is the condition of the main and return airways? Describe in detail
14. PLACE OF REFUGE:
   (a) Are there proper places of refuge on all hauling roads where workmen are required to travel?
   (b) At what intervals?
   (c) Are the top and botom man at their respective posts of duty half an hour before the hoisting of coal begins in the morning and the same time after hoisting ceases for the day?

For the better protection of the lives and health of the employees, would recommend the following:

State Inspector of Coal Mines.
District

To speak of the inspection service of Illinois and fail to mention the names of two men who are yet in the service, and have given to the state and the mining fraternity the best years of their lives, would be unmindful of duty and obligation. There are many men in the state who can bear witness to the many kind acts and assistance given them by Inspectors Rutledge and Hudson, especially men who were anxious to better their condition so that they could become successful managers. These two inspectors are of the broad-minded type of men, kind hearted and generous and by this token have won many friends throughout the state.

Walton Rutledge, of Alton, and Thomas Hudson, of Galva, were both appointed inspectors in the year 1883 and served until 1891 when a change was made in the political complexion of the state administration. In 1897, they were again reappointed and are still serving in that capacity. Mr. Rutledge is the oldest man in the inspection service in the United States and he is famil-

iarly called the Dean of the Service. Following are brief sketches of their careers:

Sketch of Walton Rutledge

Walton Rutledge, inspector, 9th district, was born at Haswell, county of Durham, England, in 1835. At the age of 14 years he began working in the coal mines at that place. After about a year he was transferred to the surveying division, working with the mine examiners a part of the time. In 1854 he came to the United States, locating in the anthracite coal region, where he worked as a miner for two years. He came to Illinois, in 1856, and settled in Alton, which has been his home ever since. Here he worked in the mines until May, 1864, when he enlisted in company D, 133d regiment, Illinois infantry, as first sergeant. Afterward, in the same year, he raised a company which was mustered into the 14th regiment, and served as first lieutenant to the close of the war of the rebellion.

Walton Rutledge

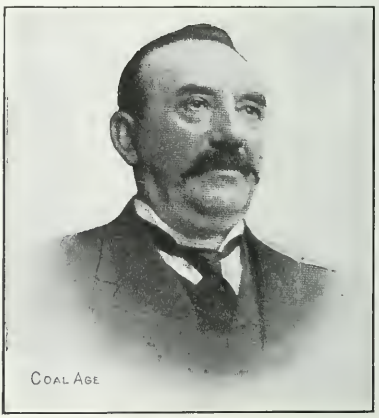
At the close of the war he again went to work in the coal mines near Alton. At the same time he was chosen secretary of the Miners' Benevolent organization, embracing the states of Illinois, Indiana and Missouri, serving that organization for two years. During the session of the constitutional convention of 1870, he was active in securing a clause in the constitution providing for a police regulation for the coal mines of the state. In after years he was a member of a committee of miners to formulate a mining law for the state. After several attempts to secure such legislation he, with others, was finally successful in securing the passage of a mining law at the session of the General Assembly of 1879, but which provided for county inspectors only. In 1883, after the passage of the law creating State inspectors of coal mines, he passed, in the first examination for inspectors, and was appointed inspector for the fourth district. He was reappointed successively each term and held the position until 1894. In 1897 he was again appointed inspector, and is still serving in that capacity.

Sketch of Thomas Hudson

Thomas Hudson, inspector, 2d district, was born in the county of Northumberland, England, in 1846, being now 67 years of age. He attended the schools in the mining districts of Northumbria until he was 13 years of age, when he commenced work in the collieries of the Bedlington coal company, going through the regular courses from trapper boy to miner.

Mr. Hudson came to the United States in 1871, locating at Henry, Marshall county, Illinois. After working two years in the coal mines at Galva, and operating a local mine at Henry, he moved to Streator, LaSalle county, where in 1873 he engaged with the Vermilion Coal Company, as a miner and remained in the employ of that company for ten years.

In 1883 the General Assembly passed an act creating the offices of state inspectors of coal mines in Illinois, dividing the state into five districts, also providing for the examination of candidates for inspectors, by a board of examiners. For some time previous to the passage of this act, Mr. Hudson had been a close student of mining literature, and was fairly well versed in the technical as well as the practical knowledge of coal mining. At the first examination held by the board he successfully passed the examination, and was at once appointed by Gov. John M. Hamilton, as state inspector of coal mines for the second district. He at once transferred his residence from Streator to Galva, the latter being more centrally located in the district. Since 1883 he has been reappointed and commissioned by every Republican governor, and now holds a commission under Gov. Deneen.



Thomas Hudson

The state of Illinois now ranks as third among the coal-producing states. In the year 1883, there were ten million tons of coal produced and twenty-three thousand employees in the mines, and five state inspectors were appointed at that time. At the present time, there are twelve state inspectors and the production for 1912 is over fifty-seven million tons and there are seventy thousand employees in the mines.

❖

By the use of steel in place of wood for mine timbering waste due to decay, framing and fitting, fire and insects is entirely overcome Steel mine timbers also call for less excavation, cost less to erect, have a greater endurance and tend toward better ventilation. While the first cost of steel is nearly twice that of the wood used for timbering, the ultimate cost is lower, as steel lasts much longer. It can be used again and again and if crushed it has a salvage value.

EDITORIALS

Pyrite in Coal

The action of iron pyrite under heat is not clearly understood. It is commonly believed that when the bisulphide of iron is heated, half the sulphur is driven off but not nearly such a large proportion can be vaporized, at least, under commercial conditions. Valentine has shown that when pyrite is heated for one hour to 1832 deg. F. in the absence of air, it gives up only 26.27 per cent. of its sulphur while at the extremely high heat of 2599 deg. F., which would appear in a furnace fire as a bright white heat, 44 per cent. of sulphur is volatilized after 1¼ hr. of heating. Thus the desulphurization of pyrite is slow and halting.

But while in the absence of air, the sulphur is hard to drive from combination, in its presence, this is easily accomplished. If the pyrite is maintained at a temperature of 1832 deg. F. for one hour, 98.8 per cent. of the sulphur is lost whereas the same degree of heat and duration of time, as has been seen only removed 26.27 per cent. of it when the heating took place where air was excluded.

Hence in a furnace, the sulphur of the pyrite is almost certainly burned away before the compound is even approximated to a monosulphide, and the iron is available therefore, for combination with the lime and alumina to form a slag. Herbert Lang, the author of a book entitled "Metallurgy" writes us as follows: "It is generally held that pyrite ('brasses') of coal become oxidized during or soon after combustion and then certainly appear in the analyses as ferrous or ferric oxide." But he adds: "If the fire were urged at a rapid rate, it is likely that some part of the pyrite would be converted into ferrous sulphide and would appear in the ashes as matte, most probably as small spherical pellets. By vanning the ashes, these spherules might be discovered."

The question arises what is that combustion rate which would produce such a result and the answer is not forthcoming. There is need for a caution which is not always shown by those who argue on this matter. It is far preferable to be non-committal than dogmatic. The temperature, at which Valentine says 98.8 per cent. of the sulphur will be burned out in one hour is that declared by M. Pouillet to be a clear cherry red.

Mr. Lang, in his letter, adds that the intermixture of sulphur compounds whether ferrous sulphides or some other such bodies with whatever portion of the iron was oxidized would not interfere with the scorification of the latter and the formation of slag. This is the condition prevailing in the matting of roasted pyrite ores of lead or copper in a large way, where sulphur is usually left in the roast to the extent of 6 or even 12 per cent. The part not expelled in fusion goes to form matte and its presence does not prevent the forming of slag.

Hence we are not justified, until more exact information appears, in allying ourselves with those who have rejected vehemently the popular idea that pyrite is objectionable. It is *possible* and likely that when sulphur is found in coal, and slag does not form, that the reason is that the iron is held as a sulphate and not in the weaker pyritic bond, but it would be obviously mistaken after what has been said to omit the word "possible" and to fail to grant that another viewpoint might be urged as a feasible working hypothesis. Some analyses introduced to defend the theory that pyrite is non-slagging appear more easily interpretable by the assumption that the sulphur is in the form of a sulphate.

An Ultimate Analysis of Modern Labor Conditions

The labor unrest so strikingly in evidence, not only in this country, but throughout the world wherever industrial development has passed beyond the most primitive stage, is now openly regarded as a serious menace to the prevailing social system. A transitional period is at hand and there is no mistaking the trend of affairs

Tangible evidence of these conditions is found on every hand—in the annual reports of our large corporations which almost uniformly comment on the situation; in the powerful lobbies by which labor is forcing the enactment of class legislation at the sacrifice of every other consideration, and even in the protracted revolution in Mexico, which is, after all, but a futile protest of the masses against the systems of peonage practiced in portions of that unfortunate country.

Capital is being forced into continually granting further concessions each of which is scarcely established before preparations for others are under way; nor does labor show any disposition to recede in times of commercial depression when the revenues of the large corporations are naturally depleted. Obviously such conditions cannot continue indefinitely and the issue *must* be met—sometime, somehow. What is the solution?

Unfortunately no feasible or practical solution has yet been advanced. But in a recent book* we find a clearer insight and a broader exposition of the basic evils responsible for prevailing conditions than seems to have yet been offered. The treatise is based on a series of articles in the *Daily Mail* written by H. G. Wells, an author of international reputation. These precipitated an almost universal discussion from able thinkers in all walks of life—business men of large affairs, labor leaders themselves, economists such as Messrs. J. Galsworthy and F. Harrison, the Duke of Marlborough and statesmen such as Earl Grey. The work is of such importance and so uniquely complete as to justify more than the ordinary review.

Mr. Wells takes the stand that the trouble is largely a psychological one, an imaginary evil, in fact a condition of the mind and hence must be dealt with as such. The situation is not new, except that labor is protesting against the fundamental conditions in our social system, rather than the mere question of hours and wages. The

*"What the Worker Wants."

proletariat is becoming more sensitive, critical and irritable, while with the wider diffusion of education, discontent is equally more diffusive, and as a result the unrest is more general and extended than in the past.

The most striking characteristic of the present-day situation is the close harmony that prevails between the different occupations, the existence of interlocking arrangements, by which the various organizations are being welded into one gigantic octopus. The trouble is most acute where the government is most representative and democratic; where minds are most alert, most intelligent and where industrial development is the greatest.

As to the actual causes of these conditions there is a great diversity of opinion. We find that Mr. Wells is inclined to shoulder much of the blame on the narrow views of the modern lawyer who resorts to unfair technicalities rather than resting his case on its true merits; in such encounters the laborer is usually beaten and hence arises a dissatisfaction and discontent that is deep-rooted and unforgivable.

In addition to this the representatives of labor in the government have been won over by the glamor of the other side and proved untrue to their trust. The representative form of government has been proved ineffective, and we find such men as the head master at Rugby and Canon Bannister, of Hereford, agreeing with the labor leaders that the present social system is unfair, unjust—and permanently so. It is even insinuated that the unrest is a moral issue for which the Church is, in a way, responsible.

One of the leading Socialists in England ascribes the trouble to the lack in purchasing power of money, the ineffective results obtained by the Labor Party, the increasing anxiety over the future and greater pressure of life. Another leading authority on industrial questions lays the disaffection to Socialistic legislation while workmen themselves write of a feeling of hopelessness that pervades the people because of the way they have lost their recent struggles. Others call attention to the change in the character of labor, which is tending towards a loss of individuality and hence creating a lack of interest and a subsequent dissatisfaction.

Mr. Galsworthy points out the evils of the fiduciary system (an essential part of large corporations) wherein the owner is displaced by a manager or agent; in his opinion this condition stands preëminently the first in the prevailing disturbance. There is no latitude granted the manager for the exhibition of generosity, even though the feeling be present, with the result that the relations between labor and capital have been reduced to a cold-blooded commercial basis. And, finally, the effects of the high cost of living are ably discussed by Profesor Ashley of the University of Birmingham. He shows that the cost of foodstuffs increased 19 per cent. during the period from 1896 to 1910, while the advance in wages during this same time was only about 11 per cent. This he regards as the basic cause of all the disturbance, for the reason that it is chiefly felt on the home life and is uniformly in effect everywhere.

Coming now to the question of a remedy, we find equally divergent opinions. Mr. Wells demands a radical readjustment in labor conditions, which, as he pertinently points out, has never been done and is, therefore, all the more necessary. One of his chief plans is the provision of old-age pensions and it is a significant fact that a number of the larger corporations are already seeking the good-will of their employees through this medium. It is, of course, obvious that a man's productive powers and effectiveness gradually develop until the maximum is attained, when it is equally clear that they must deteriorate.

Socialism is, of course, strongly advocated as a panacea of the prevailing troubles, and the exponents of this creed claim that salvation will only be obtained through "disciplined democracy." It is a significant fact, however, that such suggestions do not come from the workmen themselves. But all classes are agreed that there must be a radical readjustment in our social system and a closer understanding and more intimate relationship between the laborer and his employer.

Norman Angell pertinently reminds us that envy of the rich is not new, but boldly asserts that the representative form of government, "of the people, for the people and by the people" has been found impracticable and that this is the new condition which is responsible for all the trouble. He claims that it is an institution developed by conditions that have long since ceased to exist, such as the elimination of the oppressive political power exercised by the old-time monarchy. Now that such have been definitely relegated to the past, the instruments by which this was effected have become none the less obsolete and should likewise be abandoned. This system of government has been found effective in dealing with less intricate problems in rural districts, and even with those relating to capital crimes, but it has not been found so when called upon to decide the more complicated questions relating to credit, foreign competition, insurance, etc.

Coming finally to the question of resorting to violence, we find that both laborer and capital are agreed that such measures can only result in suicide. The stoppage of any vital function will not be tolerated and the party attempting to effect such a national calamity is facing immediate dissolution. Frederick Harrison ultimately sums up the situation with the statement that whatever the remedy, it must be one of gradual evolution; society, he thinks is far too complex, too strongly established, to be changed by any single remedy or by one revolution.

Where an Accident Becomes Suicide

That coal mining is a dangerous occupation no one will attempt to deny. Were it not so the "safety-first" movement would never have been inaugurated. Nine-tenths of the accidents occurring underground, however, are unnecessary, and are the outgrowth of either ignorance or rashness, or both. And it would appear that we need look for no very substantial reduction in the loss of life in our coal mines until all men engaged in the industry have learned to avoid all danger wherever they possibly can.

Superintendents and foremen by exercising care and diligence in properly marking and labeling the points of known danger, may render accidents inexcusable, but hardly impossible. Regardless of how it may be classified in the record of mine, State or Nation, the death of a man who has deliberately crawled over or under or through a barricade or danger sign, is not in a true sense an accident. Such a death is little, if any, short of deliberate suicide.

Mixed Lights in Mining

By J. T. Beard

In presenting the next subject for discussion in Coal Age, we have chosen one that is of greater importance in the prevention of mine explosions than is generally conceded or appreciated. That this subject is of widespread interest is amply demonstrated by the number of contributors that mentioned it, in response to our request made sometime since, asking that contributors should express their preference as to what subjects should be discussed next.

Attention has been recently drawn to the danger of using mixed lights in mines known to generate gas regularly or at intervals, from time to time, by the explosion that recently occurred in the Cincinnati mine. This was known to be a gaseous mine and safety lamps were used in all entries or headings where gas had been found; but, it is stated, the rooms in the mine were worked with open lights. The evidence given at the coroner's inquest suggests the conclusion that had safety lamps been used in the heading where the explosion started, the gas that accumulated in the brief time after the heading had penetrated a clay vein, would not have been ignited, and a great disaster would have been averted.

It is almost impossible to determine in advance when such irregularities will make their appearance and it is questionable, where gassy clay veins are found, whether open lights should be permitted under any circumstances. In the Pittsburgh district it has been customary to use open lights in rooms and then replace these with safety lamps, when the pillars are being drawn. Mining men from other regions have frequently criticised this practice, regarding it as dangerous. This open discussion will give all an opportunity to express their views.

Let us get busy and discuss this important question from a broad, practical standpoint, to determine the question of whether open lights should be used in *any* portion of a mine in which it is necessary to use safety lamps in other portions. In other words, is it safe, under any conditions incident to coal mining, to use "mixed lights," by which is understood the employment of open lights on roadways and traveling ways or in other portions of a mine in which certain sections generate sufficient gas that the use of safety lamps in those particular sections is necessary at all times?

From the standpoint of the mine inspector and the fireboss alike, this question will probably admit of only one answer. These men are charged more particularly with the responsibility of maintaining safe conditions in the mine. The decision in reference to the use of safety lamps or open lights, depending as it does on the gaseous condition of the mine air and the possibility of gas being generated in dangerous quantities, is largely in the hands of the mine inspector, whose duty it is to see that the law is obeyed. The question is often asked: Is the mining law sufficiently specific in this regard, in any of the coal-mining states in this country?

From the standpoint of the mine operator, superintendent and foreman, the question has another bearing. It is recognized that the exclusive use of safety lamps, to a certain extent, reduces the output and increases somewhat the cost of the operation of the mine. The management, however, almost without exception, regard the safety of the mine and that of the workers as the first consideration, and whenever they are convinced that the conditions demand certain requirements, these are invariably met without complaint.

From the standpoint of the miner the question of using an open lamp in preference to a safety, is one of convenience or, in many cases, reckless daring. Except under the strictest regulations and the rigid enforcement of discipline in the mine, the large majority of mine workers are willing to incur unwarranted risks in the use of an open light. The general attitude of the miner is to assume a place free from gas, unless he knows positively to the contrary. He is loath to take any precautions, under ordinary mining conditions, and will generally laugh at the one who expresses fear of a possible danger.

In the discussion of the question of mixed lights, let us have a frank, open expression of judgment and opinion, or we would rather say, conviction born of experience. Let us argue the matter from both sides, always having in view how far the question of safety must give place to convenience and economy in the operation of a mine. Let each contributor aim to present clean-cut, positive arguments in as concise a manner as possible. Let it be remembered that much of the force of an argument is lost by a superfluity of words and the lack of a strict adherence to the question at issue.

It is well to remember also that the mere expression of opinion, even though it be that of a practical man, with a thorough acquaintance of mining conditions, carries no weight unless such opinion is based on convictions that are the result of an intelligent experience. On the other hand, it is true that, owing to the lack of a sufficient knowledge of the theory and principles of mining, the experience of many good practical mining men has led to convictions that would have been different had they possessed the knowledge of those who have made mining a study.

In a few instances, contributors have allowed themselves to wander from the real point of discussion. When a writer does this he fails to arrest the attention and hold the interest of readers. We often hear good practical men, who are able to write and discuss any important mining question, make the excuse that they have not the time at their command. We have generally found, however, that the most successful men in all industries, including coal mining, are those who are never so busy but that they can find time to help in any effort made to advance the knowledge of their particular industry among the workers.

Good mine management requires that a reasonable amount of time and money should be regularly expended in the education of mining men and the advancement of mining. We hope these few words will appeal to all classes of mining men, from manager to miner, and that we shall have from them at the earliest possible moment, brief and concise statements of their convictions, based on experience. Let this discussion be one of the best that has been held in Coal Age.

DISCUSSION BY READERS

The Education of the Miner

Does the coal miner really need an education, in order to become the best coal digger in the world? As a man begins to get a little education, he ceases to be a "coal digger" and wants to start "bossing," although he can earn more money by digging coal than by bossing. As a result, there is, in this country, probably not more than 5 per cent. of English-speaking miners. Under these conditions, the education of the miner means very largely the training of the foreign-speaking miner, and this can only be done by constantly talking and showing them both the right and the wrong way of doing things. No class of men needs education more, and it would seem that this country is just beginning to realize the fact.

I remember, a few years ago, in nearly all the mining villages in the North of England, mining classes were held under the auspices of the County Council. These classes were free to all mining students, and the course embraced all the subjects incidental to mining. It was a three-year course: the first year consisted of elementary work, the second year, more advanced studies; and the third year was devoted to honors work, for securing rank. The students who completed this course were in fair shape for taking any mine foreman's examination.

I have been much interested in the discussion as to whether textbooks should be used in examinations, and would say that, in my opinion, if this became the rule and textbooks were used, everybody would have the same opportunity. As far as I have observed, there are few questions asked in Pennsylvania examinations, requiring the use of textbooks; and a man with a good practical knowledge should be able to answer these questions from his own experience. I believe it is essential that a man should know something about the laws of ventilation and be able to use the formulas required for the solution of mining problems; but I do not think it is necessary for him to master algebra and the higher branches of engineering. In splitting air, practically, in the mine, a mine foreman's experience tells him where to place the regulator; and, after a few trials, he is able to obtain the required division of air.

Speaking of the education of miners, I have heard the remark made by a superintendent that it was a good thing that a man who had taken the examination "did not learn that he had passed, while he was in the mine, as his head would get so big that he would not be able to get out." My experience has been that the majority of men who take the examination know something of the practical side of mining, and the knowledge they have gained has not given them the big head, but rather the effect has been otherwise. I think much credit is due to the man who, by his own efforts, has gained sufficient knowledge to pass a mine foreman's examination. In my own opinion, practically all of our best men are those who have risen from the ranks.

Prizes for Efficiency

I was interested in reading of the prizes offered for efficiency by the Corona Coal Co., and H. B. Swoope & Co., COAL AGE, Feb. 8, p. 229. Fifty cash prizes were to be distributed among all classes of employees who showed their willingness to assist the work in every way possible. While this no doubt will prove an incentive to many workers and accomplish good results in some ways, the fact should not be overlooked that it presents a temptation to the men to violate some of the mining laws or the regulations of the mine when they know that no one is watching them.

More than once I have seen motormen run their motors faster that the law allows. Men will take risks and endanger not only their own lives but the lives of others, in order to bring their record up to the highest possible point. The prize system, in my opinion, presents a very strong temptation to unscrupulous men to do many things that they should not do, and may often result in accidents that will cost the company much more than is to be gained through the extra amount of work done.

J. E. HOMME.

Ellsworth, Penn.

The Coking Qualities of Coal

Some time since my attention was drawn to the necessity of crushing coal in preparing the same for coking, by an article entitled "Preparing Coal for the Coke Ovens," COAL AGE, May 3, p. 683. In this connection, I desire to make the following remarks in regard to testing samples of coal to ascertain their coking qualities.

It has been the custom in some places to test coal, in this respect, by sending a nail keg full of the slack to the nearest coke plant, where it is placed in an oven, covered with the usual charge of slack and drawn out later when the oven is cool. Where this method has been used, however, it is needless to say that it has been found unsatisfactory, as the sample is far too small to give a correct indication.

When it is desired to ascertain whether the coal of a certain seam will coke satisfactorily, at least two carloads of the coal taken from different parts of the mine, should be shipped to the coking plant, so as to enable at least two ovens to be run on this coal. If the result shows that the coal, as "mine run," does not yield a satisfactory coke, it is well to grind 40 or 50 tons to slack and again try the coking test. It has been found that many coals that will not coke, as "mine run," or when the product contains lumps of considerable size, will produce an excellent coke when powdered or crushed to a more or less uniform grade. When this is found to be the case, the treatment of such coal, in coking, will involve the question of installing grinding or crushing and elevating machinery at the mine.

In some cases, it may be desired to ship the lump coal, and coke only the slack or the screenings. In this

case, enough coal should be mined to furnish a carload of screenings for the test; and this will give a very good idea of the quality of the coke to be obtained when the plant is in complete operation. A true estimate of the coking qualities of screenings cannot be obtained by grinding mine-run coal; because the slack and screenings, in the operation of the mine, always contain a larger percentage of impurities than is true of mine-run coal.

If the analysis of the trial lot of coke shows too high a percentage of ash and sulphur, for the purpose for which the coke is to be employed, it may still be possible to obtain a satisfactory coke, by first washing the coal. To determine the possibilities in this case, a carload of slack should be sent to the manufacturers of coal-washing machinery; and then passed through their experimental plant. The washed coal should then be sent to the coke ovens; and, in many cases, the resulting coke will then be found to come within the prescribed limits of purity.

As a general rule, it requires one and one-half tons of coal to make one ton of coke; and, since ash is not removed in the process of coking, a coal containing 6 per cent. of ash should yield a coke containing about 9 per cent. At times, when the analysis of coke shows more ash than might be expected from the analysis of the coal it may be due to the excess of impurities in the slack, owing to insufficient care in mining. This can generally be avoided, wholly or in part, by the exercise of proper care on the part of the miners, or by the adoption of improved methods of mining.

The amount of sulphur and phosphorus in a seam of coal will often vary widely in short distances. Inasmuch as the coke required in a blast furnace must not only contain a low percentage of impurities, but must present a uniform composition, such a variation of these objectionable features must be carefully investigated in the mine. Coke employed in the manufacture of iron, to be used in the Bessemer-steel process, must generally not exceed 10 per cent. ash, 1 per cent. sulphur, 0.02 per cent. phosphorus. A coke of uniform composition, although approaching these specified limits of impurities, is more desirable as a fuel than one averaging very much less but having a variable composition that may unexpectedly run higher than the specified percentages of these impurities. The ash and phosphorus in coal are not removed during coking, but about one-third to one-half of the sulphur is volatilized during that process and, allowing as before, one and one-half tons of coal to 1 ton of coke, a coke containing 6.5 per cent. of ash, 0.75 per cent. to 1 per cent. sulphur, and 0.013 per cent. phosphorus should yield a coke within the Bessemer limits.

Study Course in Coal Mining

By J. T. BEARD

The Coal Age Pocket Book

3. What pressure, in pounds per square inch, corresponds to a head of 200 ft of water?

Solution—

$$p = 0.434\,h = 0.434 \times 200 = 86.8 \text{ lb. per sq.in.}$$

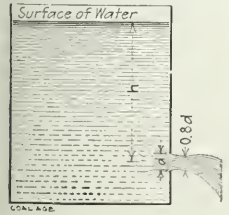
4. What head in feet of water column corresponds to a pressure of 50 lb. per sq.in.?

Solution—

$$h = 2.3\,p = 2.3 \times 50 = 115 \text{ ft.}$$

FLOW THROUGH ORIFICES

When water or other fluid, including air, flows through an orifice of comparatively small size there is always a crowding of the streams of flow toward the orifice, as indicated by the dotted lines in the accompanying figure. This crowding or converging of the stream lines toward the orifice naturally causes a contraction of the sectional area of the flowing particles, a short distance outside of the opening, as shown in the figure. The contraction is greatest at a distance from the orifice about equal to its diameter. In order that the sides of the vessel may not interfere with the converging lines, the distance of any side from the edge of the opening should not be less than 2.7 times its diameter or width.



SHOWING VENA CONTRACTA

The Vena Contracta—The contraction of area in a stream flowing from an orifice is called the "vena contracta." The amount of the contraction depends on the form of the opening through which the stream flows. The theoretical orifice is a hole in a thin plate, and the diameter of the contracted vein, in that case, is found to be 0.8 of the diameter of the hole. This makes the sectional area of the flow, at that point, $0.8^2 = 0.64$ of the area of the orifice. The ratio of the contracted area to that of the orifice is called the "coefficient of contraction." It varies with the style of orifice employed.

Quantity of Efflux or Discharge—The quantity or volume of the discharge, per unit of time, depends on the velocity of efflux, as determined by the head or pressure producing the flow, and the sectional area of the contracted vein (vena contracta). From this fact, it appears that the velocity due to the head or pressure is only attained at the point where the contraction of the vein is greatest. The velocity at the orifice, in a thin plate, is reduced in the ratio of the coefficient of contraction, and is therefore about 0.64 of that of the contracted vein.

Owing to the resistance met by the streams of flowing particles as they crowd the orifice, the velocity, even at the point

The Coal Age Pocket Book

of greatest contraction, is slightly less than the theoretical velocity due to the head, or say 0.97 of that velocity. This latter is called the "coefficient of efflux."

In order to calculate the quantity of flow (Q), for any head (h) it is necessary to combine the coefficient of efflux with the coefficient of contraction. Thus, for the flow through an orifice in a thin plate, $0.97 \times 0.64 = 0.62$ is the true coefficient of discharge. For any area (A) of the orifice in a thin plate, the area (a) of the vena contracta is $a = 0.64\ A$; and the velocity at this point, for any head (h) is $v = 0.97\sqrt{2gh}$. Therefore the quantity of discharge is

$$Q = av = 0.62\,A\sqrt{2gh}$$

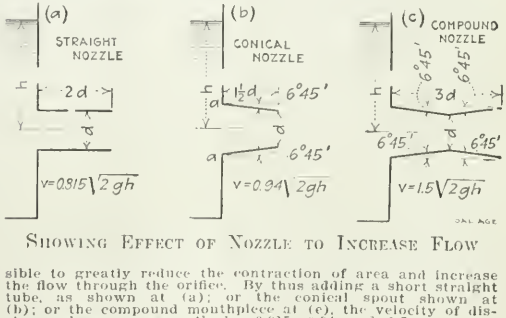
Seeing that the value of gravity (g) is given in feet per second, the head of water (h) must also be expressed in feet, and the area (A) in square feet, then the quantity (Q) will be found in cubic feet per second. The flow or discharge through an orifice having any area (A) in square inches, and for any head (h) in feet and any coefficient (c) of discharge, may be found by the following formulas:

$$Q = 3.342\,cA\sqrt{h} \text{ cu. ft. per min.} \quad (1)$$

$$Q = 25\,cA\sqrt{h} \text{ gal. per min.} \quad (2)$$

$$Q = 1500\,cA\sqrt{h} \text{ gal per hr} \quad (3)$$

Effect of Nozzle to Increase Flow—By adding a mouthpiece or nozzle to the opening, as illustrated by the accompanying diagram, (a), (b) and (c), it has been found possible to greatly reduce the contraction of area and increase the flow through the orifice. By thus adding a short straight tube, as shown at (a); or the conical spout shown at (b); or the compound mouthpiece at (c), the velocity of discharge becomes respectively, 0.815, 0.94 and 1.5 times the theoretical amount.



SHOWING EFFECT OF NOZZLE TO INCREASE FLOW

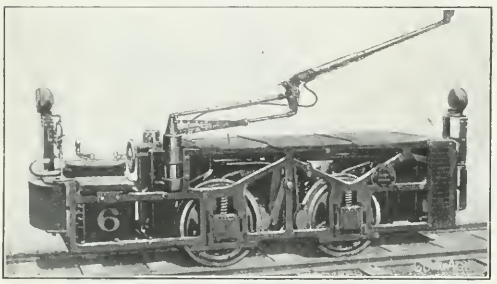
A New Locomotive Trolley Pole

The ordinary single trolley pole as employed on mining locomotives has many disadvantages and is subject to many limitations. When operated where the height of the trolley above the rail varies considerably the pressure exerted between the trolley wheel and wire also varies. This causes poor contact at the higher wire levels and extreme pressure with consequent rapid wear of wheel and harp at the lower levels.

When the wire hangs low and the pressure between wire and wheel is great if for any reason the latter leaves the wire the trolley pole strikes the roof or other obstructions with considerable violence, often causing damage.

Particularly in coal mines where the conditions of roof or overhanging rock is such that narrow entries are necessary, it is often impossible to run one of the single-pole trolley locomotives on account of an inability to reverse the trolley, because of the narrowness of the heading.

Where high cars are used and the trolley wire barely clears them, difficulty is sometimes experienced from the



SIDE VIEW OF LOCOMOTIVE WITH NEW TROLLEY POLE

trolley pole striking on the top of the car immediately following the locomotive. Furthermore with the ordinary single-pole trolley, the wheel will not follow any considerable transverse variation in the position of the wire.

To overcome these difficulties, the Westinghouse Electric & Mfg. Co. of East Pittsburgh, Penn., have placed upon the market the compound or semi-pantograph motion, trolley pole illustrated herewith. The principle advantages claimed for this device are the following:

(1) The variation in contact pressure for different trolley-wire heights is much less than that obtained by a standard single-pole trolley.

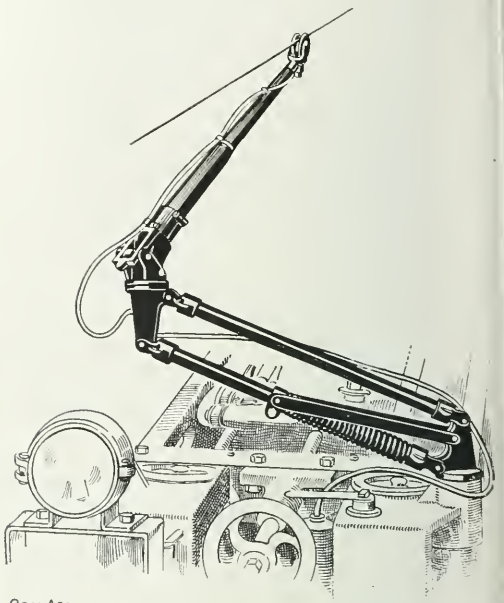
(2) Short length of trolley pole permits of its being turned around in a narrow passage.

(3) The trolley does not interfere with high trailing cars on sections where the trolley wire is low.

When the wire is at a height of five feet from the top of the rail the trolley-wheel pressure is approximately 26 lb. while at the height of 11 ft. it is about 18 lb. This shows a variation of 8 lb. in a range of 6 ft. which is much less than can be obtained by a single-pole trolley.

The new pole can be turned around in a passage from 4 to 6 ft. in width with the socket located approximately in the center of the locomotive. It will operate successfully where the trolley wire may have a variation in its location from the center of the track on which the locomotive is running of 4 ft. to the right or left without change of location of socket on the locomotive itself. This also does away with the necessity on gathering locomotives of two trolleys, one on each side.

The trolley consists of two members which operate in sockets. By means of a latch or pin at the locomotive socket the lower member can be adjusted vertically and kept in a rigid position and also can be swung horizontally and fastened in any definite place required. Furthermore it can be attached to locomotives now in service.



LOWER PART OF TROLLEY SWUNG ACROSS LOCOMOTIVE, AVOIDING NECESSITY FOR TWO SOCKETS

Coal in Alsace-Lorraine

The quantity of coal mined in Alsace-Lorraine has increased in the 40 years from 1872 to 1912 from 290,206 to 3,538,722 metric tons of 2204.6 lb., the output for 1912 being almost triple that of 1902. Coke was produced to the amount of 94,595 metric tons in 1912, against 90,275 tons in 1911, in addition to the coke used at the mines. The following byproducts were also recovered in 1912: 4250 metric tons of coal tar, 1208 tons of ammonium sulphate, and 967 tons of benzol, against 4577, 1175 and 787 tons, respectively, in 1911. Of the 3,538,722 tons of coal yielded from the mines of Lorraine in 1912, 197,475 tons were used in the works for heating the offices, firing the boilers, etc., against 221,456 tons in the preceding year. The sales amounted to 3,341,247 tons, a gain of 18.8 per cent. over 1911.

Because of its smokeless character, producer gas is destined to become an important factor in the elimination of the smoke nuisance.

EXAMINATION QUESTIONS

Ventilation, Pumping and Surveying

(*Answered by request*)

Ques.—A slope dips one foot in 12 ft., for a distance of 756 ft., measured on the incline. What is the difference in elevation between the mouth and face of the slope, and what is the horiozntal distance between these two points?

Ans.—From the reading of the question, the distance being measured on the slope, we assume the dip is one foot vertical, in each 12 ft. of slope measurement. This gives a total vertical fall, from the mouth to the foot of the slope, of $756 \div 12 = 63$ ft., which is the difference in elevation between the mouth and the face of the slope.

The horizontal distance between the same points is

$$\sqrt{756^2 - 63^2} = 753.37 \text{ ft.}$$

Ques.—A seam dips 4 in. per yd. of horizontal measurement. What is its angle of inclination?

Ans.—A dip of 4 in. per yd. is 4 in. in 36 in. of horizontal measurement, or one in 9 in. The angle (a) of inclination of the seam is then found as follows:

$$\text{Tan } a = \tfrac{1}{9} = 0.1111$$
$$a = 6° 20'$$

Ques.—How many horsepower will it take to raise 60,000 gal. of water up a shaft 250 ft. deep, in one hour? The resistance of pumps and pipes is 25 per cent.

Ans.—The weight of a single gallon of water is 7.48 lb. The total weight of water lifted per hour is, therefore, $60{,}000 \times 7.48 = 448{,}800$ lb., or 7480 lb. per min. Adding 25 per cent. to this weight for the resistance of the pumps and pipes, we have $7480 \times 1.25 = 9350$ lb. Since this weight is lifted through a vertical height of 250 ft., the work performed each minute is $9350 \times 250 = 2{,}337{,}500$ ft.-lb. The effective horsepower required for this work is, therefore, $2{,}337{,}500 \div 33{,}000 = 70+$ hp.

Ques.—An entry 5x10 ft., and 10,000 ft. long, is driven through a hill from daylight to daylight. If a large fan, say 20 ft. in diameter, placed at the mouth of this entry, circulates 100,000 cu.ft. of air per minute, what will be the water gage on the fan drift? There is no air course, but the air circulates in a single current from the intake to the discharge opening.

Ans.—In this case, the total length of the air course is 10,000 ft.; the perimeter $2(5 + 10) = 30$ ft.; and the area $5 \times 10 = 50$ sq.ft. The rubbing surface is $10{,}000 \times 30 = 300{,}000$ sq.ft. The water gage producing this circulation is calculated in the usual manner; thus,

$$w.g. = \frac{0.00000002 \times 300{,}000 \times 100{,}000^2}{5.2 \times 50 \times 50 \times 50} = 92 + in.$$

Note—Such a water gage is never attained in practice. It is due here to carrying the air in a single current, at the high velocity of 2000 ft. per min., a distance of nearly two miles.

Ques.—If the length of an airway is doubled, how will this affect the power; the velocity and the area of the airway remaining the same?

Ans.—The formula for power, expressed in terms of the velocity of the air current, is

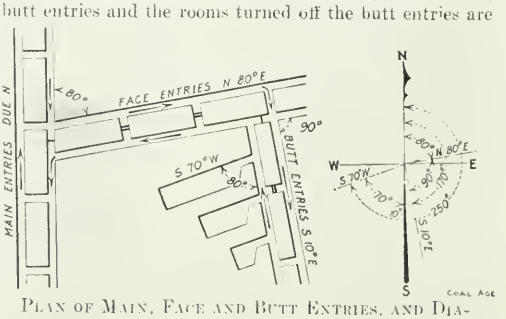
$$u = klov^3$$

It is observed from this formula that, for a given velocity produced by a given power, the *area* of the airway is not concerned. Assuming the cross-section of the airway remains unchanged, the perimeter (o) is constant, and k and v being constant, the power (u) varies as the length (l) of the airway. Therefore, to produce the same velocity of the air current when the length of the airway is doubled, the power must also be doubled.

**

Ques.—(a) If the course of a main entry is due north, what is the course of a face entry turned off to the right, at an angle of 80 deg.? (b) What is the course of a butt entry turned off the face entry to the right, at an angle of 90 deg.? (c) What is the course of a room turned off the butt entry, at an angle of 80 deg. to the right?

Ans.—(a) In the accompanying sketch, the general position and direction of the main entries, face entries, butt entries and the rooms turned off the butt entries are



PLAN OF MAIN, FACE AND BUTT ENTRIES, AND DIAGRAM SHOWING THE CORRESPONDING AZIMUTHS

shown. The course of the main entries being due north and the face entries being turned to the right an angle of 80 deg., the course of these entries will lie in the northeast quadrant, as shown on the right of the figure, and its bearing is N 80° E.

(b) The butt entries being turned 90 deg., again, to the right, the azimuth of their course is $80 + 90 = 170$ deg. Since this azimuth lies between 90 deg. and 180 deg., the course of the butt entries lies in the southeast quadrant. All bearings in the southeast and southwest quadrants being estimated from the south end of the meridian, the angle of bearing, in this case, is found by subtracting the azimuth from 180 deg. Thus, $180 - 170 = 10$ deg. The bearing of the butt entries is then S 10° E.

(c) The rooms being turned 80 deg. to the right of the butt entry, the azimuth of the rooms is $170 + 80 = 250$ deg. Since this angle lies between 180 deg. and 270 deg., the course of the rooms lies in the southwest quadrant, and the angle of bearing measured from the south end of the meridian is $250 - 180 = 70$ deg. The course of the rooms is, therefore, S 70° W.

SOCIOLOGICAL DEPARTMENT

State Miners' Hospital at Fairmont, W. Va.

By A. W. Hesse*

SYNOPSIS—The state of West Virginia has provided three hospitals for its miners of which that at Fairmont is one. It accommodates 49 patients. Those injured at their regular employment are admitted free.

By an act passed by the state legislature of West Virginia, during the session of 1899, three hospitals were created for the free care of those accidentally injured. These, designated as Miners' Hospitals Nos. 1, 2 and 3, were located at Welch, McKendree and Fairmont, respectively.

The site for the Fairmont hospital was donated by the people of that city. It consists of an acre of ground on a gently sloping knoll, easy of access and about four blocks from the Baltimore & Ohio R.R. station. Paved walks and roadways lead to and around the property.

Description of Building

The building consists of a main section and two wings, one at each end extending back 18 ft. The walls are of red brick and the corners finished with buff shale brick; the roofs are of slate. The partitions are built of studding, lath and plaster; the walls are covered with hard plaster filled and finished with paint.

The ground floor has two wards, each having 11 beds and three wards, each accommodating three beds. On the second floor there are nine rooms in each wing each containing one bed. So in all there is provision for 49 patients at one time. The second floor of the main building is for the living and sleeping rooms of the officials, nurses and other employees. Convenient bath and toilet rooms are located on both floors of the main building and wings. The office rooms are in the main building and occupy the ground floor being on the left of the building and facing the front. The operating, preparatory and sterilizing rooms are across the hallway in the rear of the main building and on the left of the same. The kitchen is between the wings to the rear of the hallway and easy of access for the serving of trays to patients. The large well-lighted dining room in the rear center is for the officials and nurses.

The Fairmont Hospital for Miners, Erected by the State of West Virginia

The stable has a stone foundation, red brick walls and corners finished to correspond with the main building. It is seen to the right of the hospital as shown by the front view herewith.

Both buildings are plumbed for gas and water. Electric light and power are furnished by a plant located in the basement of the hospital building.

*Assistant chief engineer, Consolidation Coal Co., West Virginia division, Fairmont, W. Va.

The Power Plant

The generating equipment consists of a 20-hp. Bessemer gas engine driving a 13.2-kw. dynamo and a 5-hp. Bessemer gas engine driving a 2.3-kw. dynamo. A deep-well pump driven by a 3-hp. motor supplies the operating plant, and with the tank and air compressor thrown into use will supply the institution in case of emergency. The refrigeration plant is in a 7x10 ft. room in which a 3 hp. motor drives a one-ton Brunswick compressor.

All laundry work for the institution is done in the building, the laundry being equipped with three large slate tubs with hot and cold water, large hot and cold mangles and a large rotary washer driven by a 3-hp. motor.

Free to Those Injured at Work

The act creating these hospitals provides, "That it shall be the duty of the board of directors of each of these hospitals to admit under their rules and regulations persons requiring hospital care and to treat free of charge persons accidentally injured in the state, while engaged in their regular employment or occupation; preference at all times to be given to persons accidentally injured."

Since this hospital was opened, Oct. 1, 1901, the law governing admission to this hospital has been closely observed and the entries for the eleven following years numbered 2838 or an average of 258 per year. During the year 1910-11, 323 were admitted, this being the largest number since the institution was opened. Besides these cases requiring hospital care, an average of 600 dressings for wounds were performed each year.

Classification of Injuries

For the eleven fiscal years ending Oct. 1, 1912, the admitting diagnoses were about as follows:

Injury	Per cent.
Fractures	40
Wounds	30
Contusions	18
Burns	6
All other	3
Fractures and dislocations	2
Dislocations	1
	100

Of the last 1176 cases of fracture treated, 59 per cent. were simple fractures, 20 per cent. were comminuted compound fractures, 18 per cent. compound fractures and 3 per cent. comminuted fractures. Of these fractures 37 per cent. occurred in the tibia and fibula, 14 per cent. in the femur, 6 per cent. in radius and ulna, 5 per cent. in the skull and the balance scattered in small percentages. Seventy per cent. of all the injuries were incurred in the mines. Up to about 1911, perhaps 53 per cent. of these accidents at the mines were due to coal and slate falls and those due to cars ran about 6 per cent. During 1911 and 1912 the accidents due to falls decreased to about 40 per cent. while those due to cars increased to about 35 per cent.

When this hospital was opened in 1901, Dr. James McDonald was placed in charge and has maintained the position as superintendent since then. His staff consists of an assistant superintendent, matron, two nurses, four assistant nurses and two graduate nurses. With this force he has carried on a charitable as well as an economical work successfully and the hospital has amply supplied a much felt need.

Rear of Hospital, Showing Wings and Central Building, Latter Containing Kitchen and Rooms for Officials

Some time ago a careful classification of fractures was made with the following results:

NATURE OF FRACTURES TREATED AT FAIRMONT HOSPITAL

	Simple Fracture	Comminuted Fracture	Compound Fracture	Both Compound and Comminuted Fracture	Total	Per cent.
Clavicle	56	0	1	..	57	5.28
Femur	134	2	15	15	166	15.37
Fibula	13	1	1	..	15	1.39

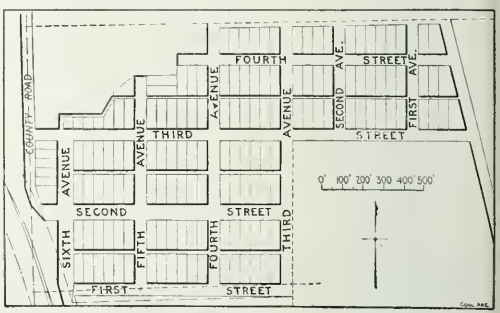
Skull	15	..	27	18	60	5.55
Sternum	8	..	..	..	8	0.74
Symphysis pubes	7	..	..	..	7	0.65
Tarsal	..	..	..	1	1	0.09
Tibia	3	..	..	..	3	0.28
Tibia and fibula	204	21	49	162	436	40.40
Vertebra	2	..	1	..	3	0.28
Frontal and nasal	..	..	1	..	1	0.09
	639	37	171	233	1080	100.00
Per cent	59.17	3.43	15.83	21.57	100.00	100.00

The classification of the contusions and wounds is too extensive for this paper and is omitted.

Coal Valley Mining Co.'s Village

The Coal Valley Mining Co.'s village at Matherville, Ill., is an evidence that miners are in many cases desirous of purchasing their own homes. In the spring of 1909, the company laid out a townsite of 150 lots near the line of the Rock Island Southern Ry. about a mile from the mine, and sold the lots under certain restrictions, prohibiting the sale of liquor, reserving the mineral rights thereunder, etc. The prices of the lots varied from $125 to $175 for a 50-ft. front and in each case they were paid for in cash. In less than one year every lot was sold and two additions have had to be made since.

Good houses, the greater number of which cost from $700 to $2800, were built by the purchasers. Most of them were constructed for the mine workers owning them by contracting concerns which furnished all material complete above the foundations; lumber, paint, hardware, roofing, etc. The architecture is pleasing and above the average of that of mining towns.



VILLAGE OF MATHERVILLE, ILL., AS ORIGINALLY PLOTTED

The streets are now being graded and filled with cinders. A good brick school building was erected last year, as well as several churches. The plots for these were donated by the coal company.

The town is lighted by electricity supplied by the corporation, which operates the electric railroad, and a movement has been started to erect water-works. Since the town was laid out several additions have been made by outside parties and by the Alden Coal Co.

Many of the southern Illinois mines are similarly not equipped with miner's houses, the workers being owners of their dwellings and not tenants.

COAL AND COKE NEWS

Washington, D. C.

The situation produced by the action of the Senate in undertaking to investigate the West Virginia coal strike conditions seems to become more and more serious daily and to involve more and more colateral issues which had hardly been expected to be drawn into the discussion.

During the past week sharp clashes have occurred on the floor of the Senate with reference to this matter while in the process of working up the investigation itself there has been serious difficulty and friction, and in the coalfields the question of prosecuting various men responsible for the mining difficulty or supposed to be so has become involved with the enforcement of the Sherman anti-trust law.

The fact that President John P. White with eighteen officers of the United Mine Workers were indicated in the Federal District Court at Charleston, West Virginia late last week is tending to complicate the situation greatly, particularly as the Department of Justice disavows having instigated or directed the proceedings. It is now stated that if the prosecution of these men is pushed it will be taken as a direct order on the part of the President while if dropped it will be construed as indicating that the President is in sympathy with the terms of the proviso in the Sundry Civil bill now pending, which forbids the use of the funds for the prosecution of combinations of labor in defiance of the Sherman anti-trust law.

Unofficial reports from West Virginia make it appear that the charges against the nineteen labor men are more serious than the technical violation of laws against conspiracy in restraint of trade ordinarily involved in widespread strikes. While indictments so far have been returned only against mine workers affiliated with the labor union, it is hinted that coal operators—not miners—in Ohio, Indiana and Pennsylvania are regarded as co-conspirators with the union men.

According to these reports, the operators in Ohio, Pennsylvania and Indiana wanted to see the unions recognized in West Virginia, wages increased, and the cost of West Virginia coal advanced to a point where these fields could not compete in the markets coveted by the operators in the other states.

If this connection between the union men and the coal operators is established and the operators also are indicted the whole aspect of the case will change. In such a circumstance it is believed, the sympathies of union labor might be on the side of the prosecution. It would not then be a trial of labor men as such. It would be a prosecution of certain laborers charged with conspiring with certain operators to restrain trade.

The proviso in the Sundry Civil Appropriations bill which caused President Taft to veto the measure was reinserted before the bill was reintroduced at the present session. At that time it was said that President Wilson had reason to believe that so many Democrats were committed to the exemption that even if he threw his influence against it many Democrats would support it and party harmony would be imperiled.

The Production of Anthracite Is Large

Information received here by Government officers shows that the production of anthracite coal during the current spring is going on rapidly. The information has been communicated to members of Congress who have been threatening more investigation to the coal situation and has apparently served to mitigate their disposition to be active in regard to the matter. According to the official statements now current about 6,000,000 tons of coal were mined during May while slightly more than the same amount was consumed.

In May of last year the mines were closed about two-thirds of the time pending the wage settlement, and the total production of coal in that month was but 1,429,000 tons. At the close of May, 1912, after nearly two months of strike the loss in tonnage, as compared with the first five months of 1911, was 9,188,893 tons. This year the production in May shows an increase of 4,566,385 tons over last year, and for five months an increase of 8,976,474 tons. From this time on the production of anthrcite coal will compare, until the end of the calendar year, with the largest output ever reported.

Every company, of course, showed a remarkable increase as compared with the output in the strike month of last year. Reading increased 922,000 tons, the Lehigh Valley, 988,000 tons, and the other companies proportionately.

From these figures it is being argued that there will be an unusually heavy aggregate output of coal for the current calendar year, the demand being large up to the present time while stocks are unusually low so that a large production is necessary to replenish the fundamental supplies.

Another Supreme Court Decision

The Supreme Court of the United States in a decision handed down on June 9 closed the long-standing litigation between the International Coal Co. and the Pennsylvania Railroad with reference to shipments of coal by holding that the company could not collect a rebate from the railway owing to the fact that no definite damages had been proven to exist so that a fixation of the damage in money terms was out of the question. The full text of the decision will not be ready for several days.

PENNSYLVANIA

Anthracite

Scranton—United Mine Workers from Scranton to Pottsville in the three anthracite districts held a large demonstration, May 30, at Mt. Carmel in the dedication of a handsome monument to the memory of the late D. F. Gallagher. Mr. Gallagher while a member of the State Assembly introduced a bill known as the Miners' Certificate Law. This law requires a person entering the mines to work as a laborer two years before he can engage as a miner.

The Temple Iron Co. has dissolved in conformity with a decree of the U. S. Supreme Court. This announcement has been made at its main offices June 5.

Wilkes-Barre—The 500 striking employees of the East Boston colliery of the W. G. Paine Co. in Luzerne, have returned to work. During the strike which lasted several days the company took the opportunity to make some necessary repairs. The men whose refusal to join the Union caused trouble have at last affiliated themselves with that organization.

Giovanni Ettor, the organizer of the Industrial Workers of the World, who figured so prominently in the Lawrence strike, is expected to come to the anthracite coal fields on the 10th of this month, to remain for a period of at least 15 days, and possibly a month. He will be accompanied by a Polish organizer and the two will endeavor to arouse interest among the foreign element of the mine workers in the organization of I. W. W. locals throughout the entire Scranton, Wilkes-Barre and Hazleton regions. Already one strike has been caused by the efforts of the I. W. W. organizers to get a foothold in territory which the U. M. W. of A. regard as their field, and there promises to be even more serious trouble should the two become embittered.

Shamokin—On June 6 rescuers equipped with oxygen helmets saved the lives of 23 miners in the Scott Colliery, following a gas explosion. Two men were killed. Fire followed the explosion but it was extinguished without any further fatalities. The colliery is operated by the Susquehanna Coal Co. an adjunct of the Pennsylvania R.R.

Bituminous

Pittsburgh—The American Mine Safety Association will hold its first annual meeting at Pittsburgh in September. A national button bearing the red circle signifying danger and the white arrow pointing the way to safety has been adopted by the society. This society is the outgrowth of the National Mine rescue and first aid conference held in Pittsburgh last fall. It has a membership of 250 and its purpose is to preserve the lives and health of miners and to reduce property loss.

Connellsville—The boiler house at the Colonial No. 4 mine of the H. C. Frick Coke Co. was recently destroyed by fire. The loss is estimated at $15,000.

Workmen in the Cincinnati mine of thhe Monongahela River Consolidated Coal & Coke Co. have found another victim of the explosion which occurred April 23. This brings the total death list up to 97.

Barnesboro—The tipple of the Lennox Mine of the Hastings Coal & Coke Co. was destroyed by fire June 2. About 100 miners will be temporarily thrown out of employment.

WEST VIRGINIA

Charleston—After a long conference with representatives of the United Mine Workers and coal operators in the Paint Creek and Cabin Creek fields, the Senate Committee is preparing to investigate West Virginia strike conditions and hearing began at Charleston June 10.

The trouble at the four mines of the New River and Ohio Coal Co. at Stanford has been satisfactorily adjusted and the mines resumed work June 6. The trouble arose when the company refused to allow a check weighman on the tipple.

Out of a class of 112 who took the examination for first-class certificates for mine foremen and fire bosses at Welch, May 20, 21 and 22, 11 received first-class certificates, 35 second-class certificates and 3 passed the examination for fire boss.

NEW JERSEY

South Amboy—According to decisions rendered by Supreme Court, taxes running into thousands of dollars will be collected by the city of South Amboy on coal of the Susquehanna Coal Co. and other companies which use coal storage yards at this place. The Court holds that the coal is not in the process of interstate shipment, and has come to rest as a part of the property within the State.

OHIO

Yorkville—After a mass meeting held June 2, 300 miners in this vicinity refused to return to work until Italians and Poles, who have been loading coal, were discharged. These nationalities have a deadly feud, and evseral battles have occurred inside the mines. Other miners fear that a battle may be started, which will endanger the lives of all under ground.

Martins Ferry—The miners at the Rush Run No. 2 Mine went out on strike June 5 because new mules had been put into service to haul the coal out of the mine. The 300 men employed declared that the new mules could not haul the coal fast enough, and that they were losing time as a result. Officials of the company sent the old seasoned animals back to the work.

Woodsfield—State Mine Inspector J. C. Davies states that he does not agree with all the findings of Coroner Elmer Radcliffe of Noble Co., on the recent explosion in the Imperial Mine at Belle Valley. The coroner states that the explosion was caused by gas coming in contact with an open lamp of one of the miners, and that the gas was forced down upon the men by a change in the course of air brought about by the removal of a brattice and the closing of a door a few minutes before the explosion occurred. Inspector Davies says the closing of the door had no effect on the explosion, and that the real cause was the failure to maintain proper air courses, which allowed the gas to accumulate.

INDIANA

Vandalia—The validity of the wide mine entry law of Indiana, requiring that the entrance to a coal mine must be kept clear of débris, was recently upheld by the Supreme Court of the United States in a decision in a suit brought by Charles E. Barrett, as agent of the Vandalia Coal Co.

ILLINOIS

Marissa—The Egyptian Coal & Mining Co. has voted a new issue of bonds for $50,000 to purchase the Meek mine at Marissa. All of the mines of the Egyptian Coal & Mining Co. are at the present time on the Illinois Central, but when the Southern Traction Co.'s line is completed that will also connect with them all.

Marion—The Watson Coal Co., with two mines northwest of Marion, has gone into voluntary bankruptcy. One of the mines has not been working for several months, on account of being flooded when the high waters prevailed in southern Illinois.

The Pittsburg Big Muddy Coal Co., operating a mine at Pittsburg, a few miles east of here, has been declared a bankrupt. The cause given is that it is impossible to market the coal at a profit, and that such conditions have existed for several months.

KANSAS

Pittsburg—John Steele, Kansas state arbitrator, has announced that the miners of No. 14 District of the United Mine Workers are right in their contention with the Cherokee-Pittsburg Coal & Mining Co. This means that the miners shall not be compelled to push their loaded cars a distance exceeding 150 feet. Mr. Steele has decided that since No. 14 is a new mine, it comes under the contract made between the miners and operators last year. Some of the other mines of the coal company are operated under old contracts, which allow a distance of 200 feet.

WYOMING

Sheridan—A severe electric storm, in the vicinity of Acme, May 28, caused a blaze which completely destroyed the power house of the Model Coal Co., entailing a loss estimated between $15,000 and $18,000. The building was entirely destroyed, together with much valuable machinery.

FOREIGN NEWS

Vancouver, B. C., Can.—Sixty-one miners brought from England to work in the coal mines at Nanaimo have refused to serve as strike breakers and are being cared for at the local headquarters of the United Mine Workres of America.

PERSONALS

A. T. Shurick of the editorial staff of "Coal Age" is the 4500th member of the order of Kokoal.

Governor Ammons of Colorado has reappointed James Dalrymple as chief inspector of coal mines.

F. L. Natt has tendered his resignation as manager of the Rock Island Fuel Co., of Moline, Ill. He expects to enjoy a short vacation and then enter into business for himself.

J. W. Finney, of Hartford, Mo., has resigned his position as commissioner for the Southwestern Coal Operators Association of Missouri, Kansas, Oklahoma, Arkansas and Texas. T. A. Freese, of Huntington, Ark., has resigned his position as State Mine Inspector, to succeed Mr. Finney.

Wm. Nicholson, who for the past four and a half years has been district mine inspector for the eleventh district has tendered his resignation to the State Mining Department, to take effect June 15th. Mr. Nicholson will assume the superintendent's duties for the Jewell Ridge Coal Co. at Richlands, Va.

Fred S. Green, of Byesville, Ohio, has been made superintendent of the Imperial Mine at Belle Valley, in which 15 miners lost their lives by an explosion two weeks ago. Mr. Green succeeds Harry Dudley, who was held responsible for the explosion by Coroner Radcliffe. Mining in the Imperial mine will be started at once.

Rowland Jones, of Avoca, who has been employed as assistant mine foreman at the Thomas Shaft, Butler Colliery, Hillside Coal & Iron Co., has been transferred to the position of foreman at the Courtright Slope, of No. 14 Colliery, Pennsylvania Coal Co., at Plainsville. He takes the place of foreman Shovlin, who was killed by a fall of rock a few weeks ago. Walter Hutchinson, assistant foreman at the Clarence Colliery, has been transferred to the Thomas Shaft, to fill the vacancy left by Mr. Jones.

CONSTRUCTION NEWS

Morn, W. Va.—The American Coal Co., of New York, is constructing mines in this vicinity, together with a model company store and office building, at a cost of $20,000.

Punxsutawney, Penn.—The Lindsey Coal Mining Co. has work underway on a new opening about three miles from Punxsutawney. It is expected that they will be ready to begin shipments by Aug. 1.

Craig, Colo.—A party of Eastern capitalists is planning on making investments in coal lands in Moffat County. It is understood that these lands will be placed in readiness for extensive operation by Oct. 1.

Connellsville, Penn.—Extensive improvements have been made by Lochrie Bros. Coal Co. at their Argentine, Butler County, plant. The daily output has been increased by nearly 150 tons, and the capacity now reaches 600 tons.

Two Harbors, Minn.—It is rumored that the city of Two Harbors will soon ask for bids for the construction of a coal

trestle to be built near the City Water & Light station, and to be used by the city in hauling coal by the cargo.

Bloomington, Ill.—Officials of the Big Four Coal Co. have received word that the contract has been let for a new coaling station at Lilly, to be erected at the cost of $10,000. This contract has been awarded to the Roberts & Schaefer Co., of Chicago, Ill.

Connellsville, Penn.—It is reported that the activities of the Maryland Steel Co., which is planning the erection of 120 new coke ovens, will soon be broadened to take in the manufacture of structural steel. About $3,000,000 will be spent on improvements.

Blairsville, Ohio—It is reported that the Buffalo, Rochester & Pittsburgh R.R. is to be extended from Josephine, through Blairsville, to Latrobe. It will cross Conemaugh River by a long trestle. A surveying corps is said to have been working out a plan of extension for some time.

Pound, Va.—Several hundred men are at work on the construction of the upper Pound River extension of the Indian Creek & Pound River R.R. from Pound, along and continuous to the Kentucky border line, in Wise County, Va., which will tap rich coal and timber fields controlled by the Tidewater Lumber Co.

Henry, Ill.—The Santa Fé R.R. has recently purchased 10,000 acres of coal land in the vicinity of its station at Toluca. The Santa Fé company is now sinking coal shafts and putting in machinery to develop this field. It is expected that this will be a source of fuel for its system in Illinois, Iowa and Missouri.

Cincinnati, Ohio—In the electrification of its lines in the Pocahontas coal district the Norfolk & Western R.R. will build its own special generating station. Several large firms interested in this class of work have been figuring on the construction. The generating station will have a 24,000-hp. capacity and will be located in the middle of the Pocahontas coal district.

Monongahela, Penn.—Engineers of the River Coal Co. are making locations for a borehole to be driven to the coal in the Cincinnati mine. This will enable to West Penn Electric Co. to run a power line to furnish electric current to run the mining machinery. The West Penn Co. expects to have connections made with all the mines of the coal company within a short time.

Huntington, W. Va.—It is reported that W. A. Liller, of Keyser, has been awarded the contract for $250,000 worth of houses to be erected for the Pond Creek Coal Co., at their operations in Pike County, Ky. This contract calls for the erection of 420 houses of modern construction. Many of them will be finished with baths and other conveniences. Each house will contain from five to six rooms.

Unionville, Mich.—A new shaft for the Handy Bros. Mining Co., near Unionville, has been sunk to a depth of 81 ft. in 12 days. The work has been done under the supervision of John Morris and William Williams. The entire depth of the shaft is to be 200 ft. The coal is of the Pennsylvania bituminous character, and it is understood that the territory will warrant mining operations for approximately 20 years.

Connellsville, Penn.—The Connellsville Coke & Fuel Co. is rushing the construction of 80 new ovens at their plant in the Ligonier Valley and have the railroad from their plant at the Marietta-Connellsville Coke Co.'s works almost graded. The new works will be modern in every respect and will be equipped with a compressed air coke drawing and loading machine, which is being built at the Scotdale Foundry & Machine Co.'s plant.

Denver, Colo.—Announcement has been made that the Colorado Fuel & Iron Co. will spend $500,000 in improvements on the Pueblo plant this summer. These improvements will consist of the installation of three open-hearth furnaces, which will be completed in about six months. These furnaces will increase the output of the mill approximately 20 per cent., and will mean the addition of more than 100,000 tons to the annual output of steel of the company.

Sykesville, Penn.—Work on the improvements at the Cascade Coal & Coke Co.'s plant is progressing rapidly. The new smokestack has been completed. The structural iron workers, who will do the iron work on the power house, have arrived and are now in shape to push their part of the construction to a finish as fast as the material arrives. The foundations for the power house are now practically completed. Work on the new ovens is well under way, much of the masonry having been already completed.

Bluefield, W. Va.—The Baltimore & Ohio R.R. Co. proposes to erect another coal railroad in Kentucky. It has acquired the charter rights of the Long Fort R.R. Co., which owns a location on the left fort of Beaver Creek. The new road, when completed, will connect with the Chesapeake & Ohio Ry. As a result of the construction of this line, there will be about 1000 acres of coal land owned by the Elkhorn Fuel Co., which will be developed. No date has yet been decided upon for starting the construction of the proposed line.

Washington, Penn.—The Chartiers Mining Co., which recently purchased a large block of coal territory in Mt. Pleasant Township, has accepted the surface of three farms on which the new openings will be made, together with other developments to establish the new mining town. The sum of $25,000 was paid for a total of 264 acres of surface land. The coal rights were purchased at the rate of $135 per acre. No active operations will be started toward the development of this block for a year or so, owing to the fact that the company is making extensive improvements in other sections of the county.

NEW INCORPORATIONS

Boston, Mass.—The Atlantic Coal Co.; capital stock, $500,000. Incorporators: P. D. Dean, J. B. Sullivan, Jr., W. G. Todd.

Medora, N. D.—The Western Coal Co.; capital stock, $60,000. Incorporators: L. H. Haliin, M. S. Mitchell, J. T. Roysten.

Portland, Me.—The Brookline Coal Co.; capital stock, $25,000; to carry on a wholesale and retail coal business. E. A. Randal, president.

New York, N. Y.—The Von Bauer-Lively Coal Products Co.; capital stock, $1,000,000. Incorporators: G. G. Stiegeler, E. F. Hellings, W. M. Pyle.

Charleston, W. Va.—The Elmo Mining Co.; capital stock, $50,000; chief works, Elmo, W. Va. Incorporators: R. M Price, R. S. Stilman, D. W. Hill, A. C. Collins, Buckner Clay

Charleston, W. Va.—The Wheeling Monroe Coal Co.; capital stock, $25,000; to operate in Monroe County, Ohio. Incorporators: J. B. McKinley, M. A. Hanning, H. P. Lockwood, L. W. Brown and H. O. Wells.

Anchor, Ky.—The R. C. Teway Mining Co. has been incorporated with a capital stock of $10,000, by R. C. Teway, E. B. Teway and W. F. Burnwinkle, for the purpose of developing a small property in that vicinity.

Leslie, Ark.—The Red River Coal & Mining Co. has been organized here with a capital of $100,000, to develop the 14-in. seam of coal near here. The officers are: G. S. Thompson, president; Edward Mays, vice-president, and A. G. Killibrew, secretary and treasurer.

Springfield, Ill.—Hickman Williams & Co., of Louisville, Ky., have been licensed to incorporate in Illinois. The capital stock is $600,000. To buy and sell pig iron, coal, coke, alloys and steel and iron products, and to own and operate glass furnaces, coke plants, coal and ore mines, and steel and iron works.

INDUSTRIAL NEWS

Roanoke, Va.—The Heuser Coal Co. has purchased 300 acres of coal and timber land on Pine Creek, near Mayking, Ky., and will develop the same within a short time.

Maracaibo, Venezuela—Development on a limited scale has been begun by the Caribbean Coal Co., an American organization, on the coal deposits on the Guajira peninsula. A diamond drill is being forwarded to the property.

Grand Haven, Mich.—A large deposit of coal has been discovered on the beach in this vicinity by a gang of workmen who were putting in the new water main.

Shelburn, Ind.—The Canada Oil Co., which is drilling on the farm of Thomas Dix, has recently shot a well at a depth of 615 ft. From all indications, it will produce from 50 to 60 bbl. a day.

Paducah, Ky.—The West Kentucky Coal Co. will begin at once the construction of 50 new barges at its plant, for the purpose of taking care of its increasing production. Since Jan. 1 the company has built 47 barges, but requires still more.

Hulbert, Ark.—Last week the Roberts & Schaefer Co. secured a contract from the Rock Island Lines for a fireproof counterbalanced bucket (Holmen type) coaling station, to be built immediately at Hulbert, Ark. Contract price approximately $15,500.

Morgantown, W. Va.—J. V. Thompson, of Uniontown, Penn., has failed to purchase several valuable tracts of coal land in this county upon which he secured options some time ago. The options were for 45 days and have expired. It is understood that the price ranged from $600 to $800 an acre.

Lynn Hollow, Ky.—The Lynn Hollow Coal Co. was recently organized by local men on the new Wasioto & Black Mountain R.R. in the Harlan field. This is another new company which is starting development work on a large scale, with promise of large production later on.

Burkburnett, Tex.—The Corsicana Petroleum Co., which has purchased the lease on 3600 acres of land in the Burkburnett oil field will bore a number of wells upon the property. There is already one well which has a production of more than 100 bbl. per day located upon the land.

Monongahela, Penn.—It is reported that leading operators of the Pittsburgh district have refused orders for 1,000,000 tons of coal during the past week or ten days, owing to the fact that they were already sold to capacity. Indications are that the mines will run steadily during the entire summer season.

Lexington, Ky.—The miners' short course which is given by the State University College of Mines and Metallurgy is proving exceedingly popular with miners, and many additions to the class which will take the course during the summer have been made, the students coming not only from all parts of Kentucky, but from other states as well.

Louisville, Ky.—A 2,000,000-bushel coal fleet arrived in Louisville a few days ago from Pittsburgh, principally intended to supply the local yards for the summer storage business. Large tows of empty barges were awaiting the arrival of the towing steamers of the fleet, to be taken back to Pittsburgh for immediate loading for the South.

Denver, Colo.—J. G. Gwyn, chief engineer of the Denver & Rio Grande Ry. Co., Denver, Colo., has just awarded a contract to the Roberts & Schaefer Co. for the building of two large counterbalanced bucket (Holmes type) locomotive coaling stations for installation on their line at Salida and Minturn, Colo. Contract price approximately $22,500.

Sargent, Ky.—A large acreage of coal and timber land on Smoot Creek has been purchased by A. H. McClure and associates, of Frankfort, Ky., and it is intended to develop the property at once ,for which purpose a complete coal-mining plant will be opened up shortly. Subsequently lumber mills will be installed for the purpose of cutting up the timber.

Harlan, Ky.—The Harlan Coal Mining Co. is taking bids on lumber to be used in the construction of 120 miners' houses which it proposes building at its mines. They will be of a little better class than the average run of such houses, as a good grade of yellow pine is to be used for the most part, and cypress shingles will be used in the roof, instead of tin or composition roofing.

Johnstown, Penn.—Mine No. 33 of the Pennsylvania Coal & Coke Corporation, at Patton, resumed operation June 2, after having been closed down for three months. The company now has about 100 men at work and is putting out about 300 tons daily. The capacity of the mine is about 1200 tons. It is said that the company is driving new headings in preparation for a rush in the coal business next fall.

Boonville, Ind.—The Big Four Coal Co. has secured an option on several hundred acres of coal land and is completing arrangements for large stripping operations in Southern Indiana. A company, which will include the Big Four company, together with outside capital, is now being formed to mine this coal by a stripping process. It is claimed that the output will reach a thousand tons daily and the company expects to be able to put the coal aboard the cars for 20c. a ton.

Owensboro, Ky.—Announcement has been made of an increase of 5c. a ton on coal from the mines in western Kentucky, on the Louisville & Nashville, after June 1. A similar increase has been ordered, also, upon the Illinois Central. The reason for the increase on the part of the Louisville & Nashville has not been given, but it is understood that the step has been taken to equalize the rates from western Kentucky mines with those from the mines in southeastern Kentucky.

New Cumberland, Penn.—The Monongahela River Consolidated Coal & Coke Co., which has lost two boats on the Ohio River, near Louisville, within the past month, suffered the loss of another a few days ago when the towboat "Tornado" struck Dam No. 9, on the Ohio River, near New Cumberland, and sank. The boat was on her way to Pittsburgh with a tow of empties when the current and high water combined to cause the accident. The crew of 28 men escaped by leaping into the river as the boat went down. It will probably not be possible to recover her.

Salt Lick, Ky.—The Licking River R.R. Co., which has been operating a 32-mile line running from Salt Lick to Yale, in Bath County, has filed notice in the office of the Kentucky Railroad Commission of its intention to quit business. The road served a region which showed considerable promise of coal and timber, but operations have evidently not proved profitable. The company has a capital stock of $50,000, and is bonded for $100,000. Stockholders holding 497 of the 500 shares filed the notice, these including J. H. Fulmer, Jr., W. W. Hubbard, H. G. Niles, Jr., J. A. Roper and Charles Bygate.

Lexington, Ky.—J. B. Allen, who is in charge of the Slemp-Camden-Mayo coal interests in Perry, Knott and Letcher Counties, Ky., proposes to conduct an elaborate and exhaustive system of prospecting over the properties which he handles during this summer, and for that purpose recently secured the services of Henry L. Noel, a member of next year's graduating class of the Kentucky University College of Mines and Metallurgy. It is intended to ascertain exactly what the properties are worth for coal-mining purposes, in order that development may proceed intelligently when it begins.

Beaver Creek, Ky.—The charter of the Long Fork R.R. Co., which owns a location for a railroad on the left fork of Beaver Creek, and whose proposed line will render accessible about 100,000 acres of coal lands owned by the Elkhorn Fuel Co. and about 8000 acres owned by the Milwaukee Coal & Gas Co., has been acquired by the Baltimore & Ohio R.R. Co. The latter company will proceed with the construction of the line, although the exact date of the beginning of the work has not been decided upon. F. L. Stuart, of Baltimore, Md., is chief engineer of the Baltimore & Ohio. The road will be about 30 miles in length.

Jenkins, Ky.—It is reported that the Consolidated Coal Co. has now increased its output to the point where it is shipping 200 cars a day from its mines at Jenkins and 60 cars from the McRoberts workings; and the output from the latter is to be doubled within two weeks. This largely increased output has necessitated the operation of more and larger trains over both the Sandy Valley & Elkhorn and the Lexington & Eastern railroads in that section. The Louisville & Nashville is rapidly getting into service in this field its new steel coal cars recently provded for, and is doing everything in its power to meet the increasing requirements of the coal operators.

Columbus, Ohio—The Chapman Mining Co., of Columbus, which has offices in the Wyandotte Bldg., is branching out and has established sales agencies at a number of points. At Mason City, Iowa, L. B. Hagerman has been stationed and A. M. Fisher is located at Detroit. W. H. Spencer is stationed at Grand Rapids. In addition to these agents the company has assigned A. S. Tingley to cover Indiana and A. L. Vogt to cover the state of Ohio.

Arrangements have been made with the New York & New England Coal Co., of Albany, Penn.; the Nayaug Coal Co., of Dunsmore, Penn., and the Mohawk Coal Co., of Carbondale, Penn., to act as selling agency in this territory.

Louisville, Ky.—The Kentucky Court of Appeals has granted to the Illinois Central R.R. Co. an order restraining Judge J. J. Rice, of Muhlenberg County, from proceeding with the trial of the 1600 damage suits filed by the miners in that section against the railroad on account of last winter's car shortage. One of the reasons alleged for the issue of the order was that Judge Rice is a candidate for reëlection, and that the number of plaintiffs involved in the suit might influence him. The amount involved in the cases is $50,000, and the appellate court holds that they should be tried in the circuit court, from which an appeal may be taken to the appellate court, in order that the full merits of the matter may be adjudicated.

Stonega, Va.—The Virginia Iron, Coal & Coke Co., which operates large coal and coke plants at Stonega, Va., two miles from the Kentucky line, has announced that it is about to start the biggest operation ever attempted in the Virginia coal fields. The new development will be along the headwaters of Guests' River for seven or eight miles along the Kentucky line, and will be reached by the Interstate R.R., the company line, which is to be extended from Norton, Va., for that purpose. For years it has been the company's intention to develop this part of its property, and it is now ready to spend in the neighborhood of $25,000,000 in the work. The construction of the railroad has begun, and engineers will soon locate the first town of the series which will be built in connection with the operation.

COAL TRADE REVIEWS

GENERAL REVIEW

The retail demand for hard coal is the best it has been for years at this season, which has enabled dealers to buy more liberally than usual. Shipments by the companies are steady and promise to continue so. There is a perceptible tendency to drag, however, and stove coal which has been the leader for several months is now comparatively easy, with broken a close second.

Some bituminous shippers in the East are so short of coal that they are being forced into the open market for small tonnages to fill out their contracts. This is a most unusual condition for this season of the year when the market is ordinarily at the lowest point. The inadequate labor supply is probably the direct cause of this condition, but the situation has been further aggravated by a heavy buying movement on the part of some consumers seeking to cover their requirements against a possible further advance in quotations. The Eastern bituminous trade is in a commanding position with the market steadily strengthening, and indications are that there will be a further shortening up in tonnages unless the labor situation improves. Forced sales, even in the low grades, are practically unknown; coal is to be had only on reasonable notice, while operators are slow about taking new business and there is a general feeling that higher prices will prevail later.

Mining in the Pittsburgh district continues active, although consumers are well taken care of on contract. The labor supply is inadequate, but not sufficiently so as to seriously affect operations and there appears to be sufficient car supply to take care of shipments; slack is the only heavy feature of the market. In outlying districts the car shortage is becoming more pronounced, particularly where prompt shipment is required. The asking price is stiff and there is no difference of opinion regarding the firm condition of the market. Operators are well sold up for several months and there is little prospect of any increase in the production.

Although the car shortage in Ohio is restricting operations, it is now evident that the lake shipments will exceed all previous records. There is still a shortage at the Hampton Road piers, and some producers are having difficulty in meeting their contracts; the dumpings at the piers fell off last week, due principally to a lack of tonnage. The Southern markets remain steady, because of the light production, as a result of a scarcity of both cars and labor.

The wave of prosperity in the coal trade now seems to have been definitely established in the Middle Western markets. Contrary to expectations, the trade continues to improve and it is now clear that there is little danger of any immediate slump in quotations. Prices are advancing because of the shortage of Eastern coal, which is forcing buyers into the Middle Western markets. Some large contracts are open and operators are showing a tendency to hold for higher prices.

BOSTON, MASS.

Bituminous—Pocahontas and New River continue quite firm in price. Some of the shippers are even short of coal for early June loading and are in the market themselves to buy of other interests at the contract figure. This is a most unusual situation for June and it points to a strong market through what is ordinarily the slow season. The far-sighted people in the trade are expecting such a shortening up of tonnage on account of the poor supply of labor in most of the districts that they are trying hard to pile up coal as fast as it can be had. There is no accumulation at any of the loading piers and the demand from the West is reported as unusually brisk. In all directions bituminous is in a commanding position.

It is significant that a further slowing up is apparent on the Georges Creek tonnage coming to tide. Steamers at Baltimore are having fair despatch, but sailing vessels and barges are now required to wait for a few days at least. At Philadelphia and New York the receipts are just beginning to be intermittent. The same is true of the highest-grade coals from Pennsylvania.

Cargoes arriving on the market are now seldom heard from and spot coal for inland distribution is only to be had on reasonable notice. There are no auction sales just now. Most of the all-rail shippers are behind on orders, but consumers have learned to be forehanded and to provide storage more liberally than used to be the case.

Water Freights are hardening from all the ports; 70c. has been paid from Hampton Roads to Providence and 80c. to Boston, both on fair-sized tonnage, while 45c. continues the rate on barges for Long Island Sound, for New York loading.

Anthracite—A slight easing up is noticed, but dealers in New England are still after shipments. The retail demand has been the best in years and it has enabled the dealers to take on rather more coal than ordinarily. Individual shippers are doing little in this market, but the few companies that are serving the trade are sending coal around with almost clock-like regularity. Stove is still the size hardest to get, although broken is not far behind.

Current wholesale prices on bituminous are about as follows:

	Clearfields	Cambrias Somersets	Georges Creek	Pocahontas New River
Mines*	$1.05@1.40	$1 30@1 60	$1.67@1.77	
Philadelphia*	2 30@2.70	2 55@2 85	2.92@3.02	
New York*	2 60@3 00	2.85@3 20	3.22@3 32	
Baltimore*			2 85@2 95	
Hampton Roads*				$2 85 *firm*
Providence†				3.73@3.78
Boston†				3.83@3 95

*F.o.b. †On cars.

PITTSBURGH, PENN.

Bituminous—Coal mining continues active but the market is relatively quiet as buyers are well taken care of by existing contracts. Free coal usually brings a premium, though not always. The labor supply is not altogether adequate, but does not curtail production materially. The car supply, while not ample, is sufficient to take the coal which can be produced, though in spots shortages develop. Shipments in the lake trade are practically at record rate for this stage in the season and the prediction continues to be made that the season will show a new record by a comfortable margin. Slack continues in heavy supply in consequence of the lake movement and frequently sells down to 60c., though some large operators refuse to shade the 90c. price. Noting that prompt lots outside of slack frequently bring premiums of 5@10c. a ton, we quote regular prices as follows: Slack, 90c.; nut and slack, $1.05; nut, $1.25; mine-run, $1.30; ¾-in., $1.40; 1¼-in. steam, $1.50; 1¼-in. domestic, $1.55, per ton at mine, Pittsburgh district.

Connellsville Coke—Prices continue to be well maintained despite light inquiry. There is a small turnover of prompt furnace, generally at $2.15 or $2.20, while the nominal asking price is $2.25. It is to be noted that sales have been made at the lower figure by operators who are committed to the $2.25 figure. Furnaces have not yet arrived at the point of being willing to pay prices asked on second half contracts, but their apathy is in large part due to the stagnant pig-iron market. It is becoming understood that the operators who have been naming $2.50 as their price for second half would be willing to close at a concession of 10 or 15c., depending on the desirability of the contract. We quote: Prompt furnace, $2.15@2.25; contract furnace, $2.35@2.50; prompt foundry, $2.85@3.25; contract foundry, $3@3.25, per ton at ovens.

NEW YORK

Bituminous—The soft-coal market has shown a tendency to ease off slightly in this section during the past week. The indications are, however, that the condition is only temporary and the unusual strength noticed in the report last week still exists, although not so clearly evident at this writing.

Mines are working about the same as last month, and the production is heavy. The growing scarcity of labor is developing to such proportions that operators are becoming seriously alarmed over the outlook. Concessions of many kinds are being offered in order to attract the men to the mining regions, but in spite of this fact operations are being seriously crippled, especially in the more undesirable districts. With production thus restricted the car supply has been sufficient, but predictions are being freely made that the situation in this respect will be quite serious the coming fall. It is a well known fact, however, that the roads are providing a great deal of additional equipment, so that it is probable they will be able to handle the situation better than is anticipated.

We continue last week's quotations on the following basis: West Virginia steam, $2.55@2.60; fair grades Pennsylvania, $2.65@2.70; good grades of Pennsylvanias, $2.75@2.80; best Miller, Pennsylvania, $3.05@3.15; Georges Creek, $3.25@3.30.

Anthracite—While there is not a great deal of snap to the local market, the trade continues moderately active and about normal for this season of the year. The demand for the prepared sizes, particularly egg and stove, is excellent; most of this is, of course, for stocking purposes, although there has probably been more than the usual consumption lately due to the rather cold weather for this period of the year. Buckwheat and barley are quite heavy and some of these grades are now going into storage.

While the hard-coal market as a whole will probably touch a still lower level in midsummer, there is a strong healthy undertone and indications point to a heavy business the coming fall. The anthracite companies are being supplied with plenty of equipment, the mines as a rule are working good, and the production is about normal.

We quote the New York hard-coal market on the following basis:

		Individual	
	Circular	Lehigh	Scranton
Broken	$4.70	$4.45@4.65	$4.50@4.70
Egg	4.95	4.90	4.95
Stove	4.95	4.90	4.95
Chestnut	5.15	5.15	5.20
Pea	3.50	3.30@3.45	3.35@3.50
Buckwheat	2.75	2.15@2.45	2.50@2.75
Rice	2.25	1.70@1.95	2.25
Barley	1.75	1.35@1.70	1.60@1.75

PHILADELPHIA, PENN.

Just at the present time, the coal trade in this vicinity, particularly in the local market, is not as favorable as both the retailer and wholesaler would like to see it. While it is understood that the companies are taking care of their output of the prepared sizes, there is a tendency to drag in almost all grades. This is particularly true of the local market, where even the demand for stove coal, which has been the leader for months, has fallen off, but this has given the operators an opportunity to furnish this size on calls in other directions. The reports of business at tidewater, however, still continue favorable, large quantities of coal going by barge to the down East points, where the demand is said to be strong.

There is, however, an unmistakable lack of snap to the market, and until after the middle of the month, not much improvement is looked for; but the approach of the first of next month, which marks a further advance of 10c. per ton, is always characterised by a spurt. Operations at all the mines are still good, and large quantities of coal are being sent to market; while it is not expected that it will be necessary to curtail production during the month of June, some of the pessimistically inclined hint at a possible intermittent suspension of mining during the next two months.

The bituminous trade is gradually rounding into shape, but the improvement is so slight that it takes an optomistic operator to indicate what it amounts to. Prices appear the same as last reported, with some few variations.

BALTIMORE, MD.

The feature of the local market during the past week was the heavy tonnage handled over the railroad piers. The Curtis Bay piers of the B. & O. R.R. were particularly active, one company alone having contracts for 66,000 tons of export and coastwise coal to be shipped at this point. The business showed a marked increase over previous weeks and promises to continue so for the next two weeks, a number of vessels being due here within that time, which will be loaded at both the Curtis Bay piers and the Port Covington piers of the Western Maryland R. R.

General market conditions continue good, with prices firm, especially on the low grades, which are selling freely at from 80@90c. Quemahoning and Georges Creek are, of course, in active demand. Some companies are reported to have insufficient production to meet their contract obligations and are being forced into the prompt market; the trouble is due to the inadequate supply of miners in the mining district.

The spot line business is exceptionally strong, with consumers insisting on prompt delivery. This would seem to indicate that buyers are stocking up at present prices rather than taking chances on the possibility of a restricted output in the future. The depression reported in other lines of industrial activity has not reached the coal trade in this vicinity as yet and operators continue to take an optimistic view of the outlook.

Export business for May was slightly below that of April, but still of sufficient proportion to show a substantial increase in this branch. The total exports for May were 88,138 tons, or a reduction of 2492 tons over that for April. Of this amount, 25,417 tons were shipped to Egypt; Brazil, Mexico and Cuba, being the other main points.

BUFFALO, N. Y.

The interest of the coal dealers and consumers is just now centered more on the threatened strike of the teamsters than on the price of coal. It is noted that there are a great many buildings in the city, with elevators and sometimes other machinery to run, that seldom have more than two days' supply ahead so the problem may be a serious one.

Otherwise the situation is without much change. The complaint of car shortage in the bituminous trade is increasing, especially where cars are to be hurried to a consignee who is about out of coal; it is usually then discovered that passing and junction points are badly congested. One shipper states that it takes from a week to ten days to make sure of a car consigned from the Alleghany Valley mines, a matter of 150 miles or so, to Black Rock, for which the East Buffalo yard probably is more or less to blame.

As a rule the members of the bituminous trade are not forgetting the long years of selling coal at cost and the consumer was not then interested in helping them out. It is felt now that coal is bringing a paying price, not on account of any corner or stress that the consumer is obliged to stand for, but because business is good and the consumer can well afford to pay a good price for his coal.

There is a growing scarcity of cars as well as miners, which makes it certain that there is no coal waiting on track to be picked up. If the jobber has no mine connection he is finding it difficult to get much coal of any sort. The bituminous trade is feeling much more confident of the future than ever before.

Quotations, therefore, are strong at $2.80 for Pittsburgh lump, $2.65 for three-quarter, $2.55 for mine-run and $2.15 for slack, with Alleghany Valley about 25c. lower, chiefly on account of freight rate, the reduction being partly divided with the consumer. Coke is unchanged and not especially strong at $4.75 for best Connellsville foundry.

There is an increasing complaint from the Allegheny Valley mines about the lack of both miners and cars. With such a large amount of coal sold on contract the situation is anything but pleasant, though it may be fully as satisfactory as when it was sold at cost. Nobody claims now that there is no profit in the business.

The anthracite situation is without feature and no stir is expected until fall except a little at the end of each month, when consumers show an interest over the saving of 10c. a ton. Shipments of anthracite from this port for the week amounted to 135,000 tons, a fairly good average. Most of the coal went to Chicago, as return cargoes from Lake Superior are not plenty.

COLUMBUS, OHIO

The chief feature of the local market is the continued strength although some weakness has developed in the small sizes. On the whole the trade is firm and prices are well maintained. No important weakness has developed and every branch of the business is on a sound basis. Prospects for the future are generally considered favorable.

The lake business is still one of the strong points of the trade. Thousands of tons are moving from Ohio mines to the Northwest, via the lakes, and since the demand from that section is strong it is freely predicted that the present season will be one of the largest in the history of the lakes. Chartering of boats is still going on and the movement of vessels is good since the early congestion at the upper lake ports is over.

Production has been somewhat restricted by an increasing car shortage. In the eastern Ohio district where cars are the scarcest the output is estimated at 70 per cent. of normal and the Pomeroy Bend district shows up with about 60 per cent. of the average. In the Hocking Valley there has been less trouble on this account and the output is close to normal. In the domestic fields there is a slight increase in the output.

Domestic trade shows some activity, although it is yet too early for much movement. Retailers are gradually accumulating supplies so as to be prepared for the stocking season when it comes. Some of the larger domestic users are already laying in their winter supply. On the whole there is bright prospects for an active domestic trade in all parts of Ohio and adjoining states.

The steam business is rather active along all lines although some factories are not buying as well as formerly. Iron and steel concerns are buying as usual. Railroads are also using quite a good deal of fuel. The freight movement is gradually increasing since the flood damage has been repaired. Some few steam contracts have not been renewed

although most of them have been closed up for the year. Most of the railroad contracts have also been signed.

Quotations in the Ohio fields are as follows:

	Hocking	Pittsburgh	Pomeroy	Kanawha
Domestic lump	$1.50		$1.50	$1 50
2 inch	1.35	$1 25	1.35	1 30
Nut	1.20		1.25	
Mine-run	1.15	1 10	1.15	1.10
Nut, pea and slack	0 70		0.70	0.65
Coarse slack	0.60	0 65	0.60	0.55

HAMPTON ROADS, VA.

Dumpings at Hampton Roads piers have not been as heavy as expected. Some large foreign shipments have been made during the week but coastwise business has not been brisk. There is still a shortage of coal at all piers and some suppliers are finding it difficult to take care of contract business. Producers having free coal have been able to dispose of it at $2.90 but even at this price there have been only one or two small sales as no one has had a large surplus at tidewater. There has been some inquiry for spot high volatile coal and no sales as suppliers are practically cleaned out of this grade.

While it was expected that the Norfolk & Western Ry. at Lamberts Point would lead in the tidewater dumpings for May yet it was hardly anticipated that they would reach over 350,000 tons. The actual dumpings, however amounted to 490,917 tons. The Chesapeake & Ohio Ry. at Newport News dumped during the month 289,990 tons and the Virginian Ry. over the one pier at Sewalls Point dumped 281,537 tons. The total dumpings for Hampton Roads for May amounted to 1,062,444 tons. The dumpings at Sewalls Point broke all previous records of that pier.

BIRMINGHAM, ALA.

The most satisfactory market locally is that on foundry and furnace coke; the usual summer weakness has not yet made its appearance, although the pig-iron market has been steadily declining for several months. The demand seems to easily absorb all coke offered by ovens which do a merchant coke business. The companies operating the furnaces make most of the coke and use same at their own smelters.

Anything that we might say regarding the coal market as a whole would be practically a repetition of last several reports. There is no price cutting worthy of serious mention, but the situation might be changed very quickly for the worse if all mines were supplied with plenty of cars and a little more labor. Unless the production is increased it is not believed that prices will reach as low a level as during former summers.

LOUISVILLE, KY.

The situation locally has not materially changed from last week, with the exception that the steam coals are slightly weaker and notably over-supplied. This is due to a heavy demand for domestic grades resulting in an excessive production of the smaller sizes; there has also been an easing off in the demand for these, due to a curtailment of industrial activity. In addition to this, railroads are taking rather more than the usual amount of the larger sizes which has further over-stocked the smaller grades. Several operators have found themselves with more of these sizes than they could dispose of, but it is believed that the demand will shortly catch up.

Domestic sizes of the better grades are in heavy demand in eastern Kentucky at $1.65@1.70, with the off qualities at about $1.50. No. 2 mine-run is selling at 90c.@$1, and 3-in. steam at 85c. The better grades of nut and slack are quoted at 70@80c. with the second quality in rather light demand at 40@60c., this latter price also prevailing on western Kentucky nut and slack. Pea and slack are weak at 30c. f.o.b. mines.

INDIANAPOLIS

Retailers of this city report a good market, the June movement of coal promising to equal or excel that of May. This buying is practically all of Eastern coals, those who burn anthracite being particularly anxious to get their winter's supply before the usual advances in price. Last winter consumers had trouble in getting anthracite, even at the highest prices on record in this market. This experience is hurrying up their orders and few will take the risk of waiting until fall to lay in their supply.

The mines of the state show little change in the extent of their operations, three to four days a week being the rule. Some operators report an improved movement to the larger industries of the state that carry a large quantity of coal in storage.

Indiana mines continue to put in half time or slightly better. Reports reach here of a slackening in industrial activity in the East, which is probably reflected to the coal business, but while the tariff may be causing some uncertainty and hesitation in the West, the wheels are kept going although factory owners have a keen eye out for any new developments. While the larger steam consumers are renewing contracts, the smaller ones seem willing to take the risks in the open market for their winter needs.

The movement of domestic from retailers' yards is fairly well divided between anthracite and the harder bituminous coals. Of the latter Pocahontas has the heaviest call, followed probably by Kanawha, Luhrig, Raymond City and Ohio Jackson in the order named.

The local wholesale market is about as follows:

No. 4 mine-run	$1 10@1 20	Domestic 4- and 5-in	$1.50@1.60
Nos. 5 and 6	1.05@1 10	Screenings No. 4	0.90@1 00
Steam lump, 1¼-in.	1 15@1.35	Screenings 5 and 6	0 80@0 90
Nut and egg	1.20@1.55	Brazil block	2.00@2 10
Domestic 3-in	1 40@1 65		

DETROIT, MICH.

Bituminous—Contrary to expectations, the soft-coal trade continues to improve, and prices are becoming stiffer generally all along the line. It is now clear that if lower prices are to appear, it will not be very soon. As a matter of fact consumers who have neglected to cover their requirements will now probably have to pay substantially higher prices. Contract business is becoming decidedly better, some operators claiming that they have all the tonnage, available for this purpose, now covered.

It is doubtful if local contract prices have ever before been as stiff as they are today, and it would only take a light buying movement to precipitate a runaway market. The only easy branch is the spot market, which is slightly softer than last week. There has been considerable slack offered in the open market, but the smaller grades as a whole have not suffered materially, and, while they will probably weaken toward midsummer, there is no reason for discouragement.

The feature of the market at the present time is the high price level on the better grades of spot coal; these have stiffened to such a degree that prompt shipment can only be had at from 5@10c. below contract figures for the year. There is a feeling that what little coal yet remains in the spot market will be commanding higher figures than contract tonnages. The market in general is regarded as exceptionally strong for this period of the year.

Prices have shown little change during the week, and the market is now quotable on the following basis:

	W. Va. Splint	Gas	Hocking	Cambridge	No. 8 Ohio	Pocahontas	Jackson Hill
Domestic lump	$1 50		$1 50			$1 99	$1 90
Egg	1 50		1 50			1 99	1 90
1¼-in. lump	1 25						
¾-in. lump	1.15	$1 15	1.15	$1.15	$1 15	..	
Mine-run	1 05	1 05	1.05	1 05	1.05	1 25	
Slack	0 80	0 85	0 40	0 85	0.80	1 10	

Anthracite—Operators of all kinds are holding firm on prices, but it is generally conceded that the outlook from now on until the fall trade opens up is rather dull, to say the least. Wholesalers are already complaining that there is a falling off in demand, although not of sufficient magnitude to restrict shipments. Supplies are coming forward as rapidly as required and no delay is experienced in satisfying the demand.

Coke—The market on this product is brisk, Connellsville, being quoted at $3, Semet Solvay, $3.10 with gas house at $2.85, all f.o.b. ovens.

MINNEAPOLIS—ST. PAUL

While it is a fact that most Illinois coals have been sold at a low price during the past month, there is a general expectation of a rise during the next two weeks and a steadiness which will prevail during the summer and fall. Eastern coals were never held on as firm a basis as they have been this year, and an actual scarcity of these exists which, with the strained labor conditions, fully warrants a maintenance of price. The amount of coal coming to the head of the Lakes was heavy during May, but the height of the ore carrying season is on and if coal is not available at Eastern loading ports, vessels will come up empty instead of waiting for cargoes

CHICAGO

Owing to a shortage of Eastern coal, increases are evident in contract prices. During the week lump, egg and nut has sold for $1.25 on the spot market. Recently buyers who have been depending for their supply upon the western Pennsylvania, Kanawha and Hocking Valley fields, found these to be practically exhausted and have turned to the Western districts for their supply, with particular attention given to the Franklin County field.

Both the contract and spot market has been strengthened as a result of this western inquiry. The coke market has been just about holding its own. Signs of activity are beginning to show in the anthracite trade, indicating that June trade will make up somewhat for the latter part of April and the first week of May.

Prevailing prices are:

	Springfield	Franklin Co.	Clinton	W. Va.
Domestic lump	$1 97@2.07	$2.30@2.40	$2.27	
Egg		2.30@2.40		$3.85
Steam lump	$1 82@1 87		2 07	3 85
Mine-run	1 77@1 82	2 20@2.30	1.97	3.30
Screenings	1 62@1 67	1.95	1.57@1 62	

Coke—Connellsville and Wise County, $5.25@5.50; byproduct egg and stove; $4.75; byproduct nut, $4.55@4.75; gas house, $4.65@4.75.

ST. LOUIS, MO.

There is an indication that prices will get better; as a matter of fact, things are picking up a little bit now in the Carterville field. However, the reverse can be said of the Standard field, for 6-in. lump has finally got down to a basis of 80c. with mine-run at about 72½c. and 2-in. lump at 77½c. Anthracite is moving remarkably well right now, and coke is coming forward rather plentifully, while smokeless is in a somewhat doubtful position.

There is very indication that business is going to be remarkably good in July, and that will also affect market conditions the latter part of the present month. Some large contracts are open at the present time, and the prices asked in many instances indicate that the operators are at last realizing that they should take advantage of the coming season to make up what they have lost in the past.

The circular has shown little change in the past few weeks, and at the present time is:

	Carterville and Franklin Co.	Big Muddy	Mt. Olive	Standard
2-in. lump				$0 80@0 85
3-in. lump			$1 20	
6-in. lump	$1 15 @ 1 25		1 25	0 85@0 90
Lump and egg		$2 00	1 20	
No. 1 nut	1 10 @ 1 20			
Screenings	0 80 @ 0 85			0 75@0 80
Mine-run	1 00 @ 1 10			0 75@0.80
No. 1 washed nut	1 40			
No. 2 washed nut	1 25			
No. 3 washed nut	1 25			
No. 4 washed nut	1 20			
No. 5 washed nut	1 05			

PORTLAND, ORE.

It is reported that the railroads in the Pacific Northwest are figuring on abandoning oil fuel and returning to coal, but no confirmation to that effect has been obtainable here as yet. The first report was to the effect that the Great Northern which is using oil fuel between Everett, Wash., and Spokane, is planning to make the change and it is also reported that many large buildings in the Pacific Northwest will install coal burners shortly. A prominent railroad operator, here, however, states that he does not take much stock in the report that the Great Northern is planning to fall back on coal after having used oil with success, instead it is possible that oil will be used farther east than Spokane, over the Rocky Mountain division. Coal men on the other hand assert that the demand for crude oil for refining is so heavy that the big oil companies find it to their advantage to refine the oil rather than dispose of it in its crude state.

PRODUCTION AND TRANSPORTATION STATISTICS

ANTHRACITE SHIPMENTS

The following is comparative statement of the anthracite shipments for May and the first five months, of the years 1912-13, in long tons:

	May			%	5 Months		%
	1913	1912	1913		1912	1913	
Phila. & Reading	1,123,869	201,575	5,703,277	19 75	4,094,665	20 57	
Lehigh Valley	1,191,632	202,747	5,408,310	18 72	3,536,978	17 77	
Cent. R.R. N. J.	745,247	128,099	3,724,219	12 89	2,521,302	12 67	
Del. Lack. & West	882,661	277,140	3,961,646	13 72	2,881,219	14 47	
Del. & Hudson	591,499	184,598	2,936,187	10 17	1,902,881	9 56	
Pennsylvania	574,468	145,702	2,656,765	9 20	1,799,217	9 04	
Erie	671,972	235,986	3,417,900	11 83	2,458,634	12 35	
Ont. & Western	214,304	53,510	1,073,503	3.72	710,437	3.57	
Total	5,995,742	1,429,357	28,881,807	.....	19,905,333	.....	

Stocks at Tidewater at the close of May were 502,626 tons as compared with 546,243 the month before.

THE CAR SITUATION

American Ry. Association reports surpluses and shortages of coal equipment for two weeks ended May 31, as follows:

	Surplus	Shortage	Net*
New England Lines	0	95	95
N. Y.; New Jersey, Del.; Maryland; Eastern Penn.	1,444	1,018	**426**
Ohio; Indiana; Michigan; Western Pennsylvania	1,538	109	**1,429**
West Virginia, Virginia, North & South Carolina	969	1,464	**495**
Kentucky, Tenn.; Miss.; Alabama, Georgia, Florida	318	249	**69**
Iowa, Illinois, Wis., Minn.; North & South Dakota	2,100	35	**2,065**
Montana, Wyoming, Nebraska	400	0	**400**
Kansas, Colorado, Missouri, Arkansas, Oklahoma	2,265	65	**2,200**
Texas, Louisiana, New Mexico	401	0	**401**
Oregon, Idaho, California, Arizona	1,991	16	**1,975**
Canadian Lines	175	58	**117**
Totals	11,601	3,109	**8,492**
Greatest surplus in 1912 (Apr. 25)	94,692	2,144	**92,548**
Greatest shortage in 1912 (Oct. 10)	6,491	14,897	8,406

*Bold face type indicate a surplus.

SOUTHWESTERN TONNAGE

The following is a comparative statement of the southwestern tonnage for March and the first three months, 1912 and 1913:

State	March		Three Months	
	1912	1913	1912	1913
Missouri	365,314	276,779	952,526	843,190
Kansas	585,217	466,709	1,625,266	1,404,727
Arkansas	187,014	137,901	618,890	451,437
Oklahoma	311,492	245,449	928,205	909,312

FOREIGN MARKETS

GREAT BRITAIN

May 30—Best Admiralty coals are still scarce, but other qualities are more plentiful.

Quotations are approximately as follows:

Best Welsh steam	$5.28@5.40	Best Monmouthshires	$4.68@4.80
Best seconds	5.04@5.16	Seconds	4.56@4.62
Seconds	4 80@4.92	Best Cardiff smalls	3.24@3.36
Best dry coals	5.04@5.16	Seconds	3.12@3.24

The prices for Cardiff coals are f.o.b. Cardiff, Penarth or Barry while those for Monmouthshire descriptions are f.o.b. Newport; both exclusive of wharfage, and for cash in 30 days—less 2½%.

SPANISH IMPORTS

Spanish imports of coal for the first three months of the current year were 640,958 tons as compared 614,593 for the same period last year. Coke imports for the same periods were 81,397 tons and 108,669 tons respectively.

COAL SECURITIES

The following table gives the range of various active coal securities and dividends paid during the week ending June 7:

Stocks	Week's Range High	Low	Last	Year's Range High	Low

No Important Dividends were announced during the week

PRICES OF MINING SUPPLIES

THE MARKETS IN GENERAL

Business is a great deal better than most of the reports emanating from New York would lead the readers to think. It is true that there is a tightness of money in New York, considerable unrest and a diminution of business in a financial way. Moreover, it is equally certain that some of the large corporations are unable to get the funds they desire at attractive rates of interest. If these companies are not able to secure a reasonable return as a result of the improvements they contemplate making, they will certainly be unwilling to pay any interest. There is no law compelling them to build fine stations or double-track their roads. They have been able to live without this and they will probably continue so for some time, and while the plea for higher freight rates is illegitimate, or at least is so considered, they will probably secure it. The great trouble is that a financial upheaval in Europe has had a serious effect in New York, through draining from New York a large supply of gold which might be used as a substantial basis for business in this country. It is probable, however, that by fall there will be some let up in the demand from Europe and by that time money will be available for the much needed crop movement in this country.

Price changes have tended toward lower levels in almost every instance, and the iron and steel markets are $1 to $2 per ton lower than a month ago, but it is significant to note that the leading interest is operating its steel production to more than 90% of capacity and in the month of May more pig iron was made in the United States than ever before in history.

The cement trade is active and prices are firm.

The tariff hill has not yet been settled and its delay in the Senate is undoubtedly having an influence on business.

Precipitated liquidation of securities in New York and foreign financial centers about the middle of June had an important effect on new construction. Until this selling runs its course and the markets of the world are able to save new capital, new construction work will be less active with a consequent reduction in the demand for supplies. This should make for lower quotations in the material markets. Contrary to the belief expressed in certain quarters the financial troubles were incident to, and not caused by, the "Rate Decision" handed down, June 9, by the U. S. Supreme Court.

LABOR

Unrest has been more widespread this month than before in several years. The number of strikes in all parts of the country is unusually large, but most of them have occurred among unskilled workers and, for the most part, those laborers securing less than $12 a week Fair-minded men believe that such laborers should have a just compensation and in many instances these strikes have been settled, the laborers securing a substantial increase. The strike of greatest importance among the skilled trades was the machinists in Baltimore, asking for higher wages and shorter hours, while the same is true in Buffalo. This, of course, has had its inception from the tremendous business automobile manufacturers have been doing, and they are still scouring the country for capable machinists.

Coal miners are in exceptionally good demand and the supply seems to be short. Immigration coming to these shores is large, the total steerage passengers arriving during the first ten months of the year numbering 750,000, while the arrivals at the port of New York alone in May there were approximately 100,000 immigrants.

IRON AND STEEL PRODUCTS

New business in April did not develop large and in fact it was a general disappointment to all classes of manufacturers. There had been a boom for a year which was expected to continue indefinitely. New orders were few and very far between and salesmen were unwilling to make quotations while consumers seemingly had no interest in the market. On the other side, it is worthy of note that the U. S. Steel Corporation were operating their finished-steel mills to 92% of capacity, while the ingot production was 99% of production, and other steel companies are working in like ratio. It is true that the unfilled orders for steel products have been rapidly declining, but on the other hand there is little suspicion that the steel mills of the country could not be kept actively engaged for six months if no other orders should come in and there should be no postponements. It is also significant to note that a prominent street railway company in applying for certain franchises urged the commission to expedite its work as it would be impossible to secure equipment in less than six months after the orders were placed.

The automobile manufacturers of the country are working as never before, one company making a popular low-priced car, being 60,000 cars behind in its orders. This means that for nearly ten weeks this company will not be able to make prompt shipment even though no other orders come in.

Railways are not buying equipment with anything like the liberality of a year ago, but the New York Central recently ordered 175 locomotives.

Unfilled orders on the books of the United States Steel Corporation decreased 650,000 tons during the month of May.

Steel Rails—A marked decline in the demand for light rails was a distinct disappointment to the steel trade and a most unexpected one. It has been conceded for some time that the railways would probably curtail their orders for standard section, but it was not believed that light rails would be so inactive. The only order of importance during the month was for 10,000 tons for export.

Quotations continue unchanged at 1.25c. per lb. per standard section weighing from 50 to 100 lb. per yard; 1.21c. for 40- to 50-lb. rail; 1.30c. for 16- to 20-lb. rail. These quotations are for carload lots, f.o.b. Pittsburgh.

In Chicago, 16- to 20-lb. rails are 1.30c.; 12-lb., 1.35c.; 8-lb., 1.40c. Relaying rails, Chicago, are $24 per gross tons and can be obtained at other points at approximately the same figure although not in any considerable quantities.

Track Supplies—Business is very inactive, although there was an enormous order for tie plates early in the month by the Lake Shore & Michigan Southern. Spikes are 2.10c. base for large lots; track bolts with square nuts, 2.40@2.50c. base, and tie plates, $34@36 per net ton. These quotations are for Chicago delivery. In Pittsburgh angle bars are from 1.50@1.60c. and spikes 1.95@2.05c. All these quotations except the tie plates are per lb. and fairly good sized lots.

Pipe—The demand for pipe has not fallen off to the same degree as has been noted in other commodities and while some revision of discounts has been made the general pipe business continues active. The fuel companies are buying in large quantities and the pipe mills have all the business they can take care of for the present. They are, however, able to make fairly prompt shipment.

Discounts are as follows:

	Black	Galvanized
¾- to 2-in. butt welded	79½%	70%
2½- to 6-in. lap welded	78½%	70%

Based on these discounts, the net price of pipe per foot are as follows in carload lots f.o.b. Pittsburgh:

Size, inches	Black	Galvanized
¾	2.35	3.40
1	3.50	3.46
1¼	4.75	6.60
1½	5.55	8.00
2½	12.60	17.50
3	16.50	23.10

Sheets—Much weakness has been manifested in the market and considerable price cutting is noticed, especially in the West. Some of the mills, which were securing premiums for prompt delivery three months ago, are now most actively engaged in cutting quotations. At the same time, the Steel Corporation is obliged to curtail operations to about 25% of capacity at the Vandergrift mills because of the lack of semi-finished steel. Shipments are fairly prompt and can easily be made eight weeks after specifications are received.

The following quotations are for lots of a few bundles f.o.b. Pittsburgh and Chicago. The price for large lots is unchanged at 2.30c. f.o.b. Pittsburgh for No. 28 black.

	Cents per Pound			
	Pittsburgh		Chicago	
	Black	Galv.	Black	Galv.
Nos. 22 and 24	2.75	3.55	2.70	3.50
Nos. 25 and 26	2.80	3.70	2.75	3.65
No. 27	2.85	3.95	2.80	3.90
No. 28	2.90	4.00	2.85	3.95

Structural Materials—Business is less active in the East and similar conditions prevail in the West, although there it is expected that considerable railroad business will develop within the next few months. The diminution in building, which is prevalent in the East, seems likely to continue for some time, and from the present outlook, when railways are obliged to pay such high rates of interest on capital, it is doubtful if they can secure the funds with which to make their improvements. Under such circumstances an early return to a large volume of business in fabricated materials is unlikely.

Quotations are without change, except the premium for prompt shipment has disappeared. Plates, beams and angles are held at 1.50c. base from Pittsburgh, and in Chicago 1.68@ 1.73c. All of these prices are per 100 lb. in carload lots.

WIRE PRODUCTS

New orders are coming in slowly and there is far less demand for wire products in the farming community than was expected early in the year. The mills are not rushed with orders and are able to make shipments fairly prompt. Quotations are as follows for large lots: Painted barbed wire, $1.86; galvanized, $2.20; annealed fence wire, $1.60; galvanized, $2.05. In Chicago annealed fence wire is $1.78 and galvanized $2.18. Barbed-wire fencing in the Chicago market is $2 and galvanized $2.40. All of these quotations are per 100 lb. For smaller lots bought from jobbers' store in these centers advances will be about 25c. per 100 lb.

Wire Rope—The demand is steady and prices are unchanged. Two-inch rope in Pittsburgh is held at 50c. per lin.ft.; 1¼-in., 23c.; ¾-in., 10c. These quotations are for the highest grade, but cheaper grades can be had at considerable concessions from these figures.

Copper Wire—Business is not especially active, but several of the important trunk lines of the country are making preparations to electrify portions of their system. This will call for an immense amount of copper and stimulate trade more than at any time since 1906. The base price of copper wire is unchanged at 17c. per lb.

Telegraph Wire—Business is fairly active with quotations unchanged as follows:

Prices are as follows in cents per pound for wire measured by the Birmingham wire gage: "Extra Best Best," Nos. 6 to 9, 4¾c.; Nos. 10 and 11, 4½c.; No. 21, 4⅝c.; No. 14, 5⅛c.; "Best" Nos. 6 to 9, 3½c.; Nos. 10 and 11, 3⅜c.; No. 12, 3½c.; No. 14, 4c. Actual freight is allowed from Trenton, N. J., where it does not exceed 25c. per 100 lb.

HARDWARE

Bar Iron and Steel—Prices are steady. Quotations from jobbers' stores in New York and Chicago are as follows:

Refined iron:	Per lb.
1 to 1⅞ in., round and square	2.10c.
1½ to 4 in. x ¾ to 1 in.	2.10c.
1½ to 4 in. x ¼ in. to ⅝ in.	2.30c.
Norway bars	3.60c.
Soft steel:	
¾ to 3 in., round and square	2.05c.
1 to 6 in. x ¾ to 1 in.	2.05c.
1 to 6 in. x ⅛ and ¼ in.	2.20c.
Rods—⅝ and ½ in.	2.15c.
Bands—1½ to 6⅜ in. to No. 8	2.35c.
Beams and channels—3 to 15 in.	2.15c.

Chain—There is less demand than a month ago. Ruling quotations per 100 lb., f.o.b. Pittsburgh, are as follows:

¼ in.	$7.50
⅜ in.	4.95
½ in.	3.95
⅝ in.	3.40
¾ in.	3.20
⅞ and 1 in.	3.00
1⅛ and 1¼ in.	2.90
1⅜ and 1½ in.	2.80
1⅝ and 1¾ in.	2.70
1 to 1¼ in.	2.60
Extras for BB	
¼ in.	1.50
⅜ in.	1.50
½ and larger	1.25
Extras for triple B (BBB)	
¼ and ⅜ in.	2c.
½ and larger	1.75c.

Nails—In the East the demand is not as active as a month ago and some falling off in the West, although not in the same proportion as along the Atlantic Coast. Prices are steady, large lots being held at 1.80c. Pittsburgh and 2.10c. Chicago. For small lots from jobbers' store the price is 2c. in Pittsburgh and 2.30 in Chicago. Approximately the same figures may be obtained in important jobbing centers throughout the Middle West as in Chicago.

Rivets—The demand continues less active than a month ago and users seem to have a sufficient supply on hand to meet their needs. Quotations are $2.20 for structural rivets and $2.30 for boiler rivets. These prices are per keg of 100 lb.

METALS

Copper—Consumers abroad continue to buy copper in large quantities and exports for the first five months of this year established a new high record for the period. American consumers are likewise buying freely and the recently published statistics of the Copper Producers' Association show that the stocks of unsold copper were again reduced during the month of May. Prices have been shaded somewhat during the last few weeks, chiefly because of the financial situation, and electrolytic can now be had at 15½@16c., while Lake copper can be had at 15¾@16¼c. These prices are for comparatively large lots.

Tin—The market continues steady, although slightly lower. Consumption abroad is large, but in the United States is falling off somewhat. The price is 47c. per lb.

Lead—The market is not as strong as a month ago, and quotations have been revised downward. In New York lead sells at 5.35c. and in St. Louis at 5.20c.

Solder—Strictly half and half solder can be had in New York at 20@27½c.

MISCELLANEOUS

Castings, Gray-Iron—The foundries making a specialty of castings having low-carbon content and being used for general building work, are anxiously looking for business, and in consequence some very low prices have been named. Rough castings of large sizes can be had at 1.65@2.20c. per lb. Small castings can be had at 2.50@3c. per lb

Portland Cement—A rather extended inquiry covering all parts of the country has been made from reports of managers of cement mills and while it is found that business is fairly satisfactory, in every part of the country except northern Indiana, Michigan and Kansas, none of the mills are especially well supplied with orders and they do not believe a serious shortage will result this year. It is thought that in some quarters a slight advance will possibly be made later in the year, but the shortage of freight cars in which to ship the cement is more likely to be an important factor than any other one thing. There have been no price changes and the following quotations are per bbl. in bulk at the mill, to which should be added 40@50c. per bbl. for the packing, giving the price f.o.b. mill; to this should be added the freight from the mill to destination. In Pittsburgh the price is 90c.@$1; Chicago, $1.05@1.10; Missouri district, $1@1.05; Chattanooga, Tenn., $1@1.05; Texas and Oklahoma, $1.10@1.20. A few mills are quoting around $1. In New York and Pittsburgh $1.58 is quoted with an allowance of 40c. per bag returned.

Bars, Concrete Reinforcing—The demand is not as large as it was early in the spring, but still it is fairly satisfactory and there has been little price cutting. The following quotations are for small lots from warehouse stock:

PITTSBURGH PRICES IN CENTS PER POUND

	Warehouse Stock
¾-in.	2.00@2.10
⅝-in.	2.05@2.15
½-in.	2.10@1.20
⅜-in.	2.25@2.35

Shafting—The largest consumer of shaft for automobile purposes entered an order for 4000 tons last month. This temporarily stiffened the market. Business continues active, and the discounts are unchanged at 58% from list for carload lots and 53% from list for less than carload lots. The following net prices per foot are based on the discount of 53%:

Diameter in inches	Cents per foot	Diameter in inches	Cents per foot
¾	4.25	2¼	31.50
1¼	10.80	2½	39.30
1½	14.05	2¾	48.00
1¾	19.20	3	56.50
2	25.00	3½	84.00

Triangular Mesh—Business is not especially active.

From mills in De Kalb, Ill., quotations are 18c. per 100 lb. higher than those quoted below, which are per 100 sq.ft. f.o.b. Pittsburgh. These are for lots of less than 10,000 sq.ft.

No. 4	$1.23	No. 32	$2.62
No. 23	2.05	No. 36	1.05
No. 26	1.42	No. 40	3.25
No. 28	1.97	No. 41	2.48

Brattice Cloth—The scarcity of material continues, and orders are in as large a volume as ever. No hope is held out that the situation, as far as lower prices are concerned, will improve during the summer.

COAL AGE

VOL. 3 NEW YORK, JUNE 21, 1913 No. 25

"To work hard, live hard, die hard and go to hell after all is hard indeed." Here we have expressed in few words the creed of the average miner. When we say this we do not wish to infer that this creed is peculiar to mining folk, it was framed long before civilization had need of the miner; in truth it is the creed of the "under dog" in all walks and occupations and probably has been since "under dogs" became necessary to the scheme of things mundane.

The peculiar thing about this creed, however, is that so few of those who have to deal with these self-styled "under dogs" are aware of its existence.

The state of mind produced by the blind acceptance of such a creed is responsible for many of the mysterious actions observed in those who profess allegiance to it. A little serious consideration of its effect on the average human being might eliminate many of the endless misunderstandings between employee and employer.

Reducing this down to words of "two syllables" here's an example:

A miner goes to a check window to draw a check; the clerk recognizes him as one who never has time ahead and promptly turns him down without taking the trouble to investigate (that's what the clerk would describe as "doing a thing on general principles"). The miner realizes that he has not been given a square deal; never having been taught that the best way to get a thing out of one's system is to run it down immediately and get rid of it, he accepts the clerk's "slap" as a thing to be expected and nurses a grudge. It has never occurred to him that possibly his employer desired that all men be given fair treatment; his creed assures him that his lot must be hard and hard he finds it.

That clerk won't always have the "whip hand." As a matter of fact when conditions become strained this miner will be one of the most enthusiastic agitators for a "strike with no quarter" and if opportunity is presented he'll make an end of that Mr. Clerk and no one will be able to explain the motive.

Of course, a conscientious boss will assure himself that he is giving his men a square deal as he can easily do. Then if the men themselves weigh and consider they will always agree with him, even though some of the under bosses, in the exercise of a little brief authority, do conduct themselves provokingly.

But until a great change is manifested in that part of the human make-up popularly known as "human nature," you must not expect men to weigh and consider. It will not do to let grudges develop and fester; you must actively exhibit some concern in the welfare of the discontented; otherwise the one vial of grievance will poison all your copious springs of good will.

Not less important than generous dealing is that spirit of friendship which destroys suspicion and supplies the key to the motives which actuate us.

When the sure-enough strike with all its enmities and misconstruction is upon us, we shall never regret that we have tried to make our manners as benign as our acts.

IDEAS AND SUGGESTIONS

Technical Language in Educational Writings

By M. E. Wadsworth*

Apparently one of the most important factors in mining education is to bridge the chasm between the uneducated and the educated mining man; and stimulate and encourage the former to undertake the necessary drudgery to acquire more or less education, at least in his chosen work. The term "practical mining man" is one that seems to be greatly abused and misused, as the educated mine expert is often as practical or even more so than the uneducated miner.

There is a common misapprehension among men uneducated in any special study, that papers upon the subject can be readily written so that they will be easily understood by those who have given it no consideration. While this simplifying process may be and ought to be applied to a greater or less extent in textbook writing, it seems to be difficult if not impossible to do so within the limits of an article prepared for a journal. As the object of a textbook is to start upon the level of the student, for whom it is designed, and to lead him up to a higher plane of knowledge, care should be taken in it to begin at the proper point, and to define and render clear every technical term and every step of the way; so that the science and its principles can be easily understood by the attentive reader. The mental discipline should be provided by the practical application of the principles and not through difficulties placed in the way of understanding those fundamentals by an obscurity of language.

It must be acknowledged, however, that the vast majority of our textbooks fail in not being adapted to the use of the persons for whom they are supposed to have been written. The uneducated mining man has a right to complain in regard to the teaching afforded by the average textbook.

While the technical language of any subject is difficult to comprehend for one unlearned in that study, it seems, as before said, impracticable for any special journal article to be written in untechnical language, unless the writer uses an excessive number of words.

Technical terms are the shorthand of scientific language that allow one, in a few words, to save many pages of untechnical writing. In fact, to the scientifically trained man, these terms are the common everyday language in which he thinks, and they are perfectly simple and clear to him. In truth, in most cases, it seems impossible for him to use different language.

All men in every walk of life employ special (technical) terms suited to the occupation they follow. All have to use that language to a greater or less extent, and when anyone desires to be at all versed in, or to understand, any subject, he must become the master of its technical language. The miner, the farmer, the baker, the brewer, the hunter, the fisherman, the printer, the merchant, the dressmaker, the milliner, and the housewife all have and use their technical phrases, which it is necessary for others to know, if they wish to talk with them understandingly upon their chosen subjects.

Even the domestic animals know to a greater or less extent some of this technical language. If this is doubted let one who has never been in a mine try to drive a mine mule, or one equally ignorant of the special language employed endeavor to guide an ox team, a cab-, coach- or race-horse, or manage a hunting dog. The street urchin, the school child, the cowboy, the burglar, sneak thief, the pickpocket, as well as the banker, lawyer, doctor, geologist and engineer all have their distinctive technical language, and, if we are to converse intelligently with them in their specialties, we must instruct ourselves in it.

Slang is technical language in which a word or a sentence conveys to the initiated that which it would take a tedious description to express—hence, however much we may frown upon it, it will ever be in popular but changing use. Even the miners themselves use different special terms in their work; for example, the coal miner and the metal miner, the German and the English miner, the Cornishman and the Australian, New Zealand and South African mining man.

Who is there who would understand a report of a game of baseball or football, if it were reported in common untechnical language or what journal would print it? Yet it is as just to ask that the language of our athletic sports shall be translated into the venacular, as to demand that mining language shall be. To bring this about, the uneducated miner would have to change the world, as his language is as obscure to others as that of the most abstruse mining article is to him.

That all writings for general or for class teaching should be made as simple as possible is a truism, but it is as necessary for the uneducated mining man to educate himself up to the standard of others as it is for the learned writer to forsake that which has become to him as his mother tongue, and use language that he has long ago forgotten; and which usually has so many different shades of meaning that it cannot convey a clear and positive technical idea. Neither class of mining men should despise the other, but both should strive to approach each other as far as practicable and become mutually helpful.

*Professor emeritus, mining engineering, University of Pittsburgh, Pittsburgh, Penn.

The Evolution of the Mine Foreman

By a Pennsylvania Engineer

The mine foreman, though employed by the mine operator, has a double service to perform, his duty to the operator and his duty to the state; these services are often in apparent or actual conflict. He serves, in effect, as both mine foreman and deputy inspector. It is almost an axiom of government that such dual service should

never be imposed on one man. There should be, therefore, at every operation, sufficiently large to justify it, two men—a mine foreman and a deputy inspector.

It is observable that the tendency of mining legislation is to place on the mine foreman a larger and larger burden of responsibility for the safety of the mine. Not only must he see that the miner is safeguarded against the hazards incident to machinery, but also he must guard him against his own misjudgment and neglect, by constant visits, inspection and counsel.

There has been no law passed compelling a woods-foreman to visit his woodsmen and to see that they use due care in handling their axes and in regulating the direction in which trees are felled so as to avoid personal injury. True, it is the duty of the company to provide safety appliances around the saws and boilers, but the absence of the mill foreman from the mill temporarily or all the time, and his omitted counsel would not subject him to reprimand and to the equivalent of dismissal or legal incapacitation for reëngagement, should any employee be hurt through some misjudgment. In fact, there is no requirement that any mill or woods-foreman should be engaged. The owner himself is the responsible party.

Mining legislation is more completely developed along paternalistic lines than any other. The larger corporations are not inclined to regard this as a disadvantage, rather adding to, than attempting to evade the requirements of the drastic laws. The main objection to such legislation is that smaller corporations are prone to seek every means of evasion rather than to fulfill the obligation of the law. In such cases, on the mine foreman rests the brunt of this fatherly law making.

He is not disposed to carp at the provision for close inspection. The ignorance of some miners, many of them aliens, nearly all of them reared in other occupations, whose mutual dependence on one another against a multiplicity of hidden dangers, the nature of which they inadequately comprehend, necessitates a close inspection of their individual methods and working places. The complaint of the mine foreman is not against inspection in itself, but against being at once both a servant of the company to advance its interests by increasing its output and by diminishing the cost per ton, and also the servant of the state, inspecting without cost to the commonwealth, the mine equipment, working methods and places of the miners and others.

Clearly his duties are peculiar in kind, almost without parallel in law. He is responsible to the law for himself, his employers and his employees. He is custodian of the law and boss in many matters both of himself, his employing operators and his men. Yet to his employer he must look for his pay, his advancement, his comforts, his reference on leaving—an anomalous position surely. He can only bring pressure to bear on his employer by resigning or by reporting the case to the inspector—an officer who cannot do anything to hold him permanently in his position should the employer be displeased at his advocacy of a lawful conduct of the duties of his office—an officer who does not wish to exercise pressure on the foreman's employer in his behalf, for fear of receiving censure for any economic inability which might be alleged or proved against his protégé.

The mine foreman should be relieved of the necessity of harmonizing conflicting purposes and of the duty of serving two masters. He cannot be both the state's man and a private employee and fill both antagonistic offices with credit to himself and satisfaction to others. The foreman of today should evolve into two specialized functions.

Does It Pay?

By W. H. Droll*

We are beginning to realize the existence of a great problem in this country, especially in our mine camps, where the problem of sanitation is a leading question. Formerly we opened a mine, and the camp soon grew up around the pit's mouth, without due regard to sanitation, building laws or layout. The development of a mining town was a helter-skelter proposition.

The more progressive coal companies realize the evil of this method and are beginning to straighten out their camps and clean them up. We all know that health is essential to good work and that a sick miner cannot accomplish as much as one who is in good health. When miners work in pairs, the sickness of one man throws his "buddy" out, and in a pitching seam this means the rearrangement of cars.

We are beginning to realize that the most important enemies of the mining companies are the typhoid germs in the drinking water. We know that the mosquito carries these bacilli and that the insect breeds and thrives in damp and wet places. We realize that the old "summer complaint" found among mining communities comes from the same source. We no longer build our camps haphazard. We lay them out so that the rain in soaking through the ground does not carry the germs from the outhouses to the nearest spring or stream. We no longer build open closets, where the deposits are picked over by chickens and hogs. We have ceased to regard the latter as a scavenger, placing our faith instead in a sanitary department, which removes the food from the housefly and prevents the mosquito from breeding.

The Coal Fields of Michigan

The coal fields of Michigan occupy an isolated basin covering approximately 11,000 square miles in almost the exact center of the lower peninsula. They are estimated to have originally contained 12 billion tons of coal, from which the exhaustion to the close of 1912 has amounted to about 30 million tons.

The principal coal-mining operations are in Bay and Saginaw Counties, but a smaller production, chiefly from local mines, is made in Clinton, Ingham and Tuscola Counties.

Coal was known to exist in Michigan early in the last century and some mining is said to have been done in the Jackson field as early as 1835. Other mines were opened at Grand Lodge in Clinton County, in 1838. It is known that some coal was produced in that place in those early years, but there is no record of the output prior to the census report of 1860, in which Michigan was credited with a production of 3320 tons. It is only within the last 12 years that the coal fields of Michigan have been worked to any considerable extent, and their development has followed in some degree the depletion of the forest resources.

Manure as a Protection for Concrete

By Newell G. Alford*

SYNOPSIS—The general conditions governing the setting of concrete and the results of a trial in utilizing the heat-producing qualities of fresh horse manure upon a large reservoir in an exposed location during severe winter weather.

Founded upon the basic heating qualities of manure from horse or mule stables lies a practical possibility for construction men to erect concrete in freezing temperatures without incurring undue expense or having to anticipate anything but the best setting results in the mixture handled. Not only will the cost of such protection be moderate, but it decreases directly as the area of the surfaces to be treated increases. Furthermore, the temperature of the manure remains practically a constant for comparatively long periods.

Not infrequently is a mine manager or superintendent confronted with the necessity of installing concrete about his surface operations in the winter season. Even though low temperatures make such construction hazardous and expensive, at the same time the work must be undertaken and pushed through in the face of possible ruin through freezing.

The new construction may be a retaining wall, a reinforced reservoir, foundation piers or some other work common to the class of concrete construction usually found about the surface plants of coal mines. However, it goes without saying that when the necessity for this character of installation occurs in the winter time it devolves upon someone to devise a scheme for accomplishing the desired result.

Cold Concrete Sets Slowly

Extensive experiments in concrete work done under severe weather conditions, and low temperatures, show that the use of calcium chloride furnishes a partial safeguard against the dangers encountered in cold weather. But this will not prevent ruin to the mixture unless there is a sufficient heating element surrounding the forms inclosing the concrete to permit it to set under normal conditions.

To quote from Prof. F. E. Turneaure: "The effect of temperature on the rate of setting and hardening in cement is very great and often requires special consideration in processes of construction. At or near 30 deg. F., the rate of setting and hardening is very slow. Experiments on natural cement mortars indicate a speed of hardening at 40 deg. about one-half that at 80 deg. on 60-day tests. Tests on portland cement show that at the temperture of 40 deg. the strength at 30 and 60 days is about two-thirds that attained at a temperature of 70 deg. At or near 32 deg. the time of setting is greatly prolonged. Cement setting in 8½ hr. at a temperature of 65 deg. required 38 hr. at 32 deg."

Under the usual conditions in winter, it is impossible to predict with any accuracy whether fires at intervals about the concrete forms will yield the desired results. In isolated cases, there are perhaps walls of neighboring

*Asst. Chief Engineer, St. Bernard Mining Co., Earlington, Ky.

structures or like shelter provided by local conditions, but these are infrequent.

Ordinarily the wind can sweep down upon the structure, always detracting from some portion of the protection afforded by the fires. Thus the temperature in which the concrete sets is variable, compelling a wide range of setting conditions for the cement mixture. Therefore, it is easily comprehended how a packing of manure within suitable retainers about the forms produces a heat, at no time subject to sudden changes, and which affords simultaneously a constant setting temperature for the entire mass of green concrete.

During the winter of 1912-1913 a reservoir was needed at the coal-washing plant of the St. Bernard Mining Co., at Earlington, Ky. Since shipment on a steel tank of the necessary capacity could not be had under 100 days, and conditions demanded an adequate water storage in 60 days, a reinforced-concrete reservoir was chosen. It was also held that the approximate life of a steel tank would be 15 years, at the end of which time the concrete installation would have only attained its maximum strength.

The reservoir was constructed 10 ft. deep and 25 ft.

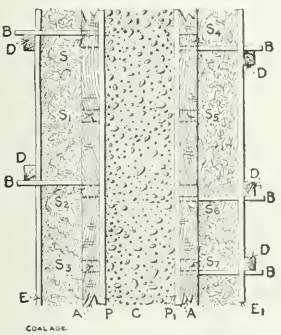

Fig. 2. Plan View of Wall with Concrete and Manure in Place

square, with walls 1 ft. thick, reinforced by ⅜-in. diameter steel rope. The capacity of the reservoir was, therefore, approximately 46,750 gal., being slightly above the amount of water required.

To facilitate proper setting of the concrete, fires were suggested, but the engineer in charge decided to substitute manure as a heating element, believing that he could thus secure better results. In order that an accurate conclusion might be arrived at concerning the effect of the manure, a minute record was made of the work as it progressed.

Details of Form Construction

The inner ring of the form was first put in place and the reinforcement suspended as shown in Fig. 1. To facilitate pouring, the outer side of the form was put up in four sectional rings, each tightly joined upon the other. When the concrete had been poured level with the top of the first section of the outside ring of the form, secondary framework was attached to the primary.

To make the method clear, consider Fig. 2, showing a section of the structure's plan. Looking down from the top, P and P_1 represent the tongued and grooved pine siding containing the concrete. C shows the concrete in place. A and A_1 represent the 2x4-in. plates, which were placed horizontally upon the ends of the vertical studding S, S_1, S_2—S_7.

To such convenient studding as S, S_2, S_4, S_6 and S_7, small boards of sufficient length were nailed to act as cleats. To the cleats B, uprights D were nailed 6 or 8 in. from the outside faces of P and P_1. The 1-in. boards E, of any width, were then nailed to D, forming a box on both sides of the concrete in which the manure was to be packed.

Manure hauled from the mine stables had been piled conveniently close to the work. This was next wheeled in barrows, dumped and tamped tightly between the vertical faces of E and P and E_1 and P_1.

This method was followed out until the entire form,

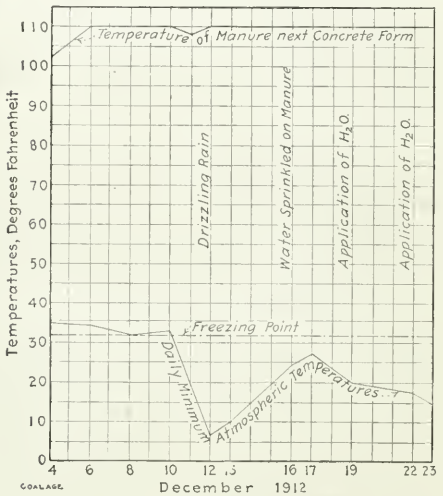

Fig. 3. Temperatures of Air and Manure Protection

10 ft. high, had been filled with concrete and manure. It then presented the appearance shown in the side view, Fig. 3, or from the hill immediately above as shown in Fig. 1.

The floor of the reservoir was also protected with manure, but was first covered with canvas to prevent its being marked. Then a layer of manure 6 in. thick was spread over the canvas, this in turn being covered carefully with 1-in. boards to prevent disturbance from the wind.

The concrete pouring was completed with the manure intact about the form on Dec. 4. In order that any variance in the temperature of the manure might be observed, readings were made and recorded during the succeeding 19 days. In observing these temperatures, a standard Fahrenheit thermometer was placed next the pine siding P and P_1, which held the concrete. In other words, there was the thickness of the manure between the thermometer and the atmosphere. Ten observations on the temperature of the manure were made at one time, the mean being taken as a fair result. These figures are recorded in the upper curve given in Fig. 5.

In order to show the existing difference between the

temperatures of the air and the manure next to the concrete atmospheric temperatures have also been plotted. These are the minimum readings recorded by the Government Weather Bureau Station, at Earlington, Ky.

The only variance in the manure temperature curve is found on Dec. 11, when the heat dropped 2 deg. This was undoubtedly caused by the severe wind which had blown during the two preceding days, and which tended to drive the moisture from the manure.

On Dec. 12 there was a slight drizzling rain despite the low atmospheric mercury reading, after which the manure was seen to steam perceptably. The temperature was, therefore, taken and found to have resumed the constant of 110 deg.

This experience indicated that periodic sprinkling of the manure with water would sustain the chemical action producing heat. Accordingly, on Dec. 16, it was given an application of water with a hose, and this was repeated on the 22nd. This effect of the moistening, as shown in the upper curve on Fig. 5, was the maintenance of a constant temperature in the manure. It will be seen that this temperature, with the exception of one day, remained at 110 deg.

On the other hand, a glimpse at the atmospheric curve indicates that the minimum temperatures ranged from 35 to 7 deg., the average being approximately 23 deg. Thus the average difference in temperature afforded by the manure was 87 deg. In this connection it is interesting to take into account the latent chemical action which causes the results.

Why Manure Heats

Horse manure is rich in nitrogenous substances, contains nitrifying bacteria, and also hydrocarbon compounds, such as cellulose, starches, etc. The nitrogenous material is first broken down by the bacteria, and in the presence of substances containing hydrogen (such as straw) forms ammonia, which is later oxidized.

If any sodium salt or potassium salt is present, sodium nitrate ($NaNO_3$) or potassium nitrate (KNO_3) is formed, so that saltpeter (KNO_3) is usually found in old manure.

The bacteria referred to will not work except in the presence of moisture, so that when water is added to the manure they work very fast, producing sufficient chemical reaction to account for an increased quantity of heat. Manure, if dried, will not ferment, but the bacteria are not killed. All they need to revive their action is an application of water. This explains the rise in temperature of the manure, shown in Fig. 5, on Dec. 12.

The manure protection on the work described above cost $59.95. If the protection had been accomplished through the medium of fires the cost would have probably reached $195.70. An analysis of the manure protection expense reveals the following:

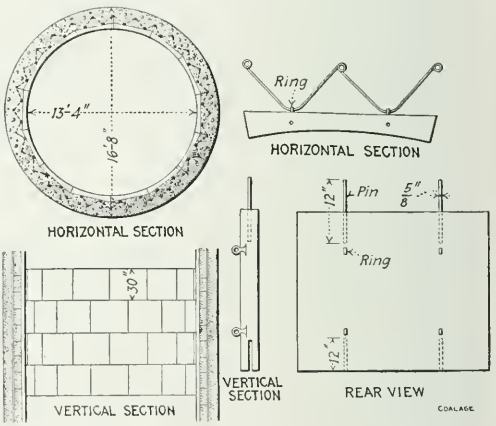
Timber for framework, etc.	$40.45
Hauling manure 1¼ mile	10.25
Labor	9.25
Total	$59.95

Since the manure possessed a fertilizing value after its removal from the concrete forms no charge was made for its use. Two thousand nine hundred and seventeen square feet of concrete surface was involved in the undertaking, which constituted a cost per square foot of $0.02. Compared with this, using driftwood with charge, the same protection by fires would have amounted to $0.067 per square foot.

Finally, the concrete was constructed at the summit of an ascent about 100 ft. above a natural basin from which the timber has been cut. The wind had access to the four sides of the structure, which, despite fires, would have made uniform setting conditions for the concrete wholly impossible. Fig. 6 shows the reservoir as it is at present, the forms having been removed and a dirt fill made next to the outer concrete surface.

Concrete Shaft Lining

At No. 1 mine of the United Collieries of Charleroi, Belgium, a small 133-ft. shaft has been sunk recently. It is about 13 ft. 4 in. in diameter and 16 ft. 8 in. over all. The lining is formed of concrete blocks, with their vertical joints staggered. Between these voussoirs and the rock, concrete is poured. The blocks were made at the mine in wooden molds. They are 30 in. high and 3.2 in. thick, in the thinnest place. Fourteen of them are needed to make a complete ring in the shaft.



Concrete Lining and Forms of Concrete for a Belgian Shaft

In each block are embedded two iron dowels 0.6 in. in diameter and 12 in. long; these project 6 in. from the top edge of the block and fit into holes in the voussoir above.

In the concrete between rock and inner lining is embedded a bent rod of iron about ½ in. thick, which is laced through rings anchored in the backs of the blocks, there being four rings to each block. The V's formed by this bent rod are joined together by bars 30 in. long and 0.4 in. in diameter. There is understood to be a further reinforcement of the cement mass, not indicated by the drawings, and reinforcement in the several blocks.

The cost of construction is figured at $8.65 per running foot. Tests have shown this lining to be equal in strength to one of masonry 32 in. thick, which would cost $13.50 per running foot of depth.

The concrete mixture used is six parts of gravel, three of sand and three of cement.

Note—Translated and abstracted from the "Annales des Mines de Belgique," by E. P. Buffet for "Coal Age."

Explosions at the Cadeby Main Colliery

By Our British Correspondent

SYNOPSIS—A brief abstract of the report of the British chief mine inspector on the explosions at the Cadeby main colliery, which killed 88 men, including 53 rescuers. A fire in the mine, which ignited the firedamp present, is believed to have been the cause of the explosions. This fire was supposed to be walled off, but apparently an inlet was left, probably along the longwall face. The inspector questions whether it is wise to risk life to bring out dead bodies.

The report of the British Home Office into the causes of the explosions at Cadeby Main Colliery, in Yorkshire, on July 9, 1912, has recently been issued. It will be remembered that there were two principal explosions, the first destroying 35 and the second 53 lives, making the total death roll 88. Among those killed, were several mine officials, including the mine manager, also three inspectors of mines, including the divisional inspector, W. H. Pickering. The report is by R. A. S. Redmayne, the chief inspector of mines of Great Britain and Ireland.

Description of Mine

The two shafts of the Cadeby main colliery are sunk to the Barnsley bed, which is the only seam worked at this mine. It lies at a depth of 2289 ft. from the surface, on the dip side of a large fault, which has a throw to the south of 378 ft. (see Fig. 1). The coal on the north side of this fault is won by a pair of headings driven through the rock at that displacement.

The output from the Cadeby mine is about 3000 tons a day, coal being hoisted at both shafts. These are 16 ft. in diameter. No. 1, the downcast, is 2256 ft. deep, and No. 2, the upcast, 2214 ft.

Thirty-Five Fires at Cadeby

It will be seen that about 49 ft. above the Barnsley bed is a seam of coal 2 ft. 2 in. thick. The top coal of that bed is of inferior quality and mixed with dirt. The immediate roof of the seam is a shale, variable as to hardness, but of moderate reliability. The Barnsley bed is a gassy seam, which, in South Yorkshire, is peculiarly liable to spontaneous combustion. At Cadeby there have been no less than 35 fires ascribable to that cause. To work this bed safely, requires the greatest care and vigilance. The dip of the seam is 1 in 14 to 1 in 12 to the southwest.

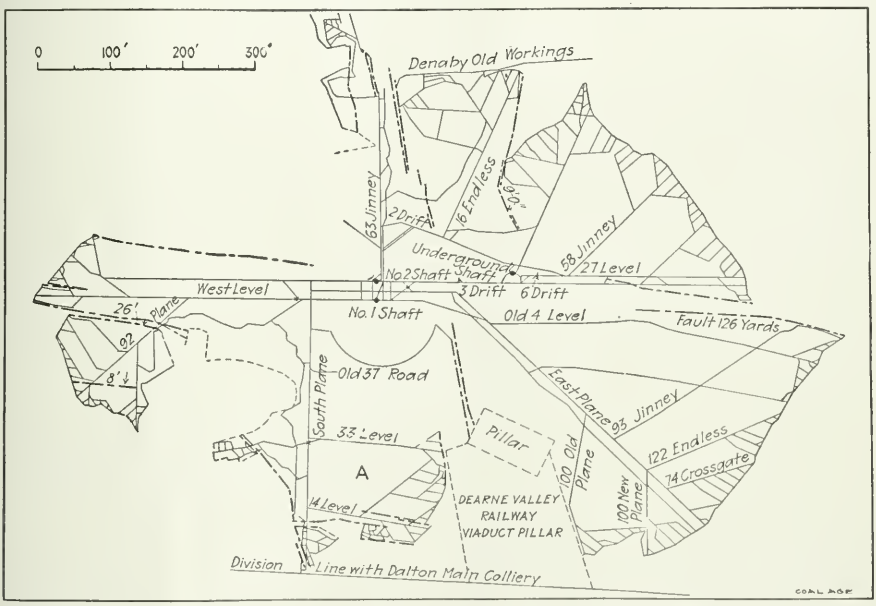


Fig. 1. Cadeby Main Colliery in South Yorkshire, England. The Section Marked *A* Was the Scene of Two Severe Explosions

Methods of Working

The system of working practiced is long wall, the distance between the gate roads being usually 120 ft. Packs, 7 ft. 6 in. wide, are built on either side of these roads, and every 21 ft. a gob pack, 6 ft. wide, is built. The material used for building the packs is stone, obtained from the waste and from the ripping in the gates. In the main roads much of the brushing has to be done in the shale roof, thus forming a large amount of stone dust. This dust considerably decreased the extent of the explosions. All the coal was mined by hand; neither coal cut-

ters nor conveyors were in use. The coal being fairly friable, a certain amount of dust was made at the face, but not an unusual quantity.

The following is a section of the seam at the shafts and of the strata immediately above and below the Barnsley bed:

SECTION OF STRATA IN CADEBY MAIN SHAFTS

		Ft.	In.
Coal	1ft.5 in. coal, hards; 2-in. bituminous shale; 7-in. coal, cannel	2	2
Dark blue shale		4	0
Coal			1
Dark blue shale		1	7
Bank			2
Dark blue shale		4	0
Strong shale		6	0

	Top hards	2	0
	Bright hards		3
	Bottom hards		9
	Bottom softs	2	0
Shale		2	0
Hard fireclay		6	0

Manager Fired All Shots

No shots were fired except in rock headings, and then only at week ends, when few persons were in the mines. As an additional safeguard the manager alone was permitted to fire the shots.

The cars were hauled in the main intakes by an endless rope, electrically-driven from the bottom of the shaft; the secondary haulage was performed by horses and ponies.

At the time of the accident, the volume of air circulating in the mine was about 163,000 cu.ft. per minute, under a water gage of about 3½ in. The air was drawn through the mine by a Schiele fan, 21 ft. in diameter, making about 119 r.p.m. Although the Cadeby and Denaby mines are connected by means of an emergency outlet, the ventilation system of the two mines was entirely separate, the iron doors in this connecting airway being kept locked.

The Marsaut type of safety lamp was used exclusively by the unofficial workmen. The lamps found after the disaster were examined and all those in places where the gas might have been fired were found to be intact.

Precautions against Screen Dust

The surface arrangements are described as admirably designed to prevent the floating dust produced by the movement of the coal at the dumps, screens, conveying belts and hoppers from being carried down the downcast shaft, and so on to the roadways of the mine. The dust is collected wherever made, by means of funnels attached to pipes connected to an exhaust fan, which creates a partial vacuum (2½-in. water gage), the current of dust-laden air passing from the fan into a cyclone where it enters a steamy atmosphere maintained by a steam jet from the boilers; this prevents any of the lighter dust from escaping by the chimney to the outer atmosphere. Where necessary, the screens and hoppers are almost entirely inclosed. This arrangement, which has been in operation for about five years, has proved effective in clearing the air of dust about the headframe and tipple. Practically none of the powdered coal is carried by t ventilation down the intake shaft to the undergrou workings.

South Plane District

The effect of the explosion was limited to the distri tributary to the South Plane, see Fig. 1. This area is d scribed as dry and dusty. The endless rope worked as f inby as the 14th level, the haulage along that road for distance of about 450 ft. being by tail rope attached the endless rope by means of a clip. Beyond this poi horse haulage was employed.

The volume of air entering the south district was 21 661 cu.ft. per minute. About half this air went alo 14 level to ventilate the district in which the explosio occurred, returning by way of 33 level, which crosses t south plane at a point about 2900 ft. from the shaf The other half went into the area at the end of the sout plane and ventilated the workings at that point.

This South Plane district had not a long life before i It was near the boundary of the Dalton Main collier on the south, while to the east, it was approaching the pi lar of coal left to support the Dearne Valley Viaduct.

Fires, Gas and an Explosion in South Plane District

Gob fires had been known in the neighborhood of th face fault for some time past, the first developing i August, 1906, at the face and occurring right up agains the fault in old 37 stall. This fire was dug out.

A second fire occurred not far away from the first, be ing on the upper side of the crossgate out of 33 level o the fault side, where some timber had been left.

A third fire, to which the explosion was probably due occurred at old 121 stall, also against this fault. Thi was discovered on Nov. 20, 1911, and when scouring road were driven to it, it was found that the fire had backe from the fault for a distance of 24 ft. into the gob. O Jan. 20, 1912, a small explosion of gas occurred at thi fire, slightly burning four men who were engaged in work ing at the face. The effect of this explosion on the ai was felt about 450 ft. distant; it frightened all the me in the district and they came out.

Five flashes were seen on Feb. 2, and also on Apr. 10 while on Apr. 2 a gas cap on the flame of the safety lam was noticed on top of the old scourings. Coming to July "gob stink" was reported in 121 old gate by deputies o the 5th, 6th, 7th and 8th of the mouth, but gas was no mentioned as being present on any of these days.

The First Explosion

From a consideration of the evidence presented, Mr Redmayne concludes that the first explosion originate about 64 gate, mostly probably in the neighborhood o the face of 7's working place, and traveled in two direc tions. Apparently, the fire just mentioned had been shu off along all the gateways leading to it, but along th front of the face fault an inlet for air had been left. Thi received the intaking air current, which, however, ha passed along the line of face from gate 131 onward, an consequently possibly contained some gas. Mr. Redmayn believes that this inlet should have been closed, and i fact urges that the intaking air current should be shut of before the return.

The explosion directed itself partly toward the intake

going down to 121 crossgate and running along that haulageway and also along the face to 12 gate. On reaching 14 level, the explosive blast seemed to have developed its greatest violence, either owing to accumulations of coal on the landing or because along this intake airway it found enough air to render the mixture of gas and dust more explosive. There was no evidence of burning by the first explosion for any distance beyond the end of 19 crossgate, but there was evidence of force up to the end of 14 level, as the cars at the outby end of this level were blown on to the plane.

The explosion also projected itself toward the return, passing down 64 gate, and with force and flame continuing along 19 landing to 19 crossgate. Mr. Redmayne does does not think, however, that the flame reached the end of 19 crossgate, but that the explosion died out along that road. He thinks it stopped for want of fuel to feed it.

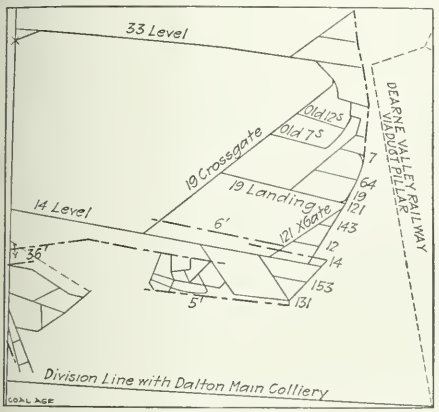

Fig. 2. The Part of Cadeby Main Colliery Where the Explosions Occurred

The supply of gas was exhausted, and the dust was too much intermixed with stone dust to allow of the continuance of the explosion. An analysis of the sample taken when an entry was made to the recovered workings in 19 crossgate below 19 landing, showed it to contain 80.81 per cent. of ash and the dust was coarse, only 10.52 per cent. passing through a 100-mesh sieve.

Probably the blast in 14 level was stopped by the same immunizing stone dust for a sample from this level at the foot of 19 crossgate contained 48.31 per cent. of ash.

The Second Explosion

The second explosion seems to have traveled wholly on 14 level and along the face, as there were no signs of force or burning other than were occasioned by the first explosion in gates 64 or 19, nor along 19 level or crossgate.

Mr. Pickering suggests that there was a large accumulation of gas on the rise side of the district after the first explosion, which, igniting at the fire, burnt more or less quietly up and down the face until an explosive mixture was formed at about 14 level, when it detonated. The force in 14 level was very much greater than in the first explosion, and the flame probably extended nearly to the outby end of that level. Had the explosion extended far on the South plane, Mr. Redmayne thinks it is probable that the whole colliery would have been wrecked, analyses of samples of dust showing that it was of a dangerous character.

Points in Rescue Work

Mr. Redmayne condemns the lack of organization which permitted men to enter the mine after the explosion without written authorization. A guard should have been placed on the outby end of the South plane to prevent unauthorized persons entering from other parts of the mine. Had this been done the loss of life occasioned by the second explosion would have been much less heavy.

Mr. Redmayne does not think, however, that the management of a colliery is justified in allowing persons to risk their lives in the recovery of dead bodies. There is always great risk of a second explosion when a fire is known to exist underground. It sometimes requires much moral courage to restrain oneself and to prohibit others from undertaking a risk of this nature.

The correct number of casualties was not definitely ascertained until three days after the disaster, owing to the indiscriminate issue of lamps after the first explosion.

Mr. Redmayne urges that until the fire had been completely isolated by stowings and stoppings, all the men not engaged in combatting the fire should have been withdrawn from the district in which it occurred.

Mr. Redmayne quotes the evidence of W. H. Chambers, the manager of the Cadeby and Denaby Main Collieries, who has had 30 years' experience of underground fires at Denaby and Cadeby, during which period he has dealt with 56 cases, some at the coal face and others in the worked-out areas.

Fire Starts in Crushed Coal of Crevices

He said that a large proportion of the face fires had occurred in the neighborhood of faults, this fact being due to presence of pulverized coal in the fissures, which offers a considerable area for the absorption of oxygen from any air, which may be found in the fissures.

There is often sufficient air to start such chemical action, but insufficient to carry off the resultant heat, and hence the fine coal gets hotter and hotter until it reaches the point at which combustion commences.

A number of fires, however, have occurred in the worked-out areas, but they generally originated in the fissures *above the goaf*, the oxygen necessary for combustion finding its way along these crevices. He said there was a "rotten" roof, and that was the reason why they could not work the whole of the seam. They had to leave the top coal to prevent the fall of the shales above it. Fires break out freely, if the workings are allowed to stand even for a few days, and even when the progress of advance of the coal face is slow, as when impeded by faults. Therefore, he found it necessary to keep the face continually advancing irrespective of the state of the coal market.

Mr. Chambers defended his present system of leaving 24-ft. wastes between gate packs 7 ft. 6 in. wide. Intermediate packs were also used, mainly because the latter were necessary to keep the face open. He did not favor the hydraulic method of stowing the waste, because he had doubts as to its efficiency in preventing the formation of fissures, and he foresaw insuperable difficulty in the way of its adoption at Cadeby colliery, owing to the fact that water was necessary if this system was used.

He had experimented with water as a means of laying the dust upon roadways, but he had found that even the small quantity required for this purpose had such an injurious effect upon the roof that the roads were closed.

Since the explosion at Cadeby Main, Mr. Chambers had, however, devised a method of dealing with gob fires by excluding the oxygen altogether, which had proved successful in the recovery of the South Plane district after the recent explosion. If a sign of heating in the gob is detected by an analysis of air or otherwise, the ordinary ventilation of the pit is excluded from that particular area, and there is forced into it a gas deficient, or entirely wanting in oxygen so that instead of the fire being fed by air containing 21 per cent. of oxygen, it is gradually stifled by an inert atmosphere of increasing density.*

Leakage, if any, would then be outwards from, not inwards to, the fire. To facilitate this procedure he would lay along the roads a system of pipes, which could be put into operation at any moment. The gas to be employed should be absolutely inert, consisting solely of nitrogen and carbon dioxide, so as to be practically innocuous from the point of view of leakage.

Occurrence of Gob Fires

J. R. R. Wilson, one of the British mine inspectors, said that at three or four collieries working the Barnsley seam in the Doncaster area, these fires were becoming increasingly frequent, and were a source of great danger. He thought it rather more than a coincidence that the system of working at each of the collieries was the same, viz., longwall, with narrow wastes and numerous gob packs, and he could not help thinking that this method was responsible for much of the trouble which was experienced with gob fires. He considered that next to stowing the goaf tight by artificial means, for example, the hydraulic method, the best course was to let the roof "stow itself" by falling. Hence he considered that wastes only 21 ft. wide with intermediate packs were inadvisable, on the ground that such a system prevented heavy breaks and did not let the roof fall sufficiently freely to tighten up the waste and exclude air until a considerable period had elapsed.

System of Working Compared

The inspector pointed out that in other parts of the same coal field, the Barnsley seam, with top coal as thick if not thicker than at Cadeby, is worked with little or no trouble from gob fires, and he thought it was significant that at all these collieries, with a 9-ft. gate and 7-ft. 6-in. gate packs, the gates are 66 ft. apart with no intermediate packs. Under this system the wide area of unsupported roof tended to fall freely to a good height, and then if the roads are well ripped and the packs tightly built, the roads are ultimately wholly in the hard stone above the goaf.

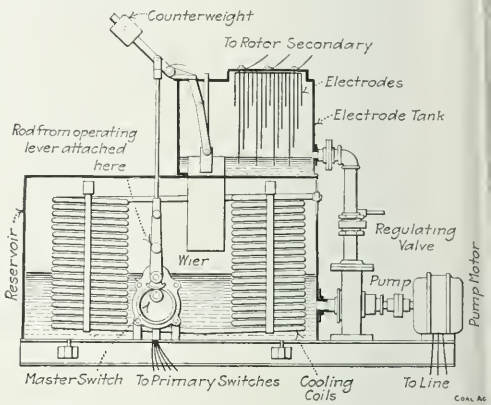
He was aware that this method had been criticized on the ground that to dispense with gob packs involved great difficulty in keeping the face open between the gates, but by the use of wood chocks this difficulty had been surmounted. He had never found that air would leak past heavy caves in sufficient measure that gob fire would be sustained.

*We do not believe that such a system needed devising, so often has it been advocated in American technical journals.—Ed.

Liquid Rheostats for Large Motors

The use of large alternating-current slip-ring motors for driving mine hoists, rolling mills, etc., has increased largely during the past few years and has created a demand for a simple, efficient and economical controller. To meet this demand the Westinghouse liquid rheostat in capacities of from 400 to 1500 hp. was developed.

These rheostats provide an infinite number of steps between the minimum and maximum limits, thus permitting fine speed adjustments and smooth acceleration. The rate of speed increase can be definitely fixed and is independent of the rate at which the operator manipulates the starting lever; it is therefore impossible to injure the motor or the machine connected thereto by too rapid acceleration.



Cross-section of Rheostat, Showing Mechanism

The principle of operation of these rheostats is clearly shown by the accompanying diagram. The apparatus consists of two compartments, an upper tank for the electrodes, and a lower reservoir. The three phases of the rotor are connected to electrodes suspended in the upper tank. A small motor-driven pump circulates a steady stream of liquid, usually a solution of soda, from the reservoir into the electrode tank, and back again over the weir.

Now by raising or lowering the weir, the height of the liquid in the electrode tank is correspondingly varied. The resistance in the rotor circuit decreases as the liquid level rises, and *vice versa*, and the motor speed, of course, changes with the rotor resistance.

The operating lever of the rheostat controls both the master switch and the weir. When the lever is in its central or off position, the primary switches are opened and the weir at its lowest level, so that the secondary resistance is maximum. Moving the lever in one direction closes the proper primary switches for starting the motor forward and raises the weir. Moving it in the opposite direction reverses the motor and again raises the weir.

A valve in the intake pipe of the electrode tank regulates the rate at which the liquid is pumped in, so that no matter how quickly the operating lever is moved, the liquid can only rise at the rate for which the valve is adjusted, thus fixing the rate of acceleration.

Erecting an Engine Underground

By B. J. Lowe*

SYNOPSIS—The methods followed to prevent the foundation from slipping upon a slanting foot-wall, of determining how much was to be removed from the lugs to bring the cylinder center lines parallel and making the two-piece flywheel tight upon the shaft with an 18-in. wrench are here described.

Properly erecting such a piece of machinery as a hoisting engine is by no means a difficult piece of work when all circumstances are propitious. Doing the same job some hundreds or thousands of feet underground by the weak, uncertain and often deceptive light of candles and carbide lamps may be a different proposition.

The writer was recently called upon to install underground, 2500 ft. from the surface, a cross-compound hoisting engine. The cylinders of this machine were 13½ and 21 in. in diameter while the length of piston travel was 24 in. Motion was transmitted from crank- to drumshaft through gearing at the ratio of 2½ to 1, the drum being 6 ft. in diameter. The engine was to operate on compressed air at 70-lb. gage and was designed to pull six loaded cars up an incline of 15 deg. at a speed of five miles per hour.

A chamber was first blasted out of the solid rock for the engine and foundation. This left a rough and decidedly sloping bottom. The height of floor line or bottom of engine base, as well as the center line of the engine, was next laid out by the mine surveyor. An ordinary template was prepared and set in place on this engine center line, with the foundation bolts properly placed therein. More than half of the foundation had to be built upon rock which sloped about 45 deg. to the horizontal, and, as considerable blasting was being done nearby, it was feared that the shock and vibration would cause the foundation to crack and slip.

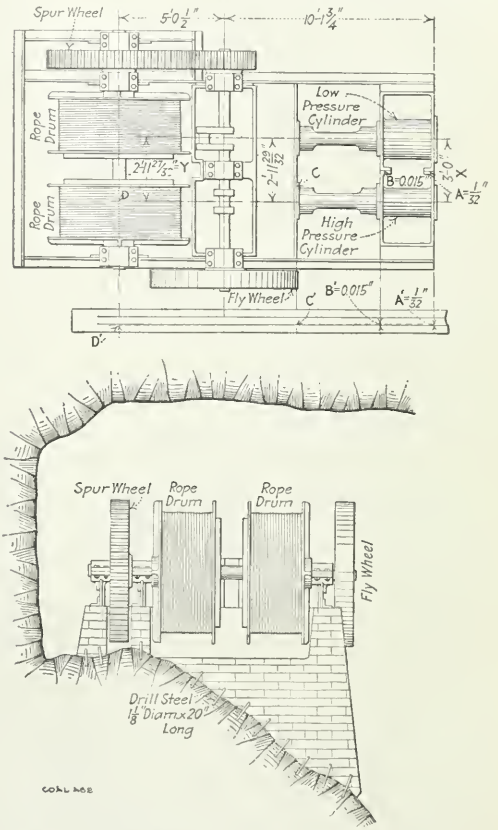
To prevent this, a number of holes were drilled into the bottom rock 10 in. deep and spaced 2 ft. each way. Pieces of old drill steel about 20 in. long were then grouted into these holes and, as the masons built up the foundation, they built in these "dowels."

When the foundations were finished, they were allowed to set for a week before any machinery was placed upon them. As many of the parts of the engine weighed over 2000 lb., a number of eye-bolts were securely fastened in the roof at convenient places for lifting purposes.

After the side frames, cylinders, trunks, pedestals, crank- and drumshafts had been put in place and securely bolted together, and the entire unit made level, fine steel wires were stretched through each of the two cylinders, extending to the drumshaft, and made central in the ordinary manner. The distance between these two wires was then carefully measured, and it was found that they converged, being $\frac{5}{32}$ in. closer together at the drumshaft than at the back of the cylinders.

As the cylinders and guides of an engine must be parallel, it became necessary to know how much must be removed from the lugs marked *A*, *B* and *C* to render the center lines of the cylinders parallel. To obtain this, a board about 12 in. wide, 2 in. thick and 18. ft. long, surfaced on one side, was placed beside the engine bed at the same height as the center line of the crankshaft. By means of a long straight-edge, two fine pencil lines were then drawn upon this board, each being parallel with one of the steel wires. These lines were accordingly out of parallel by $\frac{5}{32}$ of an inch.

Next points *A'*, *B'*, *C'* and *D'* were located upon these lines in positions exactly similar to *A*, *B*, *C* and *D* upon



Plan of Engine and Partial Section of Foundation, Underground Engine Room

the engine. As *C* was the point where the trunks were bolted to the main frame of the engine, this was considered as the pivot point, or the one where no change in the distance between center lines should take place.

The straight-edge was now placed at *C'* and swiveled until its edge became parallel with the first line. A third line was then drawn, intersecting the second at *C'* and continued each way to *A'* and *D'*. The distance between this line and the second line at the points *A'* and *B'* gave the amount which must be removed from the lugs in order to bring the center lines of the cylinders and trunks parallel.

*Germistown, Transvaal, South Africa.

It was found upon examination that the low-pressure cylinder was correct and square with the main shaft, while the high-pressure cylinder was the one at fault. This was accordingly taken off and the lugs filed down to their proper place. It was then put back and securely bolted up. The steel wire was recentralized and measurements at X and Y showed that the lines were parallel within the thickness of a fine pencil line. This was considered sufficiently accurate for all purposes.

By laying off these two lines upon the board and proceeding in the manner above described, it was only necessary to remove the cylinder once, it was not a case of "cut and try" on the amount which should be removed from the lugs, this being accurately known in the beginning.

When lining up the cylinders and trunks, as no inside micrometer caliper was at hand, touch gages made of a light piece of wood with an ordinary pin in each end were used. Being light in weight, an extremely sensitive touch could be felt. They had the further advantages of being cheap, easily made and extremely effective.

Rather strangely a 7-ft. flywheel was placed on the end of the crankshaft of this engine, a hand brake being fitted thereon to assist in holding the cars. This wheel was made in two pieces and bolted upon the shaft. As some trouble was experienced in tightening down the 1½-in. nuts, with an ordinary wrench, the bolts were removed one at a time, heated black hot, returned to their places and screwed up with an 18-in. wrench. Upon cooling off, these bolts, of course, shrunk and bound the two halves of the wheel together extremely tight.

The writer is pleased to state that this machine has now been working for some time and, to all appearances giving perfect satisfaction to all concerned. In setting up any engine under similar conditions, great care should be taken in making all measurements, as, under the very best of circumstances, the light of a candle or carbide lamp is liable to be deceptive.

Peabody Coal Co.'s Tipple at Nokomis, Ill.

SYNOPSIS—At this tipple the coal is hoisted 85 ft. above the surface and screened over bars and perforated plates, the latter being of the shaker type. The tipple will handle 3000 tons per day and hoisting will be by electricity.

The Peabody Coal Co., of Chicago, is reconstructing its mine at Nokomis, Ill. Here a 6-year-old operation, indifferently equipped and able to hoist less than 500 tons daily, is now being outfitted with an entirely new plant, above ground and below.

For a long time the mining work done below ground has only been such as to prepare the workings for a daily production of 3000 tons. It is expected that this output will be obtained as soon as the present plant is complete. The entries have been driven long distances in all direc-

TIPPLE OF PEABODY COAL CO., AT NOKOMIS, CHRISTIAN COUNTY, ILL.

tions, and upwards of 750 rooms have been necked off and widened out, ready for the mining machines and wide-work production.

The shaft has been enlarged, and a complete new surface plant installed. Everything is to be electrically driven, by power brought in from outside generating plants. It is said that the tipple will be the largest in the state of Illinois.

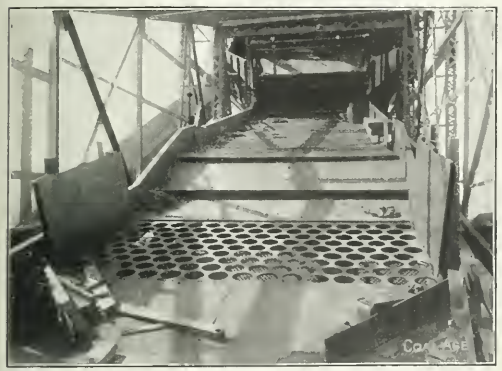
The shaft as now enlarged is of such size as to permit operation of double cages, and two cars will be hoisted at a time, side by side. The cars are to hold about four tons each, when the coal is well built up at the sides, so at each hoist there will be brought up and dumped about eight tons of coal.

The shaft depth is 640 ft. and the total hoist about 725 ft. The cages will be self dumping and operated by an electric hoist.

As the two cars brought up on each cage will usually have been loaded by different miners, there must be separate weigh hoppers to receive their contents.

The Screening Equipment

After weighing, the coal will descend directly over fixed bar screens for the removal of slack. Passing these



View of Shaking Screens, Looking Back Toward Weigh Hoppers

bars, the lump will be converged to the width of the shakers, and fed to them over an adjustable apron. The shaker screens are carried by a supporting structure completely separate from the main tipple framing. Hence, no shaker vibrations will be felt in the tipple tower.

The photograph of the screens was taken from the extreme end of the shakers, looking back at them toward the weigh hoppers. It shows clearly the arrangement of screens, veils, etc., for the preparation of all desired grades of fuel. Loading spouts beneath the screens catch the coal as it falls through and deliver it in its several sizes to railroad cars on the four tracks which will pass beneath the shaker when the grading is completed. The shakers are carefully counterbalanced and will be actuated by an electric motor.

The tipple was designed by the Peabody Coal Co.'s own engineers, and the structure was fabricated by the Wisconsin Bridge & Iron Co. The entire operative equipment, from weigh hoppers to car loading chutes, was furnished and installed by the Webster Mfg. Co., of Tiffin, Ohio.

Wastefulness at Power Plants

Addressing the meeting of the American Institute of Mining Engineers, Apr. 18, 1913, C. W. Beers made the following remarks, but it is a matter for doubt whether greater economy in mine practice would not be better than the purchasing of power for the mining load curve is often reasonably uniform.

"To understand correctly the reasons why a large producer of anthracite should find it economical to purchase central-station power, it is necessary to have a clear understanding of the ordinary steam production, and the uses to which it is applied in and around the various collieries.

"About eight or ten years ago, I was discussing with the mechanical engineer of a coal company the seemingly large amounts of steam used in various collieries, as the cry of the colliery management was constantly for more steam, although the installation of new steam-consuming devices was in no way proportional to the constantly increasing amount of steam generated.

"The mechanical engineer in reply advised that it was simply a waste of money to install more boiler capacity, and made the remark that the surest and best method of increasing the usefulness of the boiler plant was to get busy with the pumps and engines, meaning that if these steam consumers were kept in suitable repair, or rejected, and an entire new outfit substituted, that the duty of the existing boiler plants would be largely in excess of the actual steaming capacity required, and they would operate with better load factors with a consequent reduction in steam expense. A statement of this kind, coming from a liberal-minded engineer, is the unadulterated truth.

160 Lb. of Steam per Horsepower-Hour

"There are old-fashioned pumps in the mines today working on 24-hr. service that vary in age from 40 years down, and as long as they are able to push water they apparently fill the bill, regardless of the fact that they can consume easily 160 lb. (72.5 kg.) of steam per water horsepower-hour. Pumps on long-duty service are seldom touched on account of the time necessary to make suitable repairs, and when repairs are made the question is not "how economically will the pump operate?" but, rather, "how short a time will it take to make repairs?" One can imagine the condition of the cylinders, pistons, valves, etc., and with tight packing and a poor water end it is not a hard problem to guess where the steam is wasted.

"The same is true of engines. There are fine specimens of old-time workmanship and material in service 8760 hr. per year. Fans usually must be kept running at any cost, and, owing to the inability to shut down the engines to make necessary repairs, the pistons, rings and valves become badly worn with the result that large quantities of steam are used with a remarkably bad distribution. More than one fan engine shows 90 lb. (40.8 kg.) of steam per indicated horsepower-hour. These statements are advanced to show the condition of much of the machinery in use today. Colliery operations are usually conducted with the idea of getting maximum coal output, and little attention or money is spent in keeping the machinery in repair so that it may work at maximum economy."

Shaking Screens in a Concrete Tipple

By O. G. Petersen*

SYNOPSIS—A description is given in this article of a change in the design of shaking screens, so as to adapt them to use in concrete tipples, a long screen being replaced by a short-arm screen, in order to reduce the horizontal strains set up by their operation and at the same time increase the vertical strains. Moreover, the efficiency of the screens is increased by shortening the hangers, as it increases the action of gravity.

A company daring to place a device that gives as much trouble as a large shaker screen in a concrete frame, was strongly criticized at the time of completing the structure. Now that the plant has been in operation for a year and a half, the Stearns Coal & Lumber Co., of Stearns, Ky., feel that they have made a good investment.

Two factors entered into the successful design and construction of this plant. One was a shaker frame designed particularly to meet the periodical strains incident to shaker-screen operation. The other, a shaker-screen suspension system which replaces the usual longitudinal strains by vertical ones, strains that the concrete frame is well fitted to withstand.

An examination of the law governing the motion of the pendulum discloses some interesting facts when applied to shaker-screen operation.

$$T = 2\pi \sqrt{\frac{l}{g}}$$

in which

T is time of complete vibration in seconds;
π is 3.1416;
l is length of pendulum in feet;
g is value of gravity, assumed at 32.16.

The particular item of interest in this case is that the time of vibration varies as the square root of the length.

A well known and almost universally used type of shaker screen has hanger rods, which are six or seven feet long. By considering all the hanger rods as brought into one and the weight of the screens as concentrated at a point corresponding to that of the bob at the end of the pendulum and inserting the usual values in the above formula, we have

$$T = 3.1416 \sqrt{\frac{7}{32.16}}$$

$T = 2.88$ seconds for a complete swing or period. This corresponds to 21 complete swings per minute. If there were no friction at the bearing points and the screen were set in motion it would swing of its own accord at this rate.

It will be noticed from the diagram of the pendulum, Fig. 1, that when the pendulum is seven feet long and the swing or double amplitude is 4½ in., the effective component due to gravity causing the weight to move is 540 lb., when the bob weighs twenty thousand pounds.

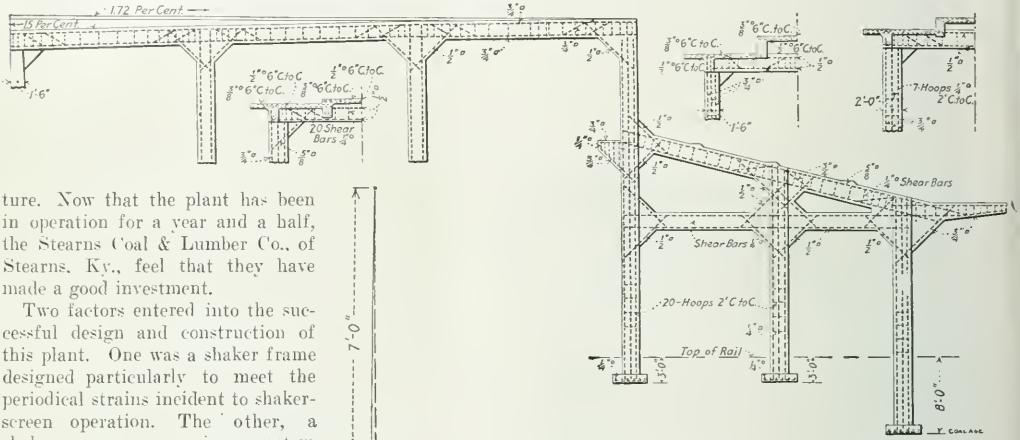


Fig. 3. Elevation of Concrete Tipple

Pendulum Diagram

Inserting new values in the first used formula by giving the pendulum a length of six inches, or 0.5 ft., we have

$$T = 3.1416 \sqrt{\frac{0.5}{32.16}}$$

T is 0.74 seconds, corresponding to 81 complete swings per minute. If there were no friction at the bearing points and the screen were set in motion it would swing of its own accord at this rate.

Greater Vertical Strains

Making a new diagram, Fig. 2, in which the pendulum is assumed at six inches, while the stroke or double amplitude is retained at 4½ in., we obtain as the effective component due to gravity 7680 lb.

Applying the two pendulum lengths to actual working conditions in having one screen with suspension rods 7 ft. long and a second with 6-in. rods or links, test instruments will show a power consumption of 15 to 25 hp. for the first when running at 110 r.p.m., and passing 250 tons per hour over a screen 72 in. wide and separating the coal into four sizes. For the second screen, running under similar conditions, the instruments record a power consumption of *six* horsepower.

A further examination of the diagram reveals an almost straight line, as the path of any point in the screen

*Assoc. Eng. Co., Louisville, Ky.

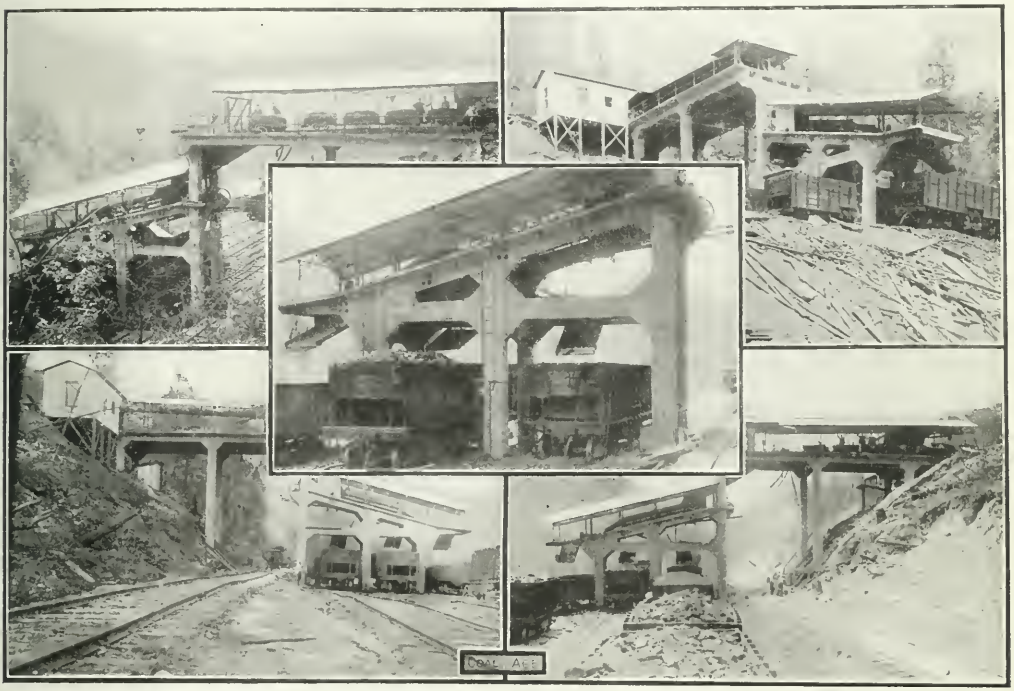
with 7-ft. rods, while the screen with 6-in. rods shows a vertical movement of almost ½ in. for the assumed stroke of 4½ in.

This vertical movement considered in connection with the path traversed by the coal on the screen, which is approximately that described by a six inch pendulum, and with the fact that the coal would therefore have a natural period of 81 per minute, while the screen is made to run at 110, shows why the screens keep themselves so clean. The screen plates actually drop away from the coal. This tends to displace the long-pointed pieces that persistantly remain in the holes of screens of the usual type and that can only be removed by the use of a punching bar.

The plant illustrated is provided with columns 2 ft. square. The beams, both shaker frame and tipple floor, are 2 ft. deep and 1 ft. thick. At all junction points braces are introduced, being 2 ft. on a side and 1 ft. thick. The tipple floor is 4 in. thick.

Shaker-frame beams are reinforced for concentrated loading. Tipple floor beams are reinforced for general loading.

Columns generally have six ¾-in. square steel bars and ⅜ in. hoop steel. The two 42-ft. columns supporting the shaker frame and the tipple floor and also transmitting the shaker strains to the tipple-floor anchorage have nine ¾-in. vertical bars. The floors have ½-in bars placed on 6-in. centers and passing from beam to



Some Views of the Tipple of the Stearns Coal & Lumber Co., Stearns, Ky.

Design of Concrete Frame

Passing to the design of the concrete frame, a review of the column and beam dimensions reveals figures far above those used for bridge and building construction. In concrete we have the means to provide, at a reasonable cost, ample mass to withstand and counteract the strains set up by the periodic screen motion.

In addition to this structural advantage are those of freedom from fire, rust, decay and vibration and, as a consequence, no burden of insurance, paint and repair bills.

In getting ready for design, a thorough examination is made of the foundation material. For rock the columns are run to bottom with no change in their cross-section. For anything other than rock, a spread foundation is utilized, the area of this being determined by the nature of the material encountered.

beam. Longitudinal temperature bars are also used. The tracks are fastened to steel stirrups, that are cast into the concrete floor. A smooth surface is presented by eliminating ties.

At the dump, where two Philips kick-back dumps are used, the beams are 30 in. deep and the shock of the return of the dump is absorbed on a 6x6-in. white-oak beam 6 ft. long. The oak beam is removable for renewal. This effectively prevents the hammer blow of the dump affecting the concrete. Quick weighing scales are introduced on the load track. All loads come over one track, are diverted to one or the other dump, and when empty automatically seek their respective empty track.

Style of Screens

The screens have screening plates ¼ in. thick and by means of valves and delivery chutes can be set to give

any of the following sizes: 1-in. slack, 2-in. slack, 1- to 2-in. slack, 1- to 2-in. nut, 1- to 3-in., 2- to 3-in., any size round coal up to 6 in., any size block from 3 in. up, or run-of-mine with or without slack.

The suspension links are made in halves for ease in erection, and are provided with steel bushings. In these 3/8-in. steel rollers 4 in. long rest on steel pins 2 in. in diameter, that act as the stationary supports.

Connecting or pitman rods are made of hickory. A flexible point is obtained by reducing the cross-section of the rods to 1x6 in. at a point 12 in. back from the screen. No springs are used, as there is no shock at the end of the stroke.

It is obvious that the design lends itself to adaptation for drift, slope and shaft mining.

J. E. Butler, general manager of the Stearns Coal & Lumber Co., is to be congratulated in having the courage to face down the adverse criticism thrown at the structure during the construction period. Both he and the owners have since felt amply repaid for taking such a radical step.

The Associated Engineering Co., of Louisville and Somerset, Ky., control the rights under which reinforced-concrete shaker buildings, tipples and headframes and also short suspension shaker screens are manufactured.

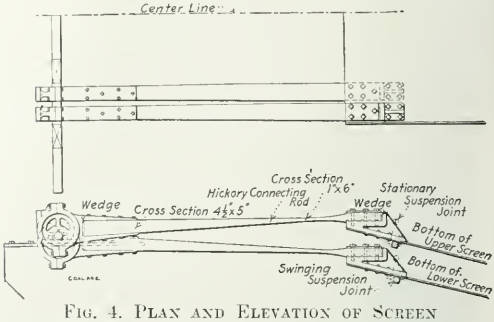


FIG. 4. PLAN AND ELEVATION OF SCREEN

They designed and built the plant illustrated in January and February, 1912, it being at that time, the first of its kind.

A New Mine-Rescue Telephone

SYNOPSIS—In mine-rescue work following a disaster there exists a strong need for a means of instant communication between the helmet party and the outside. This article describes a successful telephone equipment that does not in any way interfere with the oxygen apparatus.

The problem of devising ways and means for the protection of human life in mines is probably the most important question confronting the mining industry of today. The laws of practically every state in which mining operations are conducted, call for periodic inspections and contain many safety regulations, not the least of which in a number of states is a section making compulsory the installation of telephones underground.

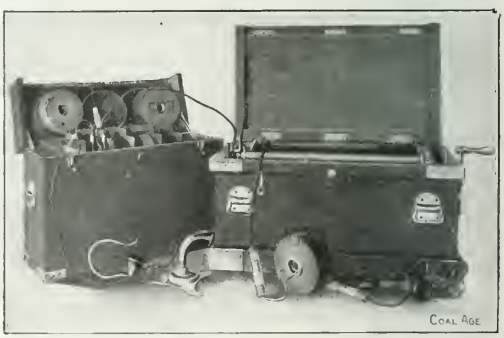
THE MANUFACTURERS KNEW THE CONDITIONS

During the past few years several thousand telephones have been sold and installed for use below the surface. The makers of these instruments were thus brought into intimate association with those interested in mine-safety work, and their attention was directed to the urgent need of some means of instant and continuous communication between an advance or rescue party equipped with its oxygen helmets and the rear party or that outside the mine. In the past, members of rescue parties have lost their lives where such loss could have been prevented by a quick and reliable means of summoning aid.

The demand for an equipment of this kind has been met by the Western Electric Co. in the production of light, serviceable and extremely simple telephone instruments for use in rescue work. In developing this apparatus the Bureau of Mines was frequently consulted, in order that every requirement for this severe service might be fully covered.

It is immediately obvious that a man wearing an oxygen helmet which effectually covers his mouth, cannot use the ordinary type of telephone transmitter. A special type, known as the throat transmitter, has been developed to meet this unusual condition. This instrument is light and compact and provided with a soft-rubber cup to adapt it to the curves of the throat.

This device has been found, by actual test, to transmit speech practically as well as the standard Bell instrument. Both receiver and transmitter are held firmly in position in such a manner that they will not interfere



COMPLETE SET OF INSTRUMENTS, INCLUDING REEL AND APPARATUS BOXES

with any type of oxygen apparatus now on the market. The telephone equipment used by the man at the outside or directing end of the line, is a standard switchboard operator's set, consisting of a chest-type transmitter and head-band receiver.

THE REARWARD CONNECTION

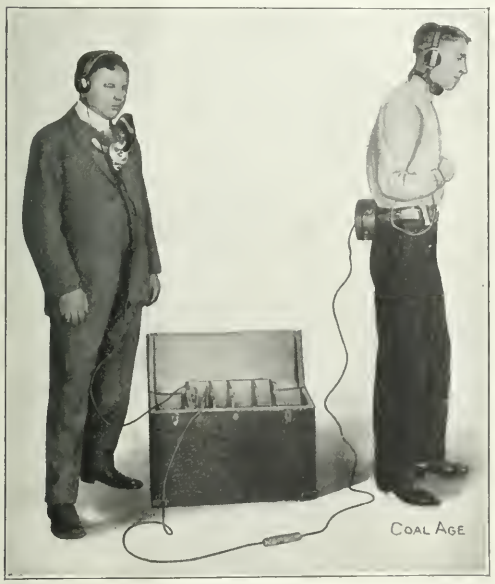
The rescue party is connected with the rear by means of a small wire cable, consisting of two copper conductors insulated with black enamel and two servings of silk, all of which is covered with a stout linen braid im-

pregnated with a moisture-resisting compound. This wire is in 500-ft. coils and is carried in a leather case fastened to the helmetman's belt, paying out as he advances.

As the coils are light, weighing less than 3 lb. each, several of them can be carried and as one is run out, another can be connected by means of a plug and jack combination. The wire is so wound that it cannot become tangled and will pay out in whatever position the rescuer may be obliged to assume. The total weight of telephone equipment carried by the helmetman, including one coil of wire, is only slightly over 5 lb.

One end of the coil is equipped with an aluminum-incased plug, which connects with the head receiver and throat transmitter by means of a similarly covered jack. The other end is equipped with a like jack connecting with a plug and cord running to a battery and apparatus box.

This box is an essential part of the equipment and



APPARATUS IN POSITION. NOTE THROAT TRANSMITTER

must be located at the point from which the rescue party is being directed. It contains eight dry batteries mounted in a Patterson screw-type battery holder, together with a key, two jacks and a battery gage, placed in a removable compartment. The operator's telephone set is connected to the apparatus and battery box by means of a cord, plug and jack. The key operates in two directions and has three positions, neutral, right and left. In the neutral position the batteries are in circuit; when operated one way the batteries are disconnected to save current when the apparatus is not in use, while in the other position the gage is connected across the battery terminals, so that the condition of the cells may be determined. It would be a serious matter after the rescue party had entered the mine to discover that the batteries were too weak for service.

HEAVY CABLE PROVIDED FOR SHAFTS

In many cases it may be found desirable to use cable for carrying the talking circuit down a shaft or into a slope or drift up to the edge of the danger zone. For this purpose a large box, including a cable reel, is furnished. This box is made of ash, heavily reinforced and provided with metal corners. It carries an aluminum reel holding 1300 ft. of specially strong and flexible twisted pair cable, having 30 per cent. pure para rubber insulation, the highest grade obtainable.

A heavy ratchet and pawl are provided to prevent the reel from turning, after enough cable has been paid out. Connections with the apparatus box and the coil carried by the helmet man are effected by means of an aluminum-incased jack and plug, while electrical contact with the inside end of the reeled cable is made through collector rings and commutator brushes connected to a jack.

This entire outfit has been designed and constructed with a view to providing practical and serviceable telephone equipment for mine-rescue parties. Service tests have proved that this object has been attained. This equipment should, therefore, be of incalculable benefit to those engaged in this work, which is at best hazardous.

Coal Trade at Marseille

Consul General A. Ganlin reports from Marseille, France, in the Consular Reports under date of May 28 concerning the coal trade at that point as follows:

The coal, coke and patent-fuel imports at Marseille during 1912 amounted to 1,470,158 metric tons, being practically equal to those of the preceding year. England furnished 1,101,816 tons, Germany 213,104 tons, and the United States 33,334 tons. The imports of American coal consisted of 15,911 tons of coke purchased by the aluminum factories of the Savoie district, 11,353 tons of steam coal, and 6070 tons of gas coal for the Marseille Gas Co.

An excellent market appears to exist here for American coke, although German competition is very keen in this line. The imports of gas coal have also given entire satisfaction and the inadequate transportation facilities and usually excessive freight rates are the chief obstacles to be overcome in order to secure transactions on a steady and profitable basis. There is always a limited demand for American steam coal in Marseille, but it is chiefly dependent upon industrial conditions in the British coal fields. Coal suitable for the manufacture of briquettes could also be sold in large quantities in this district. French coal is unsatisfactory in this respect, and certain grades of American coal could, in the opinion of competent authorities, replace most advantageously the products now used for this purpose.

The statement is made, in the Journal of the Chemical, Metallurgical and Mining Society of South Africa, that frozen dynamite or gelatin is very susceptible to fire and easily burnt. It no doubt often happens that the detonator, though failing to explode the frozen sticks of gelatin in the hole, will set them alight, thus causing a burnt-out hole, with the accompanying gases, bad heads and general discomfort to the workmen. A frozen stick of gelatin may also be the cause of a misfire accident, by remaining in the bottom of the hole unexploded, in its frozen state; but thawing out by the aid of the natural rock temperatures, and later being roughly disturbed by an auger when another hole is being drilled, it is fired and an unexpected explosion takes place.

Mine Inspectors' Institute, U. S. A.

By J. T. Beard

SYNOPSIS—The annual meeting of the Mine Inspectors' Institute of the United States of America was held at Birmingham, Ala. No papers were presented. The cordial reception of the citizens of the Iron City of the South contrasted strongly with the chilliness of the weather, which was phenomenal for the sunny South in June.

The Mine Inspector's Institute of the United States of America held its annual meeting, this year, at the Hillman Hotel, Birmingham, Ala., June 10-13. C. H. Nesbitt, chief inspector of Alabama, occupied the chair, and called on Culpepper Exum to make the opening address in which he welcomed the visitors to Alabama. To complete the expression of welcome, W. P. G. Harding, of the Chamber of Commerce, delivered an address on behalf of the city. .

Pres. Thomas K. Adams then delivered his address, an abstract of which follows:

The President's Address

This is the fifth annual convention of our Institute and we meet today under auspicious circumstances. We are, in common with all other classes of American citizens, enjoying the fruits of a prosperity never exceeded before in the history of our country, for which we should be thankful. We should feel proud of the fact, too, that in the rapidity of the accumulation of wealth no other nation has excelled us. Few nations can equal us in our enormous territorial holdings, which contain a practically inexhaustible supply of valuable minerals, capable of increasing to fabulous proportions our already acquired $119,000,000,000 of national wealth.

The coal-mining industry has kept step with the marvelous progress and development attained along all other lines of human endeavor. Sixty-three years ago there were produced 7,000,000 short tons of coal in this country, which increased to nearly 550,000,000 in 1912, and in the production of this enormous tonnage 750,000 persons found employment. While the product of the coal-mining industry is not of such large volume and value as compared with that of agriculture which amounts to nine and one-half billions of dollars, nor of the annual output of manufacturers, worth fifteen billions of dollars, yet, as mining men, we are justified in the belief that coal is king and that it is the most important pillar in the structure of the industrial life of this nation. When we realize that our country's industrial greatness has been rendered possible by the ingenuity, industry and organizing genius of our people, we have great reason for rejoicing with all other patriotic Americans.

The Mining Fatality Rates

Our industrial position, however, has been won at a great sacrifice of human life. In the year 1912, 2360 persons lost their lives in and about the mines of this country, or there were 3.15 deaths to every one thousand persons employed, which is 4.29 deaths to every one million tons of coal produced, which means that one person is killed for every 233,000 tons of coal produced. This is the best record we have had since the disastrous year of 1907, in which 690 persons lost their lives by mine explosions. While this record is better than it has been for the past six years it is still entirely too high.

We realize that the miner is engaged in a hazardous occupation, but we are equally agreed that many of the lives lost are an unnecessary sacrifice and not warranted by the hazard of the miner's occupation.

We, as mine inspectors, have greater opportunities for acquiring experience and an intimate knowledge of varied mining conditions and of the best means to eliminate the dangers incident to mine operations, than any other body of men. Furthermore, it is our duty as members of this institute, both in our individual and organized capacity, to blaze the way which will lead to the adoption of such precautionary and remedial measures as shall render the mines safer in the future than they have been in the past.

The people of this country have reason to expect that an organization of this character, composed as it is of experienced and intelligent mining men, will take the initative in securing such uniform and necessary legislation as will safeguard life.

This organization has power to accomplish much good if it has learned how to use that power effectively. If we have not been as potential or as effective in realizing the real purposes of our association, the failure is ours. By well directed efforts, earnest, united and enthusiastic work, we can make this institute a powerful agency for good or we can by our indifference make it a monumental failure. The Institute gives us a medium through which we can talk to the people of this country with a power not possible as individuals. We are also in a much better position to reach the governmental powers and obtain the enactment of reasonable and necessary laws. But these alone will avail us nothing, unless those concerned in the operation of the mines are forcibly required to obey them.

Possible Reductions in the Death Rate

Whenever the mining people of this country sincerely endeavor to eliminate 50 per cent. of the mine accidents they have the power and the knowledge to do so. This much desired result will surely come whenever the captains of the coal-mining industry find that the preservation of human life is a more valuable asset than large dividends; and, when the mine workers themselves have learned the lesson of obedience and found that their lives are more important than the acquisition of a high rate of wages. When this time comes the disastrous problems having such baneful results, will, in a large measure, be solved and eliminated.

We feel that we have good reason for encouragement because, with all our shortcomings, at no time in the history of the coal industry have greater efforts been put forth for the betterment of mining conditions in general with more laws enacted, and better enforcement of the same, than now. The dangerous elements incident to the mining of coal never were better understood; a better knowledge of mining was never so universally diffused and the mines have never been so intelligently managed

as at the present time, yet unnecessary accidents happen, many of which are of great magnitude.

Along with our wonderful progress and development in mining many more dangers have arisen. This is largely due to the introduction of a multiplicity of machinery together with dangerous powers, into the mines, and the inordinate desire to obtain big things by concentration of productive units, thus effecting greater economies. In addition to this there is the great haste of the working men striving to secure a larger tonnage and greater efficiency; this attempt, with the large numbers of unintelligent and unskilled men now employed in the mines of the country accounts for the disastrous results that have followed. In view of such facts much work remains to be done by the mining classes and especially by the mine inspectors before conditions can be secured in the mines that will better safeguard life and reduce the death rate to the proper minimum.

Those of us who had not the experience in the mines of this country before effective mining legislation was enacted can hardly imagine the great improvements in the sanitary conditions of the mines. In fact, we have been creditably informed that such conditions in the large, well regulated mines of this country are unexcelled by those in any other country. While it may be regarded in some quarters that human life is held very cheaply, especially that employed in the mines, yet, were all the adverse conditions with which we have to contend well understood, our death rate would bear a much more favorable comparison with other countries.

Responsibility of the Inspector

Institutions of this character are an absolute necessity in this country. It is the opinion of nearly all intelligent men now, that in order to accomplish the best results in any enterprise, whether of a political, social or industrial nature, success can be attained only through organized effort. We live in an age of organization.

If organization is necessary along political lines and indispensable to secure the general social uplift of society, it is certainly as necessary to the accomplishment of industrial freedom and the betterment of the working conditions. Hence good results will be accomplished through our unified, independent, unrestrained and well directed efforts.

You as mine inspectors deserve well of your state governments. No men in the service have proved themselves to be more efficient or more faithful to public duties; duties well and intelligently performed and done under adverse conditions. Your compensation for the kind of services you render, the hazards taken, and the uncertainty of employment, with no provision made by the state for your future, all show the recompense is shamefully inadequate. The great services you have rendered the state in the past, done silently and unostentatiously, putting into motion with missionary zeal forces having in view the common good of the mine workers, have had splendid effects. These may not have been done in such a demonstrative and spectacular manner as is often the case, yet we know of no single agency in the government service or otherwise that has accomplished more for the real betterment of mining conditions in general than has been done by the organized and unorganized efforts of the humble mine inspectors of this country.

Sessions and Entertainment

It was decided at the meeting that in future the papers about to be read before the Institute be published in pamphlet form before that body convenes so that the discussion will be less extempore than would otherwise be the case.

In the afternoon, in addition to a session for discussion, automobile rides were arranged for the visitors by their hosts. The trip led them to the Highlands, over Mountain Terrace, Cliff Road, and across town to Norwood and then to Fairfield.

In the evening a smoker was given at the Hotel Hillman, while the lady visitors were entertained at the theaters. The weather was ideal for automobiling and the visitors coming mostly from the North and West found the sunny South all that could be desired.

Thursday was wholly devoted to a most enjoyable and instructive trip, which consisted of a 40-mile junket around Docena, Ensley, Edgewater and Bay View. During this trip the members of the Institute and their friends were the guests of the Alabama Coal Operators' Association and the Tennessee Coal, Iron & Railroad Co. The mines and steel mills of the company were visited, and the members were further entertained and refreshed by a barbecue in the woods skirting the lake, and a baseball game between the company team and that of the Jefferson Powder Company.

The T. C., I. & R.R. Co. is to be sincerely congratulated on the success of their efforts to establish and maintain the goodwill and coöperation of all their employees. This has been accomplished, in a remarkable degree, by the untiring efforts and a generous expenditure of funds by the company, in order to give to its employees every advantage of education, physical culture and entertainment. All the camps visited displayed to a marked degree the determination of the company to leave no stone unturned that would assist in maintaining pleasant and profitable relations between employer and employed.

The Institute held a session the same evening, at which time the important question of the use of mixed lights in gassy mines was discussed. The annual election of officers then took place, which resulted in the choice of the following: David J. Roderick (Penn.), president; John Dunlop (Ill.), first vice-president; J. B. McDermott (Mont.), second vice-president; Thomas Morrison (Ohio), third vice-president; J. W. Paul (Penn.), secretary; R. S. Wheatley (Ohio), assistant secretary; R. Y. Muir (W. Va.), treasurer; and J. T. Beard (New York), editor-in-chief.

A brief session was held Friday morning, at which time the following resolution, among others, was adopted:

RESOLUTION

Following an interesting and prolonged discussion of the methods employed in different states, for the selection of mine inspectors, the Mine Inspectors' Institute, U. S. A., in session June 11, 1913, at Birmingham, Ala., unanimously adopted the following:

Resolved—That in view of the nature of the duties imposed by law upon all state mine inspectors, requiring him to act as agent for the state; and because the upright and conscientious performance of those duties often calls for the fearless, unprejudiced and unhampered exercise of an inspector's best judgment and convictions, in the face of threatening opposition of either operators or miners or both: Therefore be it

Resolved—That it is the sense and deliberate opinion of the members of this Institute, that the incumbent of the office of state mine inspector should be, as far as possible,

removed from any influence that would tend to warp his judgment, or embarrass his conclusions, or in any manner delay his action in the interest of safety and security of mining operations under his direct supervision; and further,

Resolved—That, in securing this end, it is the unqualified opinion of this body that the elective system as applied to the selection of state mine inspectors should be condemned unreservedly and abolished. In conclusion be it further,

Resolved—That due publicity be given this action by wide-spread notice in the public press and mining journals, so as to bring it prominently before state legislators and governors, in the hope that such laws may be wiped from the statute books where they exist in any state, or may be killed if contemplated.

By vote of the members present, the next annual meeting of the Institute will be held at Pittsburgh, Penn. It is the purpose of the mine inspectors of Pennsylvania to make this meeting a memorable one in the history of the Institute

Among those who attended the convention were: Charles H. Nesbitt, David Kelso, Frank Hillman, Thomas Roscoe and Mr. Hillhouse, all of Alabama; Thomas K. Adams, Thos. D. Williams, D. J. Roderick and P. G. Moore, all of Pennsylvania; James Martin, L. D. Vaughn, L. B. Holliday, Frank E. Parsons, Arthur Mitchell, R. Y. Muir and H. H. Pinkney, all of West Virginia; George E. Sylvester and John Rose, of Tennessee; F. I. Pearce, of Indiana; Hector McAllister, John Dunlop, Oscar Cartlidge, Thomas Little, W. S. Burris, Thomas P. Back, Martin Bolt and Thomas Moses, all of Illinois; J. D. McDermott, of Montana; J. W. Paul and E. R. Sutton, Federal Bureau of Mines; R. H. Beddow, of New Mexico, and J. T. Beard, senior associate editor, "Coal Age," New York.

Messrs. Bolt, Moses, Burris, Martin, Mitchell, Parsons and Vaughn were accompanied by their wives.

A New Mining Lamp

Ever since the introduction of the incandescent bulb upon a successful commercial scale, it has been the desire of many mining men to utilize this means of illumination in the miner's cap lamp.

Despite the fact that the old oil lamp is both reasonably cheap in first cost and operation, it leaves, nevertheless, much that is to be desired in the quality and steadiness of its illumination. Many experiments and trials have been conducted, therefore, in the attempt to produce a satisfactory and successful electric cap lamp.

Heretofore, practically all of the electric devices of this kind which have been placed upon the market have been of the storage-battery variety which require several hours each day to charge.

After years of experimentation and development, the Maxivolt Primary Battery Co., of 200 Fifth Ave., New York City, will shortly place upon the market their new electric mining lamp, known as the "Bulldog." This is claimed to be the lightest, most compact and most convenient apparatus of this kind ever placed before the mining industry.

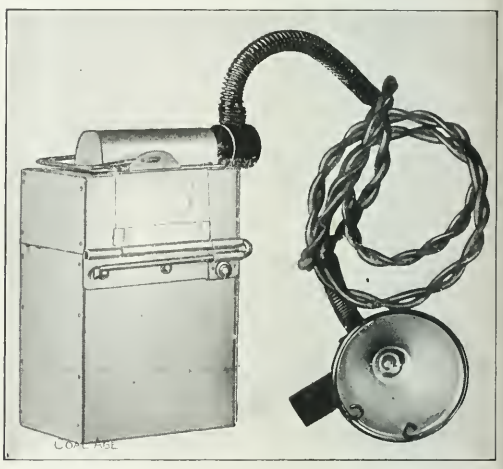
This device is a rather radical innovation in the electric mining-lamp field. It consists of an aluminum-incased primary battery which is carried on the belt. This battery requires a small amount of liquid electrolyte and a small zinc bar about the size of a lead pencil for each day's work. When thus charged, it will deliver a current of 10 amp. at 1.6 volts for 10 hr., producing a steady, clear, unflickering light of 2 cp. throughout the entire period.

The cap lamp proper is a small incandescent bulb carried in a concave reflector which is attached to the miner's cap in the ordinary manner. A carefully insulated double cable leads from the lamp back over the cap and down to the battery upon the miner's belt. At the point where this cable is subjected to the greatest flexure, it is protected by an open coil spiral spring for a distance of approximately 6 in. This prevents the cable from kinking or doubling short with consequent injury to the insulation.

By removing the cable and inserting the lamp reflector direct into the socket of the battery an extremely simple and efficient hand lamp is produced.

This device possesses many advantages which may not be immediately apparent upon a casual inspection. The battery case being made of cast aluminum is light, durable and strong. All connections are efficient but exceedingly simple. No skilled labor is required for recharging the batteries and no generating machinery is necessary at the mine where these lamps are employed.

According to the specifications of the Bureau of Mines, a battery attached to a lamp should not have a short-circuit current of more than 50 amp. at 2½ volts. The maximum short-circuit output of this battery is 18 amp. at 1.6 volts. Assuming that 50 amp. at 2½ volts is just sufficient to produce a gas-igniting spark, it may be clearly seen how remote is the possibility of such an occurrence with a battery of the current strength described above.



Car Lamp and Aluminum-Incased Primary Battery

The electrolyte used in this battery is harmless and inexpensive and cannot be spilled from the container under ordinary conditions. Both this and the necessary zinc electrodes may be purchased in quantities at small cost. Experiment has proved that this device will give a continuous light of 2 cp. for 10 hr. with an expense not exceeding four cents.

Don't ever cause anyone to receive an electric shock.

Don't think that it is smart to get an electric shock. Every time a man gets a shock it shows lack of care and knowledge.

Don't be ashamed to be careful. You owe this not only to yourself, but to others who may follow your example.

Don't handle wires or electrical apparatus of any kind unless you are told to do so.

Don't get off or on trips from the trolley-wire side.

Don't carry tools on your shoulder when crossing under the trolley wire, or when traveling in the same entry with it.

EDITORIALS

The Danger of Banked Fires

At many mining plants, particularly those of small operations, it is a common practice to bank the fires over night or during periods of light load. This may or may not be a dangerous custom, depending upon the manipulation of doors, dampers and drain pipes.

When green coal is first placed upon the fire, it passes through a process of distillation, the volatile combustible matter being driven off by the heat from below. If the gases thus evolved are not burned upon formation and are not swept away by a circulation through the furnace, they may form with the air present an explosive mixture, which only requires a tiny tongue of flame or a spark to ignite.

The violence of the explosion following an ignition of this kind, or the damage which may result therefrom, depends not only upon the proportion of the gas-and-air mixture, but also upon how thoroughly this mixture is confined within the setting walls. It is seldom that such an occurrence wrecks the brickwork, but it may be, and frequently is, sufficiently forcible to be dangerous, or even fatal to the firemen or other attendants who may be in the proximity of the doors when they are blown open.

When a fire is banked, and doors and damper are closed, the water-column drain or any other steam or hot-water pipe leading into the ashpit should never be opened. Such a procedure forces air through the grate bars and fire bed with more or less violence, and, with the proper mixture of air and gas in the passages and combustion chamber of the boiler is almost certain to result in an explosion of this kind.

It is the part of wisdom, therefore, to never blow down water columns of gage glasses (presupposing that these drains terminate in the ashpit) when the fire is banked. It is better still to make it an infallible rule never to bank the fire when the chimney damper is entirely closed.

The Financial Outlook

An unmistakable and uniform depression in securities has developed possibilities which are too potent to be ignored. As in the famous panic of 1907, the slump is due essentially to an over-straining of the world's financial reserves, but the cases are not parallel because the present depression has been anticipated to a greater or less degree. Close students of conditions have noted for some time that the investment markets have been congested to such an extent that even old-line standard securities of the most reputable kind could be sold only with difficulty. A notable example of this was the recent flotation of 27 million dollars worth of eight-months' notes, by the state of New York, on an interest basis of about 4.87 per cent. These issues are regarded among the most conservative investments obtainable and heretofore have commanded a substantial premium on an interest basis of 4 per cent.

In the coal industry itself, the money stringency has had the effect of bringing about a rigid restriction in new development. For more than a year it has been well known that some of the most powerful companies in the country have been hard pressed for funds, especially those contemplating extensive new work. While this has naturally caused some temporary embarrassment to those affected, it has perhaps been beneficial to the permanent interests of the trade since it has discouraged the increase of our already excessive capacity.

Apparently, the effect of the tight-money situation has not yet reached the coal markets. Whether it ultimately will do so is a question yet to be solved, and is, of course, dependent on the duration of the present conditions; although, as a fact, the coal trade has seldom been in such a strong position at this season of the year. Shipments in all the principal mining regions are exceedingly heavy and limited only by the labor supply, while prices are unusually buoyant and display a strong rising tendency. The consumption is large and well distributed among the various branches of industrial activity, so that a recession in any one department (as now seems to be impending in steel) should not have any serious effect on the trade as a whole.

Returning again to the money situation, it is interesting to review some of the causes that have led up to the present conditions. The trouble, no doubt, originated with the European wars, although these alone could not have developed such an acute situation as now prevails. Following this came the uncertainty, in this country, because of the tariff revision, and more recently the appointing of receivers for the defunct St. Louis & San Francisco R.R. At about this same time an abnormally heavy flotation of government, state, municipal and corporation securities appeared, which congested the markets and made it clear that credits were over-strained. Notably among these was the announcement of an impending issue of 56 million dollars of German and Prussian government bonds. Since it is mandatory on the German bankers to subscribe for government securities, the necessity of providing the required funds resulted in a heavy liquidation of American issues and was probably the cause for the recent spectacular slump in the Canadian Pacific stock.

Thus it appears that the trouble is due to a combination of untoward and unforseen conditions. The result has been to cause a general retrenchment and establish business on a more equable and sound basis. It has also brought a renewed feeling of confidence, because of the strong resistance offered to a series of conditions that would, on other occasions, have resulted much more seriously. Secretary McAdoo's announcement that the government is prepared to make loans to the extent of 500 million dollars, under provisions of the Aldrich-Vreeland act, had an immediately stimulating effect upon all securities. This removes any possibility of a tight money market when the crop movement starts and has materially relieved the situation generally.

The Sherman Act

We imagine that everyone was grieved to learn that some over-zealous government official was endeavoring to apply the Sherman Act to remedy the evils in the Paint and Cabin Creek districts. The most unfortunate feature is that there is only too much hope that the prosecution may be successful. The public is not in sympathy with any attempt to restrain the formation of unions in places where wages are not equal to those in other industries or even in other centers of the same industry. It will be thought peculiarly reprehensible that such an attempt has been made in West Virginia.

We are not sanguine that any great increase of wages will result from any action of the United Mine Workers of America, still less from the violence of the irresponsible Industrial Workers of the World, but we believe that an attempt to penalize the formation of a union will result solely in the passage of an amendment removing labor organizations and agricultural associations from the operation of such organic law.

The country needs this weapon of defense against attempts like those made abroad to tie up the labor market for purely political reasons, to obtain class legislation or to reinstate some union man whose discharge is dictated by the welfare and safety of the public. This defense is not to be used to victimize men who only seek to procure equal rates of pay with those customary elsewhere.

If any charges are to be made, let them be that the union has promoted violent attacks on the majesty of the law. We do not know whether such charges could be proved, but if they cannot, the courts should not be asked to convict men whose acts could not be proved unlawful and contrary to public advantage.

We are inclined to believe the Union is not in bad hands. Perhaps our judgment is in error, but we are disposed to feel that even in the anthracite region, the will to break contracts is more marked among certain irresponsible miners and inferior organizers than among those who are the head and front of the organization. Certainly the Union is only impatiently tolerating the evil and not encouraging it.

We cannot believe that if both labor representatives and capitalists are proved to have conspired to unionize and raise wages that the public will be disposed to condemn either for that action. Only those whose consummate blindness to public opinion has caused the present trouble could be bewildered enough to overlook the fact that the whole United States is in a league of sympathy with the Union in the present attempt to secure recognition. Whether the miners are getting a living wage or are paying too much for their necessaries of life, whether the mine guards did or did not violate the laws of the state or of common humanity, are points far more debatable.

But while we believe the operators should permit and not attempt in any way to restrain the formation of a union, we do not feel disposed to put the blame upon them of having caused the declaration of martial law. It was not unreasonable for Mr. Glasscock, who was then governor, to advise a recognition of the Union, as we are now doing, but it is distinctly unfair to blame the operators for all these troubles if the only crime they have committed is that of failing to acknowledge the Union. Recognition is not obligatory by law or by moral considerations, but we confess the right to form a Union is a fundamental property of all men and should not be abridged until the powers thus acquired are arbitrarily exercised to the disadvantage of the commonwealth or to the peril of the public.

In 1834, a group of men, known since as the "Six Men of Dorset," were sentenced to seven years' penal servitude for asking unitedly for an increase in wages of one English shilling a week. Fifty thousand men marched to demand their release. In 1912, a monument was raised to these early martyrs of industrial oppression. We thought the matter settled years and years gone by, and that the prison ship "Success" sailed into New York harbor this summer, to hail the fact that such crimes had long ceased. But the proof has all to be demonstrated again that the Caucasian race does not consider it to be a conspiracy to seek with others or for others an increase in pay.

Mark the Piping

Around mining power plants it is not common to find the various piping systems marked or designated in any way. Aside from the circumstances that the live steam pipes are frequently covered with asbestos or magnesia, and that water-supply pipes are sometimes made of cast iron, the person unfamiliar with the intricacies of the piping system is at an utter loss to know which conductor carries steam, water or air.

In time of excitement, emergency or accident, even the best of engineers and firemen are liable to become confused; but on such occasions the "greenest man" about the place should not be obliged to hunt around and trace out the logical course of the steam in order to ascertain which valve to close or open to relieve the situation or, perhaps, prevent loss of life.

Various color schemes have been tried and adopted at different plants, any of which are better than no designation whatever, but each leaving much to be desired. Not only are the various colors employed unintelligible to the novice, but they utterly fail to show the direction in which the fluid carried normally flows.

By stenciling upon each pipe at suitable intervals legends stating both the contents and its direction of travel, there need be no confusion as to which particular pipe carries steam and which carries water or air. Such a system of stencils could be easily designed and cut from paper or tin either in the company's drafting room or in the power plant itself. The main steam header as it leaves the boiler room might well be marked "Live (or high-pressure) Steam to Power Plant" followed by an arrow pointing the direction of flow. The same pipe entering the engine room would be marked "Live Steam from Boiler Plant" again followed by the index arrow.

It is, of course, possible that under the ordinary conditions of everyday operation, such a system as above described would have comparatively little utility. But in times of emergency, disaster or danger, the most easily comprehended layout of piping ever devised, if unmarked, can be readily misunderstood and mismanipulated. It frequently happens, also, when human life depends upon the prompt closing or opening of a certain valve, that he who blunders, blunders but once.

EXAMINATION QUESTIONS

Miscellaneous Questions

(*Answered by request*)

Ques.—(a) How many gallons of water will be contained in a sump 8 ft. wide, 90 ft. long, and 10 ft. deep? (b) How long will it take a pump discharging 80 gal. of water per minute to empty this sump?

Ans.—(a) The cubical contents of this sump is $8 \times 90 \times 10 = 7200$ cu.ft. Its capacity is, therefore,

$$\frac{7200 \times 1728}{231} = 53{,}860 \text{ gal., nearly}$$

Approximately the same result is found by multiplying the cubical contents by 7.48, since 1 cu.ft. contains 7.48 gal. of water. Thus, $7200 \times 7.48 = 53{,}856$ gal.

Ques.—An engine developed 60 hp., as shown by an indicator card taken when the engine was pulling a load of 3 tons up a shaft 148.5 ft. in depth, in 30 sec. Neglecting the friction of the load or hoist, what is the efficiency of this engine?

Ans.—Disregarding friction, the work performed in each hoist is $3 \times 2000 \times 148.5 = 891{,}000$ ft.-lb. Since this work is performed in 30 sec., or ½ min., the work performed per minute is double this amount, or 1,782,000 ft.-lb. The effective horsepower is then, $1{,}782{,}000 \div 33{,}000 = 54$ hp. The efficiency of the engine, in this case, is

$$K = \frac{54 \times 100}{60} = 90 \text{ per cent.}$$

Ques.—Find the safe working load of a ¾-in. extra-strong, cast-steel hoisting rope, having six strands and nineteen wires in each strand.

Ans.—The breaking load of a 1-in. extra-strong, cast-steel hoisting rope of six strands and nineteen wires is 39 tons. Then, since the load a rope will carry varies as the square of the diameter of the rope and using a factor of safety of 5, the safe working load for a ¾-in. rope of this kind is

$$L = \frac{39\,d^2}{5} = \frac{39 \times 0.75^2}{5} = 4.39 \text{ tons}$$

Ques.—The belt wheel on a dynamo is 2 ft. in diameter and should be run at a speed of 600 r.p.m.; the belt wheel on the engine is 14.5 ft. in diameter. At what speed must the engine run to produce the required speed in the dynamo?

Ans.—The speed of two belt-connected wheels, disregarding any slip of the belt, varies inversely as their diameters. In other words, the speed ratio is equal to the inverse diameter ratio. In this case, calling the required speed x

$$\frac{x}{600} = \frac{2}{14.5}$$

$$x = \frac{600 \times 2}{14.5} = 82.75 \text{ r.p.m.}$$

Ques.—What precautions are necessary in the installation, use and operation of electricity in mines, to safeguard the employees and preserve the property?

Ans.—The bituminous-mine law (Art. 11), specifies clearly and in detail the requirements in regard to the installation of electricity in mines. When electricity is to be installed in a mine, the work should be in charge of an electrician who is competent and familiar with the requirements of the law. The principal precautions to be taken relate to the size and power of the electrical apparatus, the insulation of the wires, the limitations of voltage to be used for different purposes, the proper grounding of metallic coverings, frames and bedplates of generators, transformers and motors, and the proper arrangement of switchboards and other necessary apparatus, and the safeguarding, by suitable means, of all places where men or animals are liable to come in contact with live wires. As far as practicable, power lines should not be installed on traveling ways and suitable danger signals should always be placed at points where these wires are exposed. The wiring should be such as to avoid, as far as possible, the risk of the ignition of gas by sparking, or the ignition of timber or other combustible material, by the short-circuiting of wires.

Ques.—How many horsepower will it take to pull a trip of 20 loaded cars up an incline 400 ft. long, in one min.; the weight of coal in each car being 3000 lb., and the weight of each empty car 900 lb.; the resistance of the rope and pulley being 13 per cent. and the grade 7 per cent.?

Ans.—The weight of the loaded trip is 20 $(3000 + 900) = 78{,}000$ lb. The inclination being small, the pull on the rope, due to the weight of the loaded trip on the incline, is found by multiplying the weight of the loaded trip by the percentage of grade; thus $78{,}000 \times 0.07 = 5460$ lb. To this must be added 13 per cent. to cover the resistance of the rope and pulleys; thus, $5460 \times 0.13 = 709.8$, say, 710 lb. This makes the total pull on the rope, due to the weight of the loaded trip on the incline and the resistance of the rope and pulleys, $5460 + 710 = 6170$ lb. Since this pull is exerted through a distance of 400 ft. in one min., the work performed is $6170 \times 400 = 2{,}468{,}000$ ft.-lb. per min. The effective horsepower is, therefore $2{,}468{,}000 \div 33{,}000 = 74.8$, say 75 horsepower.

Ques.—The anemometer makes 120 r.p.m., in an airway that measures 8 ft. 6 in. at the top, 10 ft. 6 in. at the bottom, and is 7 ft. high; what is the quantity of air passing per minute?

Ans.—The section of this airway is a trapezoid. Its average width is one-half of the sum of the widths at the top and bottom of the airway, respectively; or 9 ft. 6 in. = 9.5 ft. The area is then $9.5 \times 7 = 66.5$ sq.ft. The anemometer is calibrated so that one revolution of the vane corresponds to 1 ft. of air-travel, and 120 r.p.m. indicates a velocity of 120 ft. per min., in the air current. In ordinary mining practice, it is not customary to make any correction of the anemometer reading; but this is taken to indicate the actual movement of the air, in feet. Assuming this is an average velocity of the air current, the quantity of air passing in this airway is $66.5 \times 120 = 7980$, say 8000 cu.ft. per min.

DISCUSSION BY READERS

Textbooks in Mining Examinations

Having read a few of the interesting and instructive letters that recently appeared in COAL AGE, in regard to education in coal mining, I want to say that I do not favor allowing candidates the use of textbooks in any examination held for the purpose of determining their proficiency to act as mine foreman or fireboss.

I have two good reasons for my opinion:

First, if a person is anxious to pass the examination and to obtain a certificate making him eligible for appointment as mine foreman or fireboss, he should be willing to give a part of his time to learn the most common formulas relating to haulage, drainage and ventilation.

Second, if textbooks were allowed candidates in examinations, the man who had a fairly good college education and knew nothing about mining practically would have a better chance to pass the examination than the practical mining man who had only a fair education but understood mining from a practical standpoint.

It is claimed by those who advocate the use of textbooks that many good mining men fail to pass the examination because they are unable to memorize the formulas required. I believe all mine foremen should be able to memorize the simple and common formulas used in mining problems. Only such questions as are considered thoroughly practical should be given.

In order to illustrate what in my opinion is not a practical question, I will quote the following question, which was given at a mine foreman's examination a few days ago.

A lever 15 ft. long is used to lift a wagon of three tons' weight. The force exerted on the end of the lever is 200 lb. Find the position of the fulcrum, neglecting the weight of the lever.

I consider this not a practical question, because not a mine foreman in existence would take the trouble to figure out the position of the fulcrum in such a case, but would proceed at once to lift the car on the track as easily as possible. The position of the fulcrum would be governed by the available power and other conditions close at hand.

Conditions re Cincinnati Mine

I have read with interest the article* by John Verner, referring to conditions in the Cincinnati mine.

Mr. Verner refers there to the increased circulation provided later in this mine, as contributing directly or indirectly to cause the explosion. A new fan had been later installed at the Cincinnati mine, and the volume of the air current was thereby increased to 120,000 cu. ft. per min. According to his statement, Mr. Verner believes that this increase of air had a tendency to cause the explosion. I note also that Mr. Hutchinson, referred to in the same article, is quoted as saying that the slowing down of the fan when exhausting had the effect of increasing the pressure throughout the mine and this increased pressure checked the inflow of gas for a time.

My experience has always been the reverse of what is here claimed; namely, when the fan was slowed down, more gas was released and found its way into the mine. My maxim has always been "Keep a good circulation going and conduct the air right to the working face. If anything goes wrong with the fan, withdraw the men at once."

Referring to mine operators and owners, permit me to say that I believe they have done and are doing all that lies in their power to eliminate accidents in and about the mines. The remainder is up to the mine foremen, firebosses and other assistants. These men know the law and should see that it is fully carried out. If this is done, great results may be expected. Impress upon every mine worker the importance of living up to the law, and I believe this will have a great tendency to reduce mine accidents. I wish COAL AGE good luck in the work it has undertaken.

THOMAS STOCKDALE,
Vivian, W. Va. Fireboss.

[In order to avoid confusion of ideas and unnecessary questions and explanations, we would draw attention to the fact that if the fan is exhausting air from the mine, the mine is ventilated under a pressure below that of the atmosphere, and when the fan is slowed down, the mine pressure is increased to that of the atmosphere, which would cause the outflow of gas into the mine to diminish.

On the other hand, if the fan is blowing air into the mine, the mine is ventilated under a pressure above that of the atmosphere. In this case, if the fan is slowed down, the mine pressure falls and the outflow of gas from the strata into the mine is increased. The statement in regard to the outflow of gas from the strata, therefore, depends on whether the fan is exhausting or blowing.—ED.]

Conditions Then and Now

I was much interested in reading the article, COAL AGE, May 31, p. 855, relating to the conditions 10 years ago as they existed in bituminous mines. At that time, most, if not all, of the bituminous mines in Pennsylvania were at or above the drainage level, and, in most cases, extended only a few hundred feet from the outcrop, with a small amount of cover. When pillars were drawn, the overlying strata naturally broke to the surface, permitting the free escape of any gas from the strata. Mines worked under these conditions naturally require the circulation of less air under a low water gage.

At the present time, many of the mines have penetrated the hills to a great distance; and, in some cases, the workings lie far below the drainage level. The worked-out and abandoned areas have also greatly increased in size. As a consequence, a larger amount of gas is given off in both the old and new workings, and pockets of gas

*Coal Age, May 31, p. 855.

are liable to be tapped by the live workings. A larger number of men are employed and a greater amount of explosives used in blasting the coal. These conditions require a larger amount of air to be circulated in the mine. To maintain the circulation of a larger air volume through longer airways requires a greater ventilating pressure than was formerly necessary.

The mining machines so largely used in mines of the present day produce more fine dust than was formerly made in pick mining. The improvements in mining to which I have referred have therefore added at least three dangers that did not formerly exist to the same extent; namely, the high velocity and pressure of the ventilating current, and the fine coal dust produced in machine mining. I believe, as has been pointed out, that the explosion of gas, or a blownout shot, causes a greater disturbance of the air under a high ventilating pressure, and more dust is thrown into the air current and carried further because of the high velocity of the air.

In my opinion, all mines where explosive gas is liable to be encountered should be worked exclusively with approved locked safety lamps and the miners thoroughly instructed in the use of same. Only permitted explosives should be used for blasting and all places should be examined before a shot is fired.

BENJAMIN HARTILL.

Johnstown, Penn.

Explanation

My attention has been attracted to an article on "Calculating Electrical Currents," COAL AGE, May 31, p. 857. Inasmuch as this inquiry comes from Michel, B. C., and is signed "Electrician," it might be taken as emanating from me, since I am the electrician in charge of the electrical plant of the Crow's Nest Pass Coal Co., at this point. I desire to state that the question submitted to you was not sent by me.

A. R. STACEY, Electrician-in-Charge,
Crow's Nest Pass Coal Co.

Michel, B. C., Canada.

[The inquiry referred to above came from one of our subscribers at Michel, who is interested in the study of electricity and, as the sender did not wish his name to appear, we signed the inquiry "Electrician," as is commonly done in such cases. A simple, clear answer was given to the question, as it relates to direct current, which the comparatively low voltage would warrant us in assuming. We think our present correspondent should give himself no uneasiness, owing to the simple nature of the question; as one capable of assuming charge of an electrical plant would not naturally ask for such information, and the term "electrician," as here used, refers only to one interested in electrical matters. We are glad, however, to give space to the above explanation.—ED.]

Study Course in Coal Mining

BY J. T. BEARD

The Coal Age Pocket Book

FLOW THROUGH CONDUITS

The flow of fluids (air, water, etc.) through conduits of any kind is governed by the same laws as the flow through orifices, previously explained. The flow is caused by a certain head or pressure, which overcomes the resistance due to friction in the conduit and creates the velocity of the flow.

Bernouilli Theorem—The law established by Bernouilli applies alike to the flow of all fluids. The principle of this law may be briefly stated as follows: In the flow of all fluids, the algebraic sum of the gravity or pressure head, the resistance head and the velocity head is zero.

The gravity or pressure head always acts to produce the flow and is therefore positive (+), while the other two heads, the resistance and velocity heads, each acts to oppose the flow and these are therefore negative(—). Hence, the law that governs the flow of fluids may be stated simply as follows: The sum of the friction head and the velocity head is always equal to the gravity head.

Formulas Expressing Flow—The following formulas are necessary to express the flow in pipe conduits. It is important in combining formulas to reduce the elements to the same denomination. Let

H = total head producing flow (ft.);
h_v = velocity head (ft.);
h_f = friction head (ft.).

Then
$$H = h_v + h_f \qquad (1)$$

Formula for Velocity Head—The formula expressing the portion of the head absorbed in producing a given velocity is developed as follows: Let

g = value of gravity (ft. per sec.);
v = velocity of flow (ft. per sec.),
Q = quantity of flow (cu.ft. per min.);
G = discharge from pipe (gal. per min.);
d = diameter of pipe (in.);
a = area of pipe (sq.ft.).

Velocity due to head h,
$$v = \sqrt{2gh} \quad ft.\ per\ sec. \qquad (2)$$

Head producing velocity v,
$$h = \frac{v^2}{2g} \quad ft. \qquad (3)$$

Quantity of flow,
$$Q = 60\,av \quad cu.ft.\ per\ min. \qquad (4)$$

Area of pipe,
$$a = \frac{0.7854\,d^2}{144} \quad sq.ft. \qquad (5)$$

Discharge of pipe,
$$G = \frac{1728\,Q}{231} \quad gal.\ per\ min. \qquad (6)$$

Combining these equations gives the following:

Velocity head,
$$h_v = 0.0026\frac{G^2}{d^4}\,ft. \qquad (7)$$

Example—What portion of the head will be absorbed in producing the velocity only, when a 3-in. pipe is discharging 200 gal. of water per minute?

Solution—
$$h_v = 0.0026\frac{200 \times 200}{3 \times 3 \times 3 \times 3} = 1.28\,ft.$$

The Coal Age Pocket Book

Friction in Conduits—The frictional resistance of conduits is due to the rubbing of the fluid on the inner surface of the conduit, which is called the "rubbing surface." The amount of friction developed depends on three factors: the extent of rubbing surface (s); the velocity of the current (v); and the coefficient of friction (f), as expressed by the formula
$$R = fsv^2$$

Pressure Equals Resistance—The pressure producing flow in a pipe conduit is the total pressure (pa) exerted on the entire sectional area of the pipe, and is always equal to the resistance it overcomes; or R = pa, and therefore,
$$pa = fsv^2$$
and
$$p = \frac{fsv^2}{a}$$

Formula for Friction Head—If the length of the pipe is l, in feet, and its diameter d, in inches.
$$\frac{s}{a} = \frac{l\pi\left(\frac{d}{12}\right)}{\frac{\pi}{4}\left(\frac{d}{12}\right)^2} = \frac{48\,l}{d}$$

But, the head corresponding to a given pressure is found by dividing that pressure in pounds per square foot, by the weight (w) of 1 cu.ft. of the flowing medium (water = 62.5 lb.). Making these substitutions in the above formula for pressure, and reducing gives finally for the pressure or friction head (assume f = 0.01)
$$h_f = \frac{flG^2}{8\,d^5} = \frac{lG^2}{800\,d^5}$$

Discharge of Pipe Line—In a pipe line, the quantity of water discharged depends on the gravity head (h) and the length (l) and diameter (d) of the pipe. Since the gravity head is always equal to the sum of the velocity head and the friction head; or $h = h_v + h_f$, we write
$$H = 0.0026\frac{G^2}{d^4} + \frac{lG^2}{800\,d^5} = \frac{G^2}{d^4}\left(\frac{2.08\,d + l}{800\,d}\right)$$
$$G = d^2\sqrt{\frac{800\,dh}{2.08\,d + l}}$$

When the diameter of the pipe in inches does not exceed its length in hundreds of feet the velocity head may be disregarded, with an error not exceeding 1 per cent.; and the formula then becomes
$$G = d^2\sqrt{\frac{800\,dh}{l}} = 28.28\,d^2\sqrt{\frac{dh}{l}}$$

The quantity of water discharged (Q), in cubic feet per minute, is likewise given by the formula
$$Q = 3.78\,d^2\sqrt{\frac{dh}{l}}$$

SOCIOLOGICAL DEPARTMENT

H. C. Frick Welfare Plans

SPECIAL CORRESPONDENCE

Sanitary drinking fountains, both underground and on the surface, are an innovation at the H. C. Frick Coke Co.'s plants. The first of these was installed at the Lambert plant, near Uniontown. The drinking bowl consists of a reducing coupling, 8 in. in diameter, such as can be found about any plant. It is supported by a 3-in. pipe, inside of which a smaller pipe is placed which carries the water supply. The space between the standard and the supply pipe serves as a drain.

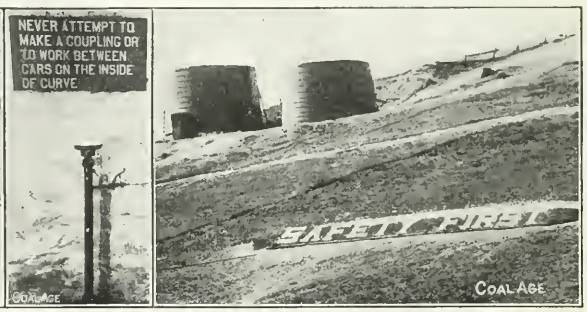
The fountain could be arranged to flow continually, but in those now in use whistle valves inverted and worked with a foot pedal start the water flowing. All mines of the H. C. Frick Coke Co. will, in a short time, be equipped with similar devices. They furnish the men an opportunity to drink during working hours without putting their lips to cups which have been contaminated by the lips of others.

The same company is preparing to inaugurate a visiting-nurse system at its various plants. The experiment has only been tried, so far, at Lambert and Hecla; but it has been so successful, that it is probable that the experiment will be tried elsewhere, and the practice may be extended to all the mines of this company. The nurses will work in conjunction with the company's physicians and will be under their direction. They will make daily reports of all cases under their care to the superintendents of the various plants.

The value of this system to the workers and their families can hardly be estimated by one who is not familiar with the class of people who are employed in the coke region. They are mostly foreigners who are unacquainted with the health needs of their families. It is the intention that these nurses shall not only take care of the sick, but also shall instruct the employees in personal cleanliness and hygiene.

Superintendent H. W. Boyd, of the Lambert plant, has erected the immense "Safety First" sign shown in the illustration. It is built on a hillside and is on a raised mound. The letters are of brick 20 ft. high and whitewashed.

SANITARY DRINKING FOUNTAIN UNDERGROUND



A 20-FT. "SAFETY FIRST" BRICK SIGN

Welfare Work in Coal Mining

BY W. H. DROLL

The Alabama Mine Operators' Association has banded together to study the sociological question and the sanitation of mine camps and the Tennessee Coal, Iron and Railroad Co. is a leader in promoting every form of mine betterment. Where other institutes and mine operators' associations have made the technology or the profits of the industry their aim, the Alabama organization has laid all stress on the advantage to the employer, of a due recognition of his social obligation.

All the Northern cities are planning playgrounds and we are as active to introduce them into our villages. We have our civic centers, with churches, schools, public dance pavilions, uptodate commissaries, sanitary closets, electric-lighted houses, and it won't be long before our mining camps will have a central heating plant. Nearly all of them have their own "first-aid teams," which meet to compete once a year, for prizes given by the company.

These companies are not doing this work for purely charitable purposes. The miner is independent and is willing to pay for what he gets and does not seek charity. These model mining camps, these first-aid teams and awards for proficiency, these competitions between tenants and prizes for the cleanest house and the best garden are not instituted for charity, but as a business proposition. Keeping the miners healthy increases the production and reduces to a minimum what are termed overhead charges and fixed expenses. The companies figure that the employees who are to mine 25 to 30 millions of tons of coal a year must be healthy men and must be kept in the best possible condition.

No. Sanitation is not charity; it is a business proposition. Do you think it pays?

COAL AND COKE NEWS

Washington, D. C.

Since the departure of the Senate committe charged with the duty of investigating the West Virginia coal strike situation there has been a renewal of the attempt to jockey with this investigation, making capital out of the subject and preparing to use the developments in speeches and discussions on the floor of the Senate. There has been little surprise here over the news that has come back from the place where the inquiry is proceeding as the information has been expected to run in substantially the way that has actually been the case.

The legal experts in congress are now taking the view as was expected that there is really nothing that can be done by the Senate no matter what may be ascertained in this inquiry and that, therefore, the sooner it ends the better. A good many senators now think that it was a great mistake to go into it at all. The same issue had to be met at the time of the Lawrence textile strike and was then decided adversely to Congressional interference. The present action it is conceded sets a bad precedent and is likely to result in dragging congress into many local squabbles.

The situation in the West Virginia case has however tended to concentrate attention upon the plan for extending the operation of the Erdman Act which was drafted by the national civic federation and was this week brought to Washington by Seth Low. The plan follows the lines made familiar a year ago, but is not likely to get much attention this session of Congress.

Recent Coal-Rate Decisions

In the Connellsville Coke Producers Association case against the B. & O. and other railroads reductions from 4 to 10 per cent. on coke in the present rates were last week ordered to take effect on Aug. 1 to Youngstown, Canton, Cleveland and Toledo, Ohio, North Cornwall, Robeson, Reading and Philadelphia, Penn., Baltimore, Md. and Newark, N. J. The decision, written by Chairman Clark, held to be reasonable the present relationship of rates as between the Connellsville district and the Fairmount district in West Virginia. The roads were ordered to maintain this relationship between the rates. Furthermore, the commission held that participation by the roads in through rates of the West Virginia and Tennessee fields which yield lower earnings per ton-mile than their rates from the Connellsville field is, under the conditions of competition between carriers which the defendant roads cannot control, neither unduly discriminatory nor unduly preferential.

In the case of the Youngstown Sheet & Tube Co. and others against the Pittsburgh and Lake Erie R.R. the commission ordered the rate of $1.35 per net ton on coke from the Connellsville district to points in the Mahoning Valley of Ohio reduced to $1.20. The new rate is to take effect Aug. 1.

In the cases of the Wisconsin Steel Co. against the Pennsylvania R.R. and other roads and the Inland Steel Co. against the Pittsburgh & Lake Erie and other roads the commission sanctioned the present rate of $2.50 per ton from the Connellsville region to Chicago.

The Interstate Commerce Commission has handed down an opinion in the investigation and suspension of rates on coal to Milwaukee and other Wisconsin points as follows:

Soft coal originating on the lines of certain of the defendant carriers and destined to points beyond Milwaukee, Manitowoc and Kewaunee, Wis., has, for 10 or more years, moved over the across-lake routes to those points at the Chicago rates. By the tariffs under suspension the carriers undertook to close certain of the routes and cancel the rates applicable to them because of a failure to arrive at agreements following a demand on the part of thhe delivering carrier for an increase in its division; Held, That the suspended tariffs must be withdrawn and the present routes kept open. An advance of 10c. per ton in the rates is permitted.

HARRISBURG, PENN.

A bill which empowers all municipalities in the anthracite region to enact ordinances, by-laws or rules prescribing all needful regulations for the mining of coal beneath such municipalities has passed both houses. It also allows councils to create bureaus of mine inspection, to consist of one practical mining engineer and whatever assistant he shall need, to be fixed by councils and approved by the chief executive. The latter has the power to appoint the mining engineer, and his assistants, the salaries of all to be fixed by the councils. Members of the bureaus are given the right to enter all mines which have workings beneath their respective municipalities. All mine owners or operators are required, within three months of the passage and approval of the ordinance to furnish to the bureaus accurate maps and plans of all their workings beneath such municipalities They must also every three months, furnish to the hureaus new maps showing all the extensions of their workings beneath the municipalities since the last map was furnished.

Operators must not remove coal, rock or earth from beneath any street, avenue, thoroughfare, court alley or highway without having first constructed sufficient adequate permanent artificial support to maintain the surface of such highways, etc

Violaters of any of the provisions of this act are subject to a fine of $1000 or imprisonment for one year or both at the discretion of the court.

The provisions of the bill are made severable and, in the event that one of them may be declared unconstitutional such a decision will not affect the validity of the remaining provisions.

PENNSYLVANIA

Anthracite

Pittston—The Henry colliery of the Lehigh Valley Coal Co at Plains resumed work June 9, after an idleness of a week. The shutdown was due to a strike caused by the invasion of the Industrial Workers of the World in this neighborhood and the consequent desertion from the ranks of the United Mine Workers. It is said, however, that the 900 men have now taken up their tools with the expectation that the difficulty will be adjusted speedily. The opposition to the Industrial Union is still bitter, and the resumption of work does not necessarily mean a cessation of hostilities.

The preliminary meeting of many of the first-aid teams of the South Pittston district of the Pennsylvania Coal Co. to choose a team to represent the district at the interdistrict meet at Valley View Park, in the fall, was held in the Y. M. C. A. at Pittston. A total of thirteen teams participated in the contest. The judges were John Huntley, of the North Pittston district, and Moses Ballentine, of the Old Forge district, and the timekeepers were Isaac Benjamin and William Coplan.

Philadelphia—The Central Labor Union of this city has voted against the state-wide strike proposed by President Morrow, of the State Federation of Labor. It is also understood that delegates to the Central Labor Union convention at Harrisburg, coming from the northeastern part of the state, will also vote against the state-wide cessation of work.

Sugar Notch—It is expected that the Hadleigh colliery of the Pittston Coal Co., which was closed down last fall to allow of the construction of a new breaker, will reopen during this month. This colliery employs about 300 men and boys.

Wilkes-Barre—The South Wilkes-Barre colliery of the Lehigh & Wilkes-Barre Coal Co., recently lost one day as the result of an unofficial strike, which affected about 1200 employees. This strike is probably the first unintentional strike that ever occurred in this region. According to the union officials, the men remained away from work under the impression that the local with which they are connected had called a "button" strike. This was not the case.

At the last pay day, a committee of five men took their position at the head of a shaft where they were to collect back dues from about 100 miners, who would then receive buttons. A number of workmen on their way into the mine were encountered by the officials with the buttons, and when asked to show their due books, came to the conclusion that a button strike was being called. Going back to the entrance to the colliery they informed the incoming men of their idea of conditions, with the consequence that the workmen did not report for work.

There was a button strike at the South Wilkes-Barre colliery on Nov. 1 last, when all of the employees were officially called out, and the colliery was tied up for some time.

Bituminous

Johnstown—The business section of the mining town of Bens Creek was entirely wiped out by a fire June 11. The damage is estimated at from 150,000 to $200,000. The town is the center of large coal operations; among the largest are the Pennsylvania Coal & Coke Co., Juniata Coal & Coke Co., and the Lilly Coke Co.

WEST VIRGINIA

Wheeling—A strike has been declared at the Pursglove mine at St. Clairsville as a result of a dismissal of an employee. Subdistrict officials of the United Mine Workers ordered the men to return to work, but they refused. About 250 are out.

Huntington—The Band mill, owned by the United States Coal & Oil Co., at Holden, W. Va., was destroyed June 10 by fire. The total loss is $30,000.

Terra Alta—As the result of the mysterious destruction of the Righter Coal & Coke Co.'s blacksmith and machine shop, at its plant on Long Creek, Sheriff R. F. Stout has stationed a posse of deputies at that point to prevent any further increase of 15c. a car for digging coal. This is the first strike trouble in this section for many years.

Charleston—General Chas. D. Elliott, of West Virginia, who was in supreme command of the military in the strike zone, was called as a witness by the United States Senatorial Committee, which is investigating the coal miners' strike in this region. General Elliott declares that martial law was heard by the strikers themselves and the United Mine Workers' officials; while the coal operators protested both to him and the governor against the issuing of such a proclamation.

MARYLAND

Cumberland—An attempt was made June 7 to organize the miners of the Georges Creek region at a big labor meeting in the public square at Cumberland. The meeting was addressed by John P. White, president of the United Mine Workers of America, and other labor leaders. The miners in this region are said to number over six thousand.

OHIO

Alliance—A consignment of powder exploded June 16 at the Jefferson mine No. 2 at Fineyfork, fatally injuring four men; eight others were seriously injured. The Jefferson Coal Co., of Cleveland, Ohio.

Steubenville—Three miners were killed June 14 by a serious fall of slate in the Dunglen mine.

ILLINOIS

Springfield—Fire at the Royal Colliery Co.'s mines near Verden caused a loss which is estimated at more than $100,000. The upper works, washery and shaft timber-works were destroyed.

Marion—Fire is sweeping the underground works of the Carterville district mine. The loss is estimated at $100,000.

Herrin—The engine and boiler houses of the St. Louis Carterville Coal Co., which were recently destroyed by fire, are to be replaced at once. Arrangements will be made so that the Burlington will be enabled to get its track in at this mine, which was impossible before on account of the location of the engine room.

Royalton—After several months' strike at the south mine, the miners have returned to work. They contended that the new company should pay them the wages that the old bankrupt company owed them, and the matter has been settled, but details were not made public.

Marion—The Illinois Hocking mine, which caught fire on May 22, has been sealed up, inasmuch as the fire got beyond the control of the men. The question of flooding the mine has been discussed.

Desoto—The mine of the Kreikemeier Coal Co. has suspended operations indefinitely. This company is involved to a considerable extent with the Mississippi Valley Fuel Co., of St. Louis, for which a petition in bankruptcy was recently filed.

ALABAMA

Birmingham—Rumors are prevalent that the coal miners in the Birmingham district are likely to strike this summer. A statement was made at the headquarters of the United Mine Workers of America, Alabama District No. 20, that no strike has been ordered, and so far as the organization was concerned, nothing of the kind was under consideration. It is not denied, however, that efforts are being made to bring about a general reorganization of the coal miners.

TRADE CATALOGS

Electric Service Supplies Co., Philadelphia, Chicago and New York. Catalog on Protected Rail Bonds and Appliances. 1913 Edition.

This is a handsome book of 72 pages, and covers the subject of rail bonding in its every phase. It is beautifully illustrated and besides showing every practical type of Rail Bond, it illustrates clearly the value of proper installation, the importance of accurate testing apparatus, and the use of bond compressors.

To the users of rail bonds this book is more than simply a catalog, it is a treatise on rail bonding in general and will prove a wonderful aid to operating men in selecting from the hundreds of different types of bonds one that will exactly suit any special requirement.

The section of this catalog describing and illustrating proper methods of installing Rail Bonds enters into the subject in detail and shows graphically the importance of assuring a perfect, moisture-proof contact with the rail.

From cover to cover this book will prove of interest to the 3000 operating men to whom it is being sent.

PERSONALS

Edward H. Coxe, of Birmingham, Ala., former general superintendent of coal mines and coke ovens for the Tennessee Coal Iron & R.R. Co., has been appointed general superintendent of the LaFollette Coal Iron & Ry. Co., with headquarters at LaFollette, Tenn., effective June 12, 1913.

Harry Sharp, formerly superintendent of the Barton mine of the Youghiogheny & Ohio Coal Co., has resigned to accept a position with the Davis Coal & Coke Co., at Thomas, W. Va. This company owns more than 100,000 acres of coal and operates 29 mines.

Chas. B. McNaught, of Reed, Shaw & McNaught, has been appointed president of the Sterling Coal Co., Ltd., and also president of the Conger Lehigh Coal Co., Ltd. In the first instance Mr. McNaught takes the place of W. F. Tye, who will still remain a director of the company. In the second case, he takes the place of R. E. Gibson, who has become vice-president.

CONSTRUCTION NEWS

Lansford, Penn.—The Lehigh Coal and Navigation Co. is planning to erect a breaker at No. 11 near Lansford.

Albia, Ia.—Harris Brothers have leased 1000 acres of land south of Albia and will open a new coal mine between Albia and Moravia.

Wilkes-Barre, Penn.—Excavations were commenced recently for an engine house to be built at the Maderia Hill Colliery near the new slope on Scotch Hill.

Ashland, Penn.—Work on the new Lehigh washery to be erected on the site of the old Bowman breaker has been commenced. Wheeler and Reilly, of Luzerne, have the contract for the work.

Punxsutawney, Penn—Another coal mine will be opened soon in Furnace Run, along the Allegheny River, where over 500 miners will be employed. There are at present about 500 miners employed in the other coal mine at Furnace Run.

Birmingham, Ala.—The new steel tipple and concrete washer at the Banner mines of the Pratt Consolidated Coal Co. will be soon finished and put into use. It will permit of an increase in production to at least 1200 to 1500 tons daily.

Williamson, W. Va.—Mingo County is on the verge of the biggest coal and gas boom in the history of the county. Over 50,000 acres of coal and gas land on both sides of county are being prepared for opening within the next six months.

Lexington, Ky.—It is said that the Baltimore & Ohio Railroad Co. proposes to construct another coal railroad in Kentucky and has acquired the charter rights of the Long Fork Railroad Co., which owns the location on the left fort of Beaver Creek.

Whitesburg, Ky.—The Consolidation Coal Co., of Lexing-

ton, Ky., has started to build a large hospital, which will take the place of the temporary hospital built a year ago. This will be the largest in eastern Kentucky, and will cost in the neighborhood of $30,000.

Pomeroy, Ohio—Two new coal tipples are to be constructed this summer on the line of the Middleport & Northwestern Ry. The Stalter & Essex Coal Co. will erect a tipple on the Kers place, and the Sherman-Essex Coal Co, will construct a tipple on the O. L. Bradford farm.

Birmingham, Ala.—Announcement was made of the opening of a new coal mine, at Pierceville, Jackson County, with a proposed daily capacity of 1000 tons. The new mine is to represent working of 23,000 acres. Grading work on nine miles of narrow gage track is now under way.

Bristol, Va.—It is understood that Chas. H. Hagen will buy the Hagen property comprising 30,000 acres of coal land in Scott county for immediate development. Mr. Hagen controls water power which will be developed to transmit electricity for mining more than 2,000,000 tons of coal annually.

Mauch Chunk, Penn.—It is understood that the new electric plant of the Lehigh Coal & Navigation Co., which is now under consideration at Hauto, will not be completed in July as originally expected. Various delays will make it impossible for the contractors to complete the work until probably late in October.

Vincennes, Ind.—The American Coal and Mining Co., organized at Brazil some time ago and which purchased a large acreage of coal land in Knox County near Bicknell, is preparing to sink two mines on the land at once. W. H. Zellar, as president, W. J. Snyder, secretary-treasurer; Hal R. McClelland of Clinton, vice-president.

Pomeroy, Penn.—The Calvin-Essex Co., of the Hocking Valley proposes to open a large mine near the Avenue Bridge, on Thomas Fork, which will be connected with the K. & M. R.R. by a spur up the creek from Bradbury. J. M. Lama, of the Hocking Valley, has leased the Elba Mine, below Middleport, and will increase its output.

Canonsburg, Penn.—Development of virgin coal tracts east of Canonsburg is to follow in the wake of the construction of the Montour and Chartiers Southern railroads. Pittsburgh Coal company will open four large mines as soon as the new roads are completed. Another mine will be located on the Park farm near McPhersons Mill, north of Chartiers Creek and the Chartiers railway.

Indianapolis, Ind.—Contracts have been let by the Big Four Coal Co., with the Roberts & Schaeffer Co., of Chicago, for the construction of five coal plants to be situated at Anderson and Lynn, Ind., Paris and Lilly, Ill., and Dayton, O. The contract price is said to be $50,000. The same company has a contract for the erection of a reinforced concrete coaling station at Chicago, for the Indiana Harbor Belt R.R.

Punxsutawney, Penn.—The Buckingham Coal Co. has recently awarded to the Andrew Lumber Co, of New Bethlehem, a contract for the erection of 20 miners' houses along the J. F. & D. R.R., near Strattonville and Somerville. Five of these dwellings will be erected in Somerville, five about one mile from that town and ten near Strattonville. Work will be started at once and the houses will be rushed to completion.

Connellsville, Penn.—With a view to reducing the cost of living for its employees, the H. C. Frick Coke Co. is making arrangements to establish dairy farms near its coking plant and coal mines. The company will supply its workmen with dairy products at the same price the farmers receive from the wholesale dealers. Similar establishments are being operated by the Pennsylvania-Maryland Coal Co., and the Ebensburg Coal Co

Des Moines, Iowa—It is understood that a $1,000,000 coal development will soon be started on the new line of the Chicago, Rock Island & Pacific R.R., between Des Moines and Charlton Four thousand acres of coal rights have been taken up in Lucas County. The deal includes the purchase of the Island Coal Co property, a mine located close to Charlton. The entire field has been prospected and much of it contains valuable deposits. In addition to investments in coal rights, it is planned to spend $200,000 in shaft sinking

Denver, Colo.—It is reported that a combination of Belgium and Paris capitalists is planning to take over 30,000 acres of valuable coal land on Routt County. A railroad will be built from Hayden, Colo, to Casper, Wyo. Plans of the combination call for the immediate expenditure of $22,000,000 in these two states. It is understood that Denver will be the source of supplies. The company has already been formed and will be known as the Yampa Fuel & Iron Co. It is said that the new railroad will be known as the Colorado Northern Railway Co.

Whitesburg, Ky.—In pursuance of its announced plans to develop its recently-acquired holdings as rapidly as possible the Elkhorn Fuel Co. has several hundred men at work in the Boone's Fork section. They are employed in making surveys, laying out towns, building temporary offices, doing grade work, and the like, the whole on a larger scale than anything before done in Eastern Kentucky. The company announces that it has let a contract for the erection of 300 buildings, including offices, stores, churches, schools, machine shops, supply houses, hotels, Y. M. C. A. buildings, hospitals and residences.

The first town to be built is to be in Potter's Fork, one mile from the main-line of the Lexington & Eastern, and will be reached by a branch from that road. Two others will be built at once, both directly on the Lexington & Eastern, one on Wright's Fork and one on Main Boone's Fork. In order that this work may be pushed as rapidly as possible, the present forces will be increased by a thousand men within a short time.

An order has been placed for several million feet of lumber to start the work, pending the installation of two big band-saw mills which will be installed on the ground and manufacture the native timber into the necessary lumber. At the outset the industrial cities of the company will be supplied with electric current from the big power plant of the Consolidation Coal Co., at Jenkins, Ky., ten miles distant. Ultimately, however, the Elkhorn Company will build its own power plant.

NEW INCORPORATIONS

Akron, Ohio—The General Hocking Fuel Co.; capital stock, $50,000; mining coal. Promoter, N. J. Odell.

Boston, Mass.—The Atlantic Coal Co.; capital stock, $500,000. Incorporators: J. B. Sullivan, Jr., and P. D. Dean.

Wilmington, Del.—The Castle-Craig Coal Co.; capital stock, $1,000,000. Incorporators: S. H. Hossecker, T. J. Bohn, Jr., and A. McGarvey.

Anchor, Ohio—The B. C. Tway Mining Co.; capital stock, $10,000; fuel business. Directors: G. A. Linton, H. G. Williamson, W. L. Morris, J. G. Long.

Buffalo, N. Y.—James Ash of Buffalo; coal, coke, ice, lumber; capital stock, $15,000. Incorporators: John G. Cloak, Charles F. Houck, Daniel C. Shearer.

Newport, Ohio—The Licking Coal and Towboat Co.; capital stock, $15,000. Incorporators: Frederick A. Laidley, George P. Qhiggin and Walie E. Quiggin.

Camden, N. J.—The Twin Rocks Coal Co.; capital stock, $100,000; to deal in coal, charcoal, etc. Incorporators: A. M. Garrison, J. H. Brooker, and D. C. Mann.

Fairmont, W. Va.—Fairmont & Cleveland Coal Co.; capital stock, $100,000. Incorporators: W. N. Engle, E. L. Henderson, R. Walls, Anthony Cowen and J. R. Burns.

Charleston, W. Va.—The Co-Operative Coal Co.; capital stock, $15,000; to deal in coal lands. Incorporators: T. C. Davis, F. W. Johnson, C. E. McCoy, and R. V. Ramsey.

Camden, N. J.—The Twin Rock Coal Co.; to acquire, purchase, mine and sell coal; capital stock, $100,000. Incorporators: A. M. Garrison, Joseph H. Brooker, C. B. Mason.

Wellsburg, W. Va.—The Ohio River Coal Co.; capital stock, $1000; to mine and deal in coal and other products. Incorporators: H. C. Cochrane, Elmer Haugh, Robert Wheeler, J. K. Capulias and H. A. Stengle.

Wellston, Ohio—The Morrow Prospecting Co.; capital stock, $10,000; drilling and prospecting coal and mineral lands. Incorporators: H. C. Morrow, W. F. Schadel, Jerry Morrow, F. C. Morrow and M. E. Martin.

Charleston, W. Va.—The Miners' Light & Power Co.; capital stock, $250,000; to produce electricity and operate coal mines. Incorporators, J. H. Gaines, A. B. Moontz, G. D. Todd, F. R. Hurlbutt, and R. K. Morton.

Birmingham, Ala.—The Esson Company has filed articles of incorporation for $2000. The concern will mine, buy and sell coal, J. F. Leary is president and treasurer and R. B. Leary is vice-president and secretary.

Sergent, Ky.—The Ross-Petroy Coal Co. is being organized at Hazzard in Perry County, on the new extension of the Lexington & Eastern R.R. The promoters are Alex Ross and

Lois E. Petroy. It is planned to develop the Curt Combs coal land tract.

Huntington, W. Va.—It is reported that a gigantic coal company has been organized to develop coal and timber land in southeastern Kentucky by C C Mayo and a number of his associates. The name of the company has not as yet been announced, nor has any details as to its future policy been given out. It is stated that the operation of the new company will be confined to Kentucky and West Virginia.

INDUSTRIAL NEWS

Beltona, Ala.—The new mine of the American Coal Corporation, at Beltona, has begun operation and it is expected that they will reach a large tonnage in a short while.

Prescott, Ia.—On June 4 cap rock was struck in the prospect hole which was started several months ago, in the hopes of finding a seam of coal. It is estimated that the seam will be 20 in. thick.

Windber, Penn.—John Lochrie has purchased from Berwind-White their large No. 41 mine and has taken over the operation of the plant. Mr. Lochrie owns a 300-acre tract in th area tapped by the mine.

Washington, Penn.—A. W. Pry, of Hickory, has sold his coal and surface to the Chartiers Mining Co. Mr. Pry purchased this farm only a few years ago for about $7000 and received in the neighborhood of $15,000.

Johnstown, Penn.—The Pennsylvania Coal & Coke Corporation has taken over the old Wigton mine near Carrolltown This mine has been closed down for 12 years. The company will attempt its operation in the near future.

Greensburg, Penn.—Former Senator J. M. Jamison has purchased from the Sunshine Coal and Coke Co., three tracts of coal land in Hempfield Township. The consideration is said to have been $72,500, which averages $1000 an acre.

Wilmington, Del.—The Nortonville Coal & Coke Co., a Delaware corporation doing business at Nortonville, Ky., has filed a petition in voluntary bankruptcy in the United States District Court. The position sets forth liabilities of $476,920, with assets of $1638.

Martins Ferry, Ohio—The Glenns Run Coal Co., will employ the stripping method of mining coal from a seam, which comes close to the surface six miles north of this city. This company will remove the surface earth with steam shovels and use the same shovels later for taking out the coal The seam is from 10 to 30 ft. under ground.

Brazil, Ind.—Crawford & McCrimmon Co., builders of mine machinery, hoisting engines, fans and mine pumps are starting construction of an entire new plant on a nine-acre tract. The buildings will be of the most modern steel fire proof construction. Considerable new machinery equipment is being installed. Practically all contracts have been let.

Torrington, Wyo.—It is known that there is a seam of coal on Horse Creek, and a number of the ranchmen in that locality have a pump and steam engine on the ground, and have dug out considerable coal. This coal is about 18 miles from Torrington and if the quality of the coal and top rock is good, it will probably be developed in the near future.

Ironton, Ohio—The Hecla Coal & Mining Co. has been dissolved in the Court of Common Pleas, June 7, as a result of a suit for dissolution brought by Chas. Campbell and Albert Campbell, both interested in the company. The Hecla Co. was incorporated at $100,000 and owns about 7000 acres in fee simple. Besides this the company has purchased some mineral rights on about 3000 acres more.

Columbus, Ohio—The affairs of the Detroit, Toledo & Ironton R.R. are nearing adjustment. Announcement of a plan looking forward to the reorganization of the Northern & Southern Divisions, after their formal sale on June 26 is made to the New York Trust Co. The latter company is acting in behalf of the holders of the $4,243,000, 4 per cent. general mortgage and divisional first mortgage bonds

Logan, Ohio—The Vinton-Jackson Coal & Mining Co., whose property lies five miles southeast of McArthur, has decided to test the Elk Fork Valley for oil and gas. A J Martindill, their representative, recently signed a contract with the Corts & Botkins Drilling Co. of Lancaster Ohio, to drill several wells into the deep sand a depth of 3,000 feet.

St. Louis, Mo.—The New England National Bank, of Kansas City, has asked that a receiver be appointed for the Farmers Coal Co., a Missouri corporation which owns coal mines in Lafayette County. The petition states that notes by the company amounting to $30,000 are due and unpaid. Furthermore, it is stated that there are first mortgage bonds on the company's property outstanding, aggregating $77,000.

Johnstown, Penn.—J. Blair Kennerly takes over the possession of the Seward Coal Company and the Seward Brick Company, both bankrupt corporations. As a result the creditors of the two concerns will receive about 85 per cent. of their claims. The interests of both properties will be merged under the name of the Nineveh Coal Company, the acquirement of which will cost Mr. Kennerly in excess of $100,000.

Fayetteville, W. Va.—The New River Coal Co., the largest corporation operating in the New River district, held its annual meeting of stockholders at the offices of the company at MacDonald, June 5, and elected a new board of directors. Robert H Gross was reëlected president and Colonel M. Scott has been reëlected general manager. A number of improvements are contemplated in the different operations, including the acquisition of additional production.

Johnstown, Penn.—Railroad men are greatly interested in the fight in which the Pennsylvania Railroad and the New York Central lines are at present engaged to obtain the right of draining large coal fields in Blair and Cambria Counties, which will be opened within a year or two. The land lies between Dongherty and Dysart, and contains, according to the estimates of mining engineers, 475,000,000 gross tons of coal, or enough to keep 19,000 miners busy for over 10 years. The project is to be financed by eastern capitalists.

Connellsville, Penn.—Efforts to obtain only picked men for work in the Charleroi mine, of the Carnegie Steel Co., will be made when operations are resumed in the summer. All applicants for work, either outside or inside, must convince the management of their sobriety. When ready for operation about 800 men will be employed and the mine will be one of the best equipped along the Monongahela river. It is understood that Geo. W. Wilkies, of Charleroi, will be named mine foreman. As yet, the superintendent has not been chosen.

Birmingham, Ala.—It is understood that the Pratt Consolidated Coal Co. is negotiating for the purchase of the property of the Sayre Mining & Manufacturing Co., which is located in the extreme western part of the county. Two mines are in operation, as well as a large battery of coke ovens. The properties belonging to the Sayre estate are considered among the best in the state. There are several thousands of acres involved and it is said to be valued at $1,000,000. The coal mined by the Sayre Mining & Manufacturing Co. is in steady demand for its coking qualities. It is largely used by the Birmingham Railway Light & Power Co.

Philadelphia, Penn.—The Electric Service Supplies Co. of Philadelphia and Chicago, has placed on the market a trolley ear adapter known as the type RB. This adapter has been very popular in mining work for use in supporting grooved trolley wires after the groove has been badly worn, or the wire twisted due to the fact that the wire is used a number of times and its location frequently changed.

These adapters are used in connection with standard 3 screw, 5-in. clamp ears, and are also used by railway companies for emergency work. They are made for grooved trolley wire of all sizes and for any standard screw clamp ear.

Winchester, Ky.—John, C. M. and Floyd Day, have transferred to a New York syndicate all of their holdings of coal land in eastern Kentucky, for a consideration involving over a million dollars. The property carries with it the Mountain Central R.R., a narrow-gage line 13 miles in length which runs from Campton Junction to Campton. The deal includes a number of stores, mills and other improvements. Considerable of the property, coal and timber lands, is located on the Lexington & Eastern. The Messrs. Day will retain an interest in the new company which will be organized to handle the property, and will have the management of it on the ground.

Whitesburg, Ky.—An Eastern syndicate has just purchased 5000 acres of rich coal lands along Lower Carrs Fork Creek, on the Knott-Letcher border, and is planning the early development of the property, which will necessitate the building of a branch line of railroad out from the Lexington & Eastern seven miles in length. The consideration paid is not known, although it is said to have reached a very large sum, running into several million dollars. The tract in question is almost the last of the large bodies of coal land not taken up, practically all of the known coal territory now being in the hands of companies which intend to develop it.

COAL TRADE REVIEWS

GENERAL REVIEW

The dominant feature of the coal market throughout the entire country is firmness. Generally speaking, there is an active call for practically all grades of coal, with just about enough production to supply the demand and replenish depleted stock in some localities.

Throughout New England some apprehension is felt for Southern coals, and the output is expected to be seriously curtailed within the next three months. Loading at Hampton Roads is slow, due to heavy takings by the Government. All-rail shipments to New England are not as firm as those sent by water.

Anthracite is still slower in shipment than last week, with indications of a good market during July and August. In New York the demand for anthracite is slightly easing up. The mines, however, are operating full force. Some price shading has been done by individuals but not by the larger companies, and the quotations remain unchanged.

Bituminous is a little easier, with no change in price. The better qualities may be had promptly and the lower grades do not appear to be coming to this market. Contract coal is firm, with gas coal active and slack easier.

Throughout eastern Pennsylvania the local demand for anthracite has fallen off, due to the warm weather, but the demand from Tidewater is insistent, and has thus far been but little affected. There is a lively traffic in bituminous and the market is strong. This branch of the industry looks more promising than formerly.

Throughout the Pittsburgh region some small strikes have been experienced, but these are of comparatively little importance. The Lake traffic is heavy, and there exists a congestion of cars en route to Lake Erie, and a car shortage is feared later. The manufacturing demand for coal has fallen off slightly, while coke prices are receding, and many furnaces are not inclined to pay over $2 per ton. In Baltimore, there is a rumor that some operators are storing coal in anticipation of a heavy demand this fall, and the trade continues strong, due to inadequate car and labor supply.

Heavy exportations are taking place from Hampton Roads, and there is less fuel on hand now than for some months. To all appearances this situation will not change unless labor conditions become better.

Throughout the Southern iron-producing districts conditions are about normal. The maximum number of furnaces have been in blast during the year, which has increased the consumption. Throughout Ohio, Michigan and the upper Mississippi Valley generally, the demand for coal is strong for this season of the year. Prices are, however, as a general thing, unchanged. Coke at Detroit is rather dull, and some of the local furnaces have been shut down. At Chicago there exists a good demand for domestic coke, which, to a measure at least, offsets the dullness in the requirements of iron and steel industry.

One of the most important, and perhaps the greatest, stabilizing factor in the present situation is the great amount of coal which is being shipped by way of the Great Lakes. The demand for fuel by the Northwest seems to be remarkably strong, and the coal-producing states lying south and east of these inland waterways are securing the benefit of a stable market at a time of the year when the demand for all grades of coal, particularly that used for domestic purposes, usually experiences a decline.

BOSTON

Bituminous—In some quarters much apprehension is felt over the situation in the coal mining districts in West Virginia. Operators in the Pocahontas and New River fields are advising their factors to go slow on sales, and all apparently expect the output to be subject to material decrease during the next three months. The government is making heavy drafts on the supply at Hampton Roads, and the loading of coastwise tonnage is consequently slow.

Some of the agencies have withdrawn all quotations, even that of $2.85 f.o.b. These conditions have seldom been effective so early in the season, and are usually construed as indicative of strained situations during the balance of the year.

Georges Creek grades are firm with a strong demand for all that comes to tide. Although cars are fairly plentiful, a labor shortage is being seriously felt in this field, and coal is not being mined up to the usual tonnage. Throughout Pennsylvania generally there seems to be a stringency. The better known coals are all practically sold up, that is, as far as the operators care to commit themselves, and there is an increasing tendency to decline orders.

The effect in New England is marked. Already some fair sized purchases have been made of coal from Somerset, Cambria and Clearfield Counties, that will net the mines from 10c. to 15c. more than was the case in April. The plain fact is that good coal is hard to get and prices are harding accordingly.

The present status of all-rail shipments is not quite as firm as for tidewater delivery. It is expected, however, that when inland buyers find their cargoes are not arriving with accustomed regularity there will be a similar bracing up in all-rail shipments.

Current wholesale prices on Bituminous are about as follows: Clearfield coal, $1.05@1.45; Cambria and Somerset, $1.30@1.60. Georges Creek, $1.67@1.77. All the above, f.o.b. mines. Pocahontas and New River coal is firm at Hampton Roads at $2.85. The same grades at Providence bring $3.78@3.83 f.o.b. cars, while at Boston, the price is $3.83@4.

Anthracite—If there is any change in the anthracite market it is in the direction of still slower shipment. Dealers are finding orders for certain kinds and prices rejected for June, and the demand for all grades continues steady. An active market for anthracite is unusual at this time of the year, and the outlook is good for a strong demand in July and August. Such a condition is something new in the hard-coal trade, strike years alone excepted, and some anxiety is felt over the shortage of broken and stove grades. These sizes are much in demand, and the proportion in any one cargo is being held down to the minimum.

PITTSBURGH

Bituminous—Several small strikes have occurred in the Monongahela valley, directed principally against the enforcement of the safety lamp and permissible explosive regulations. These have not amounted to much, however, and labor conditions are fairly satisfactory, as is the car supply. There is considerable congestion of cars enroute to Lake Erie, apparently due to a lack of motive power, and a serious car shortage later in the season is feared by some operators. Manufacturing demand for coal is slightly reduced, in anticipation of inventories, midsummer closings, etc., but on the whole demand continues good. Lake shipments are heavy.

Prompt lots of mine-run and screened coal occasionally bring premiums, while slack is going at 60@70c. for prompt; otherwise regular prices rule as follows: Slack, 90c.; nut and slack, $1.05; nut, $1.25; mine-run, $1.30; ¾-in., $1.45; 1¼-in. steam, $1.50; 1¼-in., domestic, $1.55, per ton f.o.b. mine, Pittsburgh district.

Connellsville Coke—Operators who were committed mentally to the $2.50 price on second-half furnace-coke contracts claim that this is still the asking price, but it is a fact that definite quotations have been made both by such operators and by outside sellers for $2.25, without leading to sales. The furnaces seem now to expect to secure $2 or less, or buy from time to time during the second half. Prompt furnace coke has weakened slightly, the few sales made being usually at $2.10. Foundry coke is off slightly, with only a moderate turnover. We now quote: Prompt furnace, $2.10; contract (asking), $2.25; prompt foundry, $2.85@3; contract foundry, $2.75@3, per ton at ovens.

NEW YORK

As we get further into the summer, the demand for anthracite is easing up, and the larger companies are making prompter shipment on orders than they have at any time since March. However, orders are still to be had and unfilled ones taken care of, so that the production is going along at an almost record rate.

The mines are all working, and it looks as if, even though last June's production was over 6,000,000 tons, this month's output would equal it. As mining was naturally brisk last June, after two months' suspension, this indicates the healthy condition of the market at the present time.

While we understand that some of the individual operators are shading prices on some of the prepared sizes, the larger companies seem to have a market for all they can produce, at full circular, and have not yet found it necessary to stock

prepared sizes, although some pea and buckwheat is being accumulated.

Taking it all in all the market is in a healthy condition, and while it may naturally become a little dull during July and August, the outlook is for a heavy demand for all sizes in the fall.

Prices generally remain unchanged at:

	Circular	Individual	
		Lehigh	Scranton
Broken	$4 70	$4.45@4.65	$4.50@4.70
Egg	4.95	4.90	4.95
Stove	4.95	4.90	4.95
Chestnut	5.15	5.15	5.20
Pea	3.50	3.30@3.45	3.35@3.50
Buckwheat	2 75	2 15@2.45	2 50@2.75
Rice	2 25	1.70@1.95	2 25
Barley	1 75	1.35@1.70	1.60@1.75

Bituminous—The bituminous coal situation appears to be a little easier at this writing than for the last month or six weeks. There has been little or no change in prices for spot delivery, but where it was impossible to secure some of the higher grades of coal with any degree of dispatch, it is now possible to get reasonable amounts of almost any of the higher grades promptly and at a reasonable price.

The lower qualities do not appear to be coming to this market except on orders, and prices are holding fairly firm on these grades. Operators appear to be holding their coal at the mines and are only shipping when they have orders actually in hand. As a result odd lots usually standing at the piers for sale are rather limited in quantity.

Contract prices are still held upon a firm basis, most operators having higher grades of coal being sold out on their full product for the year. Contract inquiries from consumers are rather numerous, but in most cases buyers find plenty of bids on the poorer grades with but few on the better qualities.

Gas coal is still active on Western shipment, very little being available for shipment East. Slack has become a little easier in price and shipments.

PHILADELPHIA

Unusually warm weather has caused a marked falling off in the demand for anthracite. As yet, however, the tidewater tonnage has been little affected. It is understood that the demand from the East still continues good, and with the coal that is going to the lake shipping ports, all the mines are operating to their fullest extent. As a matter of fact, the trade is holding itself together much better than was expected, judging from conditions at the beginning of the present season. All the operators claim that they do not expect there will be any cessation of mining just at present, but do not hold any views as to what conditions are likely to be during July and August.

There are distinct indications that the prediction of a few months ago that the summer would see a lively traffic in bituminous coal will be fulfilled. Car shortage, an immense demand from the Northwest, and an inability to secure sufficient miners, has had a tendency to make the market much stronger, and as the summer advances this condition of affairs is not likely to improve. The demand seems to be on the increase, and should there be any acute car shortage prices would likely take a substantial upward trend. The bituminous trade is in a better condition than it has been for some time, and the indications for the future are propitious.

BUFFALO, N. Y.

The bituminous market is as firm as ever. Dealers report that it is not easy to get a supply of Pittsburgh or Youghiogheny, as these are in such demand for shipment to the lakes. For the same reason the car supply in the Allegheny Valley is deficient. If the cars are needed for loading in the lake trade they are taken, no matter what other needs may happen to be. In a good many cases the mine owner has sold all his present output on contract and is not in the market; this also appears to be the case with the Allegheny Valley and Clearfield situation. At least operators in those districts who live in Buffalo report very much less coal for present sale than used to be the case. Jobbers are not at all anxious to sell slack for 90c. at the mine for any future time as they believe that it will go to $1 and then to $1.50 before next spring. They are, nevertheless, giving instructions to salesmen, to make some 90c. contracts when they have the opportunity. This firm feeling prevails all through this market and is shown by the absence of salesmen in the bituminous trade; a few come in but just to keep in touch with the market. There is not one of them who is anxious to make sales as the consumer comes after them. It looks, moreover, as if such would be the case all the year, unless the crops fail or congress manages to do the wrong thing.

The scarcity of men is becoming more acute so that any increase of output is not to be expected. Some operators do not care to sell another pound of coal until July and others are asking what is to be done when crops are to be moved in the fall or snow comes in winter. Nothing can avert a shortage of bituminous coal but a decided falling off in consumption. There is no difference of opinion here as to that and as a result the asking price is very stiff. If any coal is selling at reduced prices it is poor grade.

The bituminous demand is much more uniform than it often is, which is a good indication that the industries of all sorts are active and hopeful. Buffalo has a strike of teamsters on hand, but it has not caused much trouble. As a rule it is conceded that the men ought to have more pay and many settlements have been made. Bituminous prices are strong, based on $2.80 for Pittsburgh lump, $2.55 for three-quarter, $2.55 for mine-run and $2.15 for slack, with Allegheny Valley about 25c. lower. There is no stir in coke, prices being rather weak on the basis of $4.75 for best Connellsville foundry.

The anthracite trade is slack, with the exception of shipments to the lakes, which is chiefly a matter of moving the coal before winter, whether it is sold or not. Even the rail-line movement is light and local sales are small. Lake shipments for the week were 138,000 tons.

HAMPTON ROADS, VA.

The movement from the Hampton Roads piers has been good, export shipments having been particularly heavy, and the end of the week sees little coal remaining in the railway yards. There is less fuel on hand than there has been for some months, and the prospects are that this shortage will continue unless there is some improvement shortly in the labor situation in the Pocahontas-New River District. Some sales have been made during the week at $2.85 and $2.90, but only for small quantities, as the situation is such that suppliers having coal on hand prefer to hold it for contract business.

The Brazilian warship "Minas Geraes" has taken during the week 2500 tons of bunker coal from barges. This is the largest shipment of bunker coal which has been put into a foreign warship at this port for some time. The coal was from Sewalls Point.

BALTIMORE, MD.

There was no let-up in the heavy demand in the local market during the week; if anything, it was greater than during the previous week. This was particularly true on spot business, quotations in the line trade continuing to show a further stiffening. There is a purchaser for every ton of coal available and even the low grades are readily disposed of at 95c.@$1 per ton.

The heavy demand is still attributed to the restricted production caused by the shortage of labor in the mining region and the scarcity of coal equipment for loading. The shortage of cars in the Eastern markets is ascribed to the heavy shipments in the Lake trade and the slow return of the empties from the loading ports. There are rumors to the effect that some companies are putting considerable coal into storage, in the belief that the heavy demand this fall will place the producer in a position to obtain any price he asks.

The unusually cold weather over the first half of the current month stimulated the hard coal consumption to a slight extent. The coke trade shows little change with the better grades quoted around $2.60 and the supply relatively limited. Dumping of coal at the Baltimore piers has been comparatively active.

COLUMBUS, OHIO

Activity has characterized the coal trade during the past week. Increased demand is reported for lake tonnage, for steam requirements and also for domestic grades. These factors tend to strengthen the trade in every respect and in fact the entire price list is well maintained.

The domestic movement is earlier than usual which is accounted for by the depletion of domestic stocks by the recent flood. At any rate orders are coming in from dealers in all sections, showing their desire to be in a position to take care of consumers earlier than usual. Some of the dealers are placing larger orders for delivery in the months of July and August. The plan on the part of jobbers and operators is to take orders for July shipment at 5c. and for August shipment at 10c over the present circular.

Steam business is also increasing in volume. Factories generally are demanding more fuel to run their plants and there is some disposition to stock up to guard against a car shortage, which many traffic men predict. At present the situation in this respect is fair although the mines in Eastern Ohio have been crippled to a certain extent by lack of cars. Another trouble in several mining districts is the scarcity of labor.

The lake trade is still booming and no let up is in sight. The Northwest is demanding a large tonnage which the Ohio producers are making every effort to supply. All fields are rushing large shipments to the lakes. The congestion at the upper lake ports is over and there is scarcely any drawback to a free movement of coal from the mines to the docks.

Production in Ohio mines has been larger than formerly. In the Hocking Valley the output has been materially increased and the same is true of the Pomeroy Bend field. In Eastern Ohio, car and labor shortage have combined to keep down the output. In the strictly domestic fields there is a good increase in the tonnage mined.

Reports from the Hocking Valley docks at Toledo for the week ending June 13 shows that 117,000 tons were handled as compared with 108,000 tons for the previous week. Since the opening of navigation the docks have handled 830,000 tons.

Quotations in the Ohio fields are as follows:

	Hocking	Pittsburgh	Pomeroy	Kanawha
Domestic lump	$1.50		$1.50	$1.50
2 inch	1.35	$1.25	1.35	1.30
Nut	1.20		1.25	
Mine-run	1.15	1.10	1.15	1.10
Nut, pea and slack	0.60		0.60	0.60
Coarse slack	0.50	0.55	0.50	0.50

BIRMINGHAM, ALA.

Normal conditions obtain in the coal market in this district and in the coast towns supplied by Alabama mines. One feature which has strengthened the local steam market is the fact that a maximum number of blast furnaces have been in operation during the entire year, thereby consuming heavy tonnages of coal for coking purposes.

The car shortage continues, and much uneasiness is felt that no relief is in sight, especially in view of the fact that there is a rate fight on between the state of Alabama and some of the local railroads.

General reports indicate that, but for the car situation, local operators are well pleased with the coal conditions at the present time.

LOUISVILLE, KY.

Conditions in the local market are satisfactory and about normal. Both production and demand are good. Dealers are stocking up, as are also consumers who are beginning to lay in their winter supply.

The weakest branch of the trade at the present time is the steam coal. Shipments of this grade are heavy, particularly from the western Kentucky field, and the demand is not sufficient to absorb all of the arrivals. This is due to the same condition in effect several weeks ago. The strong domestic demand has also resulted in a surplus of nut and slack, so that these grades are not as active as they might be.

There is a heavy demand for eastern Kentucky coal from Chicago and other Northwestern markets, it being stated from authoritative sources that the demand from these points would be 50 per cent. greater than during last season. Judging from current shipments, however, indications are that these will exceed the estimate by nearly double. Operators are hoping that they will be able to hold these markets permanently.

The demand for coal for stocking is becoming steadily stronger especially north of the Ohio river, where there are rush shipments. In eastern Kentucky the Louisville & Nashville R.R. and several other lines have recently restricted their orders, but it is stated on good authority that this is only a temporary condition and that their tonnage requirements will be back to normal in July. Many of the operators in this latter field are practically sold up and out of the market for several months to come. In general, all indications point to an unusual prosperity in the industry for some time to come.

The market is not quotably changed from our previous report, but operators state that an advance of about 10c. per ton will go into effect the first of next month. Shipments to the Southern market will probably cease at about this same time. Operators are favoring the Northern consumer because of the more consistent and year-around demand.

INDIANAPOLIS

Local operators state that while the usual summer quietness prevails, they regard the outlook as good. The crop situation has been interesting them and they find a good wheat yield in prospect, which is the most vital factor among the grains.

Coal men can find no real pessimism among their big customers. The emergency currency order by Secretary McAdoo relieved any money stringency that threatened and the Frisco receivership is looked on as a good thing for the road. Already orders have been given to repair and get in shape the 6000 coal cars of the Chicago & Eastern Illinois, and the road to the coal fields is to be newly ballasted. This is only part of the improvements ordered. Coal men say that when railroads are thus getting ready for business, it is no time for others to be idle.

Some Indiana mines that have been idle are being operated again. On account of the light demand for domestic grades, mines have no trouble to sell screenings, the output of which is mostly under contract. In the open market it is difficult to get anything at 90c., and the price ranges up to $1. Washed coal, which is slowly finding friends, is quoted at $1.25. From the retail yards anthracite and smokeless is moving rapidly into cellars. Coal users, both big and little, are aware that the wheat harvest is on and they are thinking more or less about a probable car shortage. Prices are unchanged at the mines and in the retail yards.

DETROIT, MICH.

Bituminous—The market on certain grades is much stronger than in previous weeks, and indications are that most of the coal is well sold up into August; it looks now as if business for this last month would be considerably ahead of that for either of the two preceding months. Generally speaking, there have been good advances in prices on all grades in this market, and it is now believed that the coming fall will see the maximum quotations ever experienced locally. The movement on contract is heavy, and on domestic grades is in excess of requirements, with the result that these are rather dull. This, however, is usual at this time of the year and has not caused any uneasiness.

The local market is quotable about on the following basis:

	W. Va. Splint	Gas	Hocking	Cambridge	No. 8 Ohio	Pocahontas	Jackson Hill
Domestic lump	$1.40	....	....	....	....	$2.25	$2.00
Egg	1.40	....	....	....	....	2.25	2.00
Steam lump	1.25	....	....	....	....	....	....
¾-in. lump	1.10	$1.10	$1.10	$1.10	$1.10	....	....
Mine-run	0.90	0.90	0.90	0.90	0.90	1.50	....
Slack	0.85	0.35	0.30	0.60	0.60	Open	....

Coke—The local coke market is dull, with the result that some ovens in this vicinity have been compelled to suspend operations for the time being. Connellsville is quoted at $2.75; Semet Solvay, $3; gas house, $2.60; all f.o.b. ovens.

Anthracite—The demand for hard coal is strong, everybody apparently trying to stock up to their utmost capacity; operators are sold ahead for about two months, and premiums are being demanded on both sizes.

CHICAGO

The Chicago market is in a comparatively prosperous condition considering the fact that the usual dull time of the year is supposed to have arrived. Although buying in the spot market is light, the amount of shipments of coal indicates a fair condition of affairs. The light spot market is attributed to the fact that many retail dealers who could have been depended upon to take a large supply of coal for storage did an unusually large amount of buying in April and May, and now have in stock the same amount usually on hand in the latter part of July. Active buying recently in smokeless lump and egg has led to the fixing of the price of that coal for June at $1.90, with producers asking $2.25 for spot shipment. Quite heavy demands for steam coal in spot shipments are being made, and prices range from 80c. for small-sized low-grade screenings coming in at the low freight rate, to 90@95c. for large-sized high-grade screenings coming in on a high freight rate. Contract shipments on steam lump and mine run offsets the inactivity of this coal on the spot market now prevailing. A fairly active domestic coke trade offsets somewhat dull conditions in the iron and steel trade market.

Prevailing prices are:

	Springfield	Franklin Co.	Clinton	W. Va.
Domestic lump	$1.97@2.07		$2.27	
Egg		$2.30@2.40		$4.20
Steam lump	1.82@1.87	2.30@2.40	2.07	3.94
Mine-run	1.77@1.82	2.20@2.30	1.87	3.30
Screenings	1.62@1.67	1.95	1.62@1.67	

Coke—Connellsville and Wise County, $5.25@5.50; by-product egg and stove, $4.85; by-product nut, $4.55@4.75; gas house, $4.50@4.60.

ST. LOUIS, MO.

A forerunner of what may be expected is seen now in the Standard field in the way of contract prices for the coming season. A month ago operators were hungry for contract business, but they are not so anxious now and are

asking a price that is considered just a trifle unreasonable. The market still continues dull, with the exception of Carterville coal, which is commencing to pick up a little. There is not any great tonnage moving, but a better price is being asked and received, none of this grade being sold for less than $1.10 on the screened sizes. On the other hand, Standard coal is still below the cost of production as 6-in. lump is selling for 80c. and 2-in. lump for 75c.

It is amusing to note in the daily papers about the wonderful advantages that the Keokuk Electric Power Co. will bring to St. Louis. They forget that the Keokuk Power Dam will displace several million tons annually of screenings in the St. Louis market. A few years ago these same screenings were hauled away from the mines as ballast for the railroad companies, and the same thing will likely happen again. This means that the cost of screenings must be added to the screened sizes, and the public will have to foot the bill, so that aside from the business houses of St. Louis the Keokuk Power Dam will increase the fuel bills instead of lessening them.

Anthracite is moving fairly well and so is coke, and on account of the high prices asked for smokeless it is likely that this will lose the hold in St. Louis that it acquired last season.

The prevailing circular is:

	Carterville and Franklin Co.	Big Muddy	Mt. Olive	Standard
2-in. lump				$0.80@0 85
3-in. lump			$1.20	
6-in. lump	$1.15 @ 1.25		1 25	0 85@0.90
Lump and egg		$2.00	1 20	
No. 1 nut	1.10 @ 1 20			
Screenings	0.80 @ 0 85			0.75@0 80
Mine-run	1.00 @ 1 10			0 75@0.80
No. 1 washed nut	1 40			
No. 2 washed nut	1 25			
No. 3 washed nut	1 25			
No. 4 washed nut	1.20			
No. 5 washed nut	1 05			

St. Louis prices on May anthracite are: Chestnut, $7.15; stove and egg, $6.90; grate, $6.55. Smokeless lump and egg is $4.65 and mine-run $4. Byproduct coke is $5.10 and gas house $4.85.

PORTLAND, OREGON

Dealers report the coal business dull with little prospect of any heavy movement here for a few weeks. Although the strike in the British Columbia mines affected the market on Puget Sound, to some extent, it has not been felt here in a material way. It is reported, however, that coal is now being brought to the coast from Japan for bunker purposes. Two cargoes are said to be on the way, and others will probably follow unless conditions change soon.

PRODUCTION AND TRANSPORTATION STATISTICS

NORFOLK & WESTERN RY.

The following is a statement of tonnages shipped over this road from mines in West Virginia and the commercial and company coal, for the month of May, in short tons:

Field	Shipped	Tipple	Total	Commercial	Company
Pocahontas	1,257,150	16,941	1,274,091	1,292,130	98,546
Tug River	227,792	2,323	230,115	193,001	37,114
Thacker	258,659	18,350	277,009	186,438	90,571
Kenova	82,496	..	82,496	76,232	6,264
Clinch Valley	..	..	..	137,931	13,518
	1,826,097	37,614	1,863,711	1,885,732	246,013

Shipments of coke entirely from the Pocahontas field, were 105,737.

CHESAPEAKE & OHIO RY.

The following is a comparative statement of the coal and coke traffic over the lines of the C. & O. Ry., for April, and the ten months ending Apr. 30, 1912-13, in short tons:

	March				Nine Months	
Destination	1913	1912	1913	%	1912	%
Tidewater	273,623	533,226	2,993,615	23	3,625,675	24

Total	9,306,213	11,863,144	12,285,690	1,225,802	1,271,781
Bunker coal	5,302,750	5,832,031	5,936,461	707,848	559,386

LAKE SHIPMENTS

Anthracite Shipments through the Sault canals for the current year to June 1 were 636,159 tons as compared with 17,848 tons for the same period last year.

Bituminous Shipments for the same periods were: 2,890,789 for the current year as compared with 1,653,922 in 1912 making gross of 3,526,948 for 1913 and 1,670,870 in 1912.

COAL SECURITIES

The following table gives the range of various active coal securities and dividends paid during the week ending June 14:

	Week's Range			Year's Range

DIVIDENDS

Ashland Coal & Iron Ry.—Regular quarterly dividend of 1% payable June 20.

Mahoning Coal R.R.—Dividend of $5 payable Aug. 1 to holders of record July 15 on the common stock and $1.25 payable July 1 to holders of record June 20 on the preferred stock.

American Coal Products Co.—Regular quarterly dividend on the common of 1¾% payable July 1 to holders of record June 25. Also regular quarterly on preferred stock of 1¾% payable July 15 to holders of record July 2.

Colorado Fuel & Iron Co.—Dividend of 4% on the preferred payable July 1 to holders of record June 10. Also an additional dividend of 4% payable Jan. 1, 1914, to holders of record June 10, 1913.

Eastern Light & Fuel Co.—Regular quarterly dividend of 2% payable July 1 to holders of record June 19.

FINANCIAL DEPARTMENT

Island Creek Coal Co.

President Holden, of the Island Creek Coal Co., reports for the year of 1912, as follows:

The earnings of all companies for the year have been as follows:

Net earnings from coal and miscellaneous operations, including net profit on sales of lumber			$811,048
Deduct administrative and general expenses			57,252
Total net			753,795
Add interest received on bank deposits, etc			18,693
Total			772,489
The above profits have been appropriated as follows:			
Reserve funds for extinguishment and depreciation of coal properties, transportation plants, river and railroad equip. etc		$95,356	
Dividends declared:			
Four dividends on pfd	$298,659		
Two dividends on com	102,552		
Extra dividend of $3 per share on com.	298,728	699,939	795,295
Balance charged against surplus			22,806

The properties have been operated continuously during the year, and produced 2,039,837 tons. Net capital expenditures for the year amounted to $534,522, which have been especially required in the construction of 126 houses and the completion of 38 houses in course of construction on Jan. 1, 1912; the construction of a new hospital and its equipment; new store buildings at mines 7 and 8; a Catholic church and parsonage; new mine equipment, including twelve 6-ton locomotives and two 15-ton locomotives, mining machines, mining cars, etc.; expenditures on account of docks in Superior, Wis.; and especially the construction and equipment of the new dock at Duluth, Minn.

During the year arrangements have been made with the Chesapeake & Ohio Ry. for the operation of our railroad, with the right to have other roads jointly use our railroad, if such joint use seems to us advisable.

On Aug. 1, 1912, was paid the first dividend upon the common stock at the rate of $2 per share per year, and also an extra dividend of $3 per share. At the same time an opportunity was given to the stockholders to reinvest the $3 thus paid in the common stock at $50 per share. In this manner the cash capital of the company was not reduced, but stockholders not desiring thus to reinvest were permitted to receive a portion of the surplus which has already accumulated and for the distribution of which they had so patiently waited.

Consolidated balance sheet for last two years compares as follows:

Assets:	1912	1911
Property account	$5,001,858	$4,467,335
Current assets	1,651,548	1,759,546
Deferred chgs. to operation	22,383	14,831
Total	6,675,789	6,241,714
Liabilities:		
Capital stock	4,779,350	4,480,650
U. S. Coal stock	15,950	17,100
Current liabilities	373,050	247,698
Depreciation and reserves	455,061	420,550
Undiv. surplus subsid. cos	3,556	4,087
Surplus	1,048,821	1,071,627

⁂

Pond Creek Coal Co.

President A. T. Holden reports for the year ending Dec. 31, 1912, as follows:

Properties—Your company was organized in November, 1911, and has purchased approximately 31,000 acres of coal lands. The surface rights were purchased only when such rights appeared a necessity; the company owns some 5000 acres of surface. We have approximately 26,000 acres of demonstrated coal, a seam of from 5 to 7 ft. in thickness having been shown by openings and drillings throughout a very large percentage of the territory.

On Mar. 11, 1912, the first mine opening was begun and we now have seven mines, the highest present capacity of any one being approximately 200 tons per day, with a prospective ultimate capacity of 1000 tons per day for each. The properties, situated in Pike County, Ky., lie about 10 miles from Williamson, W. Va., a town on the Norfolk & Western R.R. The N. & W. R.R. began in May, 1912, the construction of a railroad from Williamson to our various mines and reached the first mine Nov. 1, 1912, the first shipment of coal being made on that date. At present this branch has a total constructed mileage of about 16 miles. In addition your company has built sidetracks at the various mines.

There had also been constructed on Dec. 31, 310 dwelling houses and machine and blacksmith shops, and there have been purchased mining cars, mining machines, etc. A power plant is sufficiently far advanced so that the company is already operating to some extent by electric power.

Through the selling agency that developed the market for the Island Creek coal, a market has already been developed for the Pond Creek coal, calling for a supply in excess of your company's ability to produce. Many tests have shown that the coal is a valuable byproduct coal.

Shipments—During November your company shipped 11,902 tons of coal; in December, 24,119 tons; in January, 35,142 tons; in February, 28,313 tons. The coal thus shipped is the result of the development work and the mines are not yet, and will not be for some time, upon an operating basis.

Plan—Your directors believe that the property, the railroad facilities and the market all warrant the immediate raising of sufficient money to bring your property up to a 10,000 tons per day basis. The company, Dec. 31, 1912, had on hand $784,619, but most of this was or is immediately required for the equipment and construction already begun. The stockholders are therefore requested to authorize an increase in the capital stock to $3,500,000 by adding 150,000 new shares of $1 each (none of which is to be issued at this time) and $3,000,000 bonds secured by a mortgage, of which only $2,000,000 6% bonds will be issued at present, the remaining $1,000,000 bonds to be retained for future needs. The $2,000,000 bonds, convertible into stock at $25 per share (that is, each $1000 bond convertible into forty shares of capital stock), have been underwritten by Hayden, Stone & Co., subject to your approval, to net the company 94%; that is, $1,880,000. The bonds will be convertible into stock at any time within five years of their issuance and will be callable, upon proper notice, at option of company at 105%. The bonds thus underwritten will be offered to the stockholders at par in the ratio of one bond of $1000 for each 100 shares of capital stock now outstanding; the total outstanding issue of capital stock being 200,000 shares par value $10 each.

The proceeds should suffice to develop the property to a 10,000 tons per day basis and provide working capital, so that the company may much sooner be in a position to pay dividends than if the development were to be accomplished out of earnings.

BALANCE SHEET DEC. 31, 1912 (TOTAL EACH SIDE, $2,536,173).

Real estate	$1,002,182	Capital stock (par $10)	$2,000,000
Construction, etc.	632,518	Share premium account	250,000
Cash	784,619	Accounts payable	252,047
Accounts receivable	39,517	Accrued pay-roll	13,442
Inventories, etc.	77,337	Drafts in transit	18,036
		Funds and reserves	2,648

⁂

Delaware & Hudson Co.

Delaware & Hudson Co. in 1912 earned approximately 12% on $42,500,000 stock. Earnings in 1911 were 12.32% and in 1910 12.54%. Balance for dividends was between $5,000,000 and $5,100,000, against $5,237,680 in 1911 and $5,330,189 in 1910. Notwithstanding the anthracite strike in April and May, when net after taxes fell off more than $950,000, the year closed with only a slight loss in surplus for dividends.

Considering the losses through cessation of mining operation and the increase in maintenance expenditures of about $600,000, the year's record must prove gratifying to stockholders. The decrease in net after taxes amounted to $270,000 for the twelve months. Had the directors wished they could have wiped out the small decrease by checking maintenance work. Instead the company took advantage of the open winter and carried on full maintenance, both of way and equipment, to the end of December. The company expended $435,000 more on maintenance of way in 1912 than in 1911, and $168,000 more on equipment.

Operating revenue increased almost exactly $1,000,000, of which $935,000 was contributed by freight traffic and $45,000 by passenger.

⁂

FINANCIAL NOTES

Union Pacific Coal Co.—The Union Pacific R.R. Co. owns the entire $5,000,000 of the outstanding stock of its subsidiary, the Coal Company. Of the $5,500,000 first mortgage, 5% bonds of the Coal Company, the Railroad Company owns $3,354,000, the remaining $1,646,000 being held as a sinking fund by the Coal Company.

The Reading Co.—The surplus assets of this corporation on June 30, 1912, approached $50,000,000. As a potential factor in whatever financial development the Reading directors may undertake, this exceptionally strong financial position of the concern is of interest. Another feature of this is the fact that none of its obligations mature for a long time to come. Its demands upon its cash assets are more than met with each year's operations.

COAL AGE

Vol. 3 NEW YORK, JUNE 28, 1913 No. 26

The inventor of the cash register gave his invention its "try out" at a coal-mine commissary. The owner of the establishment was so astonished at the unlooked for results that he decided that these machines had a brilliant future and forthwith he abandoned the commissary and turned his attention to cash registers. He has been interested in selling them ever since.

There are plenty of managers and bosses willing to denounce you as a fool or a crank if you so much as hint at any possible crookedness around their "diggings," and yet the first complete systematic audit of any mining company's affairs rarely fails to uncover irregularities enough to keep every one from the superintendent down to the office boy busy making explanations and suggesting changes.

There is nothing remarkable about this when you realize the difficulty of keeping in close touch with every one at a large mining operation who is responsible for entering up time and tonnage; neither should it be construed as a slur on the personnel of the coal-mining business as compared with other large industries.

There are three well known systems of obtaining easy money from coal-mining companies, and, strange though it may seem, year after year they are set moving and generally are carried to successful terminations, from the standpoint of the dishonest:

1.—Tipple weigh bosses enter into collusion with some of the miners and then credit them with as much coal as can be added to the actual tonnage sheets without exciting suspicion. At mines where part of the coal goes to ovens and the balance is shipped in cars, it is often difficult to obtain a check on the weighman's figures and his additions may assume an amazing proportion of the whole, over long periods of time. If the weighman's weights are checked by total shipments, it is still possible for him to short-weigh some men and credit his "pals" with a corresponding amount.

2.—Commissary clerks arrange with some of the employees who trade at the commissary to handle company checks for them and then instead of canceling the checks as they are presented, they retain them and pass them back out for circulation.

3.—Bosses of all kinds from coke-oven foremen down to boss trackmen have been known to pad their labor rolls and divide the profits with those who are in a position to conceal the irregularities from the paymasters.

In some camps all three systems have been discovered in action at the same time, while at others they have followed singly but with almost dizzy regularity.

Are the guilty ones punished when overtaken? Rarely.

The ill-gotten gains slip through their fingers almost mechanically and there is little or no chance to recover losses. Furthermore, in many such cases, salaried lawyers are frequently able to successfully oppose company prosecutions.

And so the loss is hushed up and the next-door neighbor is not warned of his danger.

MORAL: Auditors and red-tape experts are still useful citizens around many mining operations.

Use of Purchased Powers in Coal Mines

By H. D. Jackson*

SYNOPSIS—This is a problem which does not now greatly vex the mining industry. The day is not far distant, however, when it is destined to assume a position of considerable prominence. This article discusses some of the salient features in its consideration.

Electricity is rapidly superseding all other methods of supplying power to coal operations, except possibly in those locations where, owing to the gaseous condition of the mine, it is unsafe to carry the current into the underground workings. Even in operations of this character, electricity is used to a large extent in all operations where feasible.

The early installations were all of the direct-current type, operating at either 250 or 500 volts, and were employed mainly for lighting and haulage work. Pumps, fans, hoists, etc., were, and are still to a certain extent, operated by steam largely because the owners considered reliability of the greatest importance; and owing to their knowledge of what steam could do, they would rather trust it than the more recently developed electric motors. In case of an accident to a locomotive, it was a comparatively easy matter to put the mules again into service; but in the case of a break-down of the electric fan-motor, it was an entirely different matter.

These Plants Are Still Operating

These plants having been built, they are, to a large extent, still in operation. The owners being conservative, and the mining work paying fairly well, the question of the cost of power was a secondary consideration. Today, however, things have changed, and the power-cost, including as it does a large item in labor and fuel is becoming more and more important.

There has been a vast increase in the number of mining developments, the modern ones of which are operating at a maximum of economy, with a consequent reduction in the cost of their product.

At the present time there is an element entering into existing conditions which is of interest to the mine owner. All through the coal regions wherever such schemes seem possible, there are being established central stations, the avowed purpose of which is the furnishing of power to the mines, at such a figure that by adopting this source of supply, those operations which are now finding it difficult to operate advantageously, will be enabled to successfully compete with the more modern plants which now make power for themselves.

The idea is that these generating stations by virtue of their size and location, and the fact that the peak

Fig. 1. A Typical Hydro-Electric Central Station, Viewed from Above the Dam

loads on the different plants which they serve will probably not all come at the same time, can supply power cheaper than the mine plants can manufacture it themselves.

These new installations are carrying out an aggressive campaign to sell their product, and doubtless in many instances are securing business at a price that would warrant the investment. In other cases, however, it is seriously to be doubted if their power can compete with that furnished by the isolated plants. It must be remembered too, that the central station has to pay fixed charges on a high initial cost.

This is unavoidably the case since the installation consists not only of the generating apparatus, but also the transmission lines which are necessary for distributing the power to the various plants it supplies. It must also have a relay service in order to take care of any unit which may be shut down in case of an accident, so that the amount of its equipment is great, its load factor not good, and its fixed charges consequently high.

*88 Broad St., Boston, Mass.

In addition to this, the plant must have an organization for securing and carrying on the business, and a force to obtain necessary data for calculating and making out monthly bills.

All of these are excess items to be added to the ordinary expense of operation; so that, while it may be true that the purely manufacturing cost may be low in an installation of this character it does not necessarily follow that the total cost of power production, including all charges, is any less or even equal to that in many of the isolated plants.

Where the Central Station Has Its Greatest Advantage

It may be true, and doubtless is, that a central station can furnish current to one of the old type mining plants using electricity now solely for haulage purposes and supplying all its other power by means of steam engines located at more or less favorable points about the mine and at considerable distances from the boilers, but could it do so if this plant were rebuilt along modern lines?

This would not necessarily mean an entire reconstruction of the plant, but in many cases might involve the replacing of the steam-driven pumps, hoists, etc., by electric ones. By doing this, practically all of the machinery requiring skilled attention would be centered in the power house, reducing largely the cost of attendance and also decreasing to a far greater extent the amount of coal required for operation, as fan engines, steam pumps, and steam-driven hoists are almost universally steam eaters.

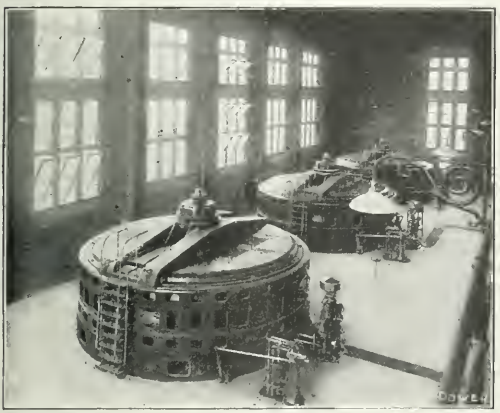

Fig. 2. Interior of a Power Plant, Showing Three Generator Units

It has long been known that steam engines operated at a distance from the boiler plant are exceedingly hard to keep in good running order, owing to the large amount of water, unavoidably condensed in long pipe lines. This condition requires engines of large clearance, which are uneconomical in the extreme.

The condensation alone represents a considerable loss, and the difficulty of keeping the long pipe lines tight is in itself a large item. Engines of the character necessary for use where attention is small must of necessity be of the simplest and most rugged type. This means that they must be practically free from all the refinements which make them economical in the use of steam, and it would be natural, if every effort were to be made to operate with the maximum of economy, that machines of this character would be abolished.

The same is true of pumps which take steam full stroke, as they are probably more wasteful thermodynamically than any other steam-operated apparatus.

Therefore, it is advisable for the owner or operator of a coal mine, when this matter of purchasing power is brought up, to consider not only what it may cost him to supply power as he is at present doing, but also what it will cost him to furnish it from his own plant if modernized; and then compare that figure with what it will cost him if purchased.

He must not lose sight of the fact that although the present equipment may not be economical when the cost of its power is compared with that as offered by the supply company, there yet remains the opportunity of calculating the price of current if the plant were put in the best possible condition. The relative advantages and disadvantages of either alternative will then be clearly perceptible and a wise decision can therefore be reached.

The Cost of Introducing Purchased Power

The price of the apparatus necessary in order to use purchased power is by no means a small item, and when one takes into consideration that the machinery in use at present must be scrapped, or practically so, the cost of its introduction runs up still more, unless it may be that the plant which is abandoned has been so long in service, and so handled financially, that it has reached a point of no value; when its discarding would represent no monetary loss.

If, however, no depreciation allowances have been made, or if the plant has not been in operation for any considerable length of time, it cannot be scrapped without a heavy financial sacrifice. The fixed charges on this loss should be added to the cost of power as purchased from the central station in order to make a correct comparison.

The cost of power from an existing plant is represented by the fixed charges on its valuation, plus the operating expense; if purchased, its price is composed of the fixed charges on the machinery required for its utilization, the operating expense, the price of current, and the fixed charges on the difference between the cost of the original plant and the amount for which it is sold.

In case power is generated after remodeling the station, its cost is represented by the fixed charges on the total value of both old and new equipment, plus the operating expense, depreciation, insurance and taxes in all cases being included in fixed charges. Whichever one of these proves the smaller is certainly the one to be chosen.

Before contracting for power, the fixed charges as well as the rate at which current can be secured should be scrutinized with care and calculations made over a considerable range of load. Under certain conditions it will probably be found quite advantageous to purchase power from an outside source. Under others it might be equally desirable to generate it at the mine plant.

Some Unreduced Death Rates in Illinois

By John Dunlop*

SYNOPSIS—The death rates from roof falls and falls of coal, and that from mine cars show no sign of reduction in Illinois, though the decrease is apparent in other parts of the United States. The author of the paper is of the opinion that shooting off the solid has not been shown to be a more important source of accident from falls than certain other methods of mining.

There is a part of the mining death rate in Illinois which legislation, inspection and the work of the federal Bureau of Mines has been unable to reduce. This part is that due to falls of roof, coal and drawslate and to the mishandling of cars.

In the last year of record between June 30, 1911, and the same date in 1912, the deaths from falling rock, coal and drawslate amounted to 54 per cent. of all fatal accidents in coal mines. Mine cars were the cause of 19 per cent. of the accidents.

The number of nonfatal accidents in the state from falls of rock, coal and drawslate were in the same period 45 per cent. of all accidents and from mine cars 26 per cent. It is surprising to learn that the loss of life from these causes per million tons mined has remained almost constant since 1901.

Longwall Workings Have More Accidents and Less Fatalities

The number of nonfatal accidents per thousand men employed is greater in the longwall workings than in the room-and-pillar mines, but it is a redeeming feature that there are less fatal accidents. This is due to the coal being thinner. A piece of loose coal or shale of sufficient weight to injure a miner working in low coal would in all probability kill him if it fell from the roof of a seam 5 ft. thick or over.

The state inspectors have been insistent in recommending that face bosses be employed, and the provision would, I am sure, save many lives. But there is a feeling against their employment. The miners believe that they would be arbitrary in performing their duties. A number of the larger companies have employed such men, and I learn that the results are not as favorable as might be expected.

The superintendent of a coal company operating two mines, and employing about thirteen hundred men, states that face bosses have been at work only a year in his mines and he cannot tell whether they have done any good. The men are taking advantage of the compensation act and are reporting injuries and seeking medical aid in cases so slight that they would not have reported the accident had it happened a year ago.

This is his statement:

TONS MINED PER ACCIDENT

	No. 1	No. 2
1912	3857	1378
1913	2364	1144

Apparently more men are injured than before the hiring of face bosses, but also the increase may be due to the concurrent effect of the compensation law.

At No. 1 of the same company, the number of accidents for the last three months shows a decided decrease over those reported in the first three months of the fiscal year.

QUARTERLY RETURN OF ACCIDENTS, NO. 1 MINE

July, August and September	1912	72
October, November and December	1912	46
January, February and March	1913	39

It is true that more powder is used where coal is being shot off the solid, and it is probable that the roof is affected by the heavy shooting, but a careful perusal of the reports of the state inspector of mines shows that 60 per cent. of the men killed by falling coal, roof and drawslate are struck down in mines where the coal is almost all undercut by machine. As these mines produce only about 52 per cent.* of the total output, it seems that they have an undue proportion of accidents, and it is not fair to ascribe the maintenance of rate or increase in accidents to shooting out of the solid.

Hence, it seems by these figures that the use of electric machines has a more detrimental effect than shooting off the solid. If props are set at a sufficient distance from the face to allow proper clearance for the working of a machine, the distance is too great for safety, especially where there is a bad roof. Under conditions of this sort, which are general through the central and southern part of the state, props should be placed before the coal is shot, and if face bosses are employed, it would be their duty to see that the place was properly timbered before any shots were fired. It must not be taken for granted that because the inspectors have strongly recommended that face bosses be employed for each 100 men in the mine, that the supervision of these men would avoid accidents.

The Car-Accident Problem

To prevent accidents to drivers is a problem more difficult to solve. This subject was earnestly discussed by the Mine Investigation Commission, and they listened attentively to suggestions of all kinds and considered the feasibility of having a law enacted to prohibit the driver from riding on the tail chain. It was agreed that such a law would not be practical in all cases. They did recommend that in mines opened after the passage of the act then prepared, all mine cars should be equipped with a bumper or bumpers on each end, which should project from the end of the car not less than 4 in. This was only palliative, and would not remedy the evil.

Not long ago, I had occasion to investigate a fatal accident which occurred to a driver. I found that he had not taken the proper care to protect himself. He attempted to come down a grade with a loaded trip and did not take time to put in sprags, but undertook to hold the trip by placing his back against the car and his feet on the rails, allowing the trip to push him down grade. His feet slipped off the rails, and as the trip was traveling rapidly, he fell in front of the car, which ran over his body injuring him, and causing his death a short time after. In this case, it was a matter of speed at the expense of safety. To prevent accidents to drivers, we must always urge "More caution and less speed."

*State mine inspector, Third district, Peoria, Ill.

Abstract of paper entitled "Safety First from the Standpoint of the Mine Inspector," delivered at the mining conference held at the dedication of the Transportation Building and Locomotive and Mining Laboratories, University of Illinois, Urbana, Ill., May 8, 9 and 10.

*Although 44 per cent. of the coal in Illinois is machine-mined, these same mines produce 4,230,077 tons of hand-mined coal and 51.8 per cent. of the whole tonnage of the state.—Editor.

A Gas Ignition Controversy

By J. W. Powell*

SYNOPSIS—A reply to questions propounded by James Ashworth, in regard to ascertaining the most probable cause of the second explosion in the Bellevue mine, Dec. 9, 1910. An account of a careful and detailed investigation of the mine by Mr. Powell, Jan. 20 and 21, 1911, followed by his theory of the explosion and its cause. Experiences in heavy-roof caves in mines in Pennsylvania and elsewhere.

In answer to the request of James Ashworth, Coal Age, Mar. 1, p. 344, I will recount my theory of the second Bellevue mine explosion, Dec. 9, 1910. I was the superintendent of the mine at that time, having resigned my position as district mine inspector of Alberta, eight days previous to the disaster.

The verdict of the coroner's jury, based upon Mr. Ashworth's evidence as mining expert, stated that the disaster was caused by the percussion of air, due to the caving of rock over chutes Nos. 76 to 78. Feeling that the responsibility of reopening and operating this mine devolved upon me as superintendent, and not feeling satisfied that this verdict was in line with the facts, I was anxious to ascertain for myself the true cause of the disaster.

After some persuasion I prevailed upon the pit boss, J. Anderson, who had served in that capacity practically since the opening of the mine six years previous, to accompany me in making an inspection of the mine. Mr. Anderson claimed that the workings were liable to cave again and with more disastrous results than before, owing to the great accumulation of gas. In this prediction he was correct, as was proved by the third and more violent cave and explosion, which occurred five days after our inspection was completed.

Referring to Fig. 1, starting Jan. 20, we first examined all points on the counter entry from No. 45 chute outward to No. 43 chute, where this entry was caved tight. We found a large amount of dust on the timbers, ribs and floor of the entry. The force was outward as shown by the direction in which the timbers were blown. Inby, from chute No. 45 to No. 49, there were large quantities of dust but no signs of coking. I found the force was upward through chute No. 45 to the surface. Going down chute No. 45 to the main entry and along that entry to chute No. 58, we examined the counter entry and section above as far as chute No. 70, proceeding at some points nearly up to the fourth crosscut. This section was slightly caved at different points and there were large quantities of dust on the fallen rock and floor and evidences of a slight coking on the corners of some of the coal pillars.

Going back to the main entry, we entered chute No. 72 and examined the counter entry in this section as far as chute No. 80. From the center of the pillar between chutes Nos. 76 and 77 as far as chute No. 79, there was no cave of roof rock, as was previously supposed when this section was examined Dec. 13, which examination was hurriedly made. I went up chutes Nos. 75 to 78, inclusive, as high as the fourth cross-pitch, and found but a slight cave crossing chutes Nos. 75 and 76 and extending about 25 ft. above the first crosscut. There was some coking in evidence on the caved rocks in this section and a slight coking appeared on some of the posts in chute No. 76.

Proceeding along the counter entry to chute No. 85, I found a large quantity of dust deposited on the bottom

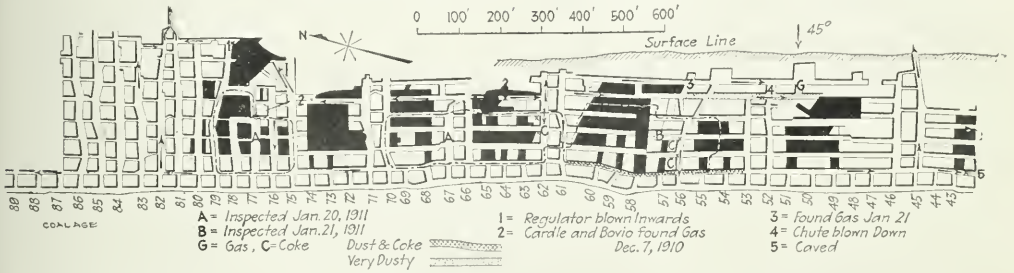

Fig. 1. Plan of Part of Bellevue Mine, Showing Areas Inspected and Points of Interest

of this entry and on the timbers, but no coking was visible. The force of the explosion in this section was inby, as indicated by the stoppings and the boards on the sides of the coal chutes. Going down chute No. 85 to the main entry, we traveled the main entry to the face at No. 129 and returned by that entry to the mouth of the mine.

The next day, Jan. 21, as indicated in Fig. 1, in company with J. Anderson, pit boss, and Frank Lewis, driver boss, I proceeded up No. 53 chute to the counter entry and along that entry to between chutes Nos. 60 and 61, where we found this entry blocked tight with coal that had been put there for a stopping to turn the air up over the workings above. This stopping had not been disturbed. There was a large amount of coking along the counter entry, between chutes Nos. 53 and 58, and a board nailed on one of the posts near chute No. 57 was charred, showing it had been subjected to a great heat. In this entry there were large globules of coked dust all along this section. You could pick up cakes of coked dust as large as your hand. Both Mr. Anderson and Mr. Lewis stated that this coking was the result of the second explosion, as they had traveled through this section many times after the first explosion and before the second oc-

*Mine manager, Columbia Coal & Coke Co., Coalmont, B. C., Canada.

curred, and were certain that there were no signs of coking then at that place. At chute No. 54 a car was tilted up, which they claimed was caused by the second explosion.

The force evidently came down chutes Nos. 56 and 57 and passed outward along the counter entry as there were no signs of coking on the corners of the pillars at the mouths of these chutes. Going up chute No. 56 and returning down chute No. 54, I found little caving in this section. I then went up chute No. 52 to the fourth cross-pitch. After building a ladder I tried to go up to the fifth cross-pitch, but was prevented by a body of gas 8 or 10 ft. above the high side of the cross-pitch. Then going back through the fourth cross-pitch to No. 56 chute, I again tried to get up the angle chute to the fifth cross-pitch, but again encountered gas at about the same height as before. We then crossed over to a point between chutes No. 57 and 58, but could go no further, as the large excavation above this point made it unsafe to proceed, and we returned by the fourth cross-pitch to No. 52 chute and thence to the main entry and the mouth of the mine.

Roof Caves and Air Percussion

Now, in respect to air percussion due to heavy caving of roof in mines, I wish to recall an experience I had in the anthracite region of Pennsylvania, in the Whites vein seam, at Williamstown, Dauphin County. The mine was operated by the Summit Branch R.R. Co. The roof of the mine was a strong, tenacious conglomerate that would hold over a large area without caving, until, finally, as the work progressed, the roof would begin to weight and, for several days before the cave would take place, it would snap and crack, and there were loud reports similar to those of rifle shots. You could hear the cracking crossing through the roof over the solid pillars similar to the cracking of ice traveling across a large pond. This was warning for everyone to get away at a respectful distance as, when it caved, there was always a great rush of air to such an extent that the sheet iron lining the chutes would sometimes be lifted and carried before the blast and twisted around props in its path. I want to say that at such times I never experienced any heat in the rush of air, nor did anyone else. On the contrary, the air was cool like a cold wind.

In Carbonado, Wash., I experienced several large caves in mines, where explosive gas was present in the old workings, I recall one experience in No. 7 mine, which was very gaseous, when the mine foreman and myself, sitting on one of the counter entries, eating our lunch, felt a great concussion accompanied, a few seconds later, by a great rush of air. Thinking that there had been an explosion in some portion of the mine, we proceeded at once to make an investigation. Meeting some of the men we were told that heavy cave had occurred in some of the pillars. The nature of the rock in this mine differed from that in the Bellevue mine, as it did not emit sparks, and there was consequently no explosion.

In Coleman, Alberta, I experienced a number of large caves in No. 2 seam. Some of these were of larger proportions than the one at Bellevue mine on Dec. 9; but I never heard of anyone feeling any heat in the rush of air that always accompanied a cave of any extent. I am told further, by Mr. Anderson, that a very heavy cave once occurred at Bellevue mine, in a section around No. 29 chute, and, in comparison with this, the cave of Dec. 9, was but a drop in a bucket. The cave caused a great rush of air and a concussion that made many think an explosion had occurred; but there was no development of heat and no explosion. The question may be asked if the roof cave, Dec. 9, produced heat sufficient to ignite the gas, why did not the previous cave, which was much greater, also produce heat and ignite gas?

Reflecting on these facts, I came to the conclusion that this disaster (Dec. 9) was not caused by percussion of the air; but that it was due to gas ignited by sparks emitted from the roof rock while "weighting," just before caving took place; or from the striking of the rocks against each other as caving occurred. The dust blown into the air undoubtedly distilled carbon monoxide, which propagated the flame of the explosion. It is a well known fact among the miners at Bellevue that the roof rock is capable of emitting sparks when struck or when falling. It has also been proven, in a reliable way, that these sparks are capable of igniting firedamp. That there was also an ignition of dust is confirmed, in my mind, by the fact that, while leading the first rescue party not more than three-quarters of an hour after the explosion occurred, I encountered smoke at No. 76 chute. The smoke was the same dull-gray color given off by a newly made bituminous coal fire and had a similar smell. It was not the mist that sometimes accompanies explosions of gas. Andrew Matson stated, in his evidence at the inquest, that he recognized the smell of smoke "a little like gas from a stove," from chutes Nos. 107 to 90, and that this got stronger as they advanced to the outside. There was also a smell similar to that of burning coal coming from the air shaft at No. 82 chute, for several weeks after the explosion. In fact, at one time, we were afraid that there was a fire burning in the mine, and I went down through No. 82 air shaft, Dec. 23, to ascertain, if possible, whether this was true: but I could find no indication of fire burning. The smell gradually became weaker as the air current carried it out of the mine.

Where the Explosion Originated

In my opinion, gas was ignited by sparks emitted by the rock that caved at the surface pillar, in the neighborhood of No. 65 chute above the fourth cross-pitch. This was one of the points where gas was found by Cardle and Bovio, Dec. 7, two days previous to the explosion. These men stated, in their evidence, that they discovered gas in this place, by standing on the loose rock lying on the floor of the seam, and raising their safety lamps to the roof; but were unable to estimate the amount of gas, owing to the broken state of the roof and the large excavation in the surface pillar above. I have shown, in Fig. 2, what I think was practically the condition of the roof in this section, near the surface pillar. In my opinion, any weighting of the roof, which is always accompanied with a grinding action, would have emitted sparks sufficient to ignite the body of gas that undoubtedly was accumulated in this place when the cave occurred. According to their evidence, the roof in this place was in a dangerous condition, at the time these men made their examination, and made it unsafe for them to venture across to chute No. 74.

Inasmuch as the cave, if any occurred in chute No. 76, was small, and since the men working on pillars Nos. 80

and 81, close to that chute, reported no weighting of the roof that day when they came off shift, only four hours previous to the explosion, it is reasonable to suppose that the explosion originated in the section between chutes 65 and 74, where the heavy cave took place. It is worthy of mention that, owing to the peculiar nature of the roof here, it gives considerable warning before caving, and the men at work there would certainly have known if there had been any movement in the roof above them. On the other hand, the weighting of the roof, in the section above chute No. 65, could not have been heard, as this section is abandoned.

Path of the Explosion

The large winged arrows in Fig. 1 are intended to show, in a general way, the direction in which the force

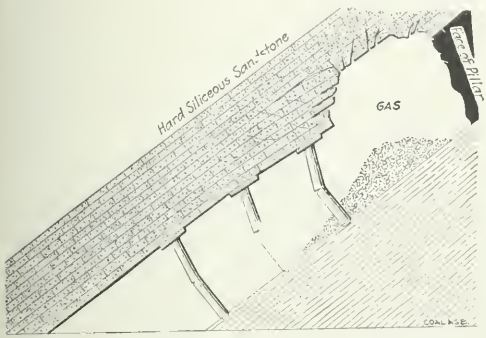

Fig. 2. Showing Condition of Roof, Where Explosion Is Assumed To Have Started

of the explosion traveled, from its point of origin above chute No. 65. Following the arrows the explosion traveled inby along the top of the workings, igniting any gas present at No. 74 chute, and blowing inward the regulator between chutes Nos. 79 and 80, and passing out through No. 82 air shaft, to the surface. Branching from this course, as shown by the arrows, some of the force of the explosion passed down through the robbed-out portion, to the counter and main entries, depositing coked dust on the rocks and the floor of the seam around chutes Nos. 75 and 76 and on some of the posts at this point. Passing along the counter entry, part of the force traveled up chutes Nos. 82 and 83 to the air shaft, while another portion continued inby along the counter entry.

Outby, the force of the explosion extended along the top of the workings, through the fourth and fifth cross-pitches. There was considerable force in evidence along the fourth cross-pitch from chute No. 57 to chute No. 49. Chutes and timber were blown out, and one of the men, who lost his life on the cross-pitch outside of chute No. 52, was buried under the débris so that it took several hours to find the body. At this point, an empty dump car was blown up on end. As shown by the arrows, the force split at chute No. 52, a part going down through this chute, tearing out the chute and manway in its path, to the counter entry. The other part traveled along the fourth cross-pitch and passed down through chute No. 49, to the counter entry; then passing outby along this entry to chute No. 13, where there was a cave completely blocking the entry. Much of the force of the blast here passed up chute No 45, to the surface. The force of the explosion also extended downward to the counter and main entries, at different points between chutes Nos. 65 and 53.

The fact that the bodies of men found on the fourth cross-pitch, just outside chute No. 52, showed signs of being subjected to great heat but no flame, indicates to my mind that the flame of the explosion was here extinguished by expansion in the large area of open workings. The men here were subjected to a rush of hot air and dust, as the blast extended outward along the fourth cross-pitch, and down through chute No. 49, which was the outlet, at the end of this cross-pitch, leading to the workings below. Men who were on the counter entry, at chute No 45, when the explosion occurred told me afterward that the rush of air and dust coming from the inside workings felt hot. It had evidently cooled off much before reaching this point.

Replying to Mr. Ashworth's Questions

My account thus far, and theory of the disaster, will practically cover points Nos. 1, 2, 11 and 15, submitted by Mr. Ashworth, Coal Age, Mar. 1, p. 344. I will endeavor now to answer briefly the remaining questions in regular order, as follows:

3. There was no evidence, as far as I remember, to show that there was any accumulation of gas at a point between the third and fourth cross-pitches, above No. 73 chute.

4. I found No. 73 chute slightly damaged.

5. This chute being but slightly damaged would not, in my opinion, indicate positively that no explosion occurred on top of this chute, 300 ft. up the pitch. That would depend on the direction of the force of the explosion.

6. Not having read the article by Stirling and Cadman, on this explosion, I cannot answer this question.

7. Yes. These pillars were all intact, with stoppings in all crosscuts except the top one, which was left open to allow the air current to pass through.

8. The pillars working on the day of the disaster were Nos. 76, 77, 78 and 79. These were the only pillars, to my knowledge, working in that section, at the time.

9. Cardle and Bovio stated that they found a small quantity of gas over chute No. 74.

10. As previously stated, I have not read the article to which you refer, but am of the opinion that the only gas that entered into this explosion was that which was accumulated in pockets above the fourth cross-pitch, and which was above the path of the ventilating current.

12. I plugged No. 81 charging station in order to turn more air into the inside charging station, where the miners were assembled who were later rescued. The charging station plugged was blown off at the T where it branched off the main line.

13. No. 53 chute was blown out completely and all the coal it contained was piled on the main entry. No. 52 chute was blown out from the fourth cross-pitch down to the counter entry. This chute was a network of timbers, sheet iron, etc. We found this chute completely blocked with débris just below the fourth cross-pitch. The coal drawn from the chute 24 or 26 hr. after the explosion occurred was very hot when drawn. The cross-pitch on the south side of No. 52 chute was strewn with timber and coal that was blown out from this chute. I

noticed no signs of great heat at this point, but the dust on the corner of No. 52 chute felt rough and cinderv to the touch; otherwise, there was no indication of heat or coking.

14. No. 52 chute was used for dumping coal from the fourth and fifth cross-pitches above. I have already described the condition of this chute from the counter entry to the fifth cross-pitch. The chute was not damaged below the counter entry, but was protected by the large amount of coal it contained.

16. Not having read the paper to which you refer, I cannot answer this question.

17. I was unable to get up to and examine the fifth cross-pitch, on account of the accumulation of gas. Chutes Nos. 45 to 52 were intact. Chutes Nos. 53, 54 and 55 were blown down, and a considerable amount of coal and timber was lying on the entry at the foot of these chutes. There was very little damage done from chutes Nos. 56 to 62, but all of these chutes were more or less ruptured and had to be repaired the night of the explosion, in order to enable us to convey the air current along the main entry to the inside workings. The chute that was driven off the rock tunnel at No. 62, and connected with the counter entry of No. 1 seam at this point, was blown down completely, the timbers and coal being piled up in the rock tunnel, at the foot of the chute, which demonstrated there was quite a force exerted downward at this point. We put a curtain across the rock tunnel outside this chute the night of the explosion, to prevent the air current short circuiting at this point.

I believe this answers all of Mr. Ashworth's questions.

A Safety Latch for Shaft Gates

On page 464 of our issue of Mar. 22, 1913, there appeared two photographs of a safety latch for mine gates as used by the H. C. Frick Coke Co. As some of our readers have made inquiry about this device, we deemed it advisable to describe it in greater detail.

The object of this safety latch is to prevent the gate at a shaft landing being opened, except when the cage is in the proper position. Fig. 1 shows a plan and side elevation of the assembled device.

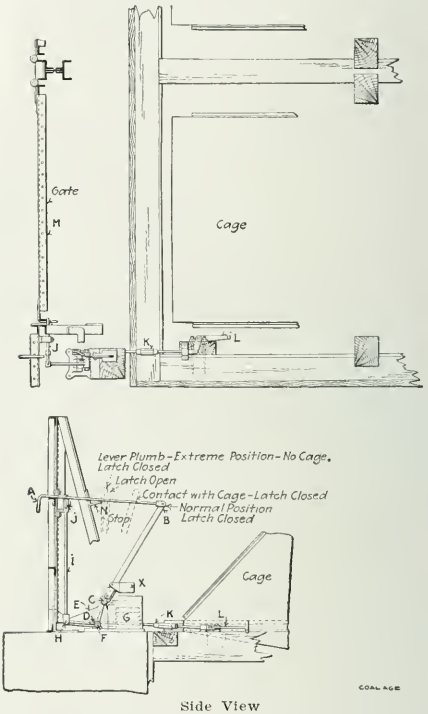
A is the hand grip or operating lever. This is connected to *B*, which is pivoted at *C* to the rocker *E*, while at its lower end it is connected at *D* to the adjustable rod *K*.

The rod *K* is connected to the bell crank *L*, which is pivoted to a stationary fulcrum on the framing or timbering of the shaft. The rocker *E* above referred to is pivoted at *F* to a stationary fulcrum attached to the landing. *E* is also heavily counterbalanced by the weights *G*, which, under ordinary circumstances, hold it in the position shown. At the point *H*, *E* is connected to the rod *I*, which, at its upper end, is pinned loosely to the latch *J*.

Suppose now that the hand grip *A* is pulled when the cage is not at the landing. The lever *B* is free to move forward as far as the stop *N*, the only effect being that the point *D* will be pushed backward, causing the rod *K* to revolve the bell crank *L* through a certain angle.

Suppose now that the cage is in the proper position at the landing. If the grip *A* is now pulled, the lever *B* will move forward and the bell crank *L* revolve until it comes in contact with a suitable plate placed upon the side of the cage. When this takes place, the bell crank *L* can move no further, and the lever *B*, instead of pivoting at the point *C*, now pivots at *D*. A further movement of *A* tilts the rocker *E* about the point *F*, raising the counterweights *G* and pulling down the point *H*, which, in turn, through the rod *I*, opens the latch of the gate, which can now be swung outward and cars or men admitted to the cage.

After a car, we will say, has been pushed upon the



Side View

MECHANISM OF THE SAFETY LATCH FOR SHAFT GATES

cage, the grip *A* is released, and the lever *B* allowed to swing backward. The counterweight *G* upon the rocker *E* now returns to its original position, closing the latch. The small counterweight *X* upon the lever *B* also pulls the latter to its original position, which rotates the bell crank *L* back from the cage and out of the way along the side of the shaft.

The cage can now be raised or lowered without interfering with any part of the latch mechanism, and the gate is closed and will remain closed until the cage is again brought to its proper level when pulling the rod *A* will again makes contact between the cage and the bell crank *L*.

A further refinement, and one which is not shown upon this drawing, is that of connecting the rocker *E* with a system of rods and levers, which can be made to actuate a pair of chocks located at a sufficient distance in front of the gate to allow the latter to swing open and which will hold a car until the cage is in position.

This device was invented by one of the employees of the H. C. Frick Coke Co., and a patent upon it has been applied for.

An Oklahoma Water-Hoist

By E. C. Reeder*

SYNOPSIS—A description of the means employed to remove water from an old mine that threatened to break into and flood a newer operation. The expense of handling this water by bailing was decidedly less than by the use of pumps.

::

Oklahoma has several important coal fields, practically all of which are in the east central part of the state. Title to most of the coal lands is vested in the Indians, who receive substantial royalties from the mining companies.

One of the largest and most important of these coal fields is the McAlester, named after Col. McAlester, one of the pioneers of this region. The town of McAlester is also named after him and is the metropolis of this part of the state. It is located adjacent to several of the large mines and is served by both the Rock Island and Missouri, Kansas & Texas lines of railroad which give outlets north and south as well as east and west.

The largest of the mining companies in this region is the Osage Coal & Mining Co. who also operate several large mines in the Wilburton District to the east of McAlester.

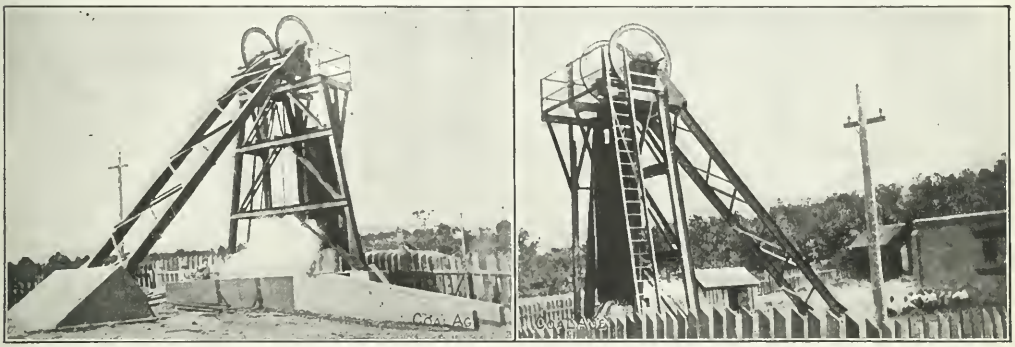
At McAlester the coal beds outcrop in a number of places and dip at a fairly uniform angle to the southwest. The angle of inclination varies only slightly but usually flattens with depth. There are several workable seams of coal, a distance of some hundreds of feet existing between the uppermost and lowest beds.

At the village of Krebs, some three miles from McAlester, the Osage company has several large mines mostly opened on the upper seam which here averages about five feet thick and dips to the southwest, the angle at the outcrop being about 15 deg., flattening to about 6 deg. at a vertical depth of 800 ft.

The Necessity for Water-Hoisting Apparatus

Cutting into the Osage company's acreage is the property of an older concern, the greater part of whose coal has been mined out and the workings abandoned and allowed to fill up with water. The Osage company is connected with the old workings at a point about 490 ft. vertically from the shaft mouth where an electric turbine pump was located which took care of the overflow from the old mine, pumping to the surface through a drill hole. As the workings of the new mine got deeper and approached these old workings below the water level, apprehension was felt that the entries might break through and be flooded, particularly as no reliable maps of the old mine were in existence.

The shafts and slopes of the old mine were in bad condition, being practically impassable and a great deal of work and expense would be entailed if the old mine were to be pumped out by the ordinary methods. It was finally decided, after much study, that the best plan was to sink a new vertical shaft, tapping the old workings at their lowest point and either install pumps or bailers to handle the water.



Front and Rear Views of Headframe with a Bailer Discharging in Each Case

A two-compartment shaft, 5 ft. by 9 ft. 9 in., inside the timbers was sunk through the shales overlying the coal at this point. It was estimated that the coal was down about 774 ft., and the shaft was stopped at a point approximately 736 ft. from the surface. The timbering was then completed, buntons put in, guides strung and the shaft finished so a cage could be run in either compartment.

About this time (November, 1910) the Osage company decided that it would install a hoist and handle the water with self-filling and self-emptying bailers, raising the same with an electric engine. This machinery was accordingly contracted for.

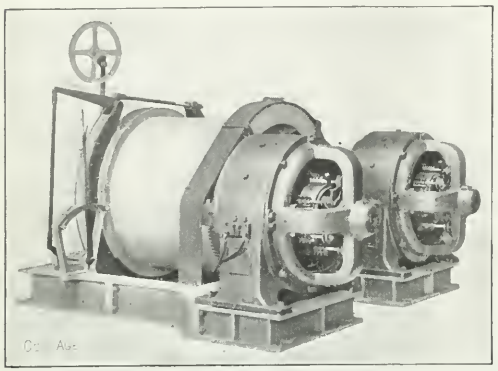
The work of finishing the shaft and tapping the water was then carried forward and completed. When the timbering was finished a churn drill was erected on the surface and a 12-in. hole drilled from the bottom of the shaft into the old mine workings. After drilling about 40 ft. the drill broke through and the water rose in the shaft to within 500 ft. of the collar.

The drill outfit was then removed and the bailing machinery erected and connected up. The bailers themselves are 3 ft. 10 in. in diameter and 12 ft. 3 in. long, built of $\frac{5}{16}$-in. plate and hold 1000 U.S. gallons. There are two

*Mining engineer, Chicago, Ill.

valves in the bottom about 14x18 in. in area, hinged on one side to open inward. One valve is connected by rods to the tripping mechanism which automatically opens it at the surface when the trip comes in contact with a guide runner placed for that purpose. The discharge of water is directed to the side by a spout attached to the bottom of the bailer.

The other valve is used for filling purposes only as both open automatically when the bucket enters the water. The bailers discharge as soon as the spout attached to the bottom clears the collar. A concrete wall surrounds the shaft and forms part of the receiving basin into which the water runs to be carried off finally by a ditch.



THE HOIST AND ITS TWO DRIVING MOTORS

A structural-steel head frame 25 ft. high, to the center of the sheaves surmounts the shaft. This carries the head sheaves and the tripping runners for emptying the bailers. The photos show the general construction of the head frame, also the bailers discharging.

HOIST DRIVEN BY DIRECT CURRENT

The hoist is arranged for operation with direct current at 600 volts, the railway circuit of the Choctaw Railway & Lighting Co. passing within a short distance of the plant. For several reasons it was decided to use two motors on the hoist with master control and magnetic contactors arrange for series-parallel operation.

One reason for using two motors was that it might be desirable to operate over indefinite periods at reduced speed, and another that in case of accident to one motor there would still remain the other for operation at either reduced speed or load.

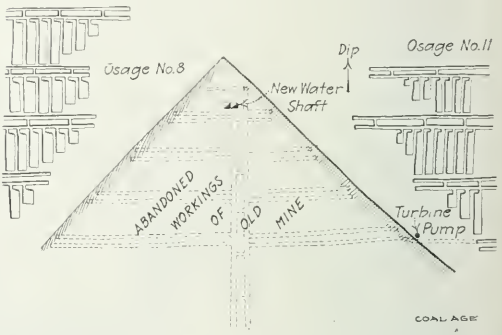
The motors are of the General Electric manufacture, 175 hp. rating, type CLC, 350 r.p.m., with commutating poles. They are geared direct to the drum shaft, the ratio of reduction being 6.1 to 1, giving a rope travel of approximately 1100 ft. per min. at full speed.

The ropes are both wound on a single drum 72 in. in diameter by 55-in. face, machine grooved for 1-in. rope, one part winding on as the other winds off. The drum gear is bolted to the drum at one end and on the opposite end is located the brake which is of the post type, operated by hand.

The operator stands on a platform at the rear of the hoist, where he commands a view of the bailers as they discharge as well as the hoist and motors. All the machinery, including the head frame, buckets and hoist, was built by the Lidgerwood Mfg. Co., of New York.

The plant was put in service in July, 1911, and has been worked continuously ever since. It has been found that operation for 10 hr. during the day is ample to keep the water level down to about 700 ft. from the surface, and the greater part of the time the hoist operates with the motors in series, running at approximately half speed and bringing up a bailer full of water about every 1½ min. On test at full speed they have hoisted a bailer every 50 sec. and kept it up for several hours, but when running at this rate would bail out the shaft in 3 or 4 hr.; hence it was found more economical to run at a slower rate.

When handling their water by means of the turbine



MAP SHOWING OLD WORKINGS AND POSITION OF PUMP AND WATER HOIST

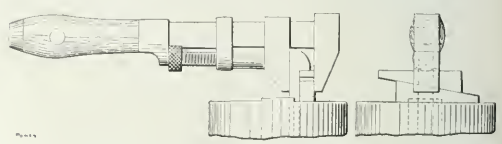
pump it cost the coal company about 4c. per 1000 gal., but since the installation of the water hoist this has been reduced to about 1¾c. per 1000 gal.

Several other mines in the district are preparing to handle their water by a method similar to that above described, and the operation of this plant has been closely watched by the parties interested in similar properties.

Removing Solidly Driven Keys

Those who have trouble in removing head keys from the valve-gears of Corliss engines and other places will find that all trouble may be avoided by adopting the following method of removing the keys, says John F. Hurst, in *Power* of June 10, 1913.

Place a monkeywrench over the key as shown and insert a compound wedge between the jaws of the wrench and under the head of the key. By applying a pressure



SHOWING USE OF WRENCH AND WEDGES FOR REMOVING KEYS

to the end of the wrench and at the same time driving the wedges, or cold chisels, whichever is used, the key will slowly but surely come out.

Coal Mining Institute of America Meeting

By R. Dawson Hall

SYNOPSIS—The courtesy of the Pittsburgh officials and the wealth of opportunity for study in that city made the meeting of the institute most profitable to all in attendance. The program, though improvised, was of great interest.

The change of place of session from Wilkes-Barre to Pittsburgh at the last minute could not fail to have its effect in reducing attendance and it was somewhat surprising that so many persons came to the meeting despite the fact that the program was hastily framed at the last moment and might be expected to show some evidences of that haste.

Everyone believed the change in venue was justified, not so much because the attendance would have been small as because the executive committee had no way of being assured of the number of persons who would probably be present. It is certain that several members had decided to attend who either did not want to avail themselves of the special train service from Pittsburgh or were too negligent to make reservations.

H. C. Frick Coke Co. Safety Exhibit

There was no program provided for a morning session, so the regular meeting did not commence till 2 o'clock in the afternoon of June 17, being held in the Assembly Hall of the Engineers' Society of Western Pennsylvania. Mr. Keller, of the H. C. Frick Coke Co., delivered the regular lecture which he is accustomed to make to the miners at the company's various plants, accompanying it with stereoptican slides illustrating different accidents and the means by which they may be prevented. The pictures show not only the right way, but also the wrong way of doing certain kinds of work and also the accidents resulting from following the wrong methods.

The result of the training seems to justify the company in its expenditure. Fatal accidents in the Frick mines are far less numerous per million tons produced than in England, Scotland or the United States, as was shown by some diagrams presented. The real merit of that fact was, however, not made plain. The H. C. Frick Coke Co. is mining the Pittsburgh bed almost exclusively and this seam is regarded as having an exceptionally dangerous roof. The remarkable record was made, therefore, despite adverse conditions.

Pennsylvania Possesses 5 per Cent. of the Coal and Mines One-Half

John W. Boileau then delivered his address on the "Pittsburgh Coal Field," illustrating it with a large map of the seam, showing its extensions in West Virginia and Ohio. He has measurements of the coal bed compiled from drillings throughout the field and perhaps no one knows better than he the characteristics and values of every portion of this coal territory. His address is abstracted as follows:

"The bituminous coal fields of Pennsylvania produce nearly 160,000,000 tons per annum. This constitutes one-third of all the coal produced in the United States. But this does not represent the whole coal output of the state for the anthracite production is about 90,000,000 tons.

"In the Pittsburgh district proper more than 60,000,000 tons are mined annually, but when the product of the Connellsville district, Fayette and Westmoreland Counties is added, the tonnage is 100,000,000, or approximately one-fifth of the entire tonnage of the United States. This includes coal sold as coal and coal made into coke. The coke region itself will produce 21,000,000 tons of coke each year, to manufacture which 32,000,000 tons of coal must be mined. The coke tonnage will probably increase 5 to 7 per cent. per annum.

"Pittsburgh and the manufactories in the Monongahela, Ohio and Allegheny Valleys within a short radius of that city form the greatest coal-consuming district in the world. While we consume in the Pittsburgh district proper 16,000,000 tons, we use enough in the form of coke to raise that figure to 25,000,000 tons.

"Pennsylvania has only about 5 per cent. of the coal area, but the state is producing nearly half the output of the entire United States. Consequently, the early exhaustion of the coal resources is to be expected, particularly of that part of the coal which is suited for coking or the manufacture of gas.

"Our great railroads are consuming immense quantities of coal and half the iron industry is located in Ohio and Pennsylvania so that the Pittsburgh bed will be rapidly exhausted. One large railroad alone uses six acres per day. The total acreage requirement of the United States is more than 325 acres daily. It is to be regretted that this exhaustion is not replaceable like that in agriculture; there is but one gleaning. If all the coal produced in Pennsylvania were drawn from one of our largest counties, like Greene or Washington, the coal in those areas would last only 8 or 10 years."

The Conditions Determining Coal Thickness

The discussion largely centered on the relation of coal thickness to the direction of the main basins and anticlines resulting from the Appalachian uplift. Mr. Boileau stated that the basins usually showed thicker coal than the anticlines and some were disposed to believe that this was an indication that the main uplift was in process of formation when the Pittsburgh bed was laid down, because the lower coal beds do not thicken in those synclines which have that particular direction. For instance, the basins which show thick coal in the Kittanings are those which run east and west and not northeast and southwest. Mr. Boileau declared that the thickness of the coal varies along the basins as well as across them and that the summits of the anticlines are sometimes eroded. The irregularity of the sulphur content was also discussed, but its presence could not be subjected to forecast, its occurrence being more irregular than that of the coal.

Visits to Points of Interest

The institute then adjourned to the offices of the weather bureau and H. Pennywitt, the local forecaster,

explained the methods by which the weather was predicted. The visitors climbed to the top of the Farmers' Bank Building, where the weather conditions are measured, the actual readings being taken in the offices below.

June 18 the members met at the Carnegie Museum and were shown through the exhibition rooms and the laboratories. As a rule, such a trip is wearisome in the extreme and not to be compared with an unconducted trip. However, with W. J. Holland, the curator, and D. Stewart, his assistant, as guides no such weariness was possible. Drs. Holland and Stewart have made the exhibit what it is, have traveled long distances to secure and excavate the specimens and are, moreover, brilliant conversationalists, their enthusiasm and extensive knowledge making every exhibit of interest.

Talking through Adam's Apple

In the afternoon a trip was made to the Bureau of Mines, where a lengthy program had been prepared. J. W. Paul demonstrated the use of rescue apparatus in the smoke room and showed how the telephone could be operated by attaching it to the throat of the rescuer. As this vibrates with the vocal chords, it is possible to use its motion to actuate the transmitter. The rescuer, therefore, speaks in the confines of his helmet and not directly in front of the diaphragm, but the instrument being attached to the throat receives and delivers the message nevertheless.

Mr. Paul also showed the action of a modern safety lamp in a mixture of air and 8.6 per cent. of explosive gas moving at a velocity of 2500 ft. per min. The flame left the wick and went up into the gauze. Then placing an unbonneted lamp in the same mixture, moving at 1500 ft. per min., he showed that it was extinguished. The Davy lamp in the same mixture exploded, though the velocity of the air current was reduced to 600 ft. per min. Passing one by one into a dark room, the visitors compared the cap of the naphtha-bonneted lamp with that of the Davy lamp in 2 per cent. of methane.

Simple Detonator Test

The nail test for determining the strength of detonators was then exhibited by C. Hall. The detonator is tied beneath a finishing nail and ignited through a fuse. The explosive bends the nail and the action measures the force of the detonator correctly. This is not true of the Trauzl block which has hitherto been the recognized method of measurement. The method invented by Mr. Hall has certainly the merit of simplicity. He exploded two detonators, one a No. 3 and the other a No. 6, and the difference in the angle to which the nail was bent was easily manifest. Weak detonators fail to produce the full strength of the powder to be detonated.

O. P. Hood described the experiments being made to determine how much of each kind of gas is exhausted by gasoline motors in every condition of working. A motor is being tested in the laboratory, but in the field the conditions of working are being ascertained so as to discover what effect the gasoline engine has on the atmosphere in a mine.

The bureau is testing carbon-dioxide recorders for determining the operating efficiency of boiler and other furnaces. The various types under test all showed the same record during the visit, but it is said that there is some lag in changing the record when the operating conditions change.

Portable Electric Lamps for Mine Use

H. H. Clark exhibited several portable electric-mining lamps, including the C. E. A. G. lamp, which has just been approved. He showed that a spark caused by a break in a current of 10 amp. at 15 volts made a large and brilliant spark. Despite the long period during which the flash was continued in the presence of gas, no explosion resulted. A smaller spark at a higher voltage ignited the gas as soon as discharged. Sparks of low voltage will not ignite methane unless the current is extremely high.

G. S. Rice announced that the state of Colorado had just passed a law requiring that oil safety lamps shall only be used for testing purposes after Jan. 1, 1914, and requiring the use of electric lamps for ordinary mining purposes. This law is to be of effect when the bureau shall determine the electric lamps which are safe for mine use.

A visit was made to the large testing machines of the Bureau of Standards. A test was being prepared of a large rock pillar, surrounded by concrete and bound by iron bands. The rock was piled loosely and filled with sand by flushing. The purpose is to ascertain the strength of the loose rock when it is confined and prevented from sliding sidewise under pressure. A yellow-pine prop about 8 in. in diameter was tested in another machine and failed under a total load of 77½ tons. The failure was wholly at the bottom and the prop was in such condition that it could be sawn off and used in a thinner bed or in a place when a shorter prop would serve. This sawing off and relocating of crushed props is effecting large economies for the Philadelphia & Reading Coal & Iron Co.

At the close of this exhibit, the meeting disbanded without further formalities.

Chilean Coal Importations

The quantity of coal imported into Chile has increased in the past few years, having doubled during the last decade; 1,577,000 tons were imported in 1912, practically all of it coming from England and Australia. At present the importation of coal from the United States is prevented by the lack of any line of ships running directly to this country. With the opening of the Panama Canal and the establishment of a fleet of ore-carrying steamers between Chile and Philadelphia, it is expected that there will be a better opportunity to sell American coal in that country, as, no doubt, the ships would take return cargoes at low rates.

Hirsch Electric Mine Lamp Approved

The Bureau of Mines has approved the safety electric miners' lamp, manufactured by the Hirsch Electric Mine Lamp Co., of 221-227 North Twenty-third St., Philadelphia, Penn. This is the first cap lamp approved by the Bureau. The battery is carried on a belt around the waist of the operator and the lamp is connected by a flexible pair cable passing over his back. The light is thus easily handled by the workman and does not interfere with his work.

Notes on the Groundhog Coal Field

By Amos Godfrey*

SYNOPSIS—The Groundhog coal field is situated in northern British Columbia and contains a large amount of high-grade coal that will come into competition with the Alaskan coals in the Pacific Coast markets. A few facts concerning it are given in this article.

The Groundhog coal field is in northern British Columbia, in the Cassiar district, and lies between 56 and 57 deg. north latitude, and about 128 deg. west longitude, covering an area about 30x45 miles in extent. The nearest town is Stewart, 90 miles away, as the crow flies, on the Portland Canal, but the town from which all supplies must be obtained is Hazelton, on the Skeena River, which is about 150 miles by trail from the coal fields. Supplies are taken up the Skeena on the ice in winter and on pack trains in the summer, both of these methods being expensive and uncertain.

In 1903, James McEvoy, formerly of the Canadian Geological Survey, took a party into the Groundhog country and staked 12 claims. In 1904, W. W. Leach went in with a party and staked four additional claims for the same company. F. A. Jackson was a member of both of these parties, his work being the hunting of caribou. On his hunting trips Mr. Jackson noticed other outcrops which the Western Development Co., for whom he had been working, did not take up. In 1909 he decided to stake his discovery. James Latham and Mr. Jackson went in during July with four horses, two pack and two saddle horses. They staked 11 claims, which were taken over by a syndicate calling itself the British Columbia Anthracite Syndicate, which was later merged into the B. C. Anthracite Coal, Ltd., claims having been added as prospects warranted until the company now owns 66 claims in all.

The next one to take an interest in the Groundhog region was Leon Benoit, of Winnipeg. In the fall of 1910, R. C. Campbell Johnson went in to examine Mr. Benoit's holdings and in 1911 took in a large party and did considerable work opening some fine anthracite coal. Since then many stakings have been made until now there are some 1500 square miles of territory staked out. No doubt much of this territory is barren.

In September last the B. C. Anthracite Coal, Ltd., had some thousand feet of tunneling driven in the several seams, the longest tunnel being 182 ft., one fault and one roll having been encountered, but in both instances the coal was normal on the other side. J. A. Challoner, writing in December last, reports upon one seam that there is 6 ft. of good, clean coal.

Character of the Coal

The geological age of this field has been classed by the Canadian Geological Survey as cretaceous, the exact position in that age not having been fully determined. The classifications of the coal by D. B. Dowling's method of split volatile ratio, are anthracite, semi-anthracite and anthracitic in character. In this connection George Watkins Evans states in a report: "From the above analysis we find that the coal field contains what can actually be classed as anthracite. It is claimed by men who have criticized the field that there is no anthracite present. I think the above partial summary should convince anyone that anthracite really does occur." The government reports upon the coal show that it is variable in the amount of fixed carbon that it contains, that constituent running from 10 to 85 per cent. and averaging around 60 per cent.

No. 4 "A" Trail Creek, Opposite Jackson Camp

Tunnel on Outcrop on Telfer Creek

Railroads into the Region

The Provincial Government has granted several railway charters. One proposed railway from Nasoga Gulf to the coal fields would be in the neighborhood of 200 miles long and traverse the Naas River valley, which has great agricultural possibilities. This road would be called the Naas & Skeena Rivers R.R. Another charter has been granted for a road to start in the town of Stewart on the Portland Canal, called the Canadian Great Eastern. This, too, would enter the upper reaches of the Naas River and possibly be laid along Currier Creek, the mouth of which is the center of the field. The length would be approximately 120 miles. Fourteen miles of this are already in operation up Fair River from Stew-

*Manager B. C. Anthracite Coal, Ltd., Groundhog P. O., B. C.

art. Another route would be a continuation of the Grand Trunk Pacific, which is in operation from Prince Rupert to Hazelton. This would follow the Skeena River from Hazelton to the coal field, the distance being approximately 200 miles and the grade would be in favor of loaded trains. The Naas & Skeena Rivers R.R. has one divide to cross, the Canadian Great Eastern has two, so, although the initial expense of the Grand Trunk Pacific would possibly be greater, it has the advantage that the actual cost of haulage would be less.

Market for the Coal

It has been thought that the opening of the Panama Canal would start a market for an immense amount of coal from this field. Moreover, the cities of the Pacific Coast are making great strides. In fact, there has been a shortage of coal in Vancouver recently, showing that a portion of the output of this field would find a market in the near-by cities along the coast. Moreover, the interior of the province is making rapid progress which will also take care of some of the output.

Coal Outcrops on Barney Creek

Alvo Mountain, Showing Basal Conglomerates

Some views are given which were taken in the Groundhog region, the first figure being a view of No. 4A Trail Creek, opposite the Jackson camp, where some prospecting has been done. This shows a drift in the bank along the creek on a coal outcrop. The second picture is of a drift which has been driven into the coal on Telfer Creek. In this the inclination of the strata can be seen dipping about 30 deg. N. E. Fig. 3 is of a stripping of the outcrop on Barney Creek, where some good anthracite coal was found. The character of the country can be seen from the background. Fig. 4 is a picture of Alva Mountain, and shows the basal conglomerates which underlie the region.

Mine Holidays

The numerous attempts which have been made to compile a list of mine workers' holidays in the anthracite coal region of Pennsylvania have so far been a complete failure. In view of the many recent "Button" and other strikes these frequent holidays are becoming an increasing source of loss and annoyance to the operators.

Capt. W. A. May, president of the Pennsylvania Coal Co., recently stated that he could never tell when a miners' holiday was coming or how many men it would involve. His company has no less than 29 nationalities on its payrolls and each has holidays peculiarly its own.

A recent compilation of the nationalities of the mine workers in the anthracite region gave them as follows: American, English, Welsh, Scotch, Irish, German, Slavonian, Italian, Polish, Hungarian, Austrian, Swedish, Russian, Belgian, Bohemian, French, Finnish, Canadian, Lithuanian, Greek, Tyrolean, Danish, Syrian, Montenegrin and Horwat. The workers classified as "American" include all of those born in this country even if their parents were foreign and did not speak a word of English, and several groups, like the Slavonians, are capable of still further subdivision.

The worst feature of these holidays is that, in many cases, the mine workers do not notify their foreman in advance, and to keep the numerous foreign holidays in his head, taking into account the changing nationalities of the shifting labor, a foreman would have to be a sort of human almanac. The celebration of most of the holidays also implies a second day off for those who have celebrated too well.

As long ago as 1906 the Lehigh Valley Coal Co. presented this difficulty as a matter for consideration to the Board of Conciliation, but the two grievances were withdrawn.

"Shooting off the Solid"

Advance sheets of his report for 1912 show that John Laing, chief of the Department of Mines, makes the proud boast that "shooting off the solid" has been nearly eliminated in West Virginia.

Government statistics show that more than 48 per cent. of deaths in coal mines are due to falls of roof. One of the causes of these falls is "shooting off the solid." A shot in the solid seam is also more likely to blow out the tamping so that the flames may set fire to coal dust or gas, thus causing an explosion that may wipe out scores of lives. In other words, reckless miners deliberately risk their own lives and the lives of others to save labor.

This dangerous practice has been discouraged in West Virginia by a vigilant system of inspection backed up by prosecutions of offenders. The 1911 report of the chief of the Department of Mines shows that 105 miners were fined an aggregate of $1303 for shooting off the solid in that year. This vigorous enforcement of the law evidently had its effect in 1912.

Our British Coal-Mining Letter

SYNOPSIS—The Rufford accident has called attention to the need for ladders and automatic hoisting control in shaft sinking. The tonnage of English mines per man employed has not decreased, despite the shortening of the hours of labor, and the increased remoteness of present operations from the shaft bottom. This uniformity of production is the result of the greater use of machinery. The utilization of the exhaust from steam engines in low-pressure turbines is an important source of the increased power in British collieries. Underground fires in Wales are found to occur frequently in the shales of the roof.

The hoisting accident at the Rufford shaft, related on p. 453 of COAL AGE, has aroused much question as to the need for ladders in shafts which are in process of sinking. It will be remembered that, owing to the fall of a water bucket, the scaffold beneath the workmen broke. They fell into the water and, probably, several of the 14 killed, perished by drowning.

Rope ladders have been suggested as furnishing the best mode of escape, but it was pointed out that if four ladders had been provided for 18 men, five or six, perhaps eight or ten, would have tried to reach one ladder, which could hardly serve as even a life line for them all. It was made apparent in the inquiry that an automatic controller should have been installed. This would have reduced the speed 42 ft. from the top of the shaft and have stopped the bucket on the surface. It was suggested that an emergency engine should have been provided so that the men could have been removed regardless of the disablement of the regular hoisting engine used for sinking purposes.

Mechanical Power in Mines

Taking as his subject the development of mechanical power in the mines of the northeastern coal field, R. Nelson, chief electrical inspector of mines, addressing the North of England branch of the Association of Mining Electrical Engineers, recalled the important part which mechanical power has played in enabling the coal-mining industry to meet the demands made upon it.

In 1911 there were in operation 511 collieries in Northumberland and Durham, and they produced 56,401,343 tons of coal, while the number of workmen employed was 216,733. Thus 260 tons were produced per person per annum. Comparing the figures for 1844, when the use of mechanical power was limited, with those for 1911, the number of workmen and the output had each been multiplied by about six, an indication of the extent to which the use of mechanical power had aided the development of coal mining, seeing that the output per man was almost maintained, although the daily hours of labor in coal mines had been reduced one-half and despite the fact that the more remote and less easily worked coal is now being mined. As regards the output per colliery, the figure for the year 1844, namely 77,600 tons, was increased to 110,000 tons by the year 1911.

Mr. Nelson then proceeded to say that the present century has so far witnessed nothing in mining comparable with the wide adoption of electricity. Motors totalling over 100,000 hp. are now at work in the mines of Northumberland and Durham. For the various operations of pumping, coal cutting and coal conveyance, electricity now stands preëminent, and a modern installation of electric motors may be made a thoroughly mechanical job, well able to withstand rough usage. Further, the apparatus may be so protected that if the current is rightly used, that is to say, only where the risk of accident arising therefrom is, so far as can be seen, negligible, the standard of safety is as high as that to be attained by any machinery in any situation.

Utilizing Steam Exhaust

The question of utilizing the power of exhaust steam is one which arises in the experience of most colliery managers, and as A. Benson reminded the Midland members of the National Association of Colliery Managers, in nearly every case the plant installed for this purpose necessarily includes a condenser. If electrical energy or compressed air is used at the mine, the most convenient way of dealing with the exhaust steam from the hoisting or other engines is to use it in a low-pressure turbine for driving electrical generators, or for actuating air compressors. Other circumstances might arise where more power is required from non-condensing engines such as the engine driving a fan, and in this case the difficulty might be met by installing a condenser of a suitable type. The advantage derived from the use of a condenser, as Mr. Benson stated are: A saving of steam of from 20 to 40 per cent, increased power of steam engine, economy of boiler plant and a supply of hot, pure feed water for the boilers.

Underground Fires

In a paper before the Scottish Institute of Mining Students, W. A. Taylor explained that apart from spontaneous ignition of the coal, fires may be caused underground by (1) ignition of timber resulting from the careless handling of naked lights; (2) badly constructed motor rooms, in which inflammable material is in too close proximity to starters, motors, cables, etc.; (3) the heating of timber or coal by steam pipes. The precautions to be taken where there is any danger of fire, suggested by the late Mr. Pickering, are recalled as follows: (a) Withdrawing as much timber from the waste as possible; (b) packing the waste as tightly as possible; (c) paying great attention to the building of side packs; (d) leaving as little coal standing as possible; (e) keeping the workings cool by means of an adequate amount of ventilation.

Blaes, a blue shale, is undoubtedly a primary cause of fires. During the past year the railway fill at Wellesley Colliery, near Methil, which is largely made up of blaes, caught fire in two places. Other embankments in the vicinity have also caught fire. A short time ago a fire took place at Rosie Colliery, belonging to the Wemyss Coal Co., in which the blaes overlying the Chemiss seam was found burning at the edge of an old pillar.

Hoisting Engineer's Eight-Hr. Day

British hoisting engineers now have their hours of employment regulated by law, the Home Secretary prescribing June 30, 1913, as the date after which a hoisting engineer may not be employed for more than eight hours in any one day, except as provided by general regulations.

Benham Coke Works, Wisconsin Steel Co.

By J. R. Foster*

SYNOPSIS—A small plant turning out a good product from beehive ovens. Two beds of coal are worked, the product of one being made into coke while that of the other goes to the market as a domestic fuel. Considerable attention is given to the sanitation of the town and the safety of the employees.

The coke works of the Wisconsin Steel Co. are situated on Big Looney Creek in Harlan County, Ky., 79 miles from Middlesboro on a branch of the Louisville & Nashville R.R. The plant proper is so located that it does not mar the beauty of the town and still is within short walking distance of all the laborers' homes.

The Geology of the Coal Beds

The region drained by the Poor Fork and Clover Fork of the Cumberland River includes the southern slope of the Pine Mountain and extends from the confluence of these two streams to Proctor Fork, a distance of about 38 miles, its extreme width being about 9 miles. Big Black Mountain, lying along the center of the region, is the most prominent feature of its topography, rising to a height of 4500 ft. above tidewater. This is the highest point in the state.

Except on the narrow flats of Poor Fork only the larger creeks have bottomlands wide enough for the economic location of coke ovens. The seams of coal in this field are divided into the upper and lower groups. Those of the lower productive group are locally designated as A, B, C and D, and are of varying section and value in the property.

Fig. 1 shows the relative distance between the seams. This group with associated rock is about 200 ft. thick. The bed A, or Harlan seam, is the lowest coal measure which has proven of any commercial value. The B seam is from 110 to 115 ft. above the A. The C, or Keokee bed, lies about 40 ft. above the B, while the D, or lower splint, is the highest of this group, lying about 75 ft. above the B.

An analysis of coal from the Keokee, or C seam, shows the following approximate results: Volatile matter 38 per cent., fixed carbon 58 per cent. and ash 2¼ per cent. The coke produced from this material contains about 1 per cent. volatile matter, 94 per cent. fixed carbon, one-half of one per cent. sulphur and a trace of phosphorus.

In many respects this coal bed resembles the Elk Horn seam of the Kentucky River section but no connection can be made between the two because of the disturbance made by the upheaval of the Pine Mountain shown in Plate 1. This coal is the one now being coked at this plant. Its height in Benham Spur averages 5 ft. 8 in.

The D, or Low Splint seam, is now operated by the company for domestic and foreign market purposes and gives the following test: Moisture, 5.012 per cent.; volatile combustible, 35.54 per cent.; fixed carbon, 52.002 per cent.; ash, 6.7855 per cent.; sulphur, 0.635 per cent.; phos., 0.025 per cent. This seam averages at the outcrop a height of 4 ft.

Only One Seam Is Coked

As stated above, the company is at present working two distinct beds of coal, one 60 ft. above the other.

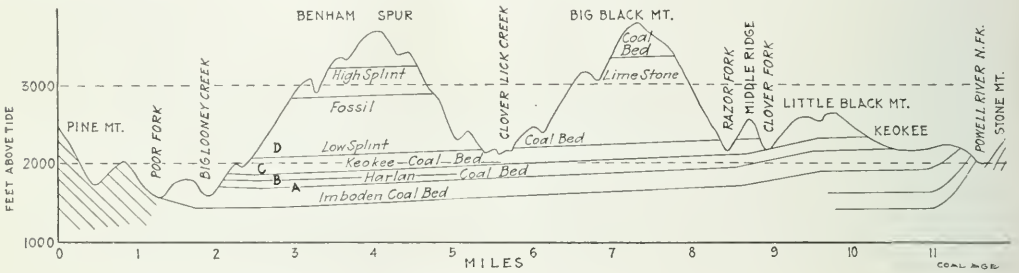


Fig. 1. Cross-Section of Coal-Bearing Strata near Benham, Ky.

Each has a separate tipple. The upper seam is worked entirely for domestic purposes and the market, none being used for the manufacture of coke. The coal is lowered to the tipple by two monitors of 5 tons capacity each, running on a three-rail, gravity incline. It is passed over gravity screens, making three sizes of coal.

The other or lower tipple is equipped with two Jeffrey swing-hammer crushers of 1500 tons capacity each. The maximum size of the crushed coal is ¼ in. and all crushing is done dry. A bin of 1200 tons capacity takes care of the fine material.

At present there are 300 coke ovens of the beehive type in operation and 108 under construction, requiring on the average 1400 tons to fill with 48-hr. charges.

All the machinery of the lower tipple is run by electric power except the crushers, which are driven by two steam engines of 150 hp. each. The power plant consists of a separate power house, equipped with two 250-kw. 250-volt generators and one 100-kw. 250-volt generator. The boiler house is equipped with four Stirling water-tube boilers of a total of 1400 hp., working under a steam pressure of 125 lb. The mine is worked on the four-entry system, all haulage being done by electric motors. It is ventilated by a Jeffrey fan, with an ultimate capacity of 200,000 cu.ft. per minute. This is now working at a capacity of 60,000 cu.ft. and a present speed of 30 r.p.m.

*Coke foreman, Wisconsin Steel Co., Benham, Ky.

As above stated, all the coke ovens in operation are of the beehive type. There are two parallel batteries, which contain 120 ovens each and one short battery of 60 ovens. The coal cokes exceedingly well, requiring little air, ¾-in. to 1-in. draft openings being used for 72-hr. coke and 1½-in. for 48-hr. coke. Six tons of coal are charged for 48-hr. and 7½ to 8 tons for 72-hr. coke.

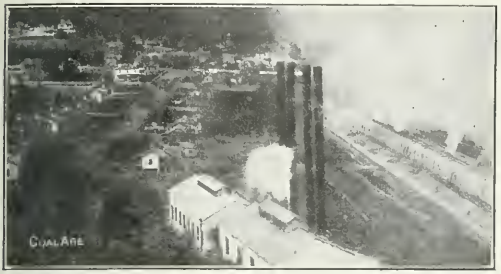

FIG. 2. BIRDSEYE VIEW OF BENHAM, SHOWING POWER PLANT AND COKE OVENS

The government test shows this coke to be among the best in the country. It has a light gray or silver color; the cell structure is small but not dense. It breaks in fingered pieces of fair size, which have a noticeable metallic ring. The 72-hr. charges make a high-grade foundry fuel. The per cent. of recovery is 63.5.

MUCH ATTENTION IS GIVEN SANITATION AND SAFETY

The town of Benham is laid off in streets and blocks, having the appearance of a well planned village rather than that of a mining camp. The houses vary in style and color, and all have hydrants in the back yards, the water supply coming from a reservoir, which is fed by mountain springs. This arrangement gives clean, wholesome water for domestic use, a separate system being provided for the power house and coke yard. The houses are

FIG. 3. BENHAM FIRST-AID TEAM AT PRACTICE

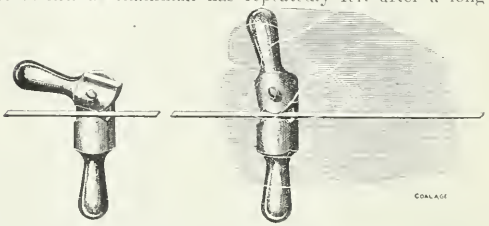
fenced and ample space is given for chicken yards and vegetable gardens at the back. Those desiring them are furnished with electric lights at a cost of 25c. per room per month.

Safety committees, made up of three men on each entry in the mine and in the different departments outside the mine, have been appointed. Each member wears a badge and it is his duty to observe closely and report any practice conflicting with the rules governing the operation of the mine or violating the mining laws of the state.

At the mouth of the main entry of the mine is printed in large letters, "Safety First." It will be easily perceived from the above that the company is sparing no effort to protect the lives and health of its employees. W. C. Tucker, superintendent, has given particular attention to the comfort and welfare of his men and to the sanitary condition of their surroundings.

A Tape Grip

The device illustrated below is a tape grip, and its purpose is to enable a chainman to obtain a firm hold at any desired point of the measuring line. In plumbing down a steep hill, using broken distances, it is not possible to make use of the hold furnished by the handles provided, but with the aid of this device, the tape can be stretched as tightly as if the whole line were being used. That soreness around the thumb and finger nails, which every conscientious chainman has repeatedly felt after a long



A DEVICE BY WHICH A TAPE CAN BE HELD AT ANY POINT ON ITS LENGTH

day's work, will be entirely removed by the use of this handy device, which he can slip in his pocket whenever it is not needed. The makers of the grip are Eugene Dietzgen Co., of 218 East Twenty-third St., New York City.

Increased Coal Output in Georgia

In 1912, for the first time in five years, the coal production of Georgia showed an increase over the preceding year, says E. W. Parker, of the United States Geological Survey. The production was 227,503 short tons, valued at $838,126. The decreased production in the last few years has been attributed to the withdrawal by the state of the convicts with which the mines had been operated.

The production in 1912 exceeded that of 1911 by 62,293 tons, or 37.7 per cent.; while the value increased $92,218. More than 50 per cent. of the increased production in 1912 was in the quantity of coal made into coke. This item amounting to 111,923 tons in 1912, against 72,677 tons in 1911, or a gain of 39,246 tons.

The total area of the coal field in Georgia is estimated at 157 sq.mi., this being the smallest coal area in the Appalachian states and not all of it workable. All of the production in 1912 was by two companies operating in Walker County.

On account of its high percentage of fixed carbon (80) and its low sulphur content, the Lookout Mountain coal of Walker County gives a large product of excellent coke, which is sold to the furnaces of Chattanooga and other points in Tennessee and Georgia.

An Italian Aërial Tramway

By Our Berlin Correspondent

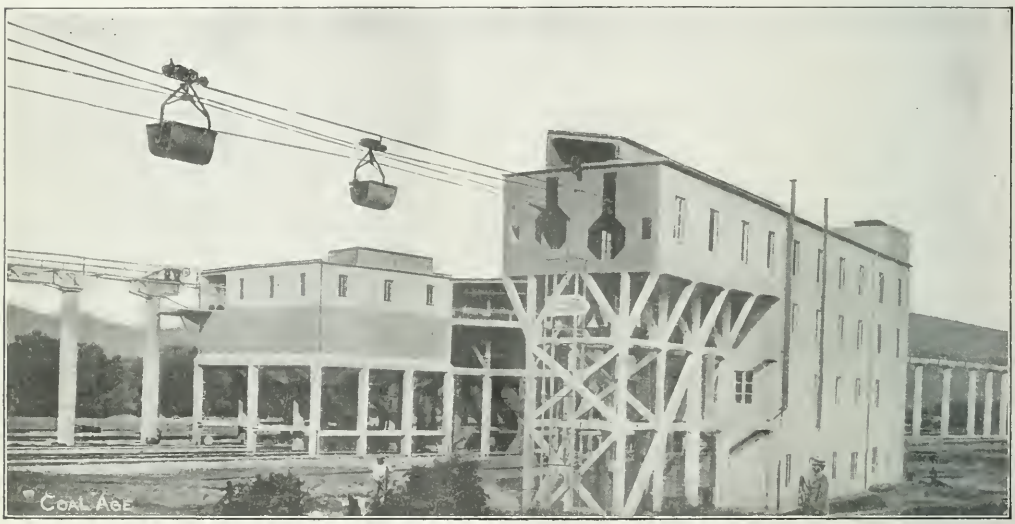
SYNOPSIS—A description of an aërial tramway which was installed to transport coal over rugged country from the harbor of Savona to the town of San Giuseppe, supplementing the facilities of a single-track railway, upon which the towns of northern Italy were dependent for their supply of coal and which could not be duplicated on account of the expense of construction.

The industries of northern Italy mainly depend for their supply of coal on the two harbors of Genoa and Savona, which, though near together, are separated by a precipitous spur of the Apennines which until a short time ago made any intercommunication impossible. Since Savona has only a single-track railroad to the interior, there were frequent disturbances in the coal supply, affecting the industry of Milan, Turin, etc. At times more than 30 coal barges would lie in the harbor unable to discharge their cargo. An improvement of this state of affairs was prevented by the expense which the installation of a second railway line, and the reconstruction of the quays of Savona would have entailed.

An Aërial Tramway 11 Miles Long

In order to avoid this expense, two Italian engineers, Carrissimo and Crotti, drew up plans for an aërial tramway to attain the same end. This plan required only small pocket installations at the terminal of the railway to act as buffers between the supply from the vessels and the actual demand. The terminal point of the ropeway was to be the railway station of San Giuseppe, which is 10.9 miles from Savona on the Lombardy slope of the Apennines and where there are railway connections with Turin and Milan. The scheme required the transportation of 900,000 to 1,200,000 tons per annum, which was found to be readily obtainable by means of a Pohlig aërial tramway. Therefore, Messrs. J. Pohlig, Ltd., with whom the scheme had been worked out, were entrusted with the installation, and the following plan was adopted:

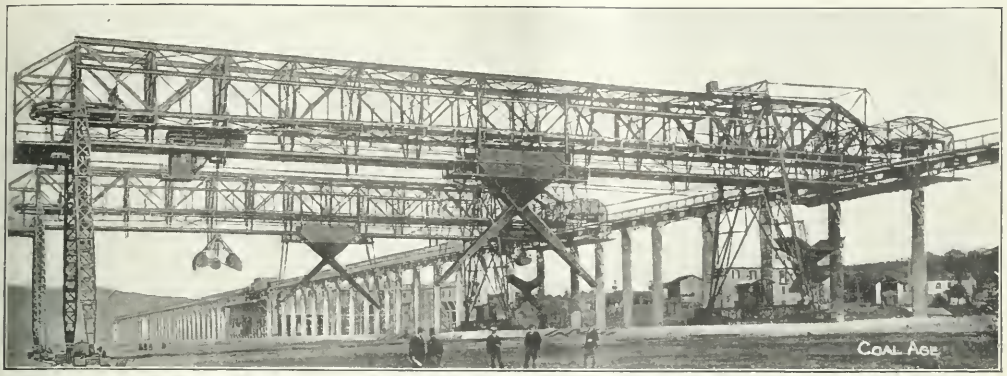
Lighters were designed for receiving buckets of 30 tons capacity. These buckets, which empty at the bottom, are lifted by gantry cranes and unloaded into pockets which serve as the loading station for the aërial tramway to which they are immediately connected. The rope railway, 10.9 miles in length, terminates at San Giuseppe in a telpher line about 2950 ft. long where it passes over pockets and open store yards. The coal from the pockets is loaded into railway cars through chutes, but on the open store yards, loading bridges and crabs with automatic grabs had to be provided.



The San Giuseppe Unloading Station, Showing the Concrete Construction

The Plant at Savona Harbor

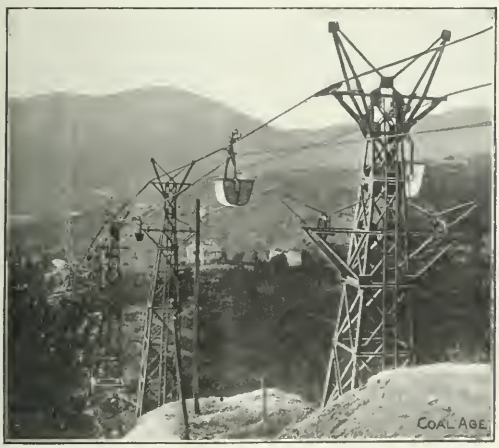
The whole plant consists of three main parts: First, lighters, cranes and pockets in Savona Harbor to unload the coal; secondly, the Savona, San Giuseppe aërial tramway; and, thirdly, a storing and unloading plant at San Giuseppe. In order to take up a minimum of the available space on the sea coast, the pockets in Savona Harbor were built out over the water as far as possible. They are made of reinforced concrete throughout and rest on concrete foundations. Each of the 24 pockets is 23x26.24 ft. in cross-section and 29.5 ft. in height, exclusive of the discharging funnel. Each compartment has a capacity of 17,650 cu.ft., corresponding to 400 tons of coal. Above these pockets, 59 ft. above the level of the water, there are three traveling gantry cranes, which can advance over the water on a projecting structure carried by pillars in order to pick up the buckets from the lighters.



View of Two Unloading Bridges and Storage Yard

A Bucket with Three Lifting Gears

Each crane has a main and two auxiliary lifting gears operated from a common lifting motor. The bucket is of the clam-shell type with two parts hinged near the top. From the main lifting gear there is suspended a transversal beam which when lowered causes the bucket to open. Transversal pieces suspended from the two auxiliary lifting gears, support the outside edges of the bucket. When raising coal, the three lifting gears are coupled together and thus operate jointly; in unloading, the two



A General View of the Line

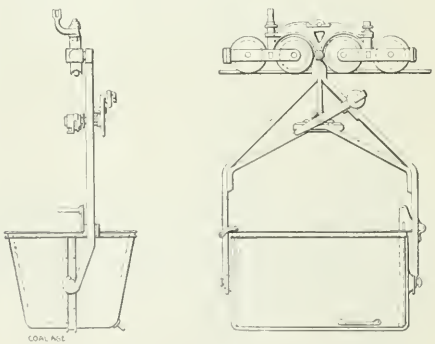
auxiliary lifting gears are kept in position while the main gear is lowered, causing the bucket to open.

The lifting motor of each crane develops 150 hp. and is designed to lift a loaded bucket 10 tons in weight at a speed of 39.1 ft. per min. It operates both the main and the auxiliary lifting gears. The crane travels at a speed of 161 ft. per min., the traversing motor developing 45 hp.; the crab is traversed by a 14-hp. motor at a speed of 82 ft. per min. Continuous current at 250 volts, reduced by a convertor from 22,000-volt three-phase current is used for operating the crane, a storage battery balancing any heavy fluctuations in current consumption.

The lighters transporting the filled buckets are built of iron throughout and are provided with double gearing fore and aft, being operated by a 10-hp. electric motor, fed from a small accumulator battery which is recharged during the time the lighters are being unloaded in front of the pockets.

A Long Ropeway with Two Large Turns

The loading station of the aërial tramway immediately adjoins the pocket. The suspended ropeway is 57,000 ft. in length and comprises five sections with intermediary stations at the points of connection. Section 1, which is 16,080 ft. in length, goes from the terminal station of San Giuseppe as far as Sella, and reaches at a distance of 2.4 miles the greatest altitude of the line, which is 1705



Bucket Showing Poihlig Traversing Gear

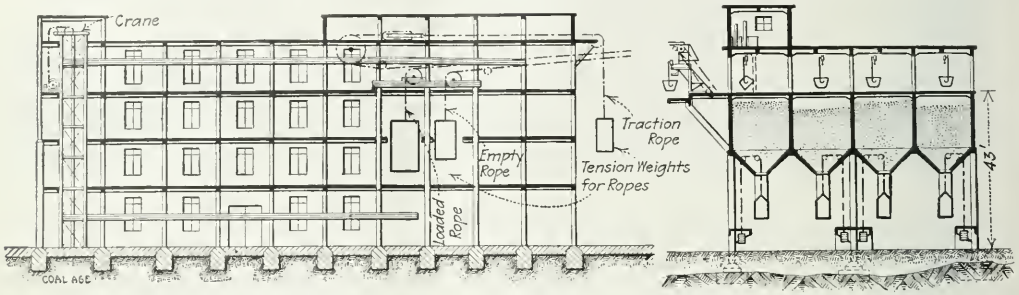
ft. The ropeway then continues in a straight line as far as Caribona, a distance of 9975 ft., and from there goes to Ciatti, 18,050 ft. At Ciatti section 3 joins section 1, which is 9300 ft. long, the ropeway at this station making an angle of about 111 deg. At Lorenzo station there is another point of dellection, the last section, 3700 ft. in length, between San Lorenzo and Savona being connected at an angle of about 105 degrees.

The track of this aërial tramway consists of locked steel cables, the load cable being 2 in. and the no-load cable 1.38 in. in diameter, with a breaking strength of 135,000 lb. per sq.in. The cables are carried by 208 iron

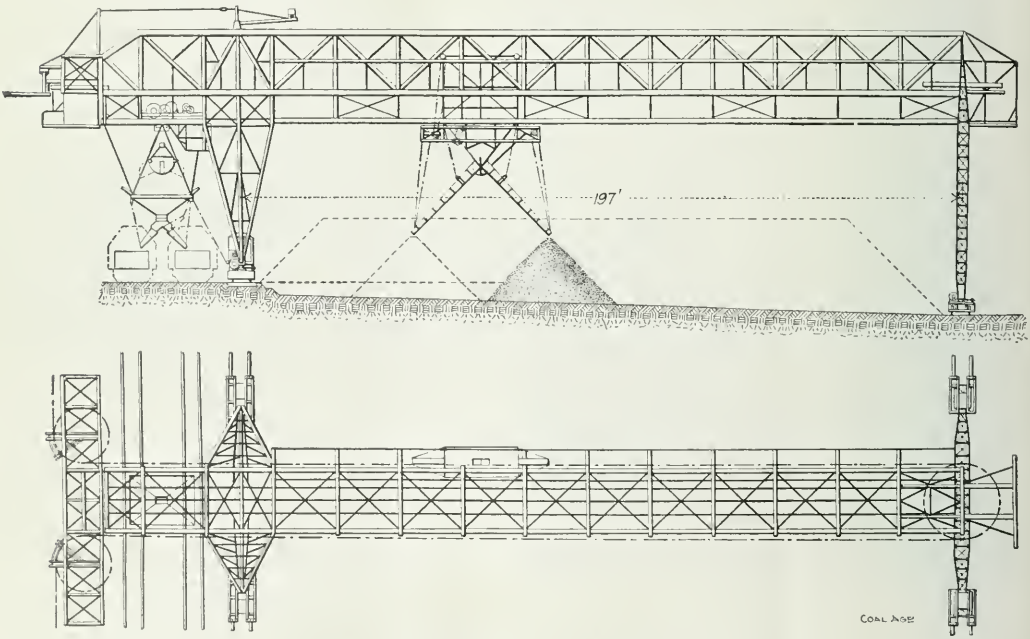
framework supports, the maximum span between two supports being 1068 ft., and the maximum height of supports 152 ft. The supporting cable is subdivided into sections of an average length of 4920 ft., which are substantially moored at one end, being kept taut at the other end by a weight. The traction cable is one inch in diameter and consists of steel wire of a breaking strength of 255,000 lb. per sq.in., and 1.58 lb. per ft. in weight.

the other buildings, is made of reinforced concrete. It is carried by hollow pillars 4.6 ft. in diameter, and about 52.5 ft. in height, which are placed at distances of 328 ft., at which point an interruption is made in the bridge to allow for temperature expansion. The two tracks for going and coming on the bridge are parallel to one another and are situated 13 ft. apart.

The aërial tramway buckets are driven on the elevated



Side and End Elevation of the San Giuseppe Station



Plan and Elevation of the Loading Bridges

Each driving station is equipped with two 180-kw., 3-phase-current motors, one of which serves as a standby. The working tension of 500 volts is obtained by transforming the 22,000-volt current supplied to the railway.

The Telpher Plant at San Giuseppe

At the terminal station the aërial tramway is connected immediately to an extensive telpher plant, the tracks of which are installed partly above the pockets, and partly on an elevated bridge 2955 ft. in length, which, like all

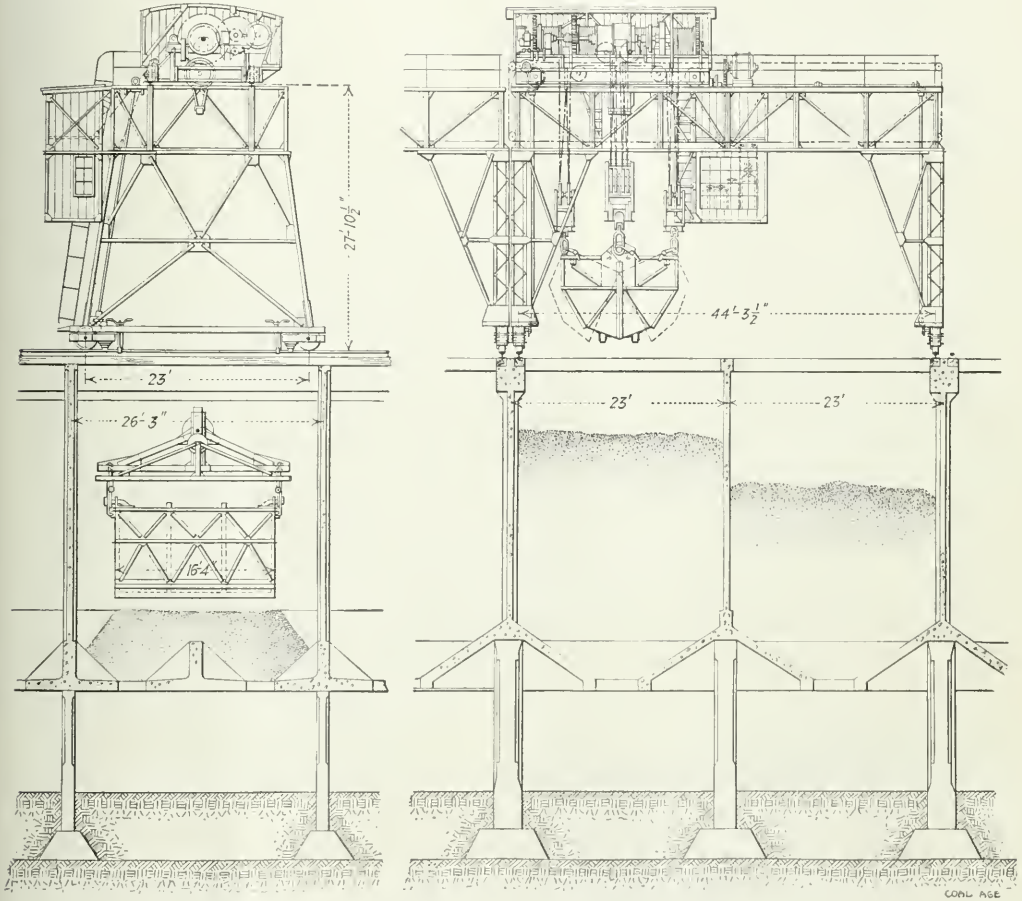
bridge by means of an endless cable arranged above the rails, the driving gear being situated near the center of the elevated bridge and operated by a 35-hp. motor. They are each designed for carrying 2200 to 2425 lb. of coal, and are about 3300 ft. in gross weight when fully loaded. As the ordinary two-wheel traveling gears could not be used to transport such high individual loads, and the adoption of twin traveling gears would have given rise to many drawbacks, a special type of four-wheel traveling gear was adopted, which has given satisfactory results in

connection with a number of heavy wire-rope tramways. The distinctive feature of the traveling gear is the design of the connecting beam above the traveling rollers. It has a hollow cast-steel body with an elliptical cross-section and possesses an extremely high resistance to torsion.

System of Unloading

The loaded cars arriving at the unloading stations are uncoupled automatically from the traction cables. They

four pairs of wheels traveling on a standard-gage double track and operated by a 50-hp. motor. Each of the two feet of the gantry pillar has a traversing gear with two pairs of traveling wheels which run likewise on a standard-gage track, being operated by a 25-hp. motor. The two supports thus have self-contained drives, the steering and balancing of any speed difference being effected from the driver's stand, which is fitted into the stationary support.



Gantry Cranes and Dropping Buckets over Concrete Pockets

are then moved by hand onto the telpher tracks above the pockets and there unloaded. Whenever the coal is to be unloaded on the storage yard, the cars are moved by hand to the coupling station on the elevated bridge, where they are automatically coupled to the cables. The cars then travel along the cables on the elevated bridge, passing onto one or another of the traveling unloading bridges in order there to be unloaded automatically. These are each 197 ft. in span, and have runways 279 ft. in length.

While the support turned toward the elevated bridge is an ordinary pillar, the other has been designed as a gantry, each foot of the former resting on

The Three Runways

The traveling speed of the bridge is 49 ft. per min. There are three runways on the bridge: First, the crab runway, which is suspended by means of brackets from the lower flange. Second, that carrying the wire rope resting on lateral projections of the lower flange. Third, the runway of the hoppers into which the cableway cars are unloaded. These hoppers, which are traversed at a speed of 79 ft. per min. by a special 8-hp. gear, have two chutes about 20 ft. in length, the lower half of which can be folded up. The crab comprises a 23-hp. traversing

motor and a 93-hp. lifting motor, the traveling speed being 591 ft., and the lifting speed 164 ft. per minute.

It is expected eventually to extend each of the two loading bridges by an additional bridge 187 ft. in length. The pockets at San Giuseppe have 48 compartments, 16½ x16½ ft. in cross-section and 16½ ft. in height. Each of these compartments has a capacity of 100 tons, and the whole plant a capacity of 4800 tons of coal. The store yard is 646,000 sq.ft. in area and has been designed to receive 300,000 tons of coal.

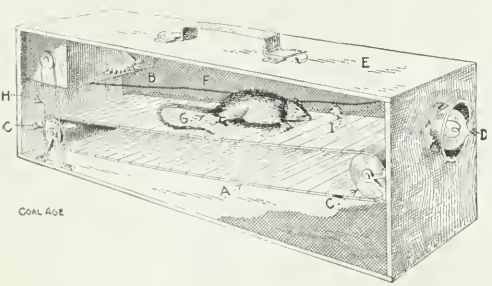
The whole plant as now completed is able to transport 900,000 to 1,200,000 tons of coal. As the need occurs, which is likely to be soon, this is to be extended by the addition of another aërial tramway of equal dimensions parallel to the former, and with duplicate pockets and loading devices at Savona Harbor, thus raising the transportation capacity to twice the present figure.

I am indebted to the *Zeitschrift des Vereines deutscher Ingenieure* for permission to publish the line drawings which accompany this article.

A Suggestion in Mine Safety Lamps

A contributor with a somewhat inventive turn of mind, and possessed of a desire to accomplish the dual purpose of detecting dangerous gas, and at the same time illuminating the gloomy corridors and passages of the mine, has sent us the accompanying drawing.

This device is simple, and requires but slight explanation. *A* is the apron of a tread mill, carried upon the ball-bearing rollers *C*. *B* is a gas-tight box containing a small electric generator, which is driven from the tread mill tail roller by means of the belt *H*. The terminals of the dynamo are connected through suitable cables to the electric bulb *D*, inclosed in an efficient reflector. The sides of the box, as may be seen in the drawing, are composed of wire netting *M*, which allows a free and practically unobstructed circulation of the mine atmosphere.



THE SUGGESTION

The motive power is furnished by a nimble and sinewy mine rat, which, for best results, should weigh approximately 3 lb., and stand about one hand, or less, high at the withers. As an incentive for vigorous and long continued action, a small piece of fragrant cheese may be suspended in the manner shown at *I*.

It is well known that all animals are easily susceptible to the action of mine gases, and the presence of the latter could therefore be easily detected from the behavior of the rat, thus dispensing with the necessity of carrying an innocent and attractive song bird to a hideous death. Furthermore, all animals work best when in their natural environment. In the dark and cavernous mines the rat, above all other creatures, should be strictly at home, and, with such an irresistible attraction before his nose as we have above named, he should be capable of proceeding at top speed (say 15 to 17 knots per hour) for as long a time as the oxygen will last in the helmet cartridges, or while the fireboss is making his nocturnal peregrination. Such a speed will make the dynamo fairly "hump itself," and send a clear penetrating beam of light far ahead.

As soon as the gas inspection is finished, or the helmet man returns to his base of supplies, the faithful animal upon the tread mill may be gently removed, carefully curried and rubbed down, given food and water, and allowed to sleep and recuperate until the next shift.

It is claimed that many advantages are to be gained from the employment of this ingenious, gas-detecting light-giving device. The supply of motive power is always abundant and cheap around coal mines, so much so, in fact, that it may be rightfully considered as a by-product. The expense of feeding an adequate number of rats while in captivity is small, since to keep them in good running condition they should not be allowed to acquire superfluous flesh, as this renders them phlegmatic and short-winded. Their care would require the services of a trained veterinary as such hardy animals thrive naturally when only sufficiently fed and properly exercised. The cost of their capture in most cases is merely nominal, amounting only to keeping an efficient wire trap baited with a few kernels of corn or other suitable lure.

L'ENVOI

"A little nonsense now and then
Is relished e'en by mining men."

[When this picture of the rat in his little box was shown to an inventive friend and the operation of this wonderful apparatus had been described to him, the dream light came into his eyes, and sitting down he composed the following lyric, in broad daylight and without the use of any subtle stimulants.—EDITOR.]

Here a little rat you see,
Held in dread captivity,
Chasing after toasted cheese
Instead of catching hungry fleas,
Doing at last some useful work,
Proving to all he is no shirk.

The rat, we almost all suppose,
In place of what we here disclose,
To be a dirty, lousy beast
Inclined upon our lunch to feast,
Tipping over our dinner cans
With scientific ratty plans.

But now he's found a job at last
And on a tread mill running fast,
He works away with all his might
To turn the wheels that give us light,
Until the time—alas!—alas!
He's overcome by deadly gas!

Say, who the —— was the —— fool cuss
Who invented this marvelous appa-rat-us.

EDITORIALS

Colliery Boiler Plants

An editorial appearing in the June 17 issue of *Power* entitled "Colliery Boiler Plants," calls attention to the lax and wasteful methods and practices prevailing in many, if not most, of such installations. The article says in part:

Many such installations are very dirty with coal strewn thickly over the floor and ashpits nearly full of ashes. When the ashpit is cleaned out, but scant attempt is made to prevent mixing good coal with the ashes and throwing all out together. Then, again, neglect is indicated by the cracked condition of the boiler settings, especially where return-tubular boilers are used, and by badly cracked furnace fronts and warped firedoors. Many of the latter are so out of shape that it is impossible to shut them tightly.

Leakage of air through the cracked boiler setting into the combustion chamber and an excessive amount of air leakage past the furnace doors above the fire produces but one result, improper combustion.

If the exteriors of the boilers show neglect, it is natural to assume that the interiors are no better, and, if so, many of them are evidently operating under dangerous conditions. The few colliery plants operating without this neglect of economy and safety, for some are kept clean and orderly, by contrast, reflect the greater discredit on the rest.

Reasons for this state of affairs are cheap coal, indifference, ignorance and lack of opportunity. The first three probably have much more to do with the effect than the last named.

None of these reasons is sufficient to excuse the situation. Even if the coal is cheap, it is worth as much in the plant coal bin as on a car ready for shipment. If a ton of coal is worth a dollar when ready for the market it is worth a dollar in the boiler room. Every ton of coal needlessly consumed in the boiler furnace is a dollar thrown away.

An increase in the selling price of coal is maintained by the mine operators as justifiable, because of the increased cost of production, but has any attention been given to the economical operation of the power plant which produces the steam and power necessary as an element in economical production? We believe not in a large number of installations.

Is not the boiler plant left in the hands of men who are coal handlers rather than men capable of keeping the boilers in proper condition? Although neglect plays an important part in the conditions existing in so many of these mine plants it would appear that ignorance regarding boiler economy and safe operation is largely responsible.

In a large measure we are inclined to agree with rather than dissent from the views of our contemporary. The conditions existing in many colliery plants are highly reprehensible and deserving of such bitter condemnation as is given above. On the other hand, there exist in many instances, circumstances which may strongly mitigate an apparent evil.

At many mines, particularly in the bituminous region where coal is sized for the market, it is only the poorest and least valuable of fuel that finds its way to the boiler furnaces. In many such plants, the best grade of slack that it is possible to secure will bring a price which is far below the cost of production. Frequently, also, the material removed from the coal in the picking process contains a considerable amount of combustible matter, and this refuse, which would otherwise have to be disposed of at an appreciable cost, is burned under the boilers.

While there is no possible excuse for dangerous methods of procedure in boiler practice, or for slovenliness in plant operation, regardless of the quality of fuel burned, yet we would call attention to the fact that good engineering in the operation of a plant upon coal costing $1 per ton may be decidedly different from the economical operation of the same plant on a fuel which costs only 25 or 30c. per ton. This practice would again vary upon the use of mine refuse, for which no legitimate charge in dollars and cents could be made.

In such a case, it may be quite true that care and forethought, together with a small investment in cash, may effect a saving of one-half in the amount of fuel burned. Considering the monetary value of the conserved material, however, we might well ask, in the language of Petroleum V. Nasby, "how much is twice nuthing?"

The Evolution of the Mine Foreman

There is some truth in the statement made by a Pennsylvania Engineer, in the preceding issue, that the mine foreman has been a victim of two opposing duties.

The belief is commonly expressed, whether it be true or false, that the cause of the inefficiency of our laws is to be found in the fact that those who enforce them are "openly and notoriously" in the pay and financial or moral control of those against whom the enforcement must proceed. "Open and notorious" indeed is the control of the mine foreman, when that control is embodied in the state statute, when all pay, emoluments, duration of service, reputation, everything in short, are dependent on one of the parties, which he is required to keep amenable to those statutes. It is as if a federal law provided that each distillery hire a gager, who shall determine the taxes upon the product of the still, or each abbatoir shall engage enough inspectors and bacteriologists to protect the public against diseased meats, said gagers, inspectors and bacteriologists to be answerable for all the acts of their employers, yet to look to them for every tittle of compensation on which they and their families depend.

The existing enactments resemble a contract so written that the contractor is bound to provide a "qualified" inspector of the work thereby contracted, is to select and to pay him with privilege to remove him at his pleasure, without reason given, is permitted to give him enough other duties to keep him continuously employed and yet provides that the decision of the said inspector or his underlings is binding should any question arise as to compliance with the specifications. But there is yet another provision that every six months or so, a real, independent inspector shall spend a day or half day on the job ordering a correction of all those defects which the *ex-parte* inspector has been unable to cover up for his employer.

In these facts are to be found an important justification of the acts about to be passed or already in force making the operator liable for accidents to the employee. The monetary interest of the operator is then centered in the safety of the men he employs and the foreman knows he is as much liable to the employer for loss of life as for waste of material or high cost of coal.

In all branches of human activity are sordid and reckless persons, and legislation which will make them pay the costs of their penuriousness and of their gambles with death is usually in the interest of humanity. There are also careless and foolish workmen. It has been hard to control such men hitherto, but it is likely that when the operator has to compensate the families of such men in case of death, men with dependents will find it hard to get employment anywhere unless they subject themselves to such reasonable discipline as will assure their safety. It is unfortunate that the laws have been so weak that the disciplining can only be effectual when the operator, who has normally nothing at stake, is compelled with some measure of injustice to restrain the wilful workman from his own destruction.

The operators who have been making money have been disposed to compel the foremen and their workingmen, when compulsion was necessary, to comply with the law, but some of those who were hardly able to make a profit have been disposed to content themselves with doing only what the inspector demanded.

Perhaps it may be necessary under a liability law to appoint a safety inspector in every mine, and it may yet come about that he will be appointed like boiler and elevator inspectors by the company which assumes the operator's risk, only his work will be continuously at one mine and not an unending travel from operation to operation. His mind will be as keenly on the liability per ton produced as the foreman's is on cost per ton and output per running day.

The West Virginia Investigation

The majority of people in this country would like to know the real truth concerning the labor situation on Paint and Cabin Creeks in West Virginia. The interest extends to the whole mass of people and is not confined to those engaged in mining, though their interest is probably greater. That disinterested citizens can and will judge fairly concerning any question, when the truth is laid before them, is demonstrated every day by the jury system used as a basis in our trial of causes. It is hard to know what the true facts are in West Virginia.

Everyone is aware that there is trouble at the mines, that a controversy is being carried on between those who own the mines and those who work in them. Some facts concerning it seem to be well established, as they are often repeated without denial. It is true that men have been employed to guard the mines and that there have been fights between them and others, so that it has been considered necessary to declare martial law throughout a certain region. It is true, also, that men have refused to work and that some mines have been idle. Statements have been issued that no strike was in progress and then a contradiction has been made. Yet all the signs of a strike and its accompanying trouble exist. From all the mass of contradictory statements it is hard to find out what is and what is not so.

It was to be hoped that the investigation by the Senate committee would disclose the true situation, but confidence that it will do so is destroyed, when the investigators do not conduct themselves in the manner of impartial judges. It is rather shocking to read in the papers that one member of the investigating committee made a speech in church on a recent Sunday in which he used flowery language concerning the fair state of West Virginia, and then boldly stated that some of its citizens had been consumed by greed. When it is realized that this same man, as a member of the committee, had listened only to the testimony of one side, it is hard to believe the mine owners will get a square deal. At a later date it is reported that the same senator used abusive language toward a man appearing before the committee.

This is not the attitude of a judge quietly seeking justice for all the people, but that of a politician to whom his colleagues have granted the favor of a place on an investigating committee, that he may have the opportunity to gain publicity so as to promote his political future.

It is doubtful if any real good can come from an inquiry conducted in such a spirit. An investigation of another sort, however, might be able to bring about an adjustment of relations between owners and miners which would result in lasting peace and prosperity.

The Operators' Attitude toward Legislation

The addresses and articles delivered by operators before institutes and contributed to the technical press are an answer to the statement that the mine owner manifests no interest in safety. Representatives of capital serve on committees to formulate new mining laws and the measures they aid to draft completely refute the assertions of those who would represent them as callous to the needs of the mine worker.

We are convinced that there are many operators who are anxious to make their mines as safe as they can be made. They will not be content simply with having their men live longer than the average man, but desire that no employee shall suffer by reason of any oversight or omitted precaution of which they may be guilty.

But as long as the law does not compel sufficient safety on all, as long as one state is more careless than another, so long the operator who would make his mines the last word in security will hesitate to expend the money which now shields him from bankruptcy.

Many a man, able to see a balance in normal years, only by closing his eyes to the value of his coal in the hill and to the depreciation of his plant, is fain to go not a step beyond the law's imperative demands till his neighbors are compelled by a new enactment to make like improvements.

This is one reason why the anthracite corporations and the subsidiaries of the several steel companies, have been more active than other bodies. Those organizations could see a balance at the end of the year's expenditures and they have unstintedly spent money which the law did not demand, for the comfort and happiness of their employees. Sometimes we wonder whether a stockholder, filled with the narrowness which only too often distinguishes those who seek to enforce the law against corporations, might not bring suit against these beneficent organizations for following the dictates of the company soul rather than the undoubted law of the land, which requires that the corporation shall conduct its business to the best interests of those who have intrusted it with their money, subject only to the law's restrictions.

SOCIOLOGICAL DEPARTMENT

Is the First-Aid Situation Muddled?

By Daniel J. Boyle*

I read the remarks entitled "The First-Aid Muddle" in your issue of May 17 with some concern. The physician who wrote this article deplores the attempt of the promoters of first aid, in this country, to perfect and promote first aid among workers in hazardous occupations.

My experience in first-aid work leads me to believe that there cannot be a definite system of treatment which will apply to all conditions. Even the St. John Ambulance Corps does not specify any individual preference for any special form of artificial respiration or of applying bandages. Moreover, it does not advocate any special appliance for use in treating injured persons. Different conditions demand varying methods of treatment.

There is an essential difference between the conditions on the field in which a meet is held from those which obtain in a mine, for the rescuemen underground do not have all kinds of antiseptic bandages and suitable appliances with which to perform their work.

It is possible that the first-aid man will have to use, in the actual conditions which confront him, part of his own clothing, pieces of lagging or bark, to bind and hold respectively a simple, a compound or even comminuted fracture.

Moreover in the case of artificial respiration, it must be remembered that the victim may be injured in several parts of the body and his ribs may be broken, or he may also be seriously burned about the chest or arms. If this is the case, he could not be treated by the Sylvester, Schafer, or Lathrop method. In fact, no form of artificial respiration could be used which would require that the operator should touch the burned or broken parts of the arms, chest or abdomen. For an injury such as that described, Laborde's method of artificial respiration, or some like method, would have to be practiced. I believe that any of these methods are good when you can use them, and that due credit to their value should be accorded by physicians and by the men whom they train. They should all be taught to first-aid men.

The first thing which rescuemen should learn is how to stop bleeding, for in case of an accident which severs a blood vessel or in any way produces a marked effusion of blood the injured man must be treated for this injury whether he is conscious or not. After the bleeding has been stopped respiration should be restored.

The physician's remarks that too much stress was placed on aseptic treatment of wounds in according the demerits at a meet are, it seems to me, unfair. No lesson can be more important to the average first-aid man. Only a few years ago, when patients were bleeding, it was thought the proper treatment to take a cud of tobacco from the mouth and put it on the cut. The man who gave up his quid may have had a cankerous mouth, or may have been a sufferer from tuberculosis, but his chew of tobacco was a styptic and therefore was thought available for use.

The Bureau of Mines, in calling a conference of first-aid workers at Pittsburgh, Penn., Sept. 25, 1912, and in forming the American Mine Safety Association, performed a valuable service to the mining community. I do not think that the principal results to be attained by such a conference, or by the formation of such an association, are to be found in the formulation of a series of standards for first-aid work. Its largest function is educational.

A British House-Building Experiment

The house shown in the illustration was designed by J. M. Milner, vicar of Poundstock, Cornwall, England. The foundation walls are built by sections in what is termed a "pattern mould," and by employing, in part, modern patented materials, a six-room cottage of two stories can be erected for $650.

The kitchen or living room measures 15x12 ft. and the height is 9 ft. 6 in. except for 3 ft. on one side where a bacon rack is hung. The stove is of cast iron, having a boiler set in brickwork and furnished with a wide shelf ("hob"). The chimney is of brick. A cupboard is provided to serve as a larder. The scullery contains a sink with a tap from the rain-water tank, while in a recess is a Thompson seamless copper boiler, with the flue entering the kitchen chimney.

An English Experiment in Cheap Housing

The other rooms are a large bedroom, two smaller sleeping rooms, and a small parlor. The walls are of weather-boarding either over a thick vulcanized sheeting or asbestos-cement sheets $\frac{3}{16}$ in. thick nailed to 3x2-in. framing and lined with $\frac{3}{4}$-in. match-boarding. These walls are of good red fir and are rain-proof. They are quite stiff and it is claimed that they are dryer than those of a stone house, the woodwork below the vulcanite being better protected than it is in a building constructed of stone.

DISCUSSION BY READERS

Mixed Lights in Mining

Letter No. 1—It is an interesting fact that in mines where the workings are extensive, certain sections may generate gas in sufficient quantities to necessitate the use of safety lamps. If the ventilating currents, however, are kept separate, no trace of gas may ever be found in the other sections of the mine. Where such conditions exist, I believe it is entirely consistent with safety, if the ventilating system is properly planned, and the overcasts and stoppings are substantially constructed, to use open lights in the nongaseous sections.

Where this is done it is advisable to use an exhaust fan and great care must be exercised to keep open lights off of the return airway. The overcasts should be of concrete reinforced with discarded mine rails and made sufficiently strong to resist the force of a possible explosion. The gaseous section of the mine should, so far as possible, be isolated from the other workings, by means of barrier pillars; but where necessary connections have been made, the stoppings in such openings should be constructed of reinforced-concrete or stone, and should be built in pairs. Then, in case of the failure of one, the probabilities are that the force of the explosion will have spent itself to such a degree that the remaining stoppings will be able to resist being blown out

I believe that the above method of isolating each section of the mine ventilated by a different current if introduced into every mine, would prove equally valuable in localizing the effect of a dust explosion.

Ernest L. Bailey, Mining Engineer.
Crumpler, W. Va.

Letter No. 2—The large majority of miners prefer to use an open light in place of a safety lamp, because it is more convenient and gives a better light, which enables them to perform more work in the same time. On this account, the miners and, too often, the mine officials are willing to assume a considerable risk in order to get out more coal, increase the output of the mine and keep down the operating expenses.

Most miners and many mine officials have never made a study of the formation and occurrence of natural gases in the strata overlying or underlying the seam of coal. They do not realize as they should that the working places and other parts of the mine that are at present free from gas may become gaseous, and that dangerous bodies of firedamp may accumulate, at any time, in such mines.

A study of the subject of mine gases makes it clear that it is practically impossible to determine, with any exactness, where gas may be expected in coal formations, or the exact location of pockets of gas, which occur frequently in the strata. Also, it is impossible to determine the amount of gas that may be given off in the mine workings.

After all that has been written in regard to mine explosions, it is quite clear that there is no means of determining, in advance, the strength and magnitude that an explosion of gas or dust in the mine may attain when such an explosion has once originated. For this reason, it is better practice to try and prevent the occurrence of an explosion by avoiding the ignition of gas or dust in the mine atmosphere. There are too many lives and too much property at stake to run any risk in this regard. In most cases, it will be found that the increased cost of operation, due to the use of safety lamps, will be offset by the increased protection afforded thereby, in the operation of the mine—protection against fire and explosion.

In my opinion, all mines where gas has been detected should be worked exclusively with safety lamps. When mines are worked with mixed lights, the miners are apt to think that open lights being used in one part of the mine, they can be used also in other portions. They become careless and often proceed to enter places where gas may exist, unconscious that they have an open light on their heads, until they are made aware of the fact by the ignition of the gas at the roof. Even with strict mine regulations, it is difficult to avoid such an occurrence where mixed lights are used.

I believe that the exclusive use of safety lamps throughout the mine where gas is generated in any part of the workings, has a tendency to make the miners more careful in regard to the gas, which they know exists in places. Safety lamps, also, offer a greater amount of protection, because they indicate more clearly the presence of dangerous gas in the mine atmosphere, and this warning permits the miner to retreat to a place of safety without igniting the gas.

Shooting Mine Timber

The seam of coal we are working is known as the "Big Seam." A section of the seam is as follows:

Top coal	2 ft. 0 in.
Rock	0 ft. 8 in.
Coal	2 ft. 0 in.
Rock	1 ft. 8 in.
Coal	3 ft. 0 in.
Total	9 ft. 4 in.

The two lower seams of coal and the one of rock between them are worked out as the rooms are driven up, the remaining top coal and rock being left up until the room has reached its limit, when they are taken down as the pillars are drawn back, or in "retreating."

Gas is found to some extent in this mine, and the method employed here of shooting instead of drawing the timbers when retreating is calculated to cause trouble. Two sticks of permitted explosives are used in each timber, making an average of 12 lb. of powder exploded on the air.

The Sylvester machine, recently described in the article, "Recovery of Mine Timber," Apr. 5, p. 529, could undoubtedly be used to advantage in some of the rooms,

in this mine; but in other rooms it could not be put into practical use, owing to the waste being built up to within a foot of the roof.

If any reader has worked a similar seam, I would be glad to know the method he employed for drawing the timbers. MINER.

Littleton, Ala.

Effect of Safety Lamps on Eyesight

There appeared some time since, in COAL AGE (Vol. 2, p. 734), a brief comment on the use of the safety lamp as affecting the eyesight of miners. The article stated three objections to the use of the safety lamp; namely, the poor light given in comparison with other lamps; the shadow thrown by the lamp on the roof and floor; and the irritation to the nerves of the eye caused by the alternate light and shadow to which the eye was exposed by reason of the alternate upward and downward glance, in observing the roof and floor of the mine.

I have used safety lamps for the past 14 years; and, while it is true that a safety lamp does not give a light equal to that of an open lamp, the security afforded by its use, in a large measure, makes up for this deficiency. The shadow cast by the lamp on the roof and floor depends largely on the style of lamp used and the way in which it is carried. The safety lamp should always be carried in an erect position. The best style of safety lamps has three standards securing the chimney of the lamp to the oil vessel. The safety lamp used by firebosses should be provided with a shield encircling about two-thirds of the lamp gauze. This shield forms a suitable screen to the eyes and reflects the light forward, which greatly improves the illuminating power of the lamp.

Any practical fireboss can put a shield on his lamp if this is not provided. The shield consists of a piece of tin, or copper, of the same height as the lamp gauze and bent in the form of a semicircle, the two edges of the shield being turned so as to partly encircle two of the lamp standards. These shields are also supplied by manufacturers on request.

From my experience, I think I am safe in stating that my eyesight has not been injured, in any manner, by the use of the safety lamp. From observation, I would say that not 5 per cent. of the firebosses employed in mines would admit that their eyesight was at all affected in this manner. I believe there is greater danger, as far as the effect on the eyesight is concerned, in the use of the carbide lamp, and in the use of a poor grade of lamp oil, such as is often sold to miners. The carbide lamp produces a strong light that requires some effort of the eye to adjust itself to the difference between the light and dark in the mine.

JOHN SUTTON, Fireboss.

Study Course in Coal Mining

BY J. T. BEARD

The Coal Age Pocket Book

Addition of Larger Numbers—When numbers of two or more figures are to be added together, proceed according to the following:

Rule—Write the numbers one under the other. Beginning on the right, place units under units, tens under tens, hundreds under hundreds, etc., etc. Add, first, the column of units, and place the units figure of this sum under the units column for the units figure of the required sum. Then carry the tens, or hundreds figures forward, writing them above their respective columns, to be added with the figures in those columns. Now, proceed to add, in turn, the tens, hundreds, etc., columns separately, including the figures carried forward from the preceding columns and written above these columns. As before, write the units figure of the sum of each column below the column added, for the corresponding figure of the required sum and carry the remaining figures forward, writing them over the next preceding columns, to be added in those columns. The full sum of the last column added, on the left, is written below for the corresponding figures of the required sum.

One or two examples will make the process clear.

1 2 3 1 2 2		1 1 2 2 2 3	
3,467,448	0	6,321,824	8
632,123	8	1,520,209	1
9,547,379	8	78,367	4
29,280	3	925,056	0
246,563	8	7,698	3
13,922,793	0	8,853,154	7

Proof by Throwing Out Nines—To prove the addition to be correct, the method of throwing out the nines is the simplest and best. It is as follows: Beginning with the top row of figures add the figures in that row, subtracting 9 whenever the sum equals or exceeds that amount. For example, taking the top row of figures, in the example on the left, and adding the figures from left to right, throwing out 9 as often as possible,

$$3 + 4 + 6 - 13| \quad 9 = 4 + 7 = 11| \quad 9 = 2| + 4 + 4 = 10| - 9$$
$$= 1 + 8 = 9| - 9 = 0$$

Again, for the second row,

$$6 + 3 = 9 \quad 9 = 0| + 2 + 1 + 2 + 3 = 8$$

The same process is repeated for each successive row of figures, including the final sum; and the result in each case is written in a separate column on the right. If the work is correct, the same process of adding the figures in this column and throwing out the 9's will give the same result as was obtained by applying this method to the final sum. For example, adding the column on the right, throwing out the 9's, and then doing the same in the final sum, we have

$$8 + 8 = 16 - 9 \quad 7 + 3 = 10| - 9 \quad 1| + 8 = 9| - 9 = 0$$
$$+ 3 + 2 + 7 = 15 \quad 9 \quad 6 + 3 = 9| \quad 9 = 0$$

The Coal Age Pocket Book

In each of the above solutions, the bar is introduced to divide the several operations, as these do not represent a continuous equation. Also, the work is simplified very much by ignoring any 9's among the figures as was done in the last operation.

SUBTRACTION

Subtraction is the operation of finding how much greater one number is than another; or, in other words, finding the difference between two given numbers. The operation is the reverse of addition. The greater number is called the "minuend" and the lesser number the "subtrahend." The sign of subtraction (—) is called "minus," and when written between two numbers indicates the number following the sign is to be taken from that preceding. Thus, $8 - 5 = 3$ shows that five taken from eight leaves three, which is called the "difference" or the "remainder."

In subtracting a less figure from a greater, the difference can be found readily by counting the number of consecutive units necessary to reach the greater number. For example, to subtract 4 from 9, it is necessary to count five units beyond 4 to reach 9, as shown thus:

1 2 3 4 5
1 2 3 4 | 5 6 7 8 9

The operation is expressed thus, $9 - 4 = 5$.

Subtraction of Larger Numbers—When numbers of two or more figures are to be subtracted, the one from the other, proceed according to the following:

Rule—Write the lesser number under the greater, placing units under units, tens under tens, etc. Beginning on the right, subtract the units figure in the subtrahend from that in the minuend and write the difference for the units figure of the remainder. It frequently happens that the figure in the subtrahend is greater than the corresponding figure in the minuend, in which case it is necessary to borrow one from the next figure on the left, writing the borrowed 1 as tens. Now, subtract the figure in the subtrahend from that in the minuend increased by ten and write the difference in the corresponding place in the remainder. When making the next subtraction, however, the figure in the minuend must be regarded as diminished by 1.

One or two examples will make the process clear.

1 1		11 11	
3,468,509	Minuend	1,630,001	Minuend
1,384,317	Subtrahend	29,999	Subtrahend
2,084,192	Remainder	1,600,002	Remainder

Proof by Addition—To prove the subtraction to be correct, add together the subtrahend and the remainder, and if the work is right the sum obtained will be the minuend.

	1 1		11 11
Proof	1,384,317	Proof	29,999
	2,084,192		1,600,002
	3,468,509		1,630,001

INQUIRIES OF GENERAL INTEREST

Working in Compressed Air

What are the effects of compressed air upon the human system when a man is following up that kind of work?

SUBSCRIBER.

Olyphant, Penn.

The effect on the human system due to working in compressed air for any given length of time varies with the health and physical condition of the individual. It has been found unsafe to allow anyone to enter an air chamber where the air is compressed to two or more atmospheres, without a previous medical examination. Even when this precaution has been taken, fatal results have ensued, the victim dying from what is known as caisson disease. At times, sudden death has resulted after the person has worked in compressed air for several months without being apparently affected thereby up to the time of his death.

The symptoms, in severe cases, are unconsciousness or paralysis, or both, accompanied by acute pain in the limbs. This was at first thought to be due to the compressed air being absorbed in the blood and tissues, and later liberated throughout the body when the pressure was relieved. The liberation of the compressed air from the blood and tissues was believed to be sufficiently violent to disrupt the tissues, froth the blood and interfere seriously with the circulation.

The continued study of the subject, both by doctors and engineers, revealed the fact, however, that the true source of the trouble could probably be ascribed to the saturation of the blood with nitrogen. It is true that aërated air contained in a bottle effervesces freely when the cork is drawn, owing to the escape of the air from the water. The effervescence is much more violent in the case of water saturated with carbon dioxide, owing to the greater solubility of this gas in water.

Dr. J. S. Haldane showed conclusively that the percentage of carbon dioxide absorbed varies inversely as the pressure on the air. For example, the percentage of carbon dioxide in the air exhaled from the lungs, under atmospheric pressure, is 5.6 per cent.; under two atmospheres, the carbon dioxide in the exhaled air is 2.8 per cent.; and, under three atmospheres, 1.86 per cent. In addition to this automatic regulation of the percentage of carbon dioxide, Dr. Haldane has said that, owing to the oxygen of the air being taken up chemically by the hemoglobin, the blood in the human system soon becomes poisoned with an excess of nitrogen, where the atmosphere is compressed.

In the practical application of this theory, the difficulty of respiration in compressed air has been, it is stated, wholly overcome by supplying a constant volume of *compressed* air per minute to the workers, instead of a constant volume of *free* air per minute. It was found that some parts of the body are affected more quickly than others; and experiment showed that 90 per cent. saturation took place in the slowest parts, in 4 hr.; while complete saturation took place, in the quickest parts, in 40 min. From this it was concluded that there was danger in removing too quickly from a compressed atmosphere, after an exposure of 40 min.

The period of time of withdrawing from a compressed atmosphere is called the period of "decompression." Observing that no serious results had occurred by rapid decompression up to about two atmospheres, Doctor Haldane concluded that no danger was to be anticipated by decompressing rapidly to the extent of one-half the absolute pressure; but, beyond this point, sufficient time must be given for complete decompression to allow desaturation of the blood to take place, depending on the time of immersion in the compressed atmosphere.

The disorders resulting from working in compressed air were seemingly removed when the person affected reentered the compressed atmosphere from which he had withdrawn. The most practicable method of avoiding the troubles arising from working in compressed air, it has been found, is to lengthen the period of withdrawing from the compressed atmosphere.

The same theory now advanced by Doctor Haldane was promulgated by one Paul Bert, about 1880. Mr. Bert then claimed that the effect on the human system was caused by the absorption of nitrogen in the blood; and he advocated withdrawing slowly from the compressed atmosphere, suggesting a period of 30 min., for compressions up to three atmospheres, and 60 min. for compressions up to four atmospheres.

In late practice, in tunnel work, two or three air locks are provided, and the men are required to spend a certain number of minutes in each lock, the time increasing as the pressure decreases in each successive air chamber. The greatest pressure under which men can work with safety may be stated as four atmospheres, although men have been exposed, for short periods, to pressures of six atmospheres, without experiencing any ill effects.

Why Compressed Air Freezes

Kindly explain why compressed air freezes.

INQUIRER.

Kingston, Penn.

Compressed air does not freeze, but the moisture it contains is deposited as frost when the air is allowed to expand by escaping into the atmosphere. This expansion is accompanied by an absorption of heat from the surrounding air, the absorbed heat becoming latent in the air. As a consequence, the temperature of the surrounding air falls sufficiently to freeze any moisture that may be present. The capacity of air for holding moisture decreases with the fall of temperature, and the moisture appears as a vapor, which is frozen immediately, if the temperature is sufficiently low.

This effect is often observed at the exhaust ports of the air cylinder of a pump operated by compressed air. It frequently happens that when the pump is driven by compressed air, the freezing of the moisture completely closes the exhaust ports of the air cylinder.

EXAMINATION QUESTIONS

Miscellaneous Questions

(*Answered by Request*)

Ques.—A mine ventilated by three splits of air showed the following distribution of current: Split A, 2500 cu.ft.; split B, 1500 cu.ft.; split C, 2000 cu.ft.; making a total of 6000 cu.ft. per min. What quantity of air will pass in each of these splits if the total quantity is increased to 75,000 cu.ft. per min.?

Ans.—Provided there is no change made in the mine airway so as to increase or decrease the resisting power of any of the splits, each split will pass the same proportion of air as before the circulation was increased. The ratio of increase is 75,000 : 60,000, or 5 : 4. The quantity of air passing in the several splits after the circulation has been increased is, therefore, as follows:

Split A,	$2500 \times \frac{5}{4} = 3125$ cu.ft. per min.
Split B,	$1500 \times \frac{5}{4} = 1875$ cu.ft. per min.
Split C,	$2000 \times \frac{5}{4} = 2500$ cu.ft. per min.
Total	7500 cu.ft. per min.

Ques.—If a barometer registers 30 in. at the surface or mouth of the shaft, what will it register at a point in the shaft, 1890 ft. below the surface?

Ans.—It is customary to allow one inch of increase in barometric pressure, for each 900 ft. of depth below the surface. Making this allowance, the increase of barometric pressure for 1890 ft. is $1890 \div 900 = 2.1$ in. The barometer would, therefore, register, in this case, $30 + 2.1 = 31.1$ in., which is approximately correct.

Ques.—What is the breaking strain of a plow-steel, hoisting rope, 1½ in. in diameter? Also, find the safe working load of this rope.

Ans.—Since the breaking strain of a 1-in., 6-strand, 19-wire, hoisting rope is 44 tons, and the strength of wire rope varies as the square of the diameter, the breaking load of a 1½ plow-steel, 6-strand, 19-wire rope is

$$L = 44\,d^2 = 44 \times 1.5^2 = 99 \text{ tons}$$

It is customary in ordinary hoisting to allow a factor of safety of 5, except for deep shafts, when this factor may be increased to 8 or 10. Using a factor of safety of 5, the safe working load is $99 \div 5 =$ say 20 tons.

Ques.—Given 10,000 cu.ft. of air circulating per minute, in an airway 8x10 ft., under a pressure of 10 lb. per sq.ft., what is the estimated length of the airway?

Ans.—The sectional area of the airway is $8 \times 10 = 80$ sq.ft. The velocity of the air current is $10{,}000 \div 80 = 125$ ft. per min. The total pressure (pa) on the entire sectional area of the airway is $10 \times 80 = 800$ lb. Since this total pressure is equal to the mine resistance (ksv^2)

$$ksv^2 = 800$$

and $$s = \frac{800}{0.00000002 \times 125^2} = 2{,}560{,}000 \text{ sq.ft.}$$

The perimeter of the airway is $2\ (8 + 10) = 36$ ft. The estimated length of the airway is, therefore: $2{,}560{,}000 \div 36 = 71{,}111$ ft. As this is an extraordinary length of airway, for a single current, it is probable that the above ventilating pressure should read 1 lb. instead of 10 lb. per sq.ft., which would make the length of airway practically 7000 ft.

Ques.—If a ventilating fan running at 80 r.p.m. produces a water gage of 3.75 in., and the fan is slowed down until the water gage reads 1.82 in., what is the speed of the fan?

Ans.—Approximately, the quantity of air in circulation varies as the speed of the fan; hence, since the pressure varies as the square of the quantity, the square root of the pressure varies as the speed. In other words, approximately, the square root of the pressure ratio is equal to the speed ratio. Calling the required speed of the fan x, we have

$$\frac{x}{80} = \sqrt{\frac{1.82}{3.75}} = \sqrt{0.4853} = 0.696$$

$$x = 80 \times 0.696 = \text{say } 56 \text{ r.p.m.}$$

Practically, the fourth power of the speed varies with the fifth power of the quantity of air in circulation; and the speed of the fan, for this reduction of pressure, would be about 51 r.p.m.

Ques.—What would be the ratio of expansion in an explosion of gas, assuming the original temperature of the gas to be 70 deg. F. and the temperature of the explosion 9564 deg. F.?

Ans.—The volume of gas or air varies as its absolute temperature; hence, the volume ratio or the ratio of expansion is equal to the absolute temperature ratio, and may be expressed as follows:

$$\frac{v_2}{v_1} = \frac{460 + 9564}{460 + 70} = \frac{10{,}024}{530} = 18.9$$

That is to say, the volume of the gas is expanded, at the moment of explosion, to 18.9 times its original volume.

Ques.—If 36,000 cu.ft. of air per min., is passing through an airway 6x10 ft., under a pressure of 3.6 lb. per sq.ft., what pressure will pass the same quantity of air through an airway 5x10 ft., of the same length?

Ans.—First, write the formula for pressure, in terms of the quantity of air in circulation; thus,

$$p = \frac{klo q^2}{a^3}$$

In this formula, the coefficient (k), the length (l), and the quantity (q) are constant; and p varies as the potential factor o/a^3. The perimeter and area of the first airway are: $o = 2\ (6 + 10) = 32$ ft.; $a = 6 \times 10 = 60$ sq.ft. The perimeter and area of the second airway are: $o = 2\ (5 + 10) = 30$ ft.; $a = 5 \times 10 = 50$ sq.ft., respectively.

In comparing these two airways, the pressure ratio is equal to the product of the perimeter ratio times the cube of the inverse area ratio. Thus, calling the required pressure x,

$$\frac{x}{3.6} = \frac{30}{32}\left(\frac{60}{50}\right)^3 = \frac{15}{16}\left(\frac{6}{5}\right)^3 = \frac{15}{16} \times \frac{216}{125}$$

$$x = \frac{3.6 \times 15 \times 216}{16 \times 125} = 5.8 \text{ lb. per sq.ft.}$$

COAL AND COKE NEWS

Washington, D. C.

Further evidence from the West Virginia field where the coal mining situation is being investigated by the special Senate Committee at work on the subject shows that there is more and more apparent certainty that there will be a positive finding against the coal mine operators, but that there is an increasing degree of certainty that nothing can be done with regard to them, no matter how severe may be the condemnation which the Committee for political reasons may choose to measure out to the operators.

The outbreak of Senator Martine during the past week with reference to the operations of the armored train which carried forces on behalf of the operators up into the regions where disorder was prevalent is regretted here by those who have been expecting to get a verdict against the mine owners as it is considered undignified and likely to prejudice the decision that may be finally arrived at.

It is understood that a final decision will not, however, be reached for some little time.

Free Coal Still on Tariff Bill

While some minor changes have been made in the paragraphs of the tariff bill relating to coal and its products, these remain substantially the same as reported by the Finance Committee of the Senate to the Senate caucus as they were in the original draft of the bill as it came from the House. The paragraphs in the free list as they stand in this latest draft reported on June 21 are as follows:

Coal, anthracite, bituminous, culm, slack, and shale; coke; compositions used for fuel in which coal or coal dust is the component material of chief value, whether in briquets or other form.

Coal tar, crude, pitch of coal tar, wood or other tar, dead or creosote oil, and products of coal tar known as anthracene and anthracene oil, naphthalin, phenol and cresol.

HARRISBURG, PENN.

The joint resolution introduced in the Senate by Senator Catlin calling for the appointment of a commission to investigate the causes of mine accidents in the anthracite region, has passed both houses and is now in the hands of the Governor for his signature.

The commission will have the authority to enter mines and make investigations, and will make tests and experiments to determine the efficacy and practibility of roof supporting materials and other methods of safety.

Dr. Holmes, director of the U. S. Bureau of Mines has tendered to the state of Pennsylvania, the use of the bureau's experimental station located at Pittsburgh, to make the necessary tests and to coöperate with the state in any effort that will tend toward the safety of those employed in the mines.

The governor is required to appoint within 30 days after the passage of the act three citizens from within the anthracite region one to be a competent mining engineer, one to be versed in anthracite mining and the other shall be a practical miner, to investigate into the causes of mine accidents. They will report the result of their investigations, etc., to the next General Assembly, together with such recommendations and drafts of such bills as in their judgment may be necessary.

Each member of the commission shall receive for his service $2400 per annum, and $25,000 is appropriated for the purpose of carrying into effect the provisions of this resolution. The commission is authorized to employ a secretary, stenographer and such other assistants as may be necessary.

The bill making it unlawful to mine or remove any pillars of coal in any anthracite mine where the seam has a pitch of 25 deg. or more unless two or more miners are employed and engaged at the same time, has passed both houses, but was amended in the Senate. The House would not concur in the amendment, and a committee from each branch has been appointed to confer on the bill, and as yet have not made a report thereon.

The Ehrhardt bill amending the act approved May 1, 1909, which provides for the health and safety of minors in bituminous coal mines and anthracite collieries or breakers by regulating the ages at which such persons may be employed, their hours of labor and prescribes rules for the obtaining of employment certificates, etc., extends to truant officers of the several districts the same right to prosecute violations of this act as has the Chief of the Department of Mines. This bill has been signed by the Governor and is known as "Act No. 48. Approved Apr. 15, 1913."

The McDermott bill has been introduced in the House making is unlawful to use electric current for any purpose in any room, breast or entry where miners are engaged in mining or loading coal in the mines of the Bituminous region that generate explosive gas. This does not apply however to the use of electricity in the main haulageways of these mines. This bill has passed second reading, and is receiving much opposition from the bituminous operators, who appeared before the mines and mining committee.

PENNSYLVANIA

Anthracite

Scranton—Another mine cave occurred in the vicinity of Prospect Avenue and Gibbons Street recently, but prompt action upon the part of the Illuminating Gas, and Water Works Co.s rendered the damage comparatively small. It is expected that the D., L. & W. Co. will repair all damage and leave both public and private property in as nearly the same condition as it was before the cave occurred as is possible.

Pittston—The North Pittston District of the Pennsylvania Coal Co. will be represented in the annual first aid meet to be held at Valley View in the fall by the Clarence team. The preliminary meet of the teams comprising this district was held in the Pittston Y. M. C. A., and the winning team received the high score of 97¾.

Wilkes-Barre—The Lehigh Valley Coal Co. will publish the first issue of its new employees magazine early in July. This is to be a monthly and will contain news from all the divisions and from the general offices, as well as articles on mining topics.

Bituminous

Monongahela—The Cincinnati mine of the Monongahela River Consolidated Coal and Coke Co., in which 97 men lost their lives in an explosion on Apr. 23, will resume operations shortly. A new ventilating system has been installed, together with a new gas proof electric coal cutting machine. Fifty men have been at work cleaning up the mine for some time.

WEST VIRGINIA

Charleston—The United Mine Workers of America have decided to call a strike in district 29, embracing Raleigh and Fayette counties, and affecting approximately 15,000 men.

Wheeling—Three hundred miners at the Pultney mine of the George M. Jones Coal Co., south of Bellaire, O., struck June 19. District officers from Bridgeport are making an effort to adjust the trouble.

OHIO

Columbus—The commission appointed by Governor Cox June 7 to investigate the report on the equitable method of weighing coal in the mines of Ohio met recently and organized by electing Judge Phil M. Crow, of Kenton, chairman and Prof. M. B. Hammond, of the Ohio State University, secretary. It is announced that sessions will start soon and that trips will be made by the commission to every mining district in the state. Testimony will be taken both from mine owners and miners. The commission will report its findings to the Governor early in the winter, in time to have it submitted to the General Assembly which meets in extraordinary session shortly after the first of the year.

INDIANA

Evansville—The old Ingle coal mines, owned by James H. Moore, of this city, and closed several weeks ago because of a fire, will reopen about July 10. More than 100 miners will be employed.

Oakland City—The Peacock Coal and Mining Co., owner of the Massey mines near this city, will abandon the present workings and sink a new shaft this summer.

Lyons—While drilling for oil on the farm of Mrs. Anna Theunds, a vein of coal nine feet thick was struck.

Sedalia—The Sedalia Lumber and Coal Co. of this town has filed preliminary notice of dissolution.

Indianapolis—The proposed increase from 50c. to 55c. a ton for coal, carried from the Indiaa fields to Indianapolis has been withdrawn by the Indiana carriers. It was vigorously opposed by shippers and buyers.

Fremont—The Fremont Lumber and Coal Co. has been incorporated here, with $10,000 capital stock, to deal in fuel. The directors are E. C. Shupp, N. G. Ball and H. I. Isbell.

ILLINOIS

Duquoin—The Leiter colliery, at Zeigler, which has been sealed up for years as the result of a series of explosions in which nearly 100 men lost their lives, was recently reopened. The task of the experts who unsealed this mine is said to have been one of the most difficult in the history of mining in Illinois.

FOREIGN NEWS

Düsseldorf, Germany—Rescuers on June 19 saved the lives of fifteen miners who were imprisoned the previous day at Lindorf by the caving in of the shaft of a coal mine.

Rotherham, England—Eight men were drowned June 17 and as many more had narrow escapes when Brown's colliery, near here, was flooded. It is believed that in extending a tunnel the workmen accidentally struck some old workings, resulting in the flooding of the mine.

Toronto, Canada—The ninth annual meeting of the Canadian Retail Coal Association was held at Toronto on June 19 and 20 with an attendance of 176 members from various points in Ontario. The delegates were welcomed to the city by Controller Church. The reply to this greeting was made by one of the directors, J. C. Hay. After the reports of officers, addresses were delivered on "The Labor Problem Solved for the Coal Merchant," by J. A. W. Archer, and "Coal from Mine to Consumer," by W. H. Lesser, an engineer of the Philadelphia & Reading Coal & Iron Co. The latter address was illustrated by 150 slides showing in an interesting way the evolution of coal.

PERSONALS

Edgar A. Perkins has been appointed chief mine inspector to take the place of Elliott R. Hooton, effective May 1.

L. Blenkinsopp has been appointed mine inspector for the 11th West Virginia district,, with headquarters at Welch, W. Va.

Alfred G. Heggem, of Pittsburgh, has been appointed petroleum engineer in the Bureau of Mines, at a salary of $3000 per annum.

J. C. Koslem has resigned as president of the Indiana Coal Operators' Association, after ten years of continuous service. Hugh Shirkle succeeds him.

A. J. Sayers, engineer in charge of the tipple and washery work of the Link-Belt Co., has just returned from a four weeks' trip in the Utah coal mining district.

Julius Anson has discovered a 4-ft. vein of coal on a deserted farm 9 miles from Boise, Ida.. It is expected that the Idaho Northern Ry. will build a spur for the purpose of developing this deposit.

George Sylvester, chief mine inspector of Tennessee has appointed the following deputy mine inspectors: John Rose, H. H. Braden and W. A. Overall. The appointments are for a period of 2 years, commencing June 1, 1913. H. B. Jackson, a former stenographer, has been appointed clerk and statistician for the mining board.

John T. Diehm, of Bluffton, Ind., was recently elected president of the Michigan-Ohio Coal Dealers' Association, succeding Robert Lake, of Jackson, Mich., who declined renomination. The other officers elected were: Vice-President, J. W. Ballard, of Detroit; Secretary, B. F. Nigh, of Columbus; Treasurer, W. A. Gibson, of Upper Sandusky. These were all elected by acclamation.

COAL AND COKE PATENTS

Miner's Lamp—W. P. Rice, Regina, Ky., 1,062,504, May 20, 1913. Filed Sept. 11, 1912. Serial No. 719,795.

Coal Drill—J. G. Huntley, Pittston, Penn., 1,055,464, March 11, 1913. Filed Sept. 3, 1912. Serial No. 718,303.

Conling System. D. A. Lee, Centerville, Iowa. 1,048,325. Dec. 24, 1912. Filed Apr. 3, 1912. Serial No. 688,241.

Smoke Consumer—W. Kelly, Memphis, Tenn., 1,002,473, May 20, 1913. Filed Aug. 3, 1912. Serial No. 713,077.

Mining Car. L. G. Helmick, Fairmont, W. Va. 1,048,309, Dec. 24, 1912. Filed July 15, 1912. Serial No. 709,581.

Smoke Consumer—A. E. Wilson, Indianapolis, Ind., 1,060,-051. Apr. 29. 1913. Filed Oct. 30. 1911. Serial No. 67,534.

Smoke Consumer—J. H. Ottman, Milwaukee, Wis., 1,059,-559, Apr. 22, 1913. Filed Oct. 14, 1909. Serial No. 522,565.

Improvements in and Relating to Miners' Safety Lamps. No. 4193 of 1913. J. Naylor, 23 The Wiend, Wigan, England.

Hand Machine to Undermine Coal—A. Roe, Beaver, Ohio, 1,062,854, May 27, 1913. Filed June 18, 1912. Serial No. 704,-286.

Automatic Coaling Bucket—J. T. Richards, Chicago, Ill., 1,062,359, May 20, 1913. Filed Mar. 22, 1911. Serial No. 616,-194.

Improvements in and Relating to Mining Machines. F. E. VanSlyke, 4 Eslington Road, Newcastle-on-Tyne; 12,364 of 1912.

Inexplosive Steam Boiler—E. Maslin, L'Estaque, France, 1,059,481, Apr. 22, 1913. Filed Jan. 22, 1911. Serial No. 605,252.

Power Loading Ash Pit—J. H. Hogston, Ladysmith, Wis., 1,059,955, Apr. 29, 1913. Filed Mar. 26, 1912. Serial No. 686,410.

Tender Coal Gate. M. A. Smith and T. J. Thornton. Albion, Penn. 1,048,222, Dec. 24, 1912. Filed Apr. 13, 1912. Serial No. 690,580.

Mining Tool—L. F. Hess assignor to Hess Dustless Mining Co., Ansted, W. Va., 1,059,463, Apr. 22, 1913. Filed Oct. 4, 1912. Serial No. 725,951.

Automatic Gate for Mine Elevator Shafts—M. W. Harvey, Sykesville, Penn. 1,055,633, March 11, 1913. Filed April 15, 1912. Serial No. 690,001.

Improvements in Blasting Detonators for Coal Mining and Like Purposes. No. 15,600 of 1912. W. A. Malson, Sheffield Road, Chesterfield, England.

Mining Tool. C. L. Aragon, assignor of one-half to O. Ellmore; both of Ely, Nev. 1,047,910, Dec. 24, 1912. Filed Oct. 12, 1911. Serial No. 654,396.

Coal Washing Apparatus—A. France, rue de l'Esperance, 223, Liege, Belgium, and P. Habets, Montegnee, Belgium. Filed in London, 22,655 of 1912.

Blower for Rollers—J. Magee assignor to Diamond Power Specialty Co., Detroit, Mich., 1,059,479, Apr. 22, 1913. Filed July 22, 1912. Serial No. 711,014.

Chamber Ovens—Especially Such as Are Suitable for the Manufacture of Coke or Gas. No. 19,812 of 1912. N. Lengersdorff, of Bunzlau, Silesia, Germany.

Gas Producer—W. F. Luick and A. J. Bassett, assignor to Luick-Bassett Producer Co. a corporation of Wisconsin. 1,062,721, May 27, 1913. Filed Oct. 2, 1911. Serial No. 652,396.

Improvements in Methods of Mining Coal, Converting it into Gas, and Then Conveying the Gas from the Mine. J. H. Hoadley, 18 East 82d St., New York, U. S. A., 14,494 of 1912.

A New and Improved Conveyor Specially Adapted for Use as a Coal Face Conveyor in Collieries. No. 1966 of 1913. H. Hirst, Crescent House, Moorelands Avenue, Dewsbury, England.

Means for Protecting the Seams of a Boiler directly exposed to the Fire. J. J. Gage assignor to Gage Co., Dayton, O., 1,059,962, Apr. 22, 1913. Filed May 20, 1912. Serial No. 698,449.

Improved Process and Apparatus for the Treatment of Coal, Shale, or the Like, in Vertical Retorts. A Waddell, Dunfermline Corporation Gas Works, Fife, Scotland; 21,991 of 1912.

Improvements in Direct Recovery of Ammonia from the Products of the Destructive Distillation of Coal or Similar Material. Chas. Stell, 2-4 Bismarckplatz, Recklinghausen, Westphalia, Germany; 28,072 of 1912.

A Method of and Apparatus for Preventing the Spreading and Effect of Coal Dust and Firedamp Explosions. No. 16,440 of 1912. G. Kahler, 31 Kaiserstrasse and F. Junker, 48 Schalgerstrasse Gelsenkirchen, Germany.

Improvements in Machines for Washing and Separating Coal, Ore and Other Granular and Like Materials. No. 10,929 of 1912. R. S. Benson, Riverside, Middleton, St. George, Durham and Head Wrightson & Co., Ltd., Teesdale Iron Yorks, Thornaby-on-Tees, England.

CONSTRUCTION NEWS

Staunton, Ill.—The Consolidated Coal Co. has recently given the Link-Belt Co., of Chicago, an order for reconstructing their No. 14 tipple at Staunton.

Sturgis, Ky.—Two 8-ton General Electric mining locomotives will soon be placed in operation in the mines of the West Kentucky Coal Co. near here.

Royalton, Ill.—The Franklin Coal and Coke Co., of St. Louis, have recently awarded a contract to the Link-Belt Co. for a large re-screening plant at No. 1 mine near Royalton.

Lansford, Penn.—The Lehigh Coal & Navigation Co. will soon place in operation a new 15-ton electric mining locomotive which has been ordered from the General Electric Co.

Jedd, W. Va.—The Jedd Coal and Coke Co. have recently awarded a contract for a complete modern steel headframe and tipple equipment to the Link-Belt Co., of Chicago, Ill.

Knoxville, Tenn.—The Asher Coal Mining Co. expect to install a mono-bar chain retarding conveyor and screening plant purchased from the Link-Belt Co. at their mines at Amru, Ky., in the near future.

Plymouth, Penn.—A 50-kw. General Electric synchronous motor-generator set will be installed in the near future in the Loomis colliery of the Delaware, Lackawanna & Western R.R. Co.

Pittsburgh, Penn.—Owing to the heavy movement of coal over the Indiana branch of the Buffalo, Rochester & Pittsburgh R.R., new sidings are being laid by a large force of men, and it is understood that the line will soon be double-tracked.

Pottsville, Penn.—The Philadelphia & Reading Coal and Iron Co. have purchased from the General Electric Co. a 125-kw. two-unit, three-bearing motor-generator set and necessary switchboard. This will be installed in the power plant of the Silver Creek colliery.

Scranton, Penn.—The Pennsylvania Coal Co. is arranging to equip its tipple with new apparatus for electrical drives, including 32 motors ranging from 10 to 200 hp., with the necessary compensators and controllers. These have been ordered from the General Electric Co.

Barnesboro, Penn.—The Cambria Coal Co., of Philadelphia, expects to install soon, in its mines near here, a 200-kw. motor-generator set and three 7½-kv-a. transformers and the necessary switchboard apparatus, all of which has been ordered from the General Electric Co.

Sunnyside, Utah.—The Utah Fuel Co. expects to increase the equipment of the plant at this place by the installation of a 625 kv-a. Curtis turbo-generator unit, a 200-kw. motor-generator set, a 200-hp. induction motor and the necessary switchboard. This apparatus was recently ordered from the General Electric Co.

Lamont, Ia.—The new coal elevator which is in course of construction by Hammer & Co. is now nearly completed. This new structure is 50 ft. long, 12 ft. wide and 38 ft. high. It has five hopper bins, also five storage bins. The coal is unloaded from hopper cars into the elevator pit, and then distributed to the different bins. The elevator is of the bucket type, 35 ft. high and operated by a 5-hp. electric motor.

Lorain, Ohio—It is rumored that the Baltimore & Ohio R.R. will erect a third coal-loading machine at this place in the near future. The new loader will probably be erected at the bend opposite the shipyard just south of the site of the old Whirlies. The erection of the loader at this point will necessitate considerable dredging, and the building of several hundred feet of new dock. There is a bare possibility that the old No. 1 loader north of the viaduct will be replaced by a more modern machine.

Duluth, Minn.—Work in connection with the erection of the Boroughian Fuel Co.'s coal dock at West Duluth is now actively under way. The plant will be one of the largest on the lakes, with a storage capacity of more than two million tons, and a coal-handling capacity during the shipping season of two million tons. It will entail an expenditure of approximately one million dollars. The contract for the structural steel required for the dock and for the large machine shop adjoining it has been awarded to the National Iron Co. It is planned to have the dock ready for operation at the opening of the 1914 season.

NEW INCORPORATIONS

Henrietta, Okla.—The Modern Coal Mining Co.; capital stock, $10,000. Incorporators: Harry Lantz, T. J. Harris and S. J. Harris.

Uniontown, Penn.—The Westmere Coal & Coke Co.; capital stock, $5000. Incorporators: C. E. Bortz, J. C. Bortz and C. C. Baldwin.

Springfield, Ill.—The Bond County Coal Co.; capital stock, $200,000; to develop coal lands. Incorporators: D. J. Gray, Joseph Folarl and J. D. Adams.

Waukegan, Ill.—The Waukegan Fuel Co.; capital stock, $25,000; general coal and fuel business. Incorporators: C. E. Bairstow, F. R. Bairstow and J. E. Hussey.

New Philadelphia, Ohio—The Horger-Heldt Coal Co., capital stock, $10,000. Incorporators: G. R. Heldt, Emil Horger, J. W. Horger, Chas. Heldt, I. M. Horger and S. Ridgley Thrapp.

Indianapolis, Ind.—The Ohio Valley Coal Co.; capital stock, $125,000; to mine coal. Directors: F. M. Ayres, Clarence Stanley, C. C. Kendall, Samuel Ashby, Harry Stout, E. E. Stout and F. B. Danner.

Charleston, W. Va.—The Monroefield Coal Co.; capital stock, $10,000; to deal in real estate, coal and mineral land, etc. Incorporators: J. A. Martin, W. J. Snee, M. C. Martin, F. P. Weaver, B. C. Weaver.

INDUSTRIAL NEWS

Bens Creek, Penn.—The Old Piper Mine, at Bens Creek, has been abandoned and dismantled. The mine has been in operation for more than 60 years.

Du Bois, Penn.—It is reported that the Brush Run Coal Co. is preparing to operate a new coal field in Jefferson County by the stripping process.

Widnoon, Penn.—Operations of the Widnoon Coal Mining Co. were suspended for four days last week on account of breaking of cables which carried their coal across the river in buckets.

Traer, Iowa—The Rock Island R.R. is said to be making Traer a coaling station. Work has been begun on a plant 100 ft. east of the depot, which will have a capacity of 200 tons, and will be automatic.

Connellsville, Penn.—F. M. Tompkins has secured a lease on a coal acreage owned by the Cambria County Coal Co., near Portage. An opening is to be made on the upper end of Trout Run in the C prime bed of coal.

McArthur, Ohio—R. B. Cutter and H. B. Stevenson of Parkersburg, W. Va., have purchased the assets of the Mohr-Minton mines of the Mohr-Minton Co. The assets consist of coal mines and a brick plant near McArthur.

Connellsville, Penn.—The Consolidation Coal Co. is opening a new mine at Wilson Creek to supplant the old workings which are now approaching exhaustion. The new heading has already been driven some distance into the coal.

Terre Haute, Ind.—The Jackson Hill Mining Co. has contracted to furnish the Inland Steel Co., at Chicago, with several hundred tons of coal daily for the next five years. Crawford Fairbanks is president of the mining company.

Chattanooga, Tenn.—H. F. Noyes has been appointed receiver for the Dayton Coal & Iron Co. It is said that the assets of the company would invoice about one million dollars, including furnaces at Dayton. The liabilities were not stated.

Pleasantville, Iowa—The city of Pleasantville has recently employed M. B. Flanders to prospect for a municipal bed of coal in the suburbs of that city. Mr. Flanders has a diamond core drill at work at that point and says that he expects to strike coal at a depth of 300 ft. or more.

Browders, Ky.—The tipple, power house and machine shop of the Caldwell Coal Co., in the western Kentucky coal district, was destroyed by fire recently, with a loss between $20,000 and $30,000. The cause of the fire is as yet unknown. No men were in or around the mine at the time of the fire.

Louisville, Ky.—The O'Donnell Coal Co. has been incorporated with a capital stock of $50,000, for the purpose of operating a number of coal mines which will shortly become the property of the company. The incorporators are Joseph W. O'Donnell, M. O'Donnell and M. Lanning, all of Louisville.

New Orleans, La.—Owing to the low stage of the Ohio River the coal movement from Pittsburgh for New Orleans has been stopped. As the high stage began early this year, more coal has been brought down the river than in any other year in the history of the industry. The movement of Kentucky coal will continue.

Monongahela, Penn.—It is reported that several large tracts of coal land have been leased in the vicinity of Bentleyville, within the past few weeks, and that some important trades are now underway. It is said that one of the companies will haul its coal several miles underground in order to bring the product to the mine opening.

Chattanooga, Tenn.—Investigation of the affairs of the Dayton Coal & Iron Co., which has been placed in the hands of a receiver, shows that the local company was doing a profitable business. The cause of the assignment is the failure of James Watson and Sons, of Glasgow. This firm held a controlling interest in the Dayton company.

Marlins Ferry, Ohio—Chief mine inspector, J. C. Davies, several deputy mine inspectors and a number of representatives of the Pittsburgh Vein Operators' Association met June 16 to start upon an inspection trip of the mines in the No. 8 coalfield, with a view to making recommendations for improving the safety of operation, as well as the production.

Portland, Ore.—The mines of the Beaver Hill Coal Co. are in operation although there is considerable agitation over wages and a number of strikes have been the result. The labor organization is trying to get a foothold in the mines but with little success. Each mine has its own scale of wages and hours of work per day, so it is not a Union camp, as yet.

Birmingham, Ala.—A recent electrical installation by the Alabama Power Co., reduced the cost of operation of the plant from $45,000 per annum to $18,000 per annum, making a saving of $27,000 yearly, which was practically the cost of the new installation, and which, therefore, would pay for itself in one year. This is a good illustration of the saving effected by electrical installation in large plants now operated by steam power.

Dubois, Penn.—The Northwestern Mining and Exchange Co. has broken ground for a big electric power plant that is planned to be one of the largest in this section of the state, It will be located a mile above Brockport close to the Johnson Run coal tract.

The new plant is to be built to furnish light and power for the various plants of the company in Toby Valley and at Crenshaw and Brockwayville.

Athens, Ohio—The Athens & Pomeroy Coal & Land Co. has leased its coal lands in Meigs County to the Calvin Essex Coal Co. of New Straitsville and arrangements are now being made to operate upon the leases this summer. The company has been taking up coal lands in this section for some time and now has 700 acres outright. L. G. Worstell, Bart Davidson, H. D. Henry and C. J. Martin are owners of the Athens & Pomeroy Company.

Carbon Hill, Ohio—Labor troubles are reported from several mines near Carbon Hill due to trouble between union and non-union miners. It is said that 400 union miners carried from the mine 12 non-union men and threatened them with violence should they return to work. The mines affected are the Snake Hollow, New Pittsburgh and Sand Run. Charles Green and L. L. Sweazy have been selected to confer with the state mine department at Columbus over the trouble.

Geneva, N. Y.—Coal has been discovered on the Wm. Barron farm, owned at present by R. A. Cooper, of the Geneva Automobile Co. Several weeks ago Mr. Cooper engaged the Comstock Drilling Co. to sink a well on his farm for water. While drilling at a depth of 390 ft., the drill penetrated a seam of coal estimated to be between 7 and 9 ft. in thickness. Tests have proved the coal to be a fine grade of anthracite. It is said that a company will be formed immediately to mine the coal.

Louisville, Ky.—The Interstate Comerce Commission has ordered the suspension of recently-issued freight tariffs canceling through rates and routes on soft coal from West Virginia and Kentucky mines across the lakes to Milwaukee and other northwestern points, on the application of coal operators, who protested that the cancelation of existing tariffs would result in prohibitive rates. The Commission, however, held that existing rates were too low, and ordered a ten-cent increase on the ton.

New Orleans, La.—After a disastrous experience above Memphis, the big tow boat Sprague arrived last week with 34,000 tons of Pennsylvania coal. The large tow was caught in the current and several of the barges were sunk. The Sprague has started on her return trip with thirty-one empty barges and one loaded with lumber.

The Jos. B. Williams, another boat in the service of the Monongahela River Consolidated Coal & Coke Co., is in port with 23,000 tons of coal. Five thousand tons of the tow were left to fill orders at Baton Rouge.

Chicago, Ill.—It is reported that a new coal-mining company with a capital stock of two million dollars, and a like amount of bonds has been formed under the laws of the State of New York, to operate in Illinois, Indiana and Ohio. The new company is to be known as the Middle States Coal Corporation, and is controlled by T. J. O'Gara, of Chicago. It is said that the company will take over the properties of the Vivian Collieries Co., two of the Imperial Mining Co.'s in Ohio, as well as that at Springfield, Ill., owned by O'Gara. The officers will be the same as those of the O'Gara Coal Co.

Elmira, N. Y.—An increase of activity in the Morris Run coal mining district is assured in the purchase by O'Donnell Brothers of the farms near the old east Mine at Morris Run, owned by Martin Yenovik and Stans Laskaski. These farms comprise 160 acres and are underlaid by the Bear Creek, Bloss, Cannel, Morgan and Seymour seams. This purchase extends the holdings of O'Donnell Brothers to the Fall Brook. They have also bought the Kiley mine at Blossburg and are now building new chutes on the east side of Morris Run. Some new openings show from 3 to 6 ft. of clean coal. The purchases are said to give the O'Donnells possession of all the available coal land at Morris Run except that held by the Morris Run Coal Mining Co.

COAL TRADE REVIEWS

GENERAL REVIEW

While there are some soft spots in the hard-coal trade, there is, nevertheless, a strong healthy undertone apparent. Dealers are becoming over-stocked on some grades but there is no indication of any let-up in the demand. However, it is becoming clear that many consumers carried over fair supplies, because of the mild winter which will, of course, curtail the summer stocking, but it is difficult to tell how the fall trade will line up yet.

In bituminous, the West Virginia strike situation is assuming serious proportions again, and the Eastern bituminous market hinges almost entirely on developments there. As a result, the trade is firm in every particular, many operators being forced into the open market for prompt tonnages to fill out their contract obligations. There has been a perceptible rush to cover on the part of consumers, and preparations for the worst are being made at a number of points. At the moment there is a good car supply, but the feeling prevails that there will be a serious shortage the coming fall. Operators, as a rule, are afraid to accept further orders, and the situation in the Eastern market may be regarded as fairly tense at the present time.

The Pittsburgh district is operating at full capacity and making heavy shipments on contracts and into the Lake trade. The labor and car supply are good, but the men cannot be induced to work steadily. No surplus coal is available, and it is difficult to get tonnages to fill out corgoes, while some dealers are persistently advocating an advance in quotations. Conservative members of the trade, however, are against any such increase, although recognizing the general stiffness of the market.

The demand in Ohio continues strong, and is well distributed among both steam and domestic consumers. Domestic dealers are stocking up for the winter and are taking more than the usual tonnage since their supplies were depleted by the flood. The manufacturing demand is steady and the railroad consumption large, due to the heavy freight movement.

Most of the producers at Hampton Roads seem to be taking care of their contracts, but there has been a scarcity of coal all week, although the dumpings have been fair. Operators are inclined to hold any free tonnages available to apply on contracts later; with plenty of vessels awaiting tonnage in the foreign trade, the loading for coastwise shipment is becoming even slower. There has been a slight heaviness develop on steam coal in the Southern market, and producers are pushing their salesmen for orders. Conditions, as a whole, however, are about normal for this season of the year.

Consumers in the Middle West are watching the market closely in anticipation of an advance that now seems to be inevitable. Quotations are improving, particularly on the better grades, with full list prices being obtained on contract and occasional premiums on spot coal.

BOSTON, MASS.

Bituminous—Trouble having broken out anew in the New River field, news is eagerly sought from day to day. This week there has been some alarming rumors; one that there would be a general tie-up in New River beginning June 24, and others of less serious consequence. New England is certainly being prepared, so far as reports go, for the worst that can happen; during the last fortnight there has been a mild rush to cover, on the part of the few good sized buyers who had previously kept out of the market except for hand-to-mouth purchases.

With government colliers and steamers for foreign consignment, at Hampton Roads, there has begun to be an accumulation of tonnage and even slower loading is in prospect for coastwise transportation. There has been talk of $3 f.o.b. as an asking price for spot coal but no sales above $2.85 have been reported. Practically every shipper has all the business he dares take, and there is hardly any prompt coal offering. There is trouble hinted at in Pocahontas as well, and it will be an entirely new situation if both fields are kept from producing for any appreciable period. The situation is being anxiously watched, but there have been no marked developments in this market as yet.

There is practically no change in either the Georges Creek grades or those mined in Pennsylvania. There is active demand for all the good coals, and prices generally are firm at the levels reported last week. "Don't want any more business," is now the usual answer of the Pennsylvania operator. Labor troubles are heard from in nearly all the districts and it is an exceptional case where an operation is getting out a normal tonnage. For tide-water shipment the anthracite business is in such shape that transportation is not available for bituminous to the extent that was looked for this month, and that adds to the difficulty of getting adequate shipments.

Water Freights are firmer in response to a better demand. Large vessels are getting 80c., Hampton Road to Boston, and 75c. is the rate on barges, 3000 tons or so to Providence.

Anthracite—The demand continues steady. Some dealers are finding themselves with an over-stock of egg and chestnut and are therefore somewhat handicapped in their efforts to make up schedules that the companies can ship. There is, however, no present sign of any easing up in the call for hard coal. The retail business is exceptionally good for this time of the year. It is becoming apparent, however, that the mild winter has left a considerable supply in the cellars of many householders. Just what effect this will have remains to be seen.

Current wholesale prices on bituminous are about as follows:

	Clearfields	Cambrias Somersets	Georges Creek	Pocahontas New River
Mines*	$1.10@1.45	$1.30@1.65	$1.67@1.77	
Philadelphia*	2.35@2.70	2.55@2.95	2.92@3.02	
New York*	2.65@3.00	2.85@3.30	3.22@3.32	
Baltimore*		2.58@2.73	2.85@2.95	
Hampton Roads*				$2.85 *firm*
Providence†				3.836@3.88
Boston†				3.90@4.05

*F.o.b. †On cars.

PITTSBURGH, PENN.

Bituminous—Mines of the Pittsburgh district continue to operate at substantially full capacity, with heavy shipments in the lake trade and fairly heavy deliveries on contracts with commercial consumers. There has, however, been a slight seasonal decrease in the latter, and new demand is slightly less from the same cause. The market will probably make up this slight loss by the middle of July. Car supply is fairly good, but serious shortage is feared later in the season. The supply of men is good but they do not work steadily and several mines could produce a larger tonnage if more labor were available. Slack for prompt shipment continues to sell at 60@70c., well under the season price, while mine-run and screened coal occasionally bring premiums for prompt shipment, over the season level, which we continue to quote as follows. Slack, 90c.; nut and slack, $1.02; nut, $1.25; mine-run, $1.30; ¾-in., $1.40; 1¼-in. steam, $1.50; 1¼-in. domestic, $1.55, per ton at mine, Pittsburgh district.

Bituminous—If there is a "deadlock" between coke operators and blast furnacemen as to second-half furnace coke contracts, it is by no means strenuous. After the recent refusal of some furnaces to close at $2.25, when this had been named as a special price, the operators withdrew the figure and are now quoting $2.50 again as the minimum. There is a considerable tonnage, between 100,000 and 200,000 tons a month, in contracts which expire June 30. Furnacemen seem to expect to be able to renew at $2 or less and feel that they can buy in the prompt market from time to time until they obtain this figure. The operators, however, have for several months been committed to the policy of blowing out all ovens, which they do not need to operate for the filling of their contracts. The whole market situation today resolves itself into a question whether the operators will have courage to blow out ovens against the expiration of the first-half contracts mentioned. If they did this, they would run the risk of losing their operating forces, as labor is relatively scarce, but if they carried out the policy the large prompt demand created would undoubtedly stiffen the market. Meanwhile we quote as follows: Prompt furnace, $2.10@2.15; contract furnace (nominal) $2.25@2.50; prompt foundry, $2.85@3; contract foundry, $2.75@3, per ton at ovens.

NEW YORK

Bituminous—The local market on soft coal is firmer, alarming reports regarding the labor situation in West Virginia having caused prices to harden quite perceptibly. The consumption continues large in all directions, but the movement is almost entirely on contract. Further contracts are being delayed pending a return of more settled conditions in West Virginia; at the present moment operators would not consider entering into any further agreement for tonnage.

Production at the mines continues at a high rate. While the labor supply is not up to full requirements, it is still fairly plentiful, the chief difficulty being the numerous holidays which the miners insist on taking. The car supply is fair and fully up to the requirements of the mines. The local market is not quotably changed, and we continue previous quotations with prices firm in every respect as follows: West Virginia steam, $2.55@2.60; fair grades of Pennsylvania, $2.65@2.70; good grades of Pennsylvania, $2.75@2.80; best Miller Pennsylvania, $3.05@3.15; George's Creek, $3.25@3.30.

Local water freights are firm with tonnage difficult to obtain.

Anthracite—The last week of the month naturally sees some activity in hard coal as dealers and consumers are anxious to buy before the next reduction in the discount. Aside from this temporary activity the general trade is dull and flat. Furthermore, this condition will no doubt prevail now until September, since the discount during the intervening months is too small to interest the buyers generally.

On the whole, however, the market is in a fairly strong position, considering the period of the year, and is fully as good, if not better than is to be expected at this time. Stove coal is still in rather short supply, while dealers are becoming overstocked with chestnut and buckwheat. The domestic sizes of all kinds are dull, but as a rule are not so flat as the steam grades. Some companies report that they are entirely cleaned up on rice coal, but there is no doubt that plenty of this could be obtained for reasonably prompt shipment.

The New York hard coal market is quotable about on the following basis:

		Individual		
	Circular	Lehigh	Scranton	Schuylkill
Broken	$5.00	$5.00	.	.
Egg	5.25	4.55	.	.
Stove	5.25	4.85	.	.
Chestnut	5.50	.	.	$4.90
Pea	3.50	3.60	.	.
Buckwheat	2.75	. .	$2.50	2.35
Rice	2.25	. .	2.25	1.80
Barley	1.75	. .	. .	1.15

PHILADELPHIA, PENN.

The anthracite coal trade is beginning to show additional signs of slowing up in this particular vicinity. All the dealers are complaining about lack of business, although admitting that the conditions are not abnormal, but the contrast between what they were doing last year and now is so marked, that they are inclined to feel somewhat dissatisfied. Last year, the market was absorbing everything from broken to barley, but this year being a normal one, with no strike demand, the dealers find the situation hardly to their liking.

The tidewater business to the East still continues good. Every week sees large sailings of barges en route for the New England market, and while the demand here is not so insistent, there seems to be another order ready as soon as the last one is shipped. All the mines are still continuing operations, although it is understood that partial suspensions are looked for during the coming month. Outside of the small sizes, very little coal has as yet gone into stock, and the demand may be such, with the curtailed mining during July and August, that the market will be able to take care of the output. There is talk of some cutting on the part of the individual operators, although confined to certain sizes. Stove coal seems to be about the only grade in this market that finds a ready sale.

The pressure for bituminous coal seems to have shaded off somewhat during the week, and in some quarters, operators are inclined to believe that the change for the better is not to be as lasting as many expected. Prices are well maintained, however, and the softening of the market is commented on by many as being only temporary.

BALTIMORE, MD.

The possibilities of a protracted shutdown in the West Virginia mining regions, because of the labor troubles there, is having its effect on the local market. A number of consumers who have heretofore consistently refused to contract signed up at the increased prices asked during the week, rather than face the possibility of being caught in a short market. The situation in the New River and Pocahontas fields, which supply much of the fuel here, is openly regarded with alarm.

As a consequence the local market remains firm in every particular. The demand for all grades is quite persistent, and reports are current that some of the large operators have such an excess of orders that they are being forced to buy from competitors in order to make prompt delivery. Line business is particularly heavy, while shipments at the piers have been active all week, and low-grade coals are in ready demand at 95c. to $1. There has been a slight improvement in the car situation, but still more equipment could be used, were it available; the lake movement continues as heavy as ever.

One of the interesting features at the moment is the coming announcement of the award of the municipal coal contract for 45,000 tons during the current year, on which a dozen or more companies are competing. The hot spell has eliminated any further interest in the anthracite market, and coke continues weak, with production still further reduced.

BUFFALO, N. Y.

Bituminous dealers are, in some cases, advising an advance in quotations. There is no surplus coal anywhere and it is difficult to get up an extra cargo or fill a rush order. Pittsburgh is steadily reporting that contracts are taking the entire output and such is also the case to a great extent in the Allegheny Valley; this in spite of the reports of shut downs by the iron furnaces, a sort of contradiction that coal men do not try to reconcile. Coal sells briskly and that is enough. So much coal is going to the lakes to make up the annual demand for 12 million tons that it is hard to get enough to go around in other parts of the market. Cases are reported where Lake Ontario shippers have paid more for coal than they are to get for it, being obliged to borrow and buy all they could find to make out a cargo.

Still, the conservative side of the trade is against any direct recognition of the stiffness and it may be well to wait another week before quotations are changed. It is becoming evident that the actions of Congress are not being taken seriously. If the crops are as good as they now promise to be the present activities will go on, regardless. At the same time it is uncertain what the markets will be in the near future. A state institution is asking for bids on a lot of slack to be furnished for a year beginning with next October, but the jobbers are not prepared to gamble to that extent. It looks as if big prices will have to be paid if a contract is made at all, as was the case with the city water-works contract.

Quotations will therefore remain strong at $2.80 for Pittsburgh lump, $2.65 for three-quarter, $2.55 for mine-run and $2.15 for slack. Coke, however, is not at all strong at former figures, $4.85 for best Connellsville foundry. Allegheny Valley coal is about 25c. under Pittsburgh. There is no change in smithing coal, which is subject to few fluctuations.

A leading reason for the shortage of bituminous is the scarcity of men in the mines and a lesser scarcity of cars, the two often conspiring to spoil a week's mining; no improvement in either direction is looked for right away and only a falling off in demand can make coal plenty.

There is no stir in anthracite. Shipments by lake are heavy, being 191,000 tons for the week.

COLUMBUS, OHIO

Trade in all grades of coal in Ohio has been quite active during the past week. The demand is distributed among the domestic and steam grades and prices all along the list have been well maintained. On the whole the market is in good condition and operators as well as shippers believe that quotations will be raised in the near future.

One of the best features of the trade is the activity shown in domestic sizes. Dealers are stocking up in preparation of the expected demand from householders; it is believed that their stocking period will arrive sooner than usual and dealers are preparing for this. Dealers' stocks as a rule, are light because of the demand upon them incidental to the flood. The extra large harvest in Ohio is also expected to furnish a market for threshing purposes.

Steam business is steady in every way; manufacturing plants are taking a large tonnage and a few show a disposition to stock up to guard against the expected car shortage. Plants in the iron and steel trade are large users of fuel and in fact a marked improvement is reported in manufacturing circles generally, railroad fuel is also in good demand there being a large freight movement. Most of the railroad contracts have been made, although a few are still hanging fire.

The tonnage moving from Ohio and West Virginia fields to the Northwest via the lakes and the docks is heavy. No

congestion of consequence has taken place either at the docks or with the vessels.

Production in all Ohio fields has been large during the past few weeks. Excepting in Eastern Ohio, there is not much trouble over the car supply and all of the mines are working with a large force. Some trouble is experienced in certain districts from a labor shortage. In the Eastern Ohio district the output is estimated at 65 per cent. and in the Pomeroy Bend field it has been 75 per cent. In the Hocking Valley, where car shortage has not affected the output the production has been about 90 per cent. of capacity. In the strictly domestic fields the output is gradually increasing.

Quotations in the Ohio fields are as follows:

	Hocking	Pittsburgh	Pomeroy	Kanawha
Domestic lump	$1.50		$1 60	$1.50
2 inch	1.35	$1.20	1.35	1.30
Nut	1.20		1.25	
Mine-run	1.15	1.10	1.15	1.10
Nut, pea and slack	0.65		0 65	0.60
Coarse slack	0.55	0.55	0.55	0.50

HAMPTON ROADS, VA.

Although there has been a continued scarcity of coal at all Tidewater piers, at the same time the dumpings have been fair and, with coal coming in daily, the end of this week finds conditions practically the same as they have been for the past month. The majority of the suppliers are taking care of contracts but are not soliciting new business or making outside sales; $2.90 has been about the prevailing price offered by buyers for spot coal but operators are preferring to hold what coal they have for contract tonnage about due and early July shipment.

Two of the largest shipments made during the week went into the U. S. Naval Colliers "Orion" at Lamberts Point and the "Proteus" at Newport News. This latter vessel is just from the Newport News shipbuilding and drydock plant and the 12,500 tons which went into her was the first cargo she had taken. She is now on her trial trip and it is expected she will be formally turned over to the Government during the next week or ten days.

BIRMINGHAM, ALA.

There is a slight heaviness noticeable in the local steam market, so that some operators are pushing their sales agents for more business. No serious alarm is felt over the situation, however, as similar conditions appear every summer; as a matter of fact they have been less frequent so far this season than ever before.

Prices on Alabama foundry and furnace coke remain unchanged, although there has been a considerable reduction on the West Virginia cokes which enter into competition with the local product in certain of the Southern markets. Reports on business conditions in the South are encouraging, and indications point to a highly profitable business the coming fall.

DETROIT, MICH.

Bituminous—Full list prices are being obtained on contract shipments with fairly substantial premiums being offered for spot delivery. Buyers are now finding that it is not so easy to place orders as they had anticipated it would be. The domestic grades are the feature of the situation at the present time, the inquiry being heavy, and a good stiff asking price prevailing; dealers are unanimous in the belief that these coals will bring from 75c. to $1 more than during last season, and all are anxious to obtain a good stock and assure themselves of a steady supply through the winter.

The local market is quotable on about the following basis:

	W. Va. Splint	Gas	Hocking	Cambridge	No. 8 Ohio	Pocahontas	Jackson Hill
Domestic lump	$1.70	..				$2 25	$2 00
Egg	1 70	..				2 25	2 00
Steam lump	1.40	..					
2-in. lump	1.25	$1 25	$1 25	$1 25	$1 25		
Mine-run	1 10	1 10	1 10	1 10	1 10	1 50	
Slack	0.85	0.85	0.85	0 85	0 85		

Anthracite—Orders for hard coal are coming in fully as fast as last month, and there does not seem to be any easing off likely to occur at any time in the immediate future. The movement is quite heavy, and many dealers are unable to obtain prompt shipments, due apparently to the scarcity of cars at the mines.

Coke—The local coke market has not been active during the week, because several of the large local foundries have been compelled to suspend operations; this, of course, had an immediate effect on the trade. The market is now quotable about as follows: Connellsville, $2.25; Sement Solvay, $2.85 and Gas House, $2.75, f.o.b. ovens.

LOUISVILLE, KY.

The continued hot weather during the past week has had little effect upon the market, inasmuch as all the domestic business is confined to storage for next winter; however, the orders showed a tendency to slacken up during the week. The heavy movement into the North and Northwest continues unabated; there are also considerable orders from points in Iowa and Nebraska, indicating that the Kentucky product is steadily enlarging its field. Favorable prices are being made in this new trade, in some cases as much as 25c. below quotations offered the Southern consumer. On the other hand, prices made at some of the large southern competitive points, such as Louisville and Knoxville, where competition is keen, are often 25 to 30c. below those prevailing in more competitive districts.

There has been little change in the steam coal situation, the market remaining rather weak. Production is still running considerably ahead of consumption, and dealers are having considerable difficulty in placing these grades. Western Kentucky pea and slack continue to lead in excess supply, and are being freely offered at 35c. f.o.b. mines, with the better grades of nut and slack at 75c., and second grades at 50 to 60c. per ton.

The domestic grades for July shipments are holding fairly strong, some Jellico producers maintaining a minimum for June delivery of $1.90 on block, with indications that they may continue at this same figure through July; block and lump are held at $1.60 to $1.65, and round at $1.35. Most of the mines in the Eastern part of the State have had sufficient orders to keep them working full time, and indications are that this will continue until the customary fall demand opens up.

INDIANAPOLIS

Consumers are watching the market closely for the advance that now seems to be inevitable. It is said some of the local wholesalers are ready to make their first ante-winter raise but they have not been able to get unanimous action. They have not been any too successful in getting their orders filled at the Eastern mines, even when offering a premium. Their own customers have been taking coal from the yards liberally and they are not accumulating the surpluses they would like to have in the face of the present demand. The wheat harvest is on in Indiana and there is the threshing machine demand to fill now also.

There seems to be growing confidence that the basis for business—good crops—is assured. Indiana mines are not losing ground but instead are making slight gains. The factory situation is steadily becoming better, not in a very marked way, but enough to show it is moving in the right direction. Coal dealers in this city are beginning to talk about a difficulty in getting coal similar to that in effect last fall and consumers are deciding they will run no risk, so are ordering summer deliveries. All this causes a general strain that tends to advance prices. There are no changes in prices yet at Indiana mines, or with wholesalers and retailers.

The summer schedule in the retail yards of this city still prevails, quotations being as follows:

Anthracite, chestnut	$8.00	Hocking Valley lump	$4.50
Anthracite, stove and egg	7.75	Luhrig lump	4.50
Anthracite, grate	7.50	Luhrig washed egg	4.75
Pocahontas, forked lump	5.50	Cannel	6.50
Pocahontas, shoveled lump	5.00	Linton No. 4 lump	3.25

ST. LOUIS, MO.

Local conditions are improving slightly on the high grade fuels, but the Standard coals are still trying to reach a low record price. Retailers who are buying coal on contract are able to sell it to manufacturing plants at 75c. f.o.b. the mines for 2-in. lump coal.

Anthracite conditions are improving, while the smokeless demand is lagging back with no coal to take care of what little demand there is. The coke market has been brisk, but the chances are that it will slacken up some now, and coke will be plentiful in July.

Owing to the large number of mines shut down in the Carterville and Franklin County fields, such coal as is coming in is bringing a good price. There are a few inferior qualities, however, that are still hanging around the dollar price, but even then it is largely a matter of poor salesmanship that accounts for lack of a better figure.

It is understood that the Consolidation Coal Co. of Cin-

...secured the coke contract from the Laclede Gas Light Co. running until Jan. 1, 1915. From now until Jan. 1, 1914 there will be about 10,000 tons of gas house coke, and for the following twelve months the production will be about 90,000 tons. This is about 20,000 tons more than the St. Louis market is able to take care of, and the price at which the contract went, it is rumored, is so high that cheaper outside cokes will give the local product brisk competition.

	Carterville and Franklin Co.	Big Muddy	Mt Olive	Standard
2-in. lump				$0.80@0 85
3-in. lump			$1.20	
6-in. lump	$1 15 @ 1 25		1.20	0 85@0 90
Lump and egg		$2 00		
No. 1 nut	1.10 @ 1 20			
Screenings	0 80 @ 0 85			0 75@0 80
Mine-run	1 00 @ 1 10			0 75@0 80
No. 1 washed nut	1 40 @ 1 50			
No. 2 washed nut	1 25 @ 1 30			
No. 3 washed nut	1 25 @ 1 30			
No. 4 washed nut	1 25 @ 1 30			
No. 5 washed nut	1 00 @ 1 05			

St. Louis prices on June anthracite are: Chestnut, $7.15; stove and egg, $6.90; grate, $6.65. Smokeless lump and egg is $4.65 and mine-run $4. Byproduct coke is $5.10 and gas house $4.85.

PORTLAND, ORE.

While business is not now active, the season for placing orders for next winter will soon be open and hence dealers are looking for considerable activity in the near future. The market is steady and it is believed the demand for next winter will be greater than a year ago. Wood, which takes an important part in the local fuel situation, is selling at $5.50 per cord, which is about as low as it has been at this time for some years. This naturally has an effect on the coal trade for domestic purposes.

FOREIGN MARKETS

GREAT BRITAIN

June 13—Business is slow and as supplies are plentiful, an easy tone prevails in all sections.

Best Welsh steam	$4 80@5.04	Best Monmouthshires	$4 26@4.32
Best seconds	4 62@4.74	Seconds	4.08@4.20
Seconds	4 44@4.56	Best Cardiff smalls	2 40@2 52
Best dry coals	4 76@4 80	Seconds	2.28@2 40

British Exports—The following is a comparative statement of British exports for May and the first five months of the last three years, in long tons:

	May			5 Months	
	1912	1913	1911	1912	1913
Anthracite	196,423	251,117	986,525	784,220	1,188,283
Steam	4,659,433	4,318,911	19,138,316	14,791,968	21,636,454
Gas	1,120,763	929,955	4,215,605	3,326,247	4,523,898
Household	140,711	128,856	613,181	485,999	710,583
Other sorts	331,706	301,108	1,301,439	1,028,645	1,460,607
Total	6,449,036	5,929,747	26,255,066	20,416,679	29,589,825
Coke	48,765	71,944	392,889	336,969	424,334
Manufactured fuel	131,446	145,723	717,655	526,634	837,070
Grand total	6,629,247	6,147,614	27,365,610	21,280,282	30,781,229

PRODUCTION AND TRANSPORTATION STATISTICS

The Car Situation

American Ry. Association reports surpluses and shortages of coal equipment for two weeks ended June 14, as follows:

	Surplus	Shortage	Net*
New England Lines	6	85	79
N. Y.; New Jersey, Del.; Maryland, Eastern Penn	715	0	715
Ohio; Indiana; Michigan; Western Pennsylvania	1,756	135	1,621
West Virginia, Virginia, North & South Carolina	939	1,202	263
Kentucky, Tenn.; Miss.; Alabama, Georgia, Florida	425	280	145
Iowa, Illinois, Wis., Minn.; North & South Dakota	1,706	152	1,554
Montana, Wyoming, Nebraska	398	0	398
Kansas, Colorado, Missouri, Arkansas, Oklahoma	2,000	128	1,872
Texas, Louisiana, New Mexico	263	4	259
Oregon, Idaho, California, Arizona	2,694	0	2,694
Canadian Lines	196	47	142
Totals	11,098	2,033	9,065
Greatest surplus in 1912 (Apr. 25)	94,692	2,144	92,548
Greatest shortage in 1912 (Oct. 10)	6,491	14,897	8,406

*Bold face type indicate a surplus

NORFOLK & WESTERN RY.

The following is a statement of the tonnages shipped over this road during May, 1913, and for the five months ending May 31, as compared with corresponding periods of 1912 in short tons:

Destination	May 1912	May 1913	5 Months 1912	5 Months 1913
Coal				
Tidewater, foreign	123,380	165,695	712,582	700,906
Tidewater, coastwise	379,303	340,073	1,516,662	1,640,744
Domestic	1,452,812	1,625,977	6,847,814	7,027,891
Coke				
Tidewater, foreign	12,687	5,857	37,834	22,841
Domestic	93,862	132,391	603,781	693,860
Total	2,062,044	2,269,993	9,718,673	10,086,422

PENNSYLVANIA RAILROAD

The following is a statement of shipments over the P. R.R. Co.'s lines east of Pittsburgh and Erie for May, and first five months of this year and last year in short tons:

	May		Five Months	
	1913	1912	1913	1912
Anthracite	967,898	109,341	4,641,994	3,688,943
Bituminous	4,178,271	3,495,016	20,092,450	18,956,936
Coke	1,238,083	1,150,080	6,225,387	5,340,912
	6,384,252	4,754,437	30,959,831	27,986,791

COAL SECURITIES

The following table gives the range of various active coal securities and dividends paid during the week ending June 21.

Stocks	Week's Range High	Week's Range Low	Week's Range Last	Year's Range High	Year's Range Low
American Coal Products	87	87	87	87	87

DIVIDENDS

Lykens Valley R.R. & Coal Co.—Dividend of 2%, payable July 1 to holders of record June 15.

Mine Hill & Schuylkill Haven—Dividend of $1.50 payable July 15 to holders of record June 20.

Reading Co.—Regular quarterly dividend of 2% on the common stock payable Aug. 14 to holders of record July 29. Regular quarterly on the first preferred of 1% payable Sept. 11 to holders of record Aug. 26. Regular quarterly on the second preferred of 1% payable July 10 to holders of record June 28.

St. Louis, Rocky Mountain & Pacific—Quarterly dividend No. 4 on preferred of 1¼% payable June 30 to holders of record June 21.

Central Coal & Coke Co.—Dividend of 1½% on the common and 1¼% on the preferred, both payable July 15 to holders of record July 1.

Island Creek Coal Co.—Regular quarterly on the common of 50c., and an extra dividend on the common of $3, payable Aug. 1 to holders of record July 15. Also regular quarterly on the preferred of $1.50 payable July 1 to holders of record June 25.

American Coal—In 1903 this company paid a 20 per cent. extra dividend from the proceeds of a sale of real estate and in 1907, a 25 per cent. distribution was declared from the sale of their railroad.

INDEX OF COAL LITERATURE

We will furnish copy of any article (if in print) in the original language for the price quoted. Where no price is quoted, the cost is unknown. Inasmuch as the papers must be ordered from the publishers, there will be some delay for foreign papers. Remittance must be sent with order.

BLASTING, EXPLOSIVES

Blasting Accident at the Glückauf Mine in Westphalia, May 8, 1911. (Unfall bei der Schiessarbeit auf der Zeche Glückauf Tiefbau in Westfalen am 8. Mai 1911.) Zeit. f. d. Berg-Hütten- u. Salinenwesen, 1912; 6 pp., illus. 40c.

Permissible Explosives Tested Prior to March 1, 1913. Bureau of Mines, Tech. Paper 52; 7 pp.

Study of Magazines for Black Powder. Tests at Droitaumont of the Permanent Commission on Gas and Explosives. (Etude des Dépots de Poudre Noire.) Ann. des Mines, Vol. 3, No. 1, 1913; 40 pp., illus.

Use of High Explosives in Northern Mines. F. H. Gunsolus. Coll. Engr., June, 1913; 1 p. 40c.

BORING, SHAFT-SINKING & TUNNELING

Sinking Shaft III of the Minister Achenbach Colliery to the Coal Measures. (Das Abteufen des Schachtes III der Zeche Minister Achenbach bis zum Steinkohlengebirge.) Norkus. Bergbau, Apr. 24, May 1, 1913; 7 pp., illus. 80c.

COAL DUST

The Influence of Incombustible Dusts on the Inflammation of Gaseous Mixtures. Coll. Guard. Apr. 18 and 26, 1913; 5¼ pp., illus. 80c.

Dust Explosions. C. M. Young. Coal Tr. Bull., May 15, 1913; 3½ pp. 25c.

COKE

A New Coke Quenching, Screening and Loading Car. Gas World, May 3, 1913; 1 p., illus. 40c.

Bee-Hive Oven and By-Product Methods of Coke Manufacture Contrasted. Coal & Coke Op., June 5, 1913; 1½ pp. 20c.

Mechanical Coke Quenching and Loading Appliances of the Neumühl Colliery. (Maschinelle Kokslösch- und verladeeinrichtung der Zeche Neumühl.) Braunsteiner. Glückauf, Apr. 26, 1913; 4½ pp., illus. 40c.

Strength of Blast Furnace Coke. (Ueber dis Festigkeit von Hochofenkoks.) A. Wagener. Bergbau, May 15, 1913; 3¾ pp., 4 tables. 40c.

The Ostwald Process for Making Nitric Acid from Ammonia. Iron Coal Tr. Rev., May 23, 1913; 1¾ pp., illus. 40c.

The "Agglutinating Power" of Coals. (Paper read by J. T. Dunn before the Newcastle Section of the Soc. of Chem. Indus.) Iron Coal Tr. Rev., May 9, 1913; ¼ p. 40c.

The Rise and Development of By-Product Coking—III. Gas World, May 3, 1913; 1 p. 40c.

ELECTRICITY

The Series-Wound Electric Motor Working at Constant Pressure and with Constant Current. Sydney F. Walker, Coll. Guard., May 23, 1913; 1¾ pp., illus. 40c.

The Production, Transmission and Application of Power at Collieries in Scotland. (Paper read by W. H. Telfer at joint meeting of Scottish Branches of N. A. C. M. and A. M. E.E.) Iron Coal Tr. Rev., May 23, 1913; 2 pp. 40c.

Electricity in Anthracite Mining. Wm. P. Jennings. School of Mines Quart., January, 1913; 4 pp., illus. 60c.

Colliery Cables. W. T. Anderson, Trans. Manchester Geol. & Min. Soc., Part V. Vol. XXXIII; 21½ pp., illus.

Gas Power for Collieries. Sydney F. Walker. Coll. Engr., June, 1913; 3½ pp., illus. 40c.

EXPLOSIONS

Firedamp Explosion at the Osterfeld Workings I, II, III, of the Oberhausen Colliery, Rhineland, July 3, 1912. (Die Schlagwetterexplosion auf der Schachtanlage Osterfeld I, II, III des Steinkohlenbergwerks Oberhausen Rheinland, am 3. Juli 1912.) Koepe. Zeit. f. d. Berg- Hutten- u. Sallenenwesen, 1912; 7½ pp., illus. 40c.

Earthquakes, Strains and Stresses in Relation to Colliery Explosions. F. N. Denison. Trans. Can. Min. Inst., 1912; 6 pp.

Firedamp Explosion at the Lothringen Coal Mine in Westphalia, Aug. 8, 1912. (Die Schlagwetterexplosion auf der Steinkohlenzeche Lothringen in Westfalen am 8. Aug. 1912.) Grassy. Zeit. f. d. Berg-Hütten- u. Salinenwesen, 1912; 14 pp. 40c.

FUEL TESTING

A Modification of the Jäger Method of Gas Analysis. S. H. Worrell. Met. & Chem. Eng., May, 1913; 2½ pp., illus. 35c.

Coal Testing. A simplified method. Gas World, May 24, 1913; 1 p., illus. 40c.

Determination of Water in Coal. (Paper read by P. L. Teed May 22 at meeting of Inst. of Mining & Metallurgy.) Iron Coal Tr. Rev., May 23, 1913; ½ p., illus. 40c.

Heat in the Volatile Matter of Coal. (Abstract of paper by A. M. Peter read at Kentucky Min. Inst., May 17, 1913.) Coal Age, May 31, 1913; 2½ pp. 10c.

Laboratory Apparatus for the Exact Analysis of Flue Gas. Met. & Chem. Eng., May, 1913; 1½ pp., illus. 35c.

The Specific Properties and Differences of Solid and Liquid Fuels and Their Technical Significance. (Die spezifischen Eigenschaften und Unterschiede der festen und flüssigen Brennstoffe und ihre technische Bedeutung.) Dr. Aufhauser. Glückauf, Apr. 19, 1913; 11 pp., illus. 40c.

GAS

Commercial Trend of the Producer-Gas Power Plant. R. H. Fernald. Bureau of Mines, Bull. 55, 85 pp., illus.

New Coal Gas Plant at Atlanta. (Paper read by R. C. Congdon at recent meeting of Southern Gas Assn.) June 2, 1913; 3 pp., illus. 20c.

Proposed Regulations for the Drilling of Gas and Oil Wells, With Comments Thereon. O. P. Hood and A. G. Heggem. Bureau of Mines, Tech. Paper 53; 23 pp., illus.

Wastes in the Production and Utilization of Natural Gas and Means for Their Prevention. R. Arnold & E. G. Clapp. Bureau of Mines, Tech. Paper 28, 24 pp.
