The Problem at Washington

DIFFICULT as are the problems that will confront the coal miner and the coal operator at the Washington conference they will be far less puzzling than those which the President and his advisers must face. Having adopted a "hands-off" policy so long as seemed advisable, the administration now judges the time ripe for action. To delay would seem likely to entail serious consequences to the country. The point taken by the President seems fuly justified and it cannot be gainsaid that his decision is well timed.

The immediate interest of the consuming public is coal—coal enough to meet the demand without exciting to panic prices. Occasionally a word is printed about the need for a better functioning industry, about the reforms that should be accomplished and the "ills" that should be cured, but the general public knows little of what it is all about and, unfortunately, cares less. In what the President has set about the public at large can see nothing except the government getting the miners back in the mines in order that it may have coal.

If Washington sees no further than this its problem is simple. If all that is desired is to get production Washington can soon bring that to pass. The miners are impatient and must work; they have reason to feel that all is not well with their cause. A compromise with them could easily be arranged; a compromise, for instance, that would give them no reduction in wages in the hard-coal mines and a slight reduction in the bituminous fields coupled with their demanded interstate agreement. Such a settlement would be equivalent to victory for them and would be a fitting crown for the efforts of the International officers of the United Mine Workers until, stocks being again replenished, the non-union bituminous field would once again have all the spot orders for soft coal and all the contracts also. That concession is the utmost they can hope for and probably as much as they expect to receive.

Compromise No Principles

It is not inconceivable that the President could force the operators into such a compromise, for the power of the Chief Executive in molding opinion in such a matter is tremendous. Washington, however, is too well advised on all sides of the controversy unwittingly to drive matters in this course. The danger lies rather in an impatient public demanding a hasty action that would not be in the best national interest. The problem has two well-recognized aspects, one of which is to patch up a temporary settlement, the other to provide against repetitions of like kind. The temporary arrangement must be of such character as not to prejudice a proper and permanent solution. It is important that in the haste to get coal before it be too late, no principles be compromised.

The miner's right to collective bargaining and to strike are the fundamental principles on the one side. On the other side the principle of the right of management to manage and to employ whomsoever it will without forcing tribute to the union must be reinstated. Above all, in the interest of the public the principle of obedience to the laws of the land which stamp murder as murder and which guarantee to every individual the right to work where he will must be sustained. The problem at Washington is to evolve a formula under which the production of coal may be resumed without abridging the rights of the contestants or compromising these principles. This will prove to be no easy task.

The operators who are meeting at the request of the President have not called into question the rights of the men to organize or to strike. The United Mine Workers, however, is challenging the right of the owner to manage his property and of the individual worker to live, just as it has and is challenging the laws of the land. It were better that President Harding take over every mine, put an American flag on every tippie and give the country coal, rather than submit to the collective threatening of the union.

Lower Wages the Immediate Issue

Majority opinion has from the beginning held that the positions of the miners and of the operators were so opposite and so strongly held that some form of federal intervention was inevitable. It is now materializing. John Lewis has begun a repetition of the pilgrimages to Washington that preceded the end of the 1919 strike. The government saved him from his friends on that occasion; perhaps it will save him again. In other words, the end is in sight even though the details of the road to be followed are but dimly discernible.

The fundamental strategy of the miners' union, of course, is to prevent wage reductions. This accomplished, the prestige of United Mine Workers is enhanced and the incumbency of the officials made secure. Leaders that win have no fear for their jobs. The insistence on a joint interstate settlement—a national wage agreement—which is the war cry of the union, has no other significance. The miners reason correctly that to accede to state or district settlements is tantamount to lower wages. It is to get wages down that the operators are insisting on that form of negotiations, just as the miners in 1920 were quite willing to resort to state agreements to get their day wage raised from $6 to $7.50.

The miners cannot win in a straight endurance test with the operators, but as against the country they have an advantage. In that all-important sense it is the consuming public against the miner, for the consumer pays the wages of the miner, up or down, and he is the one who needs the coal and must go short and
suffer if sufficient fuel is not produced. The government represents the interests of the public in this matter, and in the last analysis the interest of the public is paramount.

One need ascribe no altruistic motives to the operators in saying that their efforts to reduce the cost of producing coal by lowering wages is in the public interest. The public demand for lower-priced household fuel is an issue which the anthracite operators know cannot be denied. They are but transmitting to mine labor the pressure they already feel. The operators of bituminous-coal mines in the union fields face competition from the non-union areas that will overwhelm them if it is not met. The government, acting for the consumer, is as much concerned as the operator in the lowering of the cost of production by a reduction of wages.

Nor does anyone deny the right of the miners' union to seek as high wages as it can get and hold. Labor may not be a commodity but, like capital, it must in the end take as its recompense that which it brings on the market and that which the ultimate consumer can afford to pay. But when competition is removed and there is no limit to the price save the conscience of the vendor, public policy dictates another course. Last month the country witnessed the self-restraint of those operators who were producing coal in holding to a price level below that which the market afforded. Capital, it is clear, is amenable to such restraint. Similarly last month the country also witnessed labor in the full exercise of its monopoly. Murder and wanton massacre at Herrin measured the self-restraint of the United Mine Workers of America when their monopoly was threatened.

There is ample evidence to indicate that the rank and file of the union miners recognize the fairness as well as the inevitability of wage reductions, but because of the leaven of radicalism in the union their leaders dare not make such an admission. Quite recently a majority of the representatives of the union miners in Nova Scotia agreed to a wage reduction. They even had the courage to defend their course before a meeting of their constituents. They repudiated the action of their duly appointed agents and wound up the meeting by voting to ask the Canadian Government to lend the Russian Soviet Government fifteen million dollars. The moral is that it is political suicide for John Lewis and his lieutenants to abandon their extreme position even though they and all their members know that in the end it cannot be maintained. That is why the coal operators refuse to put their fortunes in the hands of this particular labor monopoly.

**Destruction of the Union Not Sought**

Those who hold to the belief that the policy of the operators against a Central Competitive Field agreement is a policy aimed at the destruction of the United Mine Workers are misinformed. In all this land there are no truer friends of the union coal miner, no stauncher advocates of collective bargaining, than among the operators of the southern Ohio field. Yet it was the southern Ohio operators who to a man first took the stand that has prevented a central field conference. With hands tied behind its back by wage scales and working conditions dictated in Central Competitive Field agreements by a national labor union and by operators in larger fields to the north and west with which it is not now and has not for a score of years been competitive, southern Ohio has had to submit to having its throat cut by non-union fields to the south. With this field it is not a question of how its wage scales and costs compare with eastern Ohio or Indiana but how they compare with West Virginia. No one in Washington can induce this field to abandon its decision to seek the right of self-determination. Southern Ohio is significant in that it represents a type.

The problem of Washington, then, is to find a formula that will save the face of the union and at the same time preserve to the operators in the several fields the right to negotiate with their men wage scales that will be truly competitive one with another and with those without the fold. That is, we may witness a conference of the United Mine Workers and all union coal operators dealing with general principles but not setting district wages.

**Let It Be a Non-Partisan Board**

Whatever the process by which the miners are returned to work to meet the immediate requirements for coal it must from the very nature of the circumstances be of temporary character. Matters of policy and matters of fact interwoven in the issues of this controversy cannot be disposed of lightly. The present outlook therefore contemplates some form of commission that will, after the men are back at work, make an intensive and extensive study of the problems and report on the merits of each. It is further contemplated that this shall be an arbitration commission and that each side will be expected to agree in advance to abide by its findings.

We have evidence at the outset that the miners do not favor arbitration. It has been offered to them in the anthracite region after nearly three months of fruitless negotiations and they have refused to accept it. They are not disposed to abide by the findings of arbitrators ever after they have so agreed, as witness the fruits of the two Presidential commission awards in 1920. There is hope, however, that henceforth the labor unions may be induced to have greater respect for their contracts and that arbitration awards, unfortunately at best but compromises, may become more effective.

Transcending in importance the possible terms of settlement with respect to wages and working conditions that may be laid down by the commission now generally expected to be offered and appointed by the President are the principles governing future conduct for the coal industry that we have a right to expect, nay, even demand, from such a body. Twenty years of comparative tranquility in the anthracite region followed the adoption of procedure laid down by the Roosevelt commission. That record would not have been broken in this year of 1922 were it not for the overpowering ambition of the United Mine Workers to exert its "full economic strength" against the country to win in the soft-coal strike.

Pressure will be exerted to have representatives of the miners and of the operators on this commission. Already there is local talk among the hard-coal miners as to who should be chosen to represent them and there is some evidence of a feeling that a willingness to submit to the findings of a board should be predicated on the pledge that the personnel will be acceptable to them. The supreme problem of Washington is to take a stand for a commission overwhelmingly non-partisan and to insist on time for adequate investigation.
Fading Soft-Coal Stocks as Well as Lack of Anthracite Attest Timeliness of Efforts for Resumption

Unprecedented Stores of 67,000,000 Tons on April 1 Take
Record Drop of 47,000,000 Tons in Three Months—Consumption Estimate of 34,500,000 Per Month Indicates Seriousness of Situation

ADMINISTRATION efforts to start the coal mines are being taken none too soon if a serious coal shortage during the coming winter is to be averted. There are practically no available above-ground supplies of anthracite except those held by retail dealers and that already in the cellars of householders. Pea is the only size that can be had from producers in quantity, small lots only of both larger and smaller sizes being available to replenish yard supplies. The total is equivalent to less than one month’s production. The hard-coal mines have no overcapacity with which to make up deficiencies and there is no non-union production to supplement that now on strike. If the anthracite mines were now at work, producers would be obliged to allocate shipments, and every day’s output lost from now on will add to their troubles next winter and sharpen the demand to a point where runaway prices for some of the independent coal will give to the trade the “color of profiteering” it had in 1920.

On top of this potential shortage of anthracite the country faces a situation with respect to bituminous coal that under similar circumstances in the past has resulted in panic prices and exhibited all the symptoms of a shortage. Production measured against demand, not consumption, sets the price. If the definition be that there is a coal shortage when every buyer cannot get coal when he wants it, then the stage is all set for a soft-coal shortage. Demand from now on will equal consumption plus what the buyer would like to store against next winter.

It will be recalled that the Geological Survey, in its estimates of stocks on April 1, reported at least 65,000,000 net tons of bituminous coal in the hands of consumers. The study of official data on the three interrelated factors, production, stocks and consumption, summarized in the accompanying diagram shows that stocks were in fact around 67,000,000 net tons, exclusive of coal on upper Lake docks but including coal in cars not yet delivered to consumers. A new high record was thus set.

Never before has so much coal been delivered—and held by consumers in this country. Preparations against the strike were as complete as consumers could make them. In the months of April, May and June another record was set, for the stocks of coal took the biggest drop on record. From the peak of 67,000,000 net tons on April 1 to 20,000,000 tons on July 1 represents a draft of 47,000,000 tons. That the country had this reserve supply on which to draw while the union mines are closed explains the equanimity with which the strike has been viewed so far. Compared with the decrease of 47,000,000 tons in the past three months is the record of 40,000,000 tons in the seven months from the Armistice in 1918 to July 1, 1919.

In the first six months of 1921 the production of bituminous coal was 196,292,000 tons and exports less imports were 12,555,000 tons, leaving 183,737,000 tons available for consumption. Stocks were reduced 3,000-
000 tons, which, added to available production, indicates a consumption of 186,737,000 tons in that 6-month period. Production of bituminous coal in the corresponding period of 1922 was 186,415,000 tons, and exports less imports were around 3,558,000 net tons, giving a total net available for consumption of 183,857,000 tons. Stocks were reduced from Jan. 1 to July 1 an estimated 24,200,000 tons, which indicates a consumption of 207,257,000 tons. That is, the consumption of bituminous coal in the United States from January to the end of June this year was 20,500,000 tons greater than in the corresponding six months of last year.

Although production in the half year of 1922 was 9,877,000 tons less than the same period of 1921, exports also were less by 9,197,000 tons, leaving the country with some 680,000 tons less production for home use. Offsetting this small loss has been the draft on stocks exceeding last year by 21,200,000 tons.

The draft on stocks by months is estimated as 19,-500,000 tons in April, 14,700,000 tons in May and 13,000,000 tons in June. Assuming no resumption of mining in July, making allowance for the holiday which affects both production and consumption, and anticipating a sharp increase in demand sufficient to call forth every possible ton of production, we would expect a further reduction in stocks in July of at least 10,000,000 tons, leaving on Aug. 1 but 10,000,000 tons on hand. These figures are, of course, but estimates, for in the very nature of the case no other data can be had. But if as estimates they are within 20 per cent of correct, and we feel that the limit of error is not much more than half of that, it is apparent why the President has begun to act.

Judging from the history of the past seven years, an above-ground stock of bituminous coal of only ten million tons represents an impossible situation in this country. During 1917 and 1918, when consumption was at the rate of about 40,000,000 tons per month, there was a serious coal shortage when stocks were as low as 20,000,000 tons—that is, when the average for the country was equal to two weeks’ requirements. Consumption is now estimated to be at the rate of 34,500,000 per month and two weeks’ supply is therefore some 17,000,000 tons. Although skating close to the danger mark, the country had not by July 1 reached a crisis. Some time before Aug. 1 that point will have been reached if production is not resumed. In other words, by that time, but for successful intervention by Washington, the United Mine Workers will have the country where it wants to be—helpless and begging for coal.

From April 1 to Aug. 1, 1921, the estimated rate of consumption of bituminous coal was 28,200,000 tons per month. From Aug. 1 to Nov. 1 the rate was 35,-890,000 tons per month and from Nov. 1 to March 1, 1922, the rate was increased to 34,200,000 tons. Since that date the rate of consumption is estimated at an average of 34,500,000 per month, with the figure
at the end of June somewhat above that figure. In
the thirteen weeks ending with July 1 the requirement
for consumption and exports (less imports) has been
8,085,000 tons, or in round numbers eight million tons
per week.

Railroads are the largest single consumers of coal and
likewise the largest holders of stocks. Figures
recently assembled by the American Railway Associa-
tion of coal on hand for railroad use furnish an interest-
ing check on our estimates. All roads had on April 1
19,843,833 tons of coal. By May 1 this had been
diminished by 4,800,000 tons to 15,052,268 tons and by
June 1 still further reduced by 4,200,000 tons to 10,-
846,567 tons. Business on the railroads was greater
in June than in May and it is safe to estimate that on
July 1 their stocks were not in excess of 6,500,000
tons, equivalent to 23 days' requirements, if no new pro-
duction be used. Our estimate of total reserve on May
1 is 71 per cent of the supply on April 1. Compared
to this the railroads held 79 per cent of their maximum.
On June 1 the figures are 79 per cent for the country
and 72 per cent for the roads, and on July 1 it is
estimated that both the country as a whole and the
railroads had 60 per cent as much coal as 30 days pre-
viously.

Looking ahead it is apparent that were the produc-
tion of bituminous coal to be increased barely suffi-
ciently to meet the weekly requirements of around
8,000,000 tons that would not suffice. Stocks must again
be built up against the winter's need. If production
is not resumed in time and at a sufficient rate to meet
all current requirements and to put at least 30 days' supply
on the average into consumers' storage piles by
Nov. 1, at the latest, we will have a perpetual coal short-
age throughout the coming winter. On top of the output indicated is the need for some 20,000,000
tons of shipments for the upper Lake docks, all of
which must be produced and shipped before the close
of navigation—that is, by the middle of December.
There is, furthermore, the very evident possibility
that the certain shortage of anthracite will add still
further demands on the bituminous-coal industry.

STOCKS OF BITUMINOUS COAL COMPARED WITH PRODUCTION AND CONSUMPTION

From a peak of 67,000,000 tons on April 1, stocks declined to 20,000,000 tons on July 1,
a shrinkage of 47,000,000 tons in three months
Razing of Seneca Hoist Tower
By Dynamite
And Rebuilding of Breaker

BY DEVER C. ASHMEAD*
Kingston, Pa.

Dynamite Sticks Placed in Its Ten Legs Are Exploded While Locomotive and Stump Puller Pull Structure Out of Perpendicular—Good Example of Modern Breaker of Moderate Dimensions

SeVERAL years ago an estimate was made of the quantity of coal available at the Seneca Colliery of the Lehigh Valley Coal Co., and the calculation showed that approximately 2,000,000 tons of coal could be drawn from the mine, which, according to the present rate of mining, would have lasted until about 1920. This period is past and the mine is still operating. About one year after the date set for the possible abandonment of the mine another estimate was made showing 2,500,000 tons more available than when the first estimate was made.

The original breaker at this colliery was built in 1888 and the first coal was run through it on June 18 of that year. The building was of wood and in 1919 it became necessary to remodel it. The work was done a little at a time, but in July, 1921, the company decided to cease operating the breaker until the remodeling was completed. This reconstruction work began at a time when the mine, according to estimates, was supposed to have been exhausted. Advances in the art of mining and not errors in the estimate enabled the company to extend the life of the mine, and it is possible that other new methods of operation will be found that will further extend the duration of the plant beyond the limit now set.

For this reason the Lehigh Valley Coal Co. is well justified in expending the money needed for the complete remodeling of the breaker, not only on account of the increased life of the property, which in itself would justify such an expenditure, but also because of the probable life of the mine, which while it cannot be calculated can be surmised as being of considerable length. Many thin beds and seams which are not now considered commercially valuable are to be found in the area tributary to the colliery, and they probably will be mined by the time the coal covered by the estimate has been removed, for improved methods of mining and preparation make coal available that in earlier days could not have been operated.

In order to permit operation to continue the old tipple had been braced. The lower timbers of the old tower had become so rotten that it had settled about 2 ft. and was a little out of plumb. The company decided to remove the tower hoist which lifted the coal to the top of the breaker and to install a dragline scraper in its place. This called for the erection of a 10x42-in. flight conveyor.

Perhaps the most difficult problem encountered in the remodeling of the breaker was the removal of the old tower hoist. The following description of the manner of its razing is by J. H. Rockefeller, Jr., of the mechani-

*Anthracite editor, Coal Age.
The dynamite had to be placed in the legs of the tower with due judgment, or damage might have been done to the breaker posts that were adjacent. For this reason one-quarter stick only was used in each leg.

The tower was first cut loose from the main part of the breaker throughout its entire height, so that it rested on ten 12 x 12-in. posts, arranged in two rows of five. Holes were bored in the five posts of the outer row at points 3 ft. above the ground and in those of the inner row at an elevation 3 ft. higher. Each hole was charged with about one-fourth of a stick of dynamite, the charges in the front row of posts being connected in series and those in the back row being similarly connected but in another series.

In the meantime a hand-operated stump pulser was anchored to the ground about 200 ft. from the center of the tower in the direction in which it was desired to have the building fall. A rope from the winch was connected with two pulling ropes, the ends of which were fastened to the outside posts of the tower at a height of 140 ft. above the ground. Power was applied to the winch so that the pull on the building was 250 tons. In consequence the tower at its top was pulled away from the old structure about 6 in.

To take up any slack that might be in the ropes and to compel the tower to fall in the desired direction, a steam locomotive was attached to them. The explosive charges in the outside row of posts were now fired.

The tower started to fall. The locomotive then began to take up the slack in the rope. An instant later the charges in the inside posts were fired, causing the tower to stretch itself over the ground in the direction planned. The operation was entirely successful.

Although the locomotive which was used to pull the ropes was straining on them when the charges were fired and its wheels were spinning when the tower began to fall, the locomotive was not able to move fast enough to keep the ropes tight.

The old tower was 170 ft. high and by the use of the dragline conveyor to take the coal to the top of the breaker this height has been reduced to about 105 ft. The accompanying illustrations show the breaker before any remodeling commenced, the early stages of the remodeling, the tower in the act of falling, the cloud of dust that arose just as the tower hit the ground, and then the finished breaker. A minute or two after the tower had come to rest on the ground the cloud of dust had risen to a great height, and the air was black with the fine coal dust.

There is comparatively little difference in the methods of preparation in the old and the new breakers, but all the machinery has been made more accessible and fewer men are needed to operate the new breaker than were needed at the old. At present thirty-two men are required, whereas with the old arrangement forty-eight men were employed, a saving of sixteen men. This in one year's time will mean a large saving in the bill for the preparation of coal for the market.

The new breaker is of wood, as was the old, but the machinery is of the latest type, and the new structure with its equipment gives better results than its predecessor. This new breaker was constructed at a cost of about $225,000. Its capacity is approximately the same as that of the one it replaced, or about 1,800 tons in an eight-hour day.

The accompanying flow sheet not only shows the method of treatment of the coal but it also gives the number of tons of coal that pass through each process. In the description of the method of coal preparation that follows, the figures in the text refer to those shown in the flow sheet.

By means of a rotary dump the mine cars from the Seneca and William A. collieries of the Lehigh Valley Coal Co. are discharged into a hopper at the foot of the dragline conveyor. The coal is taken from the dump by means of this conveyor to the top of the breaker.
and is delivered onto a set of shakers (3 and 4). From the top deck (3) of these shakers the lump coal passes to a picking table (5) and from the bottom deck (4) the steamboat coal passes to the same picking table (5), while through deck 4 the coal passes to another shaker (6 and 7).

On picking table 5 the large rock is removed from the coal and goes to the rock dump. The cleaned coal goes to the crusher rolls (8), and from these rolls it passes to a set of shakers (9, 10, 11 and 12). The coal from the top deck (9) passes to No. 3 rolls (13). The coal from the second deck (10) and from the top deck of shaker 6 and 7 can go either to the rolls (13) or can be bypassed around them to the broken picking table (14). From this picking table the coal goes directly to the broken pocket (33), and the rock goes to the rock dump.

**Coal Above Pea Goes to Jigs for Cleaning**

Coal that is crushed in the No. 3 rolls (13) joins with the coal from decks 11 and 12 and passes to a double set of shakers (15, 16, 17, 18 and 19). The egg coal which is taken from the top deck (15) goes to the egg hoppers (30, 31 and 32) and from these hoppers it is fed directly to the egg jigs, which are of the Lehigh Valley type, after which the clean egg coal goes to the egg pocket (39). The stoved coal from the second deck (16) goes to the stoved coal hoppers (27, 28 and 29), and from these hoppers it is fed to the jigs and from the jigs to pocket 38. The nut coal from the third deck (18) goes to the nut hoppers (24, 25, and 26) and from these hoppers to the chestnut jigs and thence to the chestnut pocket (37). Pea coal, which is sized on the fourth deck (18), passes to the pea hopper (23) and then to the pea jigs and pea pocket.

The buckwheat coal, which is prepared on the fifth deck (19), passes directly to the buckwheat pocket and is ready for shipment to the market. The smaller sizes of coal go to another set of shakers (20 and 21) and the rice and barley coals are separated and go to their respective pockets or to the boiler plant to be used as fuel. The slush, which passes through the barley shaker, goes to the slush shaker (22) and then to the silt bank, and the coarser material goes to a car and is redumped and sent through the pocket. Practically all the rice and barley coal produced at this colliery, together with part of the buckwheat coal, is used for boiler fuel and is sent to the boiler house. The rock that is separated from the coal by the jigs is taken to the rock dump.

Interesting features in connection with the flow sheet of this breaker are the figures giving the distribution of the tonnage. They show the quantity of coal prepared in each jig and shaker and the waste material that has to be handled in the form of rock and also the areas of the several screens.

Before leaving the description of this breaker I want to quote once more from Mr. Rockefeller's article: "With the razing and remodeling of the Seneca breaker comes to the surface a most remarkable fact concerning its hoisting engineer. Thomas Langan was placed in charge of the tower hoisting engine when the breaker was started. He had charge of this engine continuously until it hoisted its last trip on July 19, 1921, a total of 33 years. The efficient care given by
COAL AGE  
Vol. 22, No. 1

THE engine during the 33 years handled approximately all the 8,500,000 tons of coal which has been shipped from this colliery. This means that this engine has hoisted about 12,000,000 tons of material, including boiler fuel and refuse, making in so doing approximately 6,000,000 hoists. Figuring 225 ft. of travel of cage per hoist, these cages have traveled approximately 256,000 miles, or about ten times around the earth.

The engineer who took such good care of his engine is entitled to much honor for his painstaking zeal, and the Lehigh Valley Coal Co. has not failed to show its appreciation of his services. In every company there are men who show a devotion to their work which the mine officials should not fail to recognize by due commendation and acknowledgment.

Zeigler Mine Copied Wehrum's Methods

BY CLARENCE R. CLAGHORN
Baltimore, Md.

In E. W. DAVIDSON'S article on "Zeigler No. 1 Mine," in the May 25 issue of Coal Age, p. 873, E. L. Berger, superintendent of that mine, is quoted as believing the rotary dump in use at this mine "is the first underground rotary dump ever operated."

He may be interested in knowing that two-car (tandem) power-driven rotary dumps were used underground at the shaft mines of the Lackawanna Coal & Coke Co. at Wehrum, Pa., in 1903, in connection with underground bins, pneumatic gates and self-dumping skips. In fact, at Zeigler not only the dumps but other equipment was, in many respects, patterned after the Wehrum installation and built by the same firm.

This installation, including the rotary dumps, the bins, the bin gates and irons and the skips were covered by patent No. 811,129, applied for May, 1903, and issued August 1906, so the Zeigler installation was anticipated by some fourteen years.

Copper Bond with Steel Terminals Suited For Electric Welding at Track Joints

It is now well known that the joining of steel to steel is the easiest form of electric welding. Recognizing and utilizing this fact the rail bonds shown in the accompanying illustration have been devised. These consist of copper bonds fitted with steel terminals slightly rounded so as to make it easy to join them to the rails.

As may be seen, these bonds are of two types—that known as the A.W. 7, which has one strand of any desired length and the terminals of which are welded to the base of the rail, and the A.W. 8, which is short, U-shaped and double stranded and is intended for attachment to the ball of the rail.

In both cases the ends of the strands are protected by a copper sleeve. These bonds are manufactured by the Ohio Brass Co., of Mansfield, Ohio.
Public Ownership of Coal Mines Causes Much Loss to Philippine Government and Affords Little Coal

National Coal Co. Stock Nearly All Held by Government—Coal After Five Years' Work Costs, Without Interest but Including Development, $17.50 Per Ton—First Coal So Dirty It Wouldn't Burn

By Roy C. Bennett
Manila, P. I.

Indications are that the Philippine Government, with approximately four and a half million pesos invested in coal-mining enterprises, is about ready to retire from this business and let someone who "knows the game" dig the insular fuel supply. Recent actions of the National Coal Co., a government concern whose head offices are in Manila, strongly suggest this outcome. C. Russell, manager of the coal company, said that the business in its present condition cannot well be turned over to anyone else, but that within six months the mine will be so far developed that it will be possible, he anticipates, for the government to lease the mines to an operating company on a royalty basis.

By this time the company will have invested another half million pesos and will have brought prospecting and development to such a stage that, according to the manager, the company can tell exactly what coal it has in sight. It is the opinion of Mr. Russell, and apparently of the board of directors as a whole, that the government couldn't "get out from under" just now without a heavy loss, but that the time is not far distant when it can.

No One Wants to Be Partner with Government

The National Coal Co., which has brought much criticism on the Philippine Government, was authorized and established by an act of the Philippine Legislature in 1917. The organic act specified that at least 51 per cent of the stock should be government-owned, and provided for the holding of the other 49 per cent privately or by provincial or municipal governments. The company has a capital stock of P3,000,000, all subscribed and paid in. At the present time the government owns all the stock, except P18,000 which is in private hands. The investments to date represent the sum total of the capital stock plus P2,000,000 which was borrowed from the National Development Co., another government organization. The company still has left about a half million of the loan it obtained from the development company.

Warren D. Smith, chief of the division of mines, Philippine Bureau of Science, who knows more than any other person about Philippine mineral resources and Philippine mine development, is a strong advocate of the government's getting out of the coal-mining business. In fact, after he had investigated the National Coal Co. properties he submitted a report in which he painted a very discouraging picture of the future prospects of the company, but he now gives the company full credit for the progress made since his report was written.

All Government Ownership Is Undesirable

In a report on mineral resources, just off the press, Mr. Smith says in part: "My investigation of the National Coal Co. has led me seriously to question if national mining projects, whether controlled by Filipinos, Americans or any other people, are wise. The reasons for the difficulties which this company has experienced are many, and not all of them should be laid at the doors of the Philippine Government or the Filipinos. Inexperienced Americans on the board of directors are equally responsible, but the gravest objection of all to these national projects is that they are likely to become hopelessly mixed in politics. A much safer plan and one that doubtless would bring results would be to subsidize worthy private companies, the government exacting some security for the money so lent. If the government received no more than the interest on the loan it would be amply repaid."

Mr. Smith says that coal is to be found in some quantity on practically every one of the larger islands of the Philippine archipelago. "There is no question," he says, "about the potential mineral wealth of the Philippine Islands. All those qualified to pass judg-

coals

mined

by

this

company:
The Cebu coal air slacks, but the Cotases and Butong coals, which are practically smokeless, do not. None of the three grades is subject to spontaneous combustion. Little trouble with water is experienced in any of the mines. In Cebu the coal beds dip and strike irregularly, but drillings have indicated that the Mindanao seams are more regular. The Cebu deposits have suffered much through the work of native miners who dig holes a short distance into the beds and then took out large quantities of coal, letting the earth fall in behind them. Large bodies of coal between these little mines have been made practically unminable.

**Dirty Coal Would Neither Burn Nor Sell**

As to marketing the coal the general manager wrote in the annual report the following statement:

> "Placing the coal in the market has been our principal difficulty. The first experiments with run-of-mine coal were failures, it being necessary in every case to mix our product with some bituminous coal before it would burn. We discovered that the poor results were caused by an excess of ash, a large quantity of shale being mixed with the coal during the process of mining. After this shale was removed by screening and washing we were able to obtain satisfactory results. There is no question as to our ability to sell at least 200,000 tons of semi-anthracite coal annually, provided we can produce it at a price that will allow us to compete with foreign coals."

The company formerly experienced much trouble from sickness among the employees in the Mindanao camps, where malaria was prevalent until steps were taken to remove the cause and to improve health conditions. Mr. Smith considers the mining laws in the Philippines adverse in several respects to mine development. In this connection he mentions high taxes for mines, adverse leasing regulations and other things needing reform. He particularly considers "political instability" a deterring factor.

As to labor conditions the following is quoted from the general manager's report:

> "It is difficult to give exact data on production cost at our present stage of development. It may be said, however, that it is possible in both Cebu and Mindanao to mine coal from the room and place it on the tipple at a cost of less than P4 per ton. It might be said with equal accuracy that every ton of coal produced during the year has cost, not including interest charges, but counting overhead, development expenses, railroad maintenance and operation, operation of our launches, etc., more than P35 per ton. Either statement is true but neither will give an accurate idea of the real cost of coal production. We estimate that the cost on board ships alongside the wharf in Malangas will average P8 per ton when the mine is fully developed. This allows for the depreciation of equipment as well as the proper return of the funds invested with interest, but is dependent upon the property's being developed up to full capacity. It is impossible to estimate on Cebu without more accurate information regarding the quantity of coal available. At present we have less than 200,000 tons assured. Assuming that we have 1,000,000 tons available, a not improbable amount, the cost of coal delivered in Cebu, when the mine is fully developed, should not exceed P10 per ton including all charges."

> "There are two conditions which make it difficult to market coal cheaply in the Philippines, transportation and labor. It costs us more than P11 per ton to ship coal from Malangas to Manila, whereas Japan often ships coal to Manila at as little cost as 6 yen ($3) per ton. While local production costs at the mine will compare favorably with those in the United States or Europe, the cheap labor of China and Japan, especially the former, will render competition difficult."

**Hard to Pay Dollar and Compete with Nickel**

"Chinese laborers in Borneo are contracted for at 30 centavos (15c.) per day, without subsistence. They are experienced miners, and such prices enable certain Borneo mining companies to produce coal at a low cost in spite of otherwise unfavorable conditions. In the interior of China, in the region where the Peking syndicate is operating, miners get less than 10 centavos (5c.) per day. Contrast this with Philippine conditions, where inexperienced miners are demanding, and obtaining, P2 ($1) per day."

In order to provide efficient supervision in the mines and to guarantee a supply of skilled labor the company recommends that a technical night school be conducted for the laborers.

The directors' report, which is in line with numerous
Plastic Fuel from Low-Grade Coal and Oil

In THE issue of Coal Age of June 8, p. 953, an article appeared entitled "Plastic Fuel Can Be Made of Low-Grade Coal and Oil and Can Be Coked Even If Non-Coking Coal Is Used." This article had a subtitle in which appeared the words, "With fine grinding almost all but inherent ash is removed by Trent Process." Exception having been taken to this wording, Walter E. Trent replies to a letter to one of the editors of Coal Age in the following words:

"This discussion as to the removing of inherent ash has been presented to me regularly for the past three years, first by the U. S. Bureau of Standards, then by members of the U. S. Bureau of Mines and others, all tackling the stand, exactly as you do, that the inherent ash is the silica or aluminum silicate, being the insoluble part of the original soil and mineral matter that found its way into the original wood.

"About that side of the question we need no discussion, but as to the grinding of the material sufficiently fine to detach it from the carbon, I must state that we do separate a large percentage of that impurity. We take a perfectly black piece of coal, showing no impurities whatever; grind it to approximately 200-mesh, forming of course, a large percentage of 300-, 400-, 500-, and even 1,000-mesh material. This actually separates a large part of the inherent ash, and thus its removal by the Trent Process is effected.

"I do not understand that you believe the inherent ash to be other than physically mixed in very small sizes, which is correct; but a great many people have claimed that the silica and aluminum silicate were chemically incorporated and could not be separated. This is absolutely incorrect. You will find that the U. S. Bureau of Mines, the U. S. Patent Office and everybody who has investigated our process willingly admit that we do remove inherent ash, in so far as it is physically detached from the carbon, and in some cases it amounts to from 60 to 90 per cent.

"My French company, for instance, has seven different kinds of French coals, the ash in which it is reducing to 1 per cent. I have only two coals that give this great reduction, but every single coal shows that inherent ash is removed. This question has arisen in all the principal patent examining offices in the world and has been conceded by them, and my patents are allowed in the United States, France, England, Holland, Germany and other countries."

"I am sending you copies of three patents that relate to our coal cleaning; one deals with the detachment and separation of inherent ash without any oil reaction (No. 1,420,163); another deals with the oil reaction alone (No. 1,420,164), and the third case deals with the physical detachment by pulverizing, the separation of the ash from the carbon by the oil reaction, and the distillation of the amalgam (No. 1,420,165). Will you kindly give your special attention to the parts of these patents that are marked with pencil, as they relate to the particular subject on which we are corresponding?"

Coal Age is informed that the coal, oil and water in amalgamation are agitated by paddle blades rotating at a speed of 150 r.p.m. and that where the coal is pulverized to a fineness such that it will pass readily through a 200-mesh screen a mixture of 62 gallons of light fuel oil to 2,000 lb. of coal will produce an amalgam in granules about 1 in. in diameter. The article stated 1,000 r.p.m. in the one case and 150 lb. of coal in the other.

J. J. Rutledge, superintendent of the central district experiment station of the Bureau of Mines at Urbana, Ill., calls our attention to the fact that the bottom layout at the Glen Rogers Mine, West Virginia, described by him before the Illinois Mining Institute and reported in Coal Age of June 22, 1922, page 1013, as designed by Carl Scholz was in fact designed by Oscar Cartledge, assistant to Mr. Scholz.
The Case Against Use of Purchased Power at Coal Mines

Steam Hoist with Mixed Pressure Turbine Advocated—
Cost of Stations and of Attendance Threaten Omitted in Mr. Clayton's Figures—At Nason Plant Power Cost Is 10c. Per Ton

BY C. W. SMITH†
Chicago, Ill.

IN A PAPER relative to power stations at mines a brief review of the development of mine power stations should be made in order to understand the conditions that exist at many mines even at this time.

The earlier mines used steam power only for hoisting, for ventilating and for pumping water from the shaft bottom. Mine power plants at this time were very crude. The hoist engines were small, as the cars hoisted seldom held more than a ton of coal and the shafts usually were shallow. Fans were of the old paddle-wheel type and were operated by simple slide-valve engines. The pumps at the shaft bottom were operated by steam lines running down the shaft. The boilers operating these plants were either of the long cylindrical type or its later development, the long boiler with two large flues. The coal was mined by hand and hauled to the shaft by mules. Any water inside was bailed by hand and hauled to the shaft. The coal was prepared by bar screens. At this time slack coal was either left in the mines or dumped in waste piles on top.

The next development in mining practice was the introduction of rope haulages for handling longer trips and negotiating heavier grades. The engines for operating these were steam-driven and were located either on top or underground near the shaft. This innovation represented a considerable advance in haulage practice and resulted in a remarkable increase in tonnage at most mines where the installations were made.

About the same time compressed-air puncher machines were introduced to enable more coal to be mined. This in part was made necessary by improvements in haulage.

These two developments were the last important changes made before the introduction of electricity into the mining industry. Both greatly increased the use of steam at the mines and resulted in the building of more modern boiler plants. Horizontal return-tubular boilers were installed and the power plant became the real heart of all operations about the mine.

Soon after the World's Columbian Exposition, in Chicago, many experiments were made in the use of electric locomotives for mine haulage and during the next ten years much progress was made along this line until, by 1900, many successful haulage systems were in operation. During this same time experiments were made with electric mining machines, but here progress was not so rapid, for the type of mining machine then in use was not adapted to an electric drive and it was necessary to develop the chain mining machine, a type hitherto unknown. Even after the machines had been fairly well developed the miners' organization in many instances, by opposition, prevented successful operation.

With the introduction of electricity into the mines little change was made in power-plant practice. The steam haulage engines and air compressors were replaced by steam-driven electric generators. The generator engines were of up-to-date design, and as transmission losses were much reduced the steam consumption was greatly lowered. Often after electrifying a mine it was found that even in a plant that had been previously overloaded a considerable reserve boiler capacity was available.

Boiler plants at this time consisted generally of hori-

Mixed-Pressure Turbine

A 1,000-kw. machine at the Nokomis mine of the Nason Coal Co. Power at this plant costs 5.75c. per kw.-hr. generated, but all the power is not used for generating electricity, the hoist being run by steam. Furthermore, the mine was working at that time at only 70 percent of capacity. The cost per ton was 9.86c.

†Chief engineer, Nason Coal Co.

‡This probably was true in Illinois, which at that time was quite backward, being a new field. In Pennsylvania rope haulage much antedated compressed-air punchers.—EDITOR.
Since return-tubular boilers, often as many as ten or twelve in number. Stacks were small and not over 40 or 50 ft. high. The boiler settings were of brick and they usually were in poor condition. They were fired by hand, and waste coal was used, for it must be remembered that at this time slack had little or no commercial value. The plants usually were built piece-meal, that is, boilers were added whenever the steam supply became short, and as a result piping and header lines often were improperly installed. No thought was given to efficiency of operation, because labor was cheap and coal was had for practically nothing.

From 1900 to 1910 the coal industry of Illinois marvelously developed. Many large mines were sunk and the maximum daily tonnage grew from about 2,000 in 1900 to about 4,000 in 1910. Coal production increased greatly, and most of the newer mines were well laid out and designed from an engineering standpoint. Power-plant design lagged, however, for two reasons. First, direct-current power was used entirely about the mines, and consequently no important advances could be made in its distribution. Second, boiler plants were designed as simply and as near fool-proof as possible, because it was then thought that the coal-mining organization was too busy producing coal properly to look after complicated boiler plants. The result was that simple rules of thumb and prevailing mining practice were followed in the building of this portion of the mining plant.

Mines Outgrew Their Direct-Current Plants

As a result of this system by 1910, or a little later, many of these large mines had been extended to hitherto unthought-of distances and were beginning to have great difficulty in supplying adequate power to the working face. With the direct-current power used the only way to overcome this condition was to put in more copper feeders, and in many cases the cost was almost prohibitive.

In 1912 sinking of the Nokomis mine of the Nason Coal Co. began. In 1913 coal was reached, and the first mining machines were installed. At this time the Central Illinois Public Service Co. entered this field, and after conference with their representatives and with representatives of the Sullivan Machinery Co. the Nason company decided to install the first alternating-current mining machines used in the State of Illinois. After these had proved successful in operation it was decided to install an underground motor-generator set to supply current for the trolley locomotives.

Negotiations with the State Mining Board were necessary before it would permit the transmission of high-voltage current underground, even in armored cables, but all objections eventually were overcome and the installation was completed. Power was purchased from the Central Illinois Public Service Co. at 2,300 volts and stepped down to 275 volts underground for use in the mining machines. The motor-generator sets for driving the trolley locomotives and for charging the storage motors were driven directly by 2,300-volt alternating current. Subsequently this installation was expanded and the mine now has thirty mining machines and seventeen storage-battery and four trolley locomotives in operation.

COULDN'T MIX ISOLATED AND PURCHASED POWER

This system of power generation and distribution proved economical and satisfactory. It solved the problem of power transmission in coal mines. However, as Nokomis was equipped with a boiler plant and a steam hoist, the system of purchasing a portion of the power and producing the rest proved to be too expensive. In periods of slack work it was necessary both to maintain a boiler plant and to pay the primary charges to the power company.

During certain seasons of the year power interruptions were numerous, occasioning serious delay and many losses. The combined power costs averaged nearly 15c. per ton. Finally in 1919 and 1920 two or three successive increases in purchased-power rates raised costs so that it became necessary to seek relief. As no reduction of power rates could be expected, the only alternative was to discontinue the purchase of power.

With this in mind, the power conditions at the mine were carefully studied. The plant then installed consisted of six horizontal return-tubular boilers 84 in. in diameter and 20 ft. long, each of 175 b.hp. These furnished steam to a pair of 28x48-in. Danville hoist engines, to an 18x18-in. fan engine and to some miscellaneous car-puller engines, shop engines and pumps.

At first the installation of a high-pressure turbine was recommended, but this would have made necessary a great increase in the size of the boiler plant. Finally
it was proposed that all the equipment be electrified except the hoist engine and that a mixed-pressure turbine be installed to be operated by the low-pressure exhaust steam from the hoist. C. M. Garland, of Chicago, who recommended this installation, gave it as his opinion that no additional boiler power would be required to operate this plant. After careful consideration of this project Mr. Garland was commissioned to proceed with the installation. The plant was put into operation in June, 1920, and no additional boilers were required.

The new plant consists of a 1,000-kw. Ridgway mixed-pressure turbine equipped with a surface condenser and a large Rateau regenerator, and a 300-kw. General Electric turbine equipped with a jet condenser. A complete switchboard was installed and equipped with sufficient meters to measure the power each department consumed.

As the mine did not operate steadily during the latter part of 1920, no reliable figures as to the cost of power were available until the first three months of 1921. The cost of operating the power plant during January, February and March, 1921, is given in Table I.

### Table I. Cost of Operating Plant of Nason Coal Co.

</table>

The above figures tell the whole story as far as the power company is concerned, but they are only the beginning as far as the mining company must figure. The costs given above represent the cost of power at the transformation station. In order to get the figures to the same basis as those I have given, the cost of operation of the power plant, exclusive of the hoisting engineers, must be added. In mines hoisting 4,500 tons, with electric hoists, it is customary to have an attendant in the power plant to look after the machinery, circuit breakers, motor-generator sets, etc. This will add one man at $7.25 per day for a total of 664 days to the above figures.

Depreciation, repairs, interest and taxes on the hoisting machinery, hoist and power buildings, foundations, etc., also must be figured as part of the power cost. At each of these three mines the cost of such equipment probably was $100,000.

Then, too, these three mines apparently all operate from one maximum-demand meter because the combined maximum demand is only 2,292 kw. If each were operating independently the maximum demand probably would be about 1,100 kw. per mine.

Taking these factors into account, the revised power figures for these mines would be as in Table III.

### Table III. Cost of Purchased Power at Kincade Mines with Allowances

<table>
<thead>

The Nokomis mine was the first to install alternating-current mining machines in Illinois. This was back in 1913.
During this period these mines were operating at about 74 per cent of capacity. It is apparent from a comparison of these two tables of figures that with purchased-power rates as they are now a mine equipped with a mixed-pressure turbine plant can operate as cheaply as can a completely electrified mine.

The principal advantages to mine operators in having the power plant located at the mine are as follows:

(1) The entire operation is under control of the management.
(2) Mechanics and electricians already in the employ of the mining company can operate and maintain the plant with little additional cost.
(3) Fewer losses of operating time due to power interruptions will result.
(4) Power costs in many cases are less than the cost of purchased power.
(5) When the mine is operated irregularly a large primary charge does not have to be paid each month.
(6) Alternating current is being more generally used about coal mines, so that an alternating-current plant can be built, and the power that it generates can be transmitted as effectively as purchased power.
(7) Smaller initial investment is necessary in opening up a large mine, where a future mixed-pressure plant is contemplated, than where a completely electrified mine is planned.

Would Have Mine Plants Self-Contained

It is becoming the practice of all large corporations to make their plants as self-contained as possible. Large utility companies are purchasing their own coal mines and operating them, even though their business is that of generating power. Railroads long ago purchased mines to assure their own full supply. The larger oil companies and steel companies are doing the same. A large coal company or corporation with millions invested in its mining plants cannot afford to have the very operation of those plants entirely dependent upon something beyond its control.

Within recent years the mines have become so large and their organization so complex that the operation of a power plant is a mere additional detail. Large mines must have skilled engineers, mechanics and electricians to maintain the mining equipment, and these men are capable of properly caring for a large power plant.

The chances of interruptions and the consequent loss of tonnage are much less with the power plant at the mine than where the current is brought in over 50 to 100 miles of transmission lines. At Nokomis only 15 minutes have been lost on account of interruptions since the power plant was put into operation. When power was purchased such interruptions averaged about 15 minutes for each operating day.

Power costs in many cases are less with the power plant at the mine than with purchased power. This, of course, depends upon the wage scale at the mines and upon the purchased-power rates. Large completely electrified mines have a large maximum demand and therefore a large primary charge. An article in Coal Age on May 18, 1922, by Eugene McAuliffe, who operates such a mine, shows that when the operating time is halved, the power cost is doubled. This is not true with a power plant at the mine, because operation of the plant and operating forces can be reduced at such times.

Why Not Generate Alternating Current?

Most large mines now being sunk contemplate the use of alternating current, for it is now recognized that this is the solution of transmission problems. It is as easy to generate alternating-current power in a mine plant as it is to produce direct current. In addition to this, the alternating-current machinery and equipment is less expensive than that for generating or using direct current, so that an alternating-current power plant is the cheaper and more convenient to install.

For large mines of from 5,000 tons daily capacity upward, an electrical hoist is an expensive piece of machinery. The electrical and mechanical equipment alone for such a hoist will cost from $100,000 to $125,000. When it becomes necessary to hoist coal at the main shaft, this entire sum must be expended at one time and the entire investment must be carried until the mine is brought up to full production. The capacity of an electric hoist, once it has been built, is definitely fixed and cannot be increased by deftness of operation.

On the other hand, for the same mine a steam hoist, costing perhaps $30,000, and a boiler or two could be installed and would be sufficient to operate the mine for a considerable period. If a comprehensive and complete plan is worked out for the installation of generators and boilers an efficient plant can be built and none of the units added until actually needed. In this way the total investment can be spread over a long time. A steam hoist has the additional advantage that its speed can be greatly increased by expert operation. No better example of this can be found than the performance of the Orient mine in March. Such a remarkable show-
ing would have been out of the question with an electric hoist.

It is true that the load factor of the average mine plant is much more irregular than that of a central-station plant. But by carefully planning the equipment used in a mine a fairly uniform load for at least sixteen hours can be provided. At present the consumer apparently does not reap much of the benefit from the better load factors of central-station plants because the rates seem to be based more upon the ability of the consumer to pay than upon the cost of producing power.

The time may come when the load and load conditions at each individual plant will receive more consideration than at present and when long-term contracts will be made in Illinois as they are made in other districts. Investigation has shown that in other mining fields where the central-station loads are not as well balanced as in Illinois, prevailing coal-mine power rates are in some cases only about one-half as high as in this state. It is possible that rates eventually will be reduced here and such rates guaranteed in long-term bona-fide contracts, but if this is done it probably will be only because of competition with large efficient power plants at the mines.

Mining Coal by Eighty-Foot Block System

BY J. A. GRAFT*

Beckley, W. Va.

IN a method that I have used successfully for two years and which is known as the 80-ft. block system the rooms are driven 20 ft. wide and in pairs, the pillars between the rooms in each pair being 30 ft. wide and between pairs 80 ft. It will be noted that crosscuts are driven more frequently between the rooms in each pair—that is, through the narrow pillar—than through the pillars between the pairs, which are wide.

In starting the pillar in the first room a 20-ft. slab is taken toward the main entries, thus reducing the barrier pillar which, being, before slabbing, 130 ft. wide, is made by that action only 110 ft. in width. As is shown in the second right entry, a slab is then taken of pillars A, and A in rooms 1 and 2. At the same time a cut 1 is made across the pillar to the left of room 2 and also 4 ft. from the upper edge of the pillar B, to the left of room 3. In the 4-ft. web left in the wide pillar B, frequent cuts should be made, leaving in, however, most of the coal.

When pillars A, and A are slabbed off to half their thickness, start slabbing C, and C and at the same time start crosscuts in pillar D of room 4 and another in pillar D, of room 5. When the pillars A, and A are entirely removed and C, and C are partly mined out, pillars E, and E should be slabbed and crosscuts 5 and 6 in pillars F and F, of rooms 6 and 7 should be started. The props that are found in the area formerly occupied by pillars A and A, should be taken out and the top allowed to fall, first setting sufficient props or cribs to prevent falls across the face of C, and C. When the entry has reached its limit all chain pillars and room stumps are to be drawn in retreat.

New River Mining Method

Arrangements are made so that the roof will fall in large blocks, the coal face to be mined being protected by stumps cut 4 ft. wide. The plan also provides for driving rooms in pairs with small pillars between members of the pair and large pillars between pairs. The crosscuts between pairs are roughly 70 ft. apart whereas these in the larger pillars are 95 ft. between centers. It will be noted that each cross entry has a good flanking pillar of 95 ft. and the pillar between the members of the same entry is only 40 ft. wide. This also is good practice, as crosscuts have to be made in the entry whereas none has to be driven through the flanking pillar. The pillar on the side opposite from the workings would avail but little, however, if the workings themselves were not judiciously laid out.
Safety in Timbering at the Working Face

Need of Strict Rules and Close Supervision—Impossible to Establish a Uniform System to Meet All Conditions— Safest Practice Is to Stand Timbers When and Where They Are Needed

Statistics show that a large number of accidents occurring in coal mines are due to careless or insufficient timbering by miners. Strange as it may seem, old and experienced miners suffer from these accidents as frequently as do inexperienced men.

This fact alone shows the need of making and strictly enforcing rules for the safe and practical timbering of all working places. There is an element in the make-up of the average coal miner that renders him careless and prone to take risks. A very large proportion of miners pay little attention to the timbering of their places, unless they are compelled to do so under penalty.

These remarks have been suggested by the reading of two excellent letters that have appeared in Coal Age, one by George Edwards, Vol. 20, p. 968, and the other by Ostel Bullock, Mar. 16, p. 453. In the main, I agree with what these writers have said in regard to safe timbering in mines. However, I am inclined to the opinion that it is impracticable, if not impossible, to establish any fixed rules that will apply to all the conditions that often exist in the same mine.

Different Conditions Require Different Methods

According to Mr. Bullock, his practice is to establish rules that will make safe the worst places in the mine. He says that he is then sure there will be no trouble anywhere. Apparently he means that the same amount of timber and the same method of timbering must be used throughout the mine, as is required in places where conditions are the worst.

It is needless to say that this ruling is wholly unnecessary and would be expensive. It reminds me of an experience I had several years ago when leading a shift of company miners and working two rooms having a smooth, hard and strong sandstone top. Other sections of the mine had a drawslate roof, the slate ranging in thickness from 12 to 20 in. While the coal was being taken out, this slate would appear sound; but a little later it would crack and fall off around the timbers, leaving only what was above the cap. It was the custom in this section to use cap-pieces 2 in. thick, 8 and 10 in. wide, and from 2½ to 3 ft. long.

Elsewhere, in the same mine, the coal was overlaid with a very treacherous top, having pots, horsebacks and rolls. These irregularities were often hard to detect and required careful timbering. Again, in other portions of the mine, the roof was a hard blue slate that required little timbering and, here, the cap-pieces were 4 and 5 in. wide and 18 in. long.

Readers will recognize that this was a mine where it would be impossible to establish any fixed rule of timbering that would be safe. On making his visit to our place one morning, the boss announced that he had established a new rule for timbering. From now on, timbers must be stood in all parts of the mine by a regular system, the posts to be set 4 ft. apart every way, or in 4-ft. squares.

No Fixed Rule Will Apply to All Conditions in Mines

In reply to this announcement, I invited the boss to examine the corner of my eye and see if he could find anything green there. He seemed not to comprehend my meaning and I explained that such a fixed rule would not be adequate in some parts of the mine, while in other parts it would mean a waste of timber. The boss departed and we heard no more regarding his established fixed rules.

In my opinion, the only practicable, sensible and safe thing to do is to use good judgment and stand timbers where and when they are needed. A mine foreman must be a miner of wide and varied experience and a close observer of conditions existing in each working place. From these observations, his experience will dictate the method of timbering that must be employed and the amount of timber to be used in a place. Safety lies in properly training and instructing miners in the care of their own places, since dangerous conditions often develop unexpectedly and the boss cannot be in all places at all times.

Always Best to Play Safe

While it is true, as George Edwards remarks, "When a miner makes up his mind to be trust no roof, however sound it may appear, he is playing safe," it is likewise true that some kinds of roof are less dangerous than others and do not require the same amount of timbering, which in the interest of economy should not be used. We must take conditions as we find them and study to make the mine safe.

Before closing, let me say a word regarding miners timbering their own places. Observation convinces me that where miners keep a good axe and saw in their place there is always found a much better job of timbering. I believe in having timbers of all the lengths required in the mine kept on hand in the timber yard, each length being piled or stacked by itself.

Unsafe and Careless Timbering

But, at the best, conditions in the working places are irregular and it is seldom possible to find a first-class job of timbering where the miner has no axe or saw. When the top and bottom are hard and cannot be cut with a pick, if a timber is a half-inch too long it cannot be stood plumb and might as well not be stood at all, since it is worthless as a protection.

While acting as foreman on one occasion, I went to a miner's place and found six or seven timbers near the face considerably out of plumb. Picking up another timber, I knocked out each of the posts and departed, leaving instructions for the miner to reset each post plumb. I then gave the driver orders not to set any more empties in the place until my instructions had been obeyed.

Certified Mine Superintendents

Many superintendents now hold mine foremen's certificates — Successful mine management requires knowledge and experience in every branch of the work—Need for broadminded mine officials.

In an excellent letter by S. D. Hainley, Coal Age, June 8, p. 967, mention is made of some of the requirements needed to make an ideal superintendent. It seems strange to me that the writer did not refer to the need of a superintendent holding a certificate of competency.

In my opinion, the certification of this class of mine officials would be a forward step in attaining the highest efficiency in the management and operation of mines. It is clear that the superintendent's duties and qualifications are of a higher class than those of the mine foreman and, in examination, he would be required to answer a different set of questions than what are given in foremen's examinations.
In the letter to which I have referred, the choice of a suitable superintendent has been left to the judgment of the general manager, who is expected to decide on his fitness for the position by a careful study of his several qualities.

**Men's Fitness for Positions**

As he has stated, there are superintendents who are qualified to fill that position but who would be a failure in another position. In other words, the particular requirements that go to make up a successful superintendent are of a nature wholly their own.

It is my belief that it would be difficult, for an examining board to frame a set of questions that would show the capability of men to fill this position. Most men will agree, however, that it would not be out of the way for a mine superintendent to hold a first-class mine foreman's certificate.

Observation shows that this is becoming the fact, more and more each year. Several of the larger coal companies, in this country, are now requiring this of men whom they appoint to the position of mine superintendent. In the majority of cases, the superintendent has been promoted from the position of foreman, in which he was required to hold a foreman's certificate.

**Experience Needed to Succeed**

The greatest degree of success in the management of a mine, from the superintendents' standpoint, can only be attained by the man having a previous experience in every branch of the work that now falls under his supervision. Without this experience, few men could be expected to develop a large mine, in a manner to produce results and compete successfully on the market with other producers.

There is need, today, that both the mine superintendent and the foreman shall be men who are broadminded and able to put into practice the many ideas that can come to them only through observation and experience. Some writers have spoken of the difficulty of working under a superintendent who has not the same practical knowledge of mining. Speaking for myself, this has never been my trouble. A foreman must first gain the confidence of his superior officers, by proving to them that he has a true grasp of the tasks he advocates. He will then seldom meet opposition in what he proposes.

Central City, Ky. *Ostel Bullock.*

**Certification in England**

*Overman, in England, required to hold certificate—Undermanager or overman for mine foreman in this country—A deputy or fireman is a fireboss here.*

**Some time since, I remember, a writer in Coal Age stated that, to the best of his knowledge, the mine manager was the only certified mine official in England. This statement being far from the truth, I desire to correct the impression it has left in the minds of foremen and firebosses in this country.**

In England, the undermanager, or "overman" as he is more commonly called, corresponds to the mine foreman here. Also, the deputy, or fireman, as he is called in some parts of England, corresponds to the fireboss in this country.

It was the same writer, I believe, who stated that the overman and the deputy, in the old country, were each given what he termed a "vest-pocket certificate" when appointed to their several positions by the manager. He claimed these certificates were all that was required, in the way of certification, of either of these men.

Being myself the holder of an overman's certificate, which I obtained at Newcastle-On-Tyne, in January, 1897, I am able to say positively that the statement of the writer to whom I have referred is wrong.

**Overmen Must Be Certified**

At the present time, the overman, in England, must hold either a first-class or a second-class certificate, before he can be appointed to that position. Moreover, I understand that the deputy or fireman, in the mind, is now required to hold a certificate of competency making him eligible for that position.

In support of these statements, allow me to quote one or two extracts from the English law, as follows:

*"The enactment of a mine must be under a manager responsible for the control, management and direction of the mine and holding a first-class certificate. Daily, personal supervision of the mine must be exercised by the manager or by an undermanager holding either a first- or a second-class certificate. First- and second-class certificates of competency may only be granted to men of at least five years' practical experience, who have satisfied the examiners as to competency, sobriety, experience, ability and general good conduct. Their certificates may be suspended or canceled on the ground of incompetency or gross carelessness."*

*William Dickinson.*

Lochelly, W. Va.

**Is the Game Worth the Candle?**

Qualities of the successful foreman—Requirements in England—Standard in this country too low—Many facilities for study but little incentive.

**Reading** all that has been said with reference to the required qualifications that make the successful mine manager (foreman) to ask, "Is the game worth the candle?"

Failing to fail to understand the meaning I have in mind and realize the importance of its application to the certification problem in this country.

Let us review briefly the difference between a practical mining man and one who is purely theoretical in respect to mining. The comparison will assist us to a better understanding of this vexed question.

I say "vexed question," because so many ambitious young men have struggled to equip themselves for successful filling some higher position in mining and when the fruit of their efforts was almost within their grasp, have been disappointed by seeing the
correlated position given to another less qualified.

Briefly stated, the practical man has learned by experience to do the actual work of sinking a shaft, digging coal, laying track, fencing an air-course, building brattice and a hundred other useful and necessary jobs that are required in the mine.

On the other hand, the man who has studied the principles of mining is able to estimate the proper size of a shaft and determine its equipment; calculate the horsepower of engines and motors; plan the ventilation of the mine; estimate the size and power of the ventilator, and calculate the capacity of pumps, besides ascertaining numerous other necessary details.

It is readily seen that each of these types of men possess qualities that are essential to the successful operation and development of a coal mine. In other words, the ideal foreman will combine, in one person, the qualities of two distinct personalities.

Allow me to give, here a crude illustration of my meaning, in order to press home this point. Compare the attempt to build a wall of brick without mortar, with one where the bricks are laid without compensation. The first symbolizes the practical man having the material experience, but lacking the technical knowledge that would stabilize his work.

THE SO-CALLED “VEST-POCKET CERTIFICATE” NO LONGER USED

In this connection, may I comment on the statement of R. W. Lightburn, Coal Age, Feb. 16, p. 291, regarding the “vestpocket certificate” he describes as English practice. For his information and others, I want to say that that is a thing of the past. Candidates for the position of overman (foreman) or deputy (fireboss), in England, have long since been required to pass a government examination.

It is worth of the most earnest thought that the demands coming here and the growing necessity for a more complete extraction of the coal have called for the use of the most approved types of machinery, in coal cutting, haulage, ventilation and drainage.

In order to adopt and successfully operate this class of improved machines, it has become necessary to employ men who understand principles and have mechanical ability. It is in this respect that the difference between the two types of men I have mentioned is most manifest.

Let me say here that the standard of mine foremanship, in this country, is too low to meet the present needs of the industry. Mine examining boards should be composed of men who are thoroughly up-to-date in their knowledge of present-day mining. There are instances, I regret to say, where some of the board members would be unable, themselves, to answer the questions asked by their board.

In sharp contrast with this condition, I recall my first examination, taken in the old country. Every member of the board was a recognized authority on mining, or a first-class mining engineer. To pass that examination a man had to be well qualified and, if not, he might better have stayed home. Two examinations were held each year and a different board appointed each time, so that it was impossible to tell beforehand who the examiners might be. They all served for a year.

At the present time, many facilities are open to young men, in this country, to obtain an education, but these are very largely neglected. There appears to be little incentive among the young men to study for self-improvement and the reason is not hard to find.

GIVE AMBITIOUS WORKERS A CHANCE

Few coal companies have adopted and held strictly to the rule of giving their young ambitious workers every opportunity for advancement. Vacancies have been filled, in many cases, with those less qualified by experience or technical knowledge of mining. This has virtually thrown a damper on the desire of young men for study, in order to fit themselves for a higher position. That this is true cannot be disputed; I have seen it occur many times. In one instance, recently, a young man employed as bookkeeper was taken from the office and made superintendent, although he had not worked a day underground and knew nothing of mine gases, ventilation, haulage and drainage.

Another instance was that of a miner who held an official position in the miners’ union. At the time, he was reported to be away on official business; but when he came back he informed the men that he had been appointed superintendent of the mine, though it was not known that he had any particular qualifications for that office.

In closing, let me ask: When such occurrences as these take place, is it not enough to make the student ask the question: “Is the game worth the candle?”

West Frankfort, Ill.

Inquiries Of General Interest

Electric Locomotive Operating with Wheels Of Unequal Diameter

Operating a Locomotive with Wheels of Unequal Diameter—Effect on Machine and Power Required to Operate—Advantage of Two-Motor Locomotives

KINDLY permit me to ask, through Coal Age, a few questions that I believe will be of general interest to all mine operators using electric locomotives. It will be generally admitted that the necessity frequently arises of having to replace a worn or broken wheel on the locomotive. In that case, it often happens that the new wheel is not of the same diameter as the old wheel on the machine. Or, it may chance that one or more of the wheels have become unequally worn. In any case, trouble is almost sure to be experienced in operating the machine.

The questions I want to ask are:

1.—How will a mine locomotive behave on the track if one wheel is ⅛ or ¼ in. less in diameter than the other wheels?

2.—What will be the effect in respect to the wear of the wheels, owing to a slight difference in their diameter?

3.—What will be the effect on the mine track?

W. P. ROBERTS, Mine Foreman.

Colver, Pa.

This is an important practical question and, for the purpose of getting first-hand information that would be of the greatest practical value to users of mine electric locomotives, it was submitted to Graham Bright, general engineer, Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa., whose reply follows:

1.—The axle of a locomotive on which one of the wheels is of different diameter from the other, will tend to assume a position not parallel to the other axle. There will then be a tendency of that axle to bind in the journal boxes. Also, the wheels being fast on the axle, one of the other or both will slip on the rails.

This slipping of the wheels will not only cause a considerable wear in the journal boxes, but more power will be required to operate the machine. Owing to the slipping of the wheels, also, there would be less tractive effort and the tractive power of the locomotive will be decreased in the same proportion.

2.—The wheels will, no doubt, wear considerably faster than under normal conditions. If there is much play in the journal boxes there will also result a considerable wear of the flanges. This condition may become worse instead of better if it happens that the smaller wheel slips more than the larger wheel.
3—It is hardly likely that there will be any serious effect on the mine track, since the locomotive passes over a given point in the track but a few times in the day. In other words, the wear on the rails, in excess of what occurs under normal conditions, will hardly be appreciable.

Allow me to add a few words regarding locomotives equipped with two motors, as compared with those equipped with a single motor and using either a worm drive or a chain drive to connect the two axles on the machine. In the former case, the principal damage done by wheels not being of the same diameter is a useless expenditure of power to operate the machine and an unnecessary wear on the wheels and journal boxes.

In the latter case, however, when the locomotive is equipped with a single motor, it becomes necessary for the worm drive or the chain drive to take care of any difference there may be in the size of wheels on different axles. The two axles being thus connected must revolve at the same rate of speed and it follows that any difference in the size of the wheels on the two axles will cause a slipping of the wheels and a considerable strain is thus thrown on the drive, which will greatly reduce the mechanical efficiency of the machine.

This is one of the principal objections to the use of a single-motor drive, for the reason that few mining companies check up accurately the size of the wheels and make any attempt to correct these troubles when they occur.

I recall a recent case of this kind where the locomotive was equipped with a single motor and a worm drive connecting the axles. One pair of wheels had been changed, owing to wear, while the other pair still remained on the machine. Of course, the new wheels were larger in diameter than the old ones and the attempt to operate the locomotive caused the shaft to break between the axles.

The fact is now fairly well established that a two-motor locomotive is much more economical in the use of power than a locomotive equipped with a single motor. A considerable portion of that loss is due to the control system used. No doubt, however, a large portion arises from the mechanical losses of the single-motor locomotive, because of its inability to keep all the wheels of equal size.

**Examination Questions Answered**

**Miscellaneous Examination Questions**

(Answered by Request)

**Question—** Explain the method of ventilating and working a panel of coal: (a) On the advancing system; and (b) on the retreating system of mining. Make sketches showing the plan in each case.

**Answer—** As shown in each of the two figures, cross-entries are driven off the main headings, at distances of, say 250 to 300 ft. apart. Rooms are then turned to the rise of the haulage road, on each pair of cross-entries.

(a) In the advancing system, as shown in Fig. 1, the rooms are widened inby, or in a direction away from the main heading. The track in each room is carried up the straight rib and the refuse stored in the vacant space on the other side of the track. This plan affords a good opportunity for loading the coal when drawing back the pillars. As each room reaches the limit or the barrier pillar protecting the air course on the next pair of cross-entries, the pillar adjoining the track is cut through and the work of robbing begins. As shown in the figure, it is important to keep the line of pillar work as straight as possible, in order to equalize the pressure on the ends of the pillars and avoid the crushing of the coal. This will also greatly assist the work of mining. Where machines are used in robbing, a cut three or four yards wide is started, say 2 yd. back from the end of the pillar and on the side next to the track or away from the gob, as that will afford greater protection for the men and the machine while cutting the coal.

(b) In the retreating system shown in Fig. 2, the cross-entries are driven to the limit of the panel, or to the boundary, before any rooms are turned. The first rooms are then turned, starting at the inby end or head of the entry, and driven to the rise, in the same manner as before, except that the rooms are now widened in the direction outby or toward the main heading. As before, the track is carried up the straight rib or on the inby side of the room. With the single exception of widening the rooms, robbing in the room, instead of inby, the work of driving the rooms and driving back the pillars is the same as in the advancing system just explained.

**Question—** Give the rule for determining the size of barrier pillars, in the anthracite region, in Pennsylvania.

**Answer—** A common practice in the anthracite region, and agreement of many of the larger companies, is to calculate the thickness of barrier pillar, separating adjoining coal properties, by multiplying the thickness of the seam by 1 per cent of the depth below drainage level, and adding to this product five feet for the thickness of the seam. In other words: To 1 per cent of the depth below drainage level, add 5 ft. and multiply the sum by the thickness of the coal, in feet. The product will be the required width of barrier pillar, in feet.

**Question—** What is the thickness of barrier pillar does the Pennsylvania Bituminous Law require to be left when approaching old workings containing an accumulation of water?

**Answer—** The Bituminous Mine Law of Pennsylvania, (Art. 3, Sec. 5.) requires a thickness of barrier pillar 25 per cent greater than the thickness of water to which the pillar is exposed.

**Question—** How would you prepare a burned man, before removing him from the inside to the outside of a mine?

**Answer—** Every means available should be used to keep the air from the burned portion of the body. The clothing should be cut off from those portions of the limbs and body and cautiously removed to prevent unduly injuring the flesh. In order to exclude the air from the burned surface, apply a thin paste of baking soda or dry flour. Vaseline, olive oil or cream, if available, are good and the application should be covered with a light bandage. The sufferer should be handled with great care and not exposed to the raw air outside of the mine longer than necessary.

**Question—** Explain the conditions under which coal in mines becomes dangerous as a source of explosion.

**Answer—** Any accumulation of fine dust, on the floor, sides, roof and tumberson the airways and working places of a mine, is dangerous. When this fine dust is blown into the air by the force of a shower, and acted on by the flame of a blowout, a more or less localized explosion is liable to result. Under favorable conditions, this local explosion will be extended throughout the mine.
Selling Coal Ideas: A Study of Associations

By George Cushing

IF COAL men hear a heap of quarreling in and about their associations they should not be disturbed. Instead they should feel encouraged. Some normal men do not quarrel over worthless things. They simply throw them away. Therefore the very fact that busy coal men are willing to squabble over an association is proof conclusive that its is worth a great deal—really worth dominating, for example. Also, if coal men criticize the policy of their association, it is a sure sign of growth on the part of the critics. They criticize—analyze—to find what is wrong in order to set it right. That is purposeful interest, which is growth.

I take it that much of the current discussion of the many coal-trade associations means that coal men are finally becoming dead in earnest about their associations and propose to make of them what they ought to be. On that premise I want to raise a point for consideration in connection with all of the associations in the coal trade. At that point I lose title to an idea. The great distinction which we must always keep in mind is: A coal company sells a commodity. Coal associations "sell" ideas. Their subject—coal—is the same. Their methods are, necessarily, as far apart as the poles. For instance, a commodity has bulk, weight and, therefore, substance. A given amount may be sold—if someone needs it—for a given sum of money. In case of dispute over the coal, the owner can prove title and by going into court can collect his money.

HOW EASILY ONE LOSES TITLE TO AN IDEA

Selling coal is a business which is done according to rules laid down by law. The courts stand behind the producer until his claims are satisfied. In this respect it is a very simple business, relatively speaking. But selling ideas "is something else again, Mavrus. You work for weeks, months, or years to get, develop and perfect an idea. When you have it all thought out and so accurately phrased that anyone must grasp it in a minute, you spill it into the ear of a friend. Instantly your friend says: 'Yes, that is true. I have thought of that.'"

At that point you lose title to that idea. You are as poor as on the day you were born. There is no redress; no recovery. Your friend told the truth. He has thought of it. By your very lucidity you have compelled him to think of it. Of course, your friend is careful to express himself in the past tense. He leaves with you the vague impression that years ago he hatched exactly that idea, and expressed it in its own natural language—that which you just used. You cannot deny it. If you do, you can't prove your case. As far as you know, your friend may have been born with the idea which you feel, in your inner consciousness, was coined out of your bitter experience. Yet you cannot go an inch behind the cold fact that what he says is literally true—"I have thought of that." He has thought of it and you are done.

Once I told a friend an idea. He made half a million off it and merely said: "You confirm what was my own idea." He made the money and I was done.

Again, I worked ten years to clear up a thought. A friend heard the conclusion and said: "Just what I have always contended." Again I was done.

Associations, as "sellers" of ideas, have always to face that stubborn fact. They labor and agonize over ideas. They find them, develop them and perfect the expression of them. But the instant they are expressed, they become common property. They belong to everyone. They are not patentable. They cannot be copyrighted. The intangible association may have the consciousness that it has done a good job. It may feel that it has clarified a situation. But it cannot pay dividends with any money obtained for its ideas because no money was ever paid for them. They were given away—or expropriated.

It is possible, however, to cash in even on the sale of ideas. If it were not possible this article would not be written. But it is necessary to change away from the selling methods used in a commodity and adopt those employed in marketing ideas. The great merchant groups who have actually cashed in on ideas are, in order: The statesmen, the newspapers, the lawyers and the doctors. Others who have ideas to sell will do well to study their methods. The statesman retains title to his ideas and gets full benefit of them. He does what seemingly is impossible because he has an organization behind him which realizes that it can win support for itself only by advocating the views of its leading men.

The newspaper certainly retains title to and gets the benefit of its ideas. It succeeds in what seems like a hopeless task because it throws behind its ideas the weight of incessant repetition.

CITIES ADVANTAGE OF SYSTEMATIZED THINKING

The lawyers and doctors "sell" their ideas because, in their ideas and because, in their schools, they are taught a system of thinking on their themes. All lawyers talk about the law in exactly the same way. They say certain things to every client on every occasion. Each lawyer gets the benefit of emphasis of the statements and reiterations of the lawyer thought by all other lawyers. They have made a sort of a cult of the law. Also both lawyers and doctors are bound by a code of ethics which supports and emphasizes their point of view. This code becomes at once the common defense of the whole fraternity. Thus the cardinal principles of success in selling ideas are: To have the ideas of the leaders supported by the mass, to have those ideas reiterated incessantly and to approach the formality of a code in the way the ideas are publicized. It all makes the painstaking effort at preparation and persistence in propaganda.

The coal associations can, if they will, combine all of the forces upon which all these others depend. They can put this combined force behind their ideas. That is, they can put behind their association ideas the weight of the same kind of an organization which supports the statesmen, the frequent repetition which gives authority to the ideas of the newspaper and the consciousness and formalized expression which is the backbone of the success of the lawyers and the doctors. But, before coal men can bring their associations to the full flower of their power, they must first realize the vital distinction between selling coal and selling the coal-association idea. They must realize that the personal business is a matter of selling a measured commodity. The coal association is a matter of selling the common ideas about that business. One is a matter of dealing in things. The other is a matter of dealing in mere thoughts. The selling method must be fitted to the thing to be sold.

The coal men supply the money which supports the association. It is, therefore, an expression of themselves. Its ideas are literally the money spent. They supply that money solely to have their ideas circulated and adopted. That being true, the practical question is: How can they get the greatest value for their money—the widest circulation of their ideas?
Many coal men, unfortunately, take toward the statements of their association officers much the same attitude as did the old farmer whose neighbor had lent him a copy of the writings of Socrates. When he returned the volume he said: "This fellow Socrates is a smart man. I see he is using some of my stuff."

That is, coal men are not willing to surrender wholly an idea to their association—even to the association which they support. They are hardly, as yet, willing to get behind the idea of their president, even though he expresses their own thoughts exactly. They want to keep the association going but they want to keep its ideas as their personal property. Of course, they can't do any such thing because the world can expropriate an individual's thoughts as easily as it can those of an association.

The other—and it would seem, proper—method of procedure is for each member to get wholeheartedly behind the main association idea. In season and out of season, he should say: "On that subject the Blank Association expresses not only my personal opinion but that of the entire coal trade," etc. That method would get the main idea across with one hundred to five thousand times the pulling power which could possibly attach to any individual opinion.

Let's be frank about this thing. The only reason we coal men do not give our association this ungrudging support is because we feel that if we do we will enhance the reputation of the man who put forward the idea in our name. It is true that with much enthusiasm we elected So-and-So as president of the association. It is true that we authorized him to speak for us. And, apparently, he has done a job because he has expressed an idea which we think is worth appropriating. But we are not quite willing to let him get away with the glory—if there is any—of having so accurately phrased our thought. It is unfortunate but true that human nature works in that way. What we fail to realize is that by holding out on the president, we weaken in proportion the very thing we are spending money to strengthen.

Where is your association going to end if you gentlemen withhold your endorsement from the men who express your ideas? Do you, personally, gain anything? What will be the effect on the association?

In conclusion: You sell a commodity successfully when you work alone. You sell an idea successfully when you work in a gang. Your regular business is selling a commodity. There you have to work alone. But in your association you have to work as a unit with dozens and hundreds of others. Only in making that shift from your daily practice to the other attitude can your association attain the position of power which it ought to occupy.

Fewer Mine Fatalities During May, Though Production Exceeds That of April

During May, the second month of the coal miners' strike, 74 men were killed by accidents at the mines, or 3 less than the number killed during April, according to reports received by the U. S. Bureau of Mines from state mine inspectors. All of the fatalities except one were at bituminous mines; one man was killed at an anthracite mine in Pennsylvania by falling down a shaft. None of the anthracite mines in producing coal.

The production of bituminous coal in May, as reported by the U. S. Geological Survey, was 19,015,000 tons, about four million tons more than in April, 1922, but over thirteen million tons less than in May a year ago. The fatality rate for bituminous mines in May, 1922, was 3.68 per million tons of coal produced, as compared with 4.88 for the preceding month of April and 3.87 for May, 1921. The rate for anthracite mines in May, 1921, was 5.74 per million tons; there are no comparable figures for April or May, 1922, because all of the mines are closed.

During the nine-year period 1913-1921 the month of May has averaged 176 fatalities at bituminous and anthracite mines, with an average production of 46,215,000 tons of coal, the fatality rate being 3.80 per million tons. For bituminous mines alone the nine-year fatality rate is 3.33 per million tons mined, and for anthracite mines it is 6.82.

COAL-MINE FATALITIES DURING MAY, 1922, BY CAUSES AND STATES

Congress Considers Various Phases of Coal Strike and Ways to End It

ESTABLISHMENT by Congress of a permanent fact-finding agency on the coal industry was advocated by Representative Browne, of Wisconsin, in a House speech on the coal strike. "There will be a terrible coal shortage even if the men should go back tomorrow," he stated. He placed the blame for the strike on the coal operators because of their refusal to confer with the union. Referring to court proceedings to restrain the Federal Trade Commission from obtaining cost data as to the coal industry Mr. Browne charged that the coal interests opposed developing the facts because they "fear the facts."

Representative Burke, of Pennsylvania, introduced a resolution authorizing and directing the President to take over and operate coal mines for one year or as long thereafter as in his discretion may be necessary for the public good. It would also direct the President to enter into negotiations with the miners' committee and arrange a mutually satisfactory wage and working agreement.

John L. Lewis, president of the United Mine Workers, conferred with Secretary of Labor Davis on the coal situation again on Wednesday, June 28, and reiterated his opposition to the district referendum the Congress is considering.

The President received an appeal from the Public Committee on Coal, of which Norman Haapgood is chairman and M. C. Johnston, secretary, asking for an investigation of the coal industry by a government fact-finding agency. The petition was received also by Senator Walsh, of Massachusetts, and read by him to the Senate. Senator Walsh also presented to the Senate a petition from the Lowell Coal Merchants' Association urging action to cause a re-sumption of anthracite coal mining not later than July 15 because of depleted stocks in New England.

The Herrin (Ill.) coal riots were discussed in a House debate. Representative Goodykoontz, of West Virginia, scored the miners for murder, while Representative Denison, of Illinois, in whose district the riots occurred, declared the outrages were caused by the operators and charged that reports of the affair had been exaggerated.

Mr. Denison's explanation that the reports of the riots were exaggerated was interrupted by Representative White, of Kansas, who asked: "Do you mean to say that not more than half is true in respect to the number assassinated in cold blood for exercising the national right to work?" Mr. Denison insisted that the reports had been exaggerated.

In extenuation for the strike riot Mr. Denison said the district was completely unionized and that the miners became embittered and their reason gave way to passion when the coal company imported 50 miners from Chicago to operate the mines after a contract had been made with the union to prepare the mine and operate it after the strike should have closed.

Representative Fish, of New York, introduced a resolution for the appointment of a joint committee of Congress to investigate the causes of the strike of coal miners. The committee would be composed of five Senators and five members of the House, who would be authorized to investigate the causes or causes of the strike of coal miners in the anthracite and bituminous coal regions, the question of wages, hours, conditions of employment, and the question of profits and losses of mine operators. The committee would be empowered to take testimony in Washington or elsewhere, to send for persons and papers and return its report to Congress at the earliest possible time, indicating a method of settlement of the strike which will protect and conserve the interests of the people.

Says Operators Exact Hoover Maximum, Eliminating Jobbers and Wholesalers

From the first conference held with Secretary Hoover of the Department of Commerce jobbers, wholesalers and middlemen have wondered where they would come in if the maximum price were reached and the demand were such as to turn all of the buyers to the miners. It was written in Cincinnati this week newspapers and newspapers have the virtual elimination of the wholesalers who were sufficiently conscientious to abide by the government's ruling and request. Cincinnati has been the central point of coal movement in the West since the strike began, so the jobbers and middlemen there have watched with considerable wonder the mad scramble to producing fields in Kentucky and West Virginia by buyers who were determined to deal direct with the producers.

J. C. Layne, of the Eaton Rhodes Co. and a member of the fair price committee appointed by Secretary Hoover, on June 26 sent the following telegram to Secretary Hoover:

"There is a very growing tendency on the part of coal operators to demand the maximum price announced by you, making no allowance for jobbers. This condition is forcing jobbers to add a profit, contrary to the understanding and desire of the jobber, and thus forcing the price upward. As one of your committee in eastern Kentucky will appreciate telegraphic advice as to policy to adopt. We desire to aid you in every possible way but are facing complete elimination as selling companies unless the operators are restrained or we are permitted to add a reasonable profit to the producers." In answer to this Mr. Layne received the following: "Please give specific cases, so we can lay this before the committee."

From the advices that have been received in Cincinnati it would appear that two-thirds of the southeastern Kentucky operators are culpable together with a fair sprinkling along the Norfolk & Western.

Retailers to Educate Newspaper Editors

R. WULFF, chairman of the committee on public information of the National Retail Coal Merchants' Association, has had prepared a statement on the coal situation, not for publication but, as stated by Mr. O'Toole, executive secretary of the association, "to educate newspaper editors and impress upon them the absolute necessity for differentiation in newspaper articles relating to coal between conditions applying to bituminous coal and those applying to anthracite."

This document, entitled "Two Fuels, Two Strikers," summarizes conditions in the two industries, reviews the conditions leading up to the strike and sets forth the situation as it now exists. The statement has been forwarded to all metropolitan dailies from Chicago east and may later be given even wider distribution.
Thirteenth Week of the Coal Strike

EDITORIAL REVIEW

President Harding's action in calling the union miners and operators into conference at Washington on July 1 is generally conceded to mark the beginning of the end of the strike. What is now and for some time will be going on at Washington will hold the center of public interest in the strike. Strict secrecy has marked the joint sessions of the miners and operators with secretaries Hoover and Daniels, and to all outward appearances there has so far been no relenting by either side from previously established positions. The debate so far seems to have centered on the question of district conferences and contracts versus a Central Competitive Field agreement. There is a very persistent undercurrent of feeling favoring the idea that some modification of the previous form of negotiations will be found, giving the districts separate agreements yet providing the semblance of a national character, as demanded by the miners. It yet remains to be seen which party will look back on this as the unlucky thirteenth week.

In Illinois and in Pennsylvania there have been some steps taken to initiate negotiations on a state basis. In both cases they are undoubtedly doomed to failure, if for no other reason than that of veto by the policy committee of the United Mine Workers.

Production continues to increase, though slightly, in the non-union fields of Pennsylvania. The production of West Virginia can be still further increased from mines in the northern part of the state, but apparently the limit has been reached in the southern district, due to the inability of the railroads to handle more tonnage.

Clifford B. Connelley, Commissioner of Labor and Industry of Pennsylvania, who had hopes of settling the anthracite and the bituminous strikes through conference, fixed July 6 for the bituminous conference at Pittsburgh.

"We have offered the services of the Department of Labor and Industry in a friendly way to the bituminous operators and miners of Pennsylvania in the hope that they will accept this opportunity to avert serious consequences to the industries of the state," said Commissioner Connelley in discussing his plans.

On June 29 P. T. Fagan, vice-president of District No. 5, United Mine Workers, declined the invitation.

In his letter to Mr. Connelley Mr. Fagan said that "we must at this time reject sectional settlements, because of the fact that there was an interstate joint contract existing in the competitive field between the coal operators and the United Mine Workers of America." He added that he had accepted President Harding's invitation to a conference in Washington on July 1 of operators and miners, and said: "We, therefore, cannot see the advisability of, or believe any benefit would be derived for our people or the consuming public from, a meeting such as you suggest at this time."

Baxter Charged with "Selling Out"

Union Members in Canadian Fields

J. B. McLachlan, secretary-treasurer of the Maritime district of the United Mine Workers Union, declares President Baxter of the U.M.W. for the maritime district (No. 26), "sold out" the members of the district. McLachlan has been supported in the stand by Phalen Local, one of the biggest of the locals of the district. McLachlan asserts that Baxter betrayed the miners of the Canadian coal fields, especially those employed by the British Empire Steel Corporation (Dominion Coal Co.), the start in the alleged betrayal being made at the time of the recent Montreal conference just previous to the appointment of the Scott conciliation board.

According to McLachlan the miners held aloof from the operations of this board. He said President Baxter appointed I. B. McDougall, of Inverness, as the union representative on the board because McDougall was one of his henchmen. The miners, according to Phalen Local and McLachlan, will not support either the majority or the minority report of the Scott conciliation board, which was appointed to adjust the dispute over the cut in wages ordered by the British Empire Steel Corporation at the Cape Breton collieries.

McLachlan characterizes Baxter as a traitor who used his office as president for his own financial ends. On the other hand, Baxter says he is not in sympathy with McLachlan's tactics and describes the latter as a Bolshevik who is trying to advance the cause of the One Big Union and not that of the United Mine Workers and the American Federation of Labor.

The pot is merrily boiling in U. M. W. circles in eastern Canada. Most of the talk has been coming from McLachlan; Baxter being comparatively quiet. McLachlan includes in his condemnation John P. White, who came from Indianapolis to help clear the air among the members of the U. M. W. in the Maritime district but has achieved little success thus far.

Man Shortage and a Few Disturbances

Handicap Colorado's "Busting" Output

COLORADO'S labor difficulties at the end of June were not so much those of hard feeling and resultant trouble as they were of man shortage and difficulty in supplying the keen fuel demands of the C. B. & Q. and the Union Pacific railroads. Both roads were buying all the coal they could reach, the "Q" having contracted the output of all the mines it could command, including many of the Colorado Fuel & Iron Co., the Victor-American Fuel Co. and many independents. Much of this coal is being shipped to all parts of the "Q" system, even as far east as Chicago.

No serious labor disturbances occurred in the state during the month, though small evidences of bitterness by strikers were seen here and there. On the early morning of the 29th a bridge was burned out a mile from the Ideal mine, of the Colorado Fuel & Iron Co., in the Trinidad field, thus cutting off a flow of 800 tons of steam coal a day, and here and there shots were fired at company employees, including William McLaughlin, son of the superintendent of the Fox mine, near Boulder. But operators declared the mass of miners in the state were not in sympathy with the strike, which had little effect in Colorado except in the Cañon district, where a few mines are down and where the rest are working at half capacity.

Colorado operators to a man credit Governor Shoup and the State Rangers with the good order that has prevailed. This force of 50 men has inspired such respect for itself that the state is full of stories about how a ranger dashes by motorcycle into a town where trouble is brewing and quells the incipient uprising by a word and a look. These men do not wait for a war to start. Their policy is to be there first. Many a man in Colorado is saying Illinois would not have had the Herrin massacre or anything like it if that state had such a force of law enforcers. Also they say Colorado is so full of trouble breeders that the state might easily have had war before this had it not been for the ranchers and the common knowledge that Governor Shoup will instantly lend the full strength of official Colorado to protect property and preserve peace.

As evidence of this on June 20 he ordered 500 National Guard troops into the fields to safeguard life and property because of threatened trouble that broke loose on July 1. Adjutant General Patrick J. Harlock is in command.

National Guard headquarters obtained information that radicals were planning to attract rangers to Frederick following a union meeting and to hold them at that place.
Commissary Stations for Strikers
In Indiana Post Strict Rules

Some of the signs hanging about the commissary station established recently in West Terre Haute, Ind., for the miners of that district who are striking are:

"Miners' Commissary."

"Leave Orders One Day in Advance."

"To Get Bred, Line Up and Take Your Turn and Keep Other Men Waiting."

Similar commissaries have been established in Clinton to aid miners in that field. The commissaries are the first to be established in the Indiana field. No woman may appear at the station for food unless her husband is sick, and should such a report be turned in, the case is immediately investigated to prevent miners who are engaged at other work from coming in on bogus claims. Badly paid miners who are not employed. The store door is kept closed and each miner who registered the day previous is called by name to get his basket. The apportionment is made according to the number of persons in the family, 50c. for adults and half that for children.

The men operating the commissaries come from the ranks of the miners, but are not working under the supervision of the United Mine Workers of America, but as a separate body. The men met and formed a group under the head of the Miners' Relief Association. Two committees are in different parts of the state soliciting aid for the miners and their families. Robert Pife, 88 years old, who has been in the mines since he was nine years old, starting as a trapper boy, waits in line with others for his food. He is the oldest miner in Vigo County and probably the oldest in Indiana. Mose Morgan, 77 years old, usually accompanies him to the commissary.

Smokeless Mines of West Virginia are now producing at the rate of 5,000,000 tons per month, which is the largest in the history of the region. In round numbers the Huytons field is mining 70,000 tons per day, the Tug River field 20,000 tons per day, the Winding Gulf 30,000 tons per day and the New River 20,000 tons per day.

A number of high-cost mines have resumed operation since May 31, and it is believed that at the present rate of improvement the New River field will be able to increase its production to 25,000 tons per day by July, which is more than the field was producing before the strike.

Every effort is being made by the Chesapeake & Ohio and the Norfolk & Western to keep their equipment rolling and consignment of coal to the scales at Portsmouth, Ohio, on the C. & O., and to Russell, Ky., on the C. & O., is being discontinued on account of the delinquency of loaded cars at these points. Unless through billing cars are furnished, these loads are not being moved from the tipples and in case any coal is found unconsigned at the scales at these western points the railroads immediately embargo the mines and furnish no more equipment until the unconsigned loads are furnished. This, it is claimed, holds up the rate of production.

Demonstrations Cease at Wagon Mines
Of Indiana Pending Injunction Action

No further disturbances are being reported in the wagon-mining coal fields in Indiana. Striking union miners who recently conducted demonstrations and closed non-union mines in these fields are withholding further activities pending action by the federal court at Indianapolis on an application for an injunction to prevent wagon-mining operators filed by operators of Knox County. Crowds of miners are continuing to congregate in various cities, but no signs of violence have been shown since a number of union men were arrested and arraigned in the Clay circuit court at Brazil on charges of riot and conspiracy to riot.

Kentucky Dumps Vast Volume of Coal
Onto the Country During Strike

Kentucky is breaking some records in production of coal at the present time. Figures received from the Louisville & Nashville R.R. show that in May the road handled 13,698 more cars of coal than during any previous month in its history. The total number of cars handled was 66,415, as against a previous record of 62,717 cars, a gain of 15,698 cars during the month.

Officials of the road assert that the strike lasts much longer the Louisville & Nashville R.R., which to date is out in front as the largest coal carrier of the country for 1922, will prove the premier coal carrier of the year.

During the May L. & N. had movement of Alabama and western Kentucky coal going both to Chicago and Pittsburgh, an unusually interesting movement for movement of Alabama coal. Officials of the road say that if the strike lasts much longer the Louisville & Nashville R.R., which to date is front as the largest coal carrier of the country for 1922, will prove the premier coal carrier of the year.

Mine capacity on the Cumberland division of the Louisville and Nashville railroad is running one thousand cars a day in excess of the railroad's ability to handle the coal. A representative of the American Railroad Association is on the ground, however, and there is every assurance that coal will move at the absolute maximum capacity of the division.

Affairs had reached such a pass in connection with the strike in northern West Virginia during the last week of June that miners of Monongah, a mining town in the Fairmont field, were prepared, in utter defiance of the county officials of Marion and the officials of the City of Fairmont, to storm the Marion County jail and liberate 91 men arrested on June 23 in connection with a demonstration of miners. When it was learned that the miners were gathering at Fairmont every available city police officer and county police officer was summoned to duty to prevent the entrance of the miners to the city, city officers being instructed to close water barges on the miners if they attempted to enter the city. C. F. Keeney, president of District 17, who was at the headquarters of sub-district 4 at Fairmont, was advised of developments and left immediately for Monongah. Upon his return to the city he told Prosecuting Attorney Amos that he was confident that there would be no further disorders.

Vernon W. Van Fleet, formerly judge for a period of eight years of the Superior Court of South Bend, Ind., was sworn in June 30 for a term of seven years as a member of the Federal Trade Commission, and has entered upon the discharge of his duties. Since March, 1921, Judge Van Fleet has been special assistant to the Attorney General, giving his attention particularly to reorganization work.
Government Plan Calls for More Than Temporary Adjustment of Strike Differences

BY PAUL WOOTON
Washington Correspondent of Coal Age

At the close of Sunday's conference at Washington between the bituminous operators and mine workers there were indications that an agreement finally would be reached whereby wage scales would be negotiated on a district basis. While the conferences on Saturday and Sunday were behind closed doors, there is reason to believe that the arguments presented for district conferences outweighed those advanced by John L. Lewis and his associates for a national agreement.

The belief among operators that the mine workers ultimately will come to district settlement was not altered by the vote against such procedure at the Sunday afternoon session. The recession is expected to come gradually and probably not until the delegates to this conference have discussed the matter with their constituents.

After the Monday session the conference adjourned until July 10. After the meeting Secretary Hoover expressed the hope that after the representatives of the operators and the miners had had the opportunity to discuss the situation with their associates more progress would be made. No government plan was put forward during the meetings.

It is reported that during Monday the operators in a closed meeting decided that should no result be attained in the later meeting with the miners, they would go home prepared to open important mines in each of the closed union fields. They were induced to give up this plan as far as this week is concerned. It is understood, however, that they have served notice on the miners that they will start mines next week if the union does not reach an agreement with them. They are reported to be determined to bring matters to a conclusion at once.

It is apparent that Secretary Hoover and Secretary Davis are going to insist that there be more than a temporary adjustment of differences. Every effort will be made to provide for the initiation of policies looking to the treatment of such fundamental ills as intermittency. While the remarks of President Harding to the representatives of the operators and of the mine workers are capable of being interpreted as foreshadowing action that will amount to compulsory arbitration, it is known that he is relying largely on the advice of Secretary Hoover. Mr. Hoover is known to be a strong advocate of a more permanent settlement than can come from a compromise of wage differences, which is practically the only possible outcome of arbitration.

In view of the fact that agreement is desired on a program looking to the removal of fundamental difficulties in the industry, an effort is being made to work out a plan whereby work in the union fields can be resumed pending a settlement, as such a program necessarily would extend over a considerable period of time.

At the Saturday morning session Mr. Lewis took vigorous exception to the fact that the so-called doubtful fields were not represented on the operators' side of the conference. He insisted that operators from Kanawha, New River, Colorado and other fields partly affected by the strike should be in attendance. A. M. Ogle, president of the National Coal Association and designated by the President to be chairman of the conference committee, stated that only those districts which are seeking a conference with the United Mine Workers had desired to avail themselves of the opportunity to name delegates. He pointed out that representatives of the operators were, in most instances, the presidents of the local operators' associations. In certain instances, he is understood to have explained, illness and other causes had prevented the attendance of the president of the operators' association. Representatives of most of the non-union fields were in Washington as observers.

Meetings thus far held indicate clearly that the operators believe they are certain to win the strike if it is allowed to run its course. They are practically a unit in their advocacy of district agreements. On the other hand, their is some indication that the position of the mine workers may be altered in that connection.

PUBLICITY TO BE GIVEN THROUGH GOVERNMENT

The President, in requesting that the negotiations be conducted in executive sessions, was actuated, it is believed, by desire to prevent criminations and recriminations on the part of the interests concerned. An agreement is understood to have been reached whereby all publicity will be given out through government channels.

While Secretaries Hoover and Davis were participating in the conference with the bituminous operators, Secretary Fall met with the representatives of the anthracite operators and mine workers. Secretary Fall is said to have expressed the personal opinion to the anthracite operators that their business is a public utility and should be subject to the regulations usually imposed on that class of industry. The anthracite operators are understood not to have received a satisfactory answer, when they asked Secretary Fall if the government is prepared to fix the price of coal so as to permit a fair return on the investment and to take the other steps which go with a regulation of public utilities.

When the operators and the officials of the United Mine Workers assembled at the executive offices at the White House at 10 a.m. Saturday they were received by the President. Nothing transpired at that session except the formal address of the President. There were no responses. When the President had finished his remarks he shook hands with each one present and departed almost immediately for Gettysburg. The text of his address follows in full:

Gentlemen of the coal industry. I asked you to meet here this morning, with the thought that in bringing you together I might be serving both the mine workers and the mine operators of the United States, and at the same time serve the great American public to which both you and I are obligated. I hold no specific authority under which to admonish you, but I do have the right to invite your immediate attention to a situation which deeply concerns the
country, the solution of which you collectively owe to the American people.

You who are here today represent a large sponsorship for America's supply of fuel. In that sponsorship you have an indissoluble relationship to the commonwealth of America. Coal is indispensable to our life as a people, and since this country has afforded you the opportunity of development on your part, both as workers and operators, you have created, in turn, an obligation to serve. Conflicting views as to your policies and your obligations to one another in no wise modify your obligations to that public which made possible your industrial existence.

Because of expiring agreements relating to wage scales and working conditions a large percentage of the mining activities of the country have been suspended three months to a day. It is not for me to touch upon the merits of your opposing positions. I have not called you as a partisan of the mine worker or the employer. I do not mean even to discuss a single phase of controversy. The main point is to bring you together and in that contact of men to men, mindful of the necessity of righteousness in any useful and abiding relationship, to have you frankly and fairly consider your problems in their relation to the welfare of our common country.

It is pretty generally recognized that there are fundamental difficulties in present-day coal production, the solution of which will be bound in some degree to be your daily task, and to be of every assistance possible, as official hosts to such a company.

Let me remind you that tolerance, fairness, the spirit of give and take, and finally a sense of the larger obligations to the public are essential to successful conference.

And I commend to you executive sessions, and assume full responsibility for such a recommendation, even as I assume the safeguarding of the public interest in asking you to come together. Differences are more often magnified than composed in their parading, and the call of the hour is adjusted differences, with due concern for the public welfare.

I thank you all alike for your response to my invitation, and I express the hope that in the realization of your responsibilities, and in an appraisal of your obligations, in the face-to-face, man-to-man, and citizen-to-citizen contact, you will find a way to a just concord which the American public may gladly acclaim.

Those who were appointed to represent the operators at the conference were:

A. M. Ogle, James Needham, representing the Montana Coal Operators' Association.

P. J. Qualey, president, Southern Wyoming Coal Operators' Association.

c. C. McAlpin, president, Oklahoma Coal Operators' Association.

Ira Clemens, president, Kansas Coal Operators' Association.

C. Smith, president, Colorado Coal Operators' Association.

E. S. Pfahler, representing the Iowa Coal Operators' Association.

Rice Miller, president, Illinois Coal Operators' Association.

H. C. Adams, president, Central Illinois Coal Operators' Association.

J. B. Paulley, representing the Indiana Bituminous Coal Operators' Association.

Hugh Shirkle, representing the Indiana Bituminous Coal Operators' Association.

Don Rose, representing the Pittsburgh Coal Producers' Association.

F. M. Posten, representing the Southern Ohio Coal Exchange.

Ed. Jones, representing the Southern Ohio Coal Exchange.

Michael Gallacher, president, Pittsburgh Vein Operators' Association.

T. W. Guthrie, representing the Pittsburgh Coal Producers' Association.

M. P. Pollock, president, Coal Operators' Association of the Thick Vein Freeport Seam of Pennsylvania.

C. B. Watkins, president, Central Coal Association of Pennsylvania.

B. M. Clark, president, Association of Bituminous Coal Operators of Central Pennsylvania.

In each instance the district association named its representative. Mr. Ogle had no part in designating any of the representatives of the operators, as has been stated in certain quarters.
Reed Resigns as National Coal Secretary to Take Up Accounting Practice

W. B. REED has presented his resignation as secretary of the National Coal Association and has opened an office in Washington, D. C., where he will devote his attention to the handling of matters of federal taxation and accounting, specializing in these matters particularly for bituminous-coal operators.

Mr. Reed has had an accounting experience of upward of twenty-two years with the bituminous-coal industry. Soon after the formation of the Pittsburgh Coal Co. in 1899 he entered the accounting department of that company. In 1911 he became connected with the New River Co., where he had charge of general accounting matters for that company and its operating subsidiaries, including that of its selling company, the White Oak Coal Co.

He left the New River Co. in October, 1918, to join the National Coal Association. In this connection he worked with the accountants of the Federal Trade Commission in an endeavor to produce a cost sheet which would be acceptable alike to the government and to the coal operators.

He is the author of a book on cost accounting in the bituminous industry which will be published by the McGraw-Hill Book Co. Mr. Reed has been in frequent touch with the Internal Revenue Bureau in matters of taxation and while occupying the position of secretary of the National Coal Association acted in an advisory capacity to many of the coal operators in taxation and accounting matters.

National Parley, Say Illinois Operators, Would Be Unwieldy and Unsatisfactory

I n announcing that a committee of Illinois operators would attend the conference at Washington to consider ways and means for breaking the present deadlock in the coal-mine labor question in the organized fields of the country, F. C. Honnold, secretary-treasurer of the Illinois Coal Operators’ Association, said they were going with open minds and sincerely hopeful that some appropriate and effective means would be found by which all of the anticipated benefits of such meeting could be obtained and the coal mines in all parts of the country put to work at an early date. The statement continued:

In their participation in such conference, however, the representatives from Illinois will continue to insist that, in their judgment, the coal industry as well as the public can expect to secure the best benefits only through state conferences.

“Throughout the past ten or more years the direct result of interstate negotiations has developed discriminatory and burdensome conditions in the working agreement with the miners in this state, due to the fact that the Illinois miners are both more closely organized and greater in number than in any other bituminous-coal-producing district, and on this account consideration has always been denied by the miners to every suggested change in working agreement that would permit of a reduction in the cost of coal, even when such changed conditions did not affect the annual earning capacity of the men.

“War conditions and practices as well as a sharp change in the tendencies and policies of mine-labor leaders and the increase of uncontrolled radicalism among the members have also brought about many new conditions that can be successfully reached only through local negotiations and adjustments. To a greater or less extent similar conditions prevail in the twenty-five or thirty other larger coal-producing districts in the country.

“It is therefore patent that no national consideration and adjustment of the coal-mine labor situation is at this time possible either through joint conferences of operators and miners or by a national arbitration commission.

“A national joint conference body covering all coal fields of the United States would be of such size and diversified opinion that such a method of procedure would accomplish nothing. By the same token consideration by a national arbitration commission of all of the numerous discriminatory conditions that have developed during the past 15 or 20 years would make an unsatisfactory grant and award until after the expiration of several months.

“A wage scale and working agreement calculated to best protect the public in all sections of the country must therefore be negotiated in smaller groups in order that both the miners and the public in such local districts may receive the greatest benefit. A scale of wages amply adequate and satisfactory in one section may not be sufficient in another, provisions for the mining of coal under a set of conditions prevailing in West Virginia, Maryland or Pennsylvania may be and as a matter of fact are unsatisfactory in Illinois mines.

“After 25 years’ experience in interstate collective bargaining, Illinois operators are convinced that this method of wage-scale negotiations has not only failed to justify itself either through benefit to the individual workman of the industry or to the public, but that, to the contrary, such method is distinctly prejudicial to the best interests of all parties concerned.

“It is also a discrimination against all those consuming sections of the country who are compelled to rely upon coal produced from unionized districts to pay a price for their coal that is predicated upon a wage scale made arbitrarily higher than that prevailing in non-union districts, where the right of employment is unbridled and management is unembarrassed by compulsory working conditions that are detrimental to public interests and that develop unnecessary coal cost and subsequent coal price.”

MOSCOW DISTRICT COAL OUTPUT.—Coal production in the Moscow basin in February amounted to 5,218,900, 99.7 per cent of the quantity demanded of it by the government. The output is considerably over that for January. The number of shifts working was 45.

NEW GERMAN BRIQUET PROCESS.—A German technical journal reports a new process for making hard-coal briquets without the addition of foreign binding material. By this method the fine coal is heated to the temperature at which the appearance of the slow combustion gases begins.
JULY 1 ushered in the expected rush for coal. This week has brought forth more inquiries and actual orders than have reached shippers for several weeks past. The sales offices of coal companies have been expressing wonder lately as to how long the many small consumers could hold out. They are getting their answer this week as orders for stock replenishment come in. Those who held off awaiting the reduction in freights have their answer in mine prices that more than take up the reduction. It is reported, for example, that wholesalers increased the price on Eastern coal in Milwaukee by 50c. following a freight-rate decrease of 35c. The consumer loses 15c.

Demand has by no means reached the peak on all markets, but Cincinnati reports activity exceeding that of war times and along the Atlantic seaboard nothing but the abundance of water-borne coal from the South has held prices within reason. Line points served by all-rail coal from northern West Virginia and Pennsylvania are feeling the effect of high prices.

Spot Price Index Reflects Strength of Market

Coal Age index of spot prices of bituminous coal reflects the strength of the market. From 234 on June 26, representing an average price of $3.44, the index on July 2 stood at 290, corresponding to an average mine price of $3.51 per net ton. Every advice indicates that nothing but the agreement of the operators with Mr. Hoover serves to hold the price in the South from reaching a new high level for this year.

When the country realizes the full import of the statement of the Geological Survey that five and a half million tons per week is the practical maximum for soft-coal production from mines now at work, due to lack of transportation facilities, and when it becomes apparent that the conferences at Washington now in progress show no sign of getting the men back in the mines for some time, the demand for coal will make still further gains. In other words, everything is heading up to produce a panic among buyers. The efforts of Washington are now the only hope for the consumer.

There is some lack of understanding, not yet cleared up by the government, with respect to the margin to be allowed the jobber. With the price at the mine up to the Hoover figure the jobber must either quit or exceed his agreement, or so it appears.

The anthracite deadlock, being discussed at Washington, naturally has aroused the consumer from his long period of indifference. Orders are flowing into the retailers for next winter's needs as the householder realizes that a rush period in the autumn is now sure. Retail stocks are fast going down and the dealer can do little else than file these orders for future attention. Pea is moving better and some of this coal is being used as a substitute for the scarce steam sizes. River barley is in increasing demand and prices are up.

No announcement has been made as yet as to the attitude of the producing companies regarding the levying of the Pennsylvania coal tax, pending the appeal to the high court.

The coke market is strong but not panicky. There is so little tonnage offering that spirited bidding is being done. While the output has been increased it is very little help to the market, as most of it is by furnace interests.

BITUMINOUS

“The thirteenth week of the coal strike has been marked by a recurrence of traffic congestion in certain of the non-union fields, and as there has been no compensating increase in the fields affected by the strike, production of bituminous coal will be slightly less than in the week preceding," says the Geological Survey. "Production of anthracite is still practically zero.

“Complete returns for the twelfth week (June 19-24) show a production of 5,337,000 net tons of bituminous coal and 24,000 net tons of anthracite, a total of all coal of 5,361,000 tons. In the corresponding week a year ago the total raised, including anthracite, was 9,550,000 tons. In 1920, when business was active, it was 11,900,000 tons. In

terms of all coal, therefore, the quantity now being mined weekly is 5 or 6 million tons below normal.

The situation opened with a production at a high rate. Loadings on Monday, June 26, were 16,735 cars, the largest on any Monday since the strike began. But on Tuesday, and again on Wednesday, congestion on the railroads serving southeastern Kentucky and parts of southern West Virginia began to curtail production and loadings fell off 1,000 cars. By Thursday, however, the congestion was lessening and 16,411 cars were loaded. Present indications therefore point to a total output for the week of less than 5,300,000 tons.

"The decrease in loadings is reported to be due not to scarcity of cars but to inability to move them faster than a certain limit set by the existing yard and track facilities, and it is to be noted that the railroads concerned are making new records in volume of traffic handled. Production in the non-union fields of the Middle Appalachians has reached a maximum and further gains in output are not to be expected except as mines hitherto closed by the strike resume operations. During the past week the increase in the non-union fields of Pennsylvania has been slight. In none of the strongly organized districts has work been resumed."

The rising markets on the Eastern seaboard have caused the British stevedores to look this way for an outlet. A Massachusetts port has received the first cargo of Newcastle coal and a few others are under load or on the way.

All-rail movement to New England was 669 cars during the week ended June 24. This was an increase of 155 cars as compared with the previous week. Prices on central Pennsylvania grades are firmer, but the New England market presents a poor outlook for these coals, due to the severe competition from Hampton Roads.

Dumpling at Hampton Roads for all accounts were 494,182 net tons during the week ended June 29, as compared with 450,231 tons in the preceding week. New England and North Atlantic ports are taking the bulk of this tonnage. Shippers are pulling so much of this coal into Baltimore, Philadelphia and New York, at attractive prices, that these Southern coals are the main factor in keeping down the Tidewater price on all-rail fuel. Prices Inland
from North Atlantic ports thus exceed the quotations at
the piers.

Northwestern fuel buyers are now fully aroused to the
possibility of a shortage next winter and are canvassing
the docks for tonnage. These stocks are so low, however,
that with one exception order taking is very limited. One
dock company is still accepting orders and is even shaving
prices in an endeavor to clear away the high-priced coal
accumulated this season, it being the heaviest receiver of
cargoes at the Head-of-the-Lakes this season. Congested
roads and a strong market elsewhere are holding down
the movement to the lower ports. It is this price factor that
has deterred Lake buyers all season—no one wants to
stock heavily when lower prices may be just around the
corner.

COKE

Beehive coke production increased to 109,000 net tons
during the week ended June 24 from 106,000 in the pre-
ceding week. Additional Connellsville ovens are being
fired, but the increased production is largely by furnace
interests and is off the market, which is very strong. It
is doubtful if any furnace would pay present coke prices,
as the pig-iron market would not justify it. The extremely
limited coke offerings are therefore being taken by foundries
and miscellaneous users rather than by furnaces.

ANTHRACITE

Production of anthracite is still confined to steam coal
dredged from the rivers. The scarcity of fuel, however, is
causin ged increased activity and production is larger, approx-
imately 24,000 net tons being produced during the week
ended June 24, a gain of 2,000 tons over the preceding week.
Retail stocks are dwindling as consumers are placing
more orders. The prominence of strike news in the papers
has impelled many householders to seek their next winter's
requirements. Actual deliveries are necessarily low, how-
ever, and much of this deferred business will fall into the
rush period after the strike has been settled.
Foreign Market
And Export News

British Trade Feels Export Slump

British production during the week ended June 7 was 4,350,000 gross tons, according to a cable to Coal Age, a partial recovery from the severe slump of the previous week. Prices show no strength as the supply is still tophaype. The Durham trade is very poor. Orders which have materialized lately are so spread over long periods that their effect on the market is practically nil. Several contracts for home public undertakings are the only ones to be recorded.

The Northumberland pits are better off. There is an improved demand for all steam varieties and the pits will remain active until the middle of July. The Swedish State Railways have asked for tenders for 25,000 tons of best steams, either Durhams, Northumberland or Scottish coals.

The South Wales market is uncertain and prices unsteady. Some producers are facing a shutdown. Wales has few contracts to report. The Argentine Department of Navigation and Ports has ordered 25,000 tons for delivery from August to the end of the year, and the Midland Great Western Railway of Ireland will require about 100,000 tons during the next twelve months.

Following the coal owners’ recent intimation of a coming reduction of wages notices of the reduction, effective Aug. 1, are now being posted in the collieries. The wages of employees receiving 24s. and upward per shift will be reduced by 2s. per shift and those receiving less will suffer a proportionate reduction.

Substantial reductions in the prices of domestic coal have been announced. These reductions in most cases amount to around 9s. per ton in the London area.

Strike Further Curtails Exports

That the strike curtailed exports during May is shown by the report of the Bureau of Foreign & Domestic Commerce. Only 399,551 gross tons of bituminous coal were shipped in that month, as compared with over 700,000 during April. In May of last year our exports were 2,500,374 tons, much of the tonnage being shipped as a result of the British strike.

Paragrapghs from Foreign Lands

ITALY — The price of Cardiff steam first is now 37s. 3d., according to a cable to Coal Age, a slight decline from last week’s quotation of 37s. 9d.

GERMANY — Production of coal in the Ruhr district during the week ended June 17 was 1,593,000 metric tons, cabled to Coal Age. The output during the preceding week was 1,447,000 tons.

NORWAY — The Norwegian Spitsbergen Coal Co. has been very active during the winter. The output has been up to 3,000 tons, and over 300 men have been employed. Shipping will go on during this season both to North Norway and Christiansia.

French Secure More Coal Markets

All things considered, the market for French coals remains rather satisfactory. Sarre collieries are developing their sales to Central Europe, and they are now sending increased tonnages to Germany (where they recently sold large quantities to the State railways), to Switzerland, Italy and Austria. They have just sold 50,000 tons of flaming run-of-mine to the Vienna Electrical Works at the price of 54,000 Austrian crowns per ton at the German-Austrian frontier, which is yet below the price in Austria of Czecho-Slovak or Upper-Silesian coal.

The 2-fr. rise of the British pound within the last 10 days has partly whittled down the difference in price, some Italian markets, between French and imported British coals.

Release of July 1 Orders Has Strengthening Effect

Industries That Awaited Lower Freights Find Higher Mine Prices Now—Good Coal Scarcе—Line Demand Greater Than Tidewater—Prices Lower at Tide—Eyes on Washington.

JULY 1 released many orders and strengthened the market. A number of industries had been running short of coal, but had delayed purchasing in order to obtain the benefit of the lowered freights. Mine prices have advanced, however, and it is doubtful if any material saving has been effected by this procedure. Good coals are difficult to obtain, being well sold up and unclassified fuels are about all that are offering.

Line demand exceeds that at Tidewater. Prices are lower at Tidewater, where heavy shipments of Southern coals are being taken at attractive prices. The trade is watching the Washington conference, hopeful that an early resumption of union mining will result.

PHILADELPHIA

The buyer’s interest increases, although there has been considerable hesitancy of orders in view of the conference called by the President. Since so many of the consumers, especially the moderate users, have held off so long, they are taking a little more time to get a perspective on what may be established at the meeting. On the other hand there were some orders let loose, without a doubt, on account of the lowered freight rate, and on the whole buying has been better.

Buying has actually been in advance of the increase in non-union production which has been claimed. The demand for the highest quality coals has become such that they are almost unobtainable except by the largest buyers and on contracts. Many houses are unable to get anything but unclassified coals, somewhat similar to Pool 10, and considerably lower.

A new factor entering into demand lately has been increasing inquiries coming from plants of considerable size who during the past few years adopted crude oil as a fuel. On account of the greatly increased demand for gasoline, as well as the advancing prices, producers are “cracking” all their crude for the last possible drop of “gas” and are not anxious to renew fuel contracts.

NEW YORK

Many inquiries were received at the end of last week for July delivery. Consumers as a rule put in sufficient coal to last three months. With their reserve supply nearly gone these consumers are becoming anxious.

Supplies at Tidewater are gradually growing short. On June 29 there were less than 1,100 cars at the piers, the smallest number in many weeks, but sufficient to meet all immediate demands. With the new holiday approaching shippers expected that there would be a substantial increase in the number of cars at the piers when business was resumed on July 5.

It was anticipated a new Clearfield rate to New York will be $2.74 instead of $3.11, and that the rate from the Fairmont region will be $2.95 instead of $3.36. Whether or not demand will now increase remains to be seen.

The low quotations for Pennsylvania coals at the local piers are due, many dealers declare to the heavy receipts of Southern coal here. Quotations for the latter ranged July 17 at $7.75 per ton alongside.

The new freight rates from New York have not yet been officially published, but we understand that the freight on anthracite domestic will be $2.34 per gross ton and on pea and smaller coals $2.84. Bituminous coal from Clearfield and Meyersdale now takes a rate of $2.74, Greensburg, $2.84, Westmoreland and Fairmont, $2.99, and Pittsburgh, $3.14. These rates are all to the lower ports; 5c. additional is charged to upper ports.

CENTRAL PENNSYLVANIA

United Mine Workers are devoting their time and attention to visiting local unions and encouraging the miners on strike to stick to the ranks. President John Brophy states that the morale of the men is good and that the situation is improving, as more miners join the locals and desert their work.

From the operators comes the report that production is increasing and has been more than doubled during June over May. The Central Pennsylvania Coal Producers Association held a meeting in Altoona on June 27, but gave nothing out as to whether any action has been taken relative to resuming operations. The principal gain in production is noted in the Windsor district where the Berwind-White Company has extensive mining operations.

BALTIMORE

A number of industries are running short and it is becoming more difficult to assure purchasers. More consumers are in the market every day and they are paying any reasonable price. Bunker coals are extremely scarce, the price at the piers being around $7.30 trimmed.

Baltimore is still getting oil considerable coal from Hampton Roads, and the pioneer move in this trade has been joined by other interests in bringing Pocahontas and New River fuels up the Chesapeake Bay. None of this coal is sold to local consumers, but a great part of it is reloaded for transshipment. This coal can be moved to Baltimore at $2.25 per ton, which brings it below the present cost of fuels offered in bunker trade at the local piers. The present price at the local piers is probably influenced by the fact that the heavy tonnage shipped to the piers has outstripped the demand.

From mining regions came confidential reports that the miners are growing short of funds and are becoming desperate. Only the fact that the union leaders have been using the talk of a railroad strike for July as a weapon has prevented a number of miners from returning to work, irrespective of union connections. Many of the private advices received here predict that the unions will begin to slip seriously before mid-July. There is a growing belief that the mine strike in a number of regions is near its close.

FAIRMONT

With surplus stocks in the East getting low, there was a perceptible stiffening in demand and a recovery in prices during the week. The price of coal at the Fairmont is $2.45, notwithstanding the fact that many consumers had been waiting for the advent of July with its lower freight rates. Production is still climbing, having reached a daily average of 25,000 tons. There was a marked increase in the number of mines in operation, 177 plants running on an open-shop basis, and Disturbances are somewhat more general among the strikers as they realized that there were defections in their ranks.

UPPER POTOMAC

Not only are mines gradually resuming production, but increased output at all operations owing to the larger number of men reporting for work. Sentiment for a return to work is growing among the miners and disturbances are at a minimum. Prices have advanced and all at the maximum, owing to a marked increase in demand.

West

KANSAS CITY

There is a quiet tone to the market. The wheat threshers laid in a supply early from Colorado and New Mexico, and there is practically no demand for domestic grades. Steam grades are in demand to some extent and as some mining operations have been shut down, the production is taking good care of it. Prices are unchanged.

In the Kansas fields, the miners are about equally divided between the Howat following and the national organization, and this fact no doubt has helped to keep the peace in that district. Most all of the miners that are digging coal are home owned and as they are of the radical element, no trouble is anticipated, for, as is general in all coal fields, the radical element rules.

A chestnut size of anthracite from New Mexico is being offered at retail in Kansas City at $11.25 per net ton. If this is any indication of what prices will be before the close of the year, it looks like the elimination of anthracite from Pennsylvania and a very low price for Arkansas anthracite and smokeless, which are the popular grades of domestic coal in this market.
Anthracite

Strike News, Rail and Coal, Brings More Retail Orders
Many Yards Cleared of All but Pea Coal—Consumers Able Only to Place "Applications" Pending Arrival of Replenishments—No Announcement on Pennsylvania Tax.

I NCREASING prominence of strike news—rail and coal—brought more retail orders and has cleared many yards of nearly all stocks except pea coal. The Washington conference has aroused consumers to the gravity of the situation, but retailers can do little but take "applications" for next winter's needs.

No announcement has been made as yet regarding the attitude of companies as to levying of the Pennsylvania coal tax, pending appeal to the high court.

Some pea coal is moving for steam use and mine stocks are going down. River barley is in increasing demand, production is heavier, and prices up.

NEW YORK

The efforts of the authorities at Washington to settle the mine troubles has resulted in more of the public's attention being focused on the situation. Consumers have at least seemingly become aware that they might have difficulty in getting their next winter's coal supply. Retail yards are about empty of the sizes generally used and the dealers themselves are beginning to see dark clouds ahead.

Disbarment hearing here of the decision of the Pennsylvania Courts declaring the coal tax law constitutional. Nothing has been announced as to the attitude to be taken by the companies reported to be levying the tax, pending the probable appeal to the United States Court.

Buyers are still able to pick up some buckwheat coal but it is not plentiful. River barley is coming into this market, quotations ranging $1.90@$2.15, at point of loading. Regular independent barley was scarce, but some shippers were reported as quoting $3.50 for stock coal.

BOSTON

News items from Washington have somewhat allayed public anxiety, but they come at a time when retail dealers have all the business they can possibly take care of, present stocks considered. It will be hardly more than a fortnight before the larger retailers will be in position to take nothing but "applications" for stove and chestnut. The trade is much interested in reports of a cargo of Welsh anthracite en route to New Bedford. The delivered cost is understood to be around $13.50, but opinion is as yet uncertain whether the cargo is for one retailer or whether it is to be divided up for distribution among several dealers.

BALTIMORE

The prospective rail troubles and the fact that the anthracite situation remains unsolved are menacing hard coal consumers. An inspection of the storage yards shows that there is not more than a total of several thousand tons, at most, in this city.

No hard coal is offering here. Some semi-bituminous is being brought to Baltimore and offered as a substitute, but so far is being received without enthusiasm.

PHILADELPHIA

There could not help being considerable change in the retail business, with the increasing prominence of strike news—coal and rail—in the daily papers. Even though the most prominent news seemed to promise some sort of a settlement of the coal strike through Government intervention, it would seem that the coal user was most affected by the threat of a rail tie-up. At least this was the inference of the dealers, all of whom have been called on this week to deliver coal. So strong was the demand on some of them that they all are out of everything but pea.

In accord with their belief of an early ending of the strike the retailers have slightly let up in their demand for storage pea coal, at least this size has lost some of the momentum it had been acquiring during the past three weeks.

With the exception of an occasional stray car of buckwheat the only steam coal offering is river barley and the producers of this fuel are gradually getting their price up. Recently there has been quoted a range of $2.50@$2.75 and some sales made. Thus is the advantage of the new rates of freight quickly lost.

ANTHRAHITE FIELDS

A count of the votes recently taken shows an overwhelming majority cast in favor of giving the general scale or policy committee authority to call a strike, if necessary. Action is being deferred, however, pending the outcome of the conference at Washington, called by the President.

A split has occurred in the union ranks in District 1, where an organizer has defied the local leader's order of dismissal and has secured the endorsement of 4,000 of the men. Some picketing is being done at the Woodward Company and by both the Pittsburgh Coal Co. and at the East Boston Coal Co., but otherwise the region is quiet.

BUFFALO

The lack of interest in the general market continues. Jobbers can do little more than keep in touch with the supply and wait for special needs. They quote $7@7.25 for 48-hr., Connellsville, and $8.60 for 48-hr. furnace and $4.25 for stock.

CONNELSVILLE

While production of coke continues to increase slowly, the amount offered in the open market, yet prices have not increased as at all the heavier production being by furnace interests, particularly the Frick company. The iron and steel industry shows that it is not merely maintaining its supplies of coke and coal, but is increasing them somewhat. Byproduct production continues heavy and there is probably more coke coming from West Virginia, supplementing the increased production in the Connellsville region.

Offerings of coke being very limited and there being foundries and mislabeled users who must have coke, prices have been bid up further even though it is doubtful whether any further increase would push the spot price of pig iron not justifying. It is claimed that all the coke offered now in the open market is of indifferent quality, under the distinction of "foundry" coke is lost, the market being simply for "coke."

The Courier reports coke production during the week ended June 24 at 72,700 tons by the furnace ovens, and 15,360 tons by the merchant ovens, a total of 88,060 tons, an increase of 1,200 tons.
Premium Prices Prevail, But Buying Is Backward

Congestion and Shortage of Cars in Kentucky Curtail Offerings—Only Perfunctory Sales Efforts Made With Output Largely Contracted For—Screenings Very Scarcе.

COAL was more or less at a premium on the Chicago market last week even if consumers were indisposed to buy heavily. Orders were held up as a rule because of the lower freight rates, yet prices climbed daily in the western Kentucky field and on Saturday they had reached the high mark of $4.60. A growing car congestion and shortage in the Kentucky districts made the offerings lighter each day and toward the end of the week operators were making small efforts to sell. The low production in Kentucky was pretty well contracted for and what coal was free was held at producers’ prices. Mine-run was offered at $4.50, and prepared sizes at $4.40@$4.50 at the close of the week, an advance of 25c.@35c. from the opening of the period. Screenings were a very scarce product at $4.60.

CHICAGO AND MIDWEST

Adding to the distressing car situation, locomotive equipment on the L. & N. in Kentucky was condemned and sold, but Western roads were reported sending in their own engines to haul coal for their own use. There was very little immediate buying in any of the fields reported by the railroads. Movements were on sales previously made.

Large industrials in Chicago permitted the week to drift by without any marked purchasing. What coal was taken was in small lots and there was no apparent concern over the threatened rail strike. Consumers were more affected by the news of the Washington conference and held hopes for the beginning of some kind of negotiations looking toward peace in the strike. Such a turn, it was said, will be the only thing that will break the present high Western Kentucky market. This probably had more influence on the buying than appeared on the surface. The docks at the Head of the lakes continued to call for eastern Kentucky coal, but demand for that coal was pretty well sold out and sales could not be made on any more orders. Prices in the eastern Kentucky fields remained at the Hoover mark, but only occasional reports of higher selling by jobbers. There were a number of inquiries reported from small industries and the country trade in Wisconsin, Michigan, Iowa and Illinois, as there were also in the western Kentucky fields.

West Virginia high-volatiles were in good demand at the high suggested by Secretary Hoover, and Pocahontas struggled along a little weaker at $3.25@$3.50 on mine run. The retail trade was reported as buying strong on the smokeless coals, under pressure of heavy inquiries from the weakened public and farmers who are demanding thrashing coal.

INDIANAPOLIS

Much more of an industrial demand for coal prevails. The fact that industries are running a little more than usual accounts for the activity displayed concerning prices and deliveries. The demand for domestic is quiet although there is a little winter fuel now being stored.

Prices are unchanged as far as domestic coal is concerned, inasmuch as the present supply was bought on a lower market than now prevails. In Indianapolis retailers are not disposed to buy much coal at the maximum price of $3.50, inasmuch as considerable of this coal sold on the spot market around $1.15@$2.oo.

West Virginia coal is being sold in Indianapolis while the western Kentucky grades also are being offered here with fewer takers. No Indiana coal from standard mines is on the market.

LOUISVILLE

There is a very active demand for coal, which has chased eastern Kentucky screenings up to $3.50, along with mine run. Some of the mines in the Straight Creek field are quoting $3.75 on all sizes.

Western Kentucky is getting good car supply and running on a steadily increasing tonnage basis. Labor is also plentiful, as a result of many miners from Illinois and Indiana coming into the district.

In eastern Kentucky some of the branch railroads are overburdened with tonnage, and this along with congestion at Cincinnati and other gateways, is holding back car loading. However, production is very heavy, mines operating at around 70 per cent of the capacity of the field, or better.

Jobbers report that the demand for coal is so active that it is more of a case of finding tonnage to sell, than of selling it, although many consumers are haggling over the top ten or fifteen cents a ton.

Retailers are buying a little better than they have been, retail prices being about $1.25, rather than they were in the early spring. Retailers there are worried over the threatened rail strike and long coal strike, figuring that coal will be scarce and high in the fall, with the result that they are making inquiries for prices.

WESTERN KENTUCKY

During the past few days demand has increased as a result of the threatening rail strike, reduced stocks in consumers’ hands and larger railroad consumption. There was a great deal of tonnage sold back bybuyers until after July 1, to secure freight rate reductions, which would result in a much heavier demand.

Quotations are $4.40@$4.50 for all sizes. It is not especially easy to secure the $4.50 level, but it is thought that $4.40 may be taken at 40c. Some of the jobbers had anticipated a break after the market reached the high level, but inquiry and demand continue strong, and it is expected that the price will hold.

Whether there will be any advance over the $4.50 level, which exceeds the price demanded before the Hoover conference, but not accepted by producers, the operators do not care to antagonize Washington, and there is a strong chance that the market will be held at that level.

The demand is picking up just a little, as retailers are getting better business from consumers who are afraid of the long strike making for higher prices and fall shortage. The threatened rail strike also scares consumers into stockpiling now. Retailers, however, are lucky where they are able to keep 40 per cent of their delivery equipment in service.

ST. LOUIS

There is a stronger evidence of buying on the part of large steam users. Storage piles are depleted and both Kentucky and Alabama coals are moving into this market, with west Kentucky favored on account of freight rates. The domestic demand continues quiet.

The country demand for threshing coal has slackened because the season is now on and dealers are afraid to purchase high-priced coal and have it arrive in the fall. The demand is perhaps after the threshing season is over.

Prevailing prices on west Kentucky coal in this market are $4.25 on mine run, and, although some prices have been quoted on 25-in. lump at $4.50 per ton at the mine, there seems to be nothing available but mine run and very little of that.

The fact that Mr. Lewis has been invited to Washington to attend a conference with the President with a view to starting negotiations between the miners and operators seems to have a good effect on the market. There has been a reduction of the prices this week being 25c.@40c. higher than they were a week ago.

SOUTHERN ILLINOIS

Since the disturbance in the vicinity of Marion and Herrin in the Carterville district has been instigated by local operators, it was anticipated that mining operations of any nature will be attempted until officially sanctioned by the United Mine Workers.

In the past two days sales have been made of some few cars of lump, egg and nut held in storage by operations on the Illinois Central, near Herrin, at $2.50, the Illinois Central district there is no tonnage available.

In the Standard district there are perhaps 2,000 tons in storage, all of which has been quoted at $4.50@$4.75. This is being loaded and shipped as rapidly as equipment is available and the cars can be loaded. This tonnage is principally on lines having mines located on their rails in the non-union fields and in which fields most of their equipment is at present engaged. Otherwise this small tonnage would have been moved long ago.
Northwest

Buyers Now Anxious, Having Too Long Held Off for Drop

Few Orders Being Taken—Shortage Seen Unless Mining Is Resumed Soon

—Milwaukee Price Advance Exceeds Freight Cuts—Duluth Dock Reductions
Price to Pare Heavy Stock.

The anxiety of buyers is growing. Many held off too long in the hope of lower costs while dock stocks slipped away to other users. Order taking is now infrequent and production must be resumed soon to overcome a definite shortage at the Head of the Lakes docks this winter.

At Milwaukee bituminous prices have been advanced 50c. per ton, more than absorbing the freight reduction of 35c. on all-rail coal. One dock in Duluth has cut its prices, but this move has not been followed by others. The cut is explained by the fact that the dock has been the heaviest taker of coal this season and was spurred to this action by the fear that a strike settlement would find it embarrassingly long on high-priced coal. It is this fear that has kept most docks from replenishing their stocks until new cost conditions can be determined.

DULUTH

An inexplicable weakening in prices has taken place at the Head of the Lakes. One dock has been reported as shuttered off from the market in order to insure orders. This dock is the one which has received the largest shipments this year, and it is thought that fear exists of a sudden ending of the strike and a surplus of high priced coal on hand.

Four cargoes of coal arrived last week and two were loaded out for lower ports. Two more cargoes are scheduled to go this week, and none are known to be on the way here from Lake Erie.

One indication of the scarcity of coal here is shown in the fact that vessel fuel has advanced and that docks are not loading these ships for the round trip as previously reported.

The anthracite situation is attracting considerable attention, and local consumers are filling their bins against a scarcity this winter. It is estimated that 1,100,000 tons more than the 300,000 tons now on docks will be needed to carry the territory through the winter. Unless the strike is settled by July 15 it will be physically impossible to get this amount of coal here.

Country dealers are not buying. The main factor controlling this is that they are in desperate straits financially. They have come through trying financial times and have many accounts receivable on their books which they are unable to collect. Their credit with the docks is nearly exhausted.

MINNEAPOLIS

Some coal buyers are beginning to get rather uneasy. They were well content to hold off as long as possible, but now that the season of navigation is about half gone, they are beginning to wonder if their strategy has been as satisfactory as could have been hoped. It is not too late for the Northwest to be easily provided for, if coal production is resumed soon. But there is no assurance that it will be resumed soon.

A number of the wholesale companies are not taking orders now, and those which will, would speedily be exhausted if any rush of business set in. Hence there is nothing that can be done by the buying trade but await developments. Some small business might be handled, but the stocks on hand are down to a small tonnage, after the coal covered by contract is excluded.

So the next few weeks will be rather anxious ones for the trade of the Northwest, unless there is something very tangible being done toward a resumption of production.

While the tonnage needed is much smaller, the hard coal situation is the most urgent here as elsewhere. It is probable that soft coal can be furnished from some field, sufficient to care for the most urgent needs of the Northwest. But hard coal production is at a standstill and there are no substitute fields nor coal available.

So the coal trade must needs await developments, earnestly wishing for some real action within a short time. Quotations are about withdrawn because of the scant stocks now available.

MILWAUKEE

There is an increasing demand from users of hard coal, who are becoming alarmed at the prospect of a shortage. As there is no other market, coal dealers are forced to decline orders or file them for future delivery.

Jobbers report that there is quite a demand for July shipments of soft coal, discounted from the new freight rates. The reduction amounts to about 35c. per ton on Eastern soft coal received by rail. Dealers have been notified that all soft coal, with the exception of anthracite, will be advanced 50c. for July. Western Kentucky and Alabama coals are now being offered.

An appeal has been sent to the State Railroad Commission by the Wisconsin Utilities Association requesting a relief from the coal shortage in Wisconsin. The average supply by utilities is sufficient only for but two or three weeks more.

Cargoes by Lake thus far this season aggregate 700 tons of anthracite screenings and 566,193 tons of soft coal, against 382,748 tons of anthracite and 1,104,170 tons of soft coal during the same period last year. Thus far this season 180,000 tons of soft coal have been delivered to Lake Michigan ports from Duluth. Milwaukee received one cargo, Eyovonca twin, and the remaining cargoes were delivered to Sheboygan.

New England

Inquiry Improves Somewhat, But Receipts Are No Heavier

Discounting of Freight Cut by Pocahontas and New River Shippers

Lower Prices Slightly—June Holdbacks Must Now Enter Market—Imports Interest Trade.

With the approach of July 1 there was somewhat better inquiry last week, both for spot cargoes and for shipment. Inland from rehandling plants at this end. Most of the Pocahontas and New River shippers have already discounted the 28c. reduction in tolls, and in consequence prices are modified a little as compared with a fortnight ago.

Receipts are no heavier, but buyers who waited through June are now obliged to enter the market for small tonnages. Arrival of foreign coal interests the trade.

Prices f.o.b. loading port range $6@$6.25. A few agencies are asking $6.44, this being the $3.50 Hoover price plus the reduced rate of freight from mines to the Roads.

After throwing out bids for July and August basis coal, one of the State Charitable Departments re-advertised and now has accepted new proposals on practically the same basis as the old. Contrary to the impression we gave a week ago, the rejection of the former bids was due to a misunderstanding with regard to the strike clause on the part of some of the bidders. In any case, the purchasers lost nothing by waiting.

The trade is much interested in cargoes of Newcastle coal that have begun arriving at this port. The first cargo was unloaded at the N.Y., N.H. & H.R.R. wharf and is assumed to be for engine supply, the delivered price being rumored around $6.40.

What small output of Pennsylvania coals happens to be offered is quoted at somewhat higher levels. Several mines that went on strike now shut down, due doubtless to the tragedy at Herrin, III. Receipts all-rail continue very light.

Coastwise freight rates are on the same easy basis reported last week. Steamers can be had at 90c@$1, with smaller bottoms, either barges or sailing vessels, at a range of $1.10@$1.25.
Freight and Rail Strike

Tend to Enliven Demand

Some hesitancy shown pending outcome of Washington Parley—Prices are at Hoover level and strong—Heavy Movement from Producing Fields causes congestion of Loaded Cars.

The Washington conference has created some buying hesitancy on the part of consumers in the hope that mining may be resumed and lower prices follow. Despite this factor, there is an increased demand, as July 1 released many orders which had been held in abeyance until the freight reduction became effective. The rail trouble is another factor in enlivening demand.

Coal prices are strong, being at the Hoover level, and in the case of Connellsville, $3.75. There is some congestion of loaded cars, due to the heavy volume rolling from the few producing fields and a troublesome coal shortage is predicted when reserves are being built up again.

CLEVELAND

The past week has uncovered a broader and more insistent demand than in a similar period since the beginning of the strike. Numerous consumers had been holding off ordering until after the freight reductions became effective. This event together with the rapidly dwindling stocks has helped to liven up the market. Prices continue firmer.

Operators are optimistic regarding a settlement of the strike as a result of the negotiations initiated by the administration. They insist that every week’s delay in resumption of full-time production will make a coal shortage this winter that much more probable. Only the lack of realization of the facts in the general situation has prevented any rush to buy, according to some opinions.

Greatest concern now is being felt over the Northwest. With upper docks cleaning up and with only a small fraction of the 23,000,000 tons required in that territory shipped, congestion or actual shortage is feared. Some operators are looking for a car shortage when output is started in full swing and when crop movements get under way.

COLUMBUS

A stronger demand for all grades has developed. With reserve stocks becoming depleted and with industrial revival coming on there is a more widespread call. Quotations have advanced to almost the Hoover level. In a few instances some quotations above this have been made but has brought no orders.

Retailers are still cleaning up but are fairly well sold out and will soon be in a position to take in some stock. Household consumers are getting rather anxious over the prolonged strike and are calling in a frame of mind to lay in stocks for the winter. Retail prices are growing stronger in sympathy with higher prices at the mines.

Lake business is becoming more active. The H. V. Docks at Toledo during the week ended June 28 loaded 114,000 tons, making a total of 1,131,490 tons for the season. No coal has been loaded by the T. & O. C. docks at Toledo.

PITTSBURGH

Just before President Harding called the market conference operators and miners officially for July 1 the rumors that an effort would be made in the first week of July to start some of the mines in the Pittsburgh district to work harder, but since this call was issued the rumors have been in abeyance. The general feeling is that there is much doubt whether the President’s efforts will lead to a settlement and while the common estimate is that even if they should, a month or so would probably be consumed.

The opinion of the trade for some time past has been that whenever a settlement should be reached coal would not become plentiful for quite a while. This explains the making of 60 and 90-day contracts for some time past, without much thought being given to the ending of the strike.

One cannot find in the coal market any weakening traceable to the Washington efforts to end the strike, while on the other hand some buyers are holding off for a railroad strike somewhat seriously and are not anxious to buy. The Connellsville steam coal market, which is almost all the coal marketed in Pittsburgh, quickly regained the slight loss in strength reported a week ago and has since stiffened farther, being now quite firm.

It is notable that there is but little price range now, and this is probably attributable to buyers taking a firm stand instead of huddling freely for tonnage. There is a fairly wide market, with numerous small sales, though but little more tonnage than a month ago. At no time has the market gone above the $4.59 price which the Connellsville operators wished Secretary Hoover to countenance.

DETOIT

Sluggishness and inertia continue the predominating condition of the market for bituminous. Wholesalers and jobbers are still waiting for the increased volume of business that was forecasted to come in after July 1. Its materialization apparently will be slow. Even the talk of a possible strike of railroad employees has failed to bring anything active demand.

From the jobbers’ point of view the present indifference of buyers is creating a situation that will develop into a shortage later in the year. Warnings already are being given of the probable development of coal shortage and freight traffic congestion on the railroads within a few weeks.

Smokless lump and egg is quoted $3.50. West Virginia or Kentucky lump and egg holds about the same level. Mine run is bringing $3.25 and nut, pea and slack holds around $3.10.

EASTERN OHIO

Reports of activities in the trade indicate that demand is increasing. A factor which has been a part of the present shortage is the anticipation that the present conference at Washington will result in the early resumption of用人单位, which time they expect to be able to cover their fuel needs at prices considerably under those prevailing at this time. There has not yet developed with the rank and file of industry any situation of dire straits for coal.

There has been some interference with stripping mine operations, this apparently being well on the increase. The recent outrage at Herrin, Ill. At Lafferty, Ohio, one steam shovel operator was killed and several other workers injured. Notwithstanding this interference, the stripping mines continue to produce some 40,000 tons per week.

Spot prices stiffened somewhat early in the week but have since reacted. Eastern Ohio strip runs from $3.30 to $3.40 and slack and mine run is $3.80 to $3.90, lump sizes, $4.25; eastern Ohio deep mine and No. 6 mine run, $3.75.

Receipts of bituminous coal at Cleveland during the week ended June 24 showed a decrease of 128 cars under the preceding week; industries received 995 cars, retail yards 101 cars, total 1,195.

BUFFALO

As the time progresses the inquiry increases and there is now quite an improvement in the general movement. In fact the outlook is so encouraging that a certain shipper confesses that he is holding coal on track and paying demurrage, with the idea of making money on the venture.

Still there is the bear in the trade who does not believe there is going to be a furry. He takes the position that manufacturers cannot afford to buy $5 June prices, a little higher, to which some concern with that coal for heating and this must be supplied at whatever price. All of which goes to show that nobody can tell now just what is likely to happen.

While it does not seem proper to quote coal higher than last week, it is certainly growing stronger, at $4@4.25 for 2-in. lump and $3.75@4 for mine run and slack, with the latter rather more active. The new freight rates to be added are $2.00 from Allegheny Valley, $2.24 for Pittsburgh and No. 8, with a rate for occasional shipments from the Connellsville district of $2.39.

NORTHERN PANHANDLE

The effects of the strike are being felt to some extent. All but two or three mines are running regularly. Most plants are now entirely free from any disturbance or demonstrations. During the closing days of June prices were a little firmer, the general range on mine run and slack being $3.50@$3.75.
Cincinnati Gateway

Flood of Inquiries Puts Hoover Prices to Test
Wholesalers and Jobbers Hard Put to Keep in Bounds—Big Industrial Buyers Find Retailers Competing for Fuel—Mines Ask Limit Prices.

The opening of July saw this market flooded with inquiries and most of the wholesalers and jobbers fighting an uphill task of keeping within the bounds set by Secretary Hoover. Lake, railroad and steam buyers, all of whom have been prominent in purchases for the past two weeks, saw the retailers stepping in for their share of the small doles that are being sent out from the union fields to be spread over constantly increasing demands for fuel.

The result has been an unprecedented endeavor to get coal and had there been no restraint placed upon prices as set by the government there is no telling where the values would have gone to. As it is, buyers are going directly to the mines, which are taking the full Hoover price, threatening to eliminate the wholesalers.

CINCINNATI

Both in volume of business and strength of inquiries the stiffest of the post bellum business can hardly compare with the fight that is being made for coal. Not alone was the lower freight rate inducement before the buyers, but there was a period of inactivity that has to be reckoned with for there will be little coal produced between the last day of June and July 5, and at this time every pound of coal that does not go into the cars leaves just that bigger a hole to fill.

Producers in the southeastern coal field of Kentucky and those in the Elk Horn and on the N. & W. are awaiting the full Hoover price. There have been talk of “premiums” being paid to get coal, but this is hard to trace to an actuality. The fact remains, however, that the buyers are going to the mines direct and many of these are taking the full Hoover price. This condition caused J. C. Layne of the Fair Price Company, and Mr. Hoover the latter to set up a system of affairs and who asked that specific incidents of such practices be forwarded to the Department of Commerce in Washington.

Retailers have issued a warning to buyers to get in their coal and say that if the maximum government price continues for any length of time they will be forced to a higher level. In answer to a request from Julius H. Barnes that a price committee be named the local Chamber of Commerce answered that Cincinnati prices were 60 cents below those that would have been allowed.

LOW-VOLATILE FIELDS

NEW RIVER AND THE GULF

The effect of a strike in the New River field has been reduced, owing to the progress made by producers in resuming operations. The output lacks about a shortage of labor and Market conditions were somewhat more conducive to a larger production. With the possibility of a rail strike, buyers have entered the market again and there is a fairly large volume moving to eastern and western markets.

Gulf mines are managing to maintain production at about 30,000 tons a day although having a shortage of labor to contend with and experiencing further trouble in securing the prompt placement of cars. The Virginian has been found to supply all the eminently needed. Mines were placing a large part of their output at Tidewater during the closing days of the month. Spot prices were on a somewhat higher level, the range being $2.25@$2.50.

POCAHONTAS AND TUG RIVER

Labor shortage losses were reduced to some extent in the Pocahontas region, but there was little or no gain in production, owing to tardiness of the railroad in delivering cars, growing out of congestion. The Norfolk & Western is taxed to the limit in attempting to handle the tremendous tonnage originating in the Pocahontas region. Prices have hardened somewhat, though they hardly reach the maximum.

Tug River mines are producing almost 115,000 tons a week. Operators find themselves somewhat handicapped by inability to secure placement of equipment as producers are attempting to handle the tremendous tonnage originating in the Pocahontas region. The demand for byproduct in the Western market is active and a large part of the output is being consigned to Western points.

HIGH-VOLATILE FIELDS

KANAWHA

Operators are gradually overcoming the effects of a strike, as disclosed by the fact that nearly 100 mines are now placing current conditions and promises of protection in the event of any future agreement with the union are encouraging men to return to work. The demand was a little stronger toward the close of the week and one producer was the fact that stocks were dwindling and that there was a possibility of a rail strike. This brought prices near the maximum, with minimum strong at $3.90.

LOGAN AND Thacker

Logan production is well over 350,000 tons a week. Coal trains are being given the right of way over all other traffic and the movement to the Lakes and to other Western points is heavier than it has ever been. Congestion in

yards and on sidings was somewhat in evidence during the latter part of June. There is expected to be a rush for coal during July but producers will not be able to handle much more business.

Thacker mines are operating virtually at capacity. There has been more or less delay in placing cars owing to congestion and the crowded conditions of sidings and on the loading yards. More miners could be used if they were available. Toward the close of the month there appeared to be a further increase in production. Prices showed a tendency to stiffen and were not far below the maximum.

NORTHEASTERN KENTUCKY

After holding back for a month for lower freight rates consumers are securing more coal and this has appreciably stiffened the demand for all grades. Transportation difficulties, however, are holding back production, all lines being badly congested. Mine run is averaging $8.25 or better, with lump bringing $8.50@$8.75.

South

BIRMINGHAM

Alabama mines are moving a large tonnage to Western points and new business is being booked for emergency users, there being a good demand for medium and lower grades of mine run, and some better inquiry for Cabah, Black Creek and other lower-quality fuels. It is estimated that from 40,000 to 50,000 tons of steam coal is being disposed of in foreign markets and in the domestic territory.

Bonner is still restricted in the territory normally supplied, but the lowering of freight charges is having a stimulating effect. Domestic dealers are beginning to expect more interest in buying for future supply, and the lower and medium quality coals which have been hard to move, are in somewhat better demand.

Quotations f.o.b. mines follow:

<table>
<thead>
<tr>
<th>Washed</th>
<th>Lump and Edge</th>
</tr>
</thead>
<tbody>
<tr>

<tr>
<td>Montevallo</td>
<td>2.50@$2.75</td>
</tr>
</tbody>
</table>

Both commercial and furnace company mines are operating on better schedules and production is on the increase in all parts of the district. There is some shortage of skilled labor.

VIRGINIA

With the demand somewhat stronger during the closing days of the week and during preceding weeks, production being almost equal to capacity in some sections of the district. Consumers had been without holding orders for production of furnace coals, but seem to have become somewhat alarmed as to a railroad strike. Car and labor shortage losses are the principal items in this territory. Mine run is holding up the best in point of demand, domestic sizes have a little better market, as retailers have commenced to replenish their stocks.
ALABAMA

The County Coal Co. is making extensive improvements on its properties in the County, Tuscaloosa and Birmingham districts, where work is being under way on a spur track for connecting with the larger system of the company's lines. The steel bridge over the Cahaba River is practically completed and work is being pushed on the other steel bridges that steel tipples will be built at the junctions of the new lines. The work is being done under the supervision of the company's engineers.

The company is also getting under way on a large road-building project, and plans are being made to put in new machinery to meet the increased demand for coal. The company is looking to the future with confidence and is planning to expand its operations in all directions.

INDIANA

The State of Indiana has started a test suit against the Western Indiana Company for damages sustained by the property of the company from the Elwood district of Indiana. The suit was filed against the Western Indiana Coal Co. of Terre Haute, to ascertain who owns the coal under the Wabash River in that county. The suit was filed against the company under the provisions of the law which authorizes the state to recover damages sustained by its property from trespassing on its lands.

The suit charges that the company has taken and used the coal from beneath the river bed. The first question to be determined is whether the river is navigable in Vigo County. If it is found to be true, the State of Indiana is in possession of its claim to ownership of coal that has been taken out and used for navigation.

The case is now under the jurisdiction of the State's attorney, who will prosecute it. The company will make a demand for the return of the property and if it is not returned, it will enter a counterclaim for damages sustained by the company from the trespass.

The case is important to the company, as it involves the right to use the river for navigation, and the company is determined to recover its property and hold it against the State of Indiana.

MISSOURI

As soon as a suitable site is definitely decided upon, construction work will be begun on the new main coal yard. The company has purchased a tract of 4,000 acres of land at a cost of $18 million, and has been conducting extensive surveys and engineering work to determine the best location for the new yard.

Construction will begin immediately, and the work will be carried on in two phases. The first phase will be the construction of the main plant, including the main building, offices, and other necessary structures. The second phase will be the construction of the coal yard, including the ruins, hoppers, and other necessary structures.

The company is preparing to begin operations at the new yard in 1899, and is determined to make it one of the largest and most modern yards in the country.

NEW YORK

The Pittsburgh Fuel Co. has leased from the state of New York for a term of forty-two years, the water front property at 125th St. and the Harlem River, New York. A coal plant consisting of eight coke ovens,四个 coke ovens, and other modern equipment will be erected on the property.

The Rubel Coal & Ice Co., of East New York, Brooklyn, recently purchased the Jamaica Coal Co., and is now in possession of the coal at Ozone Park, Elyria Hills, and the Hyatt-wood Coal Co., of Jamaica.

Anson W. Burchard, vice-chairman of the board of directors of the Electric Steel Co., has been elected president and chairman of the board of directors of the International General Electric Co., succeeding Mr. J. F. A. Jenks, who was recently chosen president of the two companies, and Charles Neave, former chairman of the L. G. E. Co., in the election.

Nearly four million tons of coal and coke were consumed in supplying Greater New York during 1921, according to reports filed by the gas and electric companies with the Public Service Commission. Of this tonnage the gas companies used 1,744,620 tons, coke and the electric companies 2,185,876 tons, in the production of steam and electricity.

In the same period two of the gas companies made 425,145 tons of coke, of which they sold 281,039 tons and sold 144,659 tons.

OHIO

Opposing views of operators and mine workers on the strike which has tied up all Ohio producing for the fifth month in a row were presented before the annual meeting of the Columbus Chamber of Commerce by W. D. McKinney, secretary of the Western Ohio District, who represents the operators, and Lee Hall, secretary of the Ohio District, who represents the workers. Each speaker was allowed 20 minutes to develop his side of the question.

The meeting has been managed by H. H. Liggett, president of the Liggett Brothers Coal Co., Cincinnati, that his company had signed a mine workers' contract with the Liggett Coal Mining Co. of Canton, was present. The company has planned to erect hoppers in its storage yards at a cost of $25,000.

The White-Barr Coal Co., Cincinnati, has been chartering vessels with a capital of $30,000 by W. L. Barr and others.

The Rutledge Coal & Mining Co., Toronto, has returned to operating and is using the mine and mine coal in the eastern Ohio field. Among the incorporators are James W. Rutledge & Co.

The C. D. Peters Ice & Coal Co., Cincinnati, has been chartering vessels with a capital of $25,000 to do a retail business by C. D. Peters, S. C. Domahuc and others.

A. Wright, president of the New Coal & Coke Co., has returned to his headquarters in Cincinnati after a brief absence due to sickness. He makes the recovery of $10,144,07, which has been negotiated for a contract for domestic use in Cincinnati, smokeless coal, and is now more and more into vogue in that city.

The United States District Judge John W. Drink Wurzburg, in the case of the United States v. Ohio Coal Co., held a meeting for filing of a new action, the suit of the Tidblades Coal Co., Cincinnati, against H. D. C. Peters, including all other parties in interest. The recovery of $10,144,07, which has been negotiated for a contract for domestic use in Cincinnati, smokeless coal, and is now more and more into vogue in that city.

Southern and Kentucky coal dealers at the Cincinnati market recently were: D. C. Thayer, president of the Ohio Coal Co. of Knoxville; A. R. Anderson, of the Liberty Coal & Coke Co., of Strathaird, and R. F. Brown, president of the Ohio Coal & Coke Co. of Knoxville; J. R. Clark, of the Cincinnati Coal Co., W. V. and W. T. Funk, of Sutton, Ky.

PENNSYLVANIA

The National Mining Co., a subsidiary of the United States Steel Corporation, will open two mines in Washington County, Pa., in the vicinity of a large coal mine. The larger development is planned, and the other mine will be used for coke. The mining district is in the vicinity of Washington, on the Monongahela pike, has been selected as the site for the new coal town and development. It has at least 3,500,000 tons of coal. The steel corporation is operating a large coal mine in the vicinity of Washington, and the coal company is now purchasing 20,000 tons of coal at a cost of $5 per ton. The coal company is reported to be interested in the coal in the county with a river frontage. The field was formed by the H. C. Frick Coal Co. & Co., and the Minco Coal Co., both of which are subsidiaries of the steel company.

The field was formed by the H. C. Frick Coal Co. & Co., and the Minco Coal Co., both of which are subsidiaries of the steel company.

In addition to the holdings of the H. C. Frick Coke Co., in this section and the Ohio Coal Co., the Liggett Coal Mining Co., has purchased all the coal leases in the county, and the coals are being shipped to the Minco Coal Co. of Pittsburgh.

The board of directors of the Liggett Coal Mining Co. has arranged with T. M. Chance for the operation of the Chance Flotation System Plant at one of its mines.
mines unless the proposed appeal to the United States Supreme Court from the circuit court's decision is granted. There are some 5,000 miners working in the coal-striking region.

During the week the tax bills were sent out the produce of which is the subject of this report, the taxable valuation is down to the 1912 date. The tax assessors were heard by the courts on the point of whether the tax would be payable on the basis of the 1912 valuation or the 1922 valuation. The tax court decided against the 1922 valuation and awarded the minerals to the 1912 valuation.

In the meantime the coal companies have been paying the taxes on the basis of the 1912 valuation and have been deducting the taxes from the wages paid to the miners. The result has been a strike by the miners, who feel that they are being taxed on the basis of a valuation that is lower than the actual value of their coal.

The coal companies have been forced to pay the taxes on the basis of the 1912 valuation, and the miners have been forced to work for the coal companies on the basis of a valuation that is lower than the actual value of their coal.

BRITISH COLUMBIA

Dr. J. D. MacKenzie, of the Geological Survey of Canada, made examinations of the underground structure of the Cornoa coal field which he believes will determine the extent of the field and its relation to the overlying strata of shale.

The Community Coal & Coke Co. has been organized to take over and exploit the old coal property in the lower Lower Valley. Recently a 10 ft. seam of high quality coal was discovered in a tunnel driven above the government road. It is proposed to commence mining and shipping in a small way immediately.

ONTARIO

Toronto Furnaces, Limited, has been organized in Toronto, and has been granted an Ontario incorporation. Incorporators are J. W. Gage, E. H. Roy and J. W. F. MacPherson, all of whom are prominent engineers. The company will build a furnace for the production of steel.

The Western Coal Operators' Association has now advised the Minister of Labor at Ottawa that, as a guarantee of its readi-ness to accept the basis of wages proposed in the meeting of the executive members of section 3 of the Conciliation Board, which section on the average has agreed to approximately 10 per cent over that proposed on contract rates. The association offers to the Labor Board to negotiate on opening its mines, an agreement to be on the basis.

C. W. Moss and W. D. Smith, of the Vulcan Coal Co., went this week to the Mining Ministers at Ottawa to make representations to the government on the coal situation.

The Steeple & Nicoll Mining Co. has been granted a charter to incorporate, the incorporators being C. W. Steeple, W. H. Nicoll, R. R. Ceder and others. The capital stock of the company is $50,000.

Frank Howard, of the Belleview Coal Co., has been appointed a director of the Toronto coal company. He is a director of the Toronto Coal Co. and a member of the executive committee of the latter company. Howard has been an active director of the Belleview Coal Co. for the past three years.

WASHINGTON, D. C.

The executive committee of the American Wholesale Coal Association announces that it will be represented at Washington on August 11. The committee will approximate the association at Washington and its officers are:

The committee is devoting itself to the consideration of the problems which have been suggested as possible candidates for this position. The committee will appreciate suggestions from members. The committee is a part of the American Wholesale Coal Association and consists of the following members:

M. A. S. T. Brown, 19th Ave. and W. Pike St.; Mr. A. M. L. Johnson, 6th Ave. and S. W. 7th St.; Mr. E. M. E. Smith, 2nd Ave. and W. 10th St.; and Mr. J. A. C. Miller, 1st Ave. and N. W. 12th St.

In discussion of Navy coal before the Senate Appropriations Committee recently, Secretary of the Navy, Mr. E. H. Stimson, said that last year, up to April 1, 1921, the Navy had purchased 8,000,000 tons of coal from Pennsylvania mines. Since April 1, 1921, through the end of the fiscal year, the Navy purchased 1,200,000 tons of coal from Pennsylvania mines. That is a decrease of 68 per cent. The Secretary also said that the price of coal to the Navy has been quoted at $2.50 per ton. In the period from April through November, the Secretary said that the price of coal to the Navy has been quoted at $2.75 per ton. In the period from April through November, the Secretary said that the price of coal in the Atlantic has been quoted at $3.30 per ton.

The Secretary also said that the price of coal in the Pacific has been quoted at $3.90 per ton. In the period from April through November, the Secretary said that the price of coal in the Pacific has been quoted at $4.25 per ton. In the period from April through November, the Secretary said that the price of coal in the Pacific has been quoted at $4.50 per ton. In the period from April through November, the Secretary said that the price of coal in the Pacific has been quoted at $4.75 per ton. In the period from April through November, the Secretary said that the price of coal in the Pacific has been quoted at $5.00 per ton.

In the period from April through November, the Secretary said that the price of coal in the Pacific has been quoted at $5.25 per ton. In the period from April through November, the Secretary said that the price of coal in the Pacific has been quoted at $5.50 per ton. In the period from April through November, the Secretary said that the price of coal in the Pacific has been quoted at $5.75 per ton. In the period from April through November, the Secretary said that the price of coal in the Pacific has been quoted at $6.00 per ton. In the period from April through November, the Secretary said that the price of coal in the Pacific has been quoted at $6.25 per ton. In the period from April through November, the Secretary said that the price of coal in the Pacific has been quoted at $6.50 per ton. In the period from April through November, the Secretary said that the price of coal in the Pacific has been quoted at $6.75 per ton. In the period from April through November, the Secretary said that the price of coal in the Pacific has been quoted at $7.00 per ton. In the period from April through November, the Secretary said that the price of coal in the Pacific has been quoted at $7.25 per ton. In the period from April through November, the Secretary said that the price of coal in the Pacific has been quoted at $7.50 per ton. In the period from April through November, the Secretary said that the price of coal in the Pacific has been quoted at $7.75 per ton. In the period from April through November, the Secretary said that the price of coal in the Pacific has been quoted at $8.00 per ton. In the period from April through November, the Secretary said that the price of coal in the Pacific has been quoted at $8.25 per ton. In the period from April through November, the Secretary said that the price of coal in the Pacific has been quoted at $8.50 per ton. In the period from April through November, the Secretary said that the price of coal in the Pacific has been quoted at $8.75 per ton. In the period from April through November, the Secretary said that the price of coal in the Pacific has been quoted at $9.00 per ton.
The President’s Proposal

WITH the best intentions but with singular lack of courage and with but dim perception of the consequences of its course, the administration at Washington has hopelessly befuddled the coal problem. Firm and defiant at Marion on July 4, the President returns benign and benevolent to Washington and on July 10 avers that public interest requires that the coal operators grant the demands of the United Mine Workers. There has been no parallel to this since the passage of the Adamson law six years ago.

The situation with respect to supply of coal demands action, not delay. The solution offered by the President is no solution at all. It can and will only postpone the day of peaceful resumption of coal mining. In a panic over the coming shortage of coal, the principles at stake are to be compromised. The operators are asked to surrender to the campaign of intimidation, terrorism and massacre that has characterized the union’s conduct in this strike.

Must this country have coal at such a price?

The fundamental issue in this strike is and has been the reduction of union coal-mine labor’s wage in conformity with the same principles that prompted its war and post-war time inflation. To prevent such a reduction the United Mine Workers have wielded the big stick of a nationwide strike—they have exerted the full economic pressure of their organization. Hands dripping red from Herrin, is the union invited to Washington and told that coal production is going to be resumed at whatever mines and by whatever miners choose to work? No. On the contrary, in the most polite, hospitable manner they are invited to go to work at the wage scale that they are striking to maintain.

Knowledge and courage command respect. Who, even among the United Mine Workers present on that eventful Thanksgiving eve of 1919 at the Red Cross Building in Washington, but admired the grit, determination and command of himself and his subject exhibited by Dr. Garfield when he told the miners they could have a 14-per cent wage increase and not the 60 per cent they demanded nor the 31 per cent offered by the Secretary of Labor!

The present emergency calls for another exhibition of indomitable will and clarity of purpose. Apparently the operators must this time supply the stamina and take the punishment that attends opposition to the United Mine Workers. They have the brains, they have the perception of the issues to carry through if they but maintain their unity.

It is wholly idle to speculate on what might have been. It is sufficient to note that a week previous the coal operators offered a plan to which they were fully empowered to commit the bituminous-coal industry—a plan embracing essentially every point for which the administration had taken a stand. The plan offered the miners as a substitute for the Central Competitive Field a new grouping of districts. It provided arbitration boards to settle appeals arising from tangles in the conferences of collective bargainers. This plan was lacking only in not providing a basis for immediate resumption of work. Precedent for determination by an administrative officer of the government of a proper and suitable wage scale in such an emergency was set by Dr. Garfield in 1919. If the administration had a spark of conviction on the economic necessity of liquidation of post-war peak wages it could have accepted the operators’ concessions coupled with an ultimatum to the union on wages. The data essential for such a determination are as accessible now as in 1919.

For the operators to agree to President Harding’s proposal would be not only to surrender on the points for which they have taken a stand but to abandon the country to the rapacity of a strengthened, domineering labor monopoly. The country has patiently subjected itself to more than three months’ strike in the coal fields as a necessary travail in the economic adjustment of this basic industry. The public most assuredly will not approve official recognition and unnecessary even though temporary perpetuation of an uneconomic wage scale under conditions that will rapidly elevate the cost of all coal to previous peak levels.

The administration has offered the country a solution of the coal strike that is not even peace without victory, for so ill-considered are its terms that even though operators and miners be forced into acceptance, coal production can proceed under nothing less than an armed truce. To mine coal under such a plan is but to recondition the contestants for further trouble in 1923.
One Law for All

What ails the state authorities, especially in Illinois, that they are mustering troops in order to protect the railroads? If the transportation interests would cease to carry mails, convey passengers and haul freight there would be no violence. Instead they fly in the face of Providence—and of the union—by attempting to operate.

Some arrangement should be made with the union so that it would be willing to let the union men work, and surely the railroad companies should be prevented from attempting to hire men to do the work which the union has interdicted.

It is said that the railroads have even gone so far as to hire guards to keep order and protect men who are willing to work. Such conduct is unthinkable. They should in all things rely on the state governments, which everyone knows are never remiss in keeping order, wherever, of course, everything is done in accord with the behest of the union.

As the country does not thus reason it must view the railroad strike in a different way from that in the coal regions. It is doing in the one what it almost invariably refrains to do in the other. If the states would put men in the coal fields and instruct them to keep peace at the mines and to maintain the rights of citizens, if the public would back up private guards in the execution of such duties as the state failed to perform, if men who wanted to work were given protection, strikes and bloodshed would be less frequent.

The nation coddles the coal strike. If it ceased doing so the strike would end. The country protests against private guards and refuses protection, yet it blames the coal industry for failing to maintain order, which is the function not of individuals but of the governments of the county, state and nation. If the officers of the law fail to keep order, then they themselves are to blame. It is the police of New York City and the public that hires them that are at fault when houses in that city are entered and men are sandbagged and it is in no way a dereliction of the persons victimized.

Similarly, it is the sheriff, the militia heads, the governors, the chief executive and the public of the United States that are to blame when men are killed as at Herrin, Ill., and when the mines are closed throughout the country in the face of men who are willing to work. The operators are the victims and neither the union nor the public can lessen their own guilt by malicious criticism of those whom they victimize.

The miners have a political advantage that the railroad men do not possess. They are grouped together where they have full control of the vote, and those in mining sections who are not mine workers usually are completely controlled by them. In Williamson County, Illinois, not only the miners but the county also is, as it were, unionized. The mine workers thus congregated elect State Senators and Representatives, and so long as they can do this they can and do make state laws and control executive action. Congressmen also are elected by them, and the laws they demand are too often enacted.

The railroad men, more numerous but more scattered, are less able to use their vote and are more likely to use it sanely because, living in the family with Uncle Sam, they somehow sense his needs, whereas the mine workers, who live alone, see only what they want and nothing beyond.

It is time that the state be made responsible for mob violence. Often to make the county liable is to put the burden on the very property owners who are victimized by the disorders. They are prevented by the negligence of the sheriff from keeping order and they have to pay the bills for any injury to their property that results.

When mine workers and coal companies whose property were destroyed can claim redress, and when the families of the mine workers are as well protected by the state against mob violence and even murder as they are against accident by the employer there will be less disorder.

The public is more responsible than the coal operators or the mine workers generally for the strife and strikes in that industry. If union anarchy is allowed to reign in the coal region it is because the states and the nation have divested themselves of their police powers and have evaded those duties for which they were in the main constituted.

The Bituminous Operators' Labor Policy

It has long been a matter of speculation as to whether the bituminous-coal operators could manifest sufficient cohesion on a labor policy to devise and see through a consistent program. Sectional differences and even internal schisms in small groups have many times proved too much for the leadership of the operators. In the labor crisis of 1919 the Central Competitive Field dominated, even to the point of locking out, as it were, the operators representing the outlying fields.

The surprising unity with which the operators met the miners at Washington is the outcome of the leadership and concert of purpose developed by the National Coal Association. It is not necessary to infer that it is the association itself that has brought this to pass as an official function, although the decision this year to admit the subject of labor to the councils of that organization has been a potent factor. It is rather that five years of meeting and agreeing on other matters of great concern to all or to large portions of the coal producers has trained what before the war was a provincial aggregation in the manner of associating for a common purpose and acting as a unit. In the beginning it was only necessary to dig down into their pockets for cash to finance their part of the Fuel Administration program. Then it was cost accounting, railroad problems and threatened hostile legislation. Now the highest and most formidable hurdle, labor, is being taken with all the form of a trained athlete.

When, if ever, the inside story of what has transpired within the councils of the operators this year in handling the strike situation is told it will make interesting reading. The results are apparent and are a credit not only to those who have led the way but as well to those operators who under protest have submerged their views and desires in the common cause.

The strike is not over and no one is out of the woods. If the operators will carry on as closely as they have progressed thus far, supporting without reserve the program of the majority, they will accomplish that which few expected of them—they will have demonstrated to themselves the value of association and their particular national association. One step at a time, but each step is reaching farther and leading toward that integration of the bituminous-coal industry that alone will be its salvation.
Good Coke Now Manufactured from Non-Coking Coals of Illinois, with Saving of Byproducts*

Seek to Coke Coal Before Cementing Material Is Oxidized—
Heat Graduated to Suit Thickness of Bed to Be Coked—Coking Time Lowered to Twelve Hours—Gas Introduced at Two Levels

BY H. A. PATTERSON†
Chicago, Ill.

COALS of Illinois are rich in valuable byproducts and if considered from that standpoint alone they would compete with coals from any district. They have not been utilized in coke manufacture only because they coke indifferently when treated in any of the coke ovens heretofore on the market.

Although in and near Chicago there are over 2,000 coke ovens with a capacity for coking 33,000 tons of coal per day none of the coal coked is from Illinois. This is proof that the coals of that state will not coke in these ovens, for why should the companies controlling them pay the higher freight on Eastern coals if they can successfully coke the coals from the nearby fields of Illinois and Indiana?

Broadly speaking, the coals from Illinois are lacking in the humus and resinoid bodies which act as cements during the coking process. It is notable that the Illinois coals are high in oxygen, and it is further known that this is a characteristic of most non-coking coals.

The designers of the Roberts oven have spent many years in the study of coals and their coking qualities and it was their belief that the high oxygen content in conjunction with the low content of humus matter was the cause of the non-coking quality. They further believed that a method could be devised whereby the heat could be applied uniformly and continuously to a coke oven and in such large volumes per unit of time that coke would be formed before a harmful reaction could take place between the oxygen and the small quantity of cementing constituents.

After years of experimenting and the building of test ovens the present design was finally developed, and the ovens built in accordance with it have been in successful operation at Granite City, Ill., since January, 1921. During this year and a half of operation it has been definitely proved that the theories on which the ovens are built are correct, for not only have they been successfully operated during that period on Illinois coals but with the aid of the coke produced a new world's record in both coke-oven and blast-furnace operation has been made.

Anticipating that the successful use of Illinois coals would lead to great expansion of the steel industry in the St. Louis district, the Granite City plant was laid out for an ultimate daily capacity of 3,000 tons of pig iron and 8,000 tons of coal. This will mean six blast furnaces and 320 ovens.

The first unit consists of 80 Roberts byproduct coke ovens and one blast furnace. It is probable that another furnace and at least one more battery of 40 ovens soon will be erected. The daily capacity at present is 500 tons of pig iron from the furnace, and the ovens will handle 2,000 tons of coal.

Coal cars arriving at the plant may be unloaded for immediate use to track hoppers from which the coal is delivered to conveyor belts which serve the crushers, or it may be received for storage and dumped into hoppers where by means of a bridge it is distributed to stockpiles. A car dumper of up-to-date design, also

*Abstract of paper on “Coking Illinois Coals.” This paper was read before the Illinois Mining Institute at its summer session.
†Engineer, American Coke & Chemical Co.
is installed. It is capable of handling the largest cars now engaged in interstate commerce. This car dumper has a capacity of forty cars per hour and is used for both coal and ore. These are delivered by the dumper to an electrically propelled transfer car of 100 tons capacity. This transfer car travels about 100 ft. from the dumper to the track hoppers, which deliver to the conveyor belts.

In the crusher building are two coal crushers, each of 250 tons capacity per hour. They may be operated either separately or at the same time, the coal from them being delivered to the second conveyor belt.

The crushed coal is discharged to either of two bins of 100 tons capacity, which are in the top of the mixer house. Though no difficulty has ever been encountered in making excellent metallurgical coke from Illinois coals in the Roberts oven, there are certain characteristics of ash and sulphur which may be obtained by proper mixing. By combining them in such proportions as will produce an ash content suitable to blast-furnace operation, better results are obtained in the furnaces. All Illinois coals so far tried produce a perfect coke from the standpoint of cell structure, strength and free-burning qualities.

From the mixer bins the crushed coal is delivered to the mixing belts, where the coal is mixed in any desired proportions. These belts are 30-in. apron conveyors operating under gates which may be raised to pass any desired quantity per unit of time.

The mixed coal is dropped to the hammer mills through proper chutes, and by the action of the hammers the coals are not only pulverized but very intimately mixed. The true mixing, therefore, occurs in the hammer mills, and the mills are more proportioning belts than mixers.

The storage bin is divided longitudinally and each compartment is provided with five valves in the bottom which register with the five hoppers on the larry car. By having the storage bin divided, two different coals may be charged, and it is also possible to run tests on large quantities of new coals.

There are at present two batteries of forty ovens each. These are standard Roberts recuperative ovens as built by the American Coke & Chemical Co., of Chicago. The ovens were designed to operate on 15-hour coking time but the time has been reduced to 12 hours with a charge of 15 tons. This gives a capacity of 30 tons per oven per day, the largest capacity of any oven so far designed.

The products of distillation are taken off on the pusher side of the battery through a single ascension pipe which is connected to duplex foul-gas mains, so that separation of the rich and lean gas is possible. The foul gas passes first through the primary coolers, by which the temperature is reduced to about 90 deg. F. The water flows countercurrent to the gas and is under automatic control, so that the temperature of the outlet gas is maintained constant at any given point.

From the coolers the gas passes through the Roots exhausters, which are heavy-duty machines direct-connected to Chandler & Taylor engines. There are three exhausters, the center machine being used as a spare for either rich or lean gas. The exhausters are each capable of handling more than 10,000,000 cu.ft. of gas per day and are under control by governors that are actuated by the gas pressure at the inlet of the primary coolers. In this way the pressures are maintained constant, and the differential through the coolers also will remain constant under various operating conditions.

From the exhausters the gas passes through F. A. type tar extractors. The tar-free gas passes from the tar separators to the saturators, where the ammonia is extracted. The saturators are large lead-lined tanks containing a solution of sulphuric acid and water. The bath, as it is called, usually contains about 5 per cent sulphuric acid. The ammonia combines with the acid, forming ammonium sulphate, which is a white salt valuable as a fertilizer.

By means of air lifts the solution of sulphate and the mother liquor is raised from the saturator to a draining table on which the salt settles by gravity, and the mother liquor is again returned to the saturator. This process is continuous and involves nothing more than the addition of acid from time to time to make up for the loss due to formation of the salt. From the draining table the salt is run into centrifugal driers and in them is dried to about 2 per cent moisture, after which it is carried to storage, where it is kept until shipment is made.

From the saturators the gas passes to a set of final coolers. From these it passes into steel towers about 90 ft. high, where the light oils are extracted. These towers are filled with wooden trays or hurdles so set that the gas has a tortuous passage from the bottom to the top. A paraffin oil with a high boiling point is introduced at the top of the towers and passes down counter-current to the gas. This oil has the power of absorbing the light oils from the gas and as its contact
with the gas is intimate, due to the hurdles, the absorption is efficient. The saturated wash oil is pumped directly to a still heated by steam to such a temperature that the absorbed light oils will be removed from the wash oil, which has a higher boiling point than any of the absorbed oils. This still is called a light-oil, or stripping, still. The wash oil, after removal of the light oils, is cooled and again circulated through the towers, so the process is continuous.

The crude light oils thus extracted from the wash oil are stored in tanks and may be treated as a whole for use as a motor fuel or may be fractionated for refined products. In the case of motor fuel it is common practice to wash the light oil with 66 deg. sulphuric acid to remove the impurities, then neutralize with caustic soda, then redistill in a column that is under accurate temperature control. The resultant product meets all the requirements for motor fuel, but is seldom used alone. The general practice is to mix it with kerosene or some other comparatively heavy oil. The fuel thus made is far superior to ordinary gasoline, as it produces greater power and there is a noticeable absence of carbon in the cylinders.

If the light oils are to be worked into the several fractions they are first distilled as a whole with careful temperature control, cuts being made in the fractions at about 80, 110 and 140 deg. C. These fractions are the crude benzol, toluol, solvent naphtha, etc. Thus produced they are each washed separately with sulphuric acid and neutralized with caustic soda and again distilled with exceptionally accurate temperature control. The resultant products meet specifications calling for a boiling point varying not more than a few tenths of a degree Centigrade. They will be water-white and are in every respect high-grade products. Their uses are many, especially in times of war, when the call for explosives is heavy. They also are used in the dye industry and as the basis for many articles in daily use.

After extraction of the light oils the rich gas is ready for sale, and the lean gas is returned to the battery, where it is used for heating the ovens.

We now come to a description of the ovens, which are the heart of the plant. The Roberts type differs from any other oven in that there are no flues in the walls. The wall, therefore, operates under uniform conditions and there are no dead spots or lines caused by division walls between flues.

There is but one brick shape used in the heating wall. This brick forms both sides of the space allowed for the combustion of the heating gases. The surface of this brick which is exposed to the heating gases is about two and one-half times the surface which is exposed to the coal. The result is the rapid absorption of heat by the brick and an equally rapid distribution of this heat to the coal.

The effect may be likened to that of a well-known superheater in which the steam to be superheated passes through the interior and the heating gases pass around the exterior of a tube. The exterior is made with fins similar to those on an air-cooled automobile engine. The result is that a large volume of heat is transmitted to the steam and an exceptionally high degree of superheat is attained.

In the Roberts oven the heating gases are in contact with a large surface and the heat thus absorbed is transmitted rapidly to the coal through the small surface which forms the wall of the coking chamber. By having the brick set so that they act as baffles, the combustion is complete and uniform and as all parts of the wall are identical in construction, both the generation and transmission of heat will be uniform.

The gas used for heating is admitted at the top of the heating wall at a point about 16 in. below the coal line and at this point meets the air necessary for combustion. This air is brought up through the intermediate wall from the recuperators, which are directly under the oven chamber. The air is accurately controlled by means of dampers and by slide brick which cover the air ports, and, as the gas also is under control, the combustion is maintained at the desired point with great accuracy.

The control of the gas for heating is one of the features of this type of oven and will bear a somewhat detailed description. All coke ovens have a taper from the coke side to the pusher side—that is, the side on which the coke is discharged is wider than the side from which it is pushed. This taper is given in order that the effort in pushing will be reduced. In consequence the thickness of the coal on the coke side will be greater than on the pusher side of the oven and will vary at each point between the ends of the oven. It is equally apparent that in order to have the coking of each portion of the charge completed at the same time more gas will have to be burned where the coal is thickest.

Until the Roberts oven was designed this delicate adjustment of the quantity of gas was impossible. In
that oven, however, it has been worked out in a simple manner. The gas is introduced through cocks on the top of the battery, and these have holes, through which the gas passes, drilled accurately through the core. Beginning on the pusher side, where the coal charge is thinnest, the holes in the cores are gradually enlarged until the largest will be the last cock on the coke side, where the coal charge is the thickest. As the cocks are on 21-in. centers this means that the supply of gas is graduated for each 21-in. section of the oven. Furthermore, as the cores of the cocks are cast-iron and are always at atmospheric temperature they may be drilled to the thousandth of an inch and will always maintain their correct size under operating conditions.

We have then on each side of the oven a set of accurately graduated openings for the passage of the gas and it is well known that an opening of given size will pass a quantity of a gas in direct proportion to the size of the opening and the pressure. The result in our case is that each burner passes the exact quantity of gas necessary to coke the coal in that part of the oven which is to be heated by that particular burner.

Another point that must be mentioned is the introduction of the gas at two points in the height of the wall. That is, there is what is called the "primary gas," which is introduced at a point about 16 in. below the coal line. This primary gas is about 50 per cent of the total gas necessary for the coking of the charge. With it is admitted sufficient air to sustain combustion of the total gas required. The primary gas, therefore, has a 100 per cent excess of air necessary for its own combustion. This excess air tempers the flame temperature so that the generation of heat is commensurate with the requirements in the top of the oven.

After passing through a short mixing duct the burning gases meet the staggered construction previously described, and by impingement on the neck of the wall brick the combustibles are well mixed and combustion is sustained at the desired rate.

About halfway down the wall the primary gas is exhausted, and it is here that the "secondary gas" is admitted. This gas is under the same accurate control as the primary and although at the point of introduction it is at a high temperature it is admitted into an atmosphere filled with the inert products from the primary combustion. The burning of the secondary gas is, therefore, subdued by the inerts, and the generation of heat is continued in the same uniform manner as in the upper part of the wall. The lower part of the wall is identical in construction with the upper part and the extraction and transmission of heat is carried on with the same efficiency throughout the entire combustion space.

The proportions of primary and secondary gas are maintained by the use of orifices similar to those in the cores of the individual burner cocks. The simplicity of the entire control of combustion is therefore evident. To change the coking time it is but necessary to change the pressures on the main supply to the battery. Each oven header and each burner then will automatically carry its proper quota of gas.

The products of combustion, after heating the walls, still retain a large quantity of heat which is reclaimed in the recuperators. These consist of a series of flues through which the waste gases pass, and the air to be preheated passes around the exterior of these flues. The flow of the waste gases and the air are opposite to each other, and the air, therefore, meets progressively hotter flues as it passes upward through the recuperator. With this system the air for combustion is preheated to a temperature as high as 2,000 deg. F. After passing the recuperators the waste gases, which are then about 750 deg. F., are taken to the 250-ft. stack, which maintains sufficient draft to provide for the circulation of the air and gases through the regenerators and combustion chamber.

Each point of admission of gas and air is under exact control and the waste gases also are under control, so that the proper differential always is maintained in the combustion spaces and the generation of heat is in direct proportion to the requirements for the coking time at which the oven may be operating.

After the charge is coked for the desired length of time the dampers are closed and the doors are removed from
The coke from this will average: Moisture, 4.44 per cent; volatile matter, 2.47 per cent; ash, 13.06 per cent; sulphur, 1.13 per cent.

It is interesting to note that the percentage of breeze is only 3.7 because it has been generally assumed that the use of high-volatile coals involved large losses from breeze—and this is true with any other system of coke ovens.

The coke made in the Granite City plant is used in various industries and also for domestic purposes. Practically the entire output of one battery is used in the furnace which is operated by the St. Louis Coke & Chemical Co. This furnace, which was designed by Freyn, Brassert & Co., of Chicago, is rated at 450 tons per day. During the past two months the furnace has produced about 515 tons of pig iron per day with a coke consumption of only 1,785 lb. per ton of pig iron produced.

Many attempts have been made to carbonize Illinois coals but so far the only successful method is the one herein described. The more recent experiments have been along the line of low-temperature carboniza-

Cross-Sections of Ovens

The left hand shows a half section of an oven on the pusher side, partly as cut through the primary and partly as taken through the secondary burners. On the right hand side the section is transverse, the large open spaces in the upper half being the ovens proper. Adjacent to the ovens are the flues and in the center of the wall between ovens may be seen the flue for preheated air which comes up from the regenerator in the base.
tion. This system produces a coke that makes an excellent domestic fuel but does not as yet form a metallurgical coke.

For a blast furnace, the coke must stand the rough handling that occurs in transferring it to the stock bins and from those to the skip hoists and from these again into the receiving hoppers at the top of the furnace. In the latter quantities of hard limestone will be dropped on it, and after this it will be subjected to the heavy burden of the furnace. Not only is the coke subject to the burden of ore and limestone in the furnace charge but it undergoes also a grinding action as it passes down toward the hearth. The physical structure of the coke must, therefore, be such that it will stand very rough usage.

That the Roberts oven will coke not only Illinois but Eastern coals also and equally well was completely proved at Granite City.

By Twist in Track Cars Are Turned Partly Over, Dumping Contents

BY A. F. BROSKY*
Pittsburgh, Pa.

TRANSPORTATION congestion lies at the bottom of many low-tonnage difficulties. If the cars could be dumped promptly, fewer cars would be necessary and locomotives never would have to wait while a full trip was being made up. If a hull comes for some reason in the coal received at the dumping point, the locomotives when they come will be delayed in their return by the slow dumping of cars.

These delays are quite serious, especially where plants are designed to produce 8,000 to 10,000 tons per eight-hour day. Some plants indeed are already scheduled for 13,000 tons a day, and only an element of caution prevents their designers from announcing their ambition publicly. They are afraid they may have to wait as long as did Zeigler before they reach and pass as Zeigler did the goal set. In fact, many mines fail utterly to reach their projected tonnage. One of the principal difficulties with many concerns is slow dumping, which sometimes, because it lays locomotives idle, is charged up as a failure of transportation.

But fast dumping results often in degradation—in making coal worth $2.50 a ton into slack worth only 75c. With these points in mind, a new plan has been developed by General Edward O'Toole, general manager of the United States Coal & Coke Co. He is the patentee. The device is known as a helical gravity dump. General O'Toole also is devising an endless skip hoist which promises to eliminate many of the faults of present shaft hoist arrangements. This dump discharges coal from the mine car quickly and gently with no labor and no expenditure of power, as the dump itself does not move. The cars corkscrew through the dump until they assume a position where all the coal in them is ejected; then they reverse the direction of rotation, leaving the dump in an upright position. The accompanying illustration shows a working model, one-eighth of actual size, from which an excellent conception of the dump operation may be obtained. Like the rotary dump the cars are held to the track by means of a

---

*Editor, *Coal Age*. 

Models of Helical Gravity Coal-Car Dump and Endless Skip Hoist

The cars thread through the dump turning clockwise to the position assumed by the forward car, then they reverse in a counter-clockwise direction until they right themselves. The three cars shown in the dump exhibit three of the positions assumed by the car during the cycles of dumping and reversing. The endless skip hoist is shown in model on the left. The crank shown on the sheave at the top is used to operate the hoist.
removing guide, placed at a distance from the rails equal to the diameter of the car wheels. This comes in contact with the wheel tread when the car begins to enter the dump. Unlike the rotary dump the cars are not spotted, which detail of operation results in lost energy and also lost time.

In the rotary dump all the coal is emptied from the car by rotation without movement in the direction of progress. In this dump the car partly transposes as it progresses through the dump and thus the coal is unloaded. The car while moving ahead turns over gradually, and therefore the coal itself is dumped gradually. In consequence degradation is minimized. The tracks and guides are bolted to castings each of which is shaped to give the desired pitch and twist to the rail and guides. These castings, in turn, are securely anchored to an inclined foundation so that the dump itself is immovable. The slope of the foundation depends upon the speed of dumping desired and the frictional resistance of the car. However, the inclination of the dump will be such as to cause the cars to pass through faster than would be desirable in actual operation. The speed of dumping, therefore, will be governed by a car retarder.

**Removal of Ball Bearings from Mine-Locomotive Motors**

This Operation, as Well as Their Replacement, Requires Skill and Care—Pinions and Bearings Should Be Pulled Rather Than Wedged Off

By E. Ashworth
East Pittsburgh, Pa.

In the successful operation of the ball bearings of mining motors, lubrication is the first consideration. A close second in importance is the correct removal and application of the bearings and pinions. The latter deserve attention, for the procedure commonly followed around a mine in removing or applying ball bearings is quite likely to damage them.

Fig. 1 is typical of the ball-bearing mountings used in mining motors. Various schemes for locking the bearings in place are employed. The fit of the bearing on the shaft and the results obtained usually are the same regardless of the particular scheme of locking. That is, the bore of the inner race of the bearing is slightly smaller than the shaft itself, giving a press fit upon it, which, assisted by any of the several types of locking devices, prevents rotation of the inner race with respect to the shaft. The outer race, however, has a sliding fit within the housing, so that it will creep around slowly, thus distributing the wear on the bearing and obtaining a maximum life.

To remove the pinion and ball bearings in such manner as to avoid possible damage to the shaft, bearings and housings a proper puller should be used. It is common practice to remove the pinion which is shrink onto the shaft, by driving thin wedges between it and the nuts of the ball bearings. This procedure is quite likely to damage these nuts while the shock on the bearings certainly does them no good. With some constructions if wedges are used they must be driven between the housing and the pinion. This is likely to put heavy stresses on the bearing which is arranged to take the end thrust.

Fig. 2 shows one type of pinion puller in operation.
in the center with a heavy copper bar. The jolt thus imparted will loosen the pinion without putting as great a stress on the puller as would be necessary if the plate were not thus treated.

The same puller plate is used to pull the ball bearings on both the pinion and commutator ends. In the latter case, however, the four bolts are screwed into tapped holes in the housing. It is not necessary to bump the center of the plate when pulling bearings, as they move more easily than pinions. Fig. 3 shows the bearing puller in operation.

Fig. 4 shows a type of construction with which, if wedges are used to remove the pinion, there is danger of damage being done to the pinion-end housing as well as to the commutator-end ball bearing which is arranged to take the end thrust. It will be seen that driving a wedge between the pinion and the cap of the ball bearing might break the cap. Also, all of the end thrust caused by driving the wedge will be taken by the end housing of the commutator.

Although this housing is arranged so that the thrust will be exerted against the inner race of the bearing it is quite probable that under the high pressure required to withdraw the pinion this race will bend so that part of the thrust will be taken through the balls. It will be noted that the pinion is threaded in the counterbore, thus providing for a jackscrew arrangement in its removal. The puller for this type of housing is shown in Fig. 5. The bearing cap in this case screws into the housing. To pull the bearing the cap is removed and the puller screwed into its place. The bearing may then be withdrawn by tightening the jackscrew.

Information regarding the removal of pinion nuts and ball-bearing nuts or other locking devices has been omitted. This was done, first, because it is obvious that these parts must be removed before attempting to pull the pinion or withdraw the bearings, and, second, because a great variety of schemes are used for this purpose. Whenever this information is desired it should be obtained from the manufacturer of the particular equipment.

In applying ball bearings or a pinion, clean housings and contact surfaces are primary requisites. Both shaft and housing fits on the bearing should be cleaned well and covered with blue ointment to prevent corrosion at these points. The bearing should then be placed in the housing and either driven or pressed onto the shaft. The method commonly followed is to place a piece of brass pipe fitting over the shaft and against the inner race of the bearing and drive it with a heavy block of wood. Care must be taken to start the bearing straight upon the shaft. The bearing-locking device should be made to hold the bearing as tight as possible. If a pressed-on collar is used it should always be pressed to place and never be expanded by heat and then shrunk on. When that is done the collar cools so that it does not fit tightly against the bearing.

To apply the pinion properly both the shaft fit and the pinion bore must be perfectly clean. The pinion should be heated in boiling water for about an hour. It should then be removed and, while it is still hot, be driven onto the shaft with a few taps with a 4- or 6-lb. hammer, using either a sheet of copper or a block of wood as a buffer. The pinion nut should be tightened to place only after the pinion has cooled.

Boiler Tests Recently Were Made by John A. Davis, superintendent of the Alaska experiment station of the Bureau of Mines at Fairbanks, of the steaming values of Matanuska coals in comparison with Nenana coals, the results determining the purchase price of coal by the Alaskan Engineering Commission. The coal resources of the Broad Pass region and of the Copper Mountain district in the Kantishna region are being given consideration by the Bureau of Mines.
Making the Mine Layout Match the Surface Equipment*

Much Tonnage Lost by Two-Way Development—Takes Four Years for Big Plant to Earn Its Operating Expenses—Air Should Be Split Near Foot of Airshaft—Careful Drilling Important

BY D. D. WILCOX†

We all have dreams of the ideal mine, where accidents do not occur, where there are no strikes, where the machinery does not break down and where the coal comes out in a never-ending stream. We have even seen some we thought were ideal, but they always belonged to our neighbors, not ourselves, and the probabilities are that we saw only our neighbor’s top equipment with its latest designed engines, with alternating-current turbo-generators, symmetrical tipple and beautiful buildings. He had the advantage of the knowledge and experience of the world’s best engineers for that part of his work, but the part you didn’t see was that which was left entirely to him, and that part was down below and well out of sight.

I have in mind a mine superintendent who was sent to take charge of a property, and, upon investigating, found a splendid coal field and exceptional equipment, but a bottom and mine plan that limited the mine to half of its rated capacity. Most of us are familiar with circumstances where the owners of mines have spent large sums of money to purchase new equipment with intent to increase the daily output and after the machinery was installed found that the increase in tonnage was not sufficient to justify the expenditure.

During the last few years owners and operators of coal mines have begun to realize that the designing of a mine plan is an engineering problem. The mining engineer is no longer a surveyor who puts up sights and takes levels. He is to be consulted in the plan and development so that the expensive modern top equipment may be properly co-ordinated with the work at the face.

It would be folly to attempt in a short article of this kind to dwell upon all of the features that must necessarily be considered when the development is being planned. A mere enumeration of them would take up too much time. It is evident, however, that the development of machinery and equipment has been much more rapid than underground advancement. It is not unusual to find mines with roller-bearing cars and with no place to oil them, or a mine with splendid electric haulage locomotives and with no suitable place underground for their repair. Even the safety engineer may have guards on all the machinery and no throws on the switches.

But worse than all of this is the plan that apparently takes care of all of the modern equipment, hoisting with skips, an auxiliary hoisting shaft, the bottom graded and the ribs concreted with a roof support of I-beams and concrete and yet neglects the airshaft. Every proper plan may have been made for the hoisting of the coal, but the air leaves the airshaft through a narrow entry to find its way inside if it can. A mine plan must be projected from the bottom of the airshaft and not from the bottom of the hoisting shaft. Major splits should be as near the bottom of the downcast as possible.

Most Illinois mines come under the provision of the law which now makes it necessary to install a cage

---

*Abstract of an article entitled “The Projection of a Mine Plan,” read at Illinois Mining Institute, June 9, 1922.
†Superintendent, Superior Coal Co., Gillespie, Ill.

Two-Way Development

A mine in Illinois. All the coal and all the air must pass along one or other of two roadways, cluttering up the development. The mine bears evidence at the shaft bottom of having “just grown” at first but of being well developed thereafter. Still the early error of only a double approach, with only two main airways and two returns, was not and almost could not be corrected. The lack of early layout dooms a mine to failure.
in the airshaft for the hoisting and lowering of men. Skip hoisting also makes this the more practicable. This cage is to be used also in the sending down of material. Even with this cage and the stairway it is practicable and desirable to split the air three ways directly at the bottom of the downcast with a possibility of more splits immediately adjacent. This gives almost the same security as if three or more different mines were being ventilated.

All the advancement in the underground plans of mines in Illinois has been made in all probability since the members of this institute have been connected with the mining industry. You will remember the original plan was to start off the bottom each way with a pair of entries. At intervals room entries were turned off and driven to the boundary. Caging was from both sides of the shaft, the cars usually running on flat sheets. Haulage was entirely with mules, and the trips as a rule were so short that no storage room was required for empties. But haulage machinery calls for loaded and empty storage, and instead of mule barns motor barns are necessary. With the advent of these improvements caging on one side of the shaft was accepted, and caging machines with empty trippers were developed.

The danger of squeezes and fires forced the panel system on the industry. Designing a mine layout was no longer a “hit-or-miss” proposition but one for the engineer. As it is almost a criminal offense in Illinois to cause a subsidence of the surface, the room-and-pillar system is used in most mines, and more than 96 per cent of the coal in the state is mined by that method.

Most room-and-pillar mines have not departed from two-way development. This plan has the practical effect of creating two mines with a common hoisting shaft, as the sides are separated as to haulage and ventilation, but this is not enough. It soon is found that while the coal is worked on all sides of the shaft the development is only in two directions. The cross entries after reaching a certain stage are stagnant as far as development is concerned. In other words there are as many men working there when the cross entry has been driven one-half mile as there are when it has been extended almost to the boundary.

With the knowledge that the restricted area of the shaft itself is really the greatest hindrance it has been realized that with the present system of development and the increased efficiency of the hoisting equipment the time is near at hand when more coal can be hoisted out of a single shaft than can properly be developed with the present mine plans. Meantime men show an increasing distaste to the idea of double-shifting entries, and operators of coal mines are beginning to realize that night work as a rule is not efficient. These facts have caused thought to be given to methods of development that allow a mine to be placed on an operating basis in a shorter period of time than in the past. In considering the cost of production of coal the public fails to take into account that after a mine is sunk and all equipment purchased and installed it is at least four years before the production is sufficient to pay operating expenses. In the meantime the development cost is growing.

Any plan that will cut down this time is advantageous to the owner and the consumer. Greater recovery per acre will do it, and for this the plans now in effect can with little difficulty be used, and the recovery percentage raised from 50 to almost 96. It must be recognized, however, that not much above 50 per cent can be taken out without subsidence of the surface. The attached map of an Iowa mine shows a panel system of mining where the recovery is about 90 per cent.

In order to keep sufficient development in most large mines some unusual practice is necessary. Some mines still double-shift their entries, others place a gang of men with a machine in the entry, and in others experiments are being made with entry-driving machines which cut and load the coal. We have been told that one of these has passed the experimental stage. They would solve the problem of development but would not assist us with our haulage and ventilation problems.

The attached map of the Standard Oil Co.'s mine
near Carlinville shows a splendid method for development, haulage and ventilation. The operators of this mine believe a similar plan is being used in other large mines in the state. It will be noted that instead of two main entries there are four, and the development is in four directions instead of two.

This plan goes into another pressing problem—that of haulage tracks. After watching main-line haulage motors waiting on each other or motors compelled to do relay work instead of going directly to the bottom one usually considers the double tracking of the main line. This plan allows four main lines instead of two, or four distinct sections of the mine. If it had been necessary in the first instance to drive narrow entries because of top conditions, double tracking would be more expensive than the additional entry required by this plan. It also will be noted that four distinct air splits are possible as well as four distinct haulageways.

Safety is the first consideration in the planning and development of a mine, as it is in other features of the industry. For a long time we had a definite idea that more speed made more accidents, but it was found that when we arranged for more speed we inevitably arranged for more safety. A motor cannot run fast on poor track, neither can the motorman make speed when he shares the roadway with another motor.

The installation of skips instead of self-dumping cages has made no material change in mining plans, though it is customary to run the main bottom parallel to the shaft where skips are used and across the shaft at right angles thereto where self-dumping cages are operated. Without question, however, a larger tonnage may be expected where skips have been introduced.

No industry in the world is more competitive than the coal-mining business, and in order to obtain a return on the more expensive equipment the development must be speeded up. It is true that the mines in the country are able at this time with their present equipment to more than supply the need of the consumer. It also is true that the installation of modern machinery has raised the output per miner and eased his working conditions. But the operator who develops a mine in this day must have all of the advantages of equipment and proper underground plans and development in order to get a return on the investment. He has a duty to the employee to see that the mine is so planned as to give the best working conditions possible and owes it, not only to the owner but to the public also, that the coal be put in the railroad cars at the minimum price possible.

While a few years back the large mines were equipped for an output of 4,000 tons, excellent management on the part of some, notably Orient and Zeigler, has doubled this figure and even now they are unwilling to concede that they have reached their limit. Some of the newer shafts are equipped to take care of 12,000 tons per hoisting shift. This means that places must be found for more miners. They naturally wish to work where they can make the most money per day, and the modern mine is more desirable than the obsolete operation as seen from that angle.

The mining engineer is prevented in many cases from making an exact plan of the underground work because of lack of knowledge of the contours of the coal strata. In some mines the change of plans made necessary because of adverse grades has cost thousands of dollars and, furthermore, has retarded development. Even in Illinois, where the grades usually are uniform, faults have been encountered which have disarranged the entire plan. Prospect holes should be drilled in sufficient numbers not only to ascertain the strata to be met in sinking but to establish the contour of the coal. If advantage can be taken of natural grades costly and troublesome machinery at times may be eliminated. I know of one mine where it is necessary to have in service a conveyor or drag on the loaded side of the bottom which would have been eliminated had the location of the hoisting shaft been shifted 100 ft.

Because of surface conditions or sometimes railroad service it is not always possible to locate a shaft in the center of the field and in some cases the bed or the holdings are irregular or uncertain or natural grades
or conditions make a central position impracticable. The map of the Iowa mine accompanying this article shows the possibilities even under these conditions. To figure properly the length of loaded and empty storage tracks the engineer should know the size and kind of mine cars to be used before completing his mine plan.

By taking advantage of all the information afforded by mine inspectors and the bulletins of the Illinois State University and the U. S. Bureau of Mines the planning of the underground work may be done as exactly and scientifically as is the engineering work on the surface.

Government to Expend $1,000 on Trophies for Rescue Work in Mine Disasters

COMMENTING on the remarks of J. L. Knight, of Glen White, W. Va.,* and on the statement of the Metropolitan Vickers Electrical Co.+ relative thereto, Graham Bright, general engineer, Westinghouse Electric & Manufacturing Co., in response to a question addressed to him by the editors of Coal Age, says: "The scheme is fairly old and has been described many times in various publications in this country. Mr. Sykes, formerly with our company, gave an account of this system in 1910 in an address to the American Institute of Electrical Engineers, illustrating it with a wiring diagram. At the same meeting Messrs. Pauly and Rushmore, both of the General Electric Co., submitted a paper on hoisting equipments in which they also mention the converter scheme and illustrate it in a similar manner.

"About ten years ago the Westinghouse company installed an equalizing system at the Pennsylvania R.R. docks at Cleveland, Ohio, which is practically the same as that which Mr. Knight proposes. In this case considerable load was attached to the direct-current side of the rotary converter, so that the direct-current motor with its flywheel was used largely to equalize the direct-current load on the rotary converter. Of course any alternating-current load also would receive the benefit of the equalization system. I believe that two or three plants of this type are in operation in this country, but the scheme has never been particularly popular."

Scheme for Meeting Peak Hoisting Loads

Government to Expend $1,000 on Trophies for Rescue Work in Mine Disasters

COMMENTING on the remarks of J. L. Knight, of Glen White, W. *Coal Age, Nov. 10, 1921, Vol. 20, p. 761
URGES THAT COAL OPERATORS LIVE CLOSER TO THEIR EMPLOYEES

In your valuable Coal Age it seems to me that you should urge all coal operators to run their own business—give no check-off. Urge them to live closer to their miners, and help the miners to educate their boys and girls. Teach them what the laws of this country mean; teach them to earn money, save money, and respect their companies.

I would recommend that each company have a reading room, and the superintendent employ someone to explain the laws of this country to all miners and their families, show them the average wages of miners and what other laborers earn, so that they may see how the earning capacity of the mine worker compares with the earning capacity of other labor in other lines of industry.

The coal operators of the United States should be pre¬
vailed upon to own South American coal mining stations; there should be exported enough coal from the United States to allow the coal industry of the United States to keep steadily moving.

The ruler of this nation should assist the entire coal industry in getting its valuable coal into South American markets; we should enjoy the market that Great Britain is now holding in that country.

D. W. Boone, President, New River Export Smokeless Coal Co.

Lookout, W. Va.

ATTRIBUTES WAGE DIFFICULTIES TO MINERS’ LAXITY IN OBSERVING WORKING HOURS

As I read Coal Age and the various bulletins that are coming out it occurs to me that the public should be better informed on what I consider the more salient points that the miners’ officials bring out to justify the demand that the war-time scale of wages should prevail, and that is by reason of the intermittent employment of the miners in general.

Now, there surely is a reason why there are too many miners, and the answer is simply that the miners as a class have taken upon themselves privileges which no other industrial occupation would tolerate or admit of. The miner goes to work just about when he pleases and leaves the work when it suits him. Visit any mine in any state and you will find men coming home at any hour between starting time and quitting time and this on their own volition. If a miner feels like idling a day or two or three he does it. If he was working in a mill or factory he would be compelled, except on account of sickness, to work out his day and not come out and go home at any time it suited him, nor would he be permitted to lay idle two or three days after pay day for drinking or other causes.

I have been engaged in mining over fifty years. For the past twenty years I have been employed in an official capacity. I have had ample opportunity to observe the traits, character and habits of the miner. Being one of them, I am naturally much interested in their welfare, but justice is justice and it is the truth that the public is entitled to. I have estimated, rather roughly, of course, that I have to have 20 per cent more working places, which means 20 per cent more miners, than should be necessary to a given tonnage output, but because of the men laying off at their own leisure I must necessarily have more men than should be needed.

Now, this simply means an increase in the production cost because the overhead remains the same whether all the men are at work or not. The working places all have to be examined by officials according to law. The pumphers have to attend to pumping out of the water. Timbermen have to attend to the safety conditions and, of course, there is so much more equipment tied up because of there being the additional number of working places over what should and would be necessary if the men would tend more steadily to their work. In my experience I have known a great shortage of men to harvest the crops but the miner could not be induced to go and engage in this work. Is it reasonable to expect the farmer who produces the foodstuffs to be content to work as he does work from daylight until dark and the miner expect to derive a good living from thirty hours per week?

The miner has privileges and his remuneration is so far in excess of other industries that it is beyond question. The labor-saving appliances that have been introduced during the experience have completely changed the condition of employment in mines and the miner has received nearly all the benefits derived from the introduction of these labor-saving appliances and that which is added to the safety and comfort of the men engaged in mining. He is entitled to a fair share of all these, but the public should be considered.

There are a large number of mines opened up that should never have been opened; I question whether some of them will run again for many years to come. It simply means that they were opened up ahead of their time and economic conditions will prevent their operating because the production cost would be out of balance with the prices which the public generally have a perfect right to expect from coal.

WALTER R. CALVERLEY,
Union Colliers Co., Pittsburgh, Pa.

Are Foreign Workers More Careful Than Americans in Coal Mines?

In Coal Age of May 18 there appeared a statement saying “That foreigners were more careful than Americans.”

The following statistics, sent us by R. M. Lambie, chief of Department of Mines, Charleston, W. Va., show that during the year there were 188 Americans killed, or one for every 342 men employed. These figures also bring out the surprising fact that there was one person killed for every 645 Hungarians and one for every 555 Austrians.

Redeeming the Depreciated Value of the Mine Foreman’s Certificate

What Study Does for the Mind—Value of the Certificate
Discredited by Lack of Experience—Mine Foremen Should Work to Redeem the Certificate and Restore Its True Value

That holding a certificate does not make a man more competent to take charge of a mine has been stated by more than one writer of recent letters in Coal Age. It has been urged that experience is the chief factor in successful mine foremanship. Though a matter for regret both of these statements are undoubtedly true, to a large extent, at the present time. There is one fact, however, that should not be overlooked. When a man commences to study the principles of mining, for the purpose of fitting himself to pass the examination and secure a certificate of competency, he is training his mind in a manner that will enable him to meet the various problems that will later demand his attention and call for solution.

Goal of a Man’s Ambition

The man that is truly interested and desires to make a success, in his chosen line of work, does not consider the gaining of a certificate as the goal of his efforts. When he has reached that point in his career he will still continue to study and read all that pertains to mining.

Such a man realizes that the certificate he has may rely upon the fact that he has satisfied an examining board regarding his technical knowledge of mining. The holding of a certificate may or may not cause an operator to think the man worthy of giving him a chance.

Past Record of the Worker His Surest Commendation

Every ambitious worker knows, however, that success or failure depends on himself. He has a reputation to make and sustain and, to that end, his every effort is directed. What a man has accomplished, as shown by his record in the past, is his surest commendation for the future.

It cannot be denied that the value of the certificate of competency granted by examining boards has been largely discredited by the attitude of young men of fair education taking the examination which they succeed in passing with flying colors because they are well versed in mathematics and have a mind trained to remember formulas.

Men of this type are wont to pride themselves on their technical ability and the fact that they have passed an examination in which older and more experienced men have failed owing to the lack of an early education, which made it difficult for them to answer the technical questions asked.

Disrepute of the Certificate

The result is that the certificate has fallen into disrepute with operators, who prefer to form their own independent judgment of men who apply for work, regardless of whether or not they hold a certificate.

In closing, let me ask all mine foremen to examine themselves to redeem the value of the certificate, by giving their best services in the management of the work in their charge, and proving thereby the practical value of the technical knowledge they have acquired.

William J. Walker
Aultman, Pa.
Mine Foreman

Overcoming a Handicap

Determination and concentrated effort necessary to overcome difficulties—Analyzing success in life—One who achieved extraordinary success against great odds.

Reference has been made recently, in Coal Age, to men who suffer by reason of being handicapped owing to their lack of early education, or being otherwise unqualified for the struggle they must undergo to advance to higher positions in life.

There is no question but that a handicap of this nature is a hindrance to the man thus trammeled. Nevertheless, my opinion is that the success of any man rests within himself. In launching out in any line of endeavor or business, one must first make sure that he is adapted to the work.

How to Succeed

Determination and concentrated effort are essential in any undertaking in which one hopes to win. Setbacks must be expected, at times; but these should not give rise to discouragement. By continuous effort, one must show that through constant failures he still has the power to rise.

The oft repeated adage, “There is always room at the top,” will hold true in the case of any determined worker. The world is looking for men that are able to do things of which it has been said, “The thing cannot be done.” It is not too much to say that money, fame and positions are open and within the reach of all who strive honestly to attain the goal of their ambition. One writer has analyzed success as “Five per cent inspiration and ninety-five per cent perspiration.”

One Who Overcame His Handicap and Rose to Prominence

Let no one think that these are idle words spoken for their possible effect on a few ambitious ones. They apply alike to all who accept their true meaning and are willing to work and strive for the results they hope to gain.

In this connection, let me refer to one who achieved extraordinary success against great odds. He is a man who came to this country about twenty-five or thirty years ago at which time he was unable to talk, read or write our language. It is true he had the benefit of an ordinary education obtained in his homeland, and, if I remember rightly, he had had one year in college, studying mining engineering.

This man came to our country with scarcely a sou in his pocket; took a job as laborer in a sawmill. Presenting his paycheck at the bank, at the end of a month, he was informed there were no funds and was compelled to lose that month’s hard toil.

Following this experience and in the hope of learning the language, our friend worked for a time on a farm. Later he secured a job as draftsman in a mining office, at Charleston, W. Va.

Rapid Rise Comes as Reward for Faithful Work

His faithful work soon earned for him a position as mine surveyor and, a few years later, he was appointed superintendent of some mines. From that time, his rise has been rapid, until he is now conceded to be one of the ablest mining engineers in the United States.

At the present time, the man of whom I have been writing is vice-president and general manager of a large coal company who are installing two of the modern and most efficient plants in the state of West Virginia, at a cost of several million dollars. In addition to this extraordinary record, the man is retained in a consulting capacity by several other large coal-producing companies.

No one will dispute the fact that, de-
spite his serious handicap, he has attained the pinnacle of success, which has been nothing short of marvelous. The story of such advancement gained through continuous and unremitting labor should be an incentive to all. The record exemplifies and proves the truth of the words of the poet:

The heights by great men reached and kept,
Were not attained by sudden flight,
But they, while their companions slept,
Were climbing in the night.

The lesson may often prove a hard one, but there's no other way than to accept the challenge of unremitting honest toil if we would win.

Edwright, W. Va.

Blasting Machine-Mined Coal

Three writers agree that an undercut or mining being filled with water does not constitute a solid shot—The water, unless confined, offers no resistance to support the coal.

REFFERING to the inquiry that appeared in Coal Age, Mar. 30, p. 538, raising the question as to whether a shot fired in coal mined with a machine when the undercut or mining is filled with water could be considered a solid shot, I can see no ground for such a suggestion.

The reply to the inquiry assumes that the coal has been mined to a depth of 6 ft. Then, if the depth of the hole was less than that of the undercut, it cannot be claimed that this was a shot on the solid. The water offers no resistance that tends to support the coal, which is free to fall and would fall, into the space occupied by the water, the moment it is dislodged by the shot. Let me urge you to think otherwise try the experiment in the mine and satisfy himself.

MINING LAW IN ILLINOIS Requires COMPETENT SHOTFIRERS

Our mining law relating to shotfiring requires all shots to be prepared in a practical workmanlike manner and that when so prepared they shall be fired by a competent shotfirer.

I have had machine-cut coal, dipping 10 per cent and the undercut filled with water, but have never known a shotfirer to refuse to fire such a shot when it was otherwise properly prepared and charged. There has never been a question but that such a shot was safe to fire.

In that section of the mine, the men have loaded out more coal than in any other section, and no trouble has ever resulted in the nature of solid shooting. In my judgment, this Colorado shotfirer cannot be justly accused of firing a solid shot, under the conditions described.

PETE BOLAND,
Mine Manager, Mine B.
Herrin, Ill.

ON this subject, let me say I would not consider this as being a solid shot and cannot understand how any one could have claimed that the shotfirer should refuse to light the shot when he found the undercut, mined by a machine, filled with water.

In a place going to the dip and making water, it is quite natural to find the cut full of water soon after the machine has departed. But, as stated by the editor in his reply to this inquiry, the water is not confined in the cut and, though incompressible, exerts no pressure against the coal.

PRESSURE OF WATER IS DOWNWARD

In my view, the pressure of the water is all downward in this case. Where water heads up to a higher level, it is possible for it to exert an upper pressure against a surface that is below that level; but such is not the case in this instance.

Certainly, if there is no resisting pressure offered by the water on the coal, a shot in the coal is not a solid shot. Better loading conditions will, of course, be afforded by draining the water from the cut before firing the shot.

HARRIS COPeland.
Crawford, Tenn.

WATER not being a solid can offer no solid resistance, unless it is confined, as has been stated in replying to the question as to whether the firing of a shot in coal when the undercut is full of water is the same as shooting off the solid. I can see no comparison between the two cases.

It is assumed, of course, that the hole was not drilled beyond the depth of the undercut and the charge is not, therefore, laid on the solid, which would be necessary before we can call this a solid shot.

IS THIS SOLID SHOOTING?

While it may cause some readers of Coal Age to wonder how it could be, I will cite one instance that occurred in this district. A room had been driven on a slight upgrade and the coal was undercut with a Sullivan shortwall machine to a depth of 5 ft. The drillholes were 5 ft. deep. The undercut was thoroughly cleaned of all loose coal. The shotholes had been examined, charged and fired by the shotlighter and yet it was claimed these shots were fired on the solid. Let me suggest that it will be well to study over the matter, in order to avoid a similar occurrence in one's own mine.

ANOTHER PRACTICE THAT IS EquALLY DANGEROUS

Speaking of solid shooting, let me mention another practice that is equally dangerous, though followed by 90 per cent of our shotfitters. Attention has been drawn to this matter, in Coal Age, more than once and miners cautioned against the practice.

In order to hasten the work of firing, the custom is common, here, for a shotfirer to light from one to six shots in a wide room; or, perhaps, from one to three shots in crosscuts and then rush into an adjoining room to do the same thing there.

In more than one instance, it has happened that the crosscut shots have blown through the pillars and killed the shotfirer or crippled him for life. I mention this merely in the interest of safety in shotfiring.

Crawford, Tenn. OSCAR H. JONES.

Making the Mine Safe

Run the ventilating fan continuously day and night—Equip a gassy mine with two fans—Extensive miners having large abandoned areas require watchful care to avoid disaster—Study local conditions always.

TWO things have been mentioned, recently, in Coal Age, that have a most direct bearing on making the mine safe. One of these is the question of operating the fan continuously, or shutting it down when the mine is idle; and the other, the treatment of large abandoned areas.

In respect to the first of these questions, I agree with the statement made by a Tennessee mine foreman, in a former issue of Coal Age. He remarks: "A ventilating fan should run continuously, day and night."

I am a great believer in keeping the fan running all the time, or 365 twenty-four hour days a year, particularly at gassy mines.

LONG EXPERIENCE OF SHOTFIRER IN TWO GASSY MINES

For a period of six years, I served as ventilation boss in one mine where the fan was run continuously, day and night, including Sundays and idle days, throughout the year. This was a very gassy mine that was equipped with safety lamps exclusively. At another mine I served in the same capacity for two years. That was also a gassy mine, but operated with open lights, and the fan was always kept running continuously.

These were both slope mines and very irregular in formation, besides having a deep cover. Each mine was equipped with two fans, one held in reserve in case of a breakdown. At the first mine, the speed of the fan was not slowed down on Sundays or idle days, but at the second mine, the fan was run at about one-third less speed on these days.

LARGE ABANDONED AREAS LEFT OPEN GAVE NO TROUBLE

As is commonly the case in large operations, each of the mines mentioned had extensive abandoned districts, which were left open or unsealed, though little trouble was experienced in either case. In my judgment, however, it was due very largely to the practice of running the fan continuously and giving no opportunity for gas to accumulate.

Speaking about ventilating abandoned areas, with the exception of gas accumulated on falls, it does not require more than a small steady current of air to keep such places clear. My observation is that barometric changes have little effect in a mine when the fan is run continuously.
Now, a few words in regard to whether it is safer to seal off abandoned portions of a mine or to ventilate them. It appears that the consensus of opinion, in that discussion, was in favor of ventilating large abandoned areas. In my opinion, however, this question can only be decided by a careful study of local conditions affecting the area in question.

Such areas require constant watchfulness to avoid disaster. Conditions may be such that these areas cannot be sealed off with any degree of safety, but can be ventilated more effectively. As we all know, it is an easy matter to prescribe means and remedies for the elimination of dangers in mines; but when these are applied they are not always a success. Like the Indian's gun, they cost more than they effect.

**PLAN TO AVOID LARGE ABANDONED AREAS**

The question to be solved is: In the ordinary operation of coal mines, how must the work be planned in order to avoid as far as practicable the existence of these large abandoned areas; and where they do exist, how must they be regarded as to safety?

Experience shows that these evils cannot be wholly avoided and must be safeguarded by adopting such means as a careful study of local conditions may suggest. In any case, keep the fan running continuously and make the mine safe.

**JOHN ROSE**

Former District Mine Inspector.

Dayton, Tenn.

---

**Testing a Safety Lamp**

What is a proper test to determine the safe condition of a safety lamp before entering the mine—Is such a test customary with fire bosses and men in charge of lamp rooms?

**O NLY** recently, after reading the answer to an examination question given in *Coal Age*, I had a talk with three of our fire bosses, in reference to the testing of a safety lamp to determine its safe condition before entering the mine.

During the last three years, I have employed several gas inspectors, some of whom have had long practical experience in the examination of mines. It was well known that my habits were to go into the mine, once every three months, on a Sunday afternoon, for the purpose of ascertaining what gas had accumulated in certain places since the shutting down of the fan at 11 p.m. the previous night.

**LAMPS WHEN TESTED BY FOREMAN ARE FOUND UNSAFE**

On one occasion, my fire bosses asked the privilege of accompanying me. Although it had always been my custom to make these trips alone, I gladly consented to their going along, and asked them to prepare their lamps carefully for running into sharp gas. When all was ready I decided to examine their lamps, myself, with the idea of seeing how carefully each man had prepared his lamp and to assure myself that all the lamps were safe.

Much to my surprise, I found that it was possible to blow out the light in each lamp, by blowing hard against it just below the glass cylinder, or where the glass rested on the brass ring supporting it. It was clear to all that this simple test showed that the lamp was not proof against a strong blast of air, which might be met in the examination of the mine.

**FEAR OF CRACKING THE GLASS**

In answer to my inquiries, they all explained that they had never seen a lamp tested in that manner before. They stated, moreover, that they would be afraid to tighten the lamp against the glass more than what they had done in this instance. Their fear was that the heat of the lamp would expand the parts and break the glass. But this argument did not appeal to me, knowing as I did that the expansion of brass was much greater than that of glass, which would make the result the opposite of that claimed.

However, I have since been wondering whether this test should not be applied in every case before lamps are taken into the mine and whether it is possible to tighten the lamp too much for fear of breaking the glass.

**W E R L E Y, KY.**

**JOSEPH CAIN.**

---

**Shortwall Machine for Low Coal**

Coal-puncher machine requires too much headroom for use in low coal—Shortwall machines used to good advantage, in the thin seams of Northern Illinois.

**R E F E R R I N G** to the inquiry asked a short time ago in *Coal Age*, Apr. 6, p. 578, asking if it would be of advantage to use a coal-punching machine in mining the coal from a 22-in. seam, let me say that there would not be sufficient headroom in this seam to enable a man to handle a coal-puncher.

The inquirer states that the coal is clean and the seam contains no sulphur. That being the case, the conditions are fine for employing a shortwall machine. These machines are used to good advantage in mining the low coal in Northern Illinois.

As is well known, the shortwall machine is particularly adapted to the mining of low coal. I make this suggestion in the hope that it may be of some assistance to this correspondent.

**Inquiries Of General Interest**

**Percentage of Gas Estimated from Volume Generated per Ton of Coal Mined**

Mine Gives Off 4,500 Cu.Ft. of Gas, Per Ton of Coal Mined; But Inspector's Report Says "No Gas"—What Estimated Percentage of Gas Should Be Present?

**W E N** going through the mine inspector's (Canadian) report, recently, what was my surprise to find a condition that took me back, in memory, several years when it was customary for an inspector or a fire boss, in reporting the gaseous condition of a mine, to say "a little gas," without attempting to define the degree more clearly by estimating the amount of gas generated per minute, or giving the percentage he found in the return current.

What particularly arrested my attention was the report of a certain mine known to be generated gas, the volume of which was estimated at 4,500 cu.ft. per ton of coal mined. Notwithstanding this rating of the mine with respect to gas, this fireboss' report would seem to indicate that no explosive gas had been found in the mine.

Such a thing is only what might have been expected a few years ago, before the danger point of firedamp mixtures was officially defined; but, nowadays, when every fire boss knows the inflammable and explosive limits of methane and air, and the means are at his command for determining the percentage of gas present in the air when making his examination of a mine, there is no excuse for a report not stating clearly and in intelligent language what percentage of gas is found in the return airway of a mine examined.

In this connection, I want to ask what would be a fair estimate of the percentage of gas that might be expected in the return airway of a mine rated as generating 4,500 cu.ft. of gas, per ton of coal mined? To my mind, for a report to state that no explosive gas is found in this mine is an evasion of a most important feature of the examination. The idea conveyed in the report is too ridiculous for expression and should call for a rigid investigation by some higher official in the district.

**MINING ENGINEER.**

Canada.

In replying to this inquiry, it is only possible to estimate, in a general way, what volume of air would be in circulation in a mine, as based on the
Examination Questions Answered

Miscellaneous Examination Questions

(Answered by Request)

Question—In a large mine, the board and canvas stoppages erected between the main airways have been replaced by concrete stoppages. What changes would you expect to find: (a) In the quantity of air circulating around the faces? (b) In the total quantity measured in the fan drift? (c) In the water gage reading? Explain why.

Answer—(a) Assuming the concrete stoppages are well built and sealed at the roof, the result of erecting such stoppages will be to increase the quantity of air sweeping the working faces. The reason for this increase is that the new stoppages will eliminate the loss due to leakage through the old board and canvas stoppages.

(b) Assuming that the power on the air remains unchanged, the total quantity of air passing in the fan drift will be somewhat decreased; because all the air is now traveling the entire length of the airways, instead of being short-circuited by reason of the leaky stoppages. Increasing the length of air travel increases the mine resistance and decreases the total quantity of air in circulation, the power remaining unchanged.

(c) For the same reason, the water-gage reading, in the fan drift, will be slightly increased, the increase being in proportion to the greater mine resistance.

Question—What should be the maximum adverse gradient on a haulage road, in order that a 7-ton electric locomotive having a tractive power of 2,600 lb. may haul a trip of twelve loaded cars weighing 3,000 lb. each? Assume the frictional resistance to be 1/40 of the gross weight, for the cars, and 1/70, for the locomotive.

Answer—First, calculate the frictional resistance, which is, for the locomotive, 1/70(7 × 2,000) = 200 lb.; and, for the cars, 1/40(12 × 3,000) = 900 lb. The total resistance due to friction is, therefore, 200 + 900 = 1,100 lb., which must be subtracted from the tractive power of the locomotive, making the effective tractive power 2,600 − 1,100 = 1,500 lb.

The gross weight of the entire trip, including the 7-ton locomotive and the twelve cars is 7 × 2,000 + 12 × 3,000 = 50,000 lb.

Finally, the sine of the grade angle, for the maximum grade up which a tractive force of 1,500 lb. will haul a gross weight of 50,000 lb., is 1,500 ÷ 50,000 = 0.03; corresponding to an angle of 1° 43' or a 3 per cent grade.

Question—If the distance between two lifts in a mine is 100 yd., measured on a pitch of 25 deg., what will be the pitch distance between these lifts, measured on a pitch of 55 deg.?

Answer—Assuming the vertical height between the lifts remains unchanged, this vertical height for a distance of 100 yd., on a pitch of 25 deg., is (3 × 100) sin 25° = 300 × 0.4226 = 126.786 ft. Then, the corresponding distance measured on a pitch of 55 deg., will be 126.786 ÷ sin 55° = 126.786 ÷ 0.81915 = 154.16 ft.

Question—The tidal elevation of the top of a slope is 900 ft. and that of the bottom 750 ft.: (a) What is the difference of levels between the head and foot of the slope? (b) If the slope is 1,000 ft. long, what is the grade?

Answer—(a) The difference of level between the top and bottom of the slope is found by subtracting the elevation at the foot from that at the top of the slope; thus 900 − 750 = 140 ft.

(b) Assuming the length of this slope is 1,000 ft., measured on the incline, the sine of the slope angle is 140 ÷ 1,000 = 0.14, which corresponds to an angle of, practically, 8 deg., or a grade of 14 per cent.

Question—The bearing of the main entry, in a mine, is N 30° W and the bearing of the cross-entry from it is N 30° E. Rooms turned off the cross-entry run parallel to the main entry. If the perpendicular distance between the centers of the rooms is 36 ft., what distance should be measured on the entry between their centers?

Answer—As shown in the accompanying figure, the bearing of the main entry being in the northwest quadrant and that of the cross-entry in the northeast quadrant, the angle between these two entries is the sum of their bearings or 60 deg., which is also the angle that the rooms make with the cross-entry. Then, if the perpendicular distance between the room centers is 36 ft., the distance between centers, measured on the cross-entry, is 36 + sin 60° = 36 + 0.866 = 41.57 ft.

Question—Suppose a tunnel to be driven through a mountain, from east to west, a distance of a mile or more; in which direction will the air flow through the tunnel, in the morning and again in the evening? State why.

Answer—Assuming that the height of the mountain above the two mouths of the tunnel is sufficient to produce a difference in temperature caused by the heat of the sun, which raises the air on the eastern slope in the morning and on the western slope in the evening, there will be a corresponding difference in the density of the air columns acting on the respective entrances to the tunnel.

In the morning, the denser column will be on the western slope and the result will be a blow of air from the west to the east, at that time. Again, in the evening the condition will be reversed and the denser column will then be on the eastern slope and the flow of air will then be from east to west. This reply ignores, of course, any prevailing winds that would modify the movement of air through the tunnel, even on sunny days.
The Weather Vane of Industry

News Notes Chronicling the Trend of Industrial Activities on Which Depends the Immediate and Future Market for Coal

PRACTICALLY every industry for which figures have been received by the Department of Commerce showed greater activity in May than in April. Out of 42 production movements reported 38 showed an increase and only 4 declined, compared with the month preceding. Prices have shown the greatest increase for any month in more than two years. Forward orders are increasing and business again presents the picture of prosperity.

Prices on the average have not fallen below about 40 per cent over the pre-war level. They are now nearly 50 per cent above that level. No one knows at what level prices will finally become stabilized, but it is believed that care should be used in placing large forward orders for raw materials at prices much above the present level.

Fundamental conditions in this country are for the most part favorable. The agricultural situation is particularly good. The construction industry is having the biggest boom ever known, and this carries with it a large number of contributory industries. Employment has reached a point where a scarcity of men is reported at some points. The financial situation is favorable with abundance of money available at low rates of interest.

Receipts of wool in Boston during May showed a seasonal increase in the domestic product, while receipts of foreign wool were approximately equal to those in April. Total receipts were 40,972,000 lb. There was an increase in the activity of most woolen machinery, compared with the preceding month.

The activity of cotton spindles increased over the low point reached in April, but it is still below that of the closing months of last year. Exports of cotton cloth amounted to 60,448,000 sq.yd. in May, compared with 51,615,000 sq.yd. in April. This is the largest amount recorded for any month since last October and is nearly double the amount exported in January.

Both exports and imports of iron and steel showed moderate increases in May. Exports totaling 188,000 tons were the largest since March, 1921. Production of sheet steel showed an increase, although sales and unfilled orders fell off, compared with April. Copper production took another big jump, with a total of 88,714,000 lb., the largest for any month since 1920 and four times the production recorded six months ago. The exports of both copper and tin were less than a month ago.

The May production of petroleum amounted to 46,473,000 barrels, or only slightly less than the record attained in March. Consumption, at 49,572,000 barrels, also showed a marked increase. Imports reached a new record of 14,018,000 barrels.

All of the industries associated with building and construction showed a marked increase in output during May. The lumber industry as a whole is now operating at practically 100 per cent of normal. Production, shipments and unfilled orders of brick were much greater than in any recent month. Shipments and new orders for enameled sanitary ware showed large increases, while stocks on hand declined.

Exports of wheat and wheat flour increased over April, but were less than half as large as a year ago. Exports of corn fell off in May from the high figures attained in recent months. The total of 11,306,000 bushels is still far above the average for this cereal. In general the movement of foodstuffs was larger than in April.

Rail Strike May End Soon

The strike of railway shopmen on July 1, which threatened to involve 450,000 workers, including maintenance of way men, thus far has caused little inconvenience to traffic. The maintenance of way men have refused to go out and the companies announce that a marked drift back to work is noticeable and that skilled mechanics are applying in large numbers for the places of the strikers. B. M. Jewell, head of the striking shopmen, has expressed a willingness to entertain peace proposals.

Philadelphia Industries Better

Although June normally is a month of declining industrial activity, it has not proved so in the Philadelphia district, according to the July review of business conditions issued by the Federal Reserve Bank at Philadelphia. Reviewing activities there, the bank says that the improvement noticed in April has continued. "It is true," says the bank, "that the gains made during the last month have been smaller than those of May, but the improvement has been marked. Several of the industries that heretofore had not been affected by the general upward movement have recently reported considerably heavier sales, and this, coming at a time when a decline was to be expected, is especially significant as indicative of the underlying trend of business."

New England Trade Static

Business activity in New England during June was about on a par with that of May, or slightly better, according to the July review issued by the Federal Reserve Bank at Boston, covering conditions in the First Federal Reserve District. "The change, if any," says the bank, "was so small, however, that it has been difficult to measure accurately. New England manufacturing activity has been increasing at a nominal rate for the last two months, although there has not been a corresponding increase in car loadings."

Trade Gains in Richmond District

Reports received by the Federal Reserve Bank at Richmond, Va., late in June show clearly, says the bank’s July bulletin, that the states in the Fifth Federal Reserve District are sharing in the apparently nationwide improvement in business. West Virginia is temporarily disturbed by the coal strike, and the early appearance of the boll weevil is annoying South Carolina, but elsewhere in the district signs point to better conditions and outweigh the deterrent factors. Textiles and cotton both showed improvement and agricultural prospects in general are good.
IMMEDIATE resumption of coal mining under a plan of settlement of the strike proposed by President Harding is now being considered by operators and miners. Realizing that the conference was deadlocked the President suggested last Wednesday that mining be resumed on the wage scale in effect on March 31 last. A commission to be composed of three representatives each of the miners and operators and five representing the public is suggested to investigate and report in thirty days, if possible, on a new wage scale to run until March 1, 1923. The President also stated that he would ask Congress to give authority to this commission to make a thorough investigation of the coal industry looking to its stabilization and to the promotion of peace in the industry.

The President’s conference with the operators and miners adjourned at noon. The anthracite operators conferred on the proposal at the Bureau of Mines, the bituminous operators at the Washington Hotel and the miners’ representatives at the Red Cross Building. The President asked the miners and operators to give him their answer by night.

Both operators and miners were unable to make answer to the President’s proposal at once, the union being the first to move for delay on the ground that its representatives at the conference were not authorized to accept the proposal. They at first proposed to call the general policies committee of the union in conference at Washington on Monday, July 17. President Lewis went to the White House to ask for a week’s delay and when he came away he said the general policies committee meeting would be advanced to Saturday, July 15.

No Answer at End of Day’s Conference

At the end of a day’s conference both bituminous and anthracite operators announced that they had not reached an answer to the President’s proposal. They said the delay of the miners in acting on the settlement plan was having no effect on their action in the mines. Attention was called by the bituminous operators to the fact that the miners’ representatives have been participating in the conferences looking to settlement of the strike, although they appeared to have no authority to take action, while the operators have been ready to act.

To this John Lewis countered by saying that it was all along understood that the miners’ representatives at this conference had no power to act. He also charged that the bituminous operators were not fully represented at the present conferences.

After the anthracite operators adjourned their conference announcement was made that they had not reached a conclusion on the strike settlement plan. They then went into informal conference with the bituminous operators.

President Ogle of the National Coal Association pointed out that the strike settlement offer submitted by the operators on July 3 met all suggestions advanced by the President in opening the conference and would have provided an ample and direct method of reopening the mines.

President Harding’s address to the conference Monday follows:

“Gentlemen, the information has come to me that your conference is deadlocked, or, at the best, attempting to agree on something that will require extra time to work out. I have said heretofore that the government prefers that you who are parties to the dispute should settle it among yourselves, because you best understand all the problems involved. The government cannot settle it for you. It will force no man to work against his free will, it will force no men to employ men against the free exercise of an employer’s rights. The government will not be partisan, but the government is concerned with coal production sufficient to meet the industrial and transportation requirements of the country and to safeguard against a fuel famine when winter comes again, and it is desired to have production resumed at once.

“Your government does desire to be helpful. With such a thought, therefore, I submit to you the following proposal:

“Mine workers are to return to work on the status quo wages which expired last March 31, and mines now idle because of strike or suspended operation to resume activities, without interference with activities of mines now working. The 1922 scale to be effective until Aug. 10, 1922.

“A coal commission to be created at once, consisting of three members selected by the mine workers, three members selected by the mine operators, and five members to be named by the President. All decisions by this commission shall be accepted as final.

“This commission to determine, if possible, within thirty days from today, for the miners on strike a temporary basic wage scale, which scale shall be effective until March 1, 1923. In event that the commission is unable to report its scale by Aug. 10 it shall have power to direct continued work on the President’s schedule scale.

“The commission shall investigate exhaustively every phase of the coal industry. It shall reveal every cost of production and transportation. The President will ask Congress to confer authority for the most thorough investigation, and make appropriations necessary to do such work. The commission shall make recommendations looking to the establishment and maintenance of industrial peace in the coal industry, the elimination of waste due to intermitteny and instability, and suggest plans for dependable fuel supply.

“I have taken this short cut to a resumption of operations because I believe it to be in the interest of the public welfare. It is that simple form of adjusting disputes which answers the call of good conscience and a just civilization. With two great forces not agreeing there must be a peaceful way to adjustment, and such an arbitration opens the way.

“I do not expect reply without due consideration. Please take the proposal to separate conferences. I wish you to appraise the situation, weigh your responsibilities, and then answer this proposal as you wish to be appraised by American public opinion. In making final decision in the public interest, but I am likewise mindful of the rights of both workers and operators. You also are an inseparable part of that public interest. With due regard for all concerned it ought to be easy to find a way to resume activities and command the approval of the American public.”

Operators and Miners Withhold Comment

Comment on the President’s plan has been withheld by both operators and miners. There is a general feeling that the miners sought the delay of one week in order to ascertain in advance of their decision what public opinion may develop and what progress the railroad strikers make in tying up coal production. They are no more inclined than the operators to flout the President and face public reproach. It has been suggested, however, that neither side may accept the administration’s plan in full and that each side may tack on so many reservations to their acceptance as to prevent its operation.

It is being pointed out that there might well be great difficulty in moving coal from the soft-coal mines during the anticipated short period when the miners’ wage is reduced at the old high rate and production costs high. Fake buyers, for instance, it is suggested, would hesitate at stocking such high-cost coal when lower prices were in immediate prospect. The anthracite operators are understood to fear that the same would apply to householders and retail dealers, who would postpone purchases until wages had been reduced and the mine price lowered.

On the other hand, some have seen in the power that would be delegated to the commission by the President to
extend beyond August 10 the March wage scale, providing no negotiation had been reached, a danger that the miners could hold indefinitely to their high wages, once they got started. The principal objection of the operators appears to center about the attempted imposition of the last wage scale after they have held out for over three months in an effort to get a lower wage. They appear to feel that once they accept the plan would put them back where they were when the strike started.

Another point that provokes but little comment on either side has to do with the check-off. It is not stated in the President's paper that the old contracts be resumed, but only that the men return to work at the old scale of wages, and this might be interpreted as either with or without the check-off. Non-union operators are especially apprehensive on this basis, as to hold them they would doubtless raise wages and this would raise the level of prices all over the country. Mines now working would not be affected and this is interpreted to mean that in those areas, as Kanawha, where former union operations have been started open shop, they would be permitted to continue. A large question is raised, however, in the case of the Connellsville area since full compliance by the union with the President's terms would presumably require the union to withdraw from that field and put those men back to work at the non-union scale in effect on March 31 of this year.

Observers at Washington are trying to square the government's position with railroad labor with that taken in the coal situation, and are not anticipating early acceptance by the strikers of or operators of the President's plan. In other words, those in close touch with the sides of the situation are not anticipating coal production to begin this month.

Washington, July 7.—The administration, it seems at this writing, has maneuvered itself into a position where it hardly can refuse to force the arbitration of the questions at issue between the coal operators and the United Mine Workers. There is said not to be any such agreement it placed itself in a position where it would be difficult to refuse were one of the parties to the controversy to request that an arbitration committee be set up. The anthracite operators have stated that they want to arbitrate the matter. They can say to the President that he now has tried moral suasion without result and that the time has come for him to invite the miners to agree to such a plan.

There is a widely held opinion that this will be the outcome, despite the earnest desire of Secretary Hoover to do something more fundamental than agree on wage scales which will make possible a one or two-year truce.

In that connection, however, it is suggested that the President could say that he would call upon the parties to the dispute to enter into arbitration proceedings, provided each would find itself to undertake certain obligations with a view of effecting some fundamental betterments in the coal business.

There has been considerable speculation as to the possibility of the President's initiating a movement for the creation of a tribunal along the lines of the Railroad Labor Board. There is no indication, however, that such a plan is under consideration. It is considered that the setting up of such a tribunal for a public utility, long subject to government regulation, is entirely a different matter from making the same provision for a business which has been unregulated. To set up a coal labor board, it is believed, would involve more government interference with business than the administration is prepared to undertake.

Proposals to redistrict the union territory have gotten nowhere. Nevertheless there are some who see hope of some such plan going through. One of the suggestions for redistricting would reduce the thirty-five wage-scale districts to six. Another proposal would be the division of the union territory into fourteen districts. While the mine workers are outspoken against any changes in the existing wage-scale districts, it is believed that they would prefer, if forced to negotiate on a district basis, to do so in new districts along the lines of some of the suggestions which have been made. Increased freight rates and changes in markets have made desirable certain changes in district boundaries, and it is not improbable that some such changes will be agreed on in the settlement of the existing strike.

The demand that something be done by the federal government to end the strike and start the production of coal moving to the Northwest and to New England is becoming more insistent. The most pressing appeals are coming from New England, where the public is beginning to fear for its anthracite supplies for the coming winter. The sentiment, however, is not confined to New England, for protests are reaching Washington in increasing numbers from all parts of the anthracite-consuming section of the East. As the situation now stands production of anthracite is fully 20,000,000 net tons behind the normal output. While this deficit can be overcome to a certain extent, it cannot be made up entirely and each day that the strike continues means that much further limitation on the anthracite which will be available to domestic consumers: this winter. Even if work were resumed at once, there are many thousand families who burned anthracite last winter who would not be able to obtain supplies for this winter's use.

The public in the Northwest has been particularly passive and it is only within the last week that any signs of anxiety as to next winter's fuel have developed. Senator Kellogg and certain of the members of the House of Representatives from the Northwest, however, have been, contrary to the past two weeks or more, putting pressure on Department officials in regard to the situation. The unusually large carryover at upper lake docks has made available sufficient supplies to satisfy a considerable demand during the early part of the coal year, but reports as of July 1 indicate that stocks on the upper lake docks continue large with only a very gradual increase in order. Throughout the entire time since the strike began there have been considerable supplies of coal available to the Northwest at lower lake ports.

The strike has resulted in two unusual movements of coal on the Great Lakes. The upper lake docks have been shipping coal to Lake Michigan docks, while steel plants at Buffalo have been getting coal from Lake Erie ports. There is no legal provision for either of these transfers since they are made by the National Committee on Gas and Electric Service, under the immediate direction of George H. Elliot, has been announced by F. R. Wadleigh, chief of the newly organized Coal Division of the Department of Commerce. Mr. Wadleigh's announcement reads as follows:

"The canvass of the coal stocks of electrical and artificial gas public utilities as of June 5 shows an average of 53 days' supplies in hand. A great many utilities are receiving current supplies from non-union production, and on the basis of their current encroachment on stocks it seems that their stocks would last about 12 to 15 weeks."

The canvass of stocks at metallurgical plants is about to be completed.

While isolated shipments of Nova Scotia and Welsh coal have gone to American ports recently, it is not believed that price conditions favor any important movement of these coals to the United States in the near future. There has been, however, a notable increase in the volume of Nova Scotia coal mined and it is moving up the St. Lawrence in unprecedented quantities.

A DIRECT EFFECT OF THE COAL STRIKE is seen in a considerable slump in the sale of explosives in the United States recorded for the month of April by the Bureau of Mines. The quantity of explosives sold during April for use in the United States was 25 per cent less than the record for March; 18 per cent less than for April of last year; and 46 per cent below the figures for April two years ago.
Bituminous Operators’ Plan Proposed Arbitration
By District Boards and Nationwide Probe

BITUMINOUS-COAL operators made a proposal on July 3 to the joint conference of miners and operators meeting in Washington with Secretaries Hoover and Davis. In this plan they provided for regrouping of the union fields to avoid the objections to the old Central Competitive Field and at the same time give the miners an adequate substitute. To meet the desires of the administration for a comprehensive and forward-looking program on coal the operators provided in their resolution for a non-partisan commission to be given powers to make a thoroughgoing investigation of the coal industry and to make a report on the fundamental problems of the bituminous-coal industry and to make recommendations to the President for their solution.

Local set boards of arbitration were suggested to handle disputed points, with provision that they should settle all matters in controversy by Aug. 1. The miners refused to accept this plan of the operators and withheld its publication until July 10. The resolution in full follows:

“Pursuant to the call of the President of the United States and in order to bring about a speedy termination of the strike now in progress in the bituminous coal fields the operators have voted to hold an immediate and move in adoption of

“(1) That the negotiation of wage scale contracts in all of the scale-making districts here represented be referred to the miners and operators in each scale-making district for settlement.

“(2) In accordance with the suggestions of Secretaries Hoover and Davis this conference shall appoint a committee of six miners and six operators, which committee shall consider the practicability of grouping scale-making districts, where possible and mutually agreeable to the miners and operators in the districts affected, to reduce the work of scale making.

“(3) In order that there may be a speedy resumption of work and no unnecessary delay in reaching agreements a board of arbitration shall be established in each scale-making district or group of districts, to which board shall be referred all disputed points remaining unsettled by July 15, 1922, shall be referred to the boards of arbitration as established by the President in each scale-making district. Upon questions so submitted to arbitration the boards of arbitration shall report on or before Aug. 1, 1922.

“(4) The President of the United States is requested to appoint a board of arbitration in each scale-making district. Each board of arbitration shall consist of three interested members, none of whom shall be miners or operators, nor in any way connected with the bituminous-coal industry.

“(5) In accordance with the suggestion of President Harding a board shall be appointed by him, whose duty it shall be to study the fundamental problems of the entire bituminous-coal industry and make recommendations to the President for their solution.

“(6) Negotiations shall proceed in all scale-making districts at once in order that the public may be supplied with coal of proper quality in three months. Operators were of the opinion that wages had been reduced to about 8s. 4d. a day ($1.87 at present exchange), or two guineas per week ($9.32). Wages were being brought down to only 20 per cent over those in July, 1914, whereas the cost of living was 81 per cent above that ruling at that date. Moreover the working time was short at many of the mines.

Mr. Bridgeman’s remarks ended, the Labor members started to tear the statement to pieces, speaking on a resolution to reduce the proposed appropriation. During the past fifteen months, said Mr. Adams, wages had fallen more seriously than at any other time. In his own district, Fife, the fall had been 12s. ($2.66 at present exchange) or £3 ($13.32) in an average working week. In addition to the general fall, partial reductions had been made by certain owners. In three of the fields wages had been reduced to about 8s. 4d. a day ($1.87 at present exchange), or two guineas per week ($9.32). Wages were being brought down to only 20 per cent over those in July, 1914, whereas the cost of living was 81 per cent above that ruling at that date. Moreover the working time was short at many of the mines.

Mr. Heus, another Laborite, wanted an equalization fund set up in each district and provision made that after any individual colliery had received 17 per cent of its standard wages and 17 per cent of its surplus, 50 per cent of any surplus remaining should be paid to the fund. Similarly any colliery which could not afford to pay the rate of wages fixed for the district should receive out of the fund a sum equivalent to 50 per cent of the colliery wages by which it failed to meet the charge fixed for the district wage.

Another Laborite, C. Edwards, found it hard to glory in the re-establishment of the British export trade in the presence of the low wage. He said the coal almost had been given away. Mr. Lawson said that large numbers of colliers were making no more than from £2 to £9 ($8.88 to $13.32) per week, and Mr. Walsh, another Laborite, said that “though the government expected to go week by week to the guardians to have their wages supplemented because they could not earn sufficient to keep body and soul together.”

In response Mr. Bridgeman said that the taxpayers had subsidized the miners by a gift of £25,000,000 to keep up wages and £7,000,000 to ease their decline. He could imagine no greater folly than the desire of the men to repudiate the profit-sharing arrangement just because it happened that they were now at the bottom of the wave.
Kentucky-Tennessee Operators’ Association Elects J. E. McCoy as Secretary

DIRECTORS of the Kentucky-Tennessee Coal Operators’ Association met in the offices of the association, Knoxville, Tenn., Friday, June 30, and accepted the resignation of D. S. Miller, commissioner-secretary, and elected J. E. McCoy to succeed him in the capacity of secretary only. Mr. McCoy was for twelve years secretary and treasurer of the Southern Appalachian Coal Operators’ Association.

The Kentucky-Tennessee Coal Operators’ Association is a new organization, the result of the split in the membership of the Southern Appalachian Coal Operators’ Association, and is composed of operators formerly members of the Southern Appalachian and non-members in the territory. The territory covered by the Kentucky-Tennessee Association is the southeastern district of eastern Kentucky and the State of Tennessee. The tonnage represented by the new organization is approximately 3,000,000 per annum.

Members of the Kentucky-Tennessee association operate under what they are pleased to term an “open shop, non-union” wage contract without the “check-off” feature which is provided for in all U. M. W. A. contracts.

The present contract expires March 31, 1924, and is a modification of the wage agreement negotiated for this field at Washington, in October, 1917, and approved by H. A. Garfield for the U. S. Fuel Administration. This contract provides for further modification in the matter of wages to meet competitive conditions.

Ford Offers to Lease Part of L. & N. Lines To Move Coal to Detroit

HENRY FORD has submitted an offer to lease that part of the Louisville & Nashville Railroad between Banner Fork and Corbin, Ky., and from Corbin to Cincinnati, and operate it with the present force of railway employees in order that coal may be moved to Detroit. Mr. Ford had made the offer to the president of the Louisville & Nashville after the railroad company had informed him it was unable to move 8,000 cars of coal consigned to Detroit industries because of labor troubles.

The Banner Fork branch is the coal carrying division of the railroad. Connection would be made at Cincinnati with the Detroit, Toledo & Ironton R.R., which is owned by Mr. Ford. Mr. Ford’s offer included the taking over of the railroad’s equipment on this branch under the proposed lease.

Members of the staff of W. L. Mapother, president of the Louisville & Nashville R.R., expressed surprise when they were told of the Ford offer. W. J. Michael, secretary to the president, said that press reports were the first intimation that had been received of the proposal.

Some of Ford’s coal mining interests are located at Banner Fork. Through a private agreement with his men his mines are not affected by the coal strike.

Senator Pepper Argues Against Sale of Coal Stock to Reynolds Syndicate

THAT the stock of the Lehigh & Wilkes-Barre Coal Co. may come into the control of the Lehigh Coal & Navigation Co. should the bid of the Franklin Securities Corporation for the stock of the former company be accepted, was revealed July 5 in the hearing in the Federal District Court at Philadelphia of a case growing out of the Reading dissolution suit.

Acquisition by the Lehigh Coal & Navigation Co. of the Lehigh & Wilkes-Barre coal stock would materialize, it was said, if the Franklin Securities Corporation, upon obtaining the stock decided it did not want to operate the company.

Senator George Wharton Pepper charged that such an agreement existed in an argument on the motion by the Central Railroad of New Jersey, owner of the Lehigh & Wilkes-Barre stock, for the dismissal of the petition of Isaac T. and Mary T. W. Starr, that the sale of the stock to the Reynolds Syndicate be set aside. Senator Pepper, counsel for the Starrs, contended that the Franklin Securities Corporation’s bid was better than that of the Reynolds syndicate.

The court reserved decision in the case with the announcement that if it was unable to reach a decision on the legal points raised by Senator Pepper a special master would be appointed to take testimony.

German Coal Prices Show Upward Trend

THE Information publishes a table taken from the German journal Werkstätten und Statistik showing the average monthly prices of German and foreign coal for the first quarter of the year:

<table>
<thead>
<tr>
<th>Commodity</th>
<th>December</th>
<th>January</th>
<th>February</th>
<th>March</th>
<th>April</th>
</tr>
</thead>
</table>

POTENTIAL COAL CONSUMPTION DURING MARCH

PUBLIC-UTILITY plants consumed 2,484,500 net tons of coal during May, 1922, according to the report of the Geological Survey, just published. This was a slight increase as compared with 2,457,790 tons in April, but was less than the March consumption of 2,723,561 tons. These consumers used 2,585,259 tons in February and 2,893,540 in January. The average daily consumption of coal in March was 87,900 tons, in April, 81,900 and in May, 80,100.

The coal strike may have affected the demand for electric power to some extent in the eight leading coal-producing states. Considering the mean daily output in these states during March as 100 per cent, the April figure was 94.5 per cent and May 94.7 per cent. The remaining states, excluding those on the Pacific Coast, show 97.7 per cent and 99.2 per cent, respectively. The average daily output for May was 122,600,000 kw.-hr., as compared with 120,100,000 kw.-hr. in April. The proportion of the total output produced by water power increased from 34.6 per cent in January to 42.8 per cent in May.

WITH THE BEGINNING of the new fiscal year the Department of Commerce has given coal a commodity division all its own. Heretofore coal and petroleum have been handled in a single division. This was necessary because of the lack of funds available for the commodity divisions, but with larger appropriations available for the current fiscal year the division has been effected. H. C. Morris, who has been handling the petroleum part of the work, continues as chief of the petroleum division, and F. R. Wadleigh continues handling coal matters.

AFTER A WHILE, perhaps, the leaders of certain unions will discover that wages cannot be hoisted with bombs.

—Columbia Record.
Fourteenth Week of the Coal Strike

EDITORIAL REVIEW

MUCH mystery, secrecy and, withal, quiet, marked the fourteenth week of the strike. On Monday, the day before the holiday, the third meeting of union operators and miners was held in Washington under the auspices of the government. Previous meetings on Saturday and Sunday had developed a violent debate behind closed doors with no official record into which each delegate could feel obliged to establish his stand for future reference. The miners had offered their resolution to go into negotiations through the medium of the Central Competitive Field and the operators offered their resolution for district conferences, both of which were as promptly voted down. This much was made public after the meetings.

On Monday there was word that some proposal of new and striking significance had been made by the operators. It was reported that the story had leaked, that the Associated Press had it and had been induced to withhold it. President Harding's injunction of secrecy, with the suggestion that all would be told later, was carefully observed. The delegates disappeared from the scene the eve of the Fourth, to gather again on Monday morning July 10, prepared to hear what the President should have to tell them, after hearing their report of total lack of progress in previous conferences.

What transpired on Monday, July 10, is described elsewhere in this issue. Washington is still the center of strike interest with a meeting of the Policy Committee of the United Mine Workers set for Saturday, July 15, to consider the President's proposal.

In the fields production slumped greatly because of the holiday. The miners who have been working were tired, had plenty of money and were ready and anxious for a rest and good time. They pretty largely extended their celebrations over more than the one day and nearly every district shows the effect in decreased output. Fortunately the same is true with regard to consumers and the coal business, of course, recorded a corresponding drop. The strike on the railroads has had but local and small effect on the movement of coal to date, but that is no assurance that it will not be a factor later in limiting production on some roads.

No disturbances have been reported this week in the wagon mine district in western Indiana. All the mines have resumed operation following the continuance of an injunction suit in federal court against the striking miners, officials of the United Mine Workers having promised Judge Anderson, June 29, that there would be no further interference with the operation of these mines.

Farrington Takes One More Step Toward Making Separate Wage Deal in Illinois

AS AN aftermath of the first futile conference in Washington of operators and miners, and as a forerunner of the second meeting on Monday, July 10, Frank Farrington, president of the Illinois miners, convened his executive board in Springfield Friday the 7th—minus certain members for they had left, President Lewis of the International union—and got authority to negotiate to determine a separate state wage scale in case nothing definite developed at Washington. The day of the executive board meeting Mr. Farrington emphatically denied that any move was being made toward a separate deal. But during the meeting he cleared the way for such a deal.

Various operators, in session at Chicago, disclaimed any previous knowledge of Mr. Farrington's plan and had no comment to make upon it except that the action seemed to be in line with Mr. Farrington's original promise to the operators to negotiate for a separate peace in case "an emergency should arise." During the first miner-operator conference at Washington, July 1, 2 and 3, the declaration was made that Illinois miners were going to stick it out with the International union, come what would.

Operators in that state, while strictly preserving their pledge of secrecy concerning the Washington conference, nevertheless went back to Washington Saturday night for the Monday conference with high hopes that a definite development would appear and that peace negotiations in the mine strike would soon be under way, with a resumption of mining operations.

In the meantime comparative peace appeared to reign in the mining fields of Illinois and Indiana. Union leaders have suppressed the program of threats with which many clerks and other company employees in wet mines such as those of the Madison Coal Corporation near Carterville were driven from the pumps two weeks ago to the detriment of the mining properties. By the end of last week it was reported that every pump necessary for the protection of a mine was working.

No Further Outbreaks in "Bloody" Region, But Situation There Is "Like Dynamite"

OUTSIDE of a little trouble at the McClinton mine at Johnston City everything is quiet in the southern Illinois field following the slaughter at Herrin three weeks ago, although there is some underrun that may develop into trouble at different places. Union miners have been threatening the workers who are keeping the pumps going at the mines. This, however, is about at an end by order of Frank Farrington, Illinois miners' president.

The only difficulty reported during the week took place at the McClinton mine near Johnston City, where the company, which is building a new tipple, offered the laborers $4 a day. The miners refused to take this, demanding a higher scale, whereupon the company imported labor. All of the work is outside of the jurisdiction of the United Mine Workers. That does not seem to worry the Williamson County gang, however, because apparently there is no law in the county.

Reports from southern Illinois indicate that miners from Williamson County have been going down to Kentucky in automobiles carrying moonshine whiskey and generally causing trouble, or trying to, at mines in the western Kentucky field. Several thousand miners are reported to have deserted the union ranks and gone to work in these districts and the miners justify their expeditions into the western Kentucky field by alleging that they are trying to ascertain whether the absentees from Illinois have gone to work there.

"There haven't been any further outbreaks," said an operator of the southern Illinois region, "but the situation here is like dynamite; there's no telling when something may go off."

Holiday Fever Slows Up Operations In Connellsville Coke Region

JULY 4 seems to have had a slowing-up effect on the Connellsville coke region. The H. C. Frick Coke Co. lost about forty miners at the Leisening No. 2 plant, but made this up in gains at other points, so that as a whole the company is holding its own. The Hillman Coal & Coke Co., W. J. Rainey, Inc.; American Coke Corporation and Pittsburgh Steel Co. also are about holding their own.

The Republic Iron & Steel Co. has recovered the ground lost a week ago at its Brookwood plant. The Mather Collieries Co. has lost about 20 per cent and the Crucible Fuel Co. about 85 per cent as the result of a number of miners' mass meetings and picnics in that vicinity during the past week. Railroad shipments indicate a loss of about 10 per cent as compared with a week ago.

There have been a number of small scattered dynamitings throughout the region during the past week. No one of them has done much damage. The state police are still in charge of the towns of Brownsville and South Brownsville.
Garment Workers' Union Votes Gift of $100,000 to Striking Coal Miners

THE International Ladies' Garment Workers' Union has voted to give $100,000 to assist the coal miners on strike, according to the report of the meeting of the union held in New York City July 6. Half of the sum will be available immediately. This is the first relief to be received by the striking coal miners.

The gift was voted after appeals made by Samuel Gompers, president of the American Federation of Labor, and John J. Lewis, president, and William Green, secretary, of the United Mine Workers.

In 1919 the Garment Workers' Union gave $60,000 to the steel workers.

Violence Reported in Hocking Field; Federal Judge Restores Injunction

COAL loaders, driven from a slack pile near New Straitsville, Ohio, appeared before Federal Judge Sater in Columbus June 5, seeking an injunction restraining union miners from interfering with their work. This was about the first notice of violence since the opening of the strike in the Hocking Valley field. A temporary injunction restraining the strikers from interfering with loading, which was lifted some time ago by Judge Sater, was immediately restored. Hearing on a permanent injunction will be held soon. The men appeared in overalls and working clothes and averred that they had only these clothes since their camp was burned. Several were nursing wounds as a result of shots fired into the camp. Thomas Marshall, of Altoona, Pa., was killed by the firing. The attacking party consisted of between 200 and 300 men.

Application for troops was made to Governor Harry L. Davis by the operators of stripping operations in Harrison County. A representative of the Adjutant General's office was sent to investigate and reported that there was no necessity for troops. Threats had been made and at least two men were killed in that section.

Politics Mixed in Colorado Situation; No Violence Since Arrival of Troops

APPEARANCE of state troops in the field seems to have been welcomed by the majority of citizens in Colorado, but the radical element denounced the action of Governor Oliver E. Shoup.

On July 2 Adjutant General P. J. Hamrock and Lieutenant Governor Earl Cooley, candidate for nomination for Governor on the Republican ticket, engaged in a verbal clash when the former charged that the acting Governor violated the order of Governor Shoup in addressing a meeting of union miners at Frederick, Col.

Guardsmen were ordered not to allow any mass meetings in the state. General Hamrock, it is said, told Governor Shoup that the Lieutenant Governor caused the strikers to be called together through James Barclay, president of Frederick Local of the United Mine Workers, despite the fact that he was informed by Captain John Campion, in command of the troops there, that no meetings were allowed.

Governor Shoup has cancelled his vacation trip to the Pacific Coast as a result.

No violence among miners has been reported since the troops have been sent into the field along with the State Rangers, according to Adjutant General Hamrock.

All Quiet Now in Utah, Although Guardsmen Under Arms Stay on the Job

CONDITIONS are quiet in Utah. There is, however, no talk of recalling the guardsmen. The announcement that operators would not be permitted to recruit men and send them to the mines and that only persons who paid their own fare to the coal fields would be allowed to remain, has caused much dissatisfaction among mine owners. It is pointed out that in other lines no interference is made and that the recent decision in the present strike is only a sign of weakness on the part of the chief executive officers of the state. The leading newspaper of Price (Carbon County) has made a bitter attack on Governor Mabey, and sneers about his being only an executive in a $20,000 country bank before taking his present position. On the other hand men in high places have praised his stand regarding strike breakers.

Nova Scotia Miners Threaten to Strike If Wages Are Cut; Conciliators Named

MINERS employed at the collieries of the Inverness Coal Co., Inverness, N. S., have threatened to strike owing to a dispute over wages. The company has refused to consider the demands of the men that wages be not reduced. The federal Minister of Labor, James Murdoch, has been appealed to for a special board of conciliation to adjust the dispute. He has agreed to the appointment of a similar board representing the Inverness Coal Co. will be G. McG. Mitchell, of Halifax, N. S., with L. D. Currie, of Glace Bay, N. S., representing the miners. I. D. McDougall, of Inverness, who represented the miners on the Scott board, which recently investigated the claims of the miners employed by the British Empire Steel Corporation (Dominion Coal Co.), also was appointed to represent the men of Inverness, but declined. He gave pressure of private business as a reason for not acting, but it is believed that dissatisfaction of the miners with his efforts in their behalf on the Scott board has been a factor in his refusal to act on the Inverness board.

Mr. Currie, the miners' representative on the Inverness board, recently was graduated from the Dalhousie University Law School.

Owing to the fact that Mr. Mitchell for the operators and Mr. Currie for the employees have not been able to agree on a chairman after several meetings, the Minister of Labor has been asked to appoint a chairman. This is a situation similar to that which existed at the formation of the Scott board.

J. B. McLachlan, district secretary-treasurer of the United Mine Workers, has refused to accept Robert Baxter's challenge to oppose him for the office of district president at the next annual election. In an interview, July 6, Mr. McLachlan made the following statement: "I have no intention of running for the office of president. If President Baxter wishes me to oppose him for the election, why doesn't he get some of the locals to nominate him for the office? To be secretary-treasurer is to do a perfectly well that no individual has the power to nominate himself for any office. According to the constitution that is a matter for the locals."

Going further, Mr. McLachlan said that he had received nominations already from four of the locals of the district and none of the lists contained the names of President Baxter, Vice-President Delaney, McCormick or Silby Barrett. The nominations which Mr. McLachlan has in his possession are Dan Livingstone for president, Alex S. McIntyre for vice-president, J. B. McLachlan for secretary treasurer, M. S. McNeil, of Dominion, for sub-district board member for District No. 1, and Alex Stewart, of Westville, for international board member.

Is Howat Merely Seeking Another Chance To Stir Up More Trouble for Somebody?

ALEXANDER HOWAT is ready to have his followers in Kansas return to work at once in the mines there. This decision was reached at a recent meeting of a group of about 700 men favorable to the Kansas mine-union president deposed by international headquarters of the union last autumn with his entire entourage of officers. Louis Burnskill, chairman of the meeting, said that the men saw no other way for them to become reinstated in the union than to go to work. Naturally enough, many observers doubt in this action just another effort to embarrass John Lewis and the other leaders of the United Mine Workers of America.
LAST week was a trying one for the coal buyer. Production was curtailed by the July 4 holiday and the available supply was further cut down by a serious congestion of loads in the non-union producing fields. The scarcity became so acute toward the end of the week that higher prices were inevitable. The consumer who had delayed buying in order to obtain the lower freight rate after July 1 now finds that spot prices have more than wiped out the 10-per-cent reduction. In the meantime stocks have been reduced below the safety point and the procurement of immediate supplies is becoming imperative.

Quotations have definitely slipped out of the bounds suggested by Secretary Hoover. Coal Age Index of spot bituminous prices stands at 301 on July 10, an advance of 11 points as compared with 290 on July 3. This week’s index represents an average spot price at the mines of $3.64, which is 13c. over the average for the previous week. The strengthened prices are most noticeable in western Kentucky, where no maximum price has been agreed upon. This coal is selling well over the $5 mark. Eastern Kentucky and the West Virginia high-volatiles are now using the Hoover figure of $3.50 as the minimum, with the top price strong at $4. Low-volatile prices are being held more firmly in check, but sales exceeding the Hoover maximum are becoming increasingly numerous.

MIDWEST MARKET MOST ACTIVE; PRICE NO FACTOR

The market is most active in the Middle West. Price seems to be no factor in that territory, the main desire being to get coal. Not only are the smaller consumers clamoring for tonnage but the railroads and large users are being forced to replenish their supplies on the spot market. The demand is so good that old piles of slack coal at Indiana mines, some of it on the ground for years, is being marketed around $2.50.

A panicky feeling now prevails throughout the Northwest. Commercial supplies at Duluth-Superior are less than 550,000 tons of bituminous coal and 250,000 tons of anthracite, the latter being of the less-wanted sizes. Total dock receipts this year were 288,000 tons to July 1, as compared with more than 4,000,000 tons in the corresponding period last year. Dock coal is being doled out to needy consumers and none else. It is now apparent that every day’s delay in Lake coal traffic is adding to the Northwest’s coming predicament next winter.

New England coal sales are increasing. Inquiry is only relatively better, however, as large consumers still have good supplies on hand. So many diversified demands are being made on the fields supplying the Hampton Roads piers that prices are stronger, and coastwise freights reflect this condition, although there is no dearth of vessels.

So far the railroad shopmen’s strike is not felt on the surface although it is hampering the movement of loads in the Kentucky fields. This trouble also is affecting the movement of coal South. The Erie has canceled 21 suburban trains on its New York City schedule, giving as a reason “shortage of coal.” This is surprising news, coming atop the railroad strike, as it is the first intimation that railroad fuel supplies were near the danger mark. The outstanding feature of the coal strike last week was the preparation of

(a) Subject to revision (b) Revised from last report.
certain large Pittsburgh district producers to resume operations at once, under guard. Labor shortage is beginning to be felt in Alabama, where peak production is fast being approached.

The anthracite supply is running down, despite the indifference of consumers. Retailers are listing increasing orders for delivery as soon as possible, conserving present meager supplies for hotels, hospitals, etc., which must have coal through the summer and autumn.

**BITUMINOUS**

"Production during the fourteenth week of the strike was interrupted by the Independence Day holiday," says the Geological Survey. "The total output of bituminous coal probably will fall between 3,500,000 and 4,000,000 tons, and even the average production per working day will show a decrease. Production of anthracite remains practically zero.

Complete returns for the thirteenth week (June 26-July 1) indicate an output of 5,207,000 tons of bituminous coal and 25,000 tons of anthracite, a total of 5,232,000 tons, of all coal. In the corresponding week of 1921 bituminous mines produced 7,690,000 tons and the anthracite mines 1,870,000 tons, a total of 9,560,000 tons. In 1920, a year of active business, the total coal raised was 12,064,000 tons.

"The record of daily loadings of cars of bituminous coal shown in the following statement clearly discloses the effect of the Fourth of July holiday. On Saturday, July 1, 12,614 cars were loaded as against 13,993 cars on the preceding Saturday. On Monday only 11,165 cars were loaded. On Independence Day itself production ceased almost entirely, and the recovery thereafter was slow. By Thursday, July 6, loadings had reached 14,000 cars but were still running 2,000 cars below the level of the week preceding. Even allowing for full recovery on Friday and Saturday, it does not appear likely that the week's production can pass 3,800,-000 tons."

**Coal Age Index 301, Week of July 10, 1922.** Average spot price for same period $3.61. This diagram shows the relative, not the actual, volume, on fourteen coals, representative of nearly 90 per cent of the total output of the United States, weighted in accordance first with respect to the proportions each slack, prepared and run-of-mine normally shipped and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913-1918," published by the Geological Survey and the War Industries Board. (Pittsburgh District, Illinois, Indiana and eastern Ohio prices not included in figures for last week.)

*Note: Spot market prices as of July 10, 1922. Prices in heavy type are the average of the previous week. Prices in italics are in decline, prices in regular type are unchanged.*
Lake coal dumped during the week ended July 10 was 243,946 net tons—230,362 tons cargo and 13,584 bunker—as compared with 389,452 tons last week. The total movement to date is 4,061,173 tons, as compared with 11,907,210 tons in the corresponding period last year. During June 247,542 net tons of coal, all bituminous, passed through the "Soo" for upper ports.

(a) As reported by U. S. Engineer Office, Duluth.

All-rail movement of bituminous coal to New England declined to 642 cars during the week ended July 1, as compared with 669 cars in the week preceding. Congestion of the roads supplying the West Virginia mines has curtailed the movement of water-borne coal and enabled all-rail shippers to obtain slightly higher prices for their fuel in the New England territory.

Hampton Roads dumpings for all accounts were 338,800 net tons during the week ended June 16, as compared with 494,182 tons in the previous week. Some labor trouble at the piers delayed the program somewhat and less coal is on route, as demand elsewhere is strong. Prices at the piers are up and coastwise freight rates reflect the better demand.

COKE

Beehive coke production continues to gain slowly. During the week ended July 1 the output was 114,000 net tons, as compared with 110,000 tons during the preceding week. The principal improvement was due to increased activity in the Connellsville region, although the first week of July saw some decline owing to fresh labor troubles and rail congestion. Coal consumers are more and more turning to West Virginia and Alabama cokes, as Connellsville offerings are very limited.

ANTHRACITE

Production of hard coal in the thirteenth week of the strike was approximately 25,000 net tons. Practically the same amount was produced during the preceding week. This represents steam business sizes dredged from the rivers, which are about the only steam coal being offered. Storage stocks of anthracite are reduced to egg and pea coal, the latter moving much old tonnage.

Lower prices when mining is resumed are somewhat of a question, even with the reduced freight rates, as there is still the impending Pennsylvania coal tax to be considered. Domestic consumers, however, apparently are not interested in prices, being more concerned with getting their orders on file for delivery after the strike at prices ruling when the order is filled.

Relative Activity of Markets for Bituminous Coal at End of Fourteenth Week of Strike

Demand strong. Rail congestion reduces available supply. Prices exceed Hoover level.
New England buyers coming in. Southern coals strong, as pier receipts are cut by congestion on roads.
Steam business good. Domestic demand also improves.
Still quiet.

And Export News

Dull Market Hurts British Industry

Export quotations on British coals are at best hardly firm. There is a freer line of inquiry, however, and emergency shipments to the United States are continuing. South America, India and the Continent are asking for quotations. Production during the week ended June 24 was maintained at the level of the previous week, according to a cable to Coal Age. The output was 4,334,000 gross tons as compared with 4,600,000 tons the week before. The recent poor market has been followed by the closing of some operations.

There is a well-organized campaign among the miners to secure alteration of the wage standard, and to place the wages on a level with the cost of living.

Labor Trouble Slows Roads' Tonnage

Strike of electrical operators at the three terminals at Hampton Roads failed to tie up the coal movement through this port. Although some delay was experienced in dumping, the movement has gradually increased until it is considered about normal.

When the men left their work, office men, and officials of the three railways, went immediately to the terminals, taking their places and continuing the operation. Coastwise vessels are now receiving coal as fast as they can make the round trip to New York and New England points and the situation locally is considered satisfactory.

Export clearances from Hampton Roads during the week ended July 6 were but two, namely, Nor. S.S. Thor- gerd, with a cargo of 3,824 tons for Havana, Cuba, and the Jap. S.S. Yei- fuku Marie, with a cargo for Porto- ferraio, of 7,476 tons.

French Seek Way to Reduce Prices

The coal market is very quiet as regards house coal, but shows some activity in industrial fuel. Concessions for summer delivery of 3fr.-gfr. per ton on sized coals of the Nord and Pas-de-Calais, which were to be abolished on July 1, will be maintained up to the end of September. This is a proof of the downward trend of the market.

The French Ministers of Public Works and of Labor on June 24 received a delegation of miners, in view of a discussion of the questions raised by the operators of the Nord and Pas-de-Calais at Douai on June 4, and, particularly, on the threatened reductions of wages, which have already been accomplished in a few coal fields. Great stress was laid upon the difference between the respective prices of French and foreign coals, especially British, and particularly upon the fact that the wages now paid are much higher than those received by the British miners.

The ministers concluded by asking the delegates to see for themselves how this difference could be whittled down, and they suggested, as an alternative, an effort of the miners to materially increase the individual output. At the same time, the ministers assured the miners that it was the intention of the government to extend the measures already taken in view of a reduction in coal transportation rates on French railways.

*Advances over previous week shown in heavy type: declines in reds.
Consumers Seem Shy; More Inquiries for July Delivery

Much interest evinced in spot market—Orders following freight cut not up to expectations—Where possible, buyers await Washington developments.

Consumers are still hesitant, but show considerable interest in the spot market. The freight reduction has not yet been productive of the volume of orders anticipated after July 1. The buyer who can do so is still delaying in the hope that the Washington conference will bring about an early resumption and lower coal prices. There is, however, a growing line of inquiry for July deliveries.

The rail trouble is not apparent on the surface but nevertheless it constitutes a disturbing factor in the situation for consumers, as their stocks are sadly in need of replenishment. Demand at tide is still below the line call and prices at the piers are held down by offerings of Southern coals.

**NEW YORK**

An offering of about 200 tons of Leeds (English) coal at $6.50, harbor, or about $7 alongside, was reported during the week. Those wholesale dealers who had been offered the coal were acting carefully before deciding the question of purchase. It was not thought likely that the English coal would be brought here in large quantities, at least not so long as the output of domestic coals continue on the present basis.

Inquiries are rapidly increasing, many prospective buyers asking particularly about July deliveries. There were less than a thousand cars at the piers on July 7. Line demand was stronger, with equally more strength in quotations.

Southern coals are in steady demand, with quotations gaining strength. Considerable of these coals are coming forward, most of it, as heretofore noted, on consignments. Quotations to this harbor ended $8.00 @ $8.50.

Quotations changed frequently during the week. Some unclassified coal said to be equal to Pool 9 was offered around 70c.00 a ton in the week, while later straight Pool 9 was quoted 41.5c and Pool 10, $3.85.

**PHILADELPHIA**

Hesitant but anxious fully describes the consumers' attitude. There can be no question as to their need for coal as many are believed to be much lower on their reserves than has been their wont for many a day. Yet even with the freight reduction wiped off the boards as an excuse, they are more than hopeful that the President's conference is going to send the men back to work.

So far as surface conditions are discernible the railroads are going along as usual, but underneath there is no denying that rail movement is not all that it should be. The consumer would like to have more coal if the rail strike is going to be prolonged, but he does not want to pay too much for it. Progressive action is expected as soon as mined, although considerable shrinkage in tonnage was experienced on account of the two-day holiday.

Prices have further increased, with quotations barely being made except on the unclassified coals, as all other grades are quickly moved on previously entered orders. Quotations have greatly increased of late and while a very large percentage of them can be placed in the curiosity class, quite a goodly number are productive of actual orders.

**CENTRAL PENNSYLVANIA**

Production reached the strike peak in June. Figures show 15,535 carloads, as compared with 11,015 in April and 12,122 in May. This is about a 15 per cent production in comparison with March, when the expectation of a strike led to an unusually high tonnage.

Prices were raised slightly. Pool 1, the best grade, is selling at $4.50, while Pool 10 is $4.25. Other grades are around $4.

The strike situation is very quiet throughout the field. President John Brophy of District No. 2, U. M. W., attended the Washington conference. There was no disorder over the holiday season.

**UPPER POTOMAC**

After enjoying a period of peace for a few weeks, the Upper Potomac saw further strike demonstrations last week. This resulted in the arrest of at least a hundred miners and their wives. Notwithstanding the efforts of the union to prevent operations, production continues to grow. There are approximately 35 mines now producing. There is also a brisk demand for coal, which is commanding fancy prices.

**BALTIMORE**

As the rate cut of July 1 was just about offset by tighter prices due to the fact that shipments to this point had fallen considerably just prior to that date, the price of coal failed to develop. Local consumers are buying in strictly limited quantities and no effort at storage is noted. While some 30,000 tons of coal from Hampton Roads has recently been barged to this city, as a relief to the scant movement of B. & O., and particularly Pennsylvania, several leading producers believe that the large movement of coal will be curtailed. In coal circles it is felt that a move recently made through the C. A. T. from mines direct to Baltimore will allow delivery of New River coal at a price which will prevent active water-borne competition as has been going on recently.

The all-rail tariff established to run from July 5 to Oct. 31, is $3.65. The barge-borne coal is also under an increasing handicap, as when this movement began charters were available at 50c.00 @ 60c. While at present the demand rate is between 80c.00 @ 90c.

There is a tight market evident, and little quibbling by purchasers when they actually need coal. While the export situation has been abruptly stagnant since April 10, there is now a steady growth of the use of bunkers.

**FAIRMONT**

Less mines were working during the last week of June than during the previous week and yet production was not as high as a level. With the approach of July there was much more violence and disturbance on the part of strikers than had been the case up to that time. The strike. It became necessary to swear in hundreds of deputy sheriffs for the protection of life and property.

While the supply of coal has been cut off considerably, the supply of fuel has been cut off by the strike. No special attention was paid to grades or preparation, mine-run and washed coal being loaded at the same time. The figures show the prices basis being about $2.50. Some contracts have been closed for the remainder of the coal year with railroads that formerly used western Kentucky coal, and new industrial contracts have been made in the Mississippi Valley. Inquiry from home territory is still comparatively light. Domestic demand has not improved materially.

Big Seam mine run is quoted at $2.25, washed at $2.50 @ $2.50, the prices on all other grades of mine run being around $2.50 @ $2.60, washed at $2.50 @ $2.75.

Quotations on lump and egg follow:

- **Carbon County**: $2.75 @ $3.00
- **Catharine**: $2.50 @ $3.00
- **Hiawatha**: $2.50 @ $3.00
- **Corona**: $2.50 @ $3.00
- **Montana**: $1.50 @ $1.75

Production during the week of June 24 was the highest for any similar period since 1917, the record year, a total of 300,000 tons being reported. A number of mines have been idle but the report for the past twelve to eighteen months are now active again on full time.

**SOUTH**

**BIRMINGHAM**

The market was very active last week, and there was a strong demand for all the free steam coal available. The anticipated production for the next thirty days being sold up. Railroads were the principal purchasers, most of the coal going into sections where the supply of fuel has been cut off by the strike. No special attention was paid to grades or preparation, mine-run and washed coal being loaded at the same rate. The figures show the same prices, the price basis being about $2.50. Some contracts have been closed for the remainder of the coal year with railroads that formerly used western Kentucky coal, and new industrial contracts have been made in the Mississippi Valley. Inquiry from home territory is still comparatively light. Domestic demand has not improved materially.

Big Seam mine run is quoted at $2.25, washed at $2.50 @ $2.50, the prices on all other grades of mine run being around $2.50 @ $2.60, washed at $2.50 @ $2.75.

Quotations on lump and egg follow:

- **Carbon County**: $2.75 @ $3.00
- **Catharine**: $2.50 @ $3.00
- **Hiawatha**: $2.50 @ $3.00
- **Corona**: $2.50 @ $3.00
- **Montana**: $1.50 @ $1.75

Production during the week of June 24 was the highest for any similar period since 1917, the record year, a total of 300,000 tons being reported. A number of mines have been idle but the report for the past twelve to eighteen months are now active again on full time.

**VIRGINIA**

Output is averaging 225,000 tons a week as against a potential capacity of 250,000 tons. In other words, production was averaging about 90 per cent of capacity and in some parts of the field was on even a larger scale. "Now that the fire about the mines direct to Baltimore will allow delivery of New River..."
Anthracite

Consumers Show No Concern As Domestic Stocks Dwindle

Buyers Ask Early Delivery, but Orders Are Small—Scarcity of Hard Coal Moves Storage Pea—Booking of All Steam Coal at Mines Brings River Barley to Forefront.

DOMESTIC supplies are running down, with little interest being shown by consumers. What orders the retailers do receive are being listed for delivery at the earliest possible moment, but the volume is not large. The impending State tax on coal looms as a factor which may offset the saving made possible by lowered freight rates. The freight re-
duction, of course, will not be applicable to coal now in storage, such tonnage being considered as in transit.

Storage pea is about all that is being offered now and the scarcity of hard coal is moving much old tonnage of this size. River barley is in the limelight, as practically all steam coals at the mines have been moved or booked on order.

NEW YORK

Most city dealers have nothing but pea and buckwheat in their yards. Buckwheat is fast disappearing and wholesale dealers predict that with the movement of pea coal continuing a few weeks longer on the present basis it too will soon be cleaned up.

The order books of producers are being rapidly filled, retail dealers following their usual custom of placing or-
ders for their requirements. With three months' production already lost producers and wholesale dealers are realizing that the principal question to be decided when mining is resumed will be that of distribution.

Consumers are now looking at the situation differently than they did a few weeks back and many have placed their orders, knowing they must not expect deliveries in whole.

Coal moved prior to July 1 and now in storage is considered to be in transit and will carry the old freight rate of $2.61 for domestic sizes and $2.47 for pea and smaller sizes until delivered to the purchaser. The new freight rates to this tidewater are $2.34 for the larger coals and $2.22 for pea and smaller.

PHILADELPHIA

The principal occupation of the re-
tailers during the past few days has been to list their customers' requirements for delivery at such a time as fresh-mined coal may be available. For the present the greatest pressure of this kind comes from the fellow who in the spring was absolutely cer-
tain that retail prices would drop se-
veral dollars a ton. A trip to the mining regions reveals that the miners are buoyed up by the hope that the Washington conference will be successful and are actually anxious to get back. In the matter of lower prices there are some who feel that even the advantage of lowered freight—which for P. & O. deliveries are $2.30 and for $2.14 on pea and smaller—will be lost in the imposi-
tion of the state tax on coal. While no company has made any decision in the matter, it is not expected that at least some of them add the tax as a separate item, pending a final decision by the highest court.

There is no coal left in the city but pea, and this is selling fairly well. In the steam trade the only offer-
ing is in river barley, which is moving well, with the top price still at $2.75.

Dredgers are seeking an outlet among local shippers and even yet the offer-
ings are considerably heavier than the sales.

BOSTON

There is dearth of news here on hard coal. The retail dealers in the larger cities are practically stopped taking orders for spot delivery. Res-
erves are at a low point, and these are being kept for hotels, hospitals, and other necessary summer and early fall requirements. The only fill-up orders being taken at all are in the form of memoranda for delivery later on if and when the dealer has the coal and at the price current at time of delivery. This seems to satisfy a remarkably large number of householders.

At wholesale the only merchandising is in pea and buckwheat. A fair volume of pea is being shipped at prices that are practically the same as those ruling last month. A few of the producing companies still have a supply of this grade and although bag holes have been made in the reserve.

BALTIMORE

With New England and the North-
west growing more insistent for hard coal there looks to be scant prospect of any material receipts in this terri-
tory in the near future, even should the strike come to an abrupt end. Lo-
cal yards are now almost without any stocks, but the public remains ap-
parently without great fear of short-
age. There are few inquiries for fu-
ture deliveries.

BUFFALO

No coal is coming in, as all that was held at the mines appears to have been moved and sold. A few concerns still have a little coal, but the de-
mand for it is small. It is estimated by dealers to have from 80,000 to 90,000 families in the city that have little or no coal, yet they are mak-
ing no effort to get any. The general advice is to buy substitute fuel if it is to be had. It is expected that natural gas, including the byproduct gas from the local coke

ANTHRACITE FIELDS

All interest is now centered in Wash-
ington and everyone is anxiously wait-
ing some action to be taken there. The field was quiet last week. The main question on the lips of everyone in the coal field is when it will be over. There is, however, a great deal of restlessness being displayed.

Coke

CONNELLSVILLE

The coke market has taken a stiff jump, being now quoted at $9, with higher prices talked of. There is usually no distinction between “fur-
nace” and “founding” grade. Most of the coke is in the oven 72 hours or longer, and as to selection there seems to be little if any of that, so that op-
erators offer their product merely as “coking coke.”

The advance, however, is a sort of tempest in a teapot. The amount pass-
ing through the open market is hardly large enough to operate the furnaces of moderate size. Occasionally a blast furnace may buy a little coke, but most of the sales are to foundries and miscellaneous dealers.

Consumers normally tributary to the Connellsville region are turning their attention still more to cokes from other districts, particularly West Virginia and Alabama. There is no movement to displace Connellsville, though the price redu-
tion July 1 helps as well. The by-
product ovens are the mainstay of the furnaces now.

The Courier reports production dur-
ing the week ended July 1 at 55,040 tons by the furnace ovens and 15,170 tons by the merchant ovens, a total of 70,210 tons, an increase of 2,180 tons.

UNIONTOWN

The shopmen’s strike has affected fuel movement in the Connellsville region only on one road, that of the B. & O., and there are now orders on the books for coke which the carrier is making some progress in re-
organizing repair crews. So far the Pennsylvania has been able to supply maximum requirements for coal and coke loading and to move the fuel freight promptly.

While uncertain delivery due to the shopmen’s strike has joined curtailed production to “bear” the coal market, prices have not yet commenced to soar. Steel interests are receiving de-
creases on orders placed 60 days ago but are not placing new ones. The railroads today are the principal coal buyers. There is not enough free coke being produced for blast furnace re-
quirements and the odd lots offered are being grabbed at sky-high prices.

BUFFALO

The demand has suddenly improved, on account of the discovery that some-
thing was needed to take the place of anthracite for use in the canning fac-
tories and evaporators, which cannot use ordinary bituminous. Besides the city experts are advising consumers of anthracite to buy coke. The local ovens have a supply and will sell it about on a par with the others. The regular furnace demand is still small.
Chicago and Midwest

Shortage of Coal Rules Market in Middle West

It is Now a Case of “Anything Black” Instead of “What’s Your Price?”—Disabled Transportation Plays Main Role—Market Freaks Common.

COAL trade in the Midwest region has reached a point where price is not the controlling factor. Nowadays the main struggle is to get the coal. During the past few days this region has been almost cut off from eastern Kentucky and other Eastern fields by transportation failures of one sort or another and in western Kentucky, the other principal producer, the situation was not much better. Concerns which have been jobbing coal since the strike began are now actually turning away business, informing customers that car jams and locomotive failures on the L. & N. and C. & O. have reduced the eastern Kentucky fields to 25 per cent production and western Kentucky to about 50 per cent. With stocks everywhere running low and railroads beginning to suffer, everything salable is selling, freaks of the market are common, and prices are pushing steadily upward.

“Coal men might as well take theirs now while they can,” commented one of them who has weathered many such years as this, “because this condition is absolutely unstable. Just let some definite plan for possible resumption of wages go through, it left the Washington and these prices will flop to the bottom overnight.” However, there is no unanimity of opinion on this point. This is a trend that will be so slow that the chance to change course, even if such a course is desired, is best missed.

The shortage is such that within the past two weeks railroads in Chicago have bought screenings from retail yards by the wagon load and since “anything black” will sell, slack piles in Indiana have been opened up and their contents loaded and sold at $2.50 and even $2.75. In one case a pile at a mine which was closed down years ago was selling day by day at that figure.

CHICAGO

Demand is keen, supply short and the general upward trend of prices continues. At the end of the week just closed, western Kentucky had reached $8.25 and operators in eastern Kentucky were giving distinct evidence of getting ready to break over the Hoover maximums which most of them have been observing. Reports have been current of less active companies selling at figures past $4. Unless the Washington conference produces some definite effect upon the strike at once, eastern Kentucky will get out of hand and bound upward.

The greatest difficulty is getting deliveries. The car jams and motive power shortages around the working fields may cause coal to a point where, at the end of last week, the arrival of 25 cars here was enough to stir up quite a good deal of animation. A number of railroads are getting so hard put for fuel that the fuel committee of the Western lines has fallen far short of supplying the demand and practically every road is buying whatever it can get, wherever it can get it.

Practically no smokeless is reaching here for the open market, although contract customers are getting small deliveries. Dealer demand is refreshing fast. There is a strong tendency to boost the price, although it has not crossed the $3.75-mark yet.

SOUTHERN ILLINOIS

The last 12 or 15 cars of storage coal held since March in southern Illinois moved out last week and brought $3.50@$3.75 on the market for lump, egg and nut. Nearly all mine fields are now entirely free of members of the United Mine Workers, most of the work being done is by mine foremen who are not union men.

Nothing unusual transpires in Doquin or Jackson. Storage coal in the Mt. Olive field is pretty well cleaned out and nothing is left in the Standard Coal Field except in one advance, the southernmost, which is now being loaded.

INDIANAPOLIS

Retail prices of Pocahontas have advanced 50c, prices ranging $8@$8.50. The higher retail prices have followed the advances in the mines. The decreased freight rates will lower prices on West Virginia coal about 20c, per ton, but local dealers in the last increase say they anticipated this slight cut in fixing the new prices.

Coal stocks in Indianapolis are getting toward bottom, but evidently there is sufficient of the non-union mined coal being offered to prevent any serious shortage for a time. Local jobbers say that from now on coal will be more difficult to obtain in view of the competition. Wholesale rates are only slightly high, which is creating an extra demand.

WESTERN KENTUCKY

Demand is now so heavy that the railroads are having much trouble in supplying cars. With industrial conditions as well as railroads steadily increasing their requirements as old stocks are reduced, the demand is increasing and carrying prices with it. Many buyers are in the field, grabbing all available production.

During the past few days retail inquiry has been heavier and some business has been placed. Consumers who have available cash are beginning to think about their winter needs. Prices on all coals are jumping.

In view of the fact that at the Hoover conference the request of western Kentucky operators for a maximum of $4.25 was refused it left the field under no agreement as to price, and it looks as if we were operating on an open basis of accepting the highest bid for its production.

ST. LOUIS

As a result of the storage piles being nearly wiped out, in a great many instances, Kentucky coal is in fairly good demand, for steam only. It takes from 10 to 20 days for coal to come through on the L. & N., and while the Illinois Central service is better, the operators fear that railroad cannot ship promptly.

Lump, egg, mine run and screenings from Kentucky are quoted $4.50@$5, depending upon the quality, the promptness of shipment and the preparation.

 Dealers, however, still refuse to buy Kentucky coal for domestic and even the steam buyers are going slow for the next three weeks or more.

Some Alabama coal has been moving in, but part of it has proven unsatisfactory. Some West Virginia smokeless is moving in for domestic.

LOUISVILLE

General demand continues strong, with railroad consumption steadily increasing. Retail buying is heavier. Prices in western Kentucky are shooting up, and are now $4.25@$4.50 for all sizes. Eastern Kentucky is making an effort to stay with the $3.50 maximum, but in so doing is beginning to object to paying brokerage.

Prices, except a little on the stronger freight rates, are still in the light. Further rapid increase in freight rates, more inquiries are being received, and indications are that higher markets will result, and that some operators in the East will start operating will be in the swing again.

The shopmen's strike is threatening production as a result of further congestion of already overloaded terminals and shop tracks, with cars to be repaired, and shortage of motive power to move cars.

Canada

TORONTO

Demand for anthracite is increasing and dealers find it impossible to fill orders. The call for bituminous continues light, with sufficient on hand and carrying forward and filling all demands. In addition to shipments from the non-union mines, some consignments from Nova Scotia are being received by water. Prices for bituminous are showing an upward tendency.

COAL AGE

Vol. XXII, No. 2

West

Panicky Feelings Run Through North Region

Country Cries "Coal! Coal!" When There Is No Coal—Industries Have Not Yet Suffered—Anti-Boarding Move Is on—Prices Tend Upward.

PRACTICALLY all of the Northwest is enjoying the same nightmare: Will there be enough coal for next winter? A panicky sensation fills most breasts, for the dock storage is about gone, little coal is coming in, and wholesalers are carefully portioning out contract coal to the most needy and turning away practically everybody else. A rush of orders is swamping the coal trade, especially since the drop in freight rates failed to have any effect on coal prices. In some sections, notably around Milwaukee, an effort is being made to prevent hoarding of anthracite.

Industries thus far have been able to get just enough coal to run on but none for storage. The feeling is that they will not suffer if a strike settlement comes soon. However it will have to come very soon if the Northwest as a whole is to have coal this winter at a reasonable price.

MINNEAPOLIS

The coal market in this section of the Northwest is getting panicky. Consumers are piling in orders upon coal merchants, and fill but a small percentage of them because the dock surplus which once this summer seemed so large, has been absorbed by contracts until a small supply is now gone and little is arriving. A number of wholesalers are refusing to accept business for the future because of the uncertainty. The July 1 reduction in freight rates, upon which some consumers banked for a drop in coal costs, came like a paper dividend—it is practically valueless because there is no coal.

The Washington conference between operators, miners, and the government has come plenty late enough for the Northwest’s comfort of mind. It is generally feared here that the negotiations there will lead to some sort of compromise instead of a clear cut settlement and that no marked reduction in coal prices will result in this region.

MILWAUKEE

Milwaukee is worried about coal. Dealers have plenty of orders but little with which to fill them. The situation is particularly acute in the case of hard coal. There is a small supply of egg, pea and buckwheat on hand, but most consumers want stove and chestnut sizes. At a public meeting of representatives

Northwest

of coal companies and civic organizations on July 5, a member of the trade held that if the strike is settled by Aug. 1, enough coal can be mined to supply the needs of the winter. Steps were taken to prevent hoarding of hard coal.

Manufacturers have been able to get enough soft coal thus far. Dealers think there will be no great inconvenience to industries.

Hard-coal prices remain unchanged.

Following is the schedule of prices on soft coal and coke, established July 1:

Pitts. Hooking & Yough, screened. $9.75
Pile run. 7.75
Screenings. 6.75
West Virginia screened. 8.00
Pile run. 7.00
Screenings. 6.00
Pocahontas screened. 10.75
Mine run. 9.25
Screenings. 6.50
Smoothing. 10.75
Kanawha Gas mine run. 7.50
Ill. & Ind. screened. 6.50
Pile run. 5.50
Screenings. 5.00
Coal, large sizes, Pea and nut. 10.00

Receipts of coal by Lake up to July 1 aggregate 760 tons of anthracite (screenings) and 606,261 tons of Pocahontas coal, against 392,200 tons of the former and 1,167,170 tons of the latter during the same period last year.

DULUTH

Shortage in coal has developed at the Head of the Lakes, and it is authoritatively stated that there are not more than 550,000 tons of bituminous coal and 250,000 tons of anthracite free on the docks. Matters are not yet at what will be termed a crisis, but the general outlook is far from encouraging.

One of the greatest contributing causes to the present situation are the terminal costs which have been made on the supplies here. Normal markets have taken but a small portion of the coal which has been shipped from here. Much has been sent by boat to Lake Michigan points, and even more has gone by rail to out-of-territory points.

Since last week two cargoes have been shipped to Lake Erie, and one has arrived here from Lake Erie. One more is reported as on the way. This will bring the total arrivals to 300,000 tons.

Dock men have adopted the two or three car policy here. They will not take orders for more than this amount and are endeavoring to allocate the supply as evenly among anxious customers of long standing.

The anthracite situation is even more stringent. Forty per cent of all hard coal is anthracite. A large portion of the remainder is pea. Local dealers are known to be well taken care of, but country dealers are far below their requirements.

Prices on all coals are firm with some dealers showing a disposition to raise 5c.

Unlooked For Improvement Noted in Market Conditions

Mild Reaction Surprises Trade in General—As Shipments From Some Quar- ters Rise, Others Shrink—Quotations f.o.b. Norfolk Up 20c@25c.

A MILD reaction has set in and the market shows a degree of improvement that was hardly looked for by the trade in general. While a few of the larger non-union operations are shipping coal in somewhat larger quantities, there are a good many others where local labor troubles have cropped out again. Production in the New River field, for instance, is now nearly 50 per cent, but in Somerset and other sections of Pennsylvania there is enough interruption to make output quite undesirable. Apprehension of railroad troubles also has been a factor during the past week, and taking everything together the range of quotations f.o.b. Norfolk and Newport News is up 20c. @ 25c.

At Hampton Roads on July 5 the tonnage actually available for dumping was about 100,000 tons less than on June 26. The holiday would account for some of the difference, but on the other hand more sales were made and the 25c. reduction in tolls had already been discounted.

At handling points inquiry is only relatively better, for the tonnage in request is by no means large, but buyers who waited for the freight reduction and to see if coal would not sell for less are now obliged to enter the market for current requirements. The railroads and large mills still have comfortable reserves when slack operation and reduced traffic are considered, and it is still hard to see where any broad market can develop during the summer.

Coastwise freights share the improvement that is noted in the demand for coal. On large vessels for spot loading there is a small premium being paid, a few having been chartered at 95c@$1 to Boston or Portland.

There is little change in the Pennsylvania grades, at least with respect to the amount of coal offering. Pair grades, when available, are quoted rather higher, due to improved demand at Hampton Roads and higher prices in consequence on the smokeless grades for delivery in New York harbor. Washington and New River being shipped from Tide-water re-handling points as far inland as Springfield and Holyoke, however, there is little slack. Michigan ports and Pennsylvania grades on any high range of price, even though the smokeless factors are now asking $8@$8.25 on cars at Providence, Boston, and Portland.

New England
Eastern Inland

Supply Inadequate to Meet Enormous Demand for Coal

DEMAND is enormous and the supply inadequate. Producing mines are handicapped by car jams and shortage. Prices have advanced above the Hoover level and $3.50 now represents the low of the range. Consumers eagerly take any tonnage that can be obtained. Reserves have been allowed to run down to such an extent, awaiting lower freight and the possibility of union resumption of mining, that immediate replenishment is necessary. The shortage will be serious if production cannot be increased at an early date.

Lake buyers are growing very anxious. The local demand is so if production cannot be increased at disadvantage. Much Lake tonnage must be crammed into the remainder of the season if a troublesome scarcity is to be avoided.

BUFFALO

The holiday set a slow pace for the week. Prices are a little stronger week by week. While consumers declare that they are not able to pay big prices they at the same time allow them to go up slowly. All the while the supply is rather in excess of the demand, though probably not greater than consumption. Everybody feels that the crisis is near and yet nobody is ready to express an opinion as to what is likely to be done. Consumers as a rule have coal enough for the present. Some of them report that they are offered more coal than they want and some have bought little or none yet. Others have looked for bargains and so have kept up their stocks. Prices are strong on the basis of $4.50 @$4.50 for 2-in. and $4.25 for mine run and slack, with slack most in demand. Add to this $2.69 for Allegheny Valley and $2.54 for Pittsburgh and No. 8, with various intermediate amounts for Bessemer, to cover new freight rates.

Receipts by water have run pretty uniform for the past few weeks. For the last week they were 54,980 tons; for June, 266,500 tons and for the season, 775,750 tons.

CLEVELAND

The long expected famine conditions have arrived. Demand in the last few days has been enormous and persistent, but unavailing. The railroad shipper’s strike has been a factor of importance in cutting down mining operations. Car shortages have developed and coal which was taken from the mines in the latter half of the past month passed the scales yet in many cases.

Consumption continues at an uniminished pace, despite the summer weather which has lull in business operations. As a result dealers are being bombarded with inquiries, in sharp contrast with the indifferent attitude of buyers a few weeks ago when hopes ran high for a settlement of the strike before July 1. The present condition bears out the prognosis that when the country’s total stocks fell below 20,000,000 tons the danger point would be reached. Consumers are no longer pinning any hope for immediate relief in strike settlement, believing roads and to mining production is improbable within the next few weeks, in any event. In the meantime they need coal urgently. Prices are rising, the range being $4@$4.50.

The scene on Lake is beginning to look serious. This year’s record is below the 1920 showing, when shipments were restricted early in the season by the outlawing of railroad stocks. A pooling plan for Lake shipments similar to that employed to meet the needs of the Northwest in 1920 is possible this fall.

COLUMBUS

A stronger demand has developed since July 1, when freight rates were reduced. The movement is heavier. All classes of purchasers are now coming into the market. Prices have advanced to the Hoover levels with point quotations made slightly above to cover jobbers’ commissions.

The best buyers at this time are the utilities and those who are rather long on their reserves. Railroads are buying rather briskly. Retailers are also placing orders. One of the features is the demand for threshing coal. Lake prices are progressive as well as could be expected. The H. V. Docks at Toledo loaded 170,160 tons during the week ended July 5, making a total of 1,301,650 tons for the season.

EASTERN OHIO

Consumers appear to be in imminent danger of facing a coal shortage. Due to traffic congestion on originating railroads and to intimidation and other interference with stripping mine operations in eastern Ohio, the quantity of coal available in the spot market during the first week of July was reduced to a point where the supply is having difficulty in meeting the demand.

Inquiries are noticeably more numerous and to a few shipments plants will be in dire need of coal within 30 days. Along with a more widespread demand for coal, prices have stiffened. However, local prices are cut to minimum, with steam coal quoted up to $4.15.

There has been quite a let up in receipts at the lower Lake docks during the past few days as the demand in other trades is increasing. It is quite evident that the bulk of cargo coal will have to be sent out of the Lakes during the last 60 days of the regular shipping season in view of the fact that for the current season up to July 4, including $16,080 tons sent to Buffalo and other Lake Erie ports, shipments were only 3,684,465 tons. Movement for the same period last season was 9,635,780 tons.

Receipts of bituminous coal at Cleveland during the week ended July 1 show a slight increase over the preceding week, the total being 1,747,026 cars, 1,026 to industries and 119 to retail yards.

PITTSBURGH

A policy of silence is maintained by coal operators as to the details of contracts at West. Partial admission is not made that there was something in the rumors prevalent before the President called the conference that Wellington coal operators intended to attempt a combination of the mines, on an open shop basis.

Nothing came of the proposal of the Pennsylvania state department of conciliation that a conference be held July 6 between operators of No. 2 and No. 5 districts, in Pennsylvania, of the U. M. W. and officials of the district organizations. The time was fixed at the appointed time and place and the miners’ representatives did not.

Trading is still confined almost wholly to Connellsville steam coal, which has strengthened to $6.50 at some points now at $4.75. The market is still well below the $4.50 maximum the Connells- ville operators wished. Secretary Hoover to countenance. There is a larger number of buyers in the market, while the big consumers are hardly as active as formerly, with the reason of demand is not materially changed.

One large consumer has refrained from buying spot coal for a fortnight or more in the last 60 or 90 day contracts, indicating a continuance of the belief, that after the strike coal will be far from plentiful. As a whole, the non-union strikes in the Connellsville region have not waned any in the past fortnight, as they had been doing previously.

DETROIT

Prior to July 1, it was supposed that consumers were withholding orders to be in position to take advantage of whatever saving might be possible with the application of the reduction in railroad freight rates. Now, the resumption of demand is not materially changed.

One large consumer has refrained from buying spot coal for a fortnight or more in the last 60 or 90 day contracts, indicating a continuance of the belief, that after the strike coal will be far from plentiful. As a whole, the non-union strikes in the Connellsville region have not waned any in the past fortnight, as they had been doing previously.

NORTHERN PANHANDLE

Steady gains are being made in output during the last week of June and at the outset of July. Nearly all the mines are in operation, the effort of the United Mine Workers to interfere with production having proved to be a flat failure. Mines find a ready market for their output, a large proportion of which is being utilized by transportation companies.
COAL

LOW-VOLATILE FIELDS

The strike is no longer having any material effect in curtailing New River production, which has been above 350,000 tons this week, with all mines working on a basis approaching normal, although some are without full crews. Some loss of output is due to a car shortage. Coal has accumulated at the Tidewater piers and there has been a slow movement of empties back to the mines.

POCOHONTAS AND TUG RIVER

The same factors which have been responsible for retaining production to some extent in other smokeless fields have also handicapped Pocahontas producers, although the output toward the close of June was about 450,000 tons per week, which represented the peak of production for the month. The advent of July, with lower freight rates, has brought heavier batches of orders and more inquiries.

Tug River mines slipped a cog or two during the latter part of June but were still producing in the aggregate more than 110,000 tons, not all of which however was available for commercial purposes, since a large proportion of this output was going to industrial concerns, including steel mills who control a number of the mines in this region. The demand to Western markets was particularly heavy.

HIGH-VOLATILE FIELDS

KANAWHA

The field at the outset of July began to feel a quickening of demand as a result of the lowering of freight rates. There is a ready market for what tonnage is available, further gains having been made in the output toward the close of the month despite threatened trouble on Paint and Cabin creeks which necessitated calling out two companies of militia.

LOGAN AND THACKER

All previous production records in the Logan field were smashed during June, the output reaching nearly 400,000 tons during the last fortnight of the month. This fuel produced is going to steel centers and the Lakes, with railroads also securing a large tonnage. At the beginning of July there was a better demand for domestic.

In the Kenova-Thacker field mining activity is marked as a result of the excellent demand. This field is now producing in excess of 200,000 tons a week with nothing to curtail production except the difficulty of securing more men and congestion on railroads, owing to the heavy movement.

NORTHEASTERN KENTUCKY

After holding back on account of the reduction in freight rates consumers were more conspicuous when the lower rates did become effective. This limited to increase production insofar as was possible in view of the difficulty in securing empties. There was also a better demand for domestic fuel than had been observed during the greater part of June. With buying on a heavier scale, prices stiffened somewhat.

WEST

KANSAS CITY

The one thing that stood out prominent last week was the decision by the vote of the Howat followers to return to work. As they were expelled by the miners' union and are no longer members of the U. M. W., it is not clear how the mine operator's can employ them, and as Kansas industries want coal, what will the Industrial Court Law of the state have to do if they open their mines and give the men who apply for work, their old jobs back? It looks like a shrewd move on the part of Howat to check on the operators and at the same time get back at Lewis.

One of the companies that opened two of its mines by leasing them to the miners and selling the coal on a cooperative plan, is getting out about 25 cars per day and is considering putting all of its mines on the same basis. It is said that all the men necessary to operate, have applied for work, but what they will do after the other mines open up and pay on a regular agreement basis remains to be seen. Will they continue to work for a unknown wage (which depends on the price received for the coal) or will they desert and go to the mines where a stated wage is paid?

Prices are getting very ragged. Some mine run from the Kansas field is selling as low as $3.75 and as high as $4.75 and what little slack there is available is selling for as high as $3.75, while the list is $2.85. Lump coal is bringing $5 and there is very little demand.

SALT LAKE CITY

Pacific Coast buyers are again looking to Utah for their supplies as a result of the reduction in freight rates. It is many months since local operators did any business with them and the local market has not changed much. Domestic consumers are not buying, except a little for immediate needs, with the result that the market is low. Some of those who are in touch with strike conditions are getting a little anxious. Coal is being mined today at about half the rate that was necessary if there is to be a good supply in consumers' bins next winter, according to one prominent operating official.

Some weeks ago the operators made a slight reduction to the retailers of 25c.@50c., according to grade. This was a sort of unofficial reduction and old prices—which include $4.50 for lump—are in effect again.

Traffic News

By a judgment just issued by the Railroad Commission of Colorado, the rates for carrying throughout the state of Colorado 2000 tons of coal, at $1.00 per ton, are held to be just and reasonable.

The decision was rendered by the commission in the case of the Kansas City, 1200 ton, vs. the Kansas City, 1200 ton, in which the railroad company was charged with the transportation of coal from Kansas City, Missouri, to St. Louis, Missouri.

The commission found that the rates charged by the railroad company were not excessive and that the transportation services rendered were adequate.

The decision will undoubtedly have a far-reaching effect on the transportation of coal throughout the state of Colorado.

Obituaries

John H. McEwan, Provo, Utah, who was associated with the late Joseph Knight in the development of the Spring Canyon coal mining properties, was sentenced to prison for embezzlement.

The sentencing was held in the United States district court in Provo, Utah, and the defendant was sentenced to ten years in the penitentiary.

The case involved charges of embezzlement and fraud in connection with the Spring Canyon coal mining properties.

Association Activities

Colorado and New Mexico Coal Operators' Association

The board of directors of the association met at Denver on July 21 and elected the following officers:

President: W. D. Brennan, Volunteers Coal Co., Denver, Col.

Vice-President: J. C. donors, Los Angeles, Cal.

Secretary-Treasurer: R. H. F. Stevens, Volunteers Coal Co., Denver, Col.

The annual meeting of the association will be held in Salt Lake City, Utah, on the 20th day of November next.
Tiding Over a Crisis

BITUMINOUS-COAL operators meeting in Washington this week were able after twenty-four hours of spirited debate to unite on only a partial acceptance of the President's proposal looking to the adjustment of the strike. On but one broad phase of the plan submitted to them, that of willingness to arbitrate and to participate in an investigation of the bituminous-coal industry, were they able to make an unanimous report to the President. Three important areas, embracing all of the unionized fields of Pennsylvania, save a few individuals, and the State of Indiana told the President they could not agree with his proposal. Some thirteen other districts, from the Rocky Mountain region east to Ohio made unqualified acceptance, as already had the anthracite interests. Those taking such affirmative position represent a majority of the districts involved and a majority of the tonnage.

The split in the ranks of the bituminous-coal operators is serious and extremely unfortunate. The President had placed the operators in a serious predicament, not only in his original proposal but by the terms of his subsequent interpretations of that statement. To all intents he asked them to return in every respect to a position of status quo as of March 31. They were asked to pay the peak wage scale, grant the check-off and, it is unofficially reported, reinstate the four-state agreement until such time as a commission could investigate and make recommendations and awards. In other words it was asked in the interest of national welfare that practically every point and principle for which the operators had held forth against the miners' union be subverted. On this general statement there is and was no apparent disagreement.

Where the councils of the operators divided was on a matter of policy—whether to go along with the President regardless of personal opinion as to the propriety or adequacy of his plan or to refuse. So deep is the feeling engendered by the division that all hope of unity on labor matters in the bituminous-coal industry is for the time being lost. The mine owners have proven no match for the mine workers.

The time for recrimination is past. The incomplete acceptance by the operators of the President's plan and its tentative rejection by the United Mine Workers as it were wipes the slate clean. As the President says, the point has been reached where the "good offices of the government in seeking a voluntary adjustment of the dispute between the operators and mine workers are without avail." It is now in order to put forth some other plan of action to get new coal production.

It is quite clear now that the uncompromising attitude of the Pittsburgh operators as set forth in their letter to the President and the equally unbending attitude of John L. Lewis absolutely precluded and still precludes all hope of getting both sides together unanimously. Pittsburgh and those like minded among the operators intend to carry to a conclusion at once the issues joined in the strike of 1922.

There are left the anthracite area and a substantial portion of the soft-coal areas where the President has a prospect for resumption of production on a normal basis. It is in these areas also where the issues must again be brought to focus and settled in 1923.

The Import of the Union's Position

THE United Mine Workers on July 15 declined in principle the proposal of President Harding looking to the termination of the coal strike. Hidden in much language, evidently written for home consumption, one finds that two reasons are definitely assigned for this refusal. One is that the union is opposed to arbitration of wages in any form whatsoever and the other is that, every other consideration aside, the fact that not all union and non-union areas on strike are to be included in the arbitration is a bar to their participation.

The position of the union on the second point is decidedly weak. "The only effective way," they say, to settle the strike and to get the men back in the mines is "by meeting with our representatives in interstate conference." In other words they profess to be ready to follow the deep-rutted path of a Central Competitive Field conference and settlement, which must carry with it, as in the past, subsequent working agreements in the outlying fields based on the results of the larger conference. Yet they refuse to consider a proposal for arbitration that is not national in scope. "The mine workers cannot," they say, "lightly consider the utter abandonment of more than 200,000 of their members to the whims and caprices of hostile employing interests who are publicly committed to the policy of destruction of collective bargaining in the industry."

The real import of the miners' contention here is a thinly veiled challenge to the President to force certain fields into negotiations with them—fields that otherwise are now or are seeking to be free from their yoke. In the bituminous areas there are three separate and distinct strike situations. One, and the most important from a tonnage standpoint, includes the old-established organized areas, as Ohio and Illinois. A second is represented by Kanawha, which is in the process of throwing out the union, and the third embraces districts, as the Connellsville in Pennsylvania, that were non-union before April of this year but where the union has recruited large numbers of the men and greatly curtailed production.

The union leaders are quite well aware that once they resume work on any basis in the older and more important fields their fight for recognition in New River, Kanawha and Fairmont in West Virginia and in the non-union areas of central Pennsylvania will cease to be a matter of national concern and will become instead a local irritation holding for them slim, if any, chance of victory.
What Is Americanism?

Well aware that what we term Americanism neither is nor can be restricted to America we may be assured that what we have regarded as a most cherished possession in America is the right of the American to work when he will and for whom he will without fear of intimidation, to render service to none but to the American Government and to those to whom he is under contract under the terms of that contract, to run his factory, his shop, his mill or his mine subject only to the laws of the country to which he owes allegiance, to be protected by the laws in performing such acts as the government does not proscribe, and not to be browbeaten, insulted, assaulted or robbed by any person or by any body of persons.

Since the strike of April 1 the operators of mines in union districts and the workmen they would employ have been prevented under threats of violence from performing such acts as the law approves, and this restriction has been imposed by an irresponsible body of men known as the United Mine Workers of America.

It is true no great number of acts of violence have been committed. The Herrin massacre and destruction of property is an outstanding example. There have been others which the newspapers quite generally omitted to mention, feeling that disorder was so inevitable around the mines that the violent acts committed were not worthy of notice. Dynamiting, fires, murders, violence and threats have been frequent. That they have not been more numerous is due to the fact that operators and their workers have assented by inaction to this domination—one entirely adverse to the Constitution and not contemplated by the founders of the Republic.

Meantime what has the Government of the United States, and especially of the individual states, done? A few governors like Allen, of Kansas, and Morrow, of Kentucky, have done well. The others have done nothing, and they have asked nothing of President Harding. Wherever there has been intimidation and consequent idleness this should be said to their everlasting condemnation.

In Pennsylvania the work of keeping order has fallen to the state police. The governor knows that this force is inadequate. This has been abundantly proved. Under the intimidation which that official organization has been unable to restrain, men have been afraid to work, operators have been ill-disposed to open their mines. Here and throughout the union mining regions a greater power than the state governments and the United States has arisen—the United Mine Workers of America.

President Harding has been hampered by states' rights. He is restrained by the Constitution. Thus he might be excused for taking no action. But is he disposed to remain silent and to recognize constitutional restrictions? Not at all; if indications are to be believed he prefers rather to take action still less lawful than that from which he has refrained. He is said to propose the conscription of labor and to be preparing to seize and use private property—two things utterly alien to the spirit of the Constitution.

For him to maintain order may be unconstitutional in the absence of invitation by the governors, though many authorities on constitutional law do not believe so. They hold that the lack of order by preventing the free use of labor and the free operation of the mines has impaired the social life of the United States and raised up a power which usurps the authority of our nation and its parliament, which upsets democracy and which gives to a minority a control over the Republic. The nation therefore is in danger, they contend, and action by the President is justifiable.

President Harding's alleged preference for the seizure of properties may be popular with certain noisy voters, but if consummated such a sequestration would be an utter abridgment of individual rights. It is socialism rather than democracy or Americanism, but no one will condemn the President if he tries to restart the mines by enforcing order.

Conscription to work if adopted will be much more difficult to enforce than prevention of interference with those who would work. If conscription is merely a device to give the worker a chance to deny he is a "scab," if it is merely a permissive conscription, then it is weakening to the Republic, for he who would break faith with one kind of conscription is emboldened to defy another. Having done it in peace, it will look less heinous in war.

We are short some three or four millions of tons of bituminous coal per week. Perhaps we should have five million more than we are now getting to feel perfectly safe. A small proportion of the men now idle could supply that quantity. With assurance of safety many workers—probably more than are required—would return to the mines. Even in the anthracite region many would take up their duties if duly protected; not enough at first, it is true, to furnish the coal we need but probably enough to bring the strike—a combination in restraint of trade and openly designed as a means to increase wages above that for which men are offering to work—to an end. Even if it failed of that end, the keeping of order is an action well worthy of the Executive. The first duty of this or any other government is to maintain the peace and to defend the constitutional rights of its citizens.

President Harding has failed to exercise the boldness that is expected from one in so responsible a position—except in regard to capital. When the railroads were failing to earn the interest provided by law, when the Interstate Commerce Commission showed a disposition to maintain the freight schedule in order to produce at least part of the interest which Congress has permitted, he boldly enough called for a reduction in freight rates, declaring they were too high and an impediment to commerce. He was not afraid to announce without any prior elaborate inquiry that freight rates must be reduced.

But after almost all wages had come down, after the Railroad Labor Board had reduced the wages of most of its workmen, after costs of living had been lowered, President Harding declared that he did not know whether the wages of mine workers should stay up or come down. Surely he knew that they had been fixed by a prior government commission with full knowledge and consideration of the cost of living. Undoubtedly he knew that the day workers had struck against the award and had obtained a further increase. Unquestionably he knew that the living cost was lower than when the government commission made its award and that the contract period having ended another contract recognizing the change in the cost of living was imperative. But, nevertheless, when the time came to discuss matters with the mine workers and operators he tried to make it appear that he knew none of these things.
Plan for Shaft Mine Giving Large Capacity and Saving In Stoppings, Overcasts, Doors and Air Costs*

Intakes and Returns Are Driven as Such to a Predetermined Point and Then Both Are Made to Carry Air in the Same Direct'on, So That Temporary Stoppings May Be Broken Down

BY O. J. PLESCHNER†
Westville, Ill.

Said to have originated in the coal field around Westville, Ill., the plan accompanying this article has been used for the laying out and planning of new mines in that field for many years. The general layout has a double-track storage road for loads and two single-track storage roads for empties, one being placed on each side of the main bottom. The loads pass to the bottom from each main haulage road by curves of large radius. The empty cars are pushed off the cage by the loads and from this point until they come to rest in their appropriate storage track they are moved by gravity.

Rolling from the cage to the car lift at A they are automatically raised to such a level that they will run through a spring switch into a kickback at B. The main purpose of this kickback is to give the cars the requisite speed. It handles the cars much better at this point than an "upgrade" would. This kickback can be raised sufficiently to allow a car needing repairs or oil to pass through into the car-repair shop beyond.

The empties are coupled together on the storage track, and the locomotives bringing in the loads pass from the loaded to the empty tracks either through cutoff C or D, the loads continuing toward the shaft by gravity over variable grades from one to three per cent, the latter being the grade provided at the cages.

The four main entries are driven in two pairs, a pillar 50 ft. thick being provided between the two inside entries. This plan affords several advantages both in haulage and ventilation; the first of these latter is the saving of all stoppings between main intakes and returns, except at points where panel entries are broken

*Article entitled "Description of Shaft Layout and Four-Entry System for Large Tonnage Production," read at meeting of Illinois Mining Institute on board "Golden Eagle" during a trip on the Mississippi, June 9, 1922.
†Mining Engineer, United States Fuel Co.
In Idaho Tests Are Being Made of Certain Small Semibituminous Coal Beds

BY HENRY M. PAYNE
New York City

WHERE the freight rates on coal are high all indications of coal are regarded as of great importance. Consequently much interest has been exhibited in some thin beds, or bands, of coal recently found in Idaho, despite their irregularity of thickness, their contorted character, the presence of faults and the temporary stoppings on this and the haulage entries up to this point are beginning to settle and leak.

The absence of practically all crosscuts and stoppings between the main intakes and main haulageways, or returns, fills a long-felt want and should save much of the labor and materials expended in the building and maintenance of permanent stoppings. Furthermore it should provide for a more satisfactory distribution of the air at the face of the workings. Experience has shown that these benefits greatly offset the additional expense of driving the fourth entry.

This system has a further distinct advantage in the ventilation of the mine if the crosscuts between the two entries forming intakes and returns are opened up after the permanent ventilation has been arranged. In case of a heavy roof fall in the intakes the crosscuts and intake airways will provide a detour around the fall until the rock can be cleared up. The system also prevents the air in the return from being baffled by the passage back and forth of the trips of cars. It may readily be seen how the air can circulate around a trip if the crosscuts are open.

This baffling of the air is extremely noticeable also at the hoisting shaft, which is used as an upcast in the ventilating system. In the accompanying plan provision is made to correct this baffling by having an auxiliary upcast adjacent to the downcast and separated by a concrete wall. This upcast is used also as an auxiliary hoisting shaft for the raising and lowering of men, materials, etc.

In mines giving off gas, which would make it dangerous for electric haulage to be on the return, the system can be reversed, using an exhaust instead of a force fan.

**FIG. 2. DIAGRAMMATIC CROSS-SECTION OF COULEE AND HILLS**

Note the basalt dyke on the right which forms the small cliffs in Fig. 1, the quartz dyke on the left and the line of a sharp anticline or possibly a fault which causes the coal to be either bent over or sheared, lying between the right face of the left hill and the quartz intrusion.

Igneous rock. The coal, though found above rock of the lower Miocene period and therefore in measures quite recent, has been converted by heat into a semibituminous coal containing about 26 per cent of volatile matter in the pure coal substance.

The high cost of fuel in southern Idaho has led to extensive prospecting along the Snake River and the organization of at least one coal company to develop the islands of sedimentation which occur in the basaltic formations along the north bank of that river near Cobb, on the Union Pacific Ry. Cobb is in Washington County near the line of the State of Oregon.

A general idea of the topography may be obtained from Fig. 1, which is a view looking up the coulee. A
basalt cliff is seen high on the hill to the right, and across the coulee from the wagon road are a number of old prospect holes. In none of these, however, is there any evidence of more than carboniferous shale badly interstratified with fireclay, dipping from 30 to 45 deg. northeast toward the basalt cliff. In the roof rock of one opening a partly carbonized stump is seen.

About a half mile farther up, a tunnel was driven in the left or west side of the coulee for about 750 ft., bearing around to the right and dropping on an incline, like a letter "J." The reason for this will be seen in the cross-section, Fig. 2. The "coal" bed when encountered, was rising rapidly, with the roof rock varying from draw slate to rotten sandstone. This formation suddenly appears as a violent anticline, but from surface examination probably is a fault extending along a general north-south line.

A crosscut was made at this point. The coal in this cut is shown in Fig. 3. It consists of irregular layers of coal, slate, shale, fireclay and other extraneous matter, the broadest coal bands being about 6 in. thick, but irregular and never wholly clean. About 400 ft. from the mouth of the tunnel a winze has been sunk to a depth of about 120 ft., at the bottom of which was found a rhyolitic sandstone with white quartz contacts. The general dip of the strata and a quartz outcropping on the hill above the tunnel would indicate the intrusion of the quartz at this point.

About 30 ft. below the level of the tunnel a crosscut was turned off the winze for a distance of 60 ft. to the north. Here the lesser lamina tions appear to have combined, but only one of them is worthy of note, being 8 to 12 in. thick and wavy, dipping to the northeast.

Frequent masses of fireclay intervene, the roof rock is badly broken, and all development at this point has been stopped. The workings are ventilated, as seen in Fig. 4, by a furnace fed from a pipe extending into the tunnel and down the winze a distance of approximately 450 ft., thus drawing out the air by ascensional ventilation and leaving the whole entry as an intake.

At the left of the wagon road in Fig. 1 may be seen an outcrop opening which is reproduced in Fig. 5. At this point slightly below the level of the tunnel mouth the coal bloom appears about 3 ft. thick, but was not driven to roof rock at the time of the examination. This seam dips to the northeast and probably is the same one encountered in the tunnel, extending to the fault indicated in Fig. 2.

On the south point of the hill, overlooking Snake River, is an old prospect hole showing 7 ft. of badly broken coal interstratified with fireclay and volcanic ash and dipping, like all the other exposures, to the northeast. From this point on around the hill to the west, a clearly defined bench is found, and on the west side, directly opposite the tunnel, is an abandoned prospect hole extending horizontally for about 100 ft. to an intersection with a coal seam said to have shown 18 in. of coal and dipping 45 deg. northeast. This incline is now filled with water, but the formation evidently is the same as that shown on the south hill. Below this formation occurs a stratum rich in fossils of the lower Miocene period.

Analyses of the coal taken in the tunnel crosscuts and various other exposures show volatile matter from about 11 to 20 per cent; moisture from 1.3 to 1.5 per cent; fixed carbon, 52 to 57.8 per cent, and ash, 22.8 to 33.6 per cent. The entire hill appears to contain irregular pockets or lenses corresponding to islands of sedimentation, upon which the effect of igneous contact is shown in the low moisture and volatile content of the coal. Interspersed among these are beds of ashy shales, coarse clays, coarse sandstones and lava.

The owners of the property, in their desire to exhaust all the possibilities of obtaining coal for domestic purposes, are considering core drilling. Tests also are being made of the various clays on the property for industrial uses. Inasmuch as all tertiary coals of importance have been formed in the presence of extensive sedimentation, and free from igneous metamorphic action, such deposits as exist under the conditions enumerated must necessarily be subject to irregularity in occurrence and paucity of vol-
atile matter. The coal, though of comparatively recent deposition, cannot be classed as sub-bituminous, but is rather a semibituminous, owing to the ripening effect of heat and pressure.

Pneumatic Tools Replace Pick and Shovel

IN MANY jobs involving the removal of earth the material encountered is too soft to render drilling and blasting necessary yet is too hard to permit penetration of spade or shovel. Such ground heretofore has required picking. This, as everyone knows who has ever attempted it, is hard, laborious and fatiguing work.

Mechanical picking methods now appear about to supplement manual operations, as an air-operated digger, with which one man can loosen as much soil as five men with picks, has been perfected and placed on the market. The rate at which soil can be dug with this equipment will in most instances exceed this. With this tool a man maintains a more uniform rate of work than does one equipped with a hand pick and stops much less frequently to rest, as his work is far less fatiguing.

Furthermore, danger of accident resulting from careless handling or swinging of the pick is entirely eliminated. Men are thus enabled to work closer together in trench, tunnel or shaft. This new device and its manipulation are shown in Fig. 1. The machine itself weighs only 23 lb., and a man will handle it standing upright. Essentially this device consists of an air hammer with a heavy spade at one end and a cross handle containing the throttle at the other. The over-all length is 34 in. The spade or digging blade is held in the end of the hammer mechanism by a suitable retaining device. Blows delivered in rapid succession to the upper end of the spade drive it rapidly into the earth, which may then be readily pried loose.

For work in clay the blades measure approximately 6 x 8 in. and are slightly concaved. For use in dirt they are made 8 x 9 in. and rectangular in cross-section. The face is thus flat, the thickness being 2 in. at the top and ½ in. at the point, the cutting edge being beveled from the back. Conveniently located in the handle the throttle lever may be readily pressed or released as the tool is pushed down or lifted. A buffer is provided to take the blow of the hammer if air is not shut off while the tool is being raised. An operator, however, soon learns to shut off the air automatically as he begins pulling up on the handle. This tool, known as the No. 56-H Little David clay digger, is manufactured by the Ingersoll-Rand Co., 11 Broadway, New York. As the name implies, it is a development of the tools already extensively used for tunneling through clay. These tools have in some instances reduced the cost of such operations in clay as much as 40 per cent. It is only natural that they should now be applied to the closely allied operations of trenching and shaft sinking.

A somewhat similar spader, known as DE-361 compressed-air spader or pneumatic clay-digging tool, but somewhat lighter, weighing only 16 lb. and 17 in. long, is being manufactured by the Sullivan Machinery Co. It requires a ½-in. air hose. This is recommended for the excavation of stiff clay in trenches, open cuts, caissons and tunnels where the ground is not sufficiently hard to be drilled and shot and yet is too hard to be handled readily by pick and shovel. It, like the tool just described, takes the place of the hand pick as well as of the hand spade or shovel.

In tunneling in blue glacial clay, very dry and hard, in the Chicago district these spades increased the output per man from 3 to 4 cu.yd. per eight-hour shift to from 8 to 10 cu.yd., the work being limited by the ability to get rid of the mud instead of by the rate of digging, as formerly. Any air pressure from 45 to 100 lb. can be used. The spades are made 4, 5 and 6 in. in width.

In this connection may be mentioned the Boyer clay digger, a modification of the clipping hammer of the same name, manufactured by the Chicago Pneumatic Tool Co. This spader makes 1,100 blows per minute and uses 20 cu.ft. of free air per minute at 80 lb. and 25 cu.ft. at 100 lb. pressure. The blade of the digger is 5 x 9 in. and with the shank is 14 in. long. Its weight complete is 16 lb., half that weight being accounted for by the blade. The over-all height is 34 in.

None of these spaders is electrical. They would have a broader field around the coal mine if they were. It is not at all impossible that such machines as these would be invaluable in lifting clay bottom or bottom coal left by undercutting machines as well as in surface excavation of all kinds, of which the mines have much to perform in the course of a year.
Laying Out Mine for Coal-Loading Shovel Operations

By Using Sixty-Degree Turns in Place of Right Angles
Twenty-Foot Radius Curves Can Be Installed Though Curves of Twelve-Foot Radius Can Be Negotiated by the Shovel

By William Whaley
Knoxville, Tenn.

Shoveling machines can be used with the usual system of mining coal, but to get the best results the work should be developed and transportation arranged so as to keep the machine employed to the fullest possible extent. This means concentrating the transportation so that in every working place the empty cars will be supplied to the machine and loads removed therefrom with promptitude. A system or methodical plan of working is therefore desirable. Fewer rooms are required for given tonnage, and they, therefore, can be better equipped at the same or less cost. Track should be standardized; curves, rails, turnouts, etc., should be supplied to the underground force ready to lay.

The following suggestions are advanced as a practicable method of standardizing the work: The radius for curves should be not less than 20 ft. The shoveling machine will negotiate curves as short as 12 ft., but a 20-ft. radius is an easy curve for the machine and for the locomotive and cars and makes derailment less likely. Moreover, the shovel can load on such a curve with satisfaction.

The room necks and crosscuts should be turned off the entries at an angle of 60 deg. Room crosscuts should be turned at a similar angle, thus making it possible to lay easier curves and enabling the machine to reach all of the coal that is to be loaded at any time in the room necks as well as in the rooms, crosscuts and entries, practically eliminating all hand loading.

Plate I shows a general layout of an advancing section of a mine using single-track rooms and shows standard turnouts of 20-ft. radius. Plate II illustrates the method of driving a pair of entries. The crosscuts are turned at 60 deg. and the track is connected through in such a way as to form a run-around for cars, the empty cars coming in through one crosscut and going out through the other. When the machine is loading in the haulageway the empties would be stored in the first crosscut as shown and shifted one at a time back of the machine for loading, and then dropped past the switch point for storing until a trip has been made up. This sketch is self-explanatory.

Plate III shows the arrangement of single-track rooms with track through crosscut, all curves being of 20-ft. radius and the angles of the tracks being 30 or 60 deg. Plate IV shows method of loading coal when robbing and Plate V illustrates how the shoveling machine is enabled to reach all of the coal at every shot from the first shot off of the entry, as shown in Fig. 1 of this plate, until the machine is entirely straightened out in the room neck, as shown in Fig. 3. Fig. 4 illustrates the machine passing around the curves of the crosscut and Fig. 5 illustrates the practicability of operating the machine through a 90-deg. crosscut with 12-ft. radius curves. While such sharp turns in the track and

PLATE II. TRACK LAYOUT FOR ENTRY DRIVING
Tracks are laid in two half crosscuts and one acts as a run-around to the other. With this plan shifting of cars is unusually rapid.

PLATE III. SUGGESTED LAYOUT FOR NARROW ROOMS
Rooms are connected in pairs by track through crosscut, facilitating storage and shifting of cars. Turnouts and curves should be standardized for facilitate quick laying of good track.

PLATE I. ADVANCING SECTION OF MINE
PREFERRED PLAN
The rooms are not opened at right angles to the roadway but 30 deg, therefrom. This makes it easier to negotiate the turns, though it is not absolutely necessary to put in a crooked neck of the kind shown, for machines can, if needful, make the right-angled turn. Crosscuts in rooms and entries have a similar slant.
not recommended the illustration shows that the machine can be used and moved around in an old mine with crosscuts and tracks laid in this manner.

Plate VI illustrates proposed arrangement for double-track rooms, the system of operation being similar to that previously described. Plate VII illustrates the flexibility of the shoveling machine, showing how the rear conveyor and shovel can be shifted into different positions, enabling the machine to reach into curves, across the face of a room, to discharge upon a parallel track and to pass around short curves in the mine.

In reference to Plate I, as soon as a crosscut between rooms is completed the track is connected, as shown, between rooms 5 and 6. This track forms a run-around for cars when the machine is loading in room 6, the empty cars being stored in the crosscut, as shown on Plate III, which is an enlarged detail of development as it has progressed in rooms 5 and 6. When the rooms have advanced to the stage shown in rooms 3 and 4 of Plate I, the track through the first crosscut is removed and the track in the second crosscut connected up. This brings the switching point for cars within a short distance of the face at all times and eliminates delay in removing the loaded car and bringing in the empty. This crosscut track also is well laid and entirely sufficient for moving the shoveling machine from one room to another. Therefore in moving from room 3 to 4, for instance, the machine has to run back only to the nearest crosscut and through it to the face of the adjoining rooms.

In Plate I room 1 has reached its limit and a crosscut has been driven at the end of the room. The track end is fitted with a curve and brought across the face of the pillar. The pillar is drawn back, as shown in Plate IV, the curve and track across the pillar are moved up after each cut, the cut being connected with the room track by means of inverted rail jumpers. The distance between crosscuts should be made such that the entire pillar can be taken out in this way with the exception of a protecting stump, as shown on this sketch. This protecting stump is the only part of the coal that will have to be drawn by hand.

**Arrangements Have Been Made for the shipment of two 1,000-lb. samples from the Deep River coal field of North Carolina to the central experiment station of the Bureau of Mines at Urbana, Ill., for coal washing tests.**

**A Special Study is being made by the Bureau of Mines at Pittsburgh, Pa., looking to the development of grates and furnaces to utilize lignite char, to be used in heating and cooking stoves. James Neil, fuel engineer, and M. L. Orr, assistant mechanical engineer, have been assigned to the investigation.**
Self-Dumping Cable-Bottom Mine-Refuse Car Builds Its Own Inclined Track

BY ALPHONSE F. BROSKY

Pittsburgh, Pa.

In dumping the slate, sandrock and clay that come from a mine the topographic features of the surface have a direct bearing on the choice of method. Many schemes are in successful operation for the disposal of such refuse, each working to advantage under the particular conditions that the location imposes. The problem is simplest where the surface is broken by gullies or ravines that are near enough to the tipples to make it practical to haul the slate to that point and large enough to insure dumping capacity sufficient for the life of the mine. In such cases an electric slate larry is desirable.

Slate disposal becomes more difficult, however, where the ground is level. Either of two methods may be chosen under that condition. Where a large expanse of level ground is available for dumping, an electric larry may be used here also, the slate bank rising on a slight grade. When the dump area is limited, however, it may be wise to make the inclination steeper than the use of a larry will permit and radiate dump piles away from the tipple structure.

Under these circumstances each dump somewhat resembles a miniature mountain, its height rising rapidly in the direction of its major axis. To dispose of slate in the fashion noted it is necessary to raise the car by a rope hoist.

Several of the larger companies have adopted the aerial cableway for the disposal of mine refuse on level ground. An inclined cable rises from the rock bin to a lofty tower. A rock carrier, or bucket, suspended from a pulley travels along this cable and is raised by means of a rope passing over a sheave located on the tower and leading thence to a hoist conveniently placed on the ground. When the dumping point is reached the contents of the carrier are discharged by the action of a trigger. The great disadvantage in this device lies in the erection of the tower, the weight of which is appreciable. After a slate dump of this kind has been completed the tower must be moved, and this is difficult because of its height and weight.

The H. C. Frick Coke Co. has adopted a method of slate disposal that builds a pile comparable to that constructed by the aerial cableway. The principle indeed is by no means new. The idea in fact came from the Illinois field, but since its adoption the method has been improved. It has now been accepted as standard by the company.

A self-dumping car is drawn up the steeply graded slate dump which it has gradually accumulated. At the top of the dump is an open-rail platform from which the slate is discharged. This dock is supported at its rear end by the slate pile and at the forward end by a single trestle bent.

The car is saddle-backed, or gable-bottomed. It is of a composite steel-and-wood construction. It has a capacity of 75 cu.ft. and opens and closes automatically, so that no attendant other than the hoistman is needed. The general plan of this car is shown in Fig. 1, while Fig. 2 is a photograph of the same piece of equipment. The side gates are hinged at the top and secured in place by latches. When these are released the doors fall from an inwardly inclined to a vertical hanging position. The first position, which is that assumed when traveling, is shown in the left-hand elevation of Fig. 1. The arms of the latches are end pivoted in the center of the car. Suspended from the midway point of these arms are vertical push rod bearing rollers on their lower ends which on passing over lifter tracks release the latches. The doors then swing out into the vertical position and the slate discharges onto the dump.

If conditions are such that dumping from one side only is advisable a single lifter track is placed between the rails. In that case a large sheet-iron floor plate may be inserted on the side opposite that where dumping takes place, thus making the car bottom or floor one plane. This arrangement is not shown in the drawing but has been adopted at one of the company's mines. One disadvantage entailed in discharging from

*Bituminous editor, Coal Age.

---

**FIG. 1. MINE-REFUSE CAR WITH PUSH RODS TO OPEN LATCHES AND RELEASE DOORS**

The front push-rod rollers are made higher than the rear ones so that they can pass over the first part of the lifter tracks, only to come in contact with the second part at the time when the rear push-rod rollers begin to rub on the lifter track. Thus the side gates are released at both ends at the same time. The rollers at the side of the car engage two converging cam guides which force the doors to close. The latches, being free, fall and hold the doors in place.
one side only is that the capacity of the car is much decreased.

When the car passes between two converging cam guides they force the doors to the closed position. These guides are firmly mounted on masonry piers or posts set in the ground between the bottom of the dump and the tipple. The gates are provided with contact rollers placed level with the cam guides.

It will be noted that the truck is not of standard mine-car design, being rather proportioned to suit the requirements of the body. Standard loose wheels and fixed axles are used. The inner axle collars are shrunk on and the axles are fastened to the longitudinal members of the 6 x 6-in. truck frame by means of §-in. bar-iron brackets. The design and attachment of the drawbar is such as is adaptable only to a car that operates alone. As the drawbar always is subjected to a pull, the bar is rigidly fastened and has no buffer. It consists solely of a hook bar 1 in. in diameter that passes down the center of the car and pierces the two end members of the frame. Thus there is no danger that the truck will be sundered by the pull of the drawbar. The car bottom is supported by four 3 x 6-in. oak rafters which are notched and bolted together at the peak. Insets are cut in the lower ends of these members, which rest on the truck frame and are through bolted to it.

Little difficulty should be experienced in building such a car. The one here shown is well designed and will indefinitely withstand the work for which it is intended. Through use, weak points have been overcome, and a superintendent need not hesitate in adopting the general design shown, if the conditions for its operation are favorable. It will readily handle 200 tons or more in 8 hours.

Heavy, well-joined rails are requisite where slate is dumped on the ascent. From the rock bin to the edge of the brick company uses a 70-lb. rail spiked to wood ties on the roadbed. The dumping platform consists of a pair of 30-ft. 85-lb. rails tied together by heavy angle irons bolted to the rail bases. The journal boxes of a 24-in. sheave at the outer extremity of the dock are securely bolted to an angle-iron anchorage. The farther end of the platform rests on an oak bent 16 ft. in height which is hinged to the rails. The legs of this bent are of 6 x 6-in. oak, diverging to a 9-ft. base, where they are bolted to an oak sill of similar dimensions. Tie bands of § x 2-in. strap iron add rigidity to the bent.

The bent is substantial and compact and rests on a footing in the slate pile lower than the crest. When the slate reaches the level of the platform the track may be moved outward with ease. The slate is first removed from around the bent, it being thrown forward along the line of the dump. In this way a mound is formed the crest of which is at a greater elevation than the base level of the bent. The rise is such as to correspond with the predetermined grade. The bent is jacked up and its foot moved out to the new position, the frame itself being thus held obliquely. The fishplates are removed at the joint where the 70- and 80-lb. rails meet, a rope is attached to the heavier section and the frame is pulled out over the dump until it again forces the bent to a vertical position. In accomplishing this shift the rope is carried forward parallel to the rails and passed through a snatch block, from which it returns.

Four men do the track shifting, each move advancing the dumping point 10 ft. Three pairs of 70-lb. rails, respectively 10, 20 and 30 ft. in length, are kept on hand. At the first move beyond a 30-ft. rail a 10-ft. length is inserted. On the second move this is taken out and a 20-ft. rail length put in its place. On the third move the 20-ft. rails are replaced by 30-ft. pieces, which remain permanently. The cycle is then repeated.

The four men who are employed in this work can make a shift in five hours. At an elevation of 45 ft. it is estimated that 1,200 tons of slate may be dumped from a single set-up.

A §-in. steel-wire rope is utilized for hoisting the slate car. The size of the engine needed at a dump of this kind will depend entirely upon existing conditions, particularly on the space available for dumping. The horsepower requisite for a hoist used on any par-

Doors are shown hanging vertically. Note the lifter tracks for raising the push rods, and the hinges which attach the bent to the rails.

FIG. 3

Two of the Dump Piles

At Hecla No. 1, Southwest, Pa., of the H. C. Frick Coke Co. It is difficult to obtain height so long as the grade by which the dump grows is that up which an electric jerry can climb. For this reason a ropeway is used at South- west.
Pipes are so little suited to the economical transportation of large volumes of air and so liable to accidents of many kinds that it is inadvisable to use them in regular coal-mine ventilation where, as a general rule, a cheap and superabundant air supply must be provided.

For temporary and local ventilation within reasonable limits of distance and volume, however, air pipes have advantages the possibilities which do not seem to be fully appreciated by coal-mine engineers. Instances where pipe ventilation is resorted to in coal mines undoubtedly are numerous, but in practically every case a special fan is employed to force or draw air through the pipe, when the desired result could be automatically accomplished by taking advantage of the pressure exerted on the atmosphere of the mine by the outside fan. How this is done in the simplest possible way I explained in *Coal Age* many years ago.* I now desire to treat the subject more fully, showing the possibilities of the air pipe as a practical, cheap and most efficient means of ventilation, one permitting headings and single places of comparatively great length to be driven through the most gaseous of seams with a safety and a rapidity made possible by no other known method of ventilation.

Fig. 1 shows the most efficient way of ventilating automatically by means of pipes the several faces of a heading. A temporary stopping, A, built across the aircourse is provided with two openings in which are tightly fitted the ends, B and C, of pipes 1 and 2, the other ends of which are D, near the aircourse face, and E, near the haulway face, respectively.

If the air current set in motion by the fan travels in the direction indicated by the single-point arrows, pipes 1 and 2 will discharge air toward the faces they are intended to ventilate, the tubes in this case being termed "blowpipes." If the ventilating current moves in the direction indicated by the double-point arrows, air is drawn into both pipes through their mouths.

FIG. 1. AUTOMATIC AIR PIPES WITH STOPPING ON AIRWAY

This will work with exhaust or pressure methods, the double-point arrow showing the exhaust system where the air is drawn into the pipes and the single-point arrow the pressure system where the air is forced into the pipes.

D and E, the tubes then being called "exhaust pipes."

In the former case, where the air enters the face through the pipes, if the total distance from B to E does not exceed 600 ft. and if the water gage at A is not less than a half inch, and if, moreover, 16-in. round galvanized-iron pipes are used with discharge ends D and E within 15 or 16 ft. from the faces, the air will be discharged from the pipes with such a velocity and in so great an abundance that every square inch of face will be completely swept by fresh air. Thus explosive mixtures cannot be formed, and the use of naked lights at all times will be permissible.

The pipe generally is laid on the floor against one of the ribs, the last joint being deflected a little toward the center of the place. To increase the velocity of the outflowing air without reducing its volume a conical cap 4 to 6 ft. long is placed at its extremity, one end fitting the main pipe and the other being of a diameter 12 in. less. Thanks to this cap the velocity of discharge in general is so much increased that the pipe orifice can safely be kept so far from the face that the pipe will not be injured when bursting.

In limiting, as I have done above, the ultimate length of pipe 2 to 600 ft. I have taken into account the necessity of tapping pipe 2 at F for the purpose of ventilating crosscut G by means of a secondary pipe, 3. So long as the width, X, does not exceed 50 or 60 ft., pipe 3 will be of ample size if of 12 in. diameter. Butterfly regulators, made like ordinary stove-pipe dampers, are placed in the air pipes at H and K. Moderately open at first, these regulators are gradually opened wider as the air pipes grow longer. In the case illustrated in Fig. 1 and with the length of heading, diameter of pipe and water gage given, regulator H would not require to be opened in full until after pipe 3 had been installed and put in commission. The driving of crosscut G will not retard the extension of the haulageway, for there is plenty of air for both of them. But after the new crosscut, G, is through and rail communication with the aircourse is established in that manner, stopping A is transferred to A., the base of the pipe system is advanced 500 ft. and all unnecessary steel is removed from the aircourse and crosscut L. The latter is then stopped tightly by a cement wall, thus clearing the ground for another continuous advance of 500 ft. Were it not for the necessity of placing a tee at F to ventilate

crosscut G, the haulageway could be driven in perfect safety through gaseous coal at least until the length of pipe 2 became 800 ft.

Besides providing for safety to an extent unapproachable in any other way, the ventilation system just described necessitates the driving of only one crosscut through the pillar, whereas if the ordinary method is followed, eight must be cut through. Thus the cost of laying and taking up switches and building stoppages is reduced in the proportion of eight to one. The cost of installing and maintaining good pipe systems is less than that of erecting and keeping up wood and canvas air-conveying contraptions, not, it is true, those of the flimsy, cheap, make-believe kind too often seen even in $25-called big mines but the more substantial and effective sort that is obligatory if the headings in gaseous seams are to be driven in comparative safety and with any degree of rapidity.

Continuous, never-failing safety, the kind miners soon learn to trust without question, in itself makes for rapid driving. Speed is further accelerated considerably by doing away with the delays and lost motion that would accompany the driving of numerous crosscuts and the never-ending laying of switches and building of stoppages.

In nine mines out of every ten the men who drive the two straight places of a heading insist also on driving the crosscuts, thus stopping work in the former while busy in the latter. How can headings be driven fast under these conditions, if a new crosscut has to be made every 60 ft.? No immediate profit is derived from driving headings. The longer it takes to complete them the longer the capital they absorb remains unproductive. Hence all means leading to their rapid completion and utilization will save money.

Exhaust Pipes Unsuit to Gas Removal

Referring again to Fig. 1 and assuming that the ventilating current travels in the direction indicated by the double-pointed arrows, suggesting that the mine is ventilated by an exhaust fan, it will be easily understood that, before entering the pipes at their mouths, D, E and M, the air travels through places of comparatively large cross-section. Hence it moves slowly—too slowly to have enough energy to sweep away the gas instantly as it comes out of the coal.

Even if the mouth of a pipe is kept only a few inches from the face, which cannot be done in actual practice, the suction will be insufficient to remove the gas fast enough to make the place safe for operation with naked lights. Only the gas coming out of the seam in the immediate neighborhood of the mouth of the pipe goes promptly into the latter. It is unnecessary to say that no conical cap of the kind just mentioned is used with exhaust pipes.

In mines ventilated by exhaust fans the arrangement shown in Fig. 2 is used. The operation of this system requires no lengthy explanation. That it works in all particulars as efficiently as the blowpipe arrangement fully described above is easily understood from a comparative study of Figs. 1 and 2. The door, O, constitutes a drawback, but it is inevitable when the blowpipe system is used in combination with exhaust ventilation.

Ventilation of the kind herein described is not used as extensively in this country as in Europe. I have installed with great success automatic blowpipes in a viciously gaseous West Virginia mine where work had been suspended and where serious contemplation was given to abandoning the mine, the time-honored brattice system of conveying air having proved a costly failure, practically all the men having left, being rendered apprehensive by reason of the frequency of explosions.

I have employed the same method, also in West Virginia, to drive a single heading to the outside, a distance of 1,440 ft., using without restraint the worst kind of smoky, ill-smelling dynamite and cleaning three 51-ft. cuts daily.

In Belgium a single place driven in the coal between workings in preparation at a new low level and old workings in the level immediately above is termed a "montage." In such places blowpipes with exhaust ventilation are the recognized means whereby air is supplied to the men at work. Places are driven by this means often on extremely steep pitches between levels having a difference in elevation seldom less than a thousand feet.

Weight Saved and Stiffness Added to Cars by Use of Pressed Steel Units

Stamping or pressing a tin pan or other kitchen utensil from a single piece of metal, giving the finished top a rolled edge, is an old process the product of which is familiar to everyone. The accompanying illustration shows the result of applying the same or at least an analogous process to the manufacture of mine cars.

The body of this car, which is of the "solid" type, consists of three pieces—the bed and the two ends. These are bolted together, the ends being flanged for that purpose. In the center of the bottom an inverted longitudinal groove is pressed which receives a wooden stringer that forms the bumpers at either end. These, of course, are covered and protected with a suitable forged steel plate. A through drawbar bolted to the stringer and car bottom furnishes an efficient means of coupling. The top of both the bed and ends is flanged over to afford stiffness.

Trucks of any desired type may be applied, also any of several attachments such as the car-haul lug shown in one of the accompanying illustrations or other variations which may happen to suit local conditions. In
UNDERSIDE OF Pressed STEEL CAR
An inverted longitudinal groove is pressed in along the center line of the car bottom. A wooden stringer is set in this channel and it forms the bumper at each end.

this respect, as in all others except details of construction, this car is exactly like any other of similar shape and capacity.

Although the dies for making these cars are somewhat expensive, once these are made a car can be turned out at small cost and with great rapidity. Cars of this type may be shipped knocked down, to be assembled at the mine. When thus shipped the space required is small, as the various pieces will nest readily. Should a car be disabled in a wreck the various pieces can be returned to the factory, where they can be passed through the forming press and restored to their original shape. This car will soon be manufactured to such shape and dimensions as the customer may specify by the Johnstown Steel Car & Supply Co., of Johnstown, Pa.

Wood Pipe vs. Cast-Iron for Large Lines

SO MANY large water mains are laid to mines for domestic uses and for quenching coke, as well as for draining away mine water, that a paper by J. W. Ledoux, consulting engineer of Philadelphia, Pa., read at the annual convention of the American Water Works Association will be of interest. It will be remembered that he is talking of permanent pipe, whereas mining engineers usually regard 25 years as looking far enough into the future. He says, among other things: For all water main of ordinary size, cast-iron pipe generally is regarded as standard. More cast-iron pipe is used for the carriage of water than all other pipes combined, the reason being that cast-iron pipe can be made absolutely tight under all circumstances and will remain so under all variations of pressure. For very large sizes, however, it is too costly as compared with wood or steel, and under many situations the reduction in capacity due to tuberculation is so serious that engineers will prefer a reinforced-concrete or wood pipe.

Undoubtedly wood pipe comes next to cast iron in the generality of its use. It may be conservatively stated that cast-iron pipe will last one hundred years. Although there are many modern wood pipes that have been giving good service longer than 25 years, when we compare wood with cast iron it is best to assume a short life for the wood pipe.

As an example, let us take 24-in. continuous redwood pipe and assume a life of 25 years. Say the wood pipe will have to be renewed four times in 100 years and cast-iron pipe will last indefinitely. Let us take the average discharging capacity for the wood pipe as 20 per cent greater than that of cast iron. Table I shows the details and results of a cost comparison, computed on the basis of present worth.

For machine-banded Eastern pipe (also 24 in.) the initial cost would be $28,900 as against $41,900, but after making the same calculations as are shown in Table I the present worth figures obtained for wood pipe would be $50,125 and for cast-iron pipe $86,650, a saving of $36,525.

WOOD Pipe DECLARED CHEAPEST Now and in End

For 12-in. machine-banded Eastern pipe the initial cost would be $14,900 for the wood pipe and $26,900 for the cast-iron pipe. Making the same calculations as before, the present worth of the total cost of the wood pipe would be $25,847, and of the cast-iron pipe $34,027, or a saving of $8,180, 28 per cent of the initial cost of the cast-iron pipe.

When a financial comparison on a rational basis shows such a material advantage of wood over cast-iron pipe, the question naturally arises, why is cast iron so universally preferred by most of the leading engineers? It is, no doubt, because there have been so many unfortunate experiences with wood pipe.

From our knowledge of water pipe, it may be said that the best pipe that could be obtained for any purpose would be cast iron with some sort of non-corrosive and indestructible inner lining, but in ten years from now this statement may be obsolete, and Mr. Ledoux is of the opinion that we are on the eve of great and fundamental improvements in water-pipe manufacture. However, it is believed that it will be many a decade before the use of wood pipe will be unwarranted.

Hauling taken at $2 per Ton.
Advantage of Electric Hand Lamp, One Type Of Which Contains Solid Electrolyte

Although the utility of the electric cap lamp in mine illumination is well recognized and it fills a need that has long existed, the hand lamp possesses advantages found in no other type of illuminator. Among these might be mentioned the equal diffusion of light in all directions rather than its concentration on one point or a comparatively small area, and a light flux of at least twice the volume of that emitted by the cap lamp. Furthermore, the hand lamp is hung upon a rib or timber, leaving the miner free to work unencumbered by any harness, battery or lamp. In addition to this the hand lamp is less delicate in construction and consequently less liable to derangement or injury than the cap lamp.

A new electric hand lamp, known as the Ceag RMC and embodying many innovations and advantages hitherto not employed, has recently been placed on the market by the Concordia Electric Co., of Pittsburgh, Pa. Two of these lamps, one fitted with a white dome and designed for miners' or foremen's use and one fitted with a red dome and a detachable bracket for attaching to the end gate of a car and intended to be used as a tail light, are shown in the accompanying illustration.

These lamps are, as usual, made in two parts—a lower and an upper. The lower portion consists of the battery, its container and the necessary contacts. The battery container is of pressed steel heavily tinned and fitted with an extra bottom cap welded in place. The negative battery element is placed directly inside the case, which is lead-lined, while the positive element, which is a hollow cylinder, is placed concentrically within it. Both elements are held in position at the bottom by means of celluloid crosses and rubber washers.

Probably the greatest innovation embodied in this lamp is the electrolyte employed. This is neither acid nor alkali; in fact it is not a liquid. Solidifying the electrolyte results in many advantages, chief of which is that all possibility of leakage is obviated and that turning the lamp in any position whatsoever in no wise affects the amount or brilliancy of the light emitted. Thus the lamp may be turned completely upside down without either spillage or diminution of light. The upper portion of the lamp is made of brass, which assures freedom from corrosion. It is joined to the battery case by means of a square thread and a magnetic lock. This latter will operate only when in proper contact with the magnetic unlocking device, and it thus is impossible for any unauthorized person to separate the two portions of the lamp. The light bulb is held in place within a heavy glass protecting dome by means of springs. Upon fracture of the globe these springs immediately break the electrical connections without the formation of a spark.

Specifications for this lamp are as follows: Average discharge voltage, 2; mean candlepower, 2; rated capacity in ampere-hours, 11; burning hours per charge, 12 to 13; normal charging rate, amperes, 14; length of charge period, hours, 7 to 8; total weight of complete lamp, about 5 lb. This lamp has been tested and approved by the Bureau of Mines. In addition to its applicability to underground operations it is being used in powder plants, arsenals, on battleships, submarines, in lighthouses, by municipal fire departments, in gas works, oil refineries and the like.

Mine samples of coal from the Chickaloon field in Alaska, submitted by the Naval Alaskan Coal Commission, have been analyzed at the Pittsburgh (Pa.) experiment station of the U. S. Bureau of Mines. The analyses show a high ash, low volatile coal, but it is hoped that washing will greatly reduce the amount of ash. The Department of Interior has recently taken charge for the navy of the Chickaloon mine, the Coal Creek mine, and other prospects on government reservations. Operations were placed in charge of the Alaskan Engineering Commission, the inspection, however, remaining under the Bureau of Mines. The Naval Alaskan Coal Commission mined during the month of April from the Chickaloon mine 2,352 tons and from the Coal Creek mine 33 tons. This coal was mined for the purpose of obtaining a large sample for naval testing. The Alaskan Engineering Commission is prospecting for coal with a diamond drill at Chickaloon.

In answer to questions by members of Parliament as to the coal supply of the Canadian railways, information was given by the government that the Canadian National Railway management has a contract with the Youngbrown & Ohio Coal Co., of Cleveland, for approximately 1,000,000 tons per annum, which expires Dec. 31, 1923. This tonnage covers railway requirements for western and northern Ontario and lines to Winnipeg and East, the basis of the price per ton, including duty, being substantially lower than the price at which Canadian coal can be obtained within the area mentioned. Preference is given to Canadian coal and more Canadian than American fuel always is bought by the management, but where American coal, including duty, can be delivered at Canadian points more cheaply than the domestic product, the management will continue to buy to the best advantage. The Canadian National Railways purchased 1,000,000 tons from Nova Scotia collieries between April 1, 1921, and April 1, 1922. E. C. Vaughan, vice-president of the lines, told the Public Accounts Committee of the House of Commons recently. Mr. Vaughan declared that it was hardly fair to ask the National Railways to purchase coal in Nova Scotia for Ontario lines when American coal could be delivered at Cobourg, Ont., cheaper than Nova Scotia operators were charging at the mine mouth.

At Benrush, W. Va., a 16-year-old boy who had just started to work in the mines was trained in first aid by the crew of U. S. Bureau of Mines Car No. 8. The local mine superintendent reported that a few days later this boy found drowning in a spring a three-year-old child. The boy rescued the child and performed artificial resuscitation, thus saving the child's life.
Continuous Operation of Mine Ventilating Fan

Safety the First Consideration—Expense Heavy in Idle Time
—Conditions in One Mine Afforded Satisfactory Natural Ventilation—No Fixed Rule Can Apply to All Conditions

SINCE reading the excellent letter of "Mine Foreman," Coal Age, Mar. 30, p. 537, regarding the stopping of the mine fan in idle times, we have discussed this question from every angle. It is one on which all mining men do not agree, further than to allow that safety first is the main consideration.

Personally, I have always felt that good mining practice required the continuous operation of the fan during the entire twenty-four hours of the day, under ordinary conditions. In a mine generating gas in any considerable quantity, men believe that the fan should be stopped, except in case of breakdown or urgent need for repair.

In that case, the men should be notified and withdrawn from the mine and not permitted to re-enter, until after the fan has been running a number of hours and the mine examined and reported safe for work. To guard against such emergencies a very gassy mine should be equipped with duplicate fans that can be operated alternately, one being held in reserve in case of accident to the other.

Expense of Running Fan Needlessly Must Be Considered

While I have never advocated and do not now advise the shutting down of a mine fan during a period of idleness, this question was put up to me a while ago when in charge of a mine where the equipment was entirely electrical. The fan was located at a distance of about a mile from the power plant and operated by an electric motor.

It can readily be understood that the running of this fan during a period of idleness, when there was no need for power for other purposes, involved a heavy expense that the company was anxious to avoid. At the same time, they were unwilling to provide any other equipment for running the fan independently.

Under these conditions, I began to investigate in order to ascertain what effect the shutting down of the fan would have in the mine. My surprise can well be imagined on finding that there was almost enough natural ventilation to keep the mine safe when the fan was shut down, provided the air could be carried to the face of some of the more distant workings.

After making a few needed repairs on the stoppages, however, we were able to obtain a volume of 11,000 cu.ft. of air per minute in that district, which was sufficient to keep the mine cool and safe. It should be stated here, however, that there was no explosive gas and very little gas of any kind generated in this mine. The principal object was to secure a sufficient circulation to keep the workings cool and avoid the danger of spontaneous combustion.

VENTILATION NOT WHOLLY NATURAL

Neither must it be thought that the condition I have described was wholly the result of natural ventilation. The heat from a steam pipe in the hoisting shaft, which was the upcast of the mine, greatly assisted the circulation. The steam was used to operate the pump at the foot of the shaft. Also a considerable amount of water was falling in the downcast shaft, which was another help.

The practice of shutting down the fan during an idle time has now been followed for over two years at this mine, and has proved satisfactory. The experience has taught me that no hard-and-fast rule can be applied to suit all conditions. What is safe practice in the mine just mentioned would be far from safe under other conditions and these conditions must be carefully studied, before deciding the question of stopping the fan on idle days.

Central City, Ky.: Ostell Bullock.

Speed of Fan at Firing Time

Shock ventilation and black powder cause explosion in mine—Decide to run fan at normal speed when firing.

A n instance that occurred not long since and which might have proved a fatal disaster, brings to my mind the subject of whether a mine fan should be slowed down, run at normal speed, or have its speed increased, at the time when shots are to be fired in a mine.

This subject has been widely discussed by able men and the general conclusion seems to be that there are conditions when the fan should be run slower and others when it should be run faster, at the time of firing shots.

The instance to which I refer occurred in a mine where thirty-six men were shutting coal off the solid with black powder. All shots were fired twice a day, at noon and again at 4 p.m.

The mine in question had much in its favor that would seem to render it almost immune from explosion. It is a wet mine and the 9 ft. seam has a fireclay parting about the middle, which should assist in rendering inert any dust that might accumulate.

With these conditions in its favor, however, the mine exploded at noon, one day, flames coming out of the drift in large volume. The fan was so badly damaged that new parts had to be secured before the mine could be again operated. Fortunately, no one was in the mine at the time.

In this mine, it was the custom for all the men to come outside for lunch, at the noon hour. When word was given to fire, the men would all light their shots and run for the entrance and, on this occasion, every man was safely outside of the mine when the explosion took place. The damage done inside of the mine, the force of the explosion being wholly outward, the inner workings acting as a cou de sac. Not a post was knocked down or a car displaced; but everything remained as the miners had left it a few moments before.

Lack of Ventilation the Cause

Speculation as to the cause of the explosion resulted in the unanimous conclusion that it was the natural result of insufficient ventilation at the time of firing. It can readily be imagined that the condition of the mine atmosphere would be if from fifty to one hundred shots, charged with black powder, were exploded, practically at the same time, or within a few minutes of each other.

All holes in this mine were charged with black powder; and the hot gases set free when the first shot fired furnished a highly combustible atmosphere to be ignited by the flame of the later shots. Everybody apparently knew and realized this condition and reached the same conclusion as to what was necessary to avoid another catastrophe.

It was decided by all that there was not enough air moving at the working face to dilute and render harmless the gases produced in firing. On the other hand, it was argued that to increase the speed of the fan beyond the normal would cause a dangerous velocity of the air sweeping through the workings. In view of these facts, it was the unanimous conclusion that the fan should be run regularly, at its normal speed. In addition, it was decided to
repair all stoppings and use nothing but permissible explosives in blasting. This, it was hoped, would render the mine immune from further explosion.

Pikeville, Ky.  ENGINEER.

Labor on Tonnage Basis

Economy of mine labor—Practical effect of putting mine foremen on tonnage basis.

Speaking in regard to economizing on mine labor, a mine foreman of Madisonville, Ky., in his letter, Coal Age Apr. 20, p. 660, advocates putting all mine employees, including the mine foremen, on a tonnage basis, as the best means of securing a full day’s work for a full day’s pay.

I have been wondering if our friend has stopped to consider for a moment, what would be the result of putting the mine foreman on a tonnage basis. Without reflecting any discredit on the honesty of mine foremen in general, let me ask if this proposition would not throw a temptation in the way of the average foreman.

Think for a moment what the rightful province of a mine foreman is and how he labors in a different way from the miner and other daymen working in the mine. While miners and daymen are chiefly interested in increasing the output of the mine, assuming they are all working on a tonnage basis, the foreman is responsible for looking to the future interests of the company, as well as increasing the daily tonnage. Then a mine with regard to the future and the conservation of the coal often makes present interests secondary to the future requirements. For example, areas of low coal must be worked out at once or lost; there is deadwork to be performed there, while the thorough abandonment, abandoned places made safe and the working places properly ventilated.

Responsibility of Foremen

It is up to the foreman to see that these and other matters are constantly given attention, though he knows that it means a certain curtailing of the possible output of the mine. The question is will the average foreman set aside his own personal interest in securing a heavy tonnage whereby his pay will be increased.

Now it is the nature for every man to look to his own interests first and mine foremen are no better than other men in this regard. That being true, what would be the natural result of a mine foreman being paid on a tonnage basis. Would it not result in the following conditions?

There would be the temptation to work out cheap coal; rob entry pillars and take out blocks of coal that should remain until they can be removed with greater safety and economy a little later. A place would be put to work in places that should stand idle, for a time, in order to avoid undue pressure being brought on the pillars in other sections of the mine. Finally, the work of repairing stoppings, timbering airways and keeping up the roads would often be sadly neglected.

Without going into further details, is it not true that every man’s heart, including that of the foreman himself, would be wholly set on putting out a large daily tonnage, without proper regard for what that would mean to the future welfare of the mine and the best interests of the company.

Mayport, Pa.  JAMES THOMPSON.

Importance of Checking System

Accident revealed only by failure of men to return home—Prompt rescue saves lives of two men caught by a fall—Checking system needed in every mine.

One reads with deep regret reports of fatal accidents such as that found in the news columns of Coal Age, Apr. 13, p. 641, recording the deaths of two miners, working in the Woodward mine of the Glen Alden Coal Co., at Edwardsville, Pa.

While the report states that both of these men were probably instantly killed, their necks and backs being broken, it is not known at what time the fall occurred and how long a time may have elapsed before their bodies were found. The fact of the accident was only made known by the failure of the men to return to their homes, and a search was then made to ascertain the cause of their delay.

Importance of Checking System

Reflecting on these reports that come to our knowledge from time to time, one is forcibly impressed with the importance of a thorough checking system being installed in every mine. Allowing it to be true that, in this case, such a system would not have saved the lives of these men, it still remains that there are numbers of instances occurring daily in which it would be effective.

In the present case, an investigation would have been made immediately following the time when all the men should have been out of the mine, and this instance recalls to my mind the experience some time ago of two men working on a pillar when a fall of coal and rock caught and held them fast until rescue finally came.

That accident occurred in mine 201 of the Coal Mines of the Commonwealth near Jenkins, Ky. Had it not been for the prompt report of their plight, these men also would have been killed, as shortly after their rescue another fall occurred that would have crushed out their lives.

Personally, I am strongly of the opinion that an adequate checking system should be installed in every mine, and that this should be made compulsory by law. There are numerous systems of this kind in use; but to be effective there should be a check on every man who enters the mine, and the evidence of his going in should again be, withdrawn on his coming out, whether his stay is for short or long.

Edwight, W. Va.  J. W. POWELL.

Abandoned Workings in Mines

No fixed rule possible—Many abandoned areas ventilated to advantage—Other areas dangerous if left open—Confined bodies of gas always dangerous.

In giving my views on the question of ventilating or sealing abandoned areas in mines, I must confess to having no fixed conclusion in this matter. In my opinion, it is a thing in which no hard and fast rule can be laid down.

After carefully turning over the question in my own mind, I feel that any law covering this subject should place it wholly at the discretion of the state mine inspector, who must be able to determine the method of procedure in any given case that will promise the greatest degree of safety in the operation of the mine.

No Arbitrary Standard

To say that all abandoned workings shall be sealed, or all shall be ventilated, would be too much like setting up an arbitrary standard, without regard to the particular case, or giving a proper solution to the problem in hand.

Considering the diversity of coal-mine methods and systems, as we find them in the principal coal-producing states, I believe it is generally agreed that what will apply to the conditions in one district will fail to suit conditions in another district.

While there are undoubtedly districts where abandoned areas can be ventilated in a manner to prevent the accumulation of dangerous quantities of gas, the conditions in other districts and the methods of mining employed will hardly permit of this proceeding.

Standing Gas Dangerous

On the other hand, it is quite generally agreed that a standing body of gas, even though confined in a tightly sealed area, may prove a menace to safety and the security of the property. In other words, it is a hazard that invites a catastrophe and should not be permitted if it is humanly possible to prevent it.

In general, let me say that large abandoned areas in mines should only be sealed as a last resort; when it has been finally decided that such procedure will make the mine safer, but less subject to disaster, by reason of the gaseous condition of the workings.

Pikeville, Ky.  GEORGE EDWARDS.

Maintaining Tracks in Airways

Ventilation inefficient in many mines—Airways practically neglected when tracks are drawn—Main airways blocked by falls, owing to lack of timbering.

I HAVE read many references, in Coal Age, to the insufficiency of ventilation at the working faces in mines. Almost invariably, investigation will show that the cause is neglected airways that are choked by
falls of roof which prevent the free passage of the air current.

In a few instances, no doubt, the fault will be found in long lines of brattices, many of them in bad repair and leaky stoppings on the roads, which prevent the air from reaching the working faces.

In my own experience, I have found that whenever the track is drawn from a main head or return air-course the result is that far less attention is given to the timbering of that airway; and it is not long before heavy roof falls occur, which obstruct the flow of the air and there is trouble.

SMALL FALLS OFTEN DISREGARDED

At first, these falls are small and of little consequence. But it should be remembered that they are the forerunners of larger breaks that will extend eventually several feet in height and length. Because the track has been drawn no attempt is made to clean up the falls and, for the same reason, little timber is taken into the place and set. Had the tracks been allowed to remain, the condition would be quite different and there would not be the same objection to cleaning up the airway and keeping it properly timbered.

DANGER OF REMOVING TRACK

In my judgment, the removal of track from main air-courses means their practical abandonment to the consequences just mentioned. In many instances, I have known main airways to be almost completely blocked for several hundred feet, to the extent that it was almost impossible for a man to get through them.

One can readily imagine what the effect of this condition is on the ventilation of the mine. It is a matter that needs careful consideration. In my opinion, no main air-course should be left without a track on which refuse can be hauled out and the necessary timbers taken into the mine.

Hillside, Ky.
O. KENNETT.

Inquiries
Of General Interest

Use of Carbon Monoxide Detector in Mines

Device Depends on Color Test—Absorbent Material Contained in Steel Tubes—Extra Tubes and Charge of Absorbent—Practical Tests Prove Instrument Useful

KINDLY explain the use and construction of the device known as the "Carbon Monoxide Detector," which I have heard has been used with success and is a more practical means of detecting this dangerous gas in mines, than by observing the effect of the gas on small birds and mice confined in a cage.

Safetv Inspector.

This device, as developed and manufactured by the Mine Safety Appliances Co., Pittsburgh, Pa., is illustrated in the accompanying figures. It consists of a small metallic tube or barrel A, to one end of which is screwed a headpiece B, containing two valves C, C, an inlet and an outlet valve, which control the flow of the air-charged gas in its passage through the instrument.

To the headpiece B, is attached, as shown in Fig. 1, a rubber bulb D, the compression and expansion of which first draws the air into the instrument and then forces it out through the detector tube E, which contains a highly acid substance that changes to a green color, under the action of carbon monoxide gas. The depth of the color depends on the percentage of gas present in the air passing through the tube.

As shown by the arrows in the figure, the air to be tested for gas is drawn through the metal tip or nozzle attached to the other end of the barrel A. In this barrel is contained, between two plate screens, a chemical substance that is capable of absorbing and removing from the air any gas it might contain, except carbon monoxide.

This absorbent material has been called "gasorbent." The material becomes saturated by use and must be replaced, from time to time, one extra charge being furnished with the instrument. In order to test the efficiency of the gasorbent, it is only necessary to take a fresh detector tube and make a test in the regular manner in a gas-free atmosphere. Any color appearing in the tube, after twenty squeezes of the bulb, shows the gasorbent must be replaced by a fresh charge. This is done by unscrewing the head piece B, removing the screen and pouring out the charge, refilling the barrel and replacing the screen, and head.

The detector tubes E, are made of heavy glass and filled with a specially prepared chemical solid called "holonaumite." Each end of a detector tube is sealed, by being drawn to a fine point, which is scored and easily broken off when about to make a test and before inserting the tube in place on the instrument.

When making a test with this instrument, both ends are broken off from a detector tube, which is then inserted in place on the instrument, side by side with another tube that furnishes a color scale for determining, by comparison, the percentage of gas present in the air tested.

When all is ready, squeeze the bulb ten times (Fig. 2) and compare the color produced in the detector tube, if any, with the color scale by sliding the latter along until a correspondence is reached in the color of the two tubes. The original color of the chemical is a grayish white, which changes to green, the intensity of the shade being an index of the percentage of gas present.

If no green color appears in the tube, after ten squeezes of the bulb, there is

FIG. 2. MAKING A TEST FOR GAS

less than one-tenth (0.1) of one per cent of gas in the air tested. Again, no color showing in the tube, after twenty squeezes of the bulb, indicates that there is less than five-hundredths (0.05) of one per cent of gas in the air. Should more than one-tenth per cent of gas be present, coloration of the material will result from several squeezes of the bulb.

A single detector tube will last from eight to ten tests of ten squeezes each, before being exhausted, which is determined by the color failing to fade out after a test is made. Owing to the fading of the color after a test, it is important to determine the percentage of gas quickly. The slight smoke or fumes sometimes observed coming from the end of the tube when making a test is harmless.

Rubber tubes one-eighth of an inch in diameter are supplied with the instrument, to be attached to the tip end of the barrel, for the purpose of drawing the air from some high point in the roof, if desired.

FIG. 1. LONGITUDINAL SECTION SHOWING CONSTRUCTION OF DEVICE
Examination Questions Answered

Bituminous (Pa.) Mine Foreman’s Examination Held April 11-13, 1922

(Selected Questions)

**Answer**—1. Foreman must sign reports of firebosses and assistants; make daily and weekly reports of conditions of mine and air measurements; report all accidents and fatal accidents to mine inspector; and report to the superintendent in writing any failure to remove gas from inaccessible places.

2. All working places must be examined each day by foremen or assistants.

3. Foreman or assistant to measure air at inlet, outlet, last breakthrough in last room and at face of entry, in each split, and report same once a week.

4. See that every working place is securely timbered and a plentiful supply of timber for that purpose on hand, or remove the workmen where timber is wanting.

5. Foreman must see that stoppings are built where necessary to carry the air forward to the face of the working; all stoppings on main entries and airways to be substantially built of concrete or masonry.

6. Foreman must see that accumulations of dust are kept damp, by suitable means or a sprinkling system. All dust accumulated at working faces must be loaded out of the mine.

7. Foreman must see that all dangerous places are promptly fenced off and danger signals placed to warn persons not to enter. He must see that all dangers reported are promptly removed or safeguarded.

8. The foreman is made personally responsible for all matters pertaining to ventilation and must see that a sufficient air current is kept in circulation and made to sweep all working faces throughout the mine.

9. In case of accident to fan, the foreman must remove the men from the mine and not permit them to enter again, until the mine has been examined and reported safe.

10. Foreman must attend to the drawing of all pillars in a safe manner and employ only experienced men for that purpose.

**Question**—In an entry 9 ft. wide and 53 ft. high, the anemometer reads 225 ft. per min.; what is the volume of air passing in, therefore, 49.5 x 225 = 11,137 cu. ft. per min.

(b) Show the formula by which this problem is worked.

**Answer**—(a) The sectional area of the airway is 9 x 53 = 49.5 sq. ft.; the volume of air passing is, therefore, 49.5 x 225 = 11,137 cu. ft. per min.

(b) Calling the quantity of air in circulation, Q; sectional area, a; velocity of air current, v; the required formula is \( Q = av \).

**Question**—State why, in your opinion, the pressure or water gage increases as the workings are extended, other conditions remaining the same.

**Answer**—The pressure or water gage is a measure of the mine resistance, which is determined by the extent of the rubbing surface and the velocity of the air current. As the mine is extended, the rubbing surface is increased, which increases the mine resistance and the water gage.

**Question**—(a) Name and give the symbols and specific gravities of the non-explosive gases. (b) What are their effects on life and combustion?

**Answer**—The non-explosive mine gases are carbon dioxide (CO2); specific gravity 1.529; and the nitrogen of the (N2); specific gravity 0.967.

(b) Carbon dioxide, though not a poisonous gas, has a distinctly toxic effect on the system. It is an incombustible gas that will not support life or flame, but causes death by suffocation when breathed in sufficient quantity. In less quantity, it causes headache and nausea.

Nitrogen, also, is an incombustible gas and will not support life or flame, but causes death by suffocation.

**Question**—In mine ventilation: 1. What is the minimum quantity required by law? 2. What are the advantages derived from splitting the air? 3. What is the effective limit in splitting the air current? 4. Why is it necessary to use a regulator? 5. What are the requirements of the law in regard to principal doors? 6. What does the law require in regard to checking the air current into the working places?

**Answer**—1. In non-gaseous mines, the law requires 150 cu. ft. per min.; and in gaseous mines, 200 cu. ft. per min., for each person employed and as much more as one or more of the inspectors may consider is required.

2. Splitting the air current gives a larger quantity of air circulated by the same power, at a less velocity. Each district is provided with a separate air current that isolates it more or less from other sections of the mine and the ventilation of the workings are under better control.

3. Splitting reaches the limit when the velocity is so far reduced as not to dilute, render harmless and carry away all noxious and dangerous gases.

4. A regulator is required to proportion the quantity of air to the need in each split.

5. Principal doors must be so placed that when one door is open another having the same effect on the current will remain closed. An extra door must then be provided to be used in case of necessity.

6. The law requires the mine foreman to see that cut-throughs are provided in all room and entry pillars and, in such cases with suitable stoppings, so that the air current will be made to pass through the last cut-through next to the working face.

**Question**—A siphon pipe is 4 in. in diameter and 1,000 ft. long, with a rise of 15 ft. and a fall of 23 ft. How many gallons of water will be discharged in 24 hr.?

**Answer**—Without knowing the separate lengths of the suction and discharge ends of this pipe line, it is not possible to determine if the siphon will work satisfactorily. In order to obtain the best results in siphon drainage, the diameters of the two respective parts of the siphon must be proportioned to their respective lengths and the effective head in each. However, in a general way, the flow in this pipe may be estimated from the total effective head and length, according to the following formula:

\[
G = \sqrt{\frac{800d(h_1 - h_2)}{l}}
\]

where:

- \( G \) = gallons per min.
- \( d \) = diameter in inches
- \( h_1 \) = suction head in feet
- \( h_2 \) = discharge head in feet
- \( l \) = length of pipe in feet

On this basis, the total flow in a 24-hr. day would therefore be \( 81 \times 60 \times 24 = 116,540 \) gal.

**Question**—The inlet air current of a mine has a temperature of 60 deg., and at the outlet the temperature is 65 deg., barometer 30 in. What is the difference in weight of 100 cu. ft. of air between the inlet and outlet?

**Answer**—The weight of a cubic foot of air at a temperature of 60 deg. F. bar. 30 in. is 1.2373 x 30 = 0.076575 lb.

Likewise, the weight of a cubic foot of air at a temperature of 65 deg. and the same barometer, is 1.2373 x 32 = 0.075845 lb.

Then, for 100 cu. ft. the difference in weight would be 100 (0.076575 - 0.075845) = 100 x 0.00075 = 0.073 lb.
President Harding "Invites" Operators to Return to Mine Properties and Resume Operations

BY PAUL WOOTON
Washington Correspondent of COAL Age

LATE Monday night the chief topic of speculation among coal operators was the meaning of the President's invitation to the operators "to return to your mine properties and resume operations." In the opinion of some this was taken to mean that the President intends that the production of coal must be resumed at once and the means is left to the operators to work out, but whether with a guarantee of protection is not clear.

While the President expressed disappointment at the lack of unanimity, the point was emphasized in a White House statement that all operators had subscribed broadly to the principles to which the American people are entitled.

The President's statement is Operators 385 Pennsylvania, the left the White House after his recent conference with the President, has shown the President's resume to his own properties and resume operations. But they say to you and to the American people that each and every one of them stands ready in this crisis to put his properties and his own services at your disposal and command at any instant.

When the President has received the several replies, he said:

"I have heard your decision. I would not be frank if I did not confess a disappointment in your lack of unanimity. To the large majority of you, who have pledged readiness to resume activities under the government proposal, I must express my own and the public's gratitude.

"We have now reached a point, owing to the refusal of mine workers and a minority of your operators to accept the proposed arbitration, where the good offices of the government in seeking a voluntary adjustment of the dispute between mine operators and mine workers are without avail.

"I cannot permit you to depart without reminding you that coal is a national necessity, the ample supply of which is essential likewise to common welfare and to interstate commerce.

"The freedom of action on the part of workmen and on the part of employers does not measure in importance with that of public welfare and national security. Therefore, invite you to return to your mine properties and resume operations."

After the conference, the following statement was given out at the White House:

"At five o'clock this afternoon the coal operators made extended verbal and written reports to the President. All of them subscribed broadly to the proposal to arbitrate. The majority of the districts represented in the conference accepted the President's proposal unconditionally. A minority of the districts in the conference joined in subscribing to the general principles of arbitration and collective bargaining."

Objectors to Anthracite Tax Must File Exceptions and Furnish Bond

SAMUEL S. LEWIS, Auditor General of Pennsylvania, has notified all coal companies that have not made returns or paid the anthracite coal tax to the state, pending appeals of the constitutionality of the act of 1921, that they must file specifications of objection to the tax determined to be due and furnish bond in double the amount of the tax contested and make cost provisions for the collection. The tax in question is on production for the last half of 1921, and more than $3,100,000 is due for that period, according to the records of the Auditor General's department.

After the State Supreme Court had declared the act constitutional the Auditor General informed the companies which had taken appeals from the decision of the Dauphin County court that he expected notice whether the appeals were to be withdrawn or further contested in the United States courts because of the interstate complications arising from the anthracite tax. Operators and companies not paying pending the determination of the constitutionality of the anthracite tax were told that they must pay promptly or incur the penalties provided for the non-payment of any state tax within the time limit.

In a statement by Auditor General Lewis it is shown that 161 operators have settled their tax so far. He said: "Reports have been filed by 197 operators of the 385 collieries, washeries, or operations, and accounts have been settled against 161 operators at this date. Of the concerns mentioned, eighty-five showed no production during the period referred to, or from July 1, 1921, to Dec. 31, 1921. The aggregate amount of taxes, as shown by reports of anthracite coal producers filed, is $3,164,189.02, and accounts have been settled for $2,256,778.11 of this amount, although only payments have actually been made in most cases."

Members of the Mine Inspectors' Institute of the United States, in convention at Chicago, July 11-13, missed the friendly and helpful presence of James T. Beard and re-elected him editor in chief of the Institute's proceedings.
Acrimonious Conferences of Operators Fail to Agree Unanimously to Harding Arbitration Plan

AFTER a series of conferences, described as having been the most acrimonious in the history of operators’ meetings, the representatives of the various bituminous-coal producers’ associations in unionized territory failed on Monday, July 17, to agree unanimously on the acceptance of the President’s arbitration plan. A majority report, drafted by a committee headed by H. N. Taylor, was signed by all but three of the associations. This report accepted the President’s proposal “without reservation or qualification.” The three associations which submitted dissenting replies were the Pittsburgh Coal Producers’ Association, the Indiana operators and the Central Coal Association of Pennsylvania. The text of the majority report is as follows:

“We have approached the earnest consideration of your proposal of July 10, 1922, for arbitration in the coal situation, with that degree of solemn earnestness that is due a subject that is so fraught with grave and far-reaching consequences to the whole American people that no private interests of ours can weigh in our considerations.

ACCEPT PROPOSAL WITHOUT RESERVATION

“Therefore, on behalf of the bituminous-coal operators who have been in conference with you and who represent associations producing in 1921 somewhere near 90 per cent of the bituminous coal, which was covered by collective bargaining with the United Mine Workers of America, we beg to state that we accept your proposal of July 10 without reservation and qualification. While making this unreserved acceptance we think that it is due to the public and to the industry that we should point out not only some suggestions which we believe would be helpful in the consummation of so great an undertaking but also some of our difficulties in acceptance.

“Inasmuch as the old machinery for making scales based on the Central Competitive Field has broken down, proven entirely inadequate to meet the changed economic conditions of the country, and is therefore now irretrievably abandoned, and inasmuch as the great varied technical and economic situation of the various districts makes it almost impossible for a national arbitration board to satisfy these differing situations, and inasmuch as the operators here assembled are anxious to maintain the principle of collective bargaining, we suggest that scales be made possible under a national arbitration for negotiating purposes and not taken by states or other large groupings of districts, subject to the general direction of the arbitration commission of the major issues involved. This is in the mutual interests of both operators and workers, because of the many technicalities and varied economic conditions differing in the various sections of the country.

RECENT WAGE SCALES ABOVE COUNTRY’S AVERAGE

“The wage scales expiring March 31, 1922, in the unionized industry based upon an inside day wage of $7.50 per day for mine labor, are far above the wage levels of the country. They are far above our competitors in the non-union fields. They impose a burden upon the consuming public and the whole of industry. They affect the freight rates, the costs of manufacturers, the interests of our creditors and our work people in every direction. We have no doubt that in your proposal that the miners should return to work upon this scale even temporarily, you had in mind the more essential question of immediate return to production, in order that industry should not be paralyzed, that the proper wage levels to be determined would not thus be prejudiced, and that we and the public at large could afford to make this sacrifice in your effort to secure the return of the men to work, even though it did lean entirely to the side of the miners rather than to that of equity and general public interest.

“We had thought that the scale of November, 1917, based upon $5 per day for common labor, would furnish a better medial line between the contentions of the two parties. The largest part of the non-union coal production of the country at the present moment is carried on below this level.

“We welcome an exhaustive inquiry into the functioning of the industry, as we believe any exposure of the truth of the situation will show the intolerable and wasteful conditions under which the mining is carried on under the present labor regime, and the penalties that are imposed upon the public by the inability to secure the enforcement of contracts and the thousand other ills. We suggest that it would be desirable to separate the problems of anthracite and bituminous coal. We see no objection to separating again the investigation problems from those of arbitration of the present disputes into different commissions, pending the development of some plan of stability.

“Inasmuch as the old machinery for making scales based on the Central Competitive Field has broken down, proven entirely inadequate to meet the changed economic conditions of the country, and is therefore now irretrievably abandoned, and inasmuch as the great varied technical and economic situation of the various districts makes it almost impossible for a national arbitration board to satisfy these differing situations, and inasmuch as the operators here assembled are anxious to maintain the principle of collective bargaining, we suggest that scales be made possible under a national arbitration for negotiating purposes and not taken by states or other large groupings of districts, subject to the general direction of the arbitration commission of the major issues involved. This is in the mutual interests of both operators and workers, because of the many technicalities and varied economic conditions differing in the various sections of the country.

In addition the statement was signed by the following associations: Pittsburgh Vein Operators’ Association of Ohio, Cambridge District, Fifth and Ninth District Coal Operators’ Association of Illinois, Jackson (Ohio) District, Illinois Coal Operators’ Association, Central Illinois Coal Operators’ Association, Iowa Coal Operators’ Association, Southwestern Coal Operators’ Association (Missouri, Kansas, Arkansas and Oklahoma), Oklahoma Coal Operators’ Association, Bergholz-Amsterdam District of Ohio, Montana Coal Operators’ Association, Southern Wyoming Coal Operators’ Association, Central, North, Marshall and Concho Districts of Ohio; New York coal companies’ interests in southern Ohio and Crooksville districts and some thirty individuals in various Eastern fields.

Washington, July 15.—That federal intervention in the coal strike was a great mistake is becoming increasingly evident, according to a widely held opinion in Washington. It is conceded, however, that since such a policy has been initiated there now can be no turning back. As a result of what is regarded by many as its ill-timed interference, the arbitration board is confronted with a task almost comparable in intricacy and dangerous possibilities with the Irish problem. The step having been taken, however, it is believed it would be nothing short of a public calamity were some basis of arbitration not worked out. As a consequence, it is believed that some means will be found for reaching an adjustment for the present coal year. Each side to the controversy, however, fully expects to see the government take over certain mines and operate them in the interest of those localities threatened with a shortage of fuel.

An analysis of the so-called miners’ refusal of the President’s proposition reveals that it is not a rejection of the arbitration proposal at all. The position of the policy committee of the United Mine Workers simply is to withhold their acceptance of the arbitrage, however, fully expects to see the government take over certain mines and operate them in the interest of those localities threatened with a shortage of fuel.

While it is believed that some form of arbitration is going to be brought about, no one sees how any decision can be reached that will be equitable or that can result in anything more than a truce. Arbitration, especially in view of the President’s explanatory letter, can mean little more than a Central Competitive Field agreement. More than 8,000,000 tons of annual output were not represented at the final meeting of operators when the deadlock was reported to the President. There is no way whereby the federal government can force the non-union operators to fix wage scales. It is quite apparent that operators in the Kanawha field or even in a smaller subdivision, such as the Windber district in Somerset County, Pennsylvania, are
not going to throw away large investments made in efforts to stay non-union, even if the majority of their workers have affiliated with the labor organization.

As the strike enters its sixteenth week it is evident that various events have strengthened the union position. Principal among these is the success which has attended the efforts of the railroad strikers, which has had a telling influence on the coal miners. That there is joint action between the striking miners and the striking shopmen cannot be doubted. Efforts have been concentrated on the weak spots of the coal distribution system. The movement of coal has been seriously interfered with at junction points on the Louisville & Nashville and on the Chesapeake & Ohio. The L. & N. was recognized as a weak spot and the success which attended the efforts of the shopmen to block it did not occasion great surprise, but when the better situated Norfolk & Western and the C. & O. were involved in serious difficulties before the shopmen's strike was two weeks old, it became apparent that the railroad strike is going to be a major factor in the coal strike. Students of the situation are at a loss to understand why the administration did not use its influence with the Railroad Labor Board to prevent the striking of a second crisis on the government. At the very least the railroad strike is resulting in a loss of 2,000,000 tons of coal supply just at the time that it was most needed.

The text of the reply of the Pittsburgh Coal Producers' Association, dated July 17, is as follows:

Mr. President: Your proposal for the settlement of the present bituminous-coal strike has been given most thorough and respectful analysis and consideration by the operators of the Pittsburgh district. We are very conscious of the gravity of the situation and the importance of the interest of the American public in the navigation of the waterways which can be made possible by the continued operation of the American coal industry, and we beg to say that we are not unmindful of the responsibility which is thus placed upon us, not only to our public and to the operators of the coal industry but to the American people.

We regret to say that we regard your proposition as one that will not meet the issues of the dispute or, at least, to the ultimate injury not only of the industry, miners and shopmen, but to the country as a whole.

The concession requests that we consent to arbitrate a basic wage scale for the union mines of the United States by a National Commission. We will treat it first from the economic standpoint. In the first place, we believe that you are not acquainted with the facts of the country, which are, and we believe should not be, involved in your proposition. We have not only new needs, but also new demands of our people for coal, and are able in peak times to produce 50 per cent more than the present demand. Therefore, be the function of your commission to fix a basic wage and working conditions for perhaps 50 per cent of the coal producers of the country, the privilege, from time to time, of establishing for itself such wage scale and working conditions as may best be accorded to employer and employee to meet changed economic conditions. This means that the union operator is tied to fixed standards, while the non-union operator may at any time deal with his men on a scale that suits the immediate advantage of both. The result inevitably will be to put the non-union operator in a better position. This scale will vary to give the non-union operator the business and therefore, the non-union miner will take largely the business that is left. Your plan cannot operate otherwise.

The National Wage Commission appointed by President Wilson, which had larger scope due to the war powers of the President, wage them the severest effect, and many operators in the Pittsburgh district were compelled to concede at a loss for the last year under it. We cannot conceive how we can concede out of our power to the National Commission which covers only approximately one-half of the coal industry, the very important condition of the non-union mines. The non-union miner will not be turned out of work where the union miner will take largely the business that is left. Some other solution must be found.

I propose to put the mines back to work at wages which were paid under the scale which expired March 31, 1922. This was the highest paid in the country and in the mining industry. It was to be but a temporary one, which operations were to be carried on with the aim of making the chances of getting back the higher cost of his coal in the face of an increased production. The present union scale is a sacrifice.

Is this proposal from the government fair to the non-union operator who has already liquidated his wages and who in many fields was already working at 1922 wages? Is it fair to the strikes of the United Mine Workers of America? Can he hope to keep his mines at work on the wage scales now being paid if the non-union operator may at any time deal with his men on a scale that suits the immediate future? Must the wages he offers his men be paid down to the level of the minimum which the public will require? Is it not fair to him if he pays anything that he does not pay it? If it will result otherwise than to cause dissatisfaction among his employees his wages must be increased. The public is dissatisfied with this scale and its terms are not fair. The miners have been entirely neglected. The government for the last four years has been seriously questioned in judicial proceedings, and we believe, regardless of legislative action of the Congress, the institution is so unquestionably vicious and un-American that it must be eliminated.

The check-off practice in the coal industry means more than the merely economic adjustment which has been taking place during the past years which was predicated upon a single union organization. It has become the dominating influence of the industry which is leading us to join the United Mine Workers of America and agrees to subject himself to their arbitration for the settlement of all strike orders and commands in all matters pertaining to the affairs of the union and its members.

Under this practice the operators are compelled by the United Mine Workers of America to collect for wages their due, and found and proven in many judicial records in the courts of the country, are then used by the labor organization for its own ends and purposes. All union operators have already been charged with being parties to the practice of mining and non-mining. This would include the participation in this check-off system, and the operators of the Pittsburgh Coal Producers' Association refuse voluntarily to be connected with a union organization which is so unfair and unjust.

In 1920, before the Wilson arbitration board, we earnestly asked for the elimination of the check-off system on the ground of its condemn or eliminate it. Your proposal asks us again to submit this practice to arbitration: this we cannot do. We ask you to submit this commission a bill which we have serious doubts as to whether we could be protected in the courts if you insist upon it. If your proposal is based upon it we shall refuse to eliminate it.

We come now to a consideration of the doubtful legality of making a basic wage scale for the union mines of the United
States with the check-off feature. We express no opinion as to the

It is pertinent, however, to observe that in this overdeveloped
day of our industrial life, the factors which are engan-
gaged in sharp competition in interstate commerce. The mines
in each district compete in the same market and, as a matter of

the
President Harding Interprets His Statement of July 10

To A. M. Ogle, president of the National Coal Association;

Wariner, president of the Anthracite Coal Association, and

To John L. Lewis, president of the United Mine Workers of America:

The policy committee of the United Mine Workers of America met at the Red Cross Building to adopt an answer to President Harding’s arbitration proposal. Members of the anthracite scale committee held a separate meeting earlier in the day and decided to reject the proposal. These members had participated in the general consideration of the subject.

By unanimous vote the policy committee rejected the proposal of the President, and a letter signed by the International officials and all of the district presidents of the United Mine Workers delivered to President Harding at the White House. The letter sets forth the reasons for rejection of the arbitration proposal and is as follows:

Dear Mr. President: We are in full accord with your proposal for the establishment of a commission, which, as you state, shall investigate exhaustively every phase of the coal situation and every cost of production and transportation. The President will ask Congress to confer authority for the most thorough investigation of the matter. We are appropriations necessary to do such work.

The fundamental interests of the mine workers are so directly dependent upon such action being taken. It is our belief that a thorough and impartial investigation of the entire situation is necessary.

During the past two years it has been very apparent to the mine workers that such an investigation as you now propose should be made. We have been of the opinion that every proper occasion, recommended that the work be done. When at the hearings the existing control representatives were called upon to testify before the Commission, we formally urged the creation of a commission and submitted detailed suggestions as to its composition and powers. We are, therefore, indeed gratified to accept your proposal for a comprehensive investigation of the coal mining industry by a commission representative of the mine workers, the operators and the public, and to assure you that it shall have our most earnest support.

The actual completion of the work of such a commission and the application of the findings is the practical and immediate necessity. It is, therefore, a necessity that preliminary and a necessary prerequisite, that all parties to the dispute be brought to the bar of arbitration and that the workers in the coal mining industry be brought to a just and equitable contribution toward the burden of the industry.

In my opinion, labor is only one factor in the production and distribution of coal. Labor costs are only a part of the total costs involved in the mining of coal and its transportation. The labor factors and the other cost factors are closely interrelated and independent. One factor, such as labor, cannot be condemned into a mere part of it alone. Among other things, the relation of the cost of labor to its returns and prices must be understood. Industry must also be made as to the degree of regularity of compensation of operators. At the present time, a coal miner working in the anthracite field is not receiving an adequate income for himself and his family.

By way of concrete illustration, it is stated on the basis of the facts and figures that the bituminous coal industry functions fairly and efficientluy only when the wages paid are sufficient to determine to approximmately $1 per ton on each ton of coal produced and that the industry is doomed to be unprofitable if the industry is not paid a just wage.

On the question of the cartel, it has long been evident that a close relationship has existed between the parties in the anthracite field. The President brings to the public the facts which indicate that the anthracite industry is the responsibility of the public.

We will not enter into the discussion of the facts which indicate that the anthracite industry is the responsibility of the public. It is the public interest that this question be decided without further delay.

By way of conclusion, we are of the opinion that the President’s proposal is practical and just.

July 20, 1923.

C O A L A G E

103

The coal miners have brought to the public the facts which indicate that the anthracite industry is the responsibility of the public.

By way of conclusion, we are of the opinion that the President’s proposal is practical and just.

July 20, 1923.
matter of heated and bitter controversy. The primary duty of the committee of real service, must be to collect the facts and give consideration to broad matters of principle. It would involve the recognition of a huge industry, which in itself is a prodigious undertaking.

In the face of this tremendously important issue, no wage questions should be injected.

We believe that there will be no difficulty in securing union agreement through conferences with the operators if the facts and conditions be correctly set forth on a proper basis, and that therefore, if the commission is successful in establishing proper conditions and principles of operation, and that the industry, the fixing of detailed wage scales can properly be left to the usual conferences.

The mine workers desire to point out that no such discussions have been in attendance at the recent conferences as a result of which the tentative plan of settlement for the quarter strikethroughs with the operators that these interests be represented on a basis which would in the future be submitted to them by any governmental agency. We are further advised and pray that a tender of participation in the conference be given, that these interests have not in the past been represented, that it be given at the earliest possible date.

On this plan of settlement we believe that any general settlement can be reached. It is manifestly unfair to attempt to reach a settlement which is fair and just to the operators and representatives of the contributing interests, employing hundreds of thousands of men directly and indirectly, and be free to their own selfish impulses and escape responsibility in the premises. We feel assured that your Excellence transmitted this plan of settlement with the without reservation that the strike could be adjusted upon a basis of national scope. We find upon examination and analysis, without qualifications. It is evident that the acceptance of the provision of the law, by the basis of compensation, stating only after the settlement, leaving the public to be embarrassed and industry to be jeopardized. With the present strike situation in areas coal producing areas and under these circumstances, lightly consider the utter abandonment of more than $200,000 of the provisions of the wages and working conditions, of hostile employing interests who are public representatives of the companies involved in the production of collective bargaining in the industry.

For these reasons, you are respectfully urged by the representatives of the United Mine Workers to compel their reception of acceptance of the settlement proposal submitted by you.

The mine workers are alive to the necessity of immediate resumption of coal mining operations. Already, and with no indication of a serious coal shortage next fall and winter. Industry and the public is now facing the problem of price extensions before the coal requirements are fully met. There is every moral and economic reason for the prompt resumption of the present strike in the mining industry, and the public will be demanding an immediate and fair settlement at the earliest possible date.

The development of this emergency has been constructive of an issue since last April, and we have repeatedly warned the operators and laboring interests, the futility of its approach. It would have been obviated if the operators and laboring interests had fully understood the contract obligations and made it in the usual way to adjust wage and working conditions, in the end to escape the legal and practical burden of the present strike. The only thing that will cure this situation is the early and effective way, at the present time, to escape the futility of the current strike. For these reasons, we believe the settlement proposal to be repudiated and the settlement returns in favor of the settlement proposal.

We feel confident that your attitude will command itself to your sense of right and justice and that its issue will be a reason and wisdom of all thoughtful men who love justice and humanity.

Anthracticee Operators Express Sympathy with Proposed Plan of Settlement

Dear Mr. President: On behalf of the anthracite operators and workers, we are pleased to make the following reply to the proposal of arbitration submitted to us on June 31.

We are deeply appreciative of your effort to end the present suspension of anthracite operations. It is fair to all concerned. After conferences with the representatives of the operators and workers from March 15 to June 2, it appears no agreement satisfactory to both sides could be reached.

The operators then proposed that the "Practical Mining Plan" be submitted to a commission or tribunal to arrive at a settlement. The plan was to determine the questions concerning wages and working conditions of the men. We were unable to find a practical method by which prompt operators and workers in conference to determine these questions. An added difficulty is the fact that the plan would extend to the temporary wage scale.

We are, therefore, committed to arbitration, and are entirely in sympathy with the prompt action which you have proposed.

And, under other conditions, that certain modifications of your proposal are desirable. The anthracite operators are willing that the settlement shall be speeded up and be binding upon both sides of the country.

We are, therefore, committed to arbitration, and are entirely in sympathy with the prompt action which you have proposed.

And, under other conditions, that certain modifications of your proposal are desirable. The anthracite operators are willing that the settlement shall be speeded up and be binding upon both sides of the country.

Throughout the fruitless negotiations which have occurred, the operators and workers, the anthracite operators have had two proposals in view. First—An agreement on a scale wage scale, such that adequate should be at the same time be given by the operators to the anthracite mine workers have in the past and which would be willing to settle the conditions for the product can assure. It has been the position of the anthracite operators that this is economically necessary operating anthracite, in line with adjustments which have been made with respect to other commodities.

Second—That any agreement reached should be durable for a long time and provide reasonable means of wage adjustment, in the light of changing economic conditions of the country. The operators are willing to make such a provision in the contract, the only condition is that it be effective, at the present time, to escape the futility of the current strike. For these reasons, we believe the settlement proposal to be repudiated and the settlement returns in favor of the settlement proposal.

We feel confident that your attitude will command itself to your sense of right and justice and that its issue will be a reason and wisdom of all thoughtful men who love justice and humanity.

In the anthracite situation we again emphasize that the operators recognize the principle of the eight-hour day for all men in the industry, the union, and the that the existing rates of pay. If we are aiming for a starting point for future joint negotiation and the establishment of the additional demands of the anthracite workers, we believe the settlement proposal will so simplify matters that a basis of agreement may be easily reached. In the anthracite industry the human factor in the coal industry and human con-
Fifteenth Week of the Coal Strike

EDITORIAL REVIEW

T
e principal developments in the fifteenth week of
the strike were the fruitless effort of the President
to get the operators and miners together on a
voluntary basis of settlement, and the curtailment of pro-
duction from non-union fields and from western Kentucky
caused by the strike on the railroads. Opinion is divided
as to whether the real crisis in the coal strike has been
passed, with a majority feeling that it is yet to come.
Much depends on the stand the President takes, now
that the situation created by his proposal of July 10 has
been wiped off the slate. Beyond doubt the next week will
see some turn in affairs that will point the way out.

Six Killed and Many Wounded in Attack
On Non-Union Mine in West Virginia

H. DUVAL, Sheriff of Brooke County, W. Va., and
five other men, said to have been union coal miners,
were killed Monday, July 17, at Cliftonville, W. Va., and
more than two dozen men were wounded when an armed
band of about 300 men made an attack on the tipples of
the Richland Mining Co.'s Clifton mine. After a battle lasting
an hour and a half, in which thousands of shots from
revolvers and rifles were exchanged, the attackers were
driven off and more than forty prisoners were captured
and placed in the county jail.

Production in Connellsville Region Takes
Rebound Following Holiday Slump

W
ith the passing of the July 4th holiday output in the
Connellsville coke region is on the rebound. The
H. C. Frick Coke Co. is gaining at practically all its op-
erating mines, especially at the Trotter plant, which is
working about 50 per cent of normal, most of the men
working there being old men who have returned to work.
The Hillman Coal & Coke Co. is gaining all along the line
also, shipping two or three cars of coal a day from nearly
all of its plants and a car a day of coke from Crystal plant.
W. J. Rainey, Inc., the American Coke Corporation,
the American Manganese Co. and the Connellsville Central Coke
Co. continue to improve slightly. Other operating com-
panies are holding their own or gaining.
Railroad coal shipments from the region are about 25
percent higher than a week ago and coke shipments about
the same. The Southwest branch of the Pennsylvania R.R.
and the Monongahela R.R. handled more coal July 11 than
at any time since the strike started. The former hauled
359 cars of coal that day and the latter 255 cars, and
shipments on the 12th were probably larger. The condition of
the Baltimore & Ohio R.R., due to the railroad strike, has
somewhat hampered operators who are entirely dependent
on that road for the dispositions of their product. That
condition, however, is improving.

Union Heads "Pass Up" Pittsburgh Parley;
Operators Discuss District Settlement

A
n unexpected conference between Pennsylvania Com-
missioner of Labor Connelly, coal operators, and heads of
District No. 2, District No. 5, and the United Mine
Workers in Pittsburgh on Thursday, July 6, did not ma-
teralize, at least as far as the United Mine Workers were
concerned. The meeting was attended by ten representa-
tives of the Pittsburgh Coal Producers' Association, nine
from the Bituminous Coal Operators of Central Pennsyl-
svania and twelve from the Central Coal Association. None
of the United Mine Workers heads attended. The meeting
resolved itself into a discussion of the coal-strike situation
with special reference to the feasibility and desirability of
settlement of the strike by districts.
Mr. Rose for the Pittsburgh, Mr. Clark for the Clearfield
and Charles O'Neil for the Central, separately presented
the following to Commissioner Connelly: "That it is to the
interest of the operators, the miners and the public that a
wage scale and working conditions be negotiated between
operators and the miners in each district, and that the
mining of coal is a state matter in accordance with a recent
decision of Chief Justice Taft."

The operators also made it known that they are opposed
to the check-off system as being unlawful in Pennsylvania
and it is evident that they will not consider an agreement
with the miners that would involve a continuance of the
check-off system.

The central Pennsylvania operators laid great stress on
the fact that they had a contract with the U. M. W. of District
No. 2, guaranteed by the officers of the national organiza-
tion, providing that in the event of a new scale agree-
ment not having been signed on or before March 31, 1922,
the U. M. W. of District No. 2 would continue to work for
thirty days under the wages and conditions of the agree-
ment then in effect.

Middle West Ready to Go Back to Work;
Price Level Is Subject of Speculation

H
arassee beyond measure by the strike situation as
it has been developing of late, the Midwest region sent
its operators' representatives back to Washington Saturday
to accede on Monday to President Harding's plan to resume
negotiating operations at once at last winter's wages. The
operators of Illinois and part of Indiana met in Chicago
Saturday forenoon and discussed the situation, deciding
that it is necessary to line up with the President.
It will be with mixed feelings of relief and deep concern
that the great mining region above the Ohio goes back to
work at union wages—if it does. Most operators are
anxious to produce coal with the market in its present
state of high absorbtion, but they are morally certain that if
the President's commission works out a new and lower
scale of wages there will be another strike—probably in
the middle of the winter, when the country will need fuel
more keenly than ever, thus giving the miners the buoyant
feeling that they have the world by the tail. It is generally
felt among operators that prices will remain high enough
to all winter to permit operation at a profit even with wages
at the new level.

One great question of the immediate future is: "What if operations are resumed; the railroads will be unable to haul
enough coal to supply more than half the country's demand, with the result that most mines will get very little running time." This means, without doubt, that coal prices are going to stay in the clouds. A series of questions to
operators on the probable price at which they will start their
sale elicits a few vague replies. Some set the figure for southern Illinois coal as low as $3.65. Others declare they must recoup the losses occasioned by the shut-
down and the attendant expense of building up their or-
ganizations again after resumption. These mention $4.50
and $5. Others are for getting all the market will stand.
They boldly declare the country needs coal so badly and
will be able to satisfy so little of its demand that Illinois
coal and the market elicits a few vague replies. Some set
the figure for southern Illinois coal as low as $3.65. Others declare they must recoup the losses occasioned by the shut-
down and the attendant expense of building up their or-
ganizations again after resumption. These mention $4.50

operating head of the company, said. Last week the company ordered its union engineers back to work at the union scale of wages, so that the gigantic Zeigler mines could devote the next few days to getting ready for work. The engineers demanded full pay for every day they have been off since April 1 or they wouldn’t work.

“Naturally we refused,” said Mr. Zoller. “That little item would have amounted to several thousand dollars.” So the company is doing nothing to get ready beyond keeping up the operation of pumps and the like. Quiet has reigned generally over the Illinois and Indiana fields except for threats against Indiana wagon mines by masked gangs of visitors. In one southern Illinois town the miners’ local got together and voted to remain on strike. This is open to various interpretations, one of which is that miners opposed to the policies of Frank Farrington, state president of the possible developments at Washington might open a way for Farrington to negotiate for a state settlement in Illinois, and they merely wished to speak their little piece against such a deal.

“There’s no possibility of Farrington making a separate deal,” states a well-informed Illinois operator. “He has been doing a lot of talking about it for a long time, but he knows better than to try it. He knows he couldn’t deliver, and he’s afraid of a test of strength on that issue.”

Kentucky Has Severe Railroad Handicap But Hopes to Produce Heavily Soon

For ten days or more the Harlan, Straight Creek and Fellico fields of southeastern Kentucky have been shut off as a result of a eight strike of railroad workers at Corbin, Ky., which has tied up movement of freight trains on the three divisions of the Louisville & Nashville in that section. The strikers at Corbin have intimidated the merchants, who have refused to sell food to strike breakers, and boarding houses have refused to harbor them, while the authorities have ordered imported workers to leave town when sent to Corbin or within railroad property. However, 150 men were sent to the Corbin shops on July 12 and the railroad is establishing a tent colony and commissary to take care of them. Corbin is in the mountain district, a lawless section, and difficult to handle.

Other sections of the state are not having much trouble as a result of the rail strike, and tonnage is moving freely. Hazard has had a fair supply of men, but the Chesapeake & Ohio, in eastern Kentucky, has been along giving good service. Western Kentucky also reports fair service. If the Corbin trouble is settled much heavier production will result.

Is the State of Illinois in Earnest, or Is Herrin Probe “Merely a Gesture”?

ATTORNEY-GENERAL Edward J. Brundage of the State of Illinois has made two moves giving the impression that Illinois is going to delve into the Herrin murders and prosecute the men guilty of the slaughter of a score of non-union strip miners and guards June 22. Early last week he publicly offered $1,000 “for information leading to the conviction of persons who committed murder and assault” in Williamson County on the day which the county openly exulted in having made “bloody.” Later in the week he spent two days in the county and came away declaring he had some information of value which would not be revealed now but would be used to obtain further information. He said that no action would be taken before the present session of the Williamson County Grand Jury, but he indicated the state would have its case ready for the next session, which convenes in September.

“Just a gesture” was the comment of one of the best known Illinois coal operators who has a mine in southern Illinois. “Nothing much will ever come of it. The state has no intention of going to the bottom of this thing. It only wants to go through a few less idle motions to calm the general demand that the bloody-handed gang down there be punished.”

Visitations of Coal “Ku Klux Klans” Scare Indiana Workmen from Wagon Mines

MAKED men have been making flying visits to Indiana mines warning workers there to quit and not come back if they wish to retain their good health and chances of longevity. Late last week 25 such mysterious visitors dropped in for a pleasant call at Dr. Sample’s wagon mine near Booneville, held up two men in charge, gave the warning against operation, damaged the machinery and departed. The owner has appealed to both county officials and Governor McCrory for protection. A bigger gang visited Lunenburg’s mine near the same town and ordered work there to stop.

Sees Calm in Utah a Prelude to Storm

NATIONAL GUARD rules regarding the recruiting of men to take the place of Utah mine strikers have not been strictly adhered to during the past week. There is, however, no campaign by the operators for strike breakers, as the strike leaders are opposing loudly against the action of the authorities in allowing the companies to send the few men that have been permitted to work. All is quiet but there are indications that would seem to point to another storm.

Some of the newspapers are outspoken in their disapproval of the Governor’s policy of forbidding the operators a free hand in recruiting workers to replace the strikers. One editorial asks: “Is Carbon County a Part of the State of Utah or Is It a South European Dependency?” This question was prompted by the fact that a large proportion of the men out are Greeks, Italians or other foreigners, a large number of them unnaturalized. It is believed that these attacks will compel the Executive to allow the companies to send as many men as the coal fields as they can get, and if this is done there is bound to be bloodshed.

West Virginia Mines Beat Records, Though Half Were Union at Inception of Strike

Since the coal strike was declared, on April 1, West Virginia has taken the lead in the production of soft coal, as previous production records in many fields have been broken, notwithstanding the fact that about half the mines of the state were in the union category at the outset of the strike. All this is pointed out in a statement issued by the West Virginia Coal Association, in which it is said:

“Since the strike was called the coal-mining regions of the state wherein the men were hampere by union restrictions began producing coal in a manner that surprised the buying public and astounded union officials, who had counted on endangering, according to their own statements, the nation’s fuel supply to such an extent that the government would be forced to step in.

“The Logan district, which before the strike called produced about 50,000 tons daily, now produces about 65,000 tons daily; during some weeks the output is 100,000 tons more than before the strike. The Pocahontas field, which had a normal weekly production of 360,000 tons before the strike, produced 455,000 tons last week. Tug River district, which had a normal weekly average of 90,000 tons, shipped 111,000 tons a week ago. The Kenova-Thacker district, which before the strike loaded 108,000 tons a week, now ships well above the 200,000-ton mark each week.”

Issuance of Injunctions in northern West Virginia became more frequent during the latter part of June and the first part of July owing to the difficulty operators in some instances have experienced in keeping their mines running in the face of organized interference. Among the companies which have recently obtained an injunction is the D. T. S. Coal Co., this injunction being against Louis Carpiel and other members of the United Mine Workers. It was granted by Judge W. S. Meredith, of the Marion County Circuit Court, and enjoins Carpiel and other officials of the United Mine Workers from interfering or attempting to interfere with the mining, shipping and selling of coal at the Thorn No. 1 mine in the Salt Lick Run section.
Production and the Market

Weekly Review

The long-heralded coal shortage seems to have arrived. An embarrassing lack of production, caused by the mine strike, has been increased by the railroad shopmen's strike. Normal transportation of freight has been impossible, mines which have been running have been forced to curtail operations and the slow movement all around has brought car shortage to the fore.

The coal market has reacted strongly to the combination which has limited much-needed tonnage. A general scramble for coal has resulted, in which Mr. Hoover's price list has been definitely outdistanced in the bidder's market which exists today. Large consumers are the most active purchasers, snapping up every available load on wheels. The steel industry is threatened with partial reduction of operation by the inadequate supply; railroads are insistent that a large share of the mine tonnage be turned over to them and shipping on the Great Lakes is menaced by the lack of vessel fuel.

Spot-Price Index Rises Twenty Points

Coal Age Index of spot bituminous prices reached 321 on July 17, an increase of 20 points when compared with July 10. This week's index figure represents an average price at the mine of $3.89, as compared with $3.64 a week ago.

Western Kentucky coal was the mainstay of the Middle West last week and prices were not long in reflecting the strong demand. At this writing western Kentucky is being quoted around $6.25, a full dollar over the last quotation carried on these pages, with every indication that it will go still higher. Eastern Kentucky operations were curtailed by rail troubles, as were West Virginia loadings, while western Kentucky mines were affected to a much lesser degree.

The market around Chicago continues to be the strongest of any section. Rail congestion has so delayed regular contract shipments that large consumers are buying car numbers on the spot market. Railroad supplies are on the verge of exhaustion and large consumers are forced to buy currently, as their reserves have declined below the danger mark. The same market conditions appear to be moving eastward—Cleveland and Cincinnati are hungry for coal, while the dwindling tonnage at the Hampton Roads piers and the meager all-rail receipts from Pennsylvania are being felt with increasing force in New England and the North Atlantic section.

The Northwest is on the verge of a critical fuel situation. Receipts by Lake have been pitifully low. Dock stocks at the Head of the Lakes are now around 1,500,000 net tons, as compared with 4,842,000 tons at this time last year. The railroads own 600,000 tons of the present dock stocks, 409,000 is under contract or owned by industrials, and the small balance is being doled out to old customers only under the most careful restrictions.

Retail dealers continue to ration their remaining supplies of anthracite. Consumers are placing more orders but are not at all insistent about early deliveries. Most of these orders are being filed for attention when coal is again available.

Fresh labor outbreaks have occurred in the Connellsville region following the Washington conference and production of coke has been affected. Demand for coke has increased, but the amount offering is too slight to induce blast furnaces to resume until conditions improve.

**BITUMINOUS**

“...a new cause has arisen to limit the production of coal,” says the Geological Survey, “namely: local congestion of traffic associated with the strike of the railway shopmen. Because of the uncertainties of the situation it is difficult to forecast production for last week (July 10-15), but the record of the first four days suggests that the output of bituminous coal can hardly exceed 4,200,000 tons. Production of anthracite continues practically zero. Final returns on the week of Independence Day, the fourteenth of the strike, show that 3,936,000 net tons of soft coal were produced.

“The trend of production in the fifteenth week of the strike (July 15-20) may be gaged from the following table of cars of coal loaded daily. Monday’s loadings (14,952 cars) were lower than those of Monday in other recent weeks, yet on Tuesday loading dropped to 12,829 cars, and on Thursday they fell to 11,594, the lowest on any Thursday since mid-April.

“The cause of the decrease was congestion of traffic resulting indirectly from the shopmen’s strike. The first districts to be affected were Logan and eastern Kentucky, but in western Kentucky and southwestern Virginia also loadings soon began to decrease, and by Wednesday even the Pocahontas, Tug River and Kenova-Thacker districts were producing far below normal.”

An additional lot of British coal was received in New England last week and it is understood that several charters for the shipment of Welsh coal to this country have just been closed. Should the present transportation difficulties continue, cargoes of British coal will be a common sight in North Atlantic harbors.

Hampton Roads dumpings for all accounts were 435,674 net tons during the week ended July 13, as compared with

**COAL AGE** Vol. 22, No. 3

Coal Age Index 521, Week of July 17, 1922. Average spot price for same time period 93.89. This diagram shows the relative, not the actual prices on fourteen coals, representative of nearly 90 per cent of the total output of the United States, weighted in accordance with first with respect to the proportions each of slack, prepared and run-of-mine normally shipped and second with respect to the tonnage each normally produced. The average thus obtained was compared with the average for the twelve months ended July 1914, as 100, after the manner adopted in the report of "Prices of Coal and Coke, 1915-1917," published by the Geological Survey and the War Industries Board. (Pittsburgh District, Illinois, Indiana and eastern Ohio prices not included in figures for last week.)

* bituminous coal dumped at Hampton Roads by weeks

*Imports, f. o. b., Hampton Roads.

*Indicates not available.
338,600 tons in the week previous. The heavier dumpings have reduced the pier accumulations materially, as car movement from the mines has been hard hit by the rail shippers' strike. The movement from the Southern fields was so heavy that it had taxed transportation facilities to the utmost, and with local labor troubles the railroads could not be counted on for a continuation of the heavy volume of coal freight.

New England buyers have awakened, at least in part, to the advisability of making some additional commitments. The increase is not heavy but is particularly noticeable coming just at the time when the easy movement to Hampton Roads has been interrupted. All-rail shipments were 481 cars during the week ended July 8, as compared with 642 cars in the preceding week. The light movement is confined almost entirely to railroad contracts.

Lake dumpings were 150,655 net tons during the week ended July 17—153,516 tons cargo and 6,139 tons vessel fuel—as compared with 252,105 tons in the previous week. Nearly 900,000 tons of this season's dumpings to date have gone to new destinations on Lake Erie and the Head of the Lakes apparently faces a distressing shortage of fuel next winter. Total Lake tonnage handled this year now stands at 4,233,772; in 1921 it was 11,907,210.

COKE

Beehive coke production during the week ended July 8—92,000 net tons—felt the effect of the Independence Day holiday. The labor situation in the Connellsville region was not so satisfactory last week. Demand is exceedingly strong but is mostly from foundries and miscellaneous users, as the available spot tonnage is too slight and costly to interest blast furnaces.

June production of beehive coke was 458,000 net tons; byproduct, 2,580,000, a total of 3,038,000 tons, as compared with 2,969,000 tons in May. This output consumed 4,429,000 tons of coal; 3,707,000 tons in byproduct ovens and 722,000 tons in beehive ovens.

ANTHRACITE

Production of hard coal, which is confined to river barley, was 23,000 net tons during the week ended July 8. Shipment continue to go forward from the storage yards, being 4,101 cars during the week. Aside from pea coal, there is very little free tonnage to be had.

New England stocks of hard coal have dwindled to 315,927 net tons as of July 1. On April 1 these were 726,011 tons. Since then there have been receipts of 425,920 tons and deliveries of 295,049 tons.
British Wage Question Nears Crisis

British production during the week ended July 1 was 4,550,000 gross tons, according to a cable to Coal Age, as compared with 4,354,000 tons in the previous week. The South Wales export market is unimproved and entry is softer. Rail freights have been reduced, those applying on coal by 15 per cent, and this may have a stimulating effect on the trade.

The audit of the colliery books for the month of April showed that there would be practically no profits for the industry as a whole, and that consequently wages would not rise above the minimum anywhere. It was apparent that wages would continue at the minimum throughout August and much dissatisfaction arose among the miners.

The president of the South Wales Miners' Federation, addressing the annual conference said the executive thought it quite impossible that the men could continue another six months under the conditions which had prevailed so long. It had agreed to recommend that the national executive be urged immediately to approach the coal-owners and endeavor to induce them to increase wages to not less than 60 per cent above pre-war wages, and if they failed to then meet the government and make it clear that it was quite impossible to expect miners to continue any longer under the present wage system.

A decision has been arrived at by the Nottinghamshire Miners' Association in favor of terminating the National Agreement.

French Coal Prices Slightly Lower

The French market was rather inactive during the last days of June, purchasers of industrial coal having postponed their orders pending the issue of the new price-list, effective from the 1st.

The new prices show but slight modifications—a few francs at the most—on the old schedule.

The French Minister of Public Works and Labor had a second conference with the miners' delegates, to whom they gave, at their request, more details on the cost prices of the collieries. On the other hand, the miners' delegates declared that the Eight Hour Act could not, in their opinion, be held responsible for the considerable decrease in individual output, which they ascribe to other causes.

The ministers then asked the delegates to state exactly by writing what are these other causes.

Tons on hand: 12,000,000
Tons dumped: 9,000,000
Tonnage waiting: 25,000,000

Ruhr Mine Strike is Averted

An agreement was reached on the eve of a general strike of coal miners in the Ruhr Valley after a conference between the Minister of Labor and the miners' leaders and mine owners. This, however, will require final ratification by the miners' district convention before it becomes effective.

The Ruhr coal output, including that of the collieries left of the Rhine, in May amounted to 8,081,951 metric tons (7,512,646 tons in April), or 310,844 tons (326,617 tons) per working day. In the same period, 2,075,235 tons (2,032,679 tons) of coke and 208,964 tons 302,657 metric tons of briquets were produced.

The price of unwashed coal has been raised to 1,205 m. per ton. In June, 2,000,000 tons of English coal were imported. Unless the Reparations Commission grants an added period of grace to enable her to catch up in coal deliveries, Germany will be obliged to make heavy purchases of English coal for distribution among the Allied States. The Cabinet discussed the situation in the course of a special council meeting at which it was admitted that Germany is heavily in arrears in her deliveries.

Production of coal in the Ruhr district during the week ended July 1 was 1,920,000 metric tons, according to a cable to Coal Age.

Rail Strike Cuts Supply at Roads

The strike of railway employees has spread to the clerks of the N. & W., and C. & O., with the result that the movement of coal from the mines to piers, impeded when the shopmen went out July 1, is being more seriously held up.

Less than 200,000 tons was on hand at the local piers at the end of the week, and the N. & W. notified shippers it will accept coal only for indefinite delivery.

The coal trade is in a state of mild activity with prospects of further unsettled conditions next week. Prices quoted at the local piers went up to $6.50 & @ for all grades, no distinction being made between them.

Coal Paragraphs from Foreign Lands

ITALY—The price of Cardiff steam first is now quoted at 36s. 6d., according to a cable to Coal Age.

BELGIUM—The c.i.f. contracts are being put into stock and only the classified descriptions continue to be sold in proportion to the production, the greater part going to France and Holland. The industrial market seems to be working at a slightly better half-tone. Half-burned and steaming coal is in demand, in particular slack for making briquets.

Note: The quotations are based on the assumption that the coal is shipped in heavy type of coal carloads in bulk.
North Atlantic

Stronger Demand, as Usual, Follows Curtailed Receipts

Shortage Conditions Prevail, with Less Than 500 Cars at N.Y. Piers on Monday—Rail Trouble Hits Flow of Southern Tonnage—Carriers Take Large Share of Pennsylvania Fuel Mined.

SHORTAGE conditions have followed the curtailed receipts which have prevailed for the last ten days. On Monday there were less than 500 cars at the New York piers, while the flow of Southern coals via Hampton Roads was reduced by the transportation disability caused by the railroad labor trouble. So far, the Pennsylvania mines have been given a good car supply, but the carriers have insisted on a large share of the loadings to meet their requirements.

Coincident with the reduced movement of coal has come a stronger demand, as reserves have been depleted to a point where replenishments are imperative. Prices have advanced, especially on liner business and if the scarcity continues price will be no object.

NEW YORK

Coal is becoming scarcer here. There were less than 500 cars at the loading piers on July 14 and most of it was Pool 11 or poorer quality. The line trade was strong although spotty, and quotations were higher than on the Tidewater basis.

It is reported that plenty of empty cars are at the various railroad distributing points but that the companies refuse to put them in at the mines unless assured they would secure a large percentage of the tonnage loaded.

Buyers are buying "coal" in most instances, ignoring the pool number. The poorer grades of low-volatile coals were quoted $4.25,$4.25 f.o.b. mines and the better grades $4.50.$5. High-grade gas screened coals were scarce but were held at around $5. B. R. & F. coals were quoted $4.25,$4.50.

Southern coal was being brought here in large tonnages, most of it on consignments. Free lots of these coals were quoted $8.80.$8.50. The number of loaded boats in the harbor is being steadily reduced, quotations ranging $7.40.$7.80.

PHILADELPHIA

Users of fuel are more anxious recently, especially those who have had coal on the run for some time and are finding delivery retarded. Inquiries have increased greatly during the last few days but with hardly enough coal available to meet the spot demand. The railroad situation is such that even when orders are placed no one would give any kind of assurance of time of delivery. In this respect shipments originating on the B. & O. have been particularly hard hit, and as a result gas coals for Fairmont district are difficult to purchase.

There is much dissatisfaction among the operators over the suggested plan for reclamation and there is much adverse comment heard. This feeling has been communicated to the consumer and has in itself added much urgency for more coal. The chief objections to the President's tender are from union mine owners, who say if they accept they will be at a distinct disadvantage, because the mines in non-union territory, working at the lower wage schedule, will be able to produce coal at a much lower cost and will practically have the entire market to themselves.

Prices have stiffened considerably and very little talk is heard now about an agreed price for this State. High-grade coals remain extremely difficult to procure.

CENTRAL PENNSYLVANIA

The daily output is now averaging 600 cars. Production was somewhat curtailed by the July 4 holiday and the organization of the miners at Colver, where the Davis Coal Co. had been in full operation until last week. United Mine Workers were successful in forming a local union at Colver on July 9, and called out a majority of the miners.

Prices are slightly higher. Pool 1 is ranging $4.25,$4.75; Pool 10, $4.25,$4.50, and Pool 11, $4.40.$4.25.

There is no enthusiasm among operators in this field over the President's proposal. They express the thought that if accepted, it will be only because of a sense of duty. Operators generally think the plan would only continue the high prices.

BALTIMORE

With the stocks of the larger industries here at last depreciating at a rate that has caused alarm, there has developed a rush of buying which has quickly wiped out the available coal away. At present it is not a question of price, although the advance is not marked as compared with a week ago. Even barge coals, which are almost wiped out, when available at all are under $7.30 at the piers. The major of general cargo vessels loading here are now going to Hampton Roads for barge coals.

There is practically no Pennsylvania line coal offering at this point, all-rail and blue, easy for the collieries to transport, mines when such coals are offered. Even B. & O. coals which have been in better supply since the start of the coal strike have fallen much in grades in difference in grade quotations, as had been the case for some time.

Shipments of Pocohantas and New River continue to be received from Hampton Roads by barge. Total receipts under this method have probably been close to 100,000 tons during the past six or eight weeks. While the move for a new tariff on New River coal has been averted, shipments direct from mines to Baltimore and all-rail, no considerable movement has taken place in this direction as yet.

UPPER POTOMAC

The Davis Coal & Coke Co., having secured an injunction to restrain strikers from interfering with the operation of its plants at Thomas and Henry, this company has made preparations to resume operations. Field conditions approached those nearer normal, with many of the plants in operation, some of them on a normal basis. Shipments were not affected by the striking of some employees such as the Western Maryland has had a force of strike breakers at work for some time.

FAIRMONT

Reduced operations before and after the July 4 holiday tended to lower the output. Train service was not as smooth as it had been before July 1. More coal was being sought by industries, the demand exceeding the supply. Prices were well above maximum, particularly on mine run.

South

BIRMINGHAM

While the steam demand is not quite as strong from outside territory, industrial coal goods originating from foreign and local consumers are sufficient to move all the free coal obtainable. Industries in Arkansas, Mississippi, Louisiana and Georgia bought a good deal of coal in the aggregate, nearly all business, both railroad and industrial fuel, being for prompt shipment. Quotations range from $2.25 to $2.50 per ton.

Domestic coal is moving fairly well, slightly better demand being reported for Carbon Hill grades and other medium qualities, the better grades being well sold up for several months ahead. As a rule sales were made on basis of the July schedule as given last week.

Production is holding up well, although interfered with to some extent by car and labor shortage and inability on the part of the railroads to give prompt service. Production for the week of July 1 was 360,000 net tons, as reported to the Alabama Mining Institute. Preparations are being made to start several new furnaces in the district, which will necessitate increased production in this direction.

VIRGINIA

Production continues in an upward direction, insofar as quantity and the car loadings are concerned. With coal in strong demand, little effort is being made to increase the coke output, which is now averaging about 280,000 tons a month. There are few idle mines in this territory. Prices are stronger as the result of a better demand, the steam market being especially active.
Wholesale Orders Flow In; Householder Still Apathetic

WHOLESALE dealings are confined to pea coal and river barley. With so much being heard of the strike situation in Washington, there are many orders flowing in, as the feeling prevails that mining may be resumed before long. This attitude of placing "applications" is shared, but to a lesser degree, by the retail consumer.

Some of the late business is attributable to the effect of the rail strike upon the buyer. However, the old attitude of the householder has been jarred but little from the indifference he has shown all summer. Retail stocks are being watched more jealously than ever and unless there is urgent need for the coal, retailers are not making deliveries.

NEW YORK
Dealing in anthracite is confined almost wholly to pea and river barley. The other coals have nearly all disappeared from wholesale market. Retail dealers outside of Manhattan and Brooklyn have fair stocks of all sizes while most of the dealers in the two boroughs mentioned are entirely out of the larger sizes.

Those in short supply are deeply interested in the outcome of President Harding's conference to the operators and miners. They realize now that there is bound to be a scarcity of coal this fall and winter and that they will be forced to take in their needs piece-meal.

Storage piles of pea coal are rapidly disappearing, and in Pittston, the heart of the anthracite fields, it is being sold for $8.50 per ton, as compared with $7.40 previously to the suspension. Some independent pea was reported as being quoted here at $8.75 f.o.b. mine, during the past week.

There was some river barley quoted during the week $2.50, and it was also reported that an offer of silt at $2.10 f.o.b. place of loading had been made to local dealers.

BALTIMORE
The principal feature of the market at present is that consumers are now growing restive and are calling up their retail supply connections in an effort to assure deliveries. The fact that a number of dealers are telling their customers that they can give no assurance of supplies, even when cold weather arrives, is causing a stir. The sudden turn of interest of the public was undoubtedly the result of the rail strike of shopmen and its complications.

ANTHRACITE FIELDS
The main topic of conversation in the region is the President's endeavor to secure a resumption of mining.

There is a feeling among the men that they will soon be at work again. Recently it was reported that the railroads were distributing empties, which the miners take as a sign of early resumption. There was no disorder in the region last week.

PHILADELPHIA
Retailers are quite confident that the resumption of mining is not far off, although it cannot be and their feeling of confidence is shared to the same degree by the producing end of the trade. The public also seems to feel that it will soon be at work again, which is shown by the number of orders which the dealers are asked to accept for future delivery.

There is a belief among some that even though the mines do get back to production under the President's plan, there is every chance of another suspension should the report of the commission be unfavorable to the men. With this in mind there is no question that every dealer will order in as much coal as his yard can possibly hold.

There is still considerable effort to lay in supplies, caused by the more serious aspect of the rail strike. As all dealers have pea coal, and can easily replenish their supplies, this is the one size that is being sold. A number of the larger dealers are replacing their stock of pea almost car for car. The slippers are carrying a large amount of pea for steam use, but this demand has not developed to such extent so far.

River barley remains the only steam coal on the market, with prices inclined to become firmer, $2.75.

BUFFALO
The belief that the strike is to be lifted soon may be the reason for the continued light demand. A little more call for it exists than formerly, but it is nothing remarkable. Consumers have not been accustomed to buy much coal in summer and they don't realize how much as if nothing had happened.

The complaint now is that if the government is able to propose or to force a measure to lift the strike it should have done so months ago.

BOSTON
The public continues apparently quite indifferent to the prolonged suspension and all its implications. Householders seem content to buy "applicants" and set out for their vacations with little thought for next fall and winter. Some miners in the hands of retail dealers have now dropped so low that the Massachusetts Fuel Administrator has decided to attempt nothing of a regulatory nature for the present.

Meanwhile, the originating companies have nothing but pea for shipment. For this size there is a reasonably steady demand among some of the larger cities, but there is no special inquiry that would in any way justify an advance in price.

COKE
CONNELSVILLE
Offerings of coke have decreased further, chiefly on account of some fresh striking, commonly attributed to the proposal at Washington of a plan for ending the coal strike, which the workers in the Connellsville region consider decidedly in their favor. There is also an increased demand from foundries and miscellaneous consumers. There is practically no demand for Connellsville coke for blast furnace use, both because prices are altogether too high to justify furnaces in taking hold and because the offerings are in quantities too small to interest a blast furnace.

Even $10 seems now to be out of the question, reports being of recent sales at $10.50@$11.00. The coke is usually sold simply as "coke," since selection is difficult nowadays, but the buyers include foundries.

The advance in prices is of little practical importance, on account of the small tonnage involved. Production of the region is light, 80 per cent is by furnace ovens and of the remaining 20 per cent much is moving on old contracts.

The Courier reports production during the week ended July 8 at 43,790 tons from the furnace ovens and 10,139 tons by the merchant ovens, a total of 53,929 tons, a decrease of 16,290 tons, the decrease being attributed to the holiday.

UNIONTOWN
The shopmen's strike is an active deterring factor upon coal production only upon the B. & O., where no cars have been placed for loading since the strike began two weeks ago. The Pennsylvania and Pittsburgh & Lake Erie continue to supply maximum car demands to operators in the lower Connellsville region. The conviction is slowly sinking in among striking miners that the Washington conference gives all appearances of ending the strike without considering what grievances they may have. Operators have taken advantage of the low morale of the strikers and have issued a general "work or quit" order. The county court is flooded with eviction notices, more than 400 being served this week.

The coal market is reacting strongly to the combined coal and shopmen's strike. Buyers are numerous, with steel and railroad interests the big purchasers. The car shortage is hovering over the life situation. Prices quoted are steam, $4.50@$4.75; byproduct, $4.75@$4.90.

BUFFALO
The supply is still less than the demand, but it appears to be met by the recent order for a sort of fuel that can be made to answer the purpose. Anthracite consumers are looking at it, as something that may have to be put into the place of hard coal.

ANTHRACITE
Western Kentucky Coal—Is Market’s Headliner

Chicago and Midwest

Western Kentucky coal remained the unbroken headline on the Chicago market during the past week. Almost every transaction ascended a little more than a dollar to a height of $6.25 by Saturday. And not satisfied with that, this coal was poised at the close of trading Saturday for a further flight into more rarefied market atmosphere. “We’ll have seven dollar coal right away” was the flushed prophecy of the few favored jobbers who were able to get a firm contract. Tonnage is mounting on the Kentucky field, and almost everybody in town seemed to agree with them. But few if any actual sales had crossed the $6.50 level by the end of the week, in spite of the hectic reports which fluttered around Chicago. While the market level on western Kentucky coal was astonishingly buoyant, the volume of coal was insignificant so that the total amount of money changing hands was small. Demand was keen enough at one time or another during the week in spite of the rise and fall of hope that a strike settlement was coming out of Washington, but the delivery of fuel from the field was greatly reduced by all sorts of transportation obstacles.

Eastern Kentucky operators have, in some instances, stuck to the Hoover levels of $6.50. A miner from that region got out of hand as to price so that the average quotations on this market, for what little coal changed hands, is just above $4. Smokeless and half fuel has attained about the same level. Practically no coal from any other fields was heard of on this market during the week.

ST. LOUIS

The storage piles at the smaller steam plants in St. Louis are getting dangerously thin. There is some coal moving in every day but very little and the demand continues to grow. The market is quoted at $5.50 to $5.75 for all sizes of western Kentucky. Prompt shipment cannot be promised on any road.

Some coal is moving from Alabama, but it is unsatisfactory. The prices range from $2.25 on mine run up to $5.50 on screen coal, with a freight rate of $3.57. A little Missouri coal is coming in from Monticello County to St. Louis switching limits at $5@5.50 at the mine, with a rate of $1.87.

The domestic situation is quiet locally but country demand for steam is good. Throughout the central part of Missouri, the territory is being supplied in a way by local mines and strip pits.

LOUISVILLE

Louisville sees a general improvement of transportation conditions in the eastern Kentucky fields which have been a source of great trouble and motive power. In Louisville the railroads are making progress toward better service, which has a vital effect upon the coal market.

Reports received indicate that some of the eastern Kentucky mines are sold out to August or later, but investigation shows that most concerns can fill dealing on hand quickly if they can get cars. Other than Lake and a little railroad, there has not been much contract business accepted. Demand is chiefly from public utilities, railroads, and, increasingly, from retail and general industrial buyers, while Lake movement is steady. Prices throughout the state show an increase of about a dollar a ton over last week, as eastern Kentucky is ranging from $4@$4.50 and western Kentucky, $6.00 @ $6.25 a ton, according to size. Screenings are carrying a premium.

INDIANAPOLIS

While there appears to be a fair coal supply in the city and a reasonable amount being offered, prices have broken loose from the Hoover maximum and are heading the large demand rules the prices. Public utilities and big consumers in Indianapolis have been offered both Kentucky and Western coal at $5 a ton for mine run. This with the recent quotation of $2.16 from Kentucky and slightly higher from West Virginia, brings the price close to $7.50.

Indianapolis is far from being short and while some of the larger consumers who did not buy far ahead are being compelled to pay for their experience, they have sufficient coal on hand to keep running for some time.

SOUTHERN ILLINOIS

“Calm” is the shortest word to describe the conditions here in the southern Illinois field at present. Throughout Williamson and Franklin County things are unusually quiet. The United Mine Workers’ officials are silent word to the miners in this field that the reputation of the entire organization has been damaged too much already. As a result the miners in this section are trying to avoid themselves as long as possible within the law, although a little local trouble develops occasionally when a miner meets one of the men employed in pumping out or keeping up the mine, but nothing serious has happened.

All the coal in the southern Illinois field is cleaned up and both sides are making time until the trouble is over. There is still some poverty at places but in the last few weeks the miners seem to be able to get more credit than formerly when it was clear that the merchant feels normality is near.

Much the same condition prevails in the Du Quoin, Jackson County and Mt. Olive districts. In the western district there are places where the miners are having a hard time making both ends meet.

WESTERN KENTUCKY

As a result of the railroad strike stopping production in some other fields, demand on western Kentucky has been greater than usual in this district, not being checked much by the rail strikes, is producing at a good clip, while prices are climbing. Orders have been coming in from all parts of the North and West, with some tonnage moving East as well. Today it is a question of getting any kind of coal at any price with market consumers.

Operators of western Kentucky are quoting prices over a dollar a ton higher than quotations of last week, and with the current climate of the market ranging as high as $8.35. It is reported that car service on the I. C. lines has been good.
Eastern Inland

Acute Market Conditions

**Intensified as Stocks Shrink**

Rail Strike and Congestion Further Entangle Situation—Prices Boom, $5 for Non-Union Coal Likely Soon—Lake Situation Is Critical.

MARKET conditions are more acute. Coal stocks are either dangerously low or entirely depleted and fresh supplies are extremely difficult to obtain. Rail congestion and strike troubles are delaying coal deliveries. Prices are booming and non-union coals will soon go over the $5 mark unless the strike can be settled and much needed production released. The market belongs entirely to the bidders and the urgency for fuel is daily growing more pronounced. The Lake situation is critical, and priorities are likely later on this summer as the only solution to safeguard the Northwest's winter supply.

**PITTSBURGH**

There is no operation at any of the union mines in the Pittsburgh district. Late in June plans were completed for an attempt at resumption at several mines, but President Harding's inaction of efforts to end the strike caused the operators to postpone their efforts, while it stiffened the attitude of the miners. The Washington proposal also had the effect of strengthening the non-union striking in the Connellsville region. The President's proposal of terms for a resumption of mining has been roundly criticized. The non-union operators have also joined in, under the belief that the proposal is not clear, leaving it as a possibility that the non-union operators who have strikes on their hands are expected to participate in the union settlement. As the United States Steel Corporation is notoriously on an open-shop basis an important factor is involved.

“Trading” has been lighter in the past week, offerings being diminished. Prices are higher. Westmoreland gas has been going at $1.75 and Connellsville steam coal at $4.25@4.50. Demand, in general, is greater on account of reduced deliveries of West Virginia and Kentucky coal arising out of railroad congestion, which has been accentuated by the strikes of railroad workers.

**BUFFALO**

As a rule consumers have lost out by failing to buy a little more generally, but they cannot be made to understand and are only buying a little, to enable them to wait until coal is in full supply again. A jobber reports making sales lately at $4.55 for 2-in. lump to a consumer who in April refused to pay him $1.90. The popular idea is that President Harding's reported plan, to have the men go back to work with the operators. The idea is that it would be preposterous to go back to war wages, paying the men $7.50 for eight hours’ work.

Quotations are hard to make, as there is really no regular price. Sales as high as $4.25 @ $4.50 for 2-in. and $4 @ $4.25 for mine run and slack have been made.

Only three cargoes of bituminous coal have come in from Ohio in the past seven days, total 17,600 net tons. The Buffalo furnaces have bought 200,000 tons more of this coal.

**CLEVELAND**

Conditions are becoming more acute. Railroads, brick plants and industrial users of all descriptions are flooding the market with inquiries. The main bulb of the industrial situation is the Cleveland Electric Illuminating Co. This company supplies about 75 per cent of the factories in this community with power. It demands sufficient coal to last until Aug. 15. Plants not buying power, however, are suffering. As a result prices are advancing, with every indication of higher prices if the strike settlement is not made soon.

A survey made of coal supplies in public utility plants in Ohio shows that the electric railroad companies have sufficient stocks to last to the middle of August. Artificial gas plants are virtually barren of stocks, while electric power plants have sufficient stocks to run until the last of July. The Cleveland municipal water works is inquiring for coal. The school board of Cleveland has asked for bids for 21,000 tons of slack and smaller amounts of other grades. Specifications are so exacting for this business, however, that operators are going slow in offering bids in view of the uncertainties of the situation.

The Lake situation is getting daily more acute. Shipments are not increasing and priorities loom as the only method of solving the problem later in the summer. Another phase of the matter which is worrying operators in this district is the possibility that Illinois and Indiana rail coal will be drawn upon largely to meet the needs of the Northwest. This will contribute to the car shortage.

**COLUMBUS**

With the strike continuing unabated and the situation getting worse, there are many indications of an acute demand for fuel. Hoover prices are being disregarded more and more and operators and jobbers to a certain proportion are asking as high as $4@ $4.25 for lump and mine run. But in the main a large number of the producers are asking the Hoover levels only and with the jobbers' commission this is slightly higher to the trade.

Retailers have cleaned up pretty well on stocks and as a consequence are coming into the market more and more. This, together with steam and railroad demand, will make a big market for the market entirely. Pocahontas lump is retailing around $7.75@8$, while West Virginia splints are quoted $7.25@$7.75. Only a small amount of Ohio-mined coal is available at present.

During the week ended July 12 the H. V. Docks at Toledo loaded but 95,600 tons as compared with 170,160 tons the previous week. The total tonnage handled by these docks since the opening of navigation is 1,398,338. The T. & O. C. Docks at Toledo have not opened for Lake loading.

**EASTERN OHIO**

Reports reveal an impending fuel scarcity, especially among the larger consumers. The ultra conservative stocks laid to prior to April 1, notwithstanding additions made to them by purchases of non-union coal, are nearing the point of absolute depletion. For example, it is asserted that Lake shipping may shortly be curtailed because of the acute supply situation for fuel purposes at the various docks. Within the past few days, the Detroit & Cleveland Navigation Co. is said to have wired Mr. Hoover with a view to obtaining relief.

The quantity of coal available in the spot market has precipitously declined during the past two weeks. Jobbers who have been slow in safeguarding their fuel requirements now find themselves in a position of considerable apprehension.

Another deterrent factor is the curtailed operation of eastern Ohio striping mines because of labor difficulties. It is estimated that the aggregate output of these mines at present is between 30,000 and 35,000 tons per week, as compared with 50,000 tons 30 days ago. Spot prices during the week rose to the Hoover level.

Receipts of bituminous coal at Cleveland during the week ended July 8 were the smallest in 10 weeks. Total quantity arriving was 3,972 cars; 227 cars for industrial use and 117 cars for retail yards, as compared with a total of 1,145 cars the preceding week.

**DETROIT**

Buying is proceeding very slowly. Jobbers are inclined to regard as fortuitous the fact that a greater disparity between supply and demand does not exist, in view of the circumstance that the quantity of coal available for the Detroit market has been greatly reduced within the last few weeks.

Many of the factories and industrial plants are reported to have a fair supply of coal remaining in reserve piles. Quotations are on all descriptions holding at about the level fixed by Secretary Hoover, with lump and egg at $3.75, run of mine $3.50, nut and slack $3.25.

**NORTHERN PANHANDLE**

Production continues on a large scale. There are only about three plants in this region now inactive. Not only is there a strong demand for railroad fuel but the buying of commercial coal is on a large scale. The rail strike greatly stimulated the demand. Prices are firm with mine run bringing the maximum.
Minnesota in Traval May Seize Trusty Axe

"Cut Timber" Is One Emergency Scheme That Fuel Surveyors May Propose—Whole Region Fears Future Prices Climb—Receipts Pitiful.

Reports indicate this week that part of the Northwest is getting more and more flighty over the coal crisis but that around Milwaukee there is still some confidence that the situation nationally will straighten itself out and that enough fuel will reach the region to hold down prices and prevent anything like a famine. Receipts by vessel at upper docks continue pitifully small and in Minnesota they are taking an official state canvass of the coal status which may result in a recommendation that the state turn to the forests for much of its fuel.

Prices are steadily advancing in most parts of the Northwest though so little coal is on hand that few except old customers are getting any, and delivery to even those is carefully restricted.

DULUTH

The coal situation at the Head of the Lakes is indeed serious. Free stocks on docks are at the low ebb. Orders are being refused by local dock companies and coal is allotted to old customers.

An official statement of the soft coal on docks shows that railroads own 600,000 tons and industries 400,000 tons and that first-coal totals 478,900 tons.

Shipments from the local docks for the month of June aggregated 29,654 cars. In June of last year but 9,557 cars were shipped and in May of this year only 18,587 cars went out. The shipments last month were the heaviest in eighteen months, with the exception of last October, when 28,722 cars were shipped.

Receipts have been pitifully small. In June there arrived 155,934 tons of bituminous. The season's total is 4,562 tons of anthracite and 284,174 of bituminous. This is 445,516 tons of anthracite and 3,510,971 tons of bituminous less than last year. An anthracite shortage this winter seems impossible to avert.

Prices have advanced. Lump is quoted at $7.50 by the majority of docks, coals up to 50c. less and screenings as high as $6.50, with the level around $6.

MILWAUKEE

The coal business is at a standstill. Wholesalers and retailers are filling their spikes with orders which they cannot fill until coal begins to be mined again and the railroads resume running.

Milwaukee is receiving coal by Lake almost daily, but the coal goes out as fast as it comes in. Dealers are optimistic, however, and are inclined to cry down all talk of a coal famine and high-priced coal the coming winter. President R. H. Aishton of the American Railway Association wired the Milwaukee Association of Commerce that if the coal strike is settled by Aug. 1, the railroads will have sufficient cars to carry the necessary coal from the mines to Lake Erie to meet the demand without a deficit on the docks in the Northwest.

There has been no disturbance of prices since the recent advance of 50c. in soft coal.

Thus far in July, 14 cargoes of soft coal aggregating 88,570 tons have been received, making the season's receipts to date 694,831 tons, against 1,375,653 tons last year up to this time, a shortage of 700,822 tons from last year's record. No hard coal has been received as yet, the 700,000 tons of anthracite screenings being of little account as fuel. Last year 435,200 tons of hard coal had been received up to now.

New England

Buying Interest Shown, Spot Prices Tend to Stiffen

Business Improving, Trade Is Less Inistent That Consumers Take Deliveries—Rail Strike May Mean Trouble, but Local Traffic Has Not Been Upset—Cars Disabled and Delay in Repairs Reported.

Buyers have shown more concern over purchases by the past week than at any time for several months, and to a degree spot prices have stiffened. Rehandlers at this end have had reasonably good business the past week and in the trade there is less disposition to press deliveries on the consumer than was the case a fortnight or so ago. It is realized that the striking shippers can cause trouble somewhere along the route, although in New England the men who walked out were replaced to a considerable extent without much difficulty. Traffic here has been unaffected, but reports are coming through of disabled cars in transit from the mines and of indefinite delays in repairing them.

At Norfolk and Newport News there has been a notable change in the situation, especially at the Norfolk & Western terminal. On July 15 it was stated that only about 26,000 tons of Navy standard coal was available for dumping, and that this tonnage belonged to twenty-three different agencies. On top of holiday suspension the shops troubles have further cut down output that had been kept for a considerable period on a 110 per cent basis.

Prices for spot delivery have already responded to the reduction in tonnage available and as high as $6.72 has been rumored as a sales figure, f.o.b. vessel at this point. Orders for higher figures have been refused in some instances.

Outside contracts with the Government are being canvassed and it is indicated that the price situation may be improved by the tender of a large order. The base line of $6.10 for the month of July has been gained and this has been extended to the month of August.

The mill is receiving coal by the slow boat from the West and during the past week has purchased only 2,530 tons, but 11,000 tons are under contract and are due soon by the same vessel. This vessel will be expected early this week and will decay coal and 14,000 tons will be received. There is no record on the mill's dock of any coal from the Gulf.

MINNEAPOLIS

General public apprehension over a coming coal famine grows throughout this region. The Northwest has started a fuel survey which may result in a recommendation that wood be cut as a coal substitute and distributed all over the state. Coal experts, naturally, would be an extreme measure for in few cases could wood take the place of steam coal; but it indicates the straits in which the state feels itself to be in with the Lake season so far advanced.

Many eyes are turned toward the lignite fields of North Dakota. It has been suggested that these fields could deliver to Minnesota 200,000 tons—a mere drop in the coal bucket. However, Dakota has its own fuel troubles and this source of supply is considered decidedly unstable. One expert has estimated that 6,000,000 tons of soft coal are needed here this winter. This region, always dependent upon outside sources for its fuel, probably will have to depend upon the national settlement of the coal strike, for its salvation.

Lower freight rates effective July 1 have given 20c. reduction in the cost of hard coal at the Twin Cities, this being the reduction on the haul from the docks to these cities. But that is on the basis of the old rate.

What is the cost of new coal will be, when it comes, is very uncertain.
Cincinnati Gateway

Buyers Hot After Tonnage, Prices Take Sharp Ascent

The strenuous days that coal men associate with the war and the months that followed were vividly brought back in Cincinnati and the non-union fields adjacent thereto during the past ten days. The handy deviation from the Hoover prices by applying the “premium” process having led to the exaction of larger profits, smaller operators and a class of jobbers and wholesalers are now out in the open and $5 coal has been chalking up.

The strike of the shopmen and other employees of the railroads has played a part, in that it has offered an excuse for pyramiding the price. The buyers, principally steel men, have been hot after any or all tonnage that was available and since the beginning of the week prices have shot upward. The tonnage hauled through this gateway has dropped fully 50 per cent recently, and from a transportation standpoint the situation is the worst in years.

CINCINNATI

The vast majority of the direct sales offices, old line wholesalers and others were freed of the Hoover process and are going without spot business rather than engage in evacuations. The result is that there are two separate and distinct price lists on the market, one for the coal that is in transit and close enough for connecting line delivery, and the other for coal that must take its turn in order to start moving.

All three lines engaged in heavy coal traffic, the L. & N., the N. & W., and the C. & O., have been failing in their ability to cope with the transportation problem. The tonnage passing over the bridges here has dropped fully 50 per cent from the peak that was established three weeks ago. The strike of the N. & W. clerks at Portsmouth has called a number of clerical coal men from the Pocahontas field in order to keep some of that tonnage moving to the West and the Lakes.

The situation admittedly has resolved itself into the worst state of affairs that has been known in this point for years and there are those who profess to believe that $5 coal isn’t a marker to what it may be a few days farther along. Cincinnati is holding to her faith in the river transportation for her own immediate needs. Even with the upturn to the wholesale market the retailers have shown no disposition to take advantage of the flurries except that where $8.50 was quoted as high for Pocahontas and $5.50@6 for mine run and the bituminous lump, and $5.50@6 for screenings last week, these are now the minimum prices. In other words, where a few retailers were undercuts the prices a week ago, they are now all to that level. Mine prices are steadily rising and are shown in the Weekly Review. The market is extremely sensitive.

HIGH-VOLATILE FIELDS

KANAWHA

July 4 tended to curtail production. Furthermore, congestion in yards and on sidings has tended to restrict the car supply to some extent, but as the car supply in this region is not as urgent as in some other fields where more coal is being produced, the supply has not affected the output to an appreciable extent. There was a brisk demand for steam coals in Western markets and Lake demand was reaching larger proportion.

LOGAN AND THACKER

Logan production was affected by inability to secure empty cars, production falling behind at the rate of 300 cars a day as others have been buying on a larger scale and have been urging prompt shipment for fear of the rail strike may affect delivery. There is also a growing demand at the Lakes. Shipments to the steel centers are large.

The heavy movement of Kenova-Thacker coal is preventing capacity production, owing to the difficulty of getting empties back to the mines. However, labor shortage losses are still running higher than those from car shortage. There is a ready market for all the steam coal produced. A large tonnage is being sent to the Lakes.

NORTHEASTERN KENTUCKY

Since July 1 the demand has been augmented not only by lower freight rates but also by the favoring of consumers having shipments curtailed at any time by the rail strike. Prices on all grades are at the maximum. The greatest obstacle in the way of capacity production is the difficulty of getting more equipment to the mines, congestion delaying the delivery of empties.

LOW-VOLATILE FIELDS

NEW RIVER AND THE GULF

There would have been additional gains in the New River output in the first week of July but for the intervention of the holiday. A congestion of traffic has made it almost impossible to make an unusually large production. With rates reduced, Tidewater is taking a little more coal but much of it is going to New York, Baltimore and Philadelphia instead of New England. Mines continue to increase their output as more men return to work.

Gulf mines are being handicapped by a serious congestion in the Virginias, there being more than 5,000 cars awaiting unloading at various points owing to the failure of the public to purchase. Car shortage losses are now twice as large as labor shortage losses, which for a time were the principal factors in holding back production. Much of the product is consigned to Tidewater.

POCOHONTAS AND TUG RIVER

There is an ample market for the large output of the Pocahontas region, which continues in excess of 400,000 tons a week, despite certain handicaps, such as a labor shortage and the difficulty of securing equipment, due not so much to any shortage of cars but to the impossibility of moving loads and empties with more celerity. Yards and trackage facilities are taxed to the utmost. When Tidewater became congested there was a heavy movement westward for which there is now a better market than there was before July 1. Prices have stiffened again.

Tug River mines are still producing in the order of 110,000 tons a week, not having been bothered much by a shortage of mine labor, although now beginning to feel the effect of a shortage of equipment. The principal movement from this field is to Western points.

West

SALT LAKE CITY

Business is still quiet. Probably nothing short of filling up the bins free would arouse the public to the necessity of getting in winter coal now. There is likely to be a rather serious car shortage this year and anxiety is felt in operating and retail circles.

Salt Lake City has today about 30,000 tons of coal in its yards.

Figures showing the coal produced in the state for the first half of the present year show a gain over the same period of 1921 amounting to 370,795 tons, the total tonnage being 2,106,251. Production, however, is well below that of the first half of 1920.

KANSAS CITY

The coal situation is more unsettled than ever due to the railroad shopmen’s strike, which has curtailed transportation to some extent and caused a spirited demand for such coal as is available. Prices have gone up as a result. Kansas mine run is selling as high as $5 per ton for the better grades and production appears to be on the increase with the strike.

Local dealers are advising their customers to put in coal now and as the prices are higher than last year, it is hard for the users of coal to understand, but no doubt will be made plain to them if last year’s wage scale for the miners is continued, as the prices will be based on the wage scale. This year, if wages are high, they will have to get more for the coal they handle or continue to lose money.

There is a little coal being mined now in Arkansas and while as a rule there is little demand for this grade at this season, it is moving freely. In fact the storage coal is about all used up and anything that will make steam is in demand.
ALABAMA

State convicts will be used in mining coal at Aldrich for another three months under a contract between Aldrich and David Roberts, trustee of the Montevallo Mining Co. Announcement of the contract was made recently by Mr. Roberts, who said that the contract had been agreed upon and had been approved by Governor Ford. An experimental contract for one month was made recently at the price paid to the Montevallo company for convicts labor before the company passed into the hands of the bankrupt court.

In the case of the experimental lease was the Lens Coal Co., with offices at Henry Ellen, capitalized at $2,000,000, with $1,172,600 paid in, partners to whom C. Payne, W. L. Simmons and John R. Boyle.

COLORADO

The Leyden mine, near Denver, is operating normally, according to officers of the Leyden Coal & Iron Co., at the average on the open-shop basis for 20 years. Miners on the payroll now in most instances have been with the company a good many years and do not appear to pay attention to the political fields.

The Colorado Fuel & Iron Co. has been able to increase its output half a ton per man per day this summer as a result of a campaign to stimulate men to do their best. The campaign methods include schemes of bonus, parties and prizes and pitting them against each other with daily reports "from the front" which are posted where men can see them frequently.

ILLINOIS

The Groveland Mining Co. has sold an issue of $300,000 first mortgage 7½ per cent gold bonds to John Burnham & Co., Chicago, Ill., and John H. Lumley, stories owner of the Peoria & Pekin Union Ry, which is a belt line connecting eleven railroads serving Peoria.

Horace Clark, of the Clark Coal & Coke Co., Chicago, Ill., has been appointed, D. W. Buchanan, of Chicago, president of Old Ben Coal Corporation, spent several days last week in Woodford, Ky., attending the Fourth of July, at Oconomowoc, Wis.

George B. Harrington, of Chicago, president of the Harrington & Franklin Coal Co., has returned from an Eastern business trip.

The Dixie Fuel Co., of Louisville and Nashville, has arranged to open a branch sales office at 424 Washington, Chicago, which will be in charge of John H. Rhodes, A. C. Lackey, producer and vice-president of the Dixie Fuel Co., and H. H. McElraine, vice-president of the Dixie Fuel Co., were in Chicago recently, arranging for the opening of the office there.

The Orchard Coal Co., of Marion, of which Charles Gent of that city is general manager, recently acquired the mine and property of the former Strong-Gray Co., near Dorrsville, Saline County, The Harrissburg Fuel Co., a company composed of R. A. Parks and John W. Gray.

James Forester, general superintendent of the Forest, Coal & Oil Co., of Paradise, has been on a long vacation in the West.

KENTUCKY

J. B. Bills is now superintendent of the Mountain Coal Co., formerly owned by J. P. Allen, which was formerly with the Collins Mining Co., of Lafferty. Mr. Bills, formerly with the McWebb Coal Co., is now mine superintendent of the Harlan Fuel Co., Harlan.

The Douglas Coal Co. is on the lines serving the coal fields of Kentucky and Tennessee, and is in the process of reorganizing to tie up the entire mining industry, as a result of the severe congestion at terminals where freight trains have been stopped with no prospect of continuing. There are many dead engines in the L. & W. yards at Corbin, the Eastern Kentucky, Cumberland Valley and Knoxville divisions, and the roundhouse men are out. Western Kentucky has been hardest hit so far as trouble as the eastern section.

The production of the Lewis Coal Co. at Waverly, as well as the coal and equipment, have been sold at public auction. The coal is in the market for $1.25 to $1.30 a ton, and the sale was held June 25, 1921, and has not been operated since. The property consists of 400 acres of coal rights and a mine electrically operated.

NEW YORK

D. C. Ashwood, anthracite editor of Coal Age, is broadcasting a talk on the anthracite situation from the following stations: July 21—3:45 p.m., Philadelphia, Pa.—John Wannamaker—WOC.

July 18—7:45 p.m., Springfield, Mass.—Westinghouse Elec. & Mfg. Co.—WIBZ.

July 15—2:45 p.m., Medford, Hillsdale, Mass.—American Radio Corp.—WAKV.

July 14—2:45 p.m., Schenectady, N. Y.—General Electric—WXV.

July 21—2:00 p.m., Pittsburg, Pa.—Westinghouse—WPG.

July 31—2:00 p.m., Newark, N. J.—Westinghouse Elec. & Mfg. Co.—WJW.

After an association of twenty-two years with the Steel Co., Charles H. Atwater, vice-president of the Ohio Fuel & Coke Co., has been appointed as the sales manager for George H. Lachnicht.

Announcement is made of the appointment of Vinegar J. W. C. Bowater, Inc., 66 Broadway, New York City, as the manager of the company.

The Rome Wire Co. announces that it has taken an interest in the Atlantic Insulated Wire & Cable Co., which will continue to manufacture high rubber covered wires and cables.

OHIO

The Cincinnati branch of the American Wholesalers Association has appointed Fred Leder, president of the Logan & Kenton Coal Co., E. F. Bardin, of the MacBard Coal Co., W. T. Francis, of the Tidesley Coal Co., R. H. McCormack, of the Kebo Coal Co., and Walter Welchman, of the Kentonia Coal Co., a committee to cook up some plans for the benefit of the coal miners.

Announcement is made of the appointment of J. E. B. Heilborn, Senator J. F. Bosworth, and J. D. Fitzpatrick, owners and operators of several mines in Bell County, Ky., and large acreage there were in Cincinnati recently going over the details of a big merger that will take in several of the going operations in that section of Western Kentucky. The plans call for the consolidation of eight mines and the opening of others.

Pennsylvania

The Anthracite Oil, Gas & Coal Co. of Northumberland, has notified the State Department at Harrisburg of an increase in its capital from $5,000 to $20,000.

The State Department of Mines has just compiled figures showing the production of coal in the Anthracite district of Pennsylvania. The total production of coal was 114,447,132 tons for the year ending Sept. 30, 1920, compared with 117,257,200 tons in 1919. The total value shipped to market was $71,851,896 compared with $71,370,123 in 1919. The largest consuming states were New York, New Jersey, New England, Ohio, and Maryland, with Delaware, Maryland, and Ohio, respectively, in the next three places.

The miners at Colver employed by the Ebensburg Coal Co. have been pretty thorougly organized and the new union men have struck. Eviction notices are being served on those living in company houses by the company. Evicted workers will be allowed to remain in the tent colonies.

The tipple of the Shade Coal Co., at Hagvo, was destroyed by fire recently, causing a loss of $10,000. The origin is thought to be incendiary.

Notices of dissolution of the Basin Coal Co., a furnishing company secretary of internal affairs, Harrisburg.

Cosgrove & Co., with headquarters in Johnstown, and branches in Jersey City, St. Louis and Minneapolis, have been named by the distributors of the Pennsylvania Coal Co., a Guggenheim subsidiary. The plants producing this low-volatilite coal are in the Greater Johnstown and Connellsville, Fayette counties, and are in the heart of the greatest anthracite mining area in the world, which the Cosgrove company will sell the coal as "Admiralty," and has gained such a reputation of high quality in the Eastern part of the country, and used largely by the Navy during the war.

The territory over which the Cosgrove company will sell the coal extends from Ohio, Indiana, Illinois, Michigan, and Wisconsin to组织 organized and operated by the Canadian Coal Co., of Groveland, Il., a large mine in Western Pennsylvania, and is used largely by the Navy during the war.

The territory over which the Cosgrove company will sell the coal extends from Ohio, Indiana, Illinois, Michigan, and Wisconsin to Wisconsin, and has been closed down since April 1 as the result of the strike. Resumption of operations at this mine is regarded as a favorable development owing to the fact that the union has held its ground at Thomas, the largest mining center in the Upper Potomac region.

The United Mine Workers' organization has been used for $1,000,000 by the Willis Branch Coal Co., in the New River field, to represent the miners during the strike of the U. M. W. during which period the miners were employed by the Commonwealth of West Virginia, Sept. 1, 1918, when it started to operate on an open-shop basis. The mine is a completely mechanized outfit, and it is claimed that it is the most modern coal mine in the United States. The mine is located in the town of Seneca, W. Va., and is operated by a company which is owned by the United Mine Workers' organization.

Traffic News

The Anaconda Copper Mining Co., in a brief filed with the I. C. C. in the Western coal area, states that the rate on coal between points in Wyoming, Colorado, and New Mexico and states west thereof, and destined to markets in the Pacific Ocean, is, in the opinion of the company, too low, and that the rates on coal between points in the Middle West and markets in the vicinity of the Pacific Ocean, and the rates on coal between points in the Middle West and markets west of the Rocky Mountains, is too high.

In this case the Kemmerer Rock Springs operators ask that the commission on its own motion fix on the line between Kemmerer and Rock Springs a rate of $1.25 per ton less than the rates from those points to Chicago, St. Louis, and other points to the east. The Western States Convention of mining engineers has also secured a rate of $1.25 per ton less than the rates from those points.

The Northern States Convention of mining engineers has secured a rate of $1.25 per ton less than the rates from those points.

Joseph Hallier, a well-known mining man in the Hills, was killed recently in Baltimore, due to a fall from a coal car. The coal, according to the police, was being loaded in the coal yard at Baltimore. The coal car was moving at a slow speed, and the man was attempting to reach the coal car from another car. The coal car ran over the man, and he was killed instantly.

The Northern States Convention of mining engineers has secured a rate of $1.25 per ton less than the rates from those points.

Comer Meetings

American Chemical Society's annual fall meeting will be held Sept. 4-9 at Pittsburg, Pa., at the Carnegie Institute of Technology and general meetings at Carnegie Music Hall.

American Mining Congress. Twenty-fifth annual convention of the mining and metal trade will be held at Pittsburgh, Pa., Sept. 1-3. The meetings will be held at the University of Pittsburgh, and the sessions will be held at the Hotel New Yorker, the Hollenden Hotel; E. C. Porter, connection, and the Scottie coal companies St. Lawrence shipment was approximately 2,000,000 tons.

Quebec

As a result of the American coal strike, fuel is now being brought to Montreal from the Cape Breton mines by steamers owned and operated by subsidiary companies of the Canadian Pacific Railway, and the coal is being unloaded at the Tidewater Exchage at Baltimore, where it is being processed and shipped to the industries of the United States.

In the complaint of the United Paperboard Co., an examiner of the I. C. C. recommends that the rate on coal from group A, B, and C mines in Pennsylvania to Thomson, Mo., be declared reasonable.

The Illinois Coal Traffic Bureau has filed a brief in the I. C. C. case brought by the Northern States Paper Co. It requests that it be allowed to make no changes in the rates of the Illinois Coal Traffic Bureau and that it be allowed to continue to supply on flow coal as well as on large coal.

In the complaint of the Grasselli Chemical Co., the company claimed that the rate for the reasonableness of the charge for the use of its railroad connections and the power of the railroads in the conveyance of coal and coke from the plant stock pile, is not within the jurisdiction of the commission.

The Vital Aspect of Price

SECRETARY HOOVER'S plans to distribute current coal production and to hold the price within reason are as timely and will be as well received as the conferences on prices in May that resulted in holding quotations in check from June 1 until last week.

Necessity for some control over distribution has been increasingly evident since the first week of July, and as always when acute distribution problems arise price troubles begin. Mr. Hoover again stepped in at a critical juncture. With truly remarkable foresight he anticipated the details of the approaching crisis and when the time to act arrived he was ready with a fully developed, workable plan. He has co-ordinated the Interstate Commerce Commission, the departments of Justice, Interior and Commerce, the railroads and the coal operators. He has so laid his plans that the usual protesting voices in the Senate are quiet. His plans will produce results, for he is of the type that will shape the details to the practical objections as they arise.

As to the urgency of directing the restricted flow of coal in the direction of transportation, public utilities and certain other essential users there can be no question. On the equally, if not—to the operators—more important question of prices some would hold back approval. The two cannot be separated in any practical working program. Price has been directing distribution, as for instance last week when the more than doubling in price of western Kentucky coal in Chicago acted as a magnet for large consignments of Pennsylvania high-volatile coal, the offering of which on that unusual market served to check the upward rise in quotations. When the government takes over, in effect, the current production of coal it must have a great deal to say as to the price that will be charged for that coal.

There is a larger and more vital aspect of this price question. Price is the evidence to the public of how the industry is functioning. The public is interested in wages of coal miners only as these wages are interpreted into prices of coal. The public has stood on the side lines while this strike has been in progress, quite apathetic at first, then patiently tolerant, now aroused. It has put up with the inconvenience of the strike (and will if necessary put up with more than inconvenience) because it has appreciated that the operators are trying to liquidate wages of union coal-mine labor and that the basis of the policy of the United Mine Workers is opposition to wage reductions. But what is the public saying about an industry that stages a strike to lower the wages of its workers and at the same time extorts huge prices for coal? There is no fairness in that.

An indication of how the people feel on this question is found in the action this week of the Governor of Colorado, who, when advised that certain operators in that state had increased prices one-third, warned them that he would withdraw the support of the National Guard at once unless prices were restored to their former level. He said that he had put troops at the mines in the interest of the consuming public that needs the coal and to provide work for willing miners, and not to protect anyone's pocketbook.

Price is the sore spot. The race for coal may be largely responsible for the flight of prices last week, but if the coal operators are not able—and they are not—to save themselves from this source of condemnation, the government is more than warranted in stepping in. Whether some producers like it or not they must be protected from themselves, and those producing the greater part of the current tonnage who have and will continue voluntarily to maintain a fair price are entitled to protection from those who will not.

Unreasonable wages and unreasonable prices are in the same category. The country wants neither and the government is looked to for protection from both. Mr. Hoover has said that no operator intent on robbing the public can get a car in which to load coal. And he has taken the responsibility of saying what price is reasonable. He is right. And with his usual decisiveness he has not temporized with the situation. The administration might consider the same line of policy with respect to union coal-mine wages when planning a resumption of mine operations.

A Sympathetic Strike
In the Hard-Coal Region

WHAT the anthracite operators have always feared has come to pass. The union is using the suspension in the anthracite region as a club to hold over the bituminous operators. Unless the demands of the union for the old-time four-state conference in the bituminous region are granted the strike in the anthracite region will be allowed to continue indefinitely.

There is a part of the public that is not in industry and that sympathizes but little with the woes of the manufacturer (who uses soft coal) but has, nevertheless, a keen interest in the filling with anthracite of its own domestic coal bin. The union is desirous of so sorely distressing all the people of the United States, soft-coal and hard-coal users alike, that they will be driven to give the miners what they ask—an interstate conference in which union and non-union regions will be conjoined and a check-off that will make the operators in every part of the country pay dues to the union.

When the union talks high prices it trots out the hard-coal field, because hard coal is expensive to mine, to pump and to prepare and has a wider and stronger appeal: when it talks strike it calmly forgets the anthracite mines and introduces the bituminous region, where it wants a renewal of the old conditions—the con-
tract with the Central Competitive region or something even more in restraint of trade. It asks no change in the districting of the anthracite region. There it already makes a 100-per-cent collective bargain embracing all three districts, but it is nevertheless as ill-disposed to bargain there as it is elsewhere. Loudly as it calls for the collective bargain, it would have none just at present in the anthracite region, where what might be termed a sympathetic strike is going on.

The anthracite operators have asked for arbitration. The miners reject it because, forsooth, they cannot get a restatement of the Central Competitive agreement in an entirely different and relatively non-competitive region. They give no reason for their rejection of Mr. Harding's proposition as to the arbitration of the anthracite difficulty, and Mr. Harding apparently lumped the anthracite and bituminous fields together in his thinking and makes no effort to direct public opinion to the vast difference in the two or to the game John L. Lewis is playing.

The anthracite region has become a vassal to the bituminous districts. The operators in it are permitted to make no treaty with their own men till the union wins or loses in the soft-coal field.

An Acceptable Settlement

POINTEDLY and forcefully the New York Tribune asks why Washington does not drive the miners and operators, either or both, into the open and make them face the square issue of what sort of settlement is acceptable. The miners are assailed because they ask "not arbitration but prejudgment." The operators' offer of arbitration by districts instead of on a national basis is characterized as absurd. "The coal industry is a national one. Every operator competes to some extent against every other. There must be a national wage base if there is to be industrial peace," says the Tribune.

This is all true as far as it goes, but it should go farther. What is a national wage base? Does anyone conceive for a moment that a national wage base means that a miner who undercuts the coal, shoots it down and loads it into cars, whether he work in a 9-ft. bed or in 3-ft. coal, whether he gets 300 days or but 150 days' work per year as a regular thing, whether in one mine he must lay room track, push cars and dig ditches and another not, must have the same compensation per ton of coal regardless of conditions? Does anyone maintain that the day laborer at a mine in a community where living costs are low should receive the same wage per day as one working where living costs are relatively high? Of course not. That would be absurd. The miners' union would be the last to agree to such a scheme, for the necessity and opportunity of fighting for more favorable differentials has given the union life and many an official a job.

What the Tribune is thinking about is indicated by the wording: "Suppose the arbitral board in one district decided wages should come down and in the adjacent district that wages should go up!" it says, adding "Divergent decisions would make district arbitrations no arbitration at all. As matters stand they are for arbitration in words but against it in fact."

What the Tribune really is arguing for is a national wage policy for the bituminous-coal industry—that is to say, such unified control by the operators on the one side as is exercised by the miners through the United Mine Workers on the other. Such in fact was the practical effect of the old Central Competitive Field conferences and agreements. The interstate contracts broadly set a general rate of increase—they were never successful in producing a decrease—a percentage to be applied to existing rates. The contracting parties were obligated to return to their respective districts and write the terms of the general conference into district contracts, but in no case could any provisions be added to the agreements that would increase the cost of production or decrease the earning power of the mine workers. In other words, no opportunity was offered—in fact it was expressly denied—that differentials between fields be changed. Marginal organized fields awaited the outcome of the negotiations in the Central Competitive Field before setting their wage scales. Their decisions were largely but not entirely influenced by the larger decision to which the operators were not a party though the miners were, through their international officers.

The outstanding advantages of a method of determining broad changes in wage levels such as resulted from the old interstate conference are self-evident. This process tends to work even-handed justice and to stabilize the coal industry. But a national conference is no place to solve local problems. So long ago as March 8, 1916, Mr. Moorshead, a scale committeemen from Illinois, introduced a resolution into the joint conference pointing out that "serious inequalities between the four districts" had been disclosed in years of negotiations, and that these had caused "serious conflicts, because of the many inequalities and injustices that have been forced on miners and operators alike," and asking that a commission be appointed to inquire into the setting up of new machinery for determining differentials.

A large part of the record before the President's Bituminous Coal Commission in 1920 is occupied with discussion of differentials. Both sides sought changes. The commission pleaded lack of time for consideration and instead suggested a new commission of miners and operators to take up the problem. Nothing has ever been done about either of these recommendations. Why? Because the operators East and West are wide apart in their desires and necessities and the miners see no advantage in raising the question, especially as it usually has the check-off problem pinned to it.

Sitting with Illinois and Indiana and the miners, Pittsburgh and Ohio, having but two votes in eight, have no chance in the Central Competitive conference to adjust their differentials to meet the more potent competition of West Virginia. Central Pennsylvania follows the lead of Pittsburgh as the Southwest does that of Illinois. A regrouping of districts with the State of Pennsylvania and Ohio in one; Illinois, Indiana, and western Kentucky in another, and the Southwest, Iowa and Texas a third, would give modern expression to the group idea, wherein differentials could find their proper solution and the miners lose nothing in strength and power as compared with the older and—from the standpoint of competitive conditions—obsolete Central Competitive Field. The largest of these groups would set the pace for the others, until very soon a way of getting together nationally would be found.

Why do the United Workers refuse to consider any group save the old one? Because John L. Lewis set that as his policy in this strike, and he dare not deviate a hair's breadth from the letter of his first dictum, else Frank Farrington find excuse to break away for a separate settlement in Illinois.
Belt Conveyor Supported by Suspension Bridge Used To Bring Coal Across River in Logan Field

Coal Is Dropped from Drop-Bottom Cars Into 500-Ton Bin, from Which It Is Fed to Retarding Conveyor—Coal Is Picked Clean and Fed to Belt Conveyor, Which Carries It to Tipple

By A. D. Carr*
Cincinnati, Ohio

Two seams of coal are operated by the Guyan Mining Co., a subsidiary of the Jewett, Bigelow & Brooks Coal Co., of Cincinnati, Ohio, at Wilbur, Logan County, W. Va.—the Eagle seam, a gas coal which lies approximately 100 ft. above the level of the Guyandot River at that point, and the No. 2, or Island Creek, seam, which is about 200 ft. higher in the hills. Both coal beds cover a large area.

As will be seen on the left in the frontispiece, a 500-ton storage bin has been erected on the side hill, and coal is discharged into this by the drop-bottom cars from the workings in the Island Creek seam. This bin is 200 ft. long and 20 ft. wide and over it passes a double mine-car track. Thus two trips of cars can be dumped at the same time. There are two slots in the top of this bin. These are made about 60 ft. long and consequently the cars can be and are dumped without stopping. Thus they are promptly returned to the mines. The readiness with which they are discharged makes possible a large output with but few cars.

A feeder shown at the foot of the conveyor pulls coal out of the bin and discharges it onto a retarding flight conveyor, the shed of which can be seen on the side of the hill. This conveyor is 365 ft. long and has a pitch of 35 deg. It carries the coal down to another bin that has a capacity of 100 tons, where coal from the Eagle seam is dumped from the mine cars.

The coal is removed from this bin by a 36-in. x 15-ft. plate feeder and is discharged onto a single revolving disk screen that removes the slack or fine coal, which falls directly onto a 30-in. belt conveyor, 504 ft. long. This conveyor passes under the full length of a 54-in. x 15-ft. picking table. Here the coal is well cleaned, the freedom from slack making inspection easy.

The coal discharged from the surface of the picking table falls on the same 30-in. belt. Thus the coarse coal is delivered on the top of the fine, and in this manner the belt is protected against cutting. The conveyor line and shed are supported by two 21-in. lock-coil cables which have a combined capacity of 200 tons safe load.

The belt operates on gradual-troughing ball-bearing carriers. It has a capacity of 250 tons per hour when running at the present speed, which is 250 ft. per minute. This can be increased to about 350 ft. per minute, thereby increasing the hourly capacity of the belt from 250 to 350 tons per hour. It is operated by a 30-hp. motor which is wired so that it can be controlled from either end of the conveyor. The structure that supports the belt is suspended from the cables by means of 3-in. steel rods at intervals of 5 ft. To these rods is fastened a 4 x 6-in. crosspiece on which the conveyor or gallery is built. This, of course, is made of light material and is bolted together. It has

*Chief engineer, Jewett, Bigelow & Brooks Coal Co.
BELT CONVEYOR AND SUSPENDED SHED COVERING IT

The shed slopes in the main toward the direction in which the heaviest winds come. The belt is 594 ft. long and 30 in. wide. Its capacity can be raised to 2,800 tons per eight-hour day if needed. At present it is delivering about half that quantity.

A walkway on the up-river side which is used in crossing the river and in inspecting and oiling the machinery. The roof of this gallery slopes toward the down-river side, the purpose being to lessen the wind pressure, all the heaviest wind storms coming from down the river. The gallery is covered with corrugated iron of No. 20 gage. There are windows at intervals of about 20 ft. in this gallery. At this point the river is 300 ft. wide, and the conveyor is 75 ft. in the clear above the stream. Reinforced-concrete blocks each containing 60 cu. yd. of concrete and weighing 100 tons serve as anchorages.

The discharge tower is 87 ft. high. At this point the coal falls into a chute down which it slides into a 75-ton receiving bin. This tower also serves as a support for the cables.

From this bin the coal is drawn by lift gates and loaded into cars. At present a bar screen is being used which separates the steam coal from the lump, the two being led to different tracks. The plant now produces 1,500 tons per eight-hour day, but the purpose of the company is to raise the output to 2,000 tons soon.

The erection of the suspension bridge saved the owners of the mine the high cost of a steel bridge, and the success in operating the flexible structure is believed fully to justify the substitution.
Considerations Which Should Govern When Deciding Whether to Generate or Buy Power*

BY W. C. ADAMS†
Chicago, Ill.

Groups of Mines Should Be Able to Generate Electricity for 1.8c. per Kilowatt-Hour Power-Plant Expense—At Some Mines Home-Generated Power Costs 25c. per Ton

It is impossible to make a general classification of mines which should or should not purchase power because so many variables enter into the problem. Mine power requirements depend upon the tonnage produced, the depth of the shaft, the underground conditions, the system of working and the equipment installed. The power consumption per ton of coal mined varies with the number of days during which the mine is operated, but it must not be forgotten that the fan, pumps and some of the hoisting and general work require power irrespective of the coal output.

Fully electrified mines using electric hoists, a motor-driven fan, tippers equipment and miscellaneous mechanical appliances, pumps, locomotives, gathering motors, mining machines, etc., will have a power requirement under average mining conditions when working 180 to 200 days per year of from 2.75 to 3.5-kw.-hr. per ton. The effect of additional idle days will be to increase the power consumption per ton, which during extremely slack periods may reach 150 to 160 per cent of the normal rate.

All mines, however, are not provided with mechanical equipment for performing every one of the operations noted. Such plants may use steam surface equipment, gather coal with mules or dig coal with hand picks. The power requirements obviously would depend upon the number of operations for which power is furnished and may vary from 2 to 5 hp.-hr. per ton for average mining time, with increases for additional idle days.

Mines in Midwest Have 25c. Power Charges

Most of the mines in the Middle Western coal fields that operate on power generated at the mine have extremely inefficient plants. The power costs for fully equipped mines with such generating stations is as high as 25c. per ton when fixed charges are taken into account.

Mines that have similar power requirements and use central-station current under similar conditions have a total cost of 7 to 14c. per ton of output. This includes all items chargeable to power, such as investment in, and operation of, auxiliary equipment made necessary by the installation of purchased energy. This estimate is based on Illinois power rates.

With this possible saving of from 6 to 11c. per ton in view it is evident that if the coal operation is to use power generated at the mine, the plant to produce it should be designed with a view to economy.

Some of the larger operators have rehabilitated their plants, and the resulting operations are provided with power equipment suitable for economical operation. These plants will furnish power at a cost comparable with purchased energy and ranging from 6 to 12c. per ton, depending largely on the tonnage produced. When such plants are suitably situated and arranged to furnish power for two or more large mine operations, the cost per ton can be brought well below that paid for purchased power.

Power Costs as Low as Two Cents a Ton

Generating stations at operations having a capacity of approximately 5,000 tons per day, when economically designed and with a mine operating time of 200 days per year, should produce power at a total cost chargeable to mining of from 2 to 2.5c. per kilowatt-hour when coal is charged at $2.25 per ton. Stations serving two or more such operations would have a lower cost and with mines having an aggregate capacity of 8,000,000 tons per year the total power-plant expense should be approximately 1.8c. per kilowatt-hour, including all plant charges. To this figure should be added investment costs and charges for lines, substations and such auxiliary equipment as are made necessary at those mines which are remote from the station and receive energy over a transmission line.

Some operations have been laid out with a view to using not only purchased electric energy but also steam power generated at the plant, the purpose being to avoid the investment necessary for an equalizing hoisting unit. This arrangement does not take advantage of the lower power increment of either system and cannot be recommended for general installation except in cases where the life of the operation is short. The power costs at such an installation will always be higher than could be obtained by generating all the power at an economical power plant at the mine or by purchasing all the current necessary from a central station.

*Paper, entitled "The Use of Purchased Power for Coal-Mine Operations," read before the joint session of the Western Society of Engineers with the Chicago branches of the American Institute of Electrical Engineers and the American Institute of Mining and Metallurgical Engineers, at Chicago, May 22, 1922.
†Vice-president of Allen & Garcia Co., Chicago.
With mines having a life of 20 to 25 years or even more and a daily output of 3,500 tons or better, it is generally justifiable to expend capital enough to provide such a generating station as will lower the power cost to that charged for electric energy by Illinois central stations. Mines of shorter life or lower outputs almost without exception will show operating economies in favor of purchased power.

The source of power chosen should not affect the output of a coal-mining operation provided the available sources of supply are equally reliable. Coal production costs, however, do depend on the source of energy, but the difference is not directly proportional to the costs of power delivered from the several sources, because with certain of these special equipment is made necessary and the fixed charges on this investment modify the costs that must be borne and, furthermore, direct and indirect costs inevitably result from the interruptions which arise when certain sources of supply are used.

Alternating current should be used for distributing energy from the delivery point to the converter substations at load centers except where the operations are small and are expected to have a short life. Whether the power is furnished by a central station of a public-utility company or by a generating station at the mine and operated by the mining company does not alter the design of the system by which the power should be distributed, except in the case, possibly, of small existing operations having direct-current generating stations. In such installations some advantage might be gained in the distribution system by an arrangement of underground converter substations made possible by the purchase of power. In a discussion of the proper source of electrical energy, however, only mines having reasonably efficient distribution systems should be considered, as it is impossible to classify or give general estimates of power consumption or costs for operations that waste a large part of the delivered current.

**POWER COSTS NOT THE SOLE CONSIDERATION**

Whether the power required for a coal-mining operation should be generated at the mine or purchased from a central station of a public-utility company can be decided only after a study of each individual problem, if the decision is to be based solely on a comparison of operating economies. There are, however, certain other facts and conclusions in connection with such an analysis that should be taken into consideration. Their proper evaluation may render a decision possible without making a comparison of the power costs.

It is not always good policy to place a coal-mining operation in a position where the operator cannot control the power supply. Especially is this true if a doubt exists as to the reliability of the public-utility power available, for it is not logical to consider making the output of any industrial enterprise dependent upon a power supply that is liable to frequent interruptions of uncertain duration.

Opinions as to what degree of continuity of service should be expected from public-utility plants may vary. We know, however, that it is possible to design and build power plants for mining operations in which interruptions are rare, and it would seem that an operator has a right to expect the same service from the public-utility company. There are, of course, certain interruptions which lightning, heavy storms and the like are apt to cause and which no commercial type of construction can prevent. With interruptions of this character included, however, such shutdowns should not occur on an average more than once a month.

Furthermore, the power supply must have uniform characteristics. Voltages, frequencies or steam pressures that vary are not conducive to satisfactory and economical operation of equipment and must not be permitted if the best results are to be realized.

If real service were demanded by all operators who use central-station power, or contemplate its purchase, it doubtless would be supplied, for though coal-mine loads may not be the most attractive from the central-station viewpoint, yet for the utility company operating in most coal fields such a load aids in obtaining the operating characteristics favorable to economy.

Such a demand by the power users would force the utility company to restrict its connected load to the capacity of its plant and system instead of seeking to secure all the load possible in the hope, and with the promise, that at some time, more or less remote, both would be developed to meet all requirements.

The operations at the plant are regulated by a schedule, expressed or implied, and any delays or interruptions of even short duration cause confusion and affect the morale of the men. The return of power often causes secondary interruptions which are due to the heavy combined load arising when pieces of equipment are started simultaneously. Such interruptions aggravate a situation already bad and slow up operations. The resultant loss of tonnage always equals the production of a period many times as long as the duration of the actual shutdown.

**MINERS LEAVE MINE WHEN POWER GOES OFF**

Where an interruption is unduly extended the miners as a rule leave their places and quit for the day. This dereliction of duty may not appear reasonable but it is one of the conditions with which a coal operator has to contend. All interruptions therefore reduce the coal output but do not remove the necessity of paying wages, operating and fixed charges during such shutdown periods. This results in an unproductive expense that increases the cost of coal getting. Interruptions not only reduce the margin of actual profit but deprive the operator of the profit he would have made had he produced a full run of coal. This applies to mining operations with greater force than to any other industry except, perhaps, those where a shutdown means ruin of product.

There are many instances where mines have failed because the car supply has not been reliable. An uncertain power source can produce the same result. Power sources that cannot be relied upon result in an undependable mine production. This handicaps the operator in obtaining contracts for time delivery, or if such contracts are carried the quantity of "free coal" is cut down, and upon this the mine owner often depends for his profit.

Mining operations, to be assured of power supply from a central station, should be provided with a loop system of transmission whereby power can be furnished from two or more sources. Some line trouble must be expected with any transmission system, but failure of supply from two sources because of such difficulty should be exceptional.

When central-station energy is used at a mine it is advisable to insure the steadiness of the supply of power for the fan and hoist by installing auxiliaries.
which can be put in operation when the purchased power fails. This is especially true in gaseous and deep mines, for under such conditions it is not advisable to allow the ventilation to cease, even temporarily, and means must be provided for bringing men out of the mine.

Where the record of service given by the central station in the particular field in which the operation is located has not been satisfactory and where it appears that a station and transmission capacity will not be maintained ample enough to insure a continuous power supply in times of stress the purchase of power is not justified and not advisable, provided, of course, it is possible to install a generating plant at the mine.

HAULING WATER NEGATIVES POWER ECONOMY

Where an adequate water supply for plant operation cannot be obtained it is impractical to provide an isolated generating station. It is just as unreasonable to equip a mine with a generating plant that must depend during dry months on water being hauled to it as it is to put one's trust in a public-utility company which cannot be relied on to furnish a continuous and satisfactory supply of power.

The financial condition of the operating company may not permit or justify the installation of such a generating station as will afford desirable economies. The investment necessary for such a station would increase the capital expenditure for a modern, well-equipped mine from 20 to 45 per cent, depending on the capacity of the mine. If this capital is not available and if, in order to have power generated at the mine, it is necessary to erect or continue to operate with a plant such as is found at many mines—horizontal-return tubular low-pressure boilers, non-condensing engines and similar equipment—the only excuse for not purchasing power would be its unreliability.

Hoisting equipment may be affected by the power source, as it must conform to the requirements of the public-utility company which furnishes current. In some cases these companies have a ruling that regulates the maximum size of induction-motor hoists, and this imposes a heavy investment burden on mines of small or medium capacity which require from 200 to 500 hp. Equalizing equipments between these sizes entails a cost which may run from three to four times that of the induction motor and its control.

Mixed operations using steam hoists in addition to purchased power for the purpose of avoiding this additional investment have proved highly unsatisfactory both in operation and resultant power cost. In considering the energy supply for existing mines having a remaining life of from 20 to 25 years the choice should be based on the results of an analysis of the problem presented. This choice lies between the rehabilitation of the existing power plant to meet the total requirements of the mine and the purchase of power from a central station. If decision is made in favor of a generating plant at the mine the retention of the steam hoist and the employment of mixed-pressure turbines with regenerators probably would entail the least investment. With purchased power the hoist should be electrified. The only justifiable deviation from this course would be in the case of mines having the prospect of only a short life.

A comparison of the operating cost as calculated for the two systems, other factors being equal, should determine whether a mine should use purchased power or energy furnished by a generating station at the mine site.

Knowledge of general underground conditions and the details of mine operation usually will give sufficient data to determine the power requirements with a reasonable degree of accuracy. This forms the basis for calculation of the power costs based on central-station current or on a generating station of any particular design.

Installations at the mine using purchased power usually are simple. They consist of a transformer substation and the connection to the distributing buses. The purchase of power makes necessary some auxiliary equipment that would not be required or embodied in the plant design if power were generated at the mine. In any comparative power-cost statement the investment, fixed, operating and maintenance charges in connection with such equipment should be included as a charge against central-station power.

Included under this item would be the general heating plant, auxiliary man hoist and fan drives, as well as such other equipment as would be ordinarily embodied in the power plant but required as separate installations if current is purchased.

Charges for interest and depreciation on the investment and for fixed and maintenance expense should be included as a charge against central-station power to offset similar charges included in generating-station costs.

The cost chargeable to purchased power should include: (1) Cost of power delivery, calculated on the basis of established rates of the central station; (2) interest on investment required for lines, substation and other equipment necessary to power delivery; (3) maintenance and fixed charges on lines, substation and other requirements up to the point of delivery; (4) operating labor chargeable to purchased power up to the point of delivery; (5) interest on investment for auxiliary equipment made necessary by the purchase of power; (6) maintenance and fixed charges on auxiliary equipment made necessary by the purchase of power; (7) labor chargeable to auxiliary equipment made necessary by purchasing power; (8) interest on investment for hoisting equipment; (9) maintenance and fixed charges on hoisting equipment; (10) interest and fixed charges on abandoned equipment.

SOMETIMES RAISES LOAD FACTOR 300 PER CENT

Public-utility power plants serving numerous mines, delivering energy to industrial enterprises and supplying current for lighting throughout the territory over which their systems extend have a varied load, resulting in an annual load factor seldom less than 40 per cent. The annual load factor of a single mine varies between 11 and 25 per cent. This can be increased by combining two or more mines so that both may be served by one power plant. This is advisable where a group of mines is operated under one management.

Larger capacity and its better load factor give the central station an operating advantage which offsets any superiority that the generating plant at the mine may enjoy as a result of the elimination of the freight and handling charges on coal.

A generating station at the mine cannot make power at a cost comparable with a central station unless special attention is paid to so design and operate such a plant as to obtain economies in operation such as are usually attained at central stations. The power plant
should be designed to give such economies as are justified by the character of the load, but in general the investment should not exceed 40c. per ton of annual capacity.

Consideration should be given the possibility of burning such low-grade fuels or sizes of coal as can be sold only with difficulty in the commercial field. Capacity of units should be so selected as to give economical operation under low and idle-day load requirements, as such periods normally constitute not less than 65 per cent of the total operating time. The hoist should preferably be electric, although there are cases, especially in the rehabilitation of a power plant for an existing operation, where a steam hoist with regenerator and mixed-pressure turbines is justified.

In calculating the operating cost of a generating station at the mine it is necessary to understand fully the operating conditions imposed. The low yearly load factor increases the cost of power generation materially. This being the case it is necessary to give this factor careful consideration if the expense of actual operation is to meet the calculated cost.

Coal operators differ much as to the proper method of charging fuel to their power plants. It would seem that the only proper charge is the prevailing market price of the class of coal used. The cost chargeable to power generation should include:

1. Power-plant cost. This embraces under (a) operation: Coal, (charged to the plant at the prevailing market price), water (including cost of treatment and labor), engine-room labor, boiler-room labor, coal-ash-handling labor, ash removal, electrical labor, miscellaneous engine- and boiler-room supplies; (b) maintenance costs: charges for engine room, boiler room, coal- and ash-handling apparatus, electrical apparatus; (c) fixed charges, which covers investment cost, amortization cost, administration cost, insurance and taxes.

2. Interest and fixed charges on disposed equipment.
3. Interest on investment for hoisting equipment.
4. Maintenance and fixed charges on hoisting equipment.

As has been pointed out, frequently, the production of coal and the generation of power are two distinct enterprises. Coal-mining officials generally are men having coal-mine experience and little knowledge of the economic generation of power. It is essential, therefore, that a separate department with proper talent be instituted if power is to be generated economically. This adds to the burden of the management. There is a tendency, moreover, among most coal operators to defer appropriations for plant improvement in favor of those for mine operation. This makes it difficult to maintain a low power-production cost.

In general, from an economic standpoint, if the cost of purchased power exceeds the calculated generated-power cost by 10 per cent it would still be advisable to purchase power. In other words, it is believed that the value to the operator of eliminating the necessity of building and operating a generating station at the mine can be capitalized at 10 per cent of the calculated power cost.

Dust Off the Leather Medals;
Here's a Winner

IN THE old days out on the baked plains they used to attempt "rain making." Somehow it didn't work so well. Elsewhere at various times humanity boomers have striven to create perpetual motion. Results: Ditto, if not more so. But why be discouraged? "In perseverance there is a curse," or something like that. So now comes F. F. Affelder, assistant to the president of the Hillman Coal & Coke Co., with a double-backaction case-hardened grown-on-grandpapa's-farm-in-Virginia form of contract to be used in the purchase of electric power for coal mines. It is guaranteed to be squabble-proof. With it in effect, violence cannot arise concerning quantities of power delivered, rates, meter accuracies or anything else.

Mr. Affelder has had lots of fun with it at dry engineering meetings here and there. It won eight full octaves of guffaw on May 22 in Chicago at a joint meeting of the Western Society of Engineers with the Chicago branch of the A. I. E. E. and the American available, for it is not and Metallurgical Engineers. It output of any industry D. F. (three guesses at the in-power supply that is half, respectfully submitted: uncertain duration.

Opinions as to what dep the Sale of Electric Power We know, however, that it is to furnish power to the coal-con- build power plants for mining and conditions: interruptions are rare, and it would contained herein to the has a right to expect the same a the producer such a utility company. There are, of e producer. This amount apt to cause and which no commerl constitute any and all futile requests on the part of the consumer whereby he shall request better service or lower rates. The consumer shall pay to the producer the full amount of the producer's demands and in addition thereto shall pay for the power consumed at the rate of 8c. per kilowatt hour when the crooked line on the meter chart forms a convex curve, 6c. per kilowatt hour when the line forms a concave curve, and 4c. per kilowatt hour when the line is so badly blurred that neither the producer nor the consumer is in a position to bet real money on the shape of the line, it being specifically understood and agreed that under no circumstances shall the consumer question the accuracy of the producer's meter or other apparatus.

4. The diversity factor shall be anything that shall divert the attention of the consumer from making complaints to the producer. If, for instance, the consumer's electrical engineer shall make presentation to take the form of playing golf and his average score on the four Saturday afternoons in any one month shall be less than par for the course on which he plays, a reduction of 1 per cent shall be made in the producer's bill for power in that month for each stroke that the aforesaid average shall be under par.

5. In recognition of the fact that the consumer could produce his own power more economically with a poorer grade, the producer agrees that a test shall be made four times a year of the heat value of the consumer's coal. If such tests shall show that the consumer's coal is of higher heat value than that which the producer uses at his power plant, the producer may, if he feels so inclined, make such a rebate to the consumer per 100 B.t.u. as to convince the consumer that it is more economical to buy power than to make it.

6. Recognizing the fact that the rates per kilowatt hour, as stated in the third paragraph, are entirely too high, the producer agrees to rebate 5 of the first $100, $25 of the next $100, $50 of the next $200 and as much of the remaining amount of the bill as is necessary to make the net cost to the consumer equal to an amount of between 12c. and 2c. per kilowatt hour, the producer agreeing that he will get all he can without giving the customer any real cause to figure on generating his own power.
Study of Stresses and Design Of Head Sheaves For Coal-Mine Shafts

BY J. S. WATTS
New Glasgow, N. S.

Excessive Weight, Especially in the Rim of Head Sheaves, Causes Slip in Rope—Effect of Lead—Cooling Action of Spokes in Casting Rim—Design of Bosses—Fit of Hub

SHEAVES used on the headframes of mine shafts to support the hoisting rope ordinarily are made with a cast-iron rim and hub, and wrought-iron or steel spokes cast into place. This type of construction is practically universal. It affords a neat and economical pulley and has proved very successful with the low speeds and light loads formerly used. Unfortunately the stresses imposed on the various parts are not well understood and have not received the consideration that they require.

This has resulted in pulleys being used for speeds and loads that soon wear out both themselves and the rope. In the past small pulleys, intended for light loads and low speeds, could be designed with more or less success by rule of thumb, but now that the ropes used are becoming much larger, and consequently require pulleys of greater diameter, it is necessary to reduce the rotating weight of the pulley to the lowest safe limit consistent with the strength required, in order to decrease the inertia.

Even when a pulley of the type described is made as light as is consistent with safety the high velocities and rapid acceleration and retardation now demanded sometimes render it impossible to prevent the rope from slipping a little on the pulley at the beginning and end of each trip. The hoist is brought to rest so quickly that the inertia in the rim of the pulley is sufficient to keep it revolving after the rope has come to a stop. Unless this inertia can be reduced, by cutting down the weight in the pulley rim, this slipping cannot be prevented.

The evil effect of this slippage is obvious. It wears the rope always at the same point or at any rate so long as the rope is not moved on the drum of the hoist. The wear on the pulley rim is continuous and rapid, as it occurs four times during each round trip—that is, during both the acceleration and braking periods.

Some engineers have attempted by fitting wood, leather or other soft material into the groove of the pulley to prevent this wear on the rope. This expedient doubtless reduces this wear, partly by reason of the increased friction between the rope and the pulley and partly because the softer material takes all the abrasion. Nevertheless, it has been found that this packing wears out so rapidly that it must be replaced frequently, making a sheave thus packed costly to maintain. Only in the event that the weight of the pulley cannot be reduced sufficiently to eliminate this slippage should this expedient be adopted.

By careful calculation it can be determined whether the rope will slip on the sheave. To avoid this slipping the energy in foot pounds stored in the rim of the pulley when revolving at the maximum velocity must be less than the force required to overcome the friction between the rope and pulley, in pounds, multiplied by the distance travelled by the rope, in feet, during the braking or acceleration periods. The energy in the pulley rim in foot-pounds will be \( Wv^2 \) 64.32 where \( W \) = the weight of the rim in pounds, and \( v \) = the maximum peripheral velocity of the rim in feet per second, this latter being practically equal to the speed of the rope.

**Sheave Travels Slower or Faster than Rope**

During the acceleration period the rope must supply this energy to the rim through the friction between the two and it must be returned from the rim to the rope by the same medium. This friction will equal \( LfS \) pounds. Where \( L \) = the load on the rope at the pulley during the period under consideration, \( f \) = the coefficient of friction between the rope and the pulley. The distance through which this force acts equals the length of rope wound or unwound during the acceleration or braking period under consideration. This expressed in feet we will term \( S \).

To prevent slipping, therefore, \( Wv^2 \) 64.32 must not exceed \( LfS \), or the maximum weight that the pulley rim should have, if slippage is to be avoided, is \( W = 64.32 \frac{L}{fS/v^2} \).

The coefficient of friction, \( f \), may be taken as 0.1, the rope usually being greasy and the groove in the pulley smooth. Care must be taken in using the above formula
to select figures applicable to the worst condition or that usually existing when the cage is being lowered empty.

If the weight of the rim as designed by this calculation proves to be much too heavy, it may be reduced most readily by decreasing the diameter. This reduction, however, increases the wear on the rope, which suffers severely when bent around too small a pulley. The velocity, \( v \), is not altered by reducing the diameter as it must perform be the same as that of the rope.

**Finding Diameter That Will Reduce Wear**

The point to be decided, then, is with what diameter will the sum of the wear due to slipping and that due to bending be a minimum. In general the diameter should be as large as it can be made without danger of slipping. Consequently the rim should be as light as the load will permit because when such is the case the allowable weight may be used to increase the diameter of the sheave as much as possible. The wear and tear on the rope that slipping causes will be much more destructive than that resulting from bending. The total wear will be at a minimum when the pulley is as large as it can be made, still keeping the weight below the point at which slippage would commence.

The procedure, therefore, to be followed in designing a new pulley should be to determine the maximum weight from the above formula and to calculate the section of the rim. Then, ascertaining the weight of this section per foot, we can arrive at the maximum diameter desirable.

If it proves impossible, under the speeds and loads specified, to obtain a pulley of reasonable diameter without inevitable slipping of the rope, an effort should be made to lengthen the periods of acceleration and retardation, because as the allowable weight of rim increases so does the length of these periods.

Generally speaking, this slipping of pulleys has been given little consideration by those responsible for their design, although its effect upon the rope and upon the sheave is extremely destructive and therefore deserves to be classed as the main consideration.

Sheave-rim sections are generally "designed" by rule of thumb or in proportion to some other dimension previously selected. I purpose to show later that they are almost always made much too heavy, and it is important to recognize that this excess weight merely shortens the life of the pulley.

**Rim Should Be Designed to Meet Conditions**

The shape of the rim as usually constructed is as shown in Fig. 1 and is evidently not susceptible of much improvement. The dimensions are dependent upon so many variables that it is impossible to give any empirical rules by which they may be calculated, meanwhile keeping the weight to the minimum. It is common practice to use the same pattern under any and all circumstances. This is, however, obviously a mistake, considering the higher speeds now in vogue.

Where the speed is so low that no slippage occurs, the weight of the rim is not of great importance, but under modern conditions it is essential that this weight be reduced as much as is safe. Each pulley, therefore, should be designed to suit the actual conditions under which it is expected to work. As the rims are swept in the foundry, no pattern is necessary and consequently the expense of casting a rim of new design is little more than that involved in using an old one.

The considerations which determine the section of the rim are as follows: The bottom of the groove should be machined to a radius slightly greater than that of the rope section. To avoid undue wear on the rope, even when it does not slip, the grooves should be smoothly machined from the bottom to a point about half way up the sides. Another good reason for machining this groove is that the rough casting always will warp and run somewhat out of true sideways. If this is not corrected by machining it may cause rope sway and result in the cage vibrating and rubbing hard on the guides.

The depth of the groove as well as its width at the top and the slope of the sides must be such as entirely to remove all danger that the rope will leave the groove, as such an eventuality, of course, would be disastrous. The width of the groove at the top and the slope of its sides must be such as to provide for the maximum lead angle of the rope. This is a function of the width of the hoisting-engine drum and of the distance from its center to that of the pulley.

This also usually determines the depth of the groove, but in cases where the cage is landed, and all stress taken off the rope, the groove must be deep enough to prevent the rope when slack from getting out of place. When the hoisting engine is well removed from the pulley, an additional allowance must be made for a possible swaying of the rope in windy weather.

**Side of Rim a Casting Problem in the Main**

The determination of the thickness of the metal in the sides of the rim is not based on strength but on the thinness with which it can be cast satisfactorily. The bead on the edge is for the purpose of insuring that there will be a rim in every part of the circle. If this bead were omitted and the flange of the rim run out to a comparatively thin edge, the metal would be quite likely to fail to fill the mold all around. In consequence the inequalities in the casting thus resulting would catch the rope and soon destroy it. The bead also stiffens the rim and reduces its liability to damage when being machined and erected. The size of this bead usually is left to the discretion of the foundryman, who decides how light he can make it and yet be sure of a good casting.

To determine the thickness of the rim at the bottom of the groove we must calculate the stresses imposed upon it and, if necessary, add metal at this point over that essential for the making of a good casting. The additional weight may be added with less injury at this point because most of the wear that takes place will occur here and also because weight at this point will have less energy when revolving than that located further from the center of the sheave.

At the same time the practice of making this thickness much greater than is required, in order to allow for wear, is wrong, as it defeats its own purpose by adding to the inertia of the pulley. Furthermore, it commonly causes sponginess in the casting, due to the thickness at this point being so much greater than that elsewhere. This sponginess does not usually become evident until the groove is slightly worn. Whenever it appears on the surface, however, the wear on the rope becomes so rapid that the pulley must soon be condemned.

The rim is subjected to the following stresses: A tensile stress due to centrifugal force, a compressive stress resulting from the load on the rope and tending to crush the rim, and a bending stress caused by the rope tending to take a straight line from the top of one
spoke to the top of the next. The centrifugal force is
\[ C = \frac{W^2}{32.16 R} \] where \( R \) = the radius of the rim in feet. The stress due to this force will be \( C_t = C/A \) where \( A \) = area of rim in square inches.

The compressive stress due to the load on the rope will be \( L_t = L/A \).

The tensile and compressive stresses due to the bending moment can be calculated from the formula for a beam uniformly loaded and supported at each end. This is:
\[ W = 8B_tZ/l \text{ or } B_t = \frac{Wl}{8Z} \]

Where \( B_t \) = the stress due to bending moment \( Z \) = the modulus of the section of the rim and \( W \) = the load imposed by the rope, which is determined from the triangle of force, as indicated in Fig. 2, where, as will be seen, the rope tends to take a straight line from one spoke to the next, but is prevented from doing so by the curvature of the rim. The downward thrust on the rim, \( w \), is equal to the pull on the rope, \( L \), multiplied by \( b/a \). (See Fig. 2.)

Centrifugal stress opposes the compressive stress when the pulley is running, but not when it is standing. The two compressive stresses \( B_t \) and \( L_t \) must be considered together. The two tensile stresses \( B_t \) and \( C_t \) also should be so treated, and whichever pair is the greater in proportion to its safe working stress will be the one that will govern the design.

The stresses \( B_t \) and \( L_t \) vary from maximum to zero during each revolution, and are therefore live loads. \( C_t \) is a stress gradually applied and gradually removed. The safe working stress for a cast-iron rim, under these conditions, may be taken at 4,000 lb. per square inch in compression, and 1,000 lb. in tension. The spokes should be calculated to carry their respective loads as columns fixed at both ends. This calculation needs no further comment here.

**If Spoke Enters Rim Bubbles Are Formed**

The connection between spokes and rim is often made as shown in Fig. 3, and is ill-advised, as the molten iron will almost always, when it comes into contact with the cold spoke, bubble and boil, and on solidifying, that portion around the end of the spoke will be full of blowholes. These do not show in the finished casting, but a little wear in the groove soon brings them to the surface. The effect of such flaws, in wearing out the rope, is disastrous, and will compel the scrapping of the pulley after only a short period of usefulness. Blowholes are caused by moisture from the molding sand, being deposited on the spokes. This turns to steam when the molten iron strikes it.

Polishing and tinning the spokes will reduce this deposition of moisture, but it is practically impossible to escape having blowholes at these points, and therefore the spoke should not project into the rim, but stop at its lower edge, as shown in Fig. 4. Even if there were no danger that blowholes would be formed at these points, the iron will be chilled at the end of the spoke, and when the groove is worn down to the hard spot thus formed undue wear on the rope will result. The shape of the spoke end is not of much importance, as it carries little load in tension. Probably the nearest way of insuring a mechanical hold is to swage grooves around the ends of the spokes as shown in Fig. 4.

The function of the boss cast around the spoke is to hold the end firmly, the spoke being considered as a column, fixed at each end. The boss must be rigid in order to do this. The actual stress that will come upon the boss is indeterminate, but as the total weight of the bosses can be only a small percentage of the weight of the pulley, an excess of metal at this point will do little harm. To make certain that the spoke will be held as a column, fixed at the ends, the end connection must be made sufficiently rigid to prevent any movement between spoke and rim at this point. This condition will be met if the connection is made such that its strength will be equal to the tensile strength of the spoke.

**Boss Must Embed Spoke for Ample Distance**

First, the bearing surface of the spoke in the boss must be made ample. Taking the crushing strength as twice the shearing, this condition will be fulfilled if the bearing area of the spoke in the boss is equal to one-half of the sectional area of the spoke—that is, the spoke must enter the casting for a distance equal to 0.5 of its diameter. In use this length would be insufficient to resist vibration, and it would be wise to make the connection strong enough to develop the full strength of the spoke in tension. Tests that I have made show that if the spoke projects into the casting for a distance equal to twice its diameter the grip of the casting on the spoke will be greater than the strength of the spoke in tension, even without any grooving of the end.

The diameter of the boss should be such as to give it the same strength in tension as the spoke. Taking the safe stress in tension for cast iron as 1,000 lb. and for steel as 10,000 lb. the area of cross-section of the boss must be ten times the area of the cross-section of
the spoke. This will require that the diameter of the boss be 3.3 times the diameter of the spoke.

The boss, for constructional reasons, into which it is not necessary to enter, should taper from 3.3 to 3.6 times the diameter of the spoke. The same dimensions, of course, will be necessary for the connection of the spoke to the hub.

Head sheaves frequently fail because the pulley becomes loose on the shaft and travels sideways along it. The cause of this difficulty is the side pull of the rope imposed as a result of the rope leading off the pulley at an angle when it is coiling on one or the other end of the drum. The side pull on the pulley rim is small, but it has a leverage equal to the radius of the pulley and, being reversed as each layer of rope is wound on the drum, it has the cumulative effect of a reversing stress.

This will be more clear from a study of Fig. 5, where it will be seen that any resultant force sideways on the rim has to be resisted by a reaction at the end of the hub on the shaft. Unless the hub is comparatively wide and the fit of the shaft in the bore is practically perfect the metal in the hub will crush slightly, the bore will become bell-mouthed, and ultimately the pulley will become loose on the shaft. If the shaft deflects under the load even if only a few thousandths of an inch, this crushing of the hub will be accentuated. Shaft diameters, therefore, should be carefully calculated to carry the load as a beam, with a stress not exceeding 6,600 lb. per square inch. As this stress on the shaft reverses during each revolution from a maximum compressive to a maximum tensile quantity any stress greater than that above mentioned will cause too great a deflection and ruin the fit of the shaft in the pulley.

For these reasons the hub of the pulley should be as long as possible and great pains should be taken to make certain that the bore of the hole be parallel out to the very ends. The tendency in machining a hole of this kind is to bell-mouth it slightly, and unless the bore is a good fit at each end of the hub at the start the pulley will soon become loose.

An effective method of preventing a movement of the sheave along the shaft which may happen even with a fair fit is to leave a collar turned on the shaft at one side of the pulley hub and to provide a split collar bolted to the hub and fitting into a groove in the shaft at the other side. On the other hand if the pulley is split a solid collar may be left on the shaft at both ends of the hub. The first of these methods is shown in Fig. 5, and the second does not need any further explanation.

Disk Coal Cutters Installed at Windber Mines

BY A. S. BROSKY*

Pittsburgh, Pa.

At Eureka No. 35 mine of the Berwind-White Coal Mining Co., at Windber, Pa., a cutting machine has been placed in operation which differs radically from those in use in other mines of the United States. It is an adaptation of the rotary-disk coal cutter which is extensively employed in Great Britain for longwall mining. This rotary cutting machine was designed by Harris T. Booker, mine manager of the company, and his son, R. E. Booker. At present other machines of this type are being built in the shops of the Eureka No. 35 mine.

The rotary cutter is a compact, wheel-mounted machine that weighs about 500 lb.—a surprisingly small weight for a machine of its class. Electric or air-operated coal punchers, adaptable to the same working conditions as this machine, weigh far more. Like the coal puncher, this cutter is adaptable to thin seams, especially those with rolling bottom, where chain machines cannot be used. No claims are made of its being practicable for use in thick beds except where the roof being bad timber must be set close to the face or where ribs and stumps in squeezed sections are to be withdrawn.

**MINIMIZES LOST MOTION AND VIBRATION.**

The principle of the mechanism is simple and the moving parts have ample bearing surface, so that there will be no unnecessary lost motion or vibration. Motive power is furnished by a standard 2-hp. series-wound direct-current motor inclosed in a cast-iron housing and controlled by a standard boxed-in snap switch. Although the motor covering is not provided with air ducts the temperature of the machine within has never risen beyond a safe limit. The motive power is transmitted through a 1-in. steel shaft incased in a substan-

tial, finned bearing tube that is firmly secured to the motor housing.

Because the shaft is underslung, its center line being but a few inches from the contact point of the carriage wheels, the machine is well adapted to undercutting. The resulting vertical flexibility increases its possibilities on a rolling bottom. On the motor end the shaft is actuated through a small cut-steel pinion and gear. On the head end the rotary motion is transmitted to the cutter plates through a small cut-steel bevel pinion and two gears that rotate in opposite directions. These gears are centered and bolted onto the cutter plates.

The cutter head proper is secured to the shaft tube by means of a sleeve held rigidly in place by two setscrews. This arrangement permits the head to be set horizontally for undercutting or vertically for shearing, this change being accomplished in a few moments by loosening the setscrews, swinging the head through 90 deg. and retightening the screws. The cutter plates

---

*Bituminous editor, Coal AGE.
are provided with bronze bushings that bear upon a heavy shaft and are held in place by washers and countersunk screws. This arrangement readily permits the removal of one or both cutter plates.

The bits used are similar to those of a chain machine and they are placed in the same relative position to one another. As shown in Fig. 1, the bits are secured by means of setscrews in radial slots of rectangular cross-section. Each cutter plate holds three outside clearance bits and two center bits. The bevel pinion imparting opposite rotation to the two cutter plates lessens the muscular effort on the part of the operator in directing the machine. The bits of the respective plates move toward each other and grip the coal.

Two marked advantages result from this action. The gripping tends to pull the machine toward the face, making the feed almost automatic. Practically no recoil is set up because the machine is held to the face by its own action. Consequently, as shown in Fig. 2, where the machine is set up for operation, no foot blocks are required. This removes one difficulty ordinarily encountered by the operator and enables him to concentrate his attention upon cutting. It must be conceded that hand-directed cutters may be handled more intelligently than those mechanically fed, and this advantage obtains to a greater degree where foot blocks are absent than when they are present.

CUTTER MOUNTED ON EIGHTEEN-INCH WHEELS.

When undercutting, the machine body rests upon a 1½-in. axle fitted with 18-in. truck wheels. Of course, for the purpose of shearing, wheels are provided that are of large diameter. The axle is located directly under the center of gravity of the body so that a perfect balance is obtained.

The designers of this machine contemplate several minor changes in the mechanism. These will include guards on the cutter head to prevent dust from getting into the gears, and a large shaft and supporting tube so that the depth of cut may be increased. The cutter plates will be made of larger diameter and the number of bits will be increased to eight on each plate. After these alterations the machine will cut with greater efficiency because of the increase in the number of blows or incisions per revolution of each cutter plate and the establishment of a longer fulcrum. The action then produced will more nearly approach that of a hand pick. The bits together with their slot arrangement also will be changed. The pronged center bit will be discarded and the pick-pointed cutter used exclusively. The bit stems will be straight instead of bent, the necessary side clearance being secured by slanting the bit slots.

LITTLE DUST, NO RECOIL AND LIGHT WEIGHT.

This machine has many merits hitherto unattained by other devices intended for the same purpose. These may be enumerated as follows: (1) It stirs up no dust and gives off no smoke or objectionable heat; (2) there are only four places to lubricate; (3) it makes cuttings similar to those produced by hand picks, there being no fine bug dust; (4) the control and operation is simple; (5) there is no recoil and consequently foot blocks are not required; (6) the weight is comparatively small.

By the aid of this machine headings may be driven with great rapidity, as the cuts can be made and loaded out in rapid succession, the loader of the coal also operating the cutting machine. In such work it will do the cutting about as fast as eight men with coal picks could do it. A simple construction and the entire absence of all electrical resistance, the motor being thrown directly across the line by means of a snap switch, render this machine peculiarly adapted to operation by unskilled labor, of which there is an abundance about the mines.

H. H. Stoek, of the University of Illinois, has been engaged by the Bureau of Mines to assist F. R. Wadleigh with the investigation of coal storage being made jointly by the Bureau of Mines and the Department of Commerce. While one of the objects of the survey is to have more exact data with regard to existing storage facilities, the main purpose of the work is to develop facts which will demonstrate the advisability of coal storage and thereby encourage it.
Practical Mine Ventilation

**MINING** ventilation has too often been treated from the point of view mainly of mine gases and of distribution of air, and the matter of production of air pressure has been left to the engineer. A few pretty pictures of fans have lightened the text of many former volumes on this subject, but the author, not being a fan expert, satisfied himself, or rather tried to rest satisfied, with the most meager details regarding the originating means for ventilation, mauger, it is true, of several pages on steam jets, furnaces and the trompe, which are wholly inadequate means of inducing an air current.

This book, written by J. R. Robinson, gives the fans its appropriate place without in any way being a catalogue of types. It supplies calculations in connection with the selection of fan size that will be of value to any reader who has to ventilate mines.

Interesting among his results are those on the correction of friction of air. Giving Atkinson's, Fairley's and Murgue's coefficients \( k \) as 0.0000000217, 0.00000001 and 0.000000009 respectively, Mr. Robinson adds: "These coefficients are the result of experience and are practical, but they can be used only by those who have a wide experience and knowledge of mining conditions. It will be observed that Atkinson's coefficient is nearly 2.5 times Murgue's coefficient. He does not know which coefficient to use on the particular mine that is the subject of the calculation. The author has had some mines come under his observation wherein the coefficient \( k = 0.000000069 \) and others where the coefficient \( k = 0.000000006 \), the last figure being less than 10 per cent of the former. The coefficient \( k = 0.000000006 \) will apply where a well lined shaft is present."

The book clearly shows the disadvantage of having a fan ill-fitted to the mine conditions. This is an important subject, and little has been written about it. It is fully time to get books written by manufacturers of fans to supplement those the authors of which are mine engineers, professors and theorists. The point of view is one that cannot be neglected with safety. Too often the manufacturer of mine equipment fails to publish what he knows about the practical problems of the mine, and the industry is the loser.

Interesting statements are that excessive quantities of air absorb the moisture of mine surfaces and make the mine dangerous, that large cavities in the roof of roadways simply result in baffling the air, that regulators are a great source of power loss, that the use of auxiliary fans is preferable and that these "boosters" serve to lengthen the life of primary fans. The use of regulators, so to speak, lays a tax on the whole mine so as to protect and make possible the ventilation of a split that is unusually difficult to ventilate. It is better to aid the air through that split than to burden the whole mine with an excessive water gage for that purpose.

In the case of the Federal Coal Co.'s mine at Grant Town, where it would have been necessary to use 11.87 in. of water gage to pass the 300,000 cu.ft. per minute needed in place of the 132,000 cu.ft. which 2.3 in. of water gage permitted to be passed, the management found a way to cut in an airway, and through this air current circulated, reducing the pressure 25 per cent. Other practical instances are given where attention to ventilation has made great economies.

A most valuable table is provided by W. H. Hall, of Coalwood, W. Va. He shows the most economical size of shaft, from 100,000 to 600,000 cu.ft. of air by 100,000 cu.ft. increments. Thus 100,000 cu.ft. of air calls for a 10 x 10-ft. shaft; 200,000 cu.ft., a 14 x 14-ft. shaft; 300,000 cu.ft., a 16 x 16-ft. shaft; 400,000 cu.ft., an 18 x 18-ft. shaft; 500,000 cu.ft., a 20 x 20-ft. shaft, and 600,000 cu.ft., a 22 x 22-ft. shaft. The depth of the shaft is taken as 100 ft., excavation is figured at $15 per cu.yd., concrete lining at $30 per cu.yd., life of mine at 50 years and power at 2c. per kilowatt hour.

Mr. Robinson has allowed himself to be a little discursive. He has several pages on the mechanical and historic development of the coal industry from its earliest beginnings. The story is well told and exceedingly interesting, for the coal industry is the mother of the mechanical arts. The steam engine, the pump, the railroad, the locomotive, and the fan were built largely for her service and by her engineers. The only misfortune is that having done so well in earlier years, mining engineering has been willing of late to be boosted from outside instead of by the exercise of her own activity.

This little volume, entitled "Practical Mine Ventilation," contains 225 pages measuring 5 1/4 x 8 3/4 in. and may be obtained from its publisher, J. R. Robinson, 6027 Jenkins Arcade Building, Pittsburgh, Pa.

Gas and Fuel Analyses

as part of the International Chemical Series appears a second edition of the book by Alfred H. White, professor of chemical engineering at the University of Michigan, on "Gas and Fuel Analyses," a book of 319 pages measuring 5 1/4 x 8 in. The main stress is placed by the author on gas analysis, liquid fuel having only 20 pages and coal, which is last in the train, having 86 pages committed to it.

Mr. White points out the difference in the heating value of coal which passes through the first instance of a furnace, that which goes through. The screenings gave, in all but one of the ten cases instanced, less heating value than the larger coal. In one instance—Blockton, Ala.—the screenings gave 1,646 B.t.u. less than the larger coal and in the Oak Creek (Col.) coal 1,366 B.t.u. more than the lump coal would give. The difference in each case is attributable to the impurity of the coal that has the lower heat equivalent. Screening the coal is therefore a practical method of raising the heating value of coal. In the second instance the lump had 15.07 and the screenings 6.97 per cent. Where the coal is cut in the clean part of the seam the fine coal is quite likely to be of superior purity, especially if floor and roof are of a character that they can be kept out of the coal.

The chapters on coal analysis give instructions regarding care of laboratory apparatus, sampling, analysis, drying, and the ascertainment of heating value, using Parr or other bomb calorimeters.

Housing for Coal-Mine Workers

Industrial housing has made large advances in recent years and the art of building suitable villages for operatives is a study in and by itself. Matter into it without any equipment for the work and may welcome a book by Morris Knowles on this subject entitled "Industrial Housing." The volume contains 408 pages measuring 6 x 9 in. It contains a historical review, chapters on fundamental preliminary considerations, on the selection of a site, on the development of the town plan, on streets and pavements, on water supply, on sewerage and drainage, on collection of town wastes, on gas and electric service, on houses for families, on other buildings, on the administration and supervision of construction and on the management of industrial towns.

The practice is to regard the cost of the house as the cost of housing. In three tables it is shown that the houses cost 70, 81 and 81 per cent respectively of the whole investment in three separate housing developments. Taking one instance—the first—the land cost 1.6 per cent; street grading, the same; street paving (tar-bound macadam), 3.7 per cent; concrete sidewalks, 1.7 per cent; waterworks, 3 per cent; sanitary sewers, 2.6 per cent; storm sewers, 1.1 per cent; supervision and engineering, 8.6 per cent, and interest during construction, 5.7 per cent—a total of 100 per cent. It is just as well to face the fact sooner or later that the house is only three-quarters of the problem.
Inspectors’ Institute Advances Art of Mine Safety

Proposes Uniform Underground Danger Signals—Urges Standard Methods of Sealing Off Abandoned Areas and of Gas Testing—Elects R. M. Lambie of West Virginia, President

BY E. W. DAVIDSON*

Some definite contributions to the art of making coal mines safe and to the business of keeping them so were made at the thirteenth annual meeting of the Mine Inspectors’ Institute of America, held in Chicago, July 11, 12 and 13. The Institute, after careful consideration in committee and after much earnest and expert discussion, made four recommendations for standardized methods which it hopes will be adopted and made uniform throughout the land. Also it adopted resolutions of sorrow upon the deaths, during the past year, of two charter members of the Institute, Thomas K. Adams, of Pennsylvania, and Walton Rutledge, of Illinois, father of Dr. J. J. Rutledge, mining engineer, U. S. Bureau of Mines.

Before final adjournment, the Institute selected Pittsburg, Kan., over Pittsburgh, Pa., as the place for holding the next meeting, July, 1923, and elected R. M. Lambie, chief mine inspector for West Virginia, president for the coming year, succeeding C. H. Nesbitt, chief inspector for Alabama. Twenty-two members of the Institute attended the meeting, many of them declaring at its close that the gathering had brought out its usual quota of good ideas and concrete results.

RECOMMENDS STANDARDIZATION OF METHODS

The four definite recommendations of the Institute of methods that should become standard were the following:

(1) That a new type of underground danger signal proposed be adopted.

(2) That worked-out and abandoned portions of mines either be thoroughly ventilated or sealed off with a masonry wall provided with a valve permitting periodic tests of the atmosphere within; and that such areas have vents drilled through from the surface.

(3) That tests for gas be made with a non-luminous flame, using a flame safety lamp of one of the types approved by the U. S. Bureau of Mines, and burning fuel also approved by the Bureau, for each specific type.

(4) That in cases where machine runners are equipped with electric lamps, men possessing certificates of competency as gas inspectors test every working place before a machine starts to work in the place, and make another test either during the machine run or immediately thereafter.

During the discussion that preceded the first recommendation much was said about the confusion which exists between parts of the country in the matter of underground danger signals. There are so many “codes” that men transferring from one region to another might easily misunderstand them, with disastrous results. There is a danger also in the effort commonly practiced to register the degree of danger that may exist, as “bad gas,” “little gas” and the like. Since gas is gas and since a man’s judgment of quantity may easily be in error and lead some foolhardy soul into deep danger where only slight danger is expected, the Institute held that the new signal proposed should be one that would make the nature of the danger unmistakable, but should not attempt to indicate its degree.

Hence the Institute recommended that in all mining regions an underground signal of the following description be made uniform: A square divided into four quarters by two lines drawn from opposite corners so as to cross at the middle. Each quarter of the square should be devoted to a single class of dangers: Thus, the upper left-hand quarter should be devoted to gas; the lower left-hand quarter to bad roof; the upper right-hand quarter to electric wires and the lower left-hand quarter to “blackdamp.” With this arrangement made uniform it would be possible for any man who is capable of making a cross to chalk up a danger warning that all would understand. If a man’s ability to write the English language was too limited to enable him to write “gas” or “bad roof,” or “electric wires down,” or “blackdamp” on the sign, he would merely need to put a cross in the proper quarter of the sign and the warning would be complete.

The sign could appear in any number of forms, either commercially manufactured or “home-made” of metal or wood, or merely painted or chalked or scratched on any prominent surface. The committee which brought in the recommendation for this sign consisted of V. E. Sullivan, of West Virginia; James Dalrymple, of Colorado, and Thomas Back, of Illinois.

In the discussion on how best to handle abandoned parts of mines the members of the Institute reviewed the laws and practices of various states and finally endorsed the present Pennsylvania practice, which is essentially that recommended to the whole country by the Institute. The committee which reported the plan for adoption was Dr. J. J. Rutledge, of Illinois; John G. Millhouse, of Illinois, and Frank Hillman, of Alabama.

The Institute continued its discussion of last year on standardization of inspection forms and received from a committee a model form containing a schedule of discounts based on the mining laws of Kansas. This schedule, of course, would have to be modified in accordance with the provisions of each state for use in that particular state. Ralph C. Becker, of Pittsburgh, Pa., told the Institute that the committee on standardization of coal-mine equipment of the American Mining Congress is advancing its work steadily and wants the wholehearted co-operation of coal-mining men everywhere. This committee, whose herculean job will last for about five years, will make an annual report at the next meeting of the Congress, to be held at Cleveland, Ohio, in October.

REAFFIRMS STAND ON USE OF MIXED LIGHTS

The Institute reaffirmed its position taken last year on the use of mixed lights in mines. It holds that portable electric lamps should be used for general lighting and flame safety lamps always for testing. C. L. Colburn explained a uniform plan for the collection of data on mine accidents and proposed a uniform report form for all states for the use of inspectors, compensation commissions and other such officials. After a discussion on the relative importance of subject matter in mine inspectors’ annual reports the Institute decided that statistics and conclusions on accidents and accident prevention were by all odds the most important, that production should take second place, and men employed, third.

A lengthy discussion on the relative merits of water and rock dust as preventives and restricters of explosions did not result in any definite recommendations by the Institute.

The full list of officers chosen for the year 1922-23 follows: President, R. M. Lambie, chief mine inspector of West Virginia; First Vice-President, W. E. Holland, district mine inspector of Iowa; Second Vice-President, James Sherwood, chief mine inspector of Kansas; Third Vice-President, James Dalrymple, chief coal mine inspector of Colorado; Secretary, J. W. Paul, mining engineer at the Pittsburgh Experimental Station of the U. S. Bureau of Mines, and who has been secretary since the conception of the Institute 14 years ago; Assistant Secretary, J. G. Millhouse, district mine inspector of Illinois; Treasurer, Frank Hillman, former district mine inspector of Alabama; Editor-in-Chief, J. T. Beard, associate editor of Coal Age, New York.

*Western editor, Coal Age.
Timbering in the Pittsburgh Seam in Ohio

Nature of Strata Overlying Coal—Avoid Breaking Topcoal—I-Beams Set in Hitches Cut in Drawslate Support Roof—Use of Concrete Blocks for Timber

Refering to the inquiry of "Mine Engineers," entitled "Timbering in the Pittsburgh Seam," published in Coal Age, May 25, p. 886, allow me to suggest a method of timbering that has been found satisfactory by some of the larger coal companies operating in the Pittsburgh coal, in Eastern Ohio.

Before proceeding, however, it would be well to specify more definitely the nature of the strata overlying the coal. The inquirer has given but a partial description of the character of the upper strata, which would hardly enable operators in other fields to fully appreciate the situation.

As has already been stated and as shown in Fig. 1, overlying the coal which averages 5 ft. in thickness, there is a 12-in. drawslate that is taken down as the working face is advanced.

Above the drawslate is a thin seam of coal varying from 4 to 27 in., in thickness. In most cases, this topcoal is marketable. It is overlaid with from 16 ft. to 18 ft. of limestone and shale, above which is the well-known "Redstone Formation." In working the Pittsburgh seam, what is of the first importance is to avoid breaking the topcoal, if that is possible. By that means, the air current is prevented from coming in contact with the shale and limestone. Experience has proved that if this thin upper coal can be held intact, the top will stay up without timbering from six to eight months. Where the mine is dry, indeed, the top has been known to stand for four or five years.

There are times, however, when the roof conditions are so bad that it is practically impossible to avoid breaking the topcoal and, in that case, it is necessary to adopt a suitable method of timbering on the roads.

A method that has proved most satisfactory is that shown in Fig. 2. As there appears, hitches are cut in the drawslate 8 in. wide and 6 in. deep. A 6 in. I-beam is then placed in these hitches and built up to the required height, by placing beneath each end of the beam one or more courses of common brick resting on top of the workable coal.

The use of steel I-beams in place of timber has proved to be the most economical, in the long run, although the initial cost is about one-third greater than for timber. But, it must be remembered that the life of timber, in this connection, is from six months to a year, while that of the I-beams is practically indefinite, as at least 50 per cent or more of these beams are recovered, on retreating.

Lagging to Support the Roof

As shown in Fig. 2, lagging is used above the I-beams to give better support to the roof. For that purpose, second-hand track ties are often used. Ties taken from low dump places are generally found to last longer than dry timber, under the same conditions.

Where the height to be timbered is greater than 12 in., it is necessary to use more brick under the crossbeams. In many cases, concrete blocks varying from 6 to 18 in. in length are made and brought into the mine to serve as legs for the support of the crossbeams. These blocks are usually made in large numbers so that a sufficient supply is always on hand.

In this method of timbering there is nothing to decay except the lagging, which is readily replaced when needed. Regarding a more satisfactory method of cutting the hitches than the use of a pick, it should be stated that the latter is commonly used. It is possible however, that the use of a "Little-Giant" chipping hammer, such as that manufactured by the Chicago Pneumatic Tool Co., and advertised in the eleventh Annual Equipment Number of Coal Age, p. 131 of the advertising section, may prove useful in that connection.

H. J. Griffith.

Piney Fork, Ohio.

Another Letter

Having had considerable experience in handling roofs under the conditions described in the inquiry relating to timbering in the Pittsburgh seam, kindly permit me to offer a few remarks that may be of interest.

In this connection, my first thought is that when contending with a soft roof of this character, it is not advisable to drive the entries 10 ft. wide, as indicated by the sketch presented in the inquiry.

Two Plans Suggested

My observation is, that, in cases of this kind, entries are never driven more than 8 or 9 ft. in width, and the timbers are set back into hitches cut in the ribs of the entry, where they will not be liable to be knocked out. I would suggest two methods, either of which would be applicable under the conditions described.

In the first place, steel I-beams could be used as crossbars for the support of the roof. Or, if available, heavy sections of old rails can be employed to advantage. These can always be recovered and used over and over again, when the road is to be abandoned.

A good plan is to make a hitch-hole, in the top above the coal, and a slip hitch-hole, in the slate in the opposite rib, using a good cap-piece on top of the coal, as a rest for the I-beam. Another method, which is commonly employed, is to cut hitches in the ribs for the posts on either side of the road.

Use of Jacks in Timbering

Where a large amount of timbering is to be done it would, no doubt, be convenient and greatly reduce the cost, if the timberman is supplied with two portable light jacks made out of pipes. These can be made by any handy blacksmith and will save time and labor in placing the beams or sets of timber, as the jacks can be made to hold the crossbars in place while the cap-pieces are being driven under the I-beams, or the posts fitted under the timber collars, as the case may be.

Regarding the suggestion of cutting the hitches by some other means than
Setting Post Timber

Need of setting posts firm—Conditions when roof and floor are hard—Effect of roof settlement.

REFERENCE was made in Coal Age some time ago, in answer to a question regarding the methods of setting post timber when both roof and floor are hard; and it was stated that one plan is to set the posts on a mound of dirt or other soft material that will yield when the post first takes the weight.

Long experience has taught me the need of setting a post firm. It strikes me that one of the possible reasons for this is that the timber is to be stood on any soft material such as dirt or slack. It has always been my practice to use a good cap-piece of soft wood that will enable the post to be driven tight and firm in its place.

THICK CAP-PIECES AND FOOT-BOARDS
AFTER reading the inquiry of "Mine Engineer" and his description of timbering in the Pittsburgh seam, I realize that his chief difficulty is the expense of cutting the hitches in the ribs, for the support of the legs forming a timber set.

The suggestion made by the editor in his reply, namely, to incline the short legs toward the center, has the advantage of reducing the work of cutting the hitches about one-half. In this case, the coal being 5½ ft. thick gives a headroom of 6 ft. under the collar, which eliminates what objection there might be to inclining the legs in this manner.

In my opinion, the cost of cutting hitches can be further reduced by making the cut wholly in the drawslate and resting the collars on top of the coal, instead of using the short legs mentioned. The collar should then be tightly wedged to hold it in place.

In Tennessee we have tried most of the different forms of timbering. One that we have found well adapted to conditions of this kind is to cut a good hitch in the drawslate just above the coal, on one rib. Insert one end of the bar in this hitch and rest the other end on a leg notched into the bar.

collars, wedged

AFTER the conditions stated as existing in the Pittsburgh seam, in Eastern Ohio, it is my judgment that different methods of timbering must be considered, and that form adopted which is found best suited to those conditions.

On all main and branch roads, I would recommend an electric mine-car compressor and air hammer, for digging the hitches in the drawslate above the coal. Coal should be placed in these hitches and tightened by driving small blocks or wedges in them and doing away with the posts.

On main roads, where the conditions might require or circumstances permit, I would use steel I-beams of a size suitable to carry the weight of the overlying strata. Where railroad ties were available, 6 x 8 in. or thereabout, these could be used for timbering on branch roads.

In every case, the distances of the timber sets or crossbeams must be determined by the strength and character of the roof to be supported. At times, I have used oak boards, for lagging above the collars. Where the width of the roadway will permit, it will often be found more economical to use full-length legs to support the collars, instead of cutting hitches and using short legs as mentioned in this inquiry of "Mine Engineer."

RICHARD MACDOUGAL
Pittsburgh, Pa.

Firebosses' Markings

Requirements of the Bituminous Mine Law—Purpose of making two marks in a place—Investigation made in absence of fireboss.

REFERRING to the discussion regarding the marks of a fireboss made on the face of the coal and destroyed by a fall of roof that occurred before the time for the men to enter the mine for work, allow me to refer to the Bituminous Mine Law of Pennsylvania, covering this point.

The law requires (Art. 5, Sec. 1) that the fireboss "shall examine for danger in all portions of the mine under his charge, and after each examination he shall leave, at the face and side of every place examined, the date of the examination as evidence that he has performed his duty."

The provision that a mark shall be made on the side of a place examined, in addition to the one made on the face, I believe is for the purpose of avoiding such a situation as is here presented. In my opinion, a fall of roof large enough to obliterate both marks could hardly take place within the three hours allowed, by law, for the morning inspection, without the place exhibiting some sign of danger at the time the fireboss made his visit.

Now, inasmuch as the law requires the fireboss to "examine for danger in all portions of the mine under his charge," no fireboss fulfills his duty, under the law, when he makes a test for gas and does not also make a careful inspection of the roof and the face of the coal and observe if any timbers have been discharged by the shots fired the night before, and note other dangers that may exist.

REPORT MUST SHOW DANGERS FOUND
In this instance, it may be assumed that a close inspection would have revealed broken timbers; or posts set contrary to the regulations of the mine; or an unsafe condition of the roof. As revealed, it shows the presence of slips in the roof. Any of these dangers, if found, should be entered on the report of the fireboss and prompt measures taken to avoid accidents therefrom.

Assuming that both of this fireboss' marks were destroyed, it is my belief that his report would reveal some form of danger such as I have mentioned, provided his inspection was properly made. The fact of any danger being noted in the report regarding the place would be sufficient evidence that the fireboss had been there the same morning.

While it is admittedly possible that a careful examination of the place did not reveal any apparent danger and the roof fell within the three-hour period following, such an occurrence would be unique, to say the least. In any event, justice to the fireboss demands that the circumstantial evidence there may be that he had examined the place in the regular routine of his duties.

The investigation that must follow such an occurrence should be made in the absence of the fireboss, who should not be permitted to enter the mine while the same is in progress. Every place in the district of which he has charge, should be examined in order, and his marks noted, as well as the condition of each place, in respect to danger. Assuming the investigation showed all other places properly examined and marked, I believe any jury of mining men would clear the fireboss of suspicion.

JOHN WALL, Sr.
Bayview, Ala.

ANOTHER LETTER

REGARDING the question of firebosses leaving their marks in each place examined, as evidence that they had inspected the place, allow me to refer to some incident in my own experience along this line. It may not be policy for a fireboss to place his mark on the roof, at the coal face, unless it is hard and firm, but I have known many such instances.
In one case, which was told to me a short time since, a miner who had been injured by a fall of roof at the face of his room, attempted to recover damages from the company, claiming that the fireboss had not inspected his place that morning and he was not warned of his danger.

It so happened that the fireboss had been accustomed to mark the roof of each place examined, instead of placing his mark on the face of the coal, as is often done. To prove his case, the fireboss got busy and cleaned up the fall. When a large rock, lying on the pavement, was finally reached and turned over the mark was found, showing the date and the initial of the fireboss.

Some will claim that the roof is not the proper place for a fireboss mark. Many place their mark on the timbers. I have known some to stand a shovel upside-down and hit the mark on the back of the blade. It is the custom of many firebosses and safety inspectors to mark a cross on a piece of loose top to indicate that it must be taken down or made secure with timbers. For this reason, if a fireboss should mark his inspection on the roof it may be confused with the mark indicating bad top, and it would be better to use other means of making the inspection mark.

BULLETIN BOARDS IN WORKING PLACES SERVE GOOD PURPOSE

Some years ago, while firebossing, I had bulletin boards prepared to facilitate and make legible my record of inspection. These boards were 12x18 in. and had a hole bored at the upper end so that they could be hung on a nail on a post. Each miner was made responsible for the keeping of his board. It was his duty to move the board back four or five posts before firing his shots at the close of the day, so that it would be out of danger from flying coal.

When making his rounds in the morning, the fireboss would move the board forward, mark the date and hang the board on a post next to the face of the coal to show that he had examined the place and it was safe for work. This method proved highly satisfactory to everyone. Whenever there is a hole in the roof or other place where gas might accumulate a mark should be made at the highest accessible point to indicate that a gas test has been made there.

Talk is cheap and life and health are valuable. Therefore, bad roof and other dangers should always be marked down in their presence.

Every fireboss should see that his mark of inspection is where a miner will see it on entering his place. Again, another mark should be made at the coal face or at any point of danger, to show that such point had been examined. Another fireboss must arrange to remove any danger found and prevent the men from entering the place until that is done.

Thomas, W. Va. W. H. NOONE.

Inquiries Of General Interest

Principles Relating to Post Timber

CONDITIONS in the mine where I am employed as timberman have been such as to require their special study. In one section of the mine recently developed, much trouble has been caused, owing to timbers being destroyed by the roof pressure, soon after the posts were set. The coal is 6 ft. in thickness and the seam generally flat and overlaid with a cover of shale, slate and sandstone, varying from 250 to 300 ft. in depth.

For some time, I have been seeking information regarding the essential properties of timbering rooms. My chief trouble lies in dealing with a hard roof and bottom. It has always been my practice to use good cap-pieces when setting post timber, but these do not seem to serve the purpose as fully as they should when the timbers take the weight.

TIMBERMAN.

One of the first principles that a timberman should learn to respect is the fact that when the coal is taken out from a portion of a seam, as in driving rooms and entries, there always follows a certain settlement of the overburden resting on the pillars. This is not a sagging of the roof over the opening, but a body settlement due to the weight of the overburden squeezing the pillars on which it rests.

This first or initial settlement of the roof is irresistible and no amount of

that post timber is never intended to carry the weight of the cover above it, which is far in excess of the strength of the timber. In Fig. 1, we have attempted to illustrate the condition that results from driving an opening in a seam of coal. The strain resulting from the taking out of the coal has the effect to crevice the strata above the opening, and the loosened material then overarches the opening, as indicated by the dotted line.

This overarchering of the roof acts to support the entire overburden above, throwing its weight on the pillars on either side of the opening, while the weight of the loosened material beneath the arch is held in place by the timbers set to support the roof. The height of the arching is wholly dependent on the character of the formation overlying the coal.

When setting post timber in a mine a practical timberman will never drive

a post tight, between the roof and floor, without providing a good cap-piece above, which will yield and prevent the crushing of the post, when the weight comes on the timber. This is particularly true when either the roof or the bottom, or both, are hard. If there is no yielding material provided to take up the first settlement of the roof, as here mentioned, the post will be destroyed by this irresistible pressure.

Some years ago, mine inspector Hepplewhite proposed a method of avoiding the destruction of post timber, by tapering the foot of the post. This method was very largely employed in England, but has never been used to any great extent in this country. A method that has been more commonly used in American mines, aside from providing a good cap-piece against the roof, is to set the post on a footboard placed on a low mound of

FIG. 1. OVERARCHING OF MINE ROOF WHEN DRIVING A ROOM

FIG. 2. MEANS USED TO PREVENT DESTRUCTION OF POSTS

Timber can prevent it. Its extent will vary with the depth of cover, thickness of seam, hardness of coal and ratio of pillar to opening. Calling the entire area, in a given section of a mine, A; and the area of opening, in the same section, a, the increase of roof pressure due to the taking out of the coal is in the ratio A : a, or A/a. One thing to be remembered is

...
dirt or slack, an inch or two in thickness. This method has a particular advantage in enabling the quick removal of a post when desired, by digging out the slack with a pick.

In the accompanying sketch (Fig. 2), is shown, at (a), the effect on a good cap-piece caused by the weighting of the roof. At (b), is shown the bottom portion of a post resting on a footboard placed on a thin mound of slack or dirt. Again, at (c), is shown the effect of tapering the foot of a post, when the weight comes on the timber. The furring of the tapered end of the post provides the necessary yielding that prevents the destruction of the timber.

A good rule to apply in post timbering is to make the diameter of the small end of the post, in inches, not less than its length, in feet. Thus, a 6-ft. post should have a diameter not less than 6 in., at the small end. This makes the post present an equal resistance to crushing and bending. In other words, the post will not be crushed by reason of having too small a diameter for its length, or bend by reason of being too long for its size.

It is important in setting post timbers in a flat seam to set all posts plumb. Otherwise, any movement of the roof has a tendency to discharge the post. In inclined seams, the right position of the post is nearly normal to the strata, the timber being slightly inclined up the pitch from the normal. This is done to counteract the tendency of the strata to slip downhill, and prevents the loosening of the post should that occur.

Examination Questions Answered

Bituminous(Pa.)Mine Foremen's Examination, Held April 11-13, 1922

(Selected Questions)

Question—(a) How many workable seams of coal are there in the district in which you are employed? (b) Give the local name of each. (c) What are the characteristics of the roof in each seam? (d) What name is given to the coal measures in which they occur?

Answer—(a, b, c) These questions must be answered according to the local conditions in any given district.

(d) The coal measures are known geologically as the "Carboniferous System."

Question—A ditch 18 in. wide and 12 in. deep is full of water. If the velocity is 2 ft. per sec., how many gallons are passing per minute?

Answer—The sectional area of the ditch is $18 \times 12 = 216$ sq.in. A velocity of 2 ft. per sec. is $2 \times 12 = 24$ in. per min. The quantity of flow is, therefore $(216 \times 1,440) \div 251 = 1,346.5$ gal.

Answer—1. No higher than medium voltage (300 to 650 volts) shall be used underground, except for transmission or for application to transformers or other apparatus where the high-voltage circuit is stationary. In gassy mines, high-voltage (exceeding 650 volts) transmission cables must be installed on intake airways, only; and high-voltage motors and transformers must be installed in suitable chambers ventilated by fresh intake air. All high-voltage lines and apparatus must be clearly marked to indicate their danger, the danger signals being placed at frequent intervals. Curves or signal wires must not exceed 24 volts.

2. Main and distribution switchboards must be made of insulating, incombustible material such as marble or slate and installed in as dry a position as possible. All switches or other instruments used in connection with motors or apparatus of more than 50-hp. capacity, shall be installed on a suitable switchboard with a 3-ft. passageway in front. Similar equipment, not exceeding medium voltage, or 50-hp., may be separately installed if mounted on an insulating base of slate or other material.

With high-voltage connections behind the switchboard, the passageway there shall not be less than 3 ft. clear, this space being properly floored and kept locked by a door, at each end, that can be opened from the inside without a key.

With higher than medium voltage, there must be no live-metal work on the frame of the main switchboard, within 7 ft. of the floor or platform, and the space before the switchboard must not be less than 4 ft. in the clear. Insulating floors or mats shall be provided for medium-voltage boards where live metal work is on the front.

3. Transformer rooms must be of fireproof construction. With higher than medium voltage, the entry circuit must be protected by an oil-break switch on each pole, equipped with an automatic overload trip. With medium voltage or less, each pole of the entry circuit may be protected by a switch and automatic circuit breaker; or fuses may be substituted for the latter, in case of lighting circuits and power circuits not exceeding 25-kw. All transformers must be provided with suitable ammeter, in either the primary or secondary circuits.

4. At the point where a branch leaves the main circuit, it must be provided with a switch of not less than 100 amp. capacity, on one side.

5. Where incandescent-lamp wires are connected to the trolley circuit, the lug of the trolley hanger must be drilled to receive the lighting wire, which is secured by a setscrew. The lighting wire must not be wrapped or tied about the stem or stud of the trolley hanger, and must be grounded to the track circuit. All lighting wires must be adequately insulated and stronged on porcelain or glass insulators, unless encapsled in pipes or other metallic covers. Separate uncased wires must be kept at least 3 in. apart, except where they enter the fittings and all metallic casings must be grounded efficiently.

6. All joints in conductors must be mechanically and electrically efficient and soldered, if possible; otherwise, a suitable screw clamp or other connector must be used. When the joint is covered, it must be of the same size as the same size as the rest of the wire.

7. All power wires and cables must be well insulated and firmly fixed in position, being supported at intervals not exceeding 25 ft. where their strength is not self sustaining. Unless protected by boxing, space must be maintained between them and the sides of the shaft.

8. Conductors other than trolley wires, on main haulage roads, must be protected by proper guards, unless kept at least 12 in. from any part of mine ear or locomotive. Unless provided with metallic covering, wire conductors must be hung on insulated fastenings.

9. On underground roads, trolley wires must be hung as far as practical to one side of the road and securely supported on insulated hangers, at points that will prevent a sag exceeding three inches, where the height above the rail is less than 5 ft. and the wire does not touch the roof when the trolley passes. All other wires except telephone, shotfiring and signal wires must be hung on the same side of the road with the trolley wire.

At all points where men must work on or near to the under trolley or bare power wires, less than 6 ft. above the top of the rail, such wires must be properly protected. All branch trolley lines must be provided with an automatic trolley switch, or section insulator and line switch, or a switch, other devices to cut off the current from the branch.

10. Both rails and main haulage roads must be bonded and cross-bonded, at points not to exceed 200 ft. apart.
Scenes at Salkeld Mine, Where Headworks Were Destroyed by Four Hundred Armed Strikers

At this mine, on July 17, four hundred well-armed foreigners attacked the men who were at work and killed the sheriff who, with deputies, was on guard. At least six of the attackers were killed. The mine is the property of the Richland Coal Co. and is located at Cliftonville, W. Va., near Avella, Pa., where most of the attacking party live. The picture on the top at the left shows the tangle and shed leading from the mine level. This was not destroyed. The illustration at the top on the right shows the drift mouth, which also apparently escaped injury. The two lower illustrations show the destruction wrought by the fire; that on the left shows the destroyed generator house. The attack was made on the sheriff, his deputy and twenty-one employees and deputy sheriffs, the first two having pistols and the others only riot guns and two rifles.

Pittsburgh Operators Announce Return to 1917 Scale Until Jan. 1, 1923

PITTSBURGH operators on July 20 posted notices announcing a wage scale effective until Jan. 1, 1923. The scale is that of 1917, known as the Washington scale, and is the one in effect during the months of 1919 prior to the strike of that year. In a statement given out by the association it is pointed out that under this scale loaders who worked steadily earned on an average $6.71 per day and that the average total earnings for nine months was $1,136.89. During the same period cutters had average earnings per day of $8.43 and the average total earnings for the nine months period was $1,491.16. These men worked 95 per cent of the time that the mine worked. Pick miners during the same period had average daily earnings of $7.60, and the average total earnings for the nine months period was $1,280.74. These men worked 92 per cent of the time that the mine worked.

Taking the first nine months of 1919 as a basis, it is found that for the corresponding period in 1920 the country produced 117.5 per cent while the Pittsburgh district produced but 83.8 per cent. In 1921 the country produced during the same period 85.4 per cent while the Pittsburgh district produced but 61.4 per cent, a great part of which was on contracts. The new scale will give the men steadier work and greater actual earnings at the end of the year than under the scale which was in effect during 1921, it is asserted.

Nearly All Coal-State Governors Pledge Aid to Harding

President Harding sent the following telegram at 6 p.m., July 18, to the governors of twenty-eight coal-producing states calling upon them to maintain order and protect reopened coal mines:

“The proposal of the Federal Government to the United Mine Workers and the various operators, whose mines are now open, to submit all questions in dispute to a national coal commission for arbitration, has been declined. The mine workers declined as a body. The majority of the bituminous operators pledged unqualified acceptance. The anthracite operators filed unconditional acceptance. A minority of the bituminous operators accepted the principle of arbitration but made specifications which could not be considered.

It was proposed that the operators and the mine workers in dispute should immediately resume coal production under the wage scales and working conditions which prevailed at the time of the strike on last April 1; that every question in dispute should go to a national commission to be composed of three representatives of the mine workers, three representatives of the operators and five representatives of the American people.

It was proposed to make the commission the final authority on all disputes until next March, and meanwhile the commission was to inaugurate a searching inquiry into every phase of the coal industry, in order to recommend the way to maintained understandings between workmen and employers, to promote steady employment and assure a continuous and ample fuel supply.

“The failure to secure the acceptance of this proposal for a voluntary adjustment left me no other course but to invite the mine operators to return to their mines and resume activities.

“I trust you will find it consistent to second this invitation, if you have not already done so, with the invitation to all miners and operators to resume their work. This invitation should be accompanied by such assurance of maintained order and the protection of lawful endeavor as will give assurance to everybody concerned. I want to convey to you in this message the assurance of the prompt and full support of the Federal Government whenever and wherever you find your own agencies of law and order inadequate to meet the situation.

“Your State Government and the Federal Government are jointly responsible for maintained conditions under which free men, willing to work, may work in safety. We are responsible for the production and the transportation of the fuel supply ample for the wants of the American people and the public utilities which serve them, particularly the railways engaged in interstate commerce. We must have ample coal to maintain industrial activity. We must have the coal necessary to the health, security and the activity of all the people.

“I recite to you these details because it is important to have them understood as far as the Federal Government and all going in seeking a voluntary adjustment. Thus far there has been no challenge of the right of workers to decline employment, or the right of the employers to hire as they elect.

“Our present duty is to guarantee security in the exercise of these rights, security in all lawful operations, and afford a safe opportunity for the production and distribution demanded by the necessities of the American people. A government can claim no part of a profit in the dispute between organized workers and organized employers. I do offer the only available agency which I know to effect a settlement, and these good offices have not availed.

“It becomes necessary, therefore, in the name of common welfare, to invite protection in the fulfillment of that obligation which attaches to an American industry engaged in providing any public necessity, and to afford security to all men alike who are ready and willing to work and serve the common need. No cause is so important as that of common welfare, and there must be the suppression of every unlawful hindrance to the service of that cause. To the task of lawful protection and the maintenance of order the Federal Government pledges to you every assistance at its command.”

In response to the President’s request for full protection to workers in opening and operating coal mines in their states, Mr. Harding received replies from nearly all of the twenty-eight governors promising the fullest cooperation. Governor Morrison of North Carolina and Governor Ritchie of Maryland were exceptions. Governor Morrison said that it would be vain for him to invite the miners to return to work, and he would not do so, anyway. Governor Ritchie declined to take the action suggested, declaring that the traditions of the state are “those of a people who settle such matters without bayonets or rifles.”

There is “no coal strike in Virginia,” Governor Trinkle telegraphed President Harding. “Our mines are operating,” the brief message concluded.

“Confirming my conversation with you,” Governor Sproul, of Pennsylvania, telegraphed, “I again beg to assure you of the full co-operation of the Government of the Commonwealth of Pennsylvania in your plans as outlined.”

“Indiana mine operators have been invited to resume operations,” Governor McCray, of Indiana stated. “Ample protection will be given to protect life and property.”

The message of Governor Morrow, of Kentucky, said: “Your position is unquestionably correct and should be unhesitatingly pursued. I will support and maintain it.”

“All resources of West Virginia,” wired Governor Morgan, of West Virginia, “have been and are available to afford protection to those who desire to engage in lawful employment.”

Governor Davis, of Ohio, telegraphed: “The full authority of Ohio has been and is ready to be marshaled into action, including the employment of all military or civil measures that are requisite.”

“All Kansas needs are being met,” Governor Allen, of Kansas, assured. “The Kansas Industrial Act forbids picketing of any kind, and there will be no difficulty in resuming full operations in the Kansas field.”

Governor McRae, of Arkansas, thought “the President’s message apparently requires no answer. Civil authorities seem to have the situation in the state well in hand.”

“Co-operation with President Harding and the federal authorities to the fullest extent” was promised by Governor Shoup, of Colorado.

Governor Kendall, of Iowa, pledged “every resource of the state to the support of the program you have inaugurated for the relief of the coal situation.”

“I am not apprehensive that any serious trouble will arise,” wired Governor Taylor, of Tennessee. “Should necessity require, we are absolutely able and will take care of the situation.”

Governor Robertson, of Oklahoma, said he would “co-operate fully” with the programme of the Federal Government.

“There is no trouble in this state,” Governor Hart, of Washington, telegraphed, “and I have faith in the operators and miners that no condition precipitating a demand for Federal interference will arise.”

“All coal mines are operating,” according to the message of Governor Mechem, of New Mexico, “and production is sufficient for all present needs.”

Governor Hardwick, of Georgia, pledged “full, prompt and wholehearted support.”

“Only one mine in North Dakota is affected,” the message of Governor Nestos, of North Dakota, stated.

Governor Hyde, of Missouri, promised “to take immediate steps to bring about production of coal in this state.”

“I am satisfied Utah will be able to handle the situation,” Governor Mabey telegraphed.

Governor Dixon, of Montana, wired: “There has been no disorder in Montana and I do not expect any.”
Ogle Urges Immediate Selection of Non-Partisan Commission to Investigate Coal Strike

The next important announcement on the coal situation expected from the White House is that covering the appointment of a coal commission to investigate the present strike and the coal industry in general. Decision of the President to name such a tribunal, notwithstanding failure of his recent mediation offer, was made by Mr. Harding in a letter to Mr. Sproul, of Pennsylvania.

Governor Sproul of Pennsylvania, sent the following telegram to President Harding on Thursday, July 20:

I wish to report strong public sentiment supporting my invitation to operators and union to a joint conference. I trust, however, that you are merely withholding the appointment of your commission because when arbitration was denied there was but one consistent thing to do, as I saw it, and that was to invite production. You may also have a reason of similar necessity as fuel and thereby jeopardize American life and happiness.

The President's reply, also dispatched July 20, was as follows:

The President's reply, also dispatched July 20, was as follows:

You are urged to select a commission now, and to proceed immediately with the work of investigation.

The President's reply, also dispatched July 20, was as follows:

You are urged to select a commission now, and to proceed immediately with the work of investigation.

Operators of Southwest Reiterate Readiness To Negotiate New Wage Scale

The southwestern interstate coal operators' association has addressed a letter to John L. Lewis and to George L. Pek, John Wilkinson and Arch Helm, district presidents of the union, asking for a joint conference. The letter, dated July 22, 1922, and signed by H. N. Taylor, president of the association, follows:

The southwestern interstate coal operators' association met your representatives in interstate conference March 23 and again on April 19, 10, and has reviewed the wages and conditions of working in the southwestern states. We have been discussing the南方的 wage scale for the southwest and the economic and competitive conditions of surrounding states.

We believe that the operators of the southwest have made every effort for the negotiation of a wage scale and have been called upon to bear the loss and suffering to due to which the operators, political and economic conditions that have influenced the United Mine Workers organization.

We have now conferred with the operators of the southwest and have met with them in conference, and we believe that the operators of the southwest and the economic and competitive conditions of surrounding states have been affected by the mining in the southwest and the economic and competitive conditions of surrounding states.

The operators of the southwest have not attempted to bear the loss and suffering due to the mining of the southwest and the economic and competitive conditions of surrounding states. They have not attempted to bear the loss and suffering due to the mining in the southwest and the economic and competitive conditions of surrounding states.

Farrington and Lewis Come to Parting Ways; Separate Settlement Seen

St. Louis, Mo., July 25—Frank Farrington, Illinois mine union president, has called a meeting of his executive committee to confer with operators in this city on Wednesday, July 26. It is rumored that a settlement is to be made with John L. Lewis, and that Farrington will arrange a separate settlement with operators in the Illinois field.

The Illinois operators' scale committee was in session in Chicago all day Monday. Rice Miller, president of the Illinois Operators' Association, said after the meeting that he saw no ray of hope for an early settlement. Farrington was in Chicago all day Monday but declined to make a statement.
Government to Control Prices and Regulate Distribution of Coal; Priorities Ordered

BY PAUL WOOTON
Washington Correspondent of Coal Age

Washington, D. C., July 25.—A plan for the settlement of the coal strike in the soft coal fields providing for the guarantee of a minimum wage to mine labor with a minimum of 280 days work per year has been offered to the miners and operators, it was stated by officials at the White House today.

It was not announced whether the miners or the operators had been given opportunity as yet to consider the plan and official announcement is withheld until both parties have been approached as to its workability. It will be recalled that a minimum wage guarantee was one of the suggestions made by John L. Lewis last autumn as a solution of the union miners’ troubles.

Senator Borah, chairman of the Senate Committee on Labor, today introduced a resolution calling for a commission to be appointed to inquire into and make report to the Congress on the advisability of nationalizing the coal industry.

The Interstate Commerce Commission this afternoon issued two priority orders affecting coal, both part of the program of the government to control distribution. One provides that priority be given coal in the distribution and loading of open-top cars and the other provides that in the movement of freight coal must be given preference and be shipped by the most direct route to its destination. Both orders follow the style of those of 1920 and are numbered consecutively with those of that year.

Extracts from Service Order No. 23, effective July 26, follow: “That in the supply of cars to mines upon the lines of any coal-loading carrier, such carrier is hereby authorized and directed to place, furnish and assign such coal mines with cars suitable for the loading and transportation of coal in succession as may be required for the following purposes and in the following order of classes, namely: Class 1—For such special purposes as may from time to time be specially designated by the commission or its agent therefor, and subject thereto. Class 2—(a) For fuel for railroads and other common carriers, and for bunkering ships and vessels; (b) for public utilities which directly serve the general public under a franchise therefor, with street and interurban railways, electric power and light, gas, water and sewer works, ice plants which directly serve the public generally with ice, or supply refrigeration for human foodstuffs, hospitals; (c) for the United States, State, County or Municipal Governments and for their hospitals, schools, and for their other public institutions, all to the end that such common carriers, public utilities, quasi-public utilities and governments may be kept supplied with coal for current use for such purposes, but not for storage, exchange, or sale. “Class 3—As to each coal-loading carrier which reaches mines in Pennsylvania, Ohio, West Virginia, Kentucky, Tennessee and Alabama for bituminous coal consigned to any Lake Erie port for transshipment by water to ports upon Lake Superior and subject thereto. Class 4—As to all such carriers by railroad, commercial sizes of coal for domestic use and subject thereto. Class 5—Other purposes.

No coal embraced in Classes 1, 2, 3, or 4 shall be subject to reclassification or diversion except for some purpose in the same class or a superior class in the order priority herein prescribed.”

DISTRIBUTION and rationing of the available coal supply by the government under the direction of Secretary Hoover and the Interstate Commerce Commission, along with plans to prevent profiteering by withholding cars from mines which charge exorbitant prices, having been declared legal by Attorney General Daugherty on Monday, July 24, the plan will be put into effect within a few days.

The plan tentatively drawn up follows:

(1) A committee in Washington, to be appointed by the President, will consist of representatives of the Department of Commerce and Industry, the Interstate Commerce Commission, the Department of Justice, and the Department of the Interior, to be designated the Presidential Committee. This committee will have general supervision of the measures to be taken hereunder and to authorize the execution of some of these measures as may be necessary from time to time.

(2) The Administrative Committee, comprising representatives of the coal-producing potential counties, will consist of operators, representatives of the railways, and, where necessary, representatives of the larger consuming groups.

(3) The President will appoint a representative in each coal-producing district.

(4) The President or the Committee will appoint a committee of operators in each district to be nominated by the district operators’ association or independent operators (in case of failure of the operators to take such action the Presidential Committee may appoint such operators as they see fit on such committee). The members of these district committees will be changed as determined upon by the Presidential Committee.

(5) The Presidential Committee will co-operate with the Interstate Commerce Commission and the preferential orders issued by the Commission.

(6) The governmental representatives in the districts with the co-operation of the district committees shall advise the agencies of the Interstate Commerce Commission as to local coal movement to effect the purposes of this plan.

(7) The operators will proceed with their usual business until they are affected by preference orders.

(8) It is expected that the district committees under authority of the Presidential Committee will recommend the allotment of cars of coal, to conform to the basis or basis of price determination shall be applied to all consumers, and those affecting the coal trade.

(9) The president of the order, or in his absence, pending further consideration by the Interstate Commerce Commission, the Department of Justice, of the Interior, and the Department of Commerce.

After agreeing to the government’s tentative plan the representatives of the operators returned on Tuesday to their districts, where an effort will be made to obtain their endorsement by a majority of the operators of the districts.

If a majority cannot be obtained a committee for each district will be appointed by the President’s committee. The plan will apply to all districts where a consequential amount of coal is being produced and will include anthracite, if any production is obtained.

Secretary Hoover stated on Tuesday that the Attorney General is positive that it is entirely legal to give preference to the public by a majority of the operators of the districts.

No coal can be obtained by a group of operators in the center of the western Kentucky field are adhering to the maximum price of $3.50, despite the fact that some of their fellow operators sold coal on Monday as high as $13.

Secretary Hoover pointed out that no money is available for the organization of which the government has set up. He intimated that legislation may be required to furnish the necessary appropriation. He called attention to the fact that the priority plan would displace contracts.

C. E. Bockus was elected chairman of the operators’ committee. The Department of Justice was represented at the conferences held at the Department of Commerce.

Mr. Hoover was present at the conference, which was attended by members of the Interstate Commerce Commission, and the Director General of Railroads Davis were parties to the conferences, as were officials of the American Railway Association. George Otis Smith, director of the Geological Survey, and A. H. Holbrook, acting director of the Bureau of Mines, also participated in the conferences.

Whether or not the administration asks it, there is certain to be an effort, before this session of Congress closes, to put through fact-finding legislation and possibly legisla-
tion giving the President special powers to be exercised in case of an emergency.

A question just now receiving the attention of administration officials is just how far the responsibility of the federal government goes in rationing coal. Some are of the opinion that when the needs of the domestic consumer, of the railroads, of the public utilities and of certain food industries are met there should be no further effort to apportion any remainder among other users, on the basis of their essentiality.

While regret is expressed that the President called the operators and miners together at the time he did, and that after getting them together he failed to outline definitely just what would be covered by his proposed action, there is general agreement that the situation since the first conference deadlock. Frequent claims were made during the conferences by some of the operators that the strike was about to begin to disintegrate when the federal government interfered, thereby giving the strikers encouragement. Some operators said they were just on the point of producing coal when the conference was called. Nearly all of them contend that production was all that was needed to start up their mines. Since arbitration had been declined it is believed by many that the President was justified in sending the operators home to give them an opportunity to make good their claims that they could produce enough coal to meet the situation.

It is admitted that the chances were much against the operators being able to produce enough coal in union territory to ride over the situation even if there had been no railroad strike. Some contend that the time was too precious to gamble any of it on such a hopeless plan. The tightening up of the rail strike dissipated any such chance as may have existed and incidentally gives the operators a good excuse for not trying to carry out the hazardous plan to which they were committed.

The responsibility of the state governors is the President but they give little indication that coal will be produced. The most encouraging reply was from the Governor of Michigan, who tried moral suasion, only to be told that the mines could not be opened without the consent of John L. Lewis. The only alternative is to take over the mines, so the Governor telegraphed the President asking his advice as to how this could be done. The latest advice indicates that the mines cannot be taken over until after the Legislature has been called into session. In addition, it would be necessary to have appropriations to furnish operating capital. If the Michigan mines were taken over the principal value of the move would be in the establishment of a precedent, since the state produces only 6 per cent of the bituminous coal it consumes.

Governor Sproul, of Pennsylvania, acted promptly and sent troops but he emphasized the necessity for keeping the arbitration proposal alive.

The responses from the governors indicate clearly that the strike cannot be settled by force. Even were the federal government to comply with the request of the Governor of Iowa that troops be sent to protect the state's mines, it would be a dangerous thing to do, all admit. Indiscretion on the part of an irresponsible federal soldier might precipitate a grave crisis.

Talk of taking over mines by the federal government has almost died out during the last few days. The realization that all the larger mines would have to be operated, if a sufficient quantity of coal were to be produced, brought up a train of problems in addition to that of policing the vicinity of those mines. If the government were to furnish the working capital, arrangements would have to be made for the use of several hundred millions of dollars and the setting up of a gigantic business operation. The only other way to handle such a situation is to co-operate for the time being, the mines are in private hands and the President now has no legal authority for the co-operation with one of the parties to the strike can be foreseen. Even the matter of protecting properties presents unusual difficulties in such fields as those of Illinois and Indiana, where there are no housing facilities at the mines. Before the federal government could even start to seize a mining property it probably would be necessary to declare martial law.

Production has been reduced to the point where the situation is hurrying to its climax. The one thing which might precipitate a settlement, and it is admitted that it is only the barest sort of possibility, is a separate peace in Illinois.

Even if there were no railroad strike, transportation troubles of a serious character would be certain to ensue in an effort to supply the territory north of the Potomac and Ohio rivers, which consumes 80 per cent of the coal output, from mines south of that line.

Bituminous coal must be mined at the rate of 12,000,000 tons a week for the next six months if all requirements of the country are met. It is evident, even if the effects of the shopmen's strike are overcome, that no such production can come from the non-union fields and from the weaker outlying union districts. The operators' pre-strike estimate of 6,000,000 tons of production from non-union territory has not been approximated, when one considers the average production during the sixteen weeks that the strike has lasted. The highest production obtained in a single week since the strike began was 5,360,000 tons, during the twelfth week. Production now has fallen to the point where it promises not to exceed 3,600,000 tons this week.

Deferr Assigned-Car Hearing Till Aug. 14;
Guthem and McAluliffe Testify

TO COMFORM with the desires of both the carriers and the operators of coal mines, the Interstate Commerce Commission has postponed further hearings in the assigned-car case until Aug. 14. This action was taken at the completion of the testimony of A. G. Guthem, principal witness for the carriers.

Mr. Guthem presented an imposing array of facts and figures intended to prove that assigned cars are essential to a regular and adequate supply of railroad fuel. He admitted that there is a human element to consider in the situation which does result in some misinterpretation of the rules and in some inequality of treatment, but he contended that the disadvantages are far outweighed by the advantages of the system.

Mr. McAluliffe testified briefly. He opposed any use of assigned cars or of private cars. He said cars should be distributed according to the ability of each mine to load. He took issue with the argument that assigned cars are necessary to keep the railroads properly supplied with coal.

Upper Potomac Operators Deny Car Shortage;
Intimidation Hampers Operation

SHARP issue is taken by operators of the Upper Potomac field with the statement of Governor Ritchie, of Maryland, to the President in which he said, "The Upper Potomac mining district continues partial operations but is handicapped by the railroad strike, which prevents coal being shipped from the mines."

"Governor Ritchie's wire to President Harding regarding Upper Potomac district being handicapped by railroad strike incorrect," John F. Palmer, secretary of the Upper Potomac Coal Operators' Association, says. "No car shortage in district since strike began. Five hundred surplus cars available today, also sufficient motive power."

To this Secretary Palmer has added the statement that "There never has been a car shortage in the Upper Potomac field since the strike began. It is not a question of car shortage but a question of intimidation of striking miners against men who want to work. There is a surplus of cars on the Western Maryland R.R.

Operators in the Georges Creek field, having had no protection against intimidation and violence, have engaged in no general effort to get back to a normal basis nor do they intend to do so in the absence of military protection, no matter what may happen, it is said.
Sixteenth Week of the Coal Strike

EDITORIAL REVIEW

Following the break-up of the peace moves of President Harding in the coal strike when on Monday, July 17, the announcement was made that the miners and a portion of the soft-coal operators had rejected the plan of Mr. Harding to put the mines back at work, there have been no important developments in the situation. On Tuesday the President sent a call to the governors of 28 coal-producing states saying that they give protection to such men as volunteered to return to work in the mines under the invitation that had extended to the operators to “return home and open the mines.” So far no mines are reported to have been opened under this program and as the days pass there is less likelihood of any important increment to production by this route. The hard-coal producers are not disposed to hazard their valuable top works in an effort to get out coal even if sufficient men could be induced to enter the mines. The Pittsburgh operators are said to be actively seeking to open a few mines and in the newly created “open-shop” areas, as Kanawha, progress would be more rapid than it is were it not for transportation disability on certain roads.

An investigation is being made by Attorney General Daugherty to determine whether the rail and coal strikes are sympathetic strikes. There appears to be a relationship between the rail and coal strikes, but whether it is conspired or instigated I cannot say,” said Mr. Daugherty. C. J. Albaisin, Commissioner for the Pittsburgh Vein Operators Association of Ohio, states that eastern Ohio operators intend to obey the mandate of the government to resume mining operations, but he qualifies this statement by adding that the policy of the eastern Ohio operators has not yet been definitely fixed.

Mr. Frank Ledvinka, president of the miners’ district for eastern Ohio stated that if any attempt were made to reopen the mines before a settlement is made he would call out the union pumpers and maintenance men who have been working since the strike began.

Two developments of the week served to stiffen the morale of the strikers in the non-union fields of central Pennsylvania. The first was the rejection of President Harding’s arbitration proposal by the mine workers because all operators in the county were not brought within its jurisdiction, after the strikers here had about reconciled themselves to be left “holding the bag” after the union miners and operators got together. The second was the calling out of the guardsmen. While that was done by the Governor to prevent any disorders it will be impossible to convince the strikers it is said that the soldiers were not brought into the coal fields in an effort to force them to go back to work.

As a possible solution to the coal difficulties Senator King, of Utah, on Friday, July 21, introduced a resolution in the Senate proposing the appointment of a commission of five members by the President to investigate the strike and related problems in the coal industry with a view to their solution. The Senator does not specify the manner in which the commission shall be appointed, leaving it to the discretion of the President.

At Hampton Roads the situation has shown little improvement over a week ago. Shippers who had steamers under charter have many of them exercised their option of cancelling, receipts of coal at the piers having become so undependable. The output of the smokeless fields has been very much affected, and since these districts were caring for the Eastern situation measurably well until July 4 buyers are quite apprehensive. A few interests have been offering spot coal. At low prices and freight charges, the Hoover level having been left far behind, once demand tended to exceed supply. Something of a fleet has accumulated at Hampton Roads, where a few weeks ago the accumulation was one of coal rather than of ships. Prices as high as $7.50 and $7.75 f. o. b. vessel at Norfolk are said to have been realized within a few days.

Sproul Calls Troops to Maintain Order
In Pennsylvania Bituminous Region

GOVERNOR SPROUL of Pennsylvania, signed an order July 20 detailing the 104th Cavalry, 52d Machine Gun Squadron and Motor Transport Co. 110, of the National Guard, to active service in the bituminous coal region of the state. The troops 1,110 in number, entrained July 20 for service at strategic points in Washington, Westmoreland, Cambria, Indiana and Somerset Counties, under command of Colonel E. J. Stackpole, Jr., of Harrisburg, commander of the 104th Cavalry. A proclamation was issued by the Governor calling upon the constituted authorities and the citizens to aid in seeing that order is kept.

Coal and Coke Production Suffers
Slight Setback in Connellsville Region

During the last week there was a slight falling off in the production of coal and coke in the Connellsville coal region, due to the action of the government in the coal strike and the condition of the Baltimore & Ohio R. R. brought about by the railroad strike, cars being scarce.

The following companies are operating, mostly on a considerably reduced output: Pittsburgh Steel Co., at about 10 per cent of normal; W. J. Rainey, Inc., about 10 per cent; American Coke Co., about 10 per cent; Western Columbus Coke Co., about 10 per cent; Locust Hill Coke Co., about 60 per cent; Reliance Coal & Coke Co., about 20 per cent, Consolidated Coke Co., Connellsville Central Coke Co., Hoover Coal & Coke Co. and Republic Iron & Steel Co. each at about 10 per cent; Poland Coal Co. and Redstone Coal & Coke Co., about 15 per cent each; American Manganese Co., about 50 per cent; Mather Collieries Co. and Crucible Fuel Co., about 30 per cent; Buckley Coal Co., Iron-Byrdsville Coal Co., about 25 per cent; Locust Hill Coal Co., about 50 per cent; Fancy Hill Coal Co., about 50 per cent; Walnut Hill Coal Co., about 50 per cent; Penn-Pitt Coal Co., about 25 per cent; Westmoreland-Fayette Coal & Coke Co., West Point Marion Coal Co., Atlantic Coal Co., Harrah Coal Co., Rich Hill Coal Co., Southern Connellsville Coke Co., W. J. Marshall and McIntyre Coal Co., about 75 per cent; Diamond Coal & Coke Co., Hillman Coal & Coke Co., Franklin Coal Co. and Forsythe Coal Co., about 50 per cent; Locust Hill Coal Co., about 50 per cent; Penn-Pitt Coal Co., about 25 per cent; Westmoreland-Fayette Coal & Coke Co., West Point Marion Coal Co., Atlantic Coal Co., Harrah Coal Co., Rich Hill Coal Co., Southern Connellsville Coke Co., W. J. Marshall and McIntyre Coal Co., about 75 per cent; Diamond Coal & Coke Co., Hillman Coal & Coke Co., Franklin Coal Co. and Forsythe Coal Co., about 50 per cent; Locust Hill Coal Co., about 50 per cent; Penn-Pitt Coal Co., about 25 per cent; Westmoreland-Fayette Coal & Coke Co., West Point Marion Coal Co., Atlantic Coal Co., Harrah Coal Co., Rich Hill Coal Co., Southern Connellsville Coke Co., W. J. Marshall and McIntyre Coal Co., about 75 per cent; Diamond Coal & Coke Co., Hillman Coal & Coke Co., Franklin Coal Co. and Forsythe Coal Co., about 50 per cent; Locust Hill Coal Co., about 50 per cent; Penn-Pitt Coal Co., about 25 per cent; Westmoreland-Fayette Coal & Coke Co., West Point Marion Coal Co., Atlantic Coal Co., Harrah Coal Co., Rich Hill Coal Co., Southern Connellsville Coke Co., W. J. Marshall and McIntyre Coal Co., about 75 per cent; Diamond Coal & Coke Co., Hillman Coal & Coke Co., Franklin Coal Co. and Forsythe Coal Co., about 50 per cent; Locust Hill Coal Co., about 50 per cent; Penn-Pitt Coal Co., about 25 per cent; Westmoreland-Fayette Coal & Coke Co., West Point Marion Coal Co., Atlantic Coal Co., Harrah Coal Co., Rich Hill Coal Co., Southern Connellsville Coke Co., W. J. Marshall and McIntyre Coal Co., about 75 per cent; Diamond Coal & Coke Co., Hillman Coal & Coke Co., Franklin Coal Co. and Forsythe Coal Co., about 50 per cent; Locust Hill Coal Co., about 50 per cent; Penn-Pitt Coal Co., about 25 per cent.

Midwest Region Seeks Ways of Getting
Back to Work; Michigan is About Ready

CoAL-MINING states of the Middle West are trying their level best to accept President Harding’s “invitation” to return to work and get out the coal the country needs. Michigan thinks it will soon be producing—at least for state and municipal use. Indiana and Illinois are hamstrung by the statutes on the books of each state, which, in effect, prevent the mining of coal by non-union men. The question is can these two states shake themselves free from those statutes? In Indiana Governor McCrory is making a try at a state settlement of the coal strike before action enters against the statute. He invited operators and mine leaders to confer with him in Indianapolis Tuesday, July 25, with the hope of getting somewhere.

In Illinois Lieutenant Governor Sterling, in the absence of Governor Len Small, is doing some talking, but little else.
He announced he had asked Frank Farrington, president of the state miners’ organization, to meet him. Mr. Farrington denied any such invitation, though he declared he would do anything he legitimately could to aid the Lieutenant Governor in any plan he might have to end the strike.

Business organizations of Illinois are loudly urging that a special session of the Legislature be called at once to repeal the miner’s qualifications act and that thereafter the operators open the mines with non-union labor under state protection. Letters asking for a special session have been sent by the Illinois Manufacturers’ Association and the Illinois Chamber of Commerce. They also suggest that the special session take up the question of establishing a state constabulary. The Chamber of Commerce, in its letter to Governor Small, requests him to demand that President Harding call a special session of the Legislature within 48 hours, to submit the strike questions to arbitration if they cannot settle them themselves, and to resume mining not later than Aug. 1 on some sort of temporary basis if no permanent one has been worked out by that time.

Michigan proposes to go ahead in spite of the solemn utterances of John L. Lewis, International mine union president, that miners there will not go back to work unless the state gets the permission of the union. Governor A. J. Groesbeck, having received no assurance from Washington that federal power will support him in a plan to seize the mines, has appealed to the miners to mine coal for public institutions if for nobody else. He gave them until Monday night the 24th to answer, implying in his message that the state would act if they did not.

Coal Shortage Begins to Strike Home

In Northwest and Middle Regions

At last the home folks are beginning to feel the pinch of the coal shortage throughout the territory west of Indiana. Heretofore the strike’s effect has been felt principally by railroads and large industrial consumers. But with transportation lines sagging—partly for lack of fuel—with electric light and water and gas plants all publicly figuring in the number of days they can run before shutting off service and with retail dealers turning away the first waves of people who want to buy their winter’s coal at once, the cold facts of the strike are sinking home.

In Missouri there is considerable quaking on the part of the public. St. Louis public institutions are within a few days of the end of their coal supplies. The Governor of Missouri is considering a coal apportionment board for the state and the Mayor of St. Louis is planning a coal service for the city. Throughout Illinois many a small public-utility plant is preparing to fall back on the large public-service companies. Railroads are cutting off more and more trains—because of coal shortage primarily, the officials assert—and boat lines on the Lakes, notably that operated by the Buffalo Steamship Co., have reduced schedules, thus cutting down the flow of shipping. Public institutions in Chicago, however, are supplied for at least 45 days and many of them longer.

Senator King Preparing Bills to Settle Strike; Mediation Commission Proposed

Senator King, of Utah, who was one of the Senators who conferred on the coal strike recently with Samuel Gompers, head of the American Federation of Labor, is preparing to introduce before the end of the month, unless the coal strike is ended, bills designed to meet the situation. One proposes an investigation of all the phases of the strike, with a view of determining which side to the controversy is at fault, and to expose it to the public with a view of bringing such public pressure as to force yielding on their part, which would operate to settle the issue. Another bill is prepared that a commission shall be appointed by the President to adjudicate the controversy. In connection with the strike it is said that the Shipping Board can operate vessels sufficient to import from foreign countries as much as 500,000 tons of coal a month if importation of coal has to be resorted to.

U.S. Commerce Chamber Members Asked To Support Harding Resumption Plan

Julius H. Barnes, president of the Chamber of Commerce of the United States, in a letter of July 20 called upon all members of the organization to take active steps in support of the program which President Harding has urged upon the governors of the coal-producing states.

Efforts at national arbitration in accordance with the proposal of the President having failed, Mr. Barnes points out that not only must law and order and the right of every man to work where he pleases without molestation be maintained by states and local authorities, backed up by the federal government, but that the settlement of the underlying controversy over wages and working conditions is now in the hands of governors and state authorities. Such settlements are imperative, he declares, if the country is not to experience suffering for lack of fuel when the cold weather sets in and industries are not to close down, thereby creating widespread unemployment.

Campaign of Frightfulness Unearthed Following Killing of Sheriff Duval

Simultaneously with the news of the trouble near Wellsburg, W. Va., when early in the morning of July 17 a mob of striking miners from Avella, Pa., attacked the Cliftonville mine of the Richland Coal Co., in Brooke County, and killed Sheriff H. H. Duval, announcement was made by West Virginia state officials that they had discovered and were investigating a statewide campaign of frightenedness planned by a secret organization, the dynamiting of a train of miners in Boone County being regarded as the first evidence of this plot. Under radical leadership and incendiary speeches, striking miners are being urged to tear down the flag and take the law into their own hands and the situation in West Virginia is a serious one.

Companies That Suffered in Herrin Riot File Suits Against Williamson County

The two companies principally involved in the June 22 massacre of non-union men working at the Southern Illinois Coal Co.’s mining area, Herrin, Ill., have filed suits against Williamson County to recover $217,000 for property damaged by the uncontrolled mobs of attackers. The Southern Illinois Coal Co. asks $200,000 and the Hamilton Lester Coal Co. $17,000 for its steam shovels blown up during the attack. None of the families of the 19 men killed by the mob has filed suit against the county. Under the law, as interpreted by an attorney for the coal companies, each family can recover up to $5,000.

Utah is Calm; National Guardsmen Stay On the Job; More Men Digging Coal Now

Things are very quiet in the Utah strike area, but nothing has been said so far in official circles about recalling the National Guard. Most of the strikers have been disarmed now, it is believed, and it would seem that the danger of the conflagration feared a short time ago has passed. More men are being taken on at the mines, but so far no concerted effort has been made to break up the strike, and the miners’ leaders profess to be confident of victory.

Announcement Was Made by the Pennsylvania Coal & Coke Corporation, with headquarters at Cresson, Pa., upon the return of the president, T. W. Watkins, that it has accepted the proposal of President Harding of July 10 for the resumption of operations at its mines which are located in various parts of Cambria County. Mr. Watkins has been the representative of the Central Coal Association in the negotiations at Washington and as the association has been against the acceptance of the proposal, Mr. Watkins has withdrawn as the association’s representative.
PRODUCTION

and the Market

Weekly Review

WITH a speed that takes away the breath, coal prices last week soared to levels no one ever expected to see again after the orgy of 1920. Consumer demand is now centered on a very small tonnage, for, of the coal that is getting over the strike paralyzed rails a large portion is going on short and to a lesser extent long term contracts. The majority of the spot coal reaching the market is priced at the level pegged by Secretary Hoover in June and it is a smaller portion that is rising to the bait of the long green held alluringly before the eyes of the operators by the hungry buyer.

Coal Age index of mine prices of bituminous coal rose sharply to 460 on Monday, July 24, a gain of 139 points in a week. The average spot price corresponding was $5.57, compared with $3.89 a week previously. Western Kentucky, a district that did not enter into a price agreement with Mr. Hoover, led the procession, prices for that coal reaching $11.50 on Saturday, July 22, after a series of sensational jumps averaging a dollar a day for a week. Eastern coals were but little lagged, high volatile registering $11 on Monday, July 24.

British Coal Bought Heavily for Import

The feature of the week was the wholesale purchase of British coals for importation. Not that the price on this side has been a bar to imports for some time past but that opinion suddenly crystallized in the belief that the strike had yet a long course to run and that the reserves in this country are so low that several months must elapse before demand dies down, prompted this stampede to the British Isles. Within a week after the run began not less than 500,000 gross tons of English coal had been bought and ships chartered. In fact it is lack of ships that has halted the movement. A short time only will be required, however, to condition and get into English ports all the ships that are required to carry over the coal that can expeditiously be unloaded on this side. Railroads, public utilities, industrials, jobbers and even steamship companies are now in the game, which promises for the free-lance all the excitement, profits, and chances of loss eventually found in the export game in 1920.

Production of bituminous coal lags with the blighting effect of the rail strike, which, according to John Lewis, has quite by coincidence been most effective on those roads serving the non-union coal fields which have been the mainstay of the country's coal supply so far throughout the coal strike.

To make as effective as possible what little coal is trickling through the rail strike lines and to hold down the price, the government at Washington is working out a scheme of rationing and price control that is planned to go into effect this week. The railroads and utilities are to be the first to get coal with certain other essentials. Beyond that the coal will not go far for the needs of some of these are becoming increasingly urgent. At the present rate there will be a sorry looking coal pile in Uncle Sam's back yard on Sept. 1. Coal shortages in the past in this country have been more or less myths existing in the minds of consumers,
but this time, unless the miners get to work very, very soon, the absence will be real. A shivering lot of citizens will be hovering around the gas range or warming their toes by some neighbor's fireside this fall. The coal industry will come in for a lot of verbal fixing by these same citizens.

BITUMINOUS

Traffic congestion on the railroads has so interfered with the movement of freight that the production of the non-union coal fields has been and still is shrinking. Preliminary reports to the Geological Survey for the week of July 19-22 indicate a new low record of around 3,600,000 tons, as compared with the maximum in the twelfth week of the strike of 5,363,000 tons. The Survey notes that "In comparison with normal years the present deficit in production is even more marked. Final returns on the fifteen week of the strike (July 10-15) show 4,114,000 tons of bituminous coal and 31,000 tons of anthracite, a total for all coal of 4,145,000 tons. In the corresponding week of 1921, a year of depression, the total quantity raised—anthracite and bituminous—was 9,280,000 tons; in 1920 it was 11,500,000 tons. In other words, considering anthracite and bituminous coal as a common source of supply, the present weekly output is from 5,000,000 to 6,000,000 tons below normal."

"The cause of the decrease was unmistakably traffic congestion on railroads serving the non-union fields. In Southern West Virginia and Eastern Kentucky from which the bulk of the country's supply during the strike has come, almost every field reported acute transportation disability. In Virginia, Western Kentucky and Tennessee the absence of coal support was less serious and in Alabama and the Far West it increased."

"The trend of production is shown by the following table of cars loaded daily. On Monday railroads reported loading 12,657 cars, a decrease of 2,437 cars below the preceding Monday. By Thursday loadings had dropped to 10,800 cars, the lowest on any Thursday since the strike began."

"The reports so far indicate no significant change in the number of men at work. Production in non-union Pennsylvania during the first half of the present week showed a slight decrease from the week preceding."

Some impatience is being shown in official circles in Washington by the action of New England and the Northwest in again demanding preferential treatment in the matter of coal supply. Until very recently, coal went begging at the Lower Lake ports and some 300,000 tons recently had to be shipped back from Upper Lake docks to other buyers because the Northwest would not pay the price required.

New England uses less coal than the Chicago industrial area, yet its demands are heard above those of all other sections. New England, sooner or later, will have to put up with the inconvenience of burning bituminous coal, one official said. He thinks it would be better for New England to burn a much larger proportion of soft coal this winter and send such reduced amounts of anthracite as are available to non-union sections which had not such a favorable opportunity of securing bituminous coal.

Lake dumping dropped last week to 138,438 tons, of which 16,038 tons were vessel fuel and 122,800 tons were cargo coal. This compared with 170,000 tons the week previous, 236,000 tons the week before and 370,000 tons the week ended July 2, indicates the rate at which the Lake movement is slumping. Vessel fuel is so scarce and so high-priced that boats in the ore trade are being threatened with a tie-up and passenger boat schedules are already cut. Of the slightly more than 4,000,000 tons of Lake cargo coal this year but 80 per cent has gone to normal destinations.

Movement of both hard and soft coal through the New England gateways continues at the low rate of past weeks, averaging around 400 cars of anthracite, nearly all steam Pits. A drop of about 50 cars of bituminous through the port of Boston will soon drop even below that figure. The full effect of the shortage in the East will show up as soon as canal en route has passed the gateways.
COAL

Production of beehive coke recovered after the July 4 holiday but is still below the rate of output in June. Blast furnaces are depending on byproduct coke coming from supplies of coal mined and stored before the present drop in production.

(a) Excludes screenings and breezes.

To make the coke produced, it is estimated, required 4,429,000 tons of coal, of which 3,707,000 tons was used in byproduct ovens and 722,000 tons in beehive ovens. The present monthly rate of consumption of coking coal is thus about 1,500,000 tons above the 1921 average but is still 2,429,000 tons below the average in the year of maximum demand, 1918.

COAL AGE

July 27, 1922

COKE

ANTHRACITE

Dealers in hard coal are rapidly clearing up their yards and in but few is there anything but pea coal. The supply of the unprofitable coke in swindling and two companies have withdrawn prices and longer take orders. When that stage is reached the boards are about bare. Nearly four months of production have been lost with no prospect of mine resumption and no opportunity of making up lost time, for the hard coal mines are normally run at full capacity for 12 months each year to supply the ordinary demands of the householder. The lack of steam coal will also prove embarrassing in the East.

A new weekly statistical service just inaugurated by the Geological Survey and appended herewith, shows weekly shipments from each of the major producing fields. The figures are based upon reports furnished by the railroads, giving the number of cars loaded for shipment at the mines on each railroad track. These figures of rail shipments are not identical with production, for they do not include water shipments, sales to local trade and mine fuel. Still more important, they do not include coke made into coke, which absorbs a large fraction of the output in the Connellsville district and a smaller fraction in other districts.

The grouping of railroad divisions corresponding with coal-producing districts was done by W. P. Ellis, of the Department of Commerce. The groupings used for the principle fields are shown by the footnotes, which apply to the table.
Buying of British Coal for American Needs Proceeds Rapidly; Price Reported at $9

BRITISH coal to relieve the shortage in the United States became a reality last week, when, following the refusal of the miners to arbitrate, it appeared a certainty that the strike in this country is not to be settled at once. Buyers and wholesalers here have hesitated to take a chance on bringing in foreign coal, with a two-week minimum haul, so long as there was any chance of early resumption of mining. Now that all hope is gone and the shortage produced by the railroad strikes has become acute, buying of British coal has been rapid.

In the first ten days not less than half a million tons were bought and within a few days all available bottoms had been chartered. The U.S. Shipping Board ordered all ships in foreign waters suitable for coal cargoes to the British Isles and promised to recondition and send abroad all boats needed for this trade. At present it is boats and not coal that is putting the brake on importation of coal, for Britain’s supply is ample and prices are easy.

The Shipping Board has set a price of 7s. per ton for freight and this with the current Cardiff price would put in New York Harbor for around $7.50 per gross ton. On Monday, July 24, there were reports that the price had mounted to $9 per ton.

A. S. Demand Aids British Industry.

Production in Great Britain during the week ended July 8 was 4,598,000 gross tons, according to Cable "Coal Age," as compared with 4,530,000 tons in the week preceding.

Considerable inquiries are being received in South Wales from the United States, Canada, and the West Indies. This is stimulating Continental buyers who recently have been holding back in hopes of lower prices. Newcastle reports business brisk on American inquiries for all descriptions.

During the earlier part of last year it was common assertion, and a true one, that the high cost of coal in Britain was retarding industrial recovery. Since then prices have been brought down to a point at which neither the miner nor owner is receiving adequate remuneration. The mining industry has done a great deal more than its fair share toward accelerating the revival of trade, and it can give no more.

For some months past the attention of producers and manufacturing has been directed toward the railways for relief in lightening the burden upon industry. They have submitted what is admittedly an overwhelming case for substantial reductions in transport charges, but unfortunately they have derived small satisfaction from their representations. The railway companies have so far conferred little more than their blessing on a war-stricken country. What reductions they have conceded, viz.: a 12½ percentage reduction and a lowering of the flat rate from 6d. to 3d.—amount to about a quarter of what is considered necessary to restart trade.

Publish French Prices; Demand Up.

Publication of the new prices of the Nord and Pas-de-Calais has momentarily increased the demand.

These prices, which particularly in the Paris area, are still higher than those of British imported coals—are provisional prices which were fixed pending the solution of the present conflict between operators and miners and the granting of lower transportation rates on coal.

It has been reckoned that to stem the rush of British coals French coal should be 20 frs. cheaper. One hour's extra work in the mines would decrease the cost by 10 frs. a ton. It is to be hoped that French miners will be sensible enough to listen to the dictates of reason and to agree to an increase of their effective underground working time from 61 to 71 hours.

Production was 2,588,000 metric tons in May, as compared with 2,479,000 tons in April; May output of coke was 82,000 tons, 2,000 less than the April figure. While briquette production was 212,000 tons, as compared with 190,000 tons in April.

Coal Paragraphs from Foreign Lands

ITALY—The price of Cardiff steam first was quoted at $86, $8 for July 21, according to a cable to "Coal Age." This is probably a revival of coal in the Ruhr district during the week ended July 8 was 1,629,000 metric tons, according to a cable to "Coal Age."

Hampton Roads Market in Turmoil.

The market was in a turmoil last week, with supplies rapidly diminishing and ships being diverted for lack of coal. The N. & W. piers are almost at a standstill because movement of coal over that road has been cut down to a minimum by the railroad strike. Schooners and barges pressed in service to carry coal coastwise when the rail strike began, are now lying idle in large numbers. As coal grows scarcer and quotations rise until the average price of coal this week lay between $7 to $9 for all grades.

The market was so nearly demoralized because of absence of coal to sell, that a fixed price list was impossible. Large supplies of Navy coal, held at the Naval Operating Base, were being considered for their availability to be released in the emergency to serve merchant ships.

Big Buyers and Consumers
Ward Off Panic Prices

Scarcity at Piers Causes Small Users to Offer Any Price—Railroads, Utilities and Municipalities Order English Coal—First of British Product to Arrive in a Week.

NOTHING but the extreme care being exercised by the larger consumers and buyers of coal has so far prevented a price situation in this territory as panicicky as that in Chicago. There is so little coal at the piers at New York, Baltimore and between (238 cars at New York piers, for instance, on July 24) that small consumers in need are offering any price to get coal.

Last week was notable for the sudden turn to buying of English coal. Railroads, public utilities and large industrials placed orders through their connections and some steamship companies are now reported to be undertaking importation on their own account. It will be a week yet before the first of the English coal reaches these shores and it will not be available in quantity until well into August.

NEW YORK

Lack of cars resulting in a shortage of coal was in part responsible for a rapid advance in quotations during the week. It rose as much as $1.25 and the quality of the coal offered was hardly considered.

An additional feature was the placing of orders for tonnages estimated at 100,000 tons by local houses for English coal, some of it for immediate delivery and some for August. It was figured out that this coal would be brought into New York harbor at a figure close to $7.50 c.i.f.

Public utility corporations are well supplied with coal, according to reports filed with the governing commissions.

Southern coal, because of the low production due to the lack of cars, is not being brought here in large tonnages. Quotations ranged as high as $10.50, New York harbor.

On July 21 there were 376 cars at the local piers, much of which was on contract and quickly taken away. The great majority figured in purchases and quotations ranged around $10.

Quotations changed frequently and buyers were forced to act quickly if they wanted coal. At the end of the week Pittsburgh steam coal was quoted around $6.50 f.o.b. mine; and gas coal $1 higher. While Allegheny Valley coals were quoted $7.50, some purchases were reported as having been made at a much lower figure. Clearfield coals were quoted $6@$6.50.

Baltimore

As far as can be learned, no genuine attempt is being made to re-open the mines in Maryland under the protection plan of President Harding. Governor Ritchie, of this state, has refused to send men to protect the mines at this time, taking the ground that this action is not needed at present. In his communication to President Harding, he stated that one of the troubles of the Maryland situation is that the railroads were not supplying sufficient cars to the mines, but this has been vigorously denied in railroad circles. There is no export coal loading at this port, but some fuel is still being taken in bunkers; 11 ships took 2,921 tons in bunkers from July 1 to 20 inclusive.

Quotations of price for soft coal from mining regions show a sharp advance over a week ago. Quotations from openings in fields to the south of this point are all the way from $4.25 @6.25 per net ton.

Central Pennsylvania

Feverish activity characterized the market following the breaking up of the conference at Washington. Previous to that, the market was dull, many buyers holding off in the expectation that an agreement between the miners and the operators would bring about a resumption of production and a consequent reduction in prices.

B. & O. was being sold on July 18, at $4.75 and on July 19, went to $5, then to $5.25, with every prospect of going to $6.50. Coal is scarce due to the shortage of cars, there being none distributed by the B. & O. on any sidings during the closing days of the week. Prices on P. R. R. loadings range $4.75@5.25, more of which is being produced by small mines.

Just what move will be made to operate the larger mines remains to be seen. Several operators have posted notices that they will put into operation as soon as they can be gotten ready and a sufficient number of men employed to insure a steady output.

Philadelphia

The situation is pretty badly muddled. Little coal is coming to this market. Despite the scarcity it is somewhat odd to hear shipping houses advise that the number of inquiries are far less than they would expect under such a state of trade. However, there are many inquiries from mostly from the large consumer, and there are plenty of rumors of steel plants in this neighborhood about to close down.

Prices seem to have moved into the air during the latter part of the week; in fact, many houses are simply in a position where they have no coal to offer at all. Some of the coal they have put up given up trying to purchase fuel of any particular grade and is well content to take just coal. Despite the strongest kind of efforts to keep down prices, there is a tendency toward a runaway market.

Rumors of prices as high as $8 at the mines have been heard. However, even if sales are made at these figures they cover but a meager tonnage, as there is so very little free coal.

Largely users are making inquiries for prices on English coal, although some business of this kind has been placed. The price of the coal landed at the piers here seems to be between $8@9, and it is also stated that foreign coal is booked for arrival at local piers for delivery to interior points.

Fairmont

Mining was largely at a standstill during the second week of the rail strike owing to a general break-down of transportation facilities on the B. & O. Few cars were being placed except for railroad fuel purposes. Some of the work was reported to be done by the Western Maryland began taking loads at the rate of 75 a day from the Elkins Division of the B. & O. Inquiries for fuel were numerous but most operators were not in a position to make or assure deliveries.

Upper Potomac

Mines were not affected by transportation disabilities to as great an extent as in other parts of West Virginia, the Western Maryland being able to handle the tonnage originating on its own line as well some tonnage from the B. & O. A few more mines resumed operation. There was a heavy demand for coal in all pools.

South

Birmingham

General demand for all grades continues good and some difficulty is being experienced in placing some of the spot business coming in, as there is comparatively little free coal to be had. The buying movement has become more diversified. Inquiries come in from all general directions, both in home and foreign territory and sales are reported at a premium above the regular quotations.

Another consignment of 4,000 tons of gas coal was loaded at Mobile this week for Peruvian interests, going to Cali.

B. & O. is taking care of its own immediate needs, but the demand for good grade domestic coal is light. This is primarily due to the fact that the consumption of the hard grades has been conducted on a less vigorous scale than usual, and this has resulted in an increase of the inventory of such grades of coal on hand.

Output for the week of July 15, will probably reach 340,000 tons, although much time has been lost throughout the district account of poor car supply and transportation service.

Virginia

The rail strike has operated to reduce production such curtailment growing out of the inability to move large loads promptly. The rail strike is about capacity production since there is an excellent market. Producers are generally adhering to $5.50 for mine run.

Anthracite

Clean-Up of Leftover Hard Coal Now in Sight

Withdrawal of Prices on Pea Fore-shadows End of Storage Piles—Householders Active in Market—Importance of Early Booking.

TWO of the larger companies are reported to have withdrawn prices on pea coal and others are expected to follow soon. When pea is no longer available from company storage the last of the leftover hard coal will be in the hands of dealers, and very soon thereafter, of householders.

Orders are being booked with assurances that when the mines resume the coal will be delivered in order of booking.

No attempt is being made, and none is expected to be made, by the operators in the hard-coal regions to resume work without the consent of the union, despite the assurance of the Governor that protection will be afforded to all who want to work.

NEW YORK

As the headlines in newspapers tell of a prospective coal famine consumers are aroused to the existing situation and are looking around for coal for the coming winter. Retail dealers are kept busy telling their customers there is no coal to be had, excepting pea, and that there is no telling when it will be produced.

While most dealers within the city limits are nearly out of the domestic sizes line dealers and those on the outskirts of the Greater City have a fair tonnage on hand.

Pea coal is moving rapidly. This is the only size the companies have and their large piles are rapidly disappearing.

Some independent buckwheat was offered here around $5, f.o.b. mine. River barley was quoted $2@2.25, a slight advance over the previous week. Because of the rapid increase in quotations for bituminous coal the demand for this size strengthened considerably. Loaded boats of buckwheat were reported at $7.50@$7.75, alongside.

BOURBON

Retailers' stocks in the large cities are being rapidly depleted. Practically no distributor in Boston is in position to make deliveries to householders of more than a ton or two at a time of either broken, egg, stove or chestnut. What small reserves there are the dealers are saving for hotels, hospitals and other necessary uses, rather than for dwellings, where no heat will be required for at least 60 days.

At wholesale the only size now being offered in any quantity is pea. Within a few days two of the large producing companies have withdrawn prices even on that size, and are no longer willing to obligate themselves for shipment. Certain of the anthracite roads are absorbing tonnages of pea for locomotive use and prices are likely to stiffen materially during the coming week.

BALTIMORE

The anthracite situation is tense. At this writing the city is about 250,000 tons short of the usual amount either already delivered to consumers or in the yards here. As the strike apparently is still a tight affair the dealers of Baltimore figure that there is going to be tremendous difficulty in supplying consumers even with moderate needs next autumn. Except for a small quantity of pea coal now in the yards, dealers have swept clear of supplies. Consumers are now growing restive and are calling up their retail supply connections in an effort to assure delivery of coal at present, then before cold weather sets in.

ANTHRACITE FIELDS

The mayors of Wilkes-Barre, Scranton, Carbondale, Pittston and Hazleton, accompanied by Senator Popper of Pennsylvania, called on President Harding at the White House, on July 22, and outlined a plan of settlement of the strike in the anthracite field. While not divulging its nature, the mayors stated that the plan has been discussed with John L. Lewis and will be the further subject of conference with the union leader and representatives of the operators.

BUFFALO

With the supply practically all gone it seems odd that so little is said and that nothing has been done about the resumption of mining. The inquiry for it increases steadily. Canadian dealers are anxious, but all that can be said to them is that they shall have coal as soon as it moves.

PHILADELPHIA

From a feeling of hopefulness the retailers have now fallen into a state of doubt of an early resumption of mining. There was a belief that the men would accept the arbitration plan, but this having been rejected, no definite date is set for the end of the strike.

There is a steady increase of consumers calling for coal, and as a result all retailers continue to move a fair stock of pea. Dealers from all sections are sending in moderate orders for this size.

Heavy orders for pea are coming in from the western points, as well as from Northern Pennsylvania. While the companies have now announced that it has no more for sale. Already it is reported that some of the railroads have taken some of the wheat for fuel.

River barley continues in strong demand and one of the railroads is reported as trying out a consignment of this size. Prices are firm, with an inclination to increase, a few sales being reported at $3, but the average is still $2.25@$2.75.

COKE

CONNELLSVILLE

Offerings of coke have decreased farther, partly on account of the fresh strikes that followed the assembling of the conference at Washington, and partly on account of insufficiency of transportation produced by the railroad shopmen's strike. Prices have been advancing, causing miscellaneous consumers generally to drop out of the market, as the furnaces, being long ago, while there remains buying by foundries. As coke is a small part of the cost of finished castings the foundries do not balk a price.

Connells ville foundry coke has sold at $14, and it is rumored one carload went at $15. For furnace, $13 has been quoted.

At least half a dozen furnaces have been banked or blown out in the past week on account of failure of supply, chiefly coke made at byproduct ovens there. Receipts of coke from Virginia and Kentucky coal are almost stopped by transportation disability.

The Courier reports production during the week ended July 15 at 52,300 tons by the furnaces owning, and 11,020 tons by the merchant ovens, a total of 63,920 tons, an increase of 10,000 tons, representing a two-thirds recovery from the decrease in the holiday week.

UNIONTOWN

Invitation of President Harding to operators to resume production of coal backed up by Pennsylvania National Guard has not as yet changed the situation in this region. It is expected that a more or less concerted effort will be made next week by a number of operators to bring a "showdown," although dealers are more or less guarded.

W. J. Rainey, Inc., has posted notices to the effect that it will comply with the President's invitation and resume production, but the timing has had no effect upon striking employees and no effort has been made to obtain outside labor.

Meanwhile the market is bounding upward like a skyrocket. At 25 and 50c. a ton hard-pressed consumers are pushing it upward until it is impossible to quote any price today with any certainty as to what it will be tomorrow. A price of $7.50 is generally quoted now, but there is no indication that that is the limit. Announcement from Washington that a coal-rationing plan is being considered is believed to have caused some consumers to scurry around, placing large orders before the rationing commences.

BUFFALO

The entire giving out of supply from the Connells ville district has not obliged dealers to give up quantities they may consider at this point an improvement, for byproduct coke is an uncertain quantity, and the fact that, as a rule such plants exist for the purpose of supplying nervy furnaces and the surplus is small. One jobber quotes a good byproduct at $11 for the lower grades and $11.50 for foundry, to which $1.31 must be added for freight.
Flight of Coal Prices Leaves Men Breathless

Western Kentucky Shoots Up More Than $1 a Day—As It Passes $11. Pittsburgh Coal at $9 Appears and Slows Ascent—St. Louis Suffers.

Hectic market conditions continued through the past week in the Midwest region. With Chicago always at the peak, prices soared dizzyly on every coal traded in in every market where any of it was offered. Western Kentucky reached $11.50 at Chicago Saturday night at the end of a drunken upward career—an ascent of $5 from the Monday before—and smokeless and eastern Kentucky attained $9.50, though very little of these two coals was available. The level had crawled so high that Pittsburgh coal appeared in considerable quantity and was bought greedily at $9. At the end of the week trading was in car numbers only.

Excitement in the fields tributary to this region continued at high pitch. There was no telling, from hour to hour, what coal would sell for in each succeeding period.

Even country trade has shown a noticeable pick-up, for dealers everywhere perceive the folly of expecting coal to sell at ordinary prices now winter and most of them are willing to stock right now at whatever figure the market dictates. Dealers are seeing many a consumer getting shorter and shorter of fuel and they can see plainly what is going to happen soon.

The shortage is getting so keen in the St. Louis territory that the Governor of Missouri is considering a coal apportioning plan for the state and the Mayor of St. Louis may attempt the same thing for the city. Municipal institutions there are said to be within a week of a boiler shutdown. In Illinois a number of coal consumers such as town lighting plants are suffering keenly—and without hope. In one or two cases they have shut down and are drawing power from bigger central stations.

CHICAGO

Western Kentucky coal went a long way this week toward spoiling its own game of aviation. Prices soared $5 or more on Monday morning and Saturday noon, causing consternation at times as the market made its dollar jumps each day. Many a jobber had his hands full with orders for an agreed price, only to have the coal hurdle his price before he could deliver it. That was at the first of the week. Later that practice stopped. Dealing was then altogether in car numbers and prices were never set until the coal was delivered.

The gay and hilairey of the dealers on the market up to a point finally where, by Friday, Pittsburgh coal began to appear. This newcomer, making its first appearance here in a long time, could, with a freight rate of $2.84, compete with prices $5; for by Friday western Kentucky had passed that gaggardly figure. By Friday night, in fact, western Kentucky had reached $11. But the next day its rapid flight appeared to be somewhat checked. It did not pass $11.50 in spite of herculean efforts of a few who tried to open the day at $13. The Pittsburgh coal—more than 100,000 tons of it—may have been responsible.

No other coals cut much of a figure on this market, principally because of difficulties incident to the railroads. A little smokeless and eastern Kentucky filtered into town a few cars at a time, selling readily at $9 and $9.50 at the well, but the quantities were small. A slight recovery of the Louisville & Nashville from its attack of general debility made it possible for a thin flow of coal to start from fields along its lines, but the volume which reached here was small.

SOUTHERN ILLINOIS

Peace appears to reign throughout all southern Illinois coal fields, though there is keenly felt among miners which might indicate either a willingness to go back to work at the first opportunity or a fear that the government is not going to do something to the union. The coal supply of the fields is exhausted and there is no production at any of the out-of-the-way wagon mines or strip pits.

ST. LOUIS

For the first time since last April the situation is becoming serious here. At many points in the state as well as in southern Illinois coal is unobtainable for municipal plants and other essential industries.

In St. Louis proper, another ten days will see the coal cleaned up excepting at the big utility plants and at the city water works, where there is about a month's supply ahead. The city institutions will be out of coal within a week unless relief from some unknown quarter develops. Domestic customers are making no demand for coal.

Kentucky coal, which was selling at the close of last week for $6, went up Monday to $6 and finished up the week at between $7.50 and $8 with no operators willing to take an order. They expect the price next week to be as high as $10 to $12 at the mine for mine run.

WESTERN KENTUCKY

An advance of easily $4.50 a ton in the price of western Kentucky coal was posted during last week. On Monday, July 17, the market jumped rapidly, closing at around $6.25 a ton, going to $6.50 on Tuesday, $7.50 on Wednesday. Prices are now at an unloading level with an upward tendency. Quotations (nominal as regards anthracite) are as follows:

<table>
<thead>
<tr>
<th>Description</th>
<th>Price</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bituminous</td>
<td>$7.50-$8.50</td>
</tr>
<tr>
<td>Anthracite</td>
<td>$10.00-$11.00</td>
</tr>
<tr>
<td>Coke</td>
<td>$5.00-$6.00</td>
</tr>
</tbody>
</table>

The railroads and public utilities are wild for coal. Such great companies as the Commonwealth-Edison Co. of Chicago offered $7.25 a ton, or 25c over first offers on Wednesday morning, in order to get the coal on the market.

During the past week the Harlan field got out a little tonnage for the first time since the rail strike started. The Norfolk & Western and the C. & O. are having some trouble in the Kentucky-West Virginia district, and the L. & N. has been having much difficulty, with the result that tonnage from the non-union fields of Kentucky and the Virginias has slumped badly, while surplus stocks have been reduced to a minimum and demand is increasing daily. Production is probably at about the lowest ebb since April 1.

INDIANAPOLIS

The skepticism with which the general public is viewing the invitation of Governor McCray to the operators to cease their miners' sit-downs on the coal market. During the past few days there has been a mad scramble for coal on the part of industrial users. The visible supply of shrinking and Indiana at the present time is faced with the most serious coal shortage for years.

Many industrial users have been holding off for two or three weeks and using their reserves in the forlorn hope that the strike would be over by this time. Regardless of all that is said and done, the average citizen of Indiana has but little faith in the ability of operators to successfully operate mines without the aid of the organized miners.

LOUISVILLE

Apparently the Kentucky operators have thrown all caution aside, and with this fact are figured in no danger of federal control, or that they should get every nickel possible while the getting is good. The market has been a genuine bonanza with large consumers' hands at the vanishing point, and coal must be had at any price in order to keep railroads and public utilities supplied. It is reported that at the advanced figures there will not be much Lake movement just now. Car supply has become very poor.

Canada

TORONTO

The coal situation is growing more serious every day. Domestic orders are coming in with a rush but dealers are unable to make deliveries as there is practically no anthracite in the yards—excepting a little pea coal. Soft coal is getting scarce as the railway strike prevents shipments from coming forward. Prices are much higher than usual with an upward tendency. Quotations (nominal as regards anthracite) are as follows:

<table>
<thead>
<tr>
<th>Description</th>
<th>Price</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bituminous</td>
<td>$7.50-$9.00</td>

</tr>
</tbody>
</table>
Uncertainty Among Buyers
And Sellers; Prices Mount

Feeling is that Resumption Must Come Soon—Jobbers Wary of Being Caught with High-Price Product on Hand—Rumors Emanate from Pitts-
ough uncertainty prevails among consumers and sellers of coal in this area. Prices are steadily mount-
ing as each day new consumers come into the market in urgent need of coal, but there is a feeling that the situation cannot continue for long and that the mines will soon resume operation. No jobber wishes to get caught with high-priced coal on his hands and this type of dealer is proceeding with caution.

The price is being set by the buyer in his eagerness to get car numbers, and in the process the Hoover price level has long since been passed.

At Pittsburgh there are rumors of much activity in getting certain mines ready to operate non-union, or at least without the consent of the United Mine Workers, but no coal has come from these mines as yet.

BUFFALO

Plenty of uncertainty, plenty of people to say what should be done, plenty of operators ready to go to work if the machinery will run, but nothing done yet. Coal is giving out pretty fast and will be gone in some districts before there is more. The consumers know this and are bidding high for it.

Bituminous coal is about $1.50 a ton higher than it was a week ago and if no addition is made to the output it may go still higher. Reports of selling an allotment and of plants shutting down increase.

The grain movement keeps up well and ore is moving at a good rate, but for the present the best Virginia bitu-
minous coal that came in so liberally from Ohio ports early in the season has been shut off entirely. None has been reported for a week. Bunker coal is becoming so scarce that only small amounts are to be had at any port. If this shortage continues some of the fleet will have to tie up.

PITTSBURGH

Immediately upon President Harding "inviting" the operators to return home and produce coal, active work was begun in getting several mines ready for resumption. Many miners were dis-
posed, late in June, to return to work if given full protection, but whatever the intentions may have been the actual proceedings at Washington were followed by a stiffening of the backbone of the strike, and resumption will now be more difficult.

Two entirely separate efforts at re-
sumption are in progress, by certain operators in the Pittsburgh (union) dis-
triet, under the advice of the Pittsburgh Coal Producers' Association, and by operators, primarily styling up the H. C. Frick Lake Co. (Steel Corporation) in the Connellsville region, non-union, for more than a generation although the U. M. W. declares it has been largely organized lately.

The only coal traded to any extent of late has been Connellsville, the offer-
ings of which have been heavily re-
duced by high strikes and by insuffi-
ciency of transportation. The urgency of certain buyers, particularly public service corporations, has been greatly increased, chiefly by reason of the inter-
ruption of deliveries of West Virginia and Kentucky coal. Nearly every day in the past week Connellsville coal has advanced 50c, being now strong at $7.

COLUMBUS

The combination of the coal miners' strike and the railroad trouble is pretty much a mutual advantage to both.

While there is a fair tonnage still being produced, lack of transportation facilities is causing much anxiety in all quarters and there is an acute shortage in certain sections. The entire price situation is wild and uncertain and quotations ranging $3.50 @ $7 are being heard.

Some of the larger operators are making an effort to abide by the Hoover levels but they are not meeting with much success. What free coal is on the market is commanding higher figures and since it is a bidder's market the highest bidder gets the coal.

Retailers are now coming into the market to replenish their stocks. Some householders, expressing anxiety, are buying their winters' supply. Retail prices have advanced to higher levels in sympathy with quotations.

Lake trade is falling off. The H. V. Dock at Toledo during the week ended July 19 loaded 57,345 tons as compared with 96,685 tons the previous week. A total of 1,455,692 tons has been loaded by these docks since the opening of the season.

EASTERN OHIO

That reserve stocks are nearing ex-
hhaustion and that a fuel crisis looms in eastern Ohio is evidenced by developments during the week. The quantity of coal now reaching this section is the smallest in years and operators and jobbers are being besieged by indus-
trial consumers.

Stripping operations in eastern Ohio have been curtailed, not so much by a lack of transportation as by interfer-
ence and intimidation of employees by union miners.

Indications are that public utilities in this territory have limited reserves of fuel. Industrial and steamship lines in many instances have already found it necessary to restrict their activities because of limited fuel. The Detroit & Cleveland Navigation Co. has temporarily retired two steamers between Cleveland and Detroit and in the Mahoning Valley the operations of steel plants are being seriously retarded, and blast furnaces are being banked.

Iron ore demand and the diminishing quantity of coal available have boosted prices. The maximum has moved up from $5.25 to $7@7.50. Pittsburgh and Ohio high-grade coal at $7.75@$8 f.o.b., mines, while the range of spot prices on coal from other districts is $7@8.50.

NORTHERN PANHANDLE

Since the beginning of the rail strike feeling between union and non-union miners has been intensified, striking railroad pickets have attempted to intimidate the miners to some extent. The non-union is affected much by additional strike troubles. Inability of the B. & O. to move coal is affecting production to a greater extent than the strike of miners. This is limiting the movement largely to railroad fuel.

DETO RIT

Interest of buyers is apparently not very generally aroused, as with the shortening of supply is beginning to be noticeable. Demand can scarcely be classed as active or urgent except in a few cases.

The principal difficulty now being experienced is in getting coal from mines to docks on Lake Erie or through by the all-rail route. This impediment is attributable to growth of the strike rather than the miners' strike.

Some buyers are negotiating with the mines for coal on the basis of $7 at the mines. It is believed, however, that these are exceptional instances as the business coming to jobbers and wholesalers is not of large proportions and incoming shipments are small.

CLEVELAND

The situation in this district is doubly acute. Not only are local consumers clamoring for fuel, but the demand from the Northwest is centering here. Mean-
while conditions are moving only from bad to worse. The sky is the limit for prices, recent quotations ranging up to $6.50 and $7 per ton. Even the non-union grafter, the cool, however, is extremely scarce, not only because of the enormous demand but declining receipts as well. The plight of the Northwest is reflected in the fact that at present the dumpings of coal at lower lake ports is around 500 cars daily, whereas the normal figure at this season is 2,500. The quantity of coal moved by rail is 4,000,000 tons against 11,500,000 for the same period of last year.

The Cleveland Chamber of Commerce has appointed a committee to act in the emergency.

Many Cleveland industries are being crippled. The fact that 75 per cent of the industries are supplied with power by the Cleveland Electric Illuminating Co., is preventing more widespread distress, as the illuminating company is far from full. It is estimated that the Cleveland Electric Illuminating Co. is losing $20,000 per week.

Ohio operators with headquarters in Cleveland thus far have made no move to start operations under military protection and the majority of them probably will not do so.
COAL

Northwest

Federal Distribution
Plan is Encouraging

Northwest Believes It May Get Enough
Coal by That Agency—Dock Men Are Using Allotment Scheme Already—No More Upbound Cargoes Due.

THERE is a ray of hope for the Northwest in Secretary Hoover's promise to Governor Preus, of Minnesota, and to others that the region is going to get preference in coal shipments when the government's new scheme of coal apportioning goes into effect. However, that is about the only cheerful thing the people of the Northwest have to think about in connection with coal. Lake shipment of coal from lower ports has stopped and no more cargoes are scheduled. Stocks of free coal are so low that in most cases orders will not be taken until they have been approved by dock-company headquarters. Prices generally are still going up.

Public utilities and industries throughout the region find themselves in various conditions. Most of the big utilities have enough fuel on hand to run until September, but among manufacturing plants the situation is grievous generally.

MINNEAPOLIS

With the Governor of the state making vigorous efforts to get a priority on coal for the Northwest when deliveries are resumed, buyers of this district are beginning to appreciate that the situation is serious. And there is no assurance of an adequate coal supply no matter what the government may do. Ordinarily the domestic business begins to get considerable service by September 1. Since there is little chance of that this year, consumers are starting a rush for coal. Wholesalers are refusing many orders. Bidding is being done on coal for prompt shipment, and premiums are being run up quietly, but wholesalers are endeavoring to avoid this sort of thing, realizing the hereafter that will follow anything that savors of profiteering.

Efforts to one subsection may lead to wood and lignite. Wood will be expensive but will do very well in cook stoves and airtight heaters. Lignite is difficult to handle in ordinary steam plants because it sticks and runs down through most grates.

DULUTH

Stocks on docks have decreased so heavily that the majority of dock concerns are selling only insignificant amounts from their headquarters in Minneapolis. This method of apportioning is an effort to place coal where it is most keenly needed. Latest reports show that 165,000 tons of free bituminous remaining here, with anthracite in an even worse condition. Shipments have practically stopped, one cargo only having been received last week. At the same time assurance has been received that no more cargoes will be shipped to lower lake ports from here.

Public utilities in Duluth and Iron Range cities are well taken care of according to latest reports. The local plant of the Minnesota Steel Co. and the Oliver Iron Mining Co. have sufficient coal to continue work until December. Independent mining companies are reported as being in more serious condition.

The general impression here is that the strike will be broken before a general tie-up occurs. Secretary Hoover's assurance that the Northwest will receive preferential shipments as soon as mining starts, and in this way will be able to get its accustomed amount of coal here, is giving heart to all.

Virginia Terminal Shortage
Is Felt: Market Turns

Quotations Likely to Tend Upward Till Rail or Mine Strike Ends—Textile Resumption Not in Sight—Outlook Is for Pitiful Buying in Small Lots.

SHORTAGE of coal at the Virginia terminals has made itself felt. While thus far there has not been demand enough to cause any very active bidding up of prices, it is clear that the market has turned and that quotations probably will tend steadily upward until either the shopmen's strike or the suspension of union mining is brought to an end. In this territory there are fair reserves, industrial conditions considered, but were the textile mills to resume full-time production there probably would be a notable shortage that would send prices soaring. However, there is no immediate prospect of any such general resumption here and buying will doubtless continue to be scattered and confined to relatively small tonnages.

For distribution inland, reloaders at Boston, Providence and Portland have little free coal. Receipts have begun to fall off, and factors here know that for the next few weeks their present stocks will not easily be replaced. Prices in consequence have risen to new high levels; $9 has been quoted on cars Boston, and actual sales at $8.75 are known, these prices being per gross ton. At the same time deliveries are being made on contracts, and one retail distributor in Boston has seen the way to place an average price of $7.45 per net ton delivered for 12,000 tons New River for delivery prior to Sept. 15.

With the condition it is no wonder that the British coal is likely to come here in quantity. As much as 500,000 tons has already been arranged for, it is said, all of it to be received at Atlantic ports, and this should be an influence not only in keeping prices within reasonable limits but also in making it clear to union leaders that coal consumers are not entirely helpless.

The trade is much interested in following reports from day to day of developments on the railways that serve Pocahontas and New River fields. The serious breakdown on the Norfolk & Western is still the occasion of much anxiety, and New England will hardly feel easy over supply until conditions on that line show some improvement before long. Since April 1 that particular railroad has been a main channel of supply, and any interruption has serious implications.

Spot prices are bound to be more or less buoyant the next fortnight or so, if not longer. With anxious buyers in many different sections there is bound to be a certain amount of bidding for what free coal there is, and it would not be surprising to see $9 per gross ton f.o.b. vessel at Hampton Roads reached within a relatively short time.
Cincinnati Gateway

Big Demand for "Free" Coal Creates Three Price Levels

Offers Made at Scales, Between Mine Mouth and Weighing and Before Loading—Unsettlement Laid to Rail Trouble—Non-Union Output Drops and Car Movement Slackens.

DEMAND for "free" coal has grown out of all bounds of possibility of supply. The result is that there are really three prices to be reckoned with upon coal passing through the Cincinnati gateway. One might be called the scales price—that is, a price offer for coal that is about to be weighed by the N. & W. or the C. & O. or that has hit the main line of the L. & N. The second price might be said to apply to coal from the mouth of the mines to the scales and the third that for coal still to be loaded. Even this latter is split into two prices, for there are some firms still holding to the Hoover price even on free coal, while there are others who are getting the limit that the market will stand.

The backbone of the trouble is the rail congestion caused by the breakdown in transportation. Non-union production is curtailed and those cars under load are moving in at less than 50 per cent of normal.

CINCINNATI

Lake business is "shot." One cargo gathered up on Wednesday cost $96@ $7 a ton. Casual buyers therefore are standing off. Country business is pretty much in the same boat—the dealers here come, look the market over and find out the prices that are being asked for coal and go back home again. The whole situation has been created by the breakdown in transportation attendant to the shopman's strike and the others that have surrounded it. Thousands of cars are lying on the sidings that cannot be moved. Less than 30 per cent of normal of loaded cars were brought across the river this week; in round numbers this is a drop of 5,000 cars.

Smokeless agents frankly declare that they will have no coal to offer until the middle of next month. Logan has been hard hit and is moving only a few cars out to the main line of the C. & O. Hazard has a better car supply than surrounding fields. Hazard has only one day this month. Producers say that their costs are mounting and that every ton put on the cars this week has cost them $5@$.80.

Retailers are still holding to the prices established the first of the month. They are warning customers, however, that they will soon be forced into the open market and that a rise in price can be expected.

LOW-VOLATILE FIELDS

NEW RIVER AND THE GULF

Labor troubles and the effects of the mine strike have been a serious overcomer in the New River field, but a shortage of cars has begun to seriously interfere with production. For a time there was a threat of trouble on Beard's Fork and Loramie, but the demand for steam fuel is strong. There is a heavy demand at Tidewater.

Losses due to a shortage of cars in the Gulf region were somewhat more pronounced during the week ended July 15, and tended to make inroads on the output at a time when labor shortage was being overcome. The condition of motive power is making it difficult to move coal as promptly as usual and congestion was beginning to develop on the Virginian by the middle of the month. The movement down the movement to Tidewater.

POCAHONTAS AND TUG RIVER

By the middle of July a rather serious car shortage had begun to develop in the Pocahontas region, the lack of empties entailing a loss of about 45 per cent. The market is unable to handle so large a volume as it did during June and hence there is congestion at various terminal points as well as on connecting lines. The general tendency is to move coal to Tidewater, owing to the short haul and the fact that loads did not have to be delivered to connecting lines.

Tug River mines, too, are suffering from the effects of a car shortage, amounting to about 45 per cent. There was more coal than usual on sidings and at terminals awaiting movement to market. Restricted movement of coal was tending to affect the steel operations since so large a proportion of the output of this territory is usually shipped to affiliated steel mills.

HIGH-VOLATILE FIELDS

KANAWHA

Considering the obstacles to be overcome, the field was producing a fairly large tonnage during the second week of the rail strike, increasing its output to 70,000 tons, the largest since the strike began. Coal was not being moved so promptly as had been the case during the first week of July. It was also difficult to secure empties now than it was before the rail strike, but the need for empties is not as large in the Kanawha region as in some others. There are still more than 100 mines at work, although despite some serious acts of violence.

LOGAN AND THACKER

Handicapped by decreasing railroad facilities, Logan mines have been unable to keep up the pace recently set, although there is still a large output in this territory. Each of the output is being held up at connecting points owing to congestion on other lines. Producers are not finding it possible to get coal to the steel companies in sufficient quantities to keep them stocked. With the supply dwindling the demand is reaching even stronger proportions.

In the Thacker field the only factor which is interfering seriously is the railroad situation. Cars are much harder to secure because of the congestion at terminals on the Norfolk & Western and connecting lines. Not only is there a car shortage of about 45 per cent but it is becoming more difficult to move loads. Lake buyers are seeking large tonnages and the general movement to the West is large, instead of transportation facilities permit.

NORTHEASTERN KENTUCKY

There is a serious curtailment of the output owing to the rail strike, the car shortage in that respect affecting production to the extent of about 20 per cent or more. Loads are not being moved expeditiously and congestion is resulting, in the face of a very strong demand.

KANSAS CITY

While it is true that the production of coal under normal conditions in the Kansas coal fields is small as compared with other coal producing districts, the production in Kansas today is about 25 per cent of normal. Many mines are opening up. It will be recalled that about a year ago there was a split between Alexander Howe and John L. Lewis and each had his following and the miners that followed Howe are the ones that are digging coal today and apparently without any interference from Lewis' followers.

A more peaceful mining locality than the Kansas field would be difficult to find and is an object lesson to all and clearly shows what may be expected where there are two factions about equally divided. Howe is in jail, which may have something to do with the lamb-like demeanor of the men. If that is the case, we can go farther and draw another conclusion: Free and radical labor leaders in jail and there will be peace.

Coal of all grades is scarce and hard to get. Some of the retail yards have sold out to the steam plants and are taking a chance of getting a supply later to take care of their trade. Prices fluctuate from day to day but the ruling figures on Kansas coal are about $3.75 for slack and $5 for lump.

SALT LAKE CITY

Business is improving. Some of the dealers are stocking up and there is a demand for Utah coal. The prices are firm. The U. S. Fuel Co. reports more orders in all grades than it can fill, despite the fact that its production last month was more than double that for the same period last year. Some of the operators, however, have been badly hit by the strike and are producing much less than in normal times. Large, slack, day by day, but the ruling figures indicate a little uneasiness. Local dealers and producing companies cannot meet the demand. The domestic consumer is not buying much yet but inquiries indicate a little uneasiness. Local dealers and producing companies cannot meet the demand. The domestic consumer is not buying much yet but inquiries indicate a little uneasiness.

From Field and Trade

ALABAMA

It is rumored that stockholders of the Alabama Company have been asked to vote on the sale of the properties of the company to Lloyd H. Atkinson and associates. All stockholders of the Alabama Company are given $6,250,000 in the circular letter sent out by the company, asking them to accept or reject the request for an open meeting of stockholders. The properties of the Alabama Company are in Baltimore. The properties consist of blast furnaces and company coal mines, most of which are now in operation, although they have been out of the market for a time.

Charles H. Nashott, chief mine inspector, attended the annual meeting of the Mine Inspectors’ Institute of America, which was recently held in Chicago.

ILLINOIS

Orders to start the work on the new power plant of the Central Illinois Public Service Co., at Grand Tower, have been given. The plant will be located near the Mississippi River at Grand Tower, to insure a year-round supply of water for its enormous turbines. The company furnishes a large portion of the power consumed by the mines of southern Illinois. The company has power plants now in operation in many Illinois centers in the southern part of the state.

The Union Fuel Co. announces the opening of offices in Michaelville, Illinois, Chicago, where the executive, sales and service departments will be located. Andrew Christ, Jr., has been appointed vice-president of the company and will be in charge.

A permit has been granted for the construction of the Jefferson Southwestern R. D. power plant by Judge Martin of Marion in Jefferson County. 15 miles southwest through coal lands about to be opened by the Nason Coal Co., of Chicago, to a connection with the Chicago, Burlington and Quincy, three miles from the location of a proposed huge mine. Construction of the line will begin soon and the sinking of the first of several mines on the property will start as soon as a new work agreement is negotiated with the miners.

The McDonough County Coal Co., of McComb, has been reorganized and the work of the company is being continued. The property is being enlarged to the point where the purchase of additional machinery, including a compressed air plant.

INDIANA

A merger of three of the largest coal companies in Indiana, including the American Coal Mining Co., Brazil, Indiana Coal & Mining Co., and the Olivette Coal Co., Vincennes, has been announced by H. A. Glover, Indiana's sales representative of the new organization, which will be known as the Knox Consolidated Coal Co. The new corporation will take common stock to the amount of $3,500,000, and the same amount of bonds. Two of the mines formerly owned by the American company and one each of the remaining two were owned by the Indiana Coal & Mining Co., and the Olivette interests. The purpose of the merger was merely a combination of interests to improve the position of the companies in competition. The value of the properties is $20,000,000. The Knox Consolidated Coal Co. will use the present mines, and will have a daily capacity of 2,000 tons and 3,000 tons of coal a year.

Missouri

A trust deed to secure an issue of $7,000,000 in first mortgage bonds has been filed in the offices of the First Trust & Savings Bank of Kansas City, in favor of the Kansas City, Missouri Corporation and the largest instrument in the state. The property is owned by the Kansas City, Missouri Corporation and the largest instrument in the state. The property is owned by the Kansas City, Missouri Corporation of property and the company has a mine at Camden.

The United States has been granted the Kirkville Co. to operate coal mines in the vicinity of Kirkville. The company has a capitalization of $10,000,000.

Kansas City interests are engaged in the organization of a company to operate coal mines in the vicinity of Wainwright, Callaway County, Mo. It is understood that H. M. Saunders of Kansas City, owns 3,000 acres there, and that in addition to the mining of coal the mining of clay will be carried on. It will be necessary to show the clay before the operation and it is anticipated that a brick plant will be built near the premises in the near future.

NEW YORK

J. P. Zimmermann, president of the Maxim Coal & Coke Corporation, Buffalo, since its organization, has resigned and re- signed. The company is continued with former president D. T. McCarthy elected president and treasurer and his son, F. A. McCarthy, vice-president and secretary.

Attorney General Charles D. Newton has taken steps to test the constitutionality of the Pennsylvania authorization law and has appealed the Attorney General of New Jersey, Massachusetts, Connecticut, New Hampshire, New York, New Jersey, and Delaware to join him in the movement.

F. J. Kerner Coal Co. of No. 1 Broadway, New York, has opened branch offices in Somers, Pa., and Morgantown, W. Va.

Ohio

It is reported that the old coal carrying railroad, the Marietta & Rio Grande, which has been abandoned, will be electrified shortly and used to serve a number of small mines. The company is formerly the Marietta, Columbus & Cleveland.

Virginia

It is reported that the old coal carrying railroad, the Marietta & Rio Grande, which has been abandoned, will be electrified shortly and used to serve a number of small mines. The company is formerly the Marietta, Columbus & Cleveland.

The Murphy Coal Co., Columbus, recently incorporated with a capital of $75,000, has been organized by John M. Murphy of Logan, president and H. H. Long, secretary and treasurer. The company was organized to produce coal in the vicinity of Columbus and to sell steam to the coal mines in the vicinity. The company has an option to purchase 250 acres of land in the vicinity of Columbus, and to erect a plant for the production of steam to be used in the coal mines. The company has a capitalization of $75,000.

In the suit against the Scranton Coal Co., for failure to allow a sufficient amount of plaintiff's coal, a suit for injunction, a suit for damages, and a suit for declaratory judgment, the defendant was held by Judge C. B. Witmer in an opinion in which he held the defendant liable for damages, and not a declaratory judgment. The defendant was also held liable for the breach of the contract of sale.

The Atlas Fuel Corporation of New York City, has changed its general offices to the Park Bank Building, Pittsburgh. Jay W. Johns, president, is in charge.

The Purity Coal Co., one of the Consolidated group, opened a new office in Columbus, and in Somers, Pa., recently increased its capacity by the installation of a new boiler. The company has a capitalization of $500,000.

Coal shippers are again in controversy with the New York Central, over the handling of their coal at the terminal. A conference was held in Buffalo, and the result was a decision in favor of the shippers. The conference was held at the request of the shippers, who were dissatisfied with the way their coal was being handled at the terminal.
Traffic News

In the complaint of Holmes & Hallowell Co., the commission on rearguard, has modified the rates previously prescribed on bituminous coal from the Lakes to points in Minnesota, and the Davey steamer tramway on the tramp, the rates on bituminous coal at $8.50 per ton on 20 miles and under, to $4.25 per ton on 26 to 60 miles. The rate is reduced from 14 to 19 per cent.

The Burlington line has also reduced its rates on bituminous coal from the Lakes to points in Minnesota, on a grade of 55 tons capacity, for prompt delivery. The commission has approved the reduction, and the rates will be reduced from 14 to 19 per cent.

In the case of the Northern States Power Co., the commission has reduced the rates on bituminous coal from the Lakes to points in Minnesota, on a grade of 55 tons capacity, for prompt delivery. The commission has approved the reduction, and the rates will be reduced from 14 to 19 per cent.

Coal Mining Institute of America will meet Dec. 13 and 14 at 15 at Pittsburgh, Pa., as the annual meeting of the Chamber of Commerce Blvd., Pittsburgh, Pa.

American Chemical Society's annual fall meeting will be held Sept. 4-9 at Pittsburgh, Pa., divisional meetings will be held at Carnegie Institute of Technology and general meetings at Carnegie Institute of Technology.

American Mining Congress. Twenty-fifth annual coal and iron conference and exhibition of mines and mine equipment will be held in the Phalanx Hotel, Cleveland, Ohio, Oct. 9-14. Executive officers, the Hotel, L. C. Porter, convention manager.

The Rock Island Coal Mining Institute will hold meetings at the Loyal Lodge, Galena, Ill., Sept. 6-8. Secretary, F. W. Sprague & Sons, New Port News.

Oblitary

O. R. Scott, general manager of the Pataoka Coal Co. died at his home in Indianapolis, Ind., on Aug. 22, after a long illness of about two months. Mr. Scott was born in Terre Haute, Ind., and began his business career at an early age as a delivery boy for a Terre Haute grocery. Later, he went to Indianapolis in 1912. From that time, his rise in the coal trade was steady.
On the Last Lap

Facing an unprecedented coal shortage, the result of the combined strikes of union and non-union coal miners and certain railroad employees, the country is slowly awakening to the seriousness of its situation. It was pointed out a month ago that by Aug. 1 stocks would have shrunk to the danger point, and the curtailment of output caused by the rail strike, not anticipated at that time, has in fact accentuated this condition.

It is imperative that the production of coal be resumed. It is equally imperative that a sane adjudication of the points at issue be provided and that provision be made against future serious breaks of this kind. There is now but one force in this broad land that can accomplish either—public opinion.

Settlement of the rail strike comes first because without unrestricted transportation even the coal from non-union fields is locked in the hills. Moreover, more than can be furnished by these mines is necessary. Anthracite production, cut off for four months, must be resumed if the health and security of half the householders of the country is not to be further imperiled. Industries already are halting for lack of fuel and now largely dependent on depleted reserves, with priorities turning the restricted current output to the more essential requirements of transportation and public utilities, will in a few weeks reach the bottom of their coal piles and perforce shut down. Because it is midsummer and this country has always been able to worry along somehow through previous similar situations, the great body of public opinion is indifferent. It will not remain so indefinitely.

The miners will return to work when John L. Lewis permits. He arrogantly defies anyone to get his miners to dig coal until he says the word. The strength of his position lies in his appeal to the men to preserve their organization, the United Mine Workers, at any cost of suffering or deprivation. He has taken the position that to follow any but his policy would mean the disintegration of the union. On this basis he has held his followers in line despite the fiercest kind of internal disputes. John L. Lewis will permit the miners to work when his terms are met.

Or, the miners will return to work when a force superior to John L. Lewis compels him to abandon his high and mighty attitude—drives him from his rule or ruin policy. From January to the middle of July the two parties—miners and operators—had a free hand. In that time splendid opportunities one after another were lost by the operators nationally to educate the public and mobilize opinion in the direction of a sane settlement of the issues. The anthracite operators and those groups of soft-coal producers who, struggling alone, have built up a clear record must suffer now for the lack of a united national direction. The adminis-

That Commission

One happy thought seems to be common to everyone who talks or thinks about the coal situation—let us have a commission. A commission will find all the ills and aches in the coal industry and prescribe a cure, or possibly a series of cures. Everbody seems to know a lot of things that are wrong, or at least is sure that things must be wrong, but no one knows just what, or how to correct the errors. Therefore, a commission. The commission will take the facts we have, add to them, and do the thinking for us that these collated facts suggest. This is just what the situation demands. A commission that will do one-half the things it is now hoped it can accomplish will be the best thing that ever happened to the coal industry. It will explode a lot of myths, lay down some sensible rules of conduct and, although we have but slight hope of its reorganizing the bituminous-coal industry, it will be able to expound some healthy truths about the existing forms of doing business.

Commissions on coal almost without number have been proposed in the past three years, in every instance in some form of legislation objectionable alike to operator and miner. The objections have all centered around the idea that the suggestions were designed to initiate regulation of the coal industry—wages as well as prices—through the opening wedge of compulsory fact finding. In some instances it has not been so much the actual legislation that has aroused hostility as it has been the obviously hostile spirit prompting it. The spirit of President Harding's suggestion is so entirely
free from taint of partisanship that the only one to object to his commission will be he who wants to hide facts. It cannot be otherwise than that he will appoint as commissioners men from all walks of life—eminent and unbiased. Neither miner nor operator should expect representation. It would be a modern marvel, indeed, if employee representation should produce other than a minority report, which in turn invariably results in some form of strike in protest of the majority.

It will be quite important to have the jurisdiction of this commission clearly and properly defined in advance. If it is to be an arbitration board then it can have jurisdiction over none but those party to the present controversy. The President has so indicated, to the dismay of the miners, who want nothing better than to have the government drag the non-union operators in the room where they are sitting.

On the other hand if the commission is not for compulsory arbitration and is but to investigate and study the coal industry, if it is to do any of those very important things which Mr. Hoover has indicated should be done and which some of the miners and some of the operators have advocated, then it must take in the entire coal industry. It must be national in the scope of its investigation, but with no power to force its decisions. The President has also indicated that he expects his commission to work that way too. Of course, it cannot do both and he will decide which of the two he desires the most.

The attitude of the United Mine Workers toward a commission is expressed in the following words from their reply to the President’s proposal of July 10: “When all the facts bearing on the production and distribution of coal have been collected and impartially analyzed, we shall gladly face these facts and accept them as a condition to the rehabilitation of the coal mining industry.” Those who are familiar with the readiness with which this union “accepts” findings other than its own will know best what credence to give this fine assertion.

Mr. Ogle, president of the National Coal Association but speaking for the union coal operators who attended the President’s conference on July 1, urges the immediate appointment of a fact-finding commission. The other union and the non-union operators have not so specifically expressed themselves on this matter. They have not been asked to, in fact.

As for the public, that part which has made itself heard is solidly for an investigation of everybody and everything connected with the coal industry. The idea of a commission is popular.

There will be a commission. When it comes time to lay their respective cases before that body the miners will be prepared and the operators will not be ready. The miners were ready last month, last year. They are regularly preparing data and arguments in support of their policies and positions. Such in fact is now the regular practice for all large labor unions. The union can give you a printed book, right up to date, on any subject from the “Hazards of Coal Mining” to the “Sanction of the Living Wage.” The very weight, in pounds avoirdupois, of their evidence is impressive. They know what they want to prove, and they get the figures to prove it.

There is just one point to what has gone before. Operators who have any hope of defending their cause before whatever type of tribunal or commission is certain to come, and soon, will do well to inquire into the modern style of conducting such bodies and get ready. They cannot expect anyone to prepare their case for them. The commission will gather its facts by way of evidence introduced—not by digging it out itself. The facts on which it bases its conclusions will be those placed before it.

Will Miners Expose Themselves to This?

THE miner’s qualification acts on the Illinois and Indiana statute books are precious to the United Mine Workers of America. The organization would surrender a good deal of ground undeniably gained by one means or another since April 1 rather than see those acts repealed. By that very fact a weapon of defence against coal famine is laid in the hands of the voters of those two states. “I’ll call a special session of the Legislature and repeal the Indiana act,” declared the stalwart Governor of Indiana the other day. “Don’t,” pleaded the state president of the miners; “give us forty-eight hours more,” and in his voice was the fear of the whole mine union organization. Repeal of the qualification act, behind which the union is solidly entrenched against the open shop, would be a disastrous blow to unionism.

In Indiana there is a strong possibility that the Legislature, if assembled in special session, would actually effect the repeal. In Illinois the issue would be in graver doubt. Illinois operators have made no recent move against the act and might not favor a repeal even if it were in prospect. Instead, operators there are inclined to take the position that the Governor should declare a suspension of the state mining laws during the present emergency and, with martial law in effect in the mining districts, protect sufficient non-union men in the workings to prevent suffering for coal.

However, if higgle-haggling continues in the national coal-mine situation and the country begins keenly to suffer for coal, public pressure upon the Indiana and even the Illinois legislature to force the mines open to non-union labor may become irresistible. If the United Mine Workers of America, in their desperate ring battle with the operators, permit strike conditions to reach that point, they will have exposed a vulnerable spot upon which outraged spectators climbing over the ropes may land a wicked punch.

The more urgent work of taking care of a car shortage has compelled the Interstate Commerce Commission to suspend hearings recently inaugurated on the subject of car service rules—that is, on how to distribute cars during a shortage. The last car shortage was two years ago, and since then there has been admitted necessity of giving consideration to a revision of the rules of car service. It is said that down in Arkansas they never fix the roof while the sun shines, because it does not need it, and when it rains, they cannot.

Merrill Mine, Its Housing Problems, Gravity Chute and Other Original Features

Village Located Convenient to Town—Men Travel to Mine on Railroad Train—Experience in Handling Partings in Coal—Assembling Empty and Load Trips—How Supplies Reach Mine

BY ALPHONSE S. BROSKEY
Pittsburgh, Pa.

In West Virginia coal operations are scattered and travel on the railroads is slow and arduous. In consequence it is necessary that each town be complete in itself, and to hold its men a company must provide such a town unless it can locate its village near one of the thriving centers that West Virginia is rapidly developing. While lack of easy communication makes the mine worker of that state less disposed to wander from operation to operation, it is a distinct disadvantage where a company seeks to add to its working force.

At some of the mines the valleys from which openings are made are so narrow that place for a town can hardly be found anywhere near the operating point. The Merrill mine, on Little Buffalo Creek, three miles west of the main Guyan Valley-Logan Branch of the Chesapeake & Ohio R.R., is in this predicament. A branch road built by the company runs up Buffalo Creek from the main line to the mine, but the town of Henlawson, where the men employed live, has been located almost from necessity where the two creeks meet and the branch forks from the main line. It lies at a point not far from the City of Logan, which is the center of the activities of this field.

The Merrill Coal Co., which owns the mine, has a little more than 4,000 acres of coal land which lie under the two mountain chains that flank Little Buffalo Creek on either side and extend from the mine to the village of Henlawson, the mine openings and the tipple being at the eastern end of the property. In the valley some building land is to be found, but had it been used the men would have been located conveniently neither to the mine nor to the main line and the town of Logan. Furthermore, a dirt road up the valley would have had to be maintained. Consequently it was thought best to build at the present site and transport the men by railroad.

On the three miles of track that the company owns it operates one 40- and one 60-ton shifting locomotive and two passenger coaches. A labor train leaves the town in the morning in time to get the men to their work at 7:30 a.m. As there are no houses in the valley all the 162 men employed at the mine travel to and from work on the labor train. This is run by the company, for, as at many other mines located off the main lines of railroad, the company finds it advantageous to use its own shifting engines. This insures the prompt delivery of cars from the main line to the mine and also guarantees daily removal of the loads. The railroad grade is in favor of the loaded cars, so that the number of cars taken out of the valley is almost unlimited, but only ten empties can be hauled upgrade to the mine.

Three workable seams outcrop from the two ranges, the Winnifred, the Alma-Draper and the Island Creek, but the latter is the only one being worked at the present time. As the coal is mined out the workings will approach the village and eventually the men will be entering the mine and working at points near home. The coal has no unusual dips and the grades are slight, consequently the main haulageways may extend for considerable distances along the principal axis of the mountains and coal may be brought out to the surface entirely through one main drift or it may be taken through several drifts and trammed along the mountain side to the tipple. When the haulages become too lengthy and an increase in production is desired, addi-
GATHERING LOCOMOTIVES DO ALL UNDERGROUND HAULING

Six-ton reel locomotive bringing thirteen loads from the First Flats Left. The curves leading from the mains to the flanks are of 100 ft. radius; those which join butts with flanks have a 75-ft. radius. The room curves are laid to a radius of 25 ft.

Six-ton reel locomotive bringing thirteen loads from the First Flats Left. The curves leading from the mains to the flanks are of 100 ft. radius; those which join butts with flanks have a 75-ft. radius. The room curves are laid to a radius of 25 ft.

ditional tipples may be erected at intervals from the present mine to the town. Future plans call for the erection of four additional tipples to take the coal from the two hills, thus reducing the length of the underground haulage.

The Island Creek seam at this place has an average thickness of 6 ft., and the slate roof is so unusually strong that few timbers or props need be used even along the roadways of wide rooms. Three streaks of slate which attain a maximum thickness of 1½ in. appear and play out from place to place.

The lowest streak appears 3½ in. from the bottom, and the other two streaks above are separated by 4 and 8 in. of good coal. The coal is undercut with arcowall machines and where the bottom rolls the cut is kept several inches above the floor. The bottom coal is easily removed by shovels. Where the coal is undercut it is brought down by the usual method.

An attempt has been made to cut between the first and second slate streaks, using the arcowall cutter, but it was found that after shooting the slate was badly broken up and the coal obtained was not as clean as with undercutting. The idea was abandoned, therefore, as undercutting and shooting permit the removal of the slate in pieces of a size suited to picking.

Most of the cleaning is done on the picking tables. The slate does not always fall free from the coal, and in such cases the loose slate cannot be removed in the mine and that which clings to the lump coal must be loaded out. During periods of operation when the coal passes over the picking tables in large quantity the pickers do not have time to knock the slate from the lump coal. In consequence it is the practice at this mine to pick from the table the chunks of coal having adhering slate, depositing them on the tipple deck so that during periods of no run the pickers can wield their hammers and clean the accumulated lumps of their impurity.

At the tipple the Island Creek seam lies 300 ft. above the railroad track, the headhouse lying, however, approximately midway between these two elevations. Coal is trammed from the point where the trips are made up, which is in the vicinity of the substation and not far from the drift mouths, to the headhouse, a distance of one mile, the grade being 3½ per cent in favor of the loads. Further details regarding the surface haulage arrangements will be given later.

The two mountains under which the coal lies come together at the upper end of the creek. It is at this point that the first drifts, or, as some would say, "the first mines," are being worked. The tipples, as was mentioned above, lies one mile from here, down the creek. Remembering that the coal area describes a long and narrow U the working-out plans may be followed easily. At the present time most of the coal comes from drifts emerging from the curve of the U.

TRACK LAYOUT IN ASSEMBLY YARD OF MERRILL MINE

Because the coal is brought in six to ten loads a trip by gathering locomotives and comes in from many directions the problem of yarding the cars at the surface is not easy, but ample trackage insures minimum interference and delay.

Four drifts have been driven to win the coal at the juncture of the main bodies on either side of the creek. Of these, No. 1 drift is the only one of any importance, No. 3 and No. 4 drifts having been worked out, with No. 2 in the last stages of pillaring. An irregular body of coal to the east will be worked out during the coming year, leaving the two long arms on either side of the creek to be operated in an approach to the town. No real developments have been made in the northern arm. Access is gained to the southern arm through No. 1 drift, which is the principal opening. As necessity requires other drifts will be opened progressively in the direction of the tipple and the town. When the haulages to the present tipple become too long and when other conditions favor the action, other tipples will be erected to the east of the present one.

Because of the exceptionally firm roof, rooms can be driven 24 ft. wide on 60-ft. centers without any extensive timbering along the track. They are 300 ft. long, driven in one direction only. In No. 4 drift rooms were driven in the same manner on 80-ft. centers. The procedure was found particularly valuable near the outcrop. The good roof does not warrant the wide center elsewhere, however.

On the main hauls and the tramroad 50-lb. rails are laid on a 44-in. track gage. In the rooms and on the butts 25-lb. rail has been laid. Steel ties are used.
Assembly Yard

A large motor with a trip of twenty-five cars is headed for the dump house near the tipple. After it has pulled out the smaller gathering locomotives each will bring from six to ten loads and assemble them into a trip. The substation is the only permanent building in the illustration. A steel-and-stone machine shop measuring 49 x 100 ft. will be built soon.

in the rooms and also on the butt entries. They have been adopted as standard equipment for room track in a majority of the mines of West Virginia, having been more generally used in that state than in Pennsylvania. I sometimes wonder why it is that the Keystone State is slow in adopting the steel tie in place of wood for room work. Surely it is easier to handle, has a longer life, costs less, maintains a uniform gage and for room work is more rigid than the wood tie as usually laid. Where the grades are light it may be adopted even for laying track in the butt entries, as is the practice indeed at the Merrill mine. This company has experienced no difficulties from spreading or insecure rails in the butt headings where they have been laid on steel ties. However, their use is not to be recommended where grades of one or more per cent are encountered.

In turning the butts off the flats, however, the curves are laid with 50-lb. rail on heavy wooden ties. Extreme care must be exercised in putting down the curved track, and the joints made by the light and the heavy rail must be aligned accurately and firmly joined, else the gathering motors with their trips may encounter trouble in hitting the "straightaway" at usual curve speed.

The air butts are utilized as storage tracks for empties and the live butts from which the rooms are driven serve for storing loads. Just now five 6-ton motors are used for both gathering and loading coal. When the workings have been extended, however, larger motors will be required for the main haulage. The gathering motors will deposit the loads on the main or straight way of one of the live butt entries near the curve. After backing the allotted number of empties into the aircourse butts, the main haulage motor picks up the loads from the tracked butts. Then the gathering motors have easy access to the empties through the first break-through off the flat, a distance of 80 ft.

At most operations in this state where the coal lies some distance above the railroad, the problem of transporting supplies to the coal horizon is solved by a plane and a hoist. The grades in most cases are steep, so that a self-propelled trip is not practical. Thus an ordinary mine-car truck is fitted with a body best suited for the supplies handled, and this is raised and lowered by a hoisting engine placed either at the top or foot of the hill. At the Merrill mine the industrial track is laid on a 15-per cent grade, switching back once and maintaining the same grade to the tramroad over which the coal passes. The industrial track does not cross the tramway at right angles, as is the usual practice, but is in reality a continuation of the tramway, being located on the side of the headhouse opposite from the mine. Supplies are carried to the mine openings by means of ordinary mine cars hauled by a 6-ton motor, two cars to a trip. After leaving the loading point the trip can make connections to any one of the drift mouths, passing over the empty track through the headhouse and thence to the single track or tramway. There are no pauses during a trip from the bottom landing to the destination. In the old system of hoisting supplies the cars are raised some distance above the tram track and are then dropped down on a switch to the tramway. Here a motor is coupled to the car, and both proceed to their destination.

The yard track in the vicinity of the substation is laid out in an interesting manner. One of the illustrations shows the track arrangement looking toward the substation and No. 1 drift. Another is a plan sketch of these tracks so designated as to aid in explaining how trips are made up ready for their movement to the tipple. Five 6-ton motors gather loads at the faces and, as the workings are not extended, carry them to the assembly yard. In the plan the trip of loads on the left track is headed by a 10-ton motor which is ready to move to the tipple. Immediately after this trip had pulled out a trip of ten cars emerged from No. 1 drift on track A, and crossed over at B to track C on the bridge; the motor then pulled into the clear at D. That trip was followed by ten more loads from No. 1 drift which pulled out and backed into the loads standing on the bridge.

The second motor then pulled out light and crossed over at E, where it picked up a trip of 20 empties from track J, backing into No. 1 gathering motor, which was waiting at D. The trip of 20 empties with a motor in the front and the rear proceeded inside No. 1 drift to the flats. Here the trip split in two, No. 1 motor pulling its quota to the First Flats Left section and No. 2 motor backing its trip into the First Flats Right section. Then a trip backed down off the hill on track F, directly in front of the loads which had been deposited by No. 1 and No. 2 motors on the bridge.
No. 3 motor then pulled to the miner, going light, and waited at point G until the big motor returned from the tipple with a trip of empties. The empty trip from the tipple on arrival pulled up on track A to clear the end of the trip at H. The No. 3 motor, which had been waiting at G, then backed into this trip of empties, and pulled it up the hill over G and A.

It then backed down and over the crossover 1 in the storage track J, where the cars above the number required on the hill were dropped, and the empty trip then pulled for the hill. The big motor with a trip of 25 to 30 loads then started with the tracks cleared for the tipple. A round trip from the yards to the tipple can be made in twelve minutes.

Because of the variation in the schedule and the quantity of coal coming from the several mines at different times this description does not hold for all car assemblies, but it does give one an idea as to the flexibility of car, trip and motor shifting that may be obtained with such a layout. The large motor makes from 15 to 20 trips per day to the headhouse; as a 2-ton mine car is employed, a 25-car trip averages 50 tons, or 900 to 1,000 tons per day.

**Rotary Tip Dumps Cars While Coupled**

About 150 ft. west of the headhouse the single tram track gives way to a double track, one a load and the other an empty track passing through the headhouse and continuing out past the other side for some distance, acting as storage track. The load track is a straight-line continuation of the tramway. The headhouse is about 150 ft. above the railroad tracks over which the tipple stands. The headhouse is equipped with a two-car air-operated rotary dump arranged for dumping trips while still coupled. A 75-cu.ft. compressor, running at 190 r.p.m. and driven by a 10-hp. induction motor, supplies air at 90 lb. pressure. After leaving the dump the trip progresses by gravity to the empty-storage track, where it is picked up by the big motor on its return with the next trip of loads.

The coal drops by gravity from the cars down a concrete chute placed on a 35-deg. slope ending in a 15-ton feed hopper. The chute is 94 ft. long and 17 ft. wide. The slope of this chute is greater than usually is adopted, but as the tipple is designed so that coal may drop by gravity directly into a car as mine-run, if so desired, the slope is enough to insure the sliding of the condition. The chute is large enough for storage of 180 tons of coal.

An apron feeder provides for the mine coal at a rate of 300 tons per screen, which are designed for lump and screenings. The lump and the shaker screens to picking tables, each parallel to the railroad tracks, ft. clear picking space. Each table of the receiving boom for lowering the lump and railroad cars. Screenings are loaded by means of chutes.

**Can Load Run-of-Mine with Apron Feeder**

Emergency run-of-mine may be a chute from the receiving hopper on the track without operating the tipple. From the picking table passes by and thence to a refuse bin across the tipple. Picked run-of-mine may be through the lump loading boom, the coal picked and reassembled at the load.

The receiving hopper is of steel from the concrete chute, the floor controlled by two slide gates operated from a platform alongside the slack track. The feeder is of the apron type with a steel thimble roller chain at the minute. The shaker screens are enhanced and stepped type. The upper openings for separating the slack is 5-in. openings for separating the larger.

The discharge end is so designed that the picking table without breakage is driven by babbitted eccentrics on the eccentric shaft. The screens are driven, which also drives the picking table feeder.

Each of the picking tables is large to accommodate ten men. As already noted bands of slate are found in the
be slabbled from the lump and picked out when loose. Two feet of clear picking space is apportioned to each man. The discharge ends of the tables for a distance of 31 ft. are mounted on pivoted frames, forming loading booms for lowering the picked coal into cars. The conveyor chain is of the pitch-steel roller chain type with 4-ft. carrying pans and a speed of about 60 ft. per minute. The trough of the scraper conveyor is formed of two channels and bottom plates. The flights are carried on a 9-in. pitch steel thimble roller chain driven by a 15-hp. motor at a rate of approximately 80 ft. per minute. The tipple was designed and erected by the Pittsburgh village of Henlawson, the rest of the foliage on the surrounding hills is four of these fabricated houses equipped with a bathroom rooms. They shelter eighty-five single men. As 162 men work, there are about two men to each house, each man.

Spiral Dump Is an Old Idea in a New Form

PAUL STERLING, mechanical engineer, Lehigh Valley Coal Co., Wilkes-Barre, Pa., calls attention in a letter to Coal Age to the fact that the dump shown in the article entitled “By a Twist in Track Cars Are Turned Partly Over, Dumping Contents” is quite similar to one built many years ago.

The article to which Mr. Sterling refers was written by A. F. Brosky and appeared in Coal Age of July 13, 1922, page 50. It describes a dump wherein the rails and wheel grips are spiraled through a certain number of degrees, first one way and then the other, thus changing the direction of movement. The device built by W. A. Lathrop, at that time of Pennsylvania Coal & Coke Co.”
Pulverized Coal Is Dangerous on the Surface as Well as Underground; Precautions to Be Taken in Handling It*

Cleanly Use of Powdered Coal Essential to Safety—Switches and Generators Have Been Known to Ignite Dust Clouds—Dangerous to Overheat Drier—Beware of Fire in Circulating Pipes

By L. D. Tracy†

Pittsburgh, Pa.

PLANTS in which pulverized coal is used should be carefully inspected, and the owners and operating forces should be impressed with the absolute necessity of reducing to a minimum conditions that tend to raise or ignite a cloud of coal dust.

This latter term is used advisedly. Pulverized coal in bulk is not especially hazardous, but as soon as it is raised into a cloud and mixed with air it becomes as dangerous as an unconfined body of gas. It takes only a small quantity of coal dust per cubic foot of air to form a highly explosive mixture. In tests by the Bureau of Mines 0.032 of an ounce of Pittsburgh coal dust mixed with a cubic foot of air has been found sufficient to cause an explosion when brought in contact with flame. Perhaps this danger can be visualized more readily when it is stated that all that is needed to produce such an explosion is a quantity of coal dust that can be heaped on a silver quarter of a dollar mixed with the air contained in a 12 x 12 x 12-in. box. Such a mixture needs only an open light to cause it to explode.

Some time ago the Bureau of Mines demonstrated the inflammability of powdered coal at its experimental mine. A large funnel containing pulverized coal was connected to a compressed-air line and a short distance away a piece of burning waste was placed on a small rod driven into the ground. The air was turned on, raising the coal dust into a cloud which was blown across the burning waste. Prompt ignition of the coal followed.

One form of coal dust which is exceedingly dangerous and to which perhaps too little attention is paid is that coming from small heating furnaces in which pulverized coal is used as a fuel. These furnaces are comparatively small and are used principally to heat bars and rods for small forgings. They are somewhat like the old-style blacksmith forge, being generally provided with a hood over the fire for carrying away the fumes. The pulverized coal is shot in under pressure and sometimes all of it is not completely burned but goes off into the surrounding atmosphere as floating dust which finally settles all over the platforms around the furnaces, on the beams and girders of the buildings and any other place upon which it can lodge.

I once made an investigation of a plant in which this condition existed and found this kind of dust all over the building. Samples were taken and analyzed. Many of these samples were not much different from a poor grade of pure coal.

A rather peculiar accident happened some time ago from dust of this kind in one of the Pittsburgh steel mills. At one point in the building an electric switch was so situated that dust could settle between the poles. One Sunday, when the mill was shut down, sufficient dust accumulated to form a short-circuit, and as a result a whole panel of the switchboard in the power house was burned out. Many accidents have occurred practically all of which were due to the dusty and unclean condition of the buildings.

Some hazards, however, are more or less connected with the apparatus used in pulverizing the coal and delivering it to the point of consumption, and though it is true that reduction of the fire and explosion risks rests largely with those operating such plants yet much can be done through proper inspection by well-informed authorities having proper jurisdiction. In order to get an adequate understanding of these hazards and their remedies a working knowledge of the methods and machinery used in pulverized-fuel plants is necessary. A brief description of these methods and equipment therefore may be of value.

Before coal in a finely divided state can be used for fuel it must be crushed, dried, pulverized and conveyed to the furnace or boiler where it is to be used. Generally speaking three distinct classes of pulverized coal equipment are in general use. These may be designated as (a) the circulating system, (b) the indirect system and (c) the unit system. The first two mentioned employ practically similar processes, varying perhaps in detail, but differing chiefly in the manner in which the pulverized coal is transported to the furnaces.

In the circulating system, after the coal has been pulverized it is fed in regulated quantities to a fan, by which it is forced in a cloud through pipe lines with diameters ranging from 8 or 10 in. up to 14 or 16 in.
Branch lines leading from the main line to the furnaces carry such coal as may be needed and the surplus, which has not been drawn from the main line, is returned to a point near where it started, where a separator removes the coal dust from the air and returns it to a storage bin to be blown again through the line.

In other words this system embodies a continuous circulation of coal dust. It is somewhat analogous to a gas line where the fuel is drawn off as needed. Secondary air lines, independent of the main coal feed, provide the additional air at the burners necessary for proper combustion.

The indirect system transports coal either by means of compressed air under possibly 50 to 90 lb. pressure, a screw conveyor, or a combination of air and screw conveyor to bins at the furnaces. From these bins the pulverized coal drops into a small screw conveyor by which it is either fed to an air blast which carries it into the burner, or directly to the burner itself.

**DIRECTLY AND INDIRECTLY FIRED TYPES IN USE**

An important feature of this method of utilizing pulverized coal as contrasted with the circulating and direct systems is the entire absence of a drier to expel the moisture from the raw fuel.

Two types of these driers, the directly and the indirectly fired, are at present in use. The former type consists practically of a long shell from 3 to 5 ft. in diameter, at one end of which is a furnace and at the other a stack. The hot gases pass through the center of the shell, coming in contact with the raw coal, which is fed into the drier at the stack end.

The indirectly fired drier generally is one of two kinds. The first is the double-shell type which consists of two cylinders, one inside the other. The raw coal travels through the inner shell and the hot gases move in the opposite direction in the space between the two cylinders, after which they return through the inner shell to the exhaust stack.

The other kind has an inclined single shell, the higher end of which terminates in a brick housing supporting the exhaust stack, and the lower end in a steel hood. The furnace for heating the drier is placed between the stack chamber and the hood. This furnace is provided with a large combustion chamber through which the drier shell passes. The hot gases from the combustion chamber of the furnace circulate around the outside of the drier shell.

**DRIER IS A POTENT FACTOR IN EXPLOSIONS**

The drier, directly and indirectly, doubtless is the cause of a large percentage of the fires and explosions which have occurred in coal-pulverizing plants. On the man operating the drier—by this I do not mean the man in general charge but the one actually shoveling the coal—is placed a great responsibility, akin to that laid on the man in charge of a battery of boilers. I sometimes think that the average factory or power-plant superintendent little realizes this fact. If the man tending a boiler forgets to keep the water therein at the proper level, something pretty costly is likely to occur. If the man tending a drier happens to perform his duties improperly and allows the furnace to become too hot the chances are that there will be work for the fire department in that vicinity.

This is well illustrated by an explosion and fire that occurred in a large steel plant. From evidence obtained at an investigation it was well established that the man tending the furnace of the drier for some reason built up an abnormally large fire so that the coal in the drier ignited. The flame then passed into the pulverizer, where it came into contact with fine coal dust, with the result that an explosion followed, filling the entire building, killing two men and badly burning two others.

One precaution that can be taken to prevent fires in buildings where powdered coal is used is to insist upon absolute cleanliness in the pulverizing plant. Accumulations of dust must not be allowed. One principle that should never be forgotten is that when cleaning up such a plant coal dust should never be swept up with a broom nor should accumulations be dislodged from window ledges, girders, boiler housings or platforms by blowing with compressed air, unless they have first been thoroughly wet down or mixed with incombustible dust in the proportion of seven parts of rock or shale to one of coal. Some plants that I have visited are kept almost spotless by means of a vacuum system.

Another safeguard is to isolate the drier from the rest of the pulverizing plant. If the former is not placed in a separate building it should at least be separated from the coal-consuming equipment by a blank masonry wall.

If a building the inside of which is covered with coal dust once starts burning the fire will spread with far greater rapidity than in a similar building that is clean. In fighting a fire of this nature care should be taken to avoid a sudden explosion or backfire from pulverized coal, possibly stored in a bin, but suddenly raised into a cloud by a sudden air draft or by falling material.
All driers should be equipped with recording pyrometers that make a continuous record of the temperature at which the drier is operated. Preferably this chart should be placed in the office of some responsible official. Thermocouples—that part of the pyrometer affected by the change in temperature—should be installed at the discharge end of the drier.

One of the greatest causes of fire in a drier room is the continued passage of hot gases from the furnace through the drier shell when the machine is not in operation or when the shell is not revolving and there is not a constant stream of coal passing through it. Under such circumstances a certain amount of coal may quite possibly be lying in the drier shell, which, through continued contact with the hot gases, may in time become ignited. When the drier is again put in operation this hot coal will either be delivered to the pulverizer or to the dried-coal storage bin. If it goes to the pulverizer it is likely to ignite and explode the fine dust therein; if to the dried-coal storage bin, it may possibly start a fire. Such fires usually are, and wrongly, charged to spontaneous combustion. On the other hand, through continued application of heat from the furnace, gas may be generated from the coal within the drier. This may collect in the shell and explode, with disastrous results, if brought into contact with an open flame.

Though regulation of the coal-drying equipment is largely a matter for the operating official, yet an enactment by the proper authorities requiring all driers to be equipped with bypasses, in order to prevent the gases of combustion from entering the shell when these machines are not in operation, would be of great value.

Next to the drier one of the most prolific sources of trouble is the large main which circulates the mixture of air and coal dust around the plant, returning the unused coal to the storage bin. Pulverized coal is driven through this line by air currents induced by a fan and having a pressure of about 8 or 9 oz. per square inch. Fires in this line are often of a smoldering nature but they may heat the pipe red hot. In coping with such a fire little can be done save cutting out the hot section.

In any event the blowing fan should be stopped. The most important precaution of all, however, is that the entire line be inspected to see that it is absolutely free from sparks, glowing particles or smoldering coal before the fan is again started. Otherwise there may be just enough dust lying in the bottom of the pipe line to make an explosive mixture when it is raised into a cloud by the starting of the fan. Such a mixture will cause trouble if brought into contact with any glowing particles. For this reason after a fire in a coal-circulating line the entire piping system should be thoroughly inspected before the fan is started.

At a manufacturing plant which had a large number of small furnaces drawing fuel from such a line, the main fan suddenly broke down and stopped running. The sudden cessation of pressure evidently permitted a back draft and drew hot particles of coal into the pipe line. Here they continued to smolder until several hours later when the fan was again put in operation. The air current, thus started stirred up the dust which had settled to the bottom of the pipe and simultaneously fanned the smoldering coal into flame. The result was an explosion which travelled throughout the entire length of the pipe line and ended by blowing into pieces the cast-iron housing of the fan, one man being killed and two others burned. It is perhaps needless to say that all pipe lines carrying pulverized coal should be of metal.

In a pulverized-coal plant all elevator systems and all screw conveyors should be dust-tight. This type of apparatus offends more, probably, than any other in the matter of throwing off fine dust. For a while this dust will remain in suspension, but it finally settles on some convenient flat surface. It is an easy matter to permit the joints to become loose and the cover to be jarred off.

Coal elevators should be adequately vented to the outside air. One point should be closely watched, however, in all outside vents connecting with passages wherein pulverized coal is carried and that is that the dust be not discharged in the open air in such manner or at such points that it may be drawn into the doors or windows or settle on the roof of some other building.

Fires in storage bins have been another source of trouble to users of pulverized coal. Such bins are of two kinds, those which have a capacity of 15 tons of dried coal or thereabout and those that store pulverized coal. The latter hold from one to five tons each.

**Need Self-Ignition Data for Powdered Coal**

Spontaneous combustion almost undoubtedly plays a large part in the origin of these fires. Few reliable data are available concerning spontaneous combustion under the conditions found in pulverized-coal plants. We do not have, for instance, information relating to the quantity of air that should be circulated through the bin or the temperature which once reached will cause the coal to heat rapidly. We know, however, a few things about the spontaneous combustion of coal under other conditions and they may possibly hold true for pulverized coal. One is that fine coal exposes a larger surface to the air than coal of the same weight but in larger sizes. Consequently, it will take up oxygen more rapidly. Burning is, of course, no more nor less than a rapid absorption of oxygen. Once coal is heated by any agency whatever to a temperature of 150 or 175 deg. F., it conserves enough of its own heat and absorbs oxygen so rapidly that the temperature of actual combustion is soon reached.
Accounts of the following instances of spontaneous combustion are taken from the records of the Bureau for Safe Transportation of Explosives and other Dangerous Articles, which is affiliated with the American Railway Association.

Smoke was noticed coming from a box car loaded with pulverized coal in bulk. The side doors were opened for ventilation. At first actual fire could not be detected, but the entire load was hot and smoke was rising from the surface of the coal. Three hours later the fire was seen coming to the surface. Efforts were made to transfer the contents of the car, but the dust and gas ignited where the men were shoveling. Finally the car was brought to a fire hydrant and a stream of water was used on the dust from time to time. It was eventually necessary to wash the entire load out of the car with a stream of water.

Another case was that of a shipment of pulverized coal in bags. When the doors of the car were opened smoke poured out in great volume. Several bags of the pulverized fuel which had ignited spontaneously were unloaded from the car and the fire extinguished.

An official of a large steel company in the Youngstown district stated that trouble had been experienced from fire in its pulverized-coal bins. There was no way, so far as he knew, in which burning coal could be transported to and deposited in the bins. These bins were close to the heating furnaces and thus absorbed much radiant heat. However as they were not large they probably were supposed to be emptied every 24 hours.

It is a well-known fact that for some reason pulverized coal will stick to the sides of a bin and in time become so caked that it is necessary to jar the bin or use bars to loosen it. In such cases the coal fed to the furnace comes entirely from the center of the bin.

It also is a well-established fact that pulverized or even slack coal stored in close proximity to a furnace, a steam line or a stack for exhaust gases will heat up much more quickly than it would otherwise. As the bins mentioned often caked and were close to the heating furnaces it is reasonable to assume that the coal clinging to the side walls was heated by radiation from the furnaces and in time reached a temperature high enough to cause combustion.

It is well, therefore, to locate all storage and other bins containing pulverized coal as far away from furnaces, open lights and flames as operating requirements will allow. The bins should be so located that no radiation from furnaces, boilers, steam pipes, flues or other heating appliances can materially raise the temperature of their contents. When practicable, bins used in connection with various furnaces should be placed outside the main building. Where this is not practicable they should be separated from the furnace by a non-combustible partition.

Where a bin contains any large quantity of burning coal care must be taken to guard against one important danger when making efforts to extinguish the fire. If a stream of water is poured on red-hot coal carbon monoxide is likely to be generated, and should the bin be located within a confined space men are quite likely to be overcome, for carbon monoxide is the most poisonous gas of all those ordinarily encountered. A fraction of 1 per cent is deadly when breathed. If a strong stream of water is played on a pile of powdered coal within a bin a cloud of dust may be raised, and when it comes in contact with a flame it may ignite, with serious consequences.

Probably the quickest, safest and most economical way to cope with a bin fire is to remove all the coal as soon as possible and let it lie in a pile outdoors until the fire is entirely extinguished.

When fires occur in driers their extinguishment requires considerable judgment. If the fire has not attained much headway it may be put out with water. If it is fierce and the drier shell has become red hot, however, it would hardly be well to introduce water. While I have no personal knowledge I understand that live steam is a highly effective and safe means for extinguishing a fire of this kind.

All electric wires and cables in a plant using pulverized coal should, as far as possible, be carried in conduits. All switches, as far as can be arranged, should be placed on the outside of any building in which coal dust is likely to accumulate, and where they cannot be so located they should be of the oil-immersed type. The necessity for this precaution is shown in the incident mentioned above wherein a switch short-circuited by dust and a switchboard panel was burned out.
Motors that are likely to spark are a potential source of danger. Perhaps the best illustration of this peril is the explosion which occurred at the New Brancephet colliery in England. The pulverizer was driven by a 25-hp, 500-volt direct-current motor, which was inclosed but not explosion-proof. It stood on a platform about 6 ft. from the floor. A short-circuit of one of the armature coils caused severe sparking, whereby the coal dust inside the motor casing was ignited. This caused an explosion of sufficient force to blow off the sheet-iron hood that covered the commutator end of the motor. The flame thus produced ignited the fine dust held in suspension within the building, the resulting flames extending 6 ft. outside the open door and for a height of 15 ft.

The U. S. Bureau of Mines and prominent English authorities have made extensive tests in order to determine whether a cloud of dust can be ignited by an electric arc or spark. For instance, when an arc was formed with a direct current of 100 volts and 100 amp. ignition was obtained in twenty cases out of sixty-two. With a direct current of 240 volts and 27 amp. ignition was obtained nineteen times in twenty-three trials. A motor of 5 hp. on a 220-volt circuit ignited a dust cloud once in every ten trials, and a 10-hp. motor on the same voltage ignited a dust cloud almost every time. Consequently motors of the non-sparking type, preferably squirrel-cage machines, are the nearest to being explosion-proof now available. All machinery should be thoroughly grounded to prevent sparks arising from static electricity.

Whenever inspections for fire hazards are made around any kind of plant where there is a prevalence of dust, whether it be of coal, grain, aluminum, or in fact dust of any kind, the electrical equipment should be carefully examined and especially any device that may spark, such as motors, exposed switches and electric wiring.

When portable incandescent lamps are used to illuminate any place in which there is liability of a pulverized-coal cloud forming the bulb should be protected with a wire guard. It is, however, dangerous to use these portable lights around dusty bins because the dust may be ignited by sparks from possible defective connections and short-circuits. Ordinary hand flashlights are handy and safer.

In closing I would like to emphasize the following considerations: A cloud of coal dust and air mixed in the proper proportions is as dangerous as a cloud of unconfined natural gas and air; a fire in a structure covered with coal dust, even though the dust has been partly consumed, will be difficult to fight, because if this dust once gets in suspension in the vicinity of flames an explosion is quite likely to occur. Such an explosion has no mercy on anyone who may be fighting the fire in the vicinity.

Supplementing Locally-Generated Current
With Central-Station Power

By M. E. Benedict

An ingenious method whereby locally generated power may be supplemented with central-station current has been devised and patented by H. A. Scott, of Saltsburg, Pa., chief electrician of the Kiskiminetas Coal Co. This scheme has been in successful operation at one of the mines of that company for several years.

The plant is equipped with a steam-driven generator of sufficient capacity to carry the average mine load but inadequate to handle the frequent peaks incident to mine operation. It was necessary therefore either to buy another steam-driven unit or to purchase power, which in this case was readily available. The latter course was decided on and a motor-generator set was installed in the mine as near the load center as possible, power being taken underground through a borehole. Under these conditions the motor-generator set would naturally handle most of the load, and as it was desired to hold the amount of purchased power to a minimum Mr. Scott worked out his device. The plan evolved has resulted in only about 10 per cent of the energy used being purchased from the public-service corporation.

The accompanying illustration makes clear the manner in which the device is operated. The generator A is steam-driven and is located near the drift mouth. It is equipped with the switch C and circuit breaker D. Generator B is the motor-generator set within the mine. The feeder from generator A contains the solenoid E, which, when the current output of this machine reaches a predetermined quantity, closes the contacts 1 and 2, thus establishing a shunt circuit from generator B through the solenoids F, G, and H, through the contacts 3 and 4 and 1 and 2, this circuit being marked 9. The

*Consulting engineer, Johnstown, Pa.
current traversing the solenoid \( H \) closes contacts 5 and 6, whereupon generator \( B \) feeds into the trolley through the coils \( F \) and \( G \). Current passing through the coil \( F \) by actuating its plunger closes contacts 7 and 8, which gives another path for the return of the shunt circuit 9. This is necessary, as contacts 1 and 2 will open as soon as the generator \( B \) relieves generator \( A \) of part of its load.

The plunger in the coil \( F \) is set to open by gravity when current in that coil reaches any fixed minimum, this current value being adjustable. All the load is then restored to the generator \( A \). The function of the solenoid \( G \) is to act as an overload breaker. When the load on the generator \( B \) exceeds a safe value this plunger will rise, opening contacts 3 and 4. Circuit 9 thus will be opened and generator \( B \) will be out of service until the plunger of the solenoid \( G \) returns to its low position.

### When Mines Are Moisten by Steam It May Be Necessary to Do It Split by Split

**By F. C. Cornet*  
New York City**

Though a dusty coal mine may be sprinkled by a water car or pipe line so thoroughly that the danger resulting from the presence of coal dust is greatly reduced, the process does not begin to compare, so far as effectiveness and low cost are concerned, with the method that uses the ventilating current as a carrier and distributor of humidity.

For the latter process to be possible the air entering the mine must possess a temperature higher than that of the workings and be so humid that it will reach a condition of saturation before the moment when the temperature of the ventilating current is reduced to that of the workings traversed. Thus a certain amount of moisture will precipitate and settle, as would dew, on the floor, roof, ribs and timbers, moistening every square inch of exposed surface and rendering harmless all dust deposited thereon.

Furthermore, this method of humidification has this further advantage that when the moisture precipitates and settles it carries with it the invisible dust that is in suspension in the air, the moisture so long as it remained in the state of vapor having traveled in intimate contact with the dust.

The instant that the lowering temperature causes the ventilating current to become saturated, precipitation commences and continues until the temperature of the mine has been reached, after which all water vapor left in the traveling air remains in it and returns with it to the outside.

During the greater part of the summer season the ventilating current is at a temperature sufficiently above that of our mines and contains enough moisture to insure a deposition of humidity abundant and prolonged enough to render harmless the dust present in all places traversed by the air current.

In mines abundantly and efficiently ventilated it is a matter of common observation in summer that the traveling air begins to shed humidity on entering the mine and continues to do so to the end of its underground progress. This is of great importance, for whether the ventilation be blowing or exhausting, it results in the humidification of not only the aircourses and workings proper but also of the haulage roads, which generally are dusty, often more so than the rooms themselves, a condition due to the action of the wheels on the coal falling from the cars.

What happened fifteen years ago at Monongah, W. Va., when a trolley wire fell on the track a short distance from the mine mouth and thereby caused a disastrous dust explosion, demonstrated that when measures are devised to humidify a dusty mine the

**Diagram:** System of Humidifying Mine by Separate Splits

Air must be so completely heated and so adequately humidified that when it is about to leave the mine it will still be prepared to deposit moisture when passing over surfaces of the temperature of the workings. Otherwise it will leave its work only partly done. To give the air in any one split more heat and more steam it is given all that is available, but for a short time only, and each split has its turn.
haulage roads, beginning at the first set of timbers, should not be forgotten.

The conditions of temperature and moisture under which the ventilating current is able to deposit humidity from the beginning to the end of its underground travel, through the twenty-four hours of the day, are met only during the hottest and most humid weeks of summer. There may be summer days when the atmospheric temperature is abnormally low and the ventilating current, being initially little warmer than the underground workings, deposits all the humidity it is capable of yielding before it completes its passage through the mine. But any deficiency thus caused in the humidification process is sure to be made up in a day or two, when the outside air again becomes warm.

When a mine fails in summer to be thoroughly humidified it will generally be found that the ventilating air volume is either too small or unevenly distributed. The latter occurrence is much more frequent than the former, for if the total volume of air entering a mine is, in general, amply large to satisfy all necessary humidification requirements, it is seldom rightly apportioned. Some of the separate currents into which it is subdivided are sometimes of such small volume and travel so slowly that they reach the temperature of the mine at an early stage of their travel, thus ceasing to spread moisture before reaching the places most in need of humidification.

Some Splits Take Too Much of the Moisture

Conversely, the volume of other splits may be so large that they spread moisture in needless profusion along their whole route, their temperature even on returning to the outside being often found to be higher than that of the workings they have superabundantly ventilated and humidified.

The remedy for these different conditions suggests itself. If the situation of certain workings is sometimes so dry that their humidification by the ventilating current calls for the use of an air volume seemingly out of proportion to their importance, the management of the mine is solely responsible for this condition, which in nearly every case is attributable to lack of foresight.

During seven months of the year, when for the greater part of the time the atmospheric temperature in West Virginia is lower than that of the mines, the ventilating current grows warmer as it travels underground, thereby developing a capacity for absorbing moisture which is evidenced by the drying up of all ventilated places, except, of course, those where water happens to run out of the strata. The more abundant the ventilation, the more marked is this drying process, which sometimes is so active that sprinkling, unless continuously resorted to, is powerless to check it.

When steam is turned into the ventilating current it warms the air, thus enabling it to absorb a certain amount of water vapor, which it sheds later while traveling through the workings, thereby humidifying the latter. Most coal-mining men are familiar with this method, which, however, has been found to fail in so many instances that many have hastily condemned it as not worth bothering about or, at any rate, not sufficiently satisfactory in its application to justify driving the fan by steam when electricity is more convenient.

My opinion, gained from personal experience, is that in all cases where the fan is a blower, exhaust steam turned into the ventilating current will do all that the advocates of the idea claim for it, provided the volume of air thus treated is not out of proportion to the weight and temperature of the steam exhausted by the fan engine.

When the volume of the ventilating current is too large to be humidified as a whole by the exhaust steam, it must be treated in detail, being to that end split into two or more parts, the largest of which must not overtax the heating and humidifying capacity of the steam furnished by the exhaust of the engine. The splitting must be done close enough to the fan to permit the full amount of exhaust steam to be discharged in a controllable and practical way into each split separately, heating and humidifying each in turn.

The full exhaust may thus be turned into each split at regularly recurring intervals, thereby raising its temperature sufficiently and imparting to it enough moisture to develop in it a humidifying capacity that will endure throughout the time it takes the air in each split to run through the workings assigned to it.

Gate Valves Place Heat Where Desired

How the ventilating current may be thus humidified in detail is shown in the accompanying drawing. The fan and engine appearing here are of old types; the wooden housings, having outlived their usefulness, will soon be replaced by a concrete covering of a design calculated, as may be seen, to make the plant fairly efficient. The main air current will be subdivided, as shown, into three splits within a distance of 20 yd. from the center of the fan. Two gate valves, placed near and under the engine in a double system of exhaust piping, will permit the management to direct the exhaust steam at will either into a vertical pipe leading into the atmosphere or into a horizontal pipe laid in a so-called pipe tunnel parallel with the main airway and separated from the latter by a concrete wall through which pass three branch pipes, each controlled by a gate valve and each leading into a separate split, an arrangement designed to permit the separate warming and humidifying of each split in turn.

The system is a most flexible one. All of the exhaust steam may be sent direct into the atmosphere or part of it may be sent there while the rest is directed through the horizontal pipe and one or more of its valve-controlled branches into one or more of the splits. Or again, all the steam leaving the cylinder may be sent through the tunnel pipe and its valve-controlled branches into the three splits concurrently or each split separately, in turn and in rotation.

In order to make the arrangement a success the tunnel is made easily accessible by a good stairway running down from the engine room. A hole 3 or 4 in. in diameter, made in the airway wall at the far end of the tunnel, will keep the latter continually ventilated and fairly comfortable, and two electric lights will be kept burning there at all times. The horizontal pipe will be buried in tamped cinders, as indicated, the valve-operating wheels, their stems and stuffing boxes only standing up out of the leveled and hardened fill.

Even if both lights should happen to be out at the same time, an operator used to the place will be able, despite the darkness, to find the valves rapidly and without difficulty. The latter will have to be operated often in any event, the present plan being to keep the exhaust blowing in each split for 8 hr. at a time, making it necessary to make a change in the gate valves only three times a day. The probabilities are that if the 8-hr. period is departed from it will be made longer, not shorter, thus increasing proportionately the intervals between valve changes.
Responsibilities in Firebossing

Importance of the Work—Other Duties Than Inspecting for Gas

Fireboss in a Large Mine Has No Time for Tracklaying and Timbering—Unusual for a Fireboss to Wink at Unsafe Conditions

FROM some of the letters that have appeared in Coal Age, regarding the work and duties of firebosses, it would seem that many of these officials, following their morning inspection of the mine, are put to other tasks than their own particular work.

During the past twenty-seven years, I have filled all the positions inside the mine, from trapper boy to mine superintendent. Practically, all of this time has been spent in gaseous mines employing firebosses or "gas watchmen," as they were called at times.

Except in a small mine or one that had just been opened where the duties of the fireboss did not occupy his whole time, I have never known a man acting in that capacity to be taken from his own particular work and asked to lay track or timber roadways.

Having been employed as fireboss, myself, it has always been my custom to consider the work one of the most important jobs that fall to the lot of underground workers. Its relation to the safety of life and property makes it such. My experience is that there are many duties of a fireboss other than inspecting for gas.

When a fireboss gives the attention he should to the ventilation of the working places, seeing that crosscuts are made at regular distances apart and brattices and stoppings properly built, he has little time for anything else. This is particularly true where the mine has been developed to the extent that there are abandoned workings to be looked after and kept in safe condition and doors, air bridges and other appliances to be examined daily.

Much Depends on the Fireboss

Capable firebosses are valuable men, in a gassy mine, and should be treated as such. Where they are able to work in harmony with the other mine officials and have their confidence and respect, it will generally be found that conditions in the mine are improved. I have known cases where firebosses were afraid to give orders to the men in their charge, because of the union; but such instances are comparatively few.

In my opinion, the fireboss, in a gassy mine, is of all officials the one on which the mining company must most depend. His responsibility is great and requires him to be a man of sober, industrious habits. His character and reputation for honesty must be beyond reproach.

Reference has been made, by writers, to the question of whether the fireboss should be made responsible to the state or to the company. For my part, I cannot see any material difference between the two cases, if the man is honest and conscientious in the performance of his duties. He must comply with the requirements of the mining law and act without fear or favor, whoever employs him.

It is contrary to my belief to think that any company or corporation would want their fireboss to slight their duties; because there is too much at stake in both life and property. It may happen that a mine superintendent, or a foreman, will expect his fireboss to wink at some conditions that he knows entail some risk; but such instances are the exception and not the rule. The fireboss who is content to do contrary to what his judgment tells him is safe is unworthy of respect, whether he acts according to his own will or under pressure from a superior officer.

Cumberland, Wyo. WYOMING.

Improvement Needed in Shotfiring

Progress slow in methods of blasting coal—Advantage gained by employment of special crew for that purpose—Large proportion of miners shoot their own coal.

When one considers how prone a large number of coal operators are to continue old methods and practices, in the operation of their mines, it would seem that the coal-mining industry in this country is very much like a big overgrown baby, asleep and not mindful of what is going on around it. This remark is suggested by the reading of an excellent editorial that appeared in Coal Age, May 25, p. 870. The article is entitled "Power Drilling"; but, in addition to drawing attention to the use of electric drills or jackhammers, by a few miners who have thrown aside their old hand-drills and adopted these new devices for drilling their holes and cutting hitches or footholds for timbers, the writer alludes to the need of similar improvement being made in the work of shotfiring as now performed in mines.

This is one phase of coal mining that has not been given the attention it should have received. The reason is hard to understand, inasmuch as most mining men willingly admit that the present system of shotfiring entails great risk and is expensive for both the operator and the miner. It is not too much to say that coal operators would be surprised if they could see the amount of coal that is shot to pieces and lost, if miners fire their own shots.

Thoughtful men familiar with coal mining will readily allow that there is room for improvement in this matter. The entire work of drilling, charging and tamping the holes and firing the shots should be in the hands of men whose knowledge and judgment will yield better results.

Special Crew Given the Entire Charge of Blasting

My plan would be to employ a special crew, call them "shotfiring," if you will; but charge them with the whole duty of blasting down the coal, leaving to the present day miner only the work of loading the coal into the cars ready to be hauled out of the mine. Instead of miners, these men would then be called "loaders."

There are advantages, in this arrangement, that should appeal to every coal-mining official. Not only would this dangerous work be more directly in the control of the mine superintendent or foreman, but it would afford them the opportunity to instruct in regard to the proper methods of blasting and the use of explosives; but there would be fewer accidents and a larger amount of marketable coal would be produced by the old method.

In the Interest of Safety

As a means of safety, some companies have employed shotfiring to shoot the holes, which are drilled and charged by the miners. Other companies have gone a step farther and employed "face bosses" to see that the holes are properly placed and charged with the right amount of powder. While this is a step in the right direction, it only touches the margin of the real problem.

It is my belief that an investigation would show that 95 per cent of our bituminous coal is blasted by miners. The work is in the hands of men of varying degrees of knowledge, experience and judgment in performing the work. The results can readily be imagined and no sane person will deny that there is an inestimable amount of coal lost and lives sacrificed by reason of this condition.
In closing, I want to refer, incidentally, to the benefit to be derived by the miner or miner's family, as we must now call him, by reason of the fact that he is relieved from the burden of having and maintaining his own drill and pick. Moreover, he is not charged with the expense of powder, nor has he the same responsibility for keeping his place timbered and safe.

OSTEL BULLOCK.
Central City, Ky.

Limitation of Certificates
Coal mining, past and present—Need of mine officials keeping themselves up-to-date—Limiting the life of the certificate a means to that end.

COMPARING the mining of coal, only thirty-five years ago, with present-day methods and equipment is like drawing a comparison between the old-fashioned stagecoach and the automobile. We find nothing to justify the conclusion that the method in use then is as bad now as it has been thirty-five years ago.

New methods and practices have been developed which make the coal-mining industry safe, but how often are they used? The new methods must be learned and adopted by the mine owners or by the mine officials. This is the greatest difficulty, as many of the mine owners and mine foremen are opposed to change and have a tendency to stick to the old-fashioned methods and practices which they have learned.

LIMITING LIFE OF THE CERTIFICATE GIVES INCENTIVE TO STUDY

Taking these facts into consideration, I believe it is needful that some means be undertaken that will act as an incentive to mine foremen, mine superintendents and managers to inform themselves and become familiar with all improved means and methods constantly being placed at their disposal.

Speaking of mine officials, I would say that there are a number of mine officials, including mine superintendents and foremen, assistant foremen and firebosses, who have classed this as important, a few have assumed to think that the certificate is unnecessary in the outfit of a practical mine foreman; other than their own personal ambitions.

It is with regret that we are compelled to acknowledge the lack of such ambition, in a large number of mining men holding official positions. How often has it been stated, in Coal Age, that when a man has secured his certificate, in the majority of cases, he ceases to study, read and keep himself informed in regard to new methods and appliances relating to mining.

While I cannot feel that it would be reasonable to compel certified men to go through all that they were required to pass through in order to secure their first certificate, I do feel that every holder of a certificate should be obliged, at certain set periods, to go before a board and take an examination that would prove that he had kept pace with progress, by reading and studying, and is capable and up-to-date on all matters pertaining to the mining of coal, in his present official capacity.

To my mind, this is the surest way of keeping men in touch with the present stage of mining, both in respect to safety and economy. I do not have the old certificate withdrawn, but endorsed by an examining board, from time to time, at such fixed periods as would seem best. I hope to learn the thoughts of others along this line.

Mayport, Pa.
JAMES THOMPSON.

Re-tiring Mine Locomotives

Coal of pipes surrounding wheel operated as a blower, using coal oil or gasoline and compressed air.

NOT long ago, I remember, an ingenious device for a good practical method of removing worn tires from the wheels of a mine locomotive (Coal Age, Apr. 20, p. 660). It occurred to me that a rig we have used for that purpose would be of interest to him and others.

We designed the apparatus for our own use, after reading a description of such a device in the Railway Mechanical Engineer, Jan., 1920, p. 36. We have used this apparatus now for some time and it has proved highly satisfactory.

In the accompanying figure, is shown a diagram illustrating the construction of the device, which I would call a coal-oil locomotive tire heater. Briefly described, the apparatus consists of a coil of 1 in. pipe, passing twice around the wheel from which the tire is to be removed.

The inside diameter of the coil is made slightly larger than the diameter of the wheel. We are using a 10-gal. Haupt heater coil-oil tank, having a hose connection with the coil of pipe. Compressed air at about 70 to 80 lb. pressure is used to force the oil through the coil of pipe.

As indicated in the figure, 1/16-in. holes are drilled 21 in. apart around the inside of the coil, starting at a point about 2 ft. from where the oil enters the coil. I believe the apparatus would work successfully, however, with a less air pressure than what we are using.

As stated previously, the use of this device has given complete satisfaction, both in removing wornout tires and applying new ones; and if carefully handled the operation is not dangerous. Moreover, I would suggest keeping it well away from a low roof in the mine when used underground.

J. CAMPBELL, Supt.,
The Lehigh Valley Coal Co.
Dritton, Pa.

Working Contiguous Coal Seams on Moderate Pitches

Main slope driven on the full dip—Use of machines determines direction of driving rooms—Examples of successful workings.

An INTERESTING question relating to the working of two contiguous seams of coal, lying on a moderate pitch, was answered in Coal Age, Apr. 27, p. 702. This is a matter in which I have always been deeply interested and anxious to obtain all the information possible from the experience of others.

The question to which I have referred, a 15-ft. seam of coal having a hard floor was overlaid with a 7-ft. parting of shale, which was again overlaid with a 4-ft. seam of coal having a fireclay roof. The two seams had an inclination of 23 deg.

SLOPES DRIVEN THREE ABREAST PROVIDE GOOD VENTILATION

As stated in the reply to the question, the method of attack should be to drive the main slope on the floor of the thicker and lower seam. Owing to the large amount of air that can be driven through these slopes, the roof being 23 deg, and the driving of these slopes three abreast will be expensive, but will doubtless pay in the end. The middle slope can be used as the main intake and haulage road, and the two side slopes as return air-courses for their respective sides of the mine.

If the reply to this inquiry assumes that the seams outcrop on the property, and it is stated that the average depth of cover is 700 ft., which would suggest extra care and caution being taken in the working out of the coal. It is questionable whether the shale top of the big seam will make a good roof in working that coal. Therefore, I would suggest leaving, say 2 ft. of topcoal up, in the first working, which will leave 12 ft. of coal to be taken out in two benches.

FIRECLAY ROOF TREACHEROS

In regard to the upper seam, which is only 4 ft. thick and overlaid with a bed of fireclay, it is my opinion that it will probably be better not to mine this coal at all. The fireclay would make a very treacherous roof, particularly if the strata are wet. However, if the roof can be managed and this seam is worked the coal should be taken
out through a tunnel and hoisted on the main slope in the thicker seam.

Now comes the question as to whether the mine is to supply steam coal or coal for coking. In the latter case, a large percentage of lump coal will not be required, as the product will need to be crushed in either case. On the other hand, if the mine is to supply coal for domestic purposes every effort must be made to obtain as large a percentage of lump as possible. In that case, it will be generally agreed that machine mining should be adopted in preference to pick mining; and just here is the parting of the ways.

It is evident that the answer given to this question contemplates pick mining, since it states that the coal is worked out to the rise of the levels or gangways. Driving the rooms to the rise would eliminate the use of machines on a 23-deg. pitch.

ARRANGEMENTS FOR MACHINES

Without reflecting on the method of pick mining, however, let us assume that this coal is to be mined with machines. In that case, arrangements must be made to drive the rooms practically on the strike of the seam, which was the plan adopted by the Owl Creek Coal Co. and described in my article which appeared in Coal Age, March 16, p. 439.

In that plan, instead of driving the rooms up the pitch, butt headings are driven to the rise of the levels and rooms turned to the right and left of each pair of butts, always giving the rooms a slight inclination up the pitch so as to provide a grade in favor of the loaded cars.

As explained in that article and again referred to in my letter, June 1, p. 925, a small portable hoist is set at the head of each pair of butt headings and attends to the gathering and distribution of the cars in the rooms. The same hoist also handles the machine in passing from one room to another on those headings.

This plan is working successfully at two mines in the Gebo district, where the pitch is 23 deg., and is the only plan that has given satisfaction under these conditions. The chute-mining system, previously used in the Gebo mine, proved unsuccessful and had to be abandoned for the method just described. This mine, to my knowledge, is the only one of few pitching seams using machines in mining the coal.

Denver, Colo.

C. M. SCHLOHS.

Estimating Number of Cars Needed to Operate Mine

Important to Know Height of Coal in Determining Capacity of Cars and Other Data—Length of Haul—Kind of Locomotive or System of Haulage Employed

A WHILE ago I was called on to solve a problem similar to the one asked in a recent examination and which appeared in Coal Age. The question required me to estimate the exact number of cars needed to operate a mine successfully under certain conditions. The answer given to the examination question in Coal Age showed me the method of proceeding.

However, I want to say that in order to arrive at a reliable estimate, in a problem of this kind, it is important to know more data than are commonly given in such a question. For example, one should know the height of the coal, which will determine very largely the size and capacity of the mine cars, besides giving an idea of about the amount of coal a miner will dig in a day.

It is important to know, also, the kind of haulage locomotive employed, whether a storage-battery or a trolley locomotive, as the latter is commonly operated at a greater speed than the former. These and other data such as the length of haul, grade and condition of track materially modify the actual results in practice.

The proposition presented to me was somewhat unusual from the fact that it involved an extra long haul for the very small output desired, as I was asked to estimate on a daily output of 100 tons, in 8 hr. The main haul was approximately three miles each way, with a 3 per cent grade in favor of the loaded cars.

My report was to state the capacity and number of cars needed, and the type and weight of locomotive required for the most economical operation of the mine. Although my information warranted me in assuming that a 500-volt, direct-current transmission is economical for a distance up to four miles, I decided that this small tonnage would not justify the expense of electrifying the mine for a trolley locomotive.

After carefully considering the problem from every angle, I decided to recommend the use of a storage-battery locomotive. By boosting the battery an hour at noon, each day, the locomotive would have a capacity that would enable it to operate successfully throughout the day.

My estimate was based on a speed of 3 mi. per hr., on the upgrade, and 6 mi. per hr., coasting on the downgrade, which I considered safe. On this basis, the three-mile trip outby, at 6 mi. per hr., would require 30 min.; and the same trip inby, at 3 mi. per hr., 60 min., making the time for the full round trip one hour and a half.

To be on the safe side, I allowed 15 min. for making up and changing trips at each end. This made the full time two hours per trip, or four trips a day. To handle a daily output of 100 tons, on this basis, would necessitate hauling 25 tons of coal per trip.

For ease of calculation, therefore, I estimated on hauling twelve 2-ton cars, or 24 tons of coal per trip. Then, assuming the men would load 8 tons of coal per man per day, there would be need for twelve loaders; and if these were working in pairs each place would need 24 tons a day, or two trips per hour.

In the 2-hr. interval between trips, each place would then produce two cars of coal and the six working places, together, would furnish the twelve loaded cars needed for the next trip. At the lowest estimate, I concluded there should be at least twelve cars in transit, twelve cars on the tippie unloading and twelve cars in the mine in process of loading, making thirty-six cars in all. In addition to this number, I added an extra four cars to cover what might be laid aside for repairs, or loaded with timber or other supplies awaiting movement into the mine.

***

A.MINE ENGINEER.

Colo.

The correspondent's error lies in computing the cycle of a single car. For example, each car is held 2 hr. in the mine, although it takes but an hour to load it. Then, it is 2 hr. in transit and 2 hr. waiting at the tippie for the next trip, making 5 hr. in all. Each car would then average 8 + 5 = 12 trips, per day, and haul 2 × 12 = 36 tons of coal a day. But this would make the 36 cars haul 36 × 36 = 155 tons of coal a day, which does not check with my estimate, for some reason that is not clear to me. I would appreciate being told where my error lies.

Examination Questions Answered

Kentucky Mine Foremen's Examination.
Lexington, May 30, 1922

(Selected, First-Class Questions)

QUESTION—State what, in your judgment, are the most essential qualifications to make a successful mine foreman.

ANSWER—He must be straightforward, honest and fair in all his dealings, never making promises he cannot keep. He must be broadminded, kind and patient, but firm, and a student of mine nature and a man of foresight and good judgment. He must be industrious and have a thorough technical and practical knowledge of mining, gained by study and experience.

QUESTION—Describe the various instruments that you would use first-class mine foreman or fireboss, would use to determine the condition of the mine atmosphere, the quantity of ventilation, the temperature, humidity and other general conditions. Explain fully how these are used.

ANSWER—A first-class mine foreman must have and be able to use a safety lamp of approved type, understand its construction and the danger of its misuse in the examination for gas or when used for work in a gassy mine.

The mine foreman must have and use an anemometer for determining the average velocity of the air current passing in an airway. He must be able to calculate, from the observed reading of the instrument, the quantity of air in circulation. To determine the temperature and humidity of the mine air, the foreman should have and use a wet-and-dry bulb hygrometer; and be able to calculate, from its reading, the degree of humidity or percentage of moisture in the air.

The foreman should have and use a water gage to determine the pressure producing circulation in the airways in the point where the observation is taken. He must be able to calculate, from the readings of the gage and the anemometer, the horsepower on the air. From this he should be able to estimate the efficiency of the ventilator, after ascertaining the horsepower of the engine driving the fan.

In addition to these instruments, the mine foreman should have and use a compass for setting sights, giving the desired direction of driving entries and rooms. He must have and use a tape measure for measuring distances, and finding the size of airways and break-throughs in the mine. If the seam has much inclination, the foreman should have a clinometer for measuring the degree of the pitch. Every foreman is supposed to have a reliable watch that he carries with him at all times.

In the examination of abandoned areas or workings, the foreman should have and use a carbon-monoxide detector. For the purpose of accurately determining the percentage of gas in mine air, the foreman should have and use a gas indicator that will eliminate the evil habit of guessing the percentage of gas from the height of the flame cap. This is important, as it is seldom that any two fire bosses reach the same conclusion in this respect.

QUESTION—The figure of a section of an airway is a right-angled triangle, having the base and perpendicular equal, and the length of the hypotenuse 15 ft. What is the area of this figure and what will be the quantity of air passing in this airway when the velocity of the current is 300 ft. per min.?

ANSWER—The area of the hypotenuse of a right triangle is equal to the sum of the squares of the two sides and these being equal, in this case, the square of either side is equal to one-half the square of the hypotenuse, or \( \frac{1}{2} \times 15^2 = \frac{1}{2} \times 225 = 112.5 \). Again, the two sides being equal, the square of each side is evidently twice the area of the triangle. Therefore, in this case, the area of the given triangle is \( \frac{1}{2} \times 112.5 = 56.25 \) sq.ft.

QUESTION—(a) If you were in charge of a mine, would you consider it dangerous if dry and dusty dancing face, even if gas was not present? (b) What precaution should be taken under conditions of solid shooting, in a mine of this character?

ANSWER—(a) A dry and dusty condition, at the working face in a mine, is always dangerous whether or not gas is present; but the presence of gas greatly increases the danger from dust. Also, the danger is much greater where the coal is blasted, particularly if black powder is used for that work.

(b) The practice of solid shooting should not be permitted in a dry and dusty mine. In any event, the working places should be kept free from accumulations of dust and well sprinkled before any shots are fired therein. Only permissible powder should be used. The safest practice is to employ practical shotfiers, to examine, charge and fire all holes for the miners and which, in their judgment, are safe. Each place must be examined for gas before a shot is fired.

QUESTION—(a) What should be the first thing for you to observe as a fireboss, on entering a mine? What constitutes a good safety lamp (b) for general work; (c) for testing purposes?

ANSWER—(a) On entering a mine and having regained his sight, the fireboss' first duty is to examine the condition of his lamp and know that it is burning properly, before proceeding to the main intake of the mine or section he is to examine. This does not take the place of a fireboss carefully examining and testing his lamp when assembling the same, before entering the mine. On reaching the intake his first act is to note carefully that the usual volume of air is in circulation.

(b) A good safety lamp for general work must be of a type approved by the Federal Bureau of Mines. It must give a good light and not be too sensitive to gas. It must be simple in construction, having few parts that are easily and quickly assembled. The lamp should be protected from strong air currents or a sudden rush of air, by means of a good bonnet. The air should enter the lamp from a point below the frame, in the lamp, as much as possible the tendency of the flame to smoke. Preferably, the lamp should burn a good quality of sperm or cottonseed oil, and be provided with a pricker, for cleaning the wick as may be required.

(c) A good lamp for testing purposes must give a free upward circulation of air within the lamp, which must burn a non-volatile oil and be provided with some form of indicator that will eliminate the bad habit of guessing the percentage of gas present in the air, by estimating the height of flame cap produced.

QUESTION—Is there any difference between marsh gas and firedamp? If so, what is the difference? Explain fully.

ANSWER—Yes. Marsh gas is the common name for undiluted methane (CH4), while firedamp is a mixture of this gas with air, produced in inflammable or explosive proportions. While the term "firedamp" is generally understood to refer to an inflammable or explosive mixture of methane and air, other gases may be and often are present in a firedamp mixture.

QUESTION—Are there any conditions when a large body of pure marsh gas could be rendered more dangerous than a large body of firedamp? If so, explain why.

ANSWER—This is not a practical question in its application to the presence of gas in mines; because a large body of pure marsh gas, accumulated in a mine, a greater menace to safety than the same volume of firedamp, because when the marsh gas is converted into a firedamp mixture by the addition of air, the volume of the mixture is greater than the volume of the original marsh gas.
Smokeless Output During May Exceeds That of April by Over 800,000 Tons

SMOKELESS coal production in the West Virginia fields increased from 2,860,961 net tons in April to 3,687,874 tons in May, as shown in the following table. The May output was 712,163 tons higher than for May last year, only the New River field showing a decrease.

The situation, in the opinion of many in Washington, is such as to emphasize the advisability of forming an organization within the coal industry along the lines of the Construction Council recently formed in the building industry. The possibilities of a coal council have come in for serious consideration during recent weeks. The wish has been expressed that such an organization be formed and that every effort be made to induce Secretary Hoover to become its active head. While no opportunity has been afforded for any general consideration of the plan, those who have discussed it believe it would be the most direct approach to the problem of stabilizing the coal industry. Practically the identical idea has been put into effect by the construction industries and somewhat similar ends were sought by the motion-picture industry in engaging the services of Will H. Hays and by the baseball interests in putting their affairs under the direction of Judge Landis.

That the coal industry entertains a different feeling toward Secretary Hoover from that which it had at the time the Frelunghysen bills were under discussion was shown by the anxiety occasioned in the industry when it was erroneously reported that Secretary Hoover had resigned. Numerous appeals reached Washington asking that he be induced to stay on the job at least until the coal situation had been straightened out.

Water-Borne Southern Coals Outdistance All-Rail Fuel in New England

SOUTHERN coals via tidewater seem to have captured the majority of the New England markets which can be served from rehandling points on the coast. All-rail coals practically dominated throughout 1920, with the exception of the period of the switchmen’s strike in April, and until August, 1921, reaching the peak during the first week in August, 1920, with a movement of 320,000 net tons. From that week receipts fluctuated, but with a steady downward trend, until a year later they dropped below the tonnage of water-borne coal from Hampton Roads. Since that time the all-rail suppliers have seen more and more of their territory slip over to the sellers of Southern coals, who in one week in March of this year moved 300,000 net tons from Hampton Roads alone.

The decline of the all-rail movement was definitely started when the increase in freight rates, late in 1920, put the Southern coals in better position by reason of the softening of coastwise vessel freight rates. Reduced wages in southern West Virginia mines then furthered the competitive position of those coals. Of course, the present strike has reduced production in central Pennsylvania and affected that tonnage available for distribution in New England, but even with the resumption of mining the relative positions of these two coals will not be disturbed by the July 1 freight-rate reductions, as the greater saving on all-rail freights is partly offset by a smaller reduction—mines to tide—on Southern coal. The remainder of the freight cut differential is easily overcome through low mine costs and the plenitude of coastwise vessels, which means cheap water rates.

The diagram below, compiled from the published reports of the Geological Survey up to the end of June, compares the shipments of soft coal through the New England rail gateways with cargo shipments over piers at Hampton Roads.

[Diagram showing weekly receipts of bituminous coal in New England via tide from Hampton Roads and all rail]
Text of Priority Orders, Issued July 25

Service Order No. 22, issued by the Interstate Commerce Commission Tuesday, July 25, 1922, is as follows:

The subject of routing of freight traffic being under consideration and appearing to the Commission that an emergency exists upon the lines of all carriers by railroad in the United States, the following Order is hereby made, which requires immediate action, and that each of such carriers, by reason of unfavorable local conditions and the traffic offered to it, is hereby directed, in order best to promote the service in the interest of the public and the commerce of the people, it is ordered and directed:

That from and after July 26, 1922, and until the further order or direction of this Commission, all said common carriers by rail, and all railroads in common operation with any of the carriers, are hereby directed to discontinue the routing of traffic so as to properly serve the public interests, and in order to best promote the service in the interest of the public and the commerce of the people, it is ordered and directed:

That inasmuch as such disregard of routing is deemed to be unjust, the rates applicable to traffic so forward by routes other than those designated by shippers, or by carriers from which the traffic is received, shall be the rates which were applicable at date of shipment over the routes so designated, unless the rates applicable over such designated routes are higher, in which event the rates applicable over the route of movement will apply.

That in each instance where the traffic is routed, or rerouted, by carriers by railroad under the authority of this order, the carrier responsible for such routing or rerouting shall, within three days from the date hereof, file with the Interstate Commerce Commission a notice addressed to the consignee of the traffic, stating the carrier responsible, the route or routes made by such carriers, or by carriers from which the traffic is received, or to the owner- ship of the cars, and that all rules, regulations, and agreements are hereby suspended and superseded in so far only as conflicting with the directions hereof.

That the rates applicable over the route of movement is less.

That in the case of shipments in private cars, which are subject to calculation of empty mileage, and also of fruits and vegetables, live poultry and other shipments customarily recognized as such, a telegraphic notice of the change of routing or rerouting shall be sent to the consignee by the carrier responsible therefor.

That in executing the directions of the Commission contained in this order, the common carriers involved shall proceed without reference to contracts, agreements or arrangements now existing between them with reference to the divisions of the rates of transportation applicable to said traffic; that such divisions shall be settled and adjusted between the shippers and respective routes over which the traffic is moving and that charges for such traffic shall be made in accordance with the terms and schedules of rates, fares and charges, as those terms are defined in said Act, will be the same as they would have been if such routing or rerouting had not taken place, unless, as above provided for, the rates applicable over the route of movement is less.

That in the case of shipments in private cars, which are subject to calculation of empty mileage, and also of fruits and vegetables, live poultry and other shipments customarily recognized as such, a telegraphic notice of the change of routing or rerouting shall be sent to the consignee by the carrier responsible therefor.

That in executing the directions of the Commission contained in this order, the common carriers involved shall proceed without reference to contracts, agreements or arrangements now existing between them with reference to the divisions of the rates of transportation applicable to said traffic; that such divisions shall be settled and adjusted between the shippers and respective routes over which the traffic is moving and that charges for such traffic shall be made in accordance with the terms and schedules of rates, fares and charges, as those terms are defined in said Act, will be the same as they would have been if such routing or rerouting had not taken place, unless, as above provided for, the rates applicable over the route of movement is less.

That in the case of shipments in private cars, which are subject to calculation of empty mileage, and also of fruits and vegetables, live poultry and other shipments customarily recognized as such, a telegraphic notice of the change of routing or rerouting shall be sent to the consignee by the carrier responsible therefor.

That in executing the directions of the Commission contained in this order, the common carriers involved shall proceed without reference to contracts, agreements or arrangements now existing between them with reference to the divisions of the rates of transportation applicable to said traffic; that such divisions shall be settled and adjusted between the shippers and respective routes over which the traffic is moving and that charges for such traffic shall be made in accordance with the terms and schedules of rates, fares and charges, as those terms are defined in said Act, will be the same as they would have been if such routing or rerouting had not taken place, unless, as above provided for, the rates applicable over the route of movement is less.

That in the case of shipments in private cars, which are subject to calculation of empty mileage, and also of fruits and vegetables, live poultry and other shipments customarily recognized as such, a telegraphic notice of the change of routing or rerouting shall be sent to the consignee by the carrier responsible therefor.

That in executing the directions of the Commission contained in this order, the common carriers involved shall proceed without reference to contracts, agreements or arrangements now existing between them with reference to the divisions of the rates of transportation applicable to said traffic; that such divisions shall be settled and adjusted between the shippers and respective routes over which the traffic is moving and that charges for such traffic shall be made in accordance with the terms and schedules of rates, fares and charges, as those terms are defined in said Act, will be the same as they would have been if such routing or rerouting had not taken place, unless, as above provided for, the rates applicable over the route of movement is less.

That in the case of shipments in private cars, which are subject to calculation of empty mileage, and also of fruits and vegetables, live poultry and other shipments customarily recognized as such, a telegraphic notice of the change of routing or rerouting shall be sent to the consignee by the carrier responsible therefor.

Government Control of Coal Distribution Expected To Continue Throughout Winter

By Paul Wooton
Washington Correspondent of Coal Age

Washington, July 31.—Actual control of the distribution of practically all the current coal production will be effective within forty-eight hours, Secretary Hoover announced this morning. Henry B. Spencer, administrative member of the President’s committee, opened temporary offices this morning in the old War Trades Board Building. Permanent offices are being prepared for the committee in the American Railroad Association Building, 718 18th Street.

Mr. Hoover stated this morning that there is no sign on the horizon to indicate an approaching settlement of the coal strike. He expressed the opinion that 8,500,000 tons weekly will keep the country fairly well supplied with coal if the distribution plan results in an equitable apportionment of the coal mined. He stated that practically all of the western Kentucky operators are now in line.

Officials in Washington are being deluged with requests for coal. These requests are being returned promptly to the governors of the states from which they came. Incidentally there is evidence that some of the governors do not relish the task which has fallen to them. While many governors are quick to resent federal activities which can be interpreted as an encroachment on the rights of the state, there now seems to be a desire on the part of those same governors to suggest that the federal government is in a much better position to say who shall and who shall not have coal. Secretary Hoover has made it plain that the federal government will do nothing more than allocate coal to the primary purchaser and look after the coal supplies for the interstate railroads.

While, generally speaking, the public utilities still are fairly well supplied with coal the telegrams reaching Washington indicate that there are many weak sisters among them.

The advance in the wage scale from the 1917 to the 1920 basis in some of the non-union districts is explained on the ground that poor car supply had reduced the number of working days to the point where an additional wage inducement was necessary to keep the men interested.

That control of coal distribution must continue for the remainder of the calendar year and possibly for the remainder of the coal year is becoming more and more apparent. A large corps of workers will be required. It is probable that a deficiency appropriation of $200,000 will be asked for the purpose.

The problem before the government differs considerably from that with which the Fuel Administration had to deal during the war. The situation now is a traffic problem. It is somewhat similar to the situation handled successfully by the Central Coal Committee in 1919 and 1920. As a result of the excellent work done by that committee it is probable that the new organization will be formed along the line of that committee. It may be stated, however, that the methods used by the Central Coal Committee in regard to paying for coal will not be followed. Since the situation is being controlled through the powers vested in the Interstate Commerce Commission, the execution of any plan must be carried out by the railroads. For that reason Henry B. Spencer, the former chairman of the Central Coal Committee, has been chosen as the fifth member of the President’s committee.

In addition to the need for an appropriation it is apparent that the administration soon will request legislation giving out-and-out power to fix prices and to seize coal. There is a possibility that a revolving fund will be asked, so that the administrative committee can buy and sell coal when occasion demands.

Even if arbitration negotiations were begun at once it is realized that some time necessarily must elapse before the union fields actually would be producing coal. By that time the country will be so far behind in coal production that supplies will be insufficient for all purposes. For that reason there is certain for many months to be a trying problem in the attempt to see that the more essential activities receive necessary fuel requirements. Control of distribution has not begun as yet, and it will be several days before the necessary machinery can be put into shape for its inauguration. The fact that the job is a railroad traffic problem probably is the reason why Dr. Harry A. Garfield was not requested to take over actual administration of the work. The desire was voiced in official circles that he be made the administrative member of the President’s committee as recognition of the work he did during the war and to prevent what would seem to be a further mark of ingratitude for the valuable public service that Dr. Garfield rendered as Fuel Administrator. So far as can be learned, no invitation was extended to him. The reason, doubtless, was that he already had announced that he would not accept such an appointment although the apparent fact that the actual administrator in this situation must be a traffic man may have been the compelling one.

Railroad Strike Situation Encouraging

Reports reaching Washington during the last three days as to the improvement in the railroad strike situation have been encouraging. Apparently, the railroad executives were not thoroughly aroused to the seriousness of the situation before the shopcraft strike. As a result there was hesitancy in taking drastic action to operate with new men. The seriousness of the situation soon became apparent, however, and the results of the delayed effort are only now becoming apparent, it is believed. Traffic is moving better through all the vital junction points and there have been encouraging responses to the railroads’ invitations for outside shopmen. The situation will be relieved further, it is believed, as industry is slowed down by lack of coal, thereby making available more men from whom the railroads can draw workers.

The coal operators report much better prospects of obtaining men for the mines that they are opening in the union fields. Once it is established that protection is adequate, it is believed that enough men can be obtained in the Pittsburgh district and in central Pennsylvania to produce a considerable tonnage of coal. In addition, that the building up of output from mines in the union districts will be a slow process. John L. Lewis’ efforts to call together a rump conference of operators in the Central Competitive Field is not being taken seriously by coal operators or in official circles. While it is admitted that there are certain operators in each of the four states who would join Mr. Lewis in this effort, the tonnage that they would control would be insignificant as compared with the total output of the Central Competitive Field. Nevertheless, Mr. Lewis’ utterances indicate that the idea of negotiation is being kept alive.

Secretary Hoover on July 30 announced the details of his plan covering coal distribution. His statement reads as follows:

“The federal government will limit its activities in coal distribution entirely to interstate questions. Mr. Spencer has been appointed Fuel Distributor, not Fuel Administrator, because the federal distribution is concerned with coal distribution between the different states, not with coal administration in the sense of the war organization.

“Control of coal distribution to individual consumers within the state boundaries is of course in the hands of state authorities except for railway coal. The methods of handling coal for railways responsible to the Interstate
Commerce Commission will be determined directly from Washington in maintaining interstate commerce. "Distribution problems vary in different groups of states; that in New England, Middle Atlantic, Southern, Middle West, Northern Lake States, Intermountain and Pacific States. The last two groups are able to look after themselves and are not now embraced in active administration. Each state outside the above groups has been required to canvass its situation as to stocks and requirements in order of the priority in different classes—public utilities, public institutions, households and industrial coal. "Each state has been asked to make such rules and regulations as it may see fit to control speculation and distribution within the boundaries of the state. It has been suggested that the co-operation of their state wholesale and retail dealers' associations should be secured. The federal government has no authority and can exert none in this matter beyond moral pressure. "Each state that must import coal from other states has been asked to create a central state agency or committee for the purchase or guarantee of purchases of coal that may be imported into the state from other states or from abroad, all coal to be consigned to an agency designated by the state. By this arrangement a great deal more mobility is given the state authorities in shifting coal to meet its local emergencies. Furthermore, this arrangement will remedy the financial impossibility of asking coal producers to ship to strange consumers whose reliability must be established. The repudiation of coal during the last strike caused great losses and litigation. "The Federal Fuel Distributor will place these state central agencies in contact with the coal producers in states of coal surplus and will undertake to see that coal is sold to the central purchasing agencies at a fair price. The state purchasing agencies will indicate the destinations within the states to which coal is to be shipped. "The federal distribution will prorate the available supplies between states following the general basis of priorities declared by the Interstate Commerce Commission. Where coal is already flowing through natural channels to priority concerns approved by the state agencies, it will continue, but it will form part of the state quota. "The whole plan is one of complete decentralization into the hands of the state authorities, the federal agencies acting solely in interstate commerce." Secretary Hoover emphasizes the fact that his organization is the Interstate Commerce Commission. He announced that instructions had been issued to all state authorities to limit bunkering only to the next port of call. After Aug. 1 all ships sailing from foreign ports must bunker for the round trip. While Canada will not be treated differently than would be the case were it part of the United States, there will be insistence that she take full advantage of opportunities to secure imports from elsewhere. With the return of H. Foster Bain, director of the Bureau of Mines, from Alaska, he will represent Secretary Fall on the President's committee. George Otis Smith, director of the Geological Survey, will continue to co-operate with the committee, but from this time forward will devote more of his time to the compilation of data for the subsequent use of the fact-finding commission. Secretary Hoover announced that every effort is going to be made to decentralize the handling of the coal situation. Great reliance is being placed upon the state governors, the state public utilities commissions and upon the railroad administrative officers and coal operators in the different districts. Mr. Hoover stated that there would be no direct effort from Washington to prevent retail profiteering. This he is leaving to the states, although every effort will be made to cooperate closely in any action they may take. M. H. Ayresworth, executive secretary of the National Electric Light Association, and A. I. Phillips, engineer for the American Gas Association, have been in Washington making arrangements preparatory to the opening of Washington offices so that the public utilities can cooperate closely with the government during the emergency. The utilities expect to work largely through the state public utilities commissions. The governors of the following states have undertaken to erect the necessary administration to control profiteering and distribution of coal within their states: Ohio, Indiana, Illinois, Michigan, Wisconsin, North Dakota, Minnesota, Maine, Massachusetts, Rhode Island, New York, New Jersey, Maryland, Pennsylvania, West Virginia, Iowa, Oklahoma, Florida, Kentucky, Tennessee and Louisiana. Kansas already has an establishment under its Industrial Court. It is not considered to establish coal control in the intermountain and Pacific states, as they have supplies of coal and fuel oil. "The following have so far been designated as members of the advisory committee of operators from the producing coal districts under the chairmanship of C. E. Bockus, of Virginia: E. L. Douglas, of Kentucky; George S. Francis, of Pennsylvania; E. C. Mahan, of Tennessee, and W. J. Magee and E. E. White, of West Virginia; also C. E. Tuttle to advise as to Lake and Northwest movement, and Le Buvon H. Willard to advise on bunker and tidewater movement.

Three Coal Roads Declare Embargo in Favor of Coal and Food

THE Norfolk & Western, Chesapeake & Ohio, and Louisville & Nashville railroads have declared embargoes over their lines against the acceptance and transportation of coal, coke and other fuel. They have been ordered to embargo a large number of the shipments of coal. This course was taken under the Interstate Commerce Commission's declaration of an emergency, which authorized roads embarrassed by the shortage of coal to embargo the shipments to strike if necessary to transportation. The embargo orders are designed to conserve all the equipment and facilities of the three carriers for the transportation of coal. All the railroads have been ordered to embargo the quantities of coal until the shopmen went out, after which their tonnage was immediately cut in half.

Managements of the roads notified the Interstate Commerce Commission that they would modify the embargo orders as rapidly as conditions permitted, and would gradually accept other classes of freight for movement as they were able to transport it without interfering with the shipment of coal.

Here's a Rocky Mountain Invitation

"COAL man from anywhere and everywhere will be welcomed at our fall meeting in Glenwood Springs." is the invitation of the Peabody Rock Mountain Coal Mining Institute issues to the world for its three-day session in beautiful Glenwood Springs, Col., beginning Sept. 7. The Institute has planned a program which includes the pleasures afforded by the mountain region around Glenwood Springs, in addition to technical meetings of wide scope. Papers scheduled for the meetings are these: "Electricity in Coal Mining," by L. M. Cargo and H. S. Sands, of Denver, Col.; "The Practical Use of Pulverized Fuel in Power Plant Work," by T. H. O'Brien, general manager of the Inspiration Consolidated Copper Co., Inspiration, Ariz.; "Wire Rope in Mining," by W. R. Abbott, of Denver, and J. F. Howe, of Worcester, Mass.; "Practical First-Aid Work," by W. F. Murray, of Dawson, N. M.; and "Co-operation in the Coal Industry," by Harry F. Nash, vice-president of the Oakdale Coal Co., Denver.

Results Obtained by W. J. Dunkley, gas engineer of the U. S. Bureau of Mines, in the course of experiments made at Ottawa, Ill., in the use of mixed coal and coke fuel for water-gas manufacture, show that capacities up to 97 per cent of the rated capacity with good coke fuel can be obtained, using 70 per cent Illinois coal and 30 per cent Kentucky coal, with 6 ft. gas, at efficiencies operating up to 60 hours per day. The generator fuel consumption was about 33.5 lb. of mixed fuel per 1,000 cu.ft. of gas made.

"HERE'S A DANGER SIGN. Watch me go past and find the trouble." He found it. Somebody found him.
Middle West Has Hectic Time of It: "Something New" About to Happen in Illinois and Indiana

BY E. W. DAVIDSON

Strike developments in the Midwest coal-mining region have been swift and baffling during the past week and promise to be just as swift if not so baffling in Illinois during the next few days. While Michigan and Indiana were trying without success to induce miners to work enough mines in those states to supply state institutions, Governor McCray of Indiana finally gave the men until Tuesday, Aug. 1, to do it peacefully or he would see that it was done by force—things were popping over in Illinois.

On Monday the operators of Illinois met to consider the situation. They were in session all day in Chicago. Frank Farrington, president of the Illinois miners, was in Chicago the same day. Wednesday Farrington got his state executive committee together in St. Louis, appeared to sound the sentiment of the striking miners, and then called a state union convention for Aug. 3 in Peoria, Ill. Word naturally went around that Farrington was breaking finally with national headquarters and was going to get authority from the convention to enter into peace negotiations with the Illinois operators. The state thought its mines were about to be opened.

The next day Farrington called off his convention, saying the Associated Press had befuddled the matter by stating, in the news story of the convention order, that the session was called to permit a test of strength between Farrington and Lewis. Later that same day Farrington retracted his charge against the Associated Press and said it at the door—or mouth—of John Watt, state secretary-treasurer of the union. Watt is reputed to be a Lewis man. Farrington said Watt was "a victim of running off at the mouth" and that statements of Watt and others had made strike settlement in Illinois a dead issue.

Meantime John L. Lewis had broadcasted to the whole country the news that he was on the point of obtaining a four-state conference with operators. With no more explanation for his sudden change of convention plans, Farrington took his foot in hand and scurried to Philadelphia to attend Lewis' conference of union state presidents preparatory to the announced four-state conference with operators. Before going, Farrington replied to an invitation of Acting Governor Sterling of Illinois that he would like to confer with Sterling on the acting governor's plan to get a few of the mines of the state open to supply state institutions with coal, but he really couldn't do a thing about it even if he were the one to be opened.

Up to Saturday night no date or place had been announced for the Lewis four-state conference with operators. Indiana on Friday had declined absolutely to have anything to do with such a conference and Illinois took the same attitude but had not, up to that time, received any invitation from Lewis to attend, so it was unnecessary for that state formally to write its refusal. However, the full pressure of Ohio in favor of the conference had been exerted upon both Indiana and Illinois, with no more success, it appears, than was had with the Pittsburgh operators of Pennsylvania.

"Well," commented an Illinois operator's official, "Lewis is stalling around and using up a few more days, anyway. Every day this strike continues, and every day the time approaches when the public will begin to cry for a settlement on the miners' terms, the better the union's grip on the situation."

This same official prophesied that before the end of the first week in August there will be decisive developments in the Illinois situation which will get a grip on the attention of the whole nation. He would not divulge what these developments are to be. The operators' association have already declared in favor of the opening of enough mines to insure the production of sufficient coal, under union auspices, to stave off fuel famine in Illinois. Since the federal government appears to have no intention of directing any coal from Kentucky and the East into Illinois or Indiana under the new car-distribution plan, it seems that Illinois and Indiana must dig their own coal. Governor McCray and the operators of Indiana have worked out a plan for it in that state under the protection of state troops.

Midwest Coal Men Hope for Success of Plan Of Control by Distribution of Cars

The general sentiment of the coal trade in the Middle West seems to be favorable to the new federal plan of controlling the distribution of coal through car supply. The superior men in the industry are hoping Mr. Hoover will be successful in this newest effort. Not that they think his scheme is fair and reasonable—or even legal—in every respect; but they are for him anyway.

Practically every man who expresses an opinion about it says that no doubt the Hoover plan of regulating distribution is all right and should work well; but when that same method is used to restrict the price to $3.50 a ton they think the regression of the law will have been made.

"But I doubt if anybody is going to fight it; that's the point," commented an operator whose string of mines includes one that will be affected at once by the federal scheme. "If anybody tried it, his case would daily along in the courts, while his mine stood idle, until some time in the next generation. So what good would it do to dash into court? Wise men are going to dig coal, sell it at $3.50 and keep it up—so long as this government board continues to supply them with a full quota of cars. But if the car supply fails—then will be the time to kick the Hoover price out."

Hoover Conference Results in Formation of Connellsville Operators' Association

Following the return of an operators' committee from Washington, where they held a conference with Secretary Hoover, a public meeting was held in Uniontown, Pa., when the committee reported that the price-control plan through distribution of cars had "teeth" in it and that there was nothing to do but comply. As a result of that public meeting has grown the first organization of Connellsville coal operators, the Fayette-Greene Coal Operators' Association.

George Whyle was named president; W. W. Parshall, vice-president, and E. D. Brown, secretary. The executive committee consists of the officers and the following: W. C. Rod, representing the C. Frick Coke Co.; John Sinecock, of W. J. Rainey, Inc.; M. B. Cooper, of the Hillman interest; C. F. Lingle, representing the Greene county operators; H. M. McDonald, John B. Moore and W. D. McGinnis.

While Connellsville is one of the principal coal-producing regions in the country it has never been represented by an organization of operators. The Coke Producers Association, an exclusive organization of coke operators, has been inactive for some years.

Experiments on the Treatment of Lignite, Raw and Carbonized, by the Trent Process are being made in North Dakota by W. W. Odell, fuel engineer of the U. S. Bureau of Mines. Construction of a vertical lignite carbonizing even has been completed.

Cancellation of the Assignee-Car Hearing has been announced by the Interstate Commerce Commission. The matter will be taken in a new proceeding at some future date after the passing of the emergency.
Borah Coal-Commission Plan Held in Abeyance by President Harding

SENATOR BORAH, chairman of the Senate Committee on Education and Labor, held a conference July 28 with President Harding on the Borah bill proposing that a commission study the coal question, with a view to reporting a plan, for permanent legislation to control the coal industry.

President Harding advised Senator Borah that he was in full sympathy with the purposes of the measure. The President asked Senator Borah to visit him again early this week and go over the matter further, when the President expects to know more about the outlook for a settlement of the dispute.

Since introducing his resolution Senator Borah evidently has learned that the work he prescribes for three commissioners at $8,000 a year is an undertaking which will require a large organization to carry through and will cost hundreds of thousands of dollars. The task is even more complicated than the valuation of the railroads and many years would be required to gather accurately the information which he proposes should be done in nine months.

Senator Borah’s bill, introduced July 25, proposing that a commission be created to inquire into the advisability of nationalizing the coal industry, provides that the commission be composed of three members, to be appointed by the President, subject to the advice and consent of the Senate. Members of the Senate and House, however, shall be ineligible to serve on the commission.

One member of the investigating body, the measure provides, shall be chosen from a list of three nominees presented by the National Coal Association, one from three names submitted by the United Mine Workers and the third shall represent the public, but must not be interested in a business way in the coal industry. The salary of each commissioner is to be $8,000 a year. The commission shall cease to exist one year after the passage of the act unless otherwise provided by Congress.

It shall be the duty of the commission “to investigate fully the conditions, ascertain the facts, and study the questions relating to the coal industry with a view of aiding, assisting and advising the Congress relative to legislation either in the nationalization or the regulation and control of the coal industry by the government. To this end the commission shall ascertain and report to the Congress and to the President, first, as to the ownership and title of the mines; second, cost of production; third, profits realized by the operators or owners of said mines during the last ten years, labor costs, wages paid, irregular production and suggestions as to the remedy for the same and all facts, circumstances or conditions which would be deemed essential in determining and establishing a wise policy relative to the said industry by the government.”

The bill also provides that the commission shall submit recommendations relative to:

(a) Standardizing the mines upon the basis of their productive capacity and regarding the closing down of mines which by reason of their natural limitations fall below the standard.

(b) Standardizing the cost of living for mine workers and the living conditions which must be supplied or afforded in order to surround the workmen with reasonable comforts, recognizing the psychological effect of such surroundings in respect to their efficiency.

(c) Standardizing a basis of arriving at the overhead cost of producing the coal and delivering it at the door of the consumer, recognizing in this compilation that the standardized cost of living to the miners must be the first and irreducible item of expense.

(d) The advisability or necessity of nationalizing the coal industry.

(e) The feasibility or necessity of governmental regulation and control of the coal industry.

The commission is to render its first report and recommendations as soon as practicable but not later than nine months from the passage of the bill. In making its investigation the commission may require by subpoena the attendance of any person and the production of any book, paper, document or other evidence from any place in the United States at any designated place of hearing, and no person shall be excused from attending and testifying or from producing evidence on the ground that the testimony or evidence may tend to incriminate him. The penalty for violation of this provision is $5,000 fine or imprisonment for one year, or both.

For defraying the expenses of the maintenance and establishment of the commission, including the payment of salaries, provision is made for the appropriation of $100,000 or so much thereof as may be necessary, to be available until one year after the passage of the act.

BRITISH COLLIERY OWNERS TO ERECT 10,000 HOUSES.—A scheme for the erection of colliery villages being undertaken by a British industrial association composed of colliery owners is based upon the principle of trading without profit. The program, it is stated, includes the erection of about 10,000 houses at the rate of 2,000 a year without any form of government subsidy. It is proposed to make application for a loan from the Public Works Loan Board. The difficulties which confront the mine owners in respect of the housing question, particularly where houses are provided free, was indicated at the annual general meeting of one of the large colliery groups last month. It was stated then that a workman’s cottage could be erected at a cost of £400, which was estimated to work out at a cost of 1s. 7d. per ton of coal, assuming 1½ workers per house and an average output of 250 tons per person employed.

MEMBERS OF THE HOUSE OF LORDS call themselves gentlemen, but they wouldn’t give Lady Rhondda a seat.—New York American.

A glance at the proposed tariff schedules confirms rumors that the crumbling Peak of Prices is to be restored to its former lofty grandeur.—Brooklyn Eagle.

“Sign says this ladder’s unsafe. What of it? I ain’t got time to go around.”

So he went right up—and came right down again in a heap.
Seventeenth Week of the Coal Strike

EDITORIAL REVIEW

INTEREST in the railroad strike eclipsed that in the coal strike last week. The administration at Washington directed its principal efforts in the direction of getting the railroad men settled once more in their jobs and to rounding out the federal, state and local organizations for administering the priority orders. For the time being the government has been directly engaged in making coal.sofar as there is going further and in increasing the output from the non-union fields, crippled since July 1 by the rail strikes. Efforts of operators in union fields to get their mines in operation have been practically fruitless. In the Pittsburgh district, where most was expected and where military protection has been provided, almost no coal has as yet been loaded out, and in Ohio no attempt has been made to operate any except the strip mines which were in operation in the early part of the summer and have been closed by intimidation of their workers.

Illinois and Indiana operators cannot work their shaft mines without licensed labor and have made no attempt to resume production. The Governor of Indiana has threatened to call the Legislature and to ask it to repeal the law which acts as a bar to coal production. This would be a blow to the miners.

No effort has been made to get out coal in the anthracite region and it is understood none will be until the union puts the men back.

On the union side John L. Lewis has been diverting attention from the question of the union's attitude toward arbitration by talking a great deal about getting sufficient operators together to start a joint interstate conference. In this he is quite persistent, despite the reiterated refusals of substantial groups of producers. There appears to be as wide divergence of opinion among the miners as in the ranks of the soft-coal operators, but John L. Lewis manages to hold the workers together.

There was no material change in the situation in the Connellsville coke region during the past week.

Miners Will Not Be Driven Back to Work at Starvation Wages, Says Lewis

BEFORE leaving New York for Philadelphia to confer with the presidents of the unions in the anthracite fields on July 26, John L. Lewis, president of the United Mine Workers of America, issued the following statement:

"Ten days have elapsed since the President directed the coal operators of the country whose miners are on strike to return to their homes and resume the production of coal, following which he telegraphed the governors of the several commonwealths urging them to accord military protection to all coal companies employing strike breakers.

"Despite the promulgation of this policy by the Federal Government and its punctual application by several governors, there has been no increase in coal production. Not a single union miner has returned to work throughout the length and breadth of the land and it must now be obvious to all that the American miner will not be driven back to work at starvation wages and under non-union conditions by any fanfare of trumpets or vain military display. The assembling and training of engines of war to awe American citizens who are merely exercising their inherent constitutional right to cease work in order to maintain their industrial and social status as citizens of the Republic would be a national farce did it not possess the elements of tragedy.

"The presence of federal troops in the mining communities where no transportation of the law has occurred in itself constitutes a menace to domestic tranquillity and creates a situation repugnant to the ideals of every free-born American. Aside from the question of equity and constitutional rights which are involved, the public is being heavily taxed to maintain military forces in the field to assist mining corporations who deny industrial justice to their employees and are applying labor-breaking anti-union policies.

The employment of the citizen soldiers of our country in the protection of imported strike breakers in the mining industry is bound to lessen the respect of a large part of our citizenship for the National Guard as an impartial institution. The lamentable breakdown of the federal policy actually lessens the desire of the public for further experiments of this sort. The public is primarily concerned with its future coal supply and this summer it is on the wane. Time is an important factor. The loss of an additional ten days to further develop fantastic schemes in the field of industrial experimentation can hardly be afforded.

"The mine workers are resolved not to be driven back to the mines by any threat of force and neither do they intend to return until the coal operators of the country are required to meet them in joint conference in order that a new wage scale may be negotiated.

"The principles of collective bargaining are at stake, and the right to employment at a living wage is an issue which must be considered.

"The coal strike, now in its seventeenth week, involving more than 600,000 men and affecting the welfare of our nation, is in itself a colossal industrial tragedy which reflects no credit upon our antiquated industrial relations or American statesmanship. Such a condition, by every rule of reason and logic, is indefensibly wrong and is an outrage to every moral and economic principle.

"The miners are anxious to settle this strike and resume the production of coal. We are ready to meet in joint conference with the coal operators at the earliest moment if such a conference can be arranged in harmony with the contractual obligations of the coal companies and in line with the procedure which has prevailed in the industry for more than a quarter of a century.

"The adjustment of a national strike in this national industry cannot be accomplished through the instrumentality of state or district settlement. No district conference or agreement will be sanctioned by the Mine Workers Organization. The Mine Workers' representatives will hold themselves in readiness to respond to any logical and practical attempt to effectuate an adjustment."

Miners Return to Work in Increased Numbers in Central Pennsylvania

SLIGHT increases in the number of miners who have returned to work were reported all along the line of the Cambria-Somerset-Indiana sector of the coal-strike area of central Pennsylvania up to July 28. The largest additions at the mines were reported from Colver and Twin Rocks. About one hundred reported for work at the mines of the Ebensburg Coal Co. at Colver and the largest production since the walk-out at this mine several weeks ago was reported. Ten cars were shipped from the Twin Rocks district, three of which were from the Commercial Coal Mining Co., which is operating under guard.

Operations were resumed at No. 9 mine of the Bethlehem Mine Corporation at Helmond with a few men returning to work and Mine No. 11 is expected to reopen this week. Officials are confident that the majority of the men will return to work.

At Windber the Reitz Coal Co. has a full force of men at work and production will be at a pre-strike rate within the present week. About 100 cars of coal was shipped from the Windber district, showing a substantial gain. Additional men have been called to work. Calls for guards have been received at National Guard headquarters at Ebensburg from a number of other operations.

United Mine Workers in the field are redoubling their efforts to restrain the men from returning to work, with the result that James H. Maurer, president of the State Federation of Labor, has opened headquarters in Johnstown and is addressing meetings of miners at various places.
Michigan Union Officials Refuse To Comply with Governor's Request

OFFICERS of the Michigan district of the United Mine Workers have definitely refused to comply with the request of Governor A. J. Cayton that they return to work to produce coal for state and municipal needs. The reply to the Governor, signed by Thomas L. Jones, district president, asserts that for the miners of Michigan to resume work before the end of the strike would be to "dig their own graves." It is pointed out that one year ago state institutions of Michigan were contracting with producers outside the state for coal supply, as was also the Bay City School Board.

"Inasmuch as the Michigan mine worker was denied the opportunity to supply coal for municipal and state institutions it is not to be expected that we are going to do it at this time when great principles are at stake," says the communication to the Governor.

Operators of Southwest Indorse Harding Plan for Resumption

A SPECIAL convention of the Southwestern Interstate Coal Operators' Association at Kansas City, Mo., on July 24, 1922, gave consideration to the report of the majority committee of the bituminous coal operators to President Harding in reply to his proposal to the operators and miners for an arbitration commission. Its provisions were regarded as being ample and sufficient to have brought about a peaceful and orderly settlement of the strike. Unanimous agreement on the union position was given to the plan of preserving the best interest of the public, the bituminous operators and the employees in the coal industry and regret was expressed that the miners declined.

Consideration also was given to President Harding's later invitation to resume operation of mines with such voluntary labor as could be obtained.

The report of the convention says that the members of the Southwestern Interstate Operators' Association, "realizing and appreciating their obligation to the public as producers of coal, feel that in this hour of need, as loyal citizens of our government, it becomes our duty and we hereby pledge our unanimous and hearty response to the call of President Harding for the resumption of coal mining at the earliest possible moment; notwithstanding the many obstructions and difficulties that must be overcome in connection with the plan of Harding's plan."

"In order to carry out this response to the President's direction as effectively and efficiently as possible, we make the following recommendations:

(1) That the operators in each state represented in this meeting should appoint a committee of five operators, as a state executive committee for said state. It shall be the duty of such committee to confer and arrange with the county and state authorities for the necessary protection as to the miners to protect the public property in the mining industry. Said committee shall in conjunction with each local mine owner and the association officers have jurisdiction in each state over all matters applying to and governing the preliminary operation of mines.

(2) That association mines that are now operating shall be encouraged to increase their operations and production to maximum capacity.

(3) That the offer of employment by association members shall be extended to experienced mine workers now in field, who in the judgment of the management are most suited for the purpose.

(4) That the wage scale to be paid for day rates, tonnage, dead work and yardage work shall be in conformity with the majority recommendations of the committee to President Harding.

(5) That the rules and regulations governing contract conditions for the operation of mines, adopted by the General Sales Committee and approved by the last special convention of the association, shall be adopted and put into effect in connection with the above wage scale and daily working conditions and shall be complied with and regulations governing their mines.

(6) That the law and regulations of the Western States Coal Operators' Association are not antagonistic to union nor to collective bargaining, but having failed to secure a contract with the United Mine Workers, the association is forced to conform to that scale and submit to the demands of the strikers.

The Coal Age to as far as the operators are concerned, the strikers are asking for a better wage scale, and which our obligations to the public and to our government in its call to resume mining operations and realizing the difficulties of this undertaking, through the probable resistance of the organized forces of the miners and labor generally, we ask the public to be patient in its demands for coal and to render such co-operation and assistance as all good citizens should, who believe in the orderly and peaceful procedure of industry, exercising its legal and lawful rights to meet a nation in its dire distress, and to further assist in the encouragement and enforcement of laws by all legal constituted authorities.

Court of Appeals Sustains Injunctions Except in Regard to Tent Colonies

THE U. S. Circuit Court of Appeals at Richmond has sustained Judge George W. McClintic, of the U. S. District Court for the Southern District of West Virginia, on the appeal taken by the United Mine Workers of America from the injunctions granted in five fields and has modified the injunctions granted by the lower court only to the extent that the Borderland case was modified and that is with reference to the maintenance of tent colonies.

Injunctions were obtained on Monday, July 24, by additional companies in the Kanawha field to halt the activities of the United Mine Workers in attempting to interfere with the operation of mines. The temporary restraining orders were issued by the U. S. District Court for Southern West Virginia and cover the mines of the following companies: Southern States Coal Co., Black Bird Coal Co., Valco Coal Co., Lincoln Coal & Coke Co., Piney-Pocahontas Coal Co., Glenn Coal Co., Lomo By-Products Coal Co. and Black Band Consolidated Coal Co.

Local unions at the following places are covered by the injunctions: Morrisville, Cofoco, Cheyan, Handley, Kayford, Burnwell, Dry Branch, Plymouth, Mordue, Marmet, Malden, Whitesville, Crown Hill, Shrewsbury, Montgomery, Sharon, Raymond City, Coalburg, Winifrede, East Bank, Colcord, Big Chimney, Petona, Eldale, Gallagher, Smithers, Wewaco, Canneton, Leevale, Boncar, Wake Forest, Highstoon, Dana, Sharples, Montreal.

Production in Western Canada Improved Slightly Late in July

THE British Columbia situation with respect to coal production showed little change during the latter half of July. In the Crow's Nest field the miners still are closed owing to the strike. The collieries of the Nicola-Princeton area are operating much as usual, although the Coalmont Collieries are doing somewhat better, their output averaging 800 tons a day, which is a considerable jump. On Vancouver Island the Canadian Colliers (D), Ltd., at Comox and Wellington have not yet been required to work full time to meet the demand. The Western Canadian Fuel Corporation, however, is reported to have signed contracts that will absorb its capacity production for a time. Consequently the mines at Nanaimo and in that immediate district are active. In the north there is some prospecting of the coal fields adjacent to the Grand Trunk Pacific Ry. and it is assured that mines will be operated on a small scale to meet the coal requirements of Prince Rupert and other local centers during the winter.

No Labor Trouble has been noted in the northern coal fields of Colorado since the National Guard and the Colorado Rangers were first sent into the strike districts. Rangers are widely scattered over the entire coal area in the state. Ten rangers appear to have more effect than a company of troops, as most of them are personally acquainted with the strikers and retain their respect. A prominent merchant of Denver, Col., writes us: "We have practically no coal strike here in this state. We have to thank our Governor for this state of affairs. We had some trouble during coal camp time as when the National Guard had to be called out after much damage was done."

"This time the State Rangers were in the different coal camps the day before the strike started. The result was that we had no violence since and the mines are operating.

"Our Governor, Oliver H. Shoup, deserves the thanks and recognition for the stand he has taken."
**Weekly Review**

The steadying influence of the government on the price and distribution of coal is now making itself felt. Production is again on the increase as the tangles caused by the rail strike are being straightened out. The Geological Survey estimates the output last week at 3,900,000 tons, a gain of 200,000 tons, or 5 per cent over the previous week. This increase came mainly from the non-union fields in the South, but Pennsylvania contributed some.

Prices continue strong. *Coal Age* Index of spot prices of bituminous coal at the mines rose 96 points to 556 on July 31. This corresponds to an average spot price of $6.73. Prices on Western coals, particularly those from Kentucky, declined with the collapse of the boom on the Chicago market a week ago. Cincinnati, Columbus, and Boston were the most active markets as the week opened.

**Government Price Control Now a Moral Influence**

Washington's machinery for handling the details of distribution is in the making and the control over prices is yet but a moral influence. The structure is being built from the top down, but it is being well built, extending into the states and cities through the cooperation of state commissions and local fuel administrators. Secretary Hoover is getting ready to meet a situation that is more than transient, a shortage that is yet to be fully felt and that will not be over until next spring.

The railroads are the only consumers that have found it necessary so far to take advantage of the priority orders—the Pennsylvania is taking 20 per cent of output on its lines. These orders were primarily for their protection and they are now using them to get coal. Where the roads demand the coal, shippers are letting them have it below the market rather than have it confiscated.

Buying of British coal, the feature of last week's review, has abated somewhat, mainly because both coal and ships have become scarce if wanted for immediate delivery and because prices advanced sharply. Whereas two weeks ago English coal could be had c.i.f. New York for around $7.50, it is now obtainable for late August and September delivery at around $10.

A survey just completed by officials in Washington of the Lake coal situation indicates that it is physically possible to move enough coal to give the Northwest reasonable supplies if the Lake movement is begun by Sept. 1. Such a program, however, presupposes full co-operation on the part of ship owners and that there will be no delays to vessels in obtaining coal for loading at the lower ports.

Anthracite shipments embrace mine storage and an increasing volume of river steam coals. Pea and smaller sizes are about all that are moving from the storage piles. Retailers are reordering heavily of pea, using this as a substitute for the family sizes. Railroads also are taking pea coal and are requesting the companies to reserve them a considerable amount of this tonnage in lieu of the smaller sizes. It is likely therefore that this grade will soon be off the market.

Coke offerings have decreased considerably. Connellsville spot coke is extremely scarce, the improvement in operations recently noted having referred chiefly to

furnace ovens rather than to merchant ovens. In this section byproduct ovens are now largely dependent on their reserve coal stocks, as shipments from West Virginia and Kentucky have almost ceased.

BITUMINOUS

Returns on coal output in the seventeenth week of the strike (July 24-29), according to the Geological Survey, give the first test of the response to the invitation to reopen mines. "There has been a slight recovery as compared with the sixteenth week," the Survey says. "Production is running at the rate of 3,900,000 tons, against 3,700,000 tons last week. The increase is due partly to more men at work in Pennsylvania, partly to improved car supply in southern West Virginia, and partly to heavier shipments from Alabama and the Far West. Production of anthracite remains practically at zero."

"Loadings on Monday, July 24, were 13,083 cars. This was 417 cars above the preceding Monday, but 3,664 cars below the last Monday before the shopmen's strike. On Tuesday and Wednesday loadings declined, but on Thursday a slight recovery was noted."

"It thus appears likely that the total output for the seventeenth week will be less than 4,000,000 tons, probably only 3,960,000 tons. In the lowest week of the strike 5,375,000 tons were produced and in the highest week (June 19-24) 5,365,000 tons. The decrease since June is attributable to traffic congestion resulting from the shopmen's strike. In the Middle Appalachian region the congestion is still acute, although a slight improvement over last week has been reported from certain districts."

"There is no indication of increased production in response to the invitation to reopen mines in any of the strongly organized districts. More coal is coming out of the former non-union fields in Pennsylvania and a little more from the Fairmont and Kanawha districts of West Virginia, but

  - **Rail mines:** Union in 1921, non-union in 1922.

### CAR LOADINGS AND SURPLUSSES

- **Cars loaded:**
  - **Week ended Apr. 1, 1922:** 860,907
  - **Previous week:** 718,319
  - **Same week a year ago:** 774,884

- **Surplus cars:**
  - **July 8:** 405,120
  - **July 15:** 403,180

### COKE

- Beehive coke production was 104,000 net tons during the week ended July 22. The output appears to have found a level at about 100,000 per week, the figure for the week ended July 15. The principal factor in the increase was in the Connellsville region, although this was confined mainly to furnace ovens. The amount of spot coke offering therefore has not been increased proportionately and as a result spot prices have climbed further.

---

**ANTHRACITE**

Production of anthracite during the week ended July 22—about 27,000 net tons—was practically all steam coal dredged from the rivers. Mine storage stocks now consist mainly of pea coal and smaller sizes and retailers are taking the former for distribution as a substitute for their trade. Both householders and dealers are placing orders for the family sizes to be delivered as soon as mining is resumed.

---

**Relative Activity of Markets for Bituminous Coal at End of Seventeenth Week of Strike**

- **Maximum market activity this week.**
- **Current peak in prices appears to have passed.**
- **Local market quiet, with prices up because of Northern buying.**
- **Quiet.**
American Shippers Active in British Market; Production Registers Slight Increase

AMERICAN shippers are actively seeking tonnage to replace their strike losses. Public utilities and railroads have been the heaviest users, and now that the United States Government has given priority to these consumers, considerable tonnage of domestic-coal and coals will be available to them. This makes the American market a rather uncertain and temporary one for the British shippers.

British production during the week ended July 15 was 4,627,000 tons, according to a cable to Coal Age, as compared with 4,598,000 tons for the previous week.

Some improvement is indicated in the British coal trade. Steam and gas coals especially are in better demand than for some weeks, and from 6d. to 1s. per ton increase is being offered for the better qualities of steam coals.

Among the inquiries received in the North of England are 30,000 tons of gas and coking coals for autumn shipment to the Stockholm gasworks, 8,000 tons for the Bordeaux gasworks, and one Belgian coal company is in the market for around 500,000 tons. Up to 30s. is now the price of best gas cokes and there is an appreciable market at that price. The Baltic and Holland are the most promising buyers.

Coal Paragraphs from Foreign Lands

ITALY—Cardiff steam first is now quoted at 36s. 6d., as compared to a cable to Coal Age, as compared with 36s. 3d. last week.

The Italian Government has issued an announcement covering the prices at which its surplus stocks of German coal may be purchased for industrial use. Westphalian and Silesian steam, gas, and furnace coal may be purchased for 150 lire per metric ton on board cars in transit or 165 lire f.o.b. Italian port. The sale price of Westphalian coke for metallurgical purposes is fixed at 230 lire on board cars in transit or 240 lire delivered at a port. Silesian coke, which can be shipped only by rail, will be sold at 220 lire on board cars in transit.

INDIA—The market is firm. Mills are purchasing and it is understood that

The market was demoralized with prices soaring at Hampton Roads last week, with demand double the supply. Slight improvement in coal movement was noted on all roads, although surplus supplies did not increase to any appreciable extent. Export business dwindled to nothing.

Terminal facilities were in normal condition, but movement of coal from the mines continued interrupted. The prospect for improvement was said by coal men not to be bright. Schooners and barges, prepared to carry coal to Northern points, were lying idle in the harbor.

The price of coal, soaring as high as $11 per ton in some instances, reached the highest point since the peak of business in 1920.

June Reparation Deliveries

 Deliveries from Germany to France, on reparation account, in June were:

The importation of British coal into Germany has lately assumed larger proportions owing to the insufficient supplies of German coal and the great demand has already led to an increase in price. A number of works imported British coal with a view to exchanging it through the Coal Syndicate for coke allotted to the railways. Now all the Reichskohlencommissar has ordered that imported coal could be partly taken into account in making allotments of inland coal and this appears to have led already to a noticeable decrease in the demand for British coal.

Production in the Ruhr district during the week ended July 15 was 1,760,000 metric tons, according to a cable to Coal Age. The output in the previous week was 1,629,000 tons.
British Coal Now a Factor; Softening Tendency Seen

Uncertainty Exists as to Delivery—Price Decline Would Be Disturbing, and High Prices Were Paid for Foreign Fuel—Government Activity Calms Consumers.

BRITISH coal is becoming a factor at North Atlantic ports. Many orders were placed last week and more are in prospect, although much uncertainty exists as to the question of delivery. The market shows tendencies of softening and a price decline would soon place these shippers at a disadvantage as the tonnage now on the way from Great Britain was purchased at high prices. British coal was quoted at $10, New York Harbor, early in the week.

Governmental action in the coal crisis is having a soothing effect on consumers, and there is not the urgent rush for coal that was so apparent a week ago. Receipts are still very light, however, and spot tonnage is difficult to obtain.

CENTRAL PENNSYLVANIA

The Consolidation Coal Co. at Jerome, Somerset County, was the first company to resume operations under guard, the output amounting to an average of 10 carloads a day.

The commercial Coal Mining Co. at Twin Rocks, Cambria County, has asked for guards. The mines at Vinsondale and Webster mine No. 10, at Gallitzin, also has resumed work under guard. Others are expected to follow. Car shortage cut down production, but this has been overcome.

Prices on the spot market rose rapidly and reached as high as $8.50, but little coal was sold at this price, as practically all that is mined in the district is sold under contract.

NEW YORK

The market was a trifle easier at the end of the week. There were many orders placed for British coals during the week although there was a wide range in quotations. Toward the end there was a softer market and exporters were tendering when they could expect deliveries. About fifty boats of the Shipping Board have been placed into service. Most of the orders had been booked for early August delivery and it was expected the first of these would arrive here about Aug. 10. Quotations at the end of the week were around $9, New York.

A factor which may have its effect upon the receipt of British coal here is the attitude to be taken by the Longshoremen's Union which may refuse to handle it. The matter is now under advertisement and the action taken by the men may not become known until their first cargo of British coal is in the harbor.

Southern coals are coming forward in good quantity, most of it already under contract. Several of the City Departments may run short of coal because of the strike and the failure of dealers to submit bids at the last opening, on July 18.

Quotations for unclassified Johnstown coals said to be of Pool 10 quality were around $8.25 at the end of the week, the stated scale for Pool 11 quality was quoted at $7.25@$8.

PHILADELPHIA

The amount of coal coming here is much below that needed to replenish stockpiles, but despite this there have not been any notable shutdowns. Large users are active and have forced the small consumer to buy at $7.50@$9 per ton.

Sellers are not seeking any business at present prices, although willing to buy when given definite orders. Strong efforts are being made to hold prices in check, and for this reason many commission houses are idle. The bulk of current production is taken over by the railroads or going on contracts.

The P. R. R. is in strong operating condition and is moving all shipments offered promptly.

Quite a few houses unaccustomed to tide business have made foreign connections, and there is an increasing tonnage of British fuel being sold here for August delivery. On steam coal from Wales there have been offerings of $9 a ton, and high-volatile English gas coal at $8, all delivered at the piers.

Baltimore

Co-operating with the Federal Government, Governor Ritchie consented to name a coal commission for the state of Maryland, a joint move by the chief executive and the Public Service Commission of Maryland, to prevent the widespread price changes of the last week. All railroads in the state have been notified that the fuel will be delivered at a uniform price.

Brokers have refused to take coal on consignment, and most of the dealers with mines are practically through for the balance of the month in terms of sales. The coal situation is the same in Pennsylvania and West Virginia, where conditions are particularly critical.

UPPER POTOMAC

Transportation difficulties are playing no part in holding back production in the Upper Potomac region, for the Western Maryland is placing all the cars needed and is moving coal at the rate of about 100 cars a day, giving this field an output of about 50,000 tons a week. Approximately 35 mines are operating in this territory.

FAIRMONT

General preparations were being made during the last week in July to overcome the strike, with the expectation that the miners would return to work.

KANSAS CITY

Kansas mines are doing better than those of the surrounding region, as they are unionized and will be able to supply public institutions and utilities and also a large part of the steam coal requirements of Arkansas, which has to be able to care for a part of the domestic requirements. Fuel oil is quite a factor in this section now at $1.65 per bbl. This is equivalent to steam coal at $4.95.

The split among the miners in the Kansas field will also help. Their allegiance is about equally divided between Hawwat and Still. Hawwat's fight against the Kansas operators turns out to be in the best interests of these same operators. Most of the production in that field today is the direct result of this fight.

SALT LAKE CITY

Utah operators are receiving many large orders from interests outside the state. These are hard to fill. Local retailers are buying more than they have done for some time. There is nothing like a rush, however. Slack is becoming scarce, retailing at $4.50 with an additional 50 cents for the selection.

Other small grades, while not so scarce as slack, are hard to get.

There is no actual car shortage, but a little tightening of this service is noticeable. The strike situation is about the same. The national guard is still in charge.

DENVER

Demand is picking up noticeably with the approach of the fall. Price rise, however, in spite of the fact that demand already has far exceeded the present capacity of the state's mines to produce. Shoup's ultimatum against high prices is effective. There is no sign of a public panic over coal because Colorado, with its mines running at between 70 and 80 per cent full, is sitting on a large surplus.
**Anthracite**

**Pea, Last of Family Sizes, Nearly Gone from Yards**

**PEA COAL**—the last of the family sizes—is fast disappearing from the retail yards. Dealers are still offering for replenishment but reserves at the mines are getting low and railroads are urging conservation of this coal for their use as a substitute for the smaller sizes. River steam coals are very active. Hope of getting an adequate supply of hard coal up the Lakes has about been given up.

Retailers are active in placing orders with their suppliers, for delivery when coal is again available. This process is being followed out also by the householder, and business on this basis constitutes the only life in the domestic anthracite market today.

**NEW YORK**

The pea coal supply is rapidly disappearing and with it the storage buckwheat. Some of the larger dealers have heavy tonnages of the latter on hand but the call for it is increasing. Consumers, realizing more than ever the seriousness of the situation are taking in pea coal to tide them over the cool days in case there is a delay in securing their regular supply of the larger coals. It was also announced that some of the railroads are using pea coal in place of buckwheat.

While no plan of distribution has been mapped out it is very apparent that when coal does begin to filter into this market the dealers are going to spread it as far as possible among their customers.

Some of the smaller operators have buckwheat stocked around their mining plants but owing to the attitude of the miners on strike are not having it loaded for shipment.

**PHILADELPHIA**

On account of the heavy undelivered tonnage the retail men are working hard to get in proper lines for their shippers, and even with companies who have not heretofore had them on their books. The producers have been flooded the past week with requests that orders be entered for shipment at such time as the strike is ended. Many of the companies are accepting orders on this basis, although a few decline to take any action until coal is once more being mined; on the other hand at least one concern was soliciting business on this basis recently.

In the meantime the dealers are experiencing good business on pea coal, particularly those who were foresighted enough to lay in heavy additions to stock when the rush for this size developed during the past ten days.

Prices at retail still present a great variation, running as low as $8.75 by one chronic price cutter, after which there are quotations rising 25¢ a time until the so-called standard price of $11 is reached, at which retail sales are made. In the last almost be said that the large sizes of coal are cleaned out of the yards, although there are a few exceptions where good stocks are still available and the price is a hand or two for this week and next, as compared with the ordinary price of $14.25.

In the steam trade river barley remains the only standard basis for the demand and prices are ranging from day to day. While some sales are being made at $2, most of this is for coal under order for some time, and the bulk of the business now is running between $2.50 and $3.

**BUFFALO**

There is a growing feeling of concern over the failure to take any visible steps toward getting the miners to work. At the same time the actual demand for coal is still light and probably will continue so till autumn sets in.

An effort is being made here to organize the anthracite interests, so that the distribution of what little there is left shall be to the best public advantage. Distributors generally refuse to deliver coal to anything less needy than hospitals. The small amount of steam sizes is fast going into the hands of steamboilers and other special fuel. Hope of getting a supply to the upper lakes in the fall has been given up.

**BOSTON**

The day approaches when retail dealers will be down practically to bare boards. The public still seems not greatly alarmed, but conditions, of course, grow steadily worse. Coke producers and sold up for six weeks to come and oil installations are increasingly hard to arrange for.

At wholesale there is little change. The supply of pea sizes is fast being depleted. The railroads are making every effort to have reserves on their lines saved for locomotive use.

**BALTIMORE**

Dealers are in entire accord with Governors in the belief that they have the machinery to distribute fairly. In the pinches during the coal scarcity periods of the recent war times, they allotted coal on the half-ton, one-ton and two-ton basis and kept everybody supplied. As it stands the yards are swept bare, except for a small quantity of pea, and a large majority of the homes are without supplies usually in bins at this season.

---

**Coke**

**BUFFALO**

The supply is now confined to the by-product plants, some of these in the Connellsville region. Purchases as high as $16 for foundry have been made, to which add $3.24 for freight to Buffalo. So heavy is coke demand that the local by-product plants will shut down in a few days unless a supply of coking coal is obtained. Iron ore is coming in at the rate of 50,000 tons or upwards a day by lake.

**CONNELLSVILLE**

Coke offerings in the open market have undoubtedly decreased considerably in the past 30 days. Reports of improvement in operations have referred chiefly to furnace ovens rather than to merchant ovens, and another factor, perhaps, is that several weeks ago one or two of the operators made contracts in foundry coke to the end of the year, involving coke that otherwise would have continued to come into the open market.

Practically all classes of consumers are now out of the Connellsville market, on account of price, except foundries, and even this demand is far below normal, partly because operations are lighter and partly because there are still stocks of some size. There was some stocking after the strike started, but at much lower than prices prevailing at the present time.

The market advanced about $1 in the week and is still not under $14 for furnace and $15 for foundry. Byproduct ovens are running largely on stocks of coal, as shipments from West Virginia and Kentucky have almost stopped. Several plants have decreased production and not a few furnaces have been banked or blown out. A few byproduct plants still have stocks for 30 days' operation at that rate.

The Courier reports production in the Connellsville and Lower Connellsville region in the week ended July 22 at 56,580 tons by the furnace ovens, an increase of 4,296 tons, and 12,600 tons by the merchant ovens, an increase of 470 tons, making a total of 68,670 tons, an increase of 4,750 tons.

**UNIONTOWN**

The week has shown no change whatever in the strike situation itself in this region. The call by the Rainey interests for their employees to return to work was unproductive of results. Another company of state police has been detailed to this region but no national guardsmen are on strike duty and probably will not be unless some serious outbreak occurs.

Formal acceptance by the principal operators in this region of the Hoover plan means a quick drop in the price of Connellsville coal from $8 to $3.50.

For the present the team track operators are out of business, the $3.50 figure not permitting them to operate profitably. However, Secretary Hoover indicated that where operating costs, as the first committee reported, the administration may consider a higher price.
Buoyant Hopes Ascend
As Market Goes "Flop"

A Certain Optimism Over Illinois Is Felt While Federal Control of Cars Drops Kentucky Prices—Full Car Supply Pleases Kentucky.

ALL through the midwest there were sighs of relief and the lessening of a great tension when the government's plan of controlling coal distribution—and incidentally, price—went into effect. Excitement over coal buying came to an end in the western Kentucky field. Buyers refused to pay any more sky figures for fuel, cars in both the eastern and western Kentucky fields began to appear in normal numbers for the first time in more than a month along the Louisville and Nashville with engines borrowed from many roads, and "normalcy" seemed much closer. At the same time, in Illinois, there began to spread a certain feeling of optimism regarding affairs in that state. "Something good is about to happen" was the sentiment among coal men who are usually first to hear of developments, and, all in all, the region went home over Sunday for a comfortable week-end.

The effect on coal prices of the events of last week was marked indeed. The "hooraw!" method of buying and selling coal was banished. The prospect of Hoover control of prices and the effect of the railroads and big utilities getting all the coal they need for the time being withdrew those ardent coal purchasers from the market. The drop of western Kentucky coal resulted until the region closed the week Saturday noon with quotations at $8@$8.25 in Chicago, and a prospect of much coal before the middle of this week. Eastern Kentucky followed. The market came to a grand pause to see what was going to happen next.

The feeling of operators in the Kentucky fields was wholesome, however. Eastern Kentucky, almost to a man, was delighted at the prospect of getting a full car supply after a three weeks' period of much less than half that number of cars and many of the leaders among the western Kentucky men counseled the hot heads among their number to accept the Hoover plan with good grace, as it would be more profitable in the long run for them to sell a maximum output at $3.50 than to sell one day's output a week at $10. Fuming it was easily seen, any operator who chose to fight the government control of cars probably would find his case dragging in the courts long after the present ravenous demand had passed.

SOUTHERN ILLINOIS

Calm still prevails though it is evident, here and there, that a good deal of propagandist work is being done by the Harrington and Lewis factions within the United Mine Workers to strengthen those two main divisions. The spirit of the union—and its community influence—was shown last week when a meeting of all sorts of citizens in Williamson County was held to protest violently against any program of operating mines there under guard. There are evidences at some of the mines that the operators are getting ready for a resumption of work. This is especially true of the Peabody group.

WESTERN KENTUCKY

The end of the "wild time" came at the close of last week, bringing a distinct feeling of relief to many an operator in spite of the sharp drop in the market. Some are angered by the new government plan of controlling price by car distribution, but the assurance of a car supply looks better to most men than a battle in the courts. The spirit of the miners along the L. & N. lines is viewed most hopefully. Railroad conditions generally throughout this end of the state are improving, with a consequent increase in sales of spirits in the coal fields. "Full car supply" are words that sound as good to many an operator as "ten dollar coal". There is a good prospect now of full-time operation. If practically all of the output for the next three or four weeks must sell at $3.50, the average operator will be well off and happy over it.

CHICAGO

The bottom began falling out of the western Kentucky market here early in the week when the government plan for car control and the loan of motive power between railroads was announced. Buyers withdrew, railroads and utilities felt reasonably assured they were going to get coal at $3.50 within a few days, and trading arrived, by the end of last week, at a standstill. Western Kentucky dealers declined from $11.50 to $8 in four days and other coals on this market were drawn down too. What little eastern Kentucky the traders here could get sold readily enough at the same level as the other. Smokeless was practically unobtainable.

A great activity now, on the part of coal men, is to get authority from the control board for orders they have taken. A stampede by mail, by wire and by personal solicitation toward one or another member of the board started as soon as appointments were announced. The trade here expects there will be little free coal on the market for two or three weeks unless—and there is much which may over this point—Illinois should start operating mines under martial law.

LOUISVILLE

The hectic excitement appears to be over, at least for the moment. Last week's peak prices have come and gone, the flush mob of buyers waving fists full of currency in the faces of operators, was longer a mob but merely a calm and scattered crowd, and in the readjustment, compelled partly by the new government plan of controlling distribution and partly by the volume of buying at flyghty prices when a new low level is in sight, the market has subsided markedly.

Of the western and eastern Kentucky coal slid downward to a level of about $7 by the end of last week. Most of that which was traded was coal already in stock. With the railroads getting their new privileges right over all others industrial buyers appeared to believe coal not already in transit could never be delivered to them. So they merely pulled up what they thought they thought was almost the last free coal to be available for some time, and took it only on a swiftly declining market.

Canada

MONTREAL

Welsh coal is en route to Montreal to meet the fuel shortage. A cargo of 2,400 tons of anthracite coal, recently consigned to the F. P. Kennedy Co., for the West Indians, was sold by the F. P. Kennedy Co., for a large Montreal manufacturing company, and the other will be used to meet smaller orders.

Local dealers state that in the face of a coal shortage in the Province of Quebec estimated at 300,000 tons they are confident that should be. A report is made by the Federal government of Montreal and Canada coal companies that the dealers are. Some coal companies are making every effort to supply the demand and are asking for Co. to purchase coal in order to meet the situation. They feel that with proper handling the coal will be well received.
Non-Union Receipts Low; Industries Not Pinched Yet

Inquiries increase in volume—Anxiety Felt About Future Supply—Belief That Price Will Be Fixed Holds Down Quotations—Northwest Situation Grows Perilous.

Inquiries for fuel are increasing daily, but as yet industry has not been seriously affected by a coal shortage. Receipts of bituminous coal from the non-union fields, however, are the lowest in years and anxiety is felt in all sections about the future supply. The expectation of consumers that a fixed price will soon be established has held the market from a continuation of last week's soaring prices. Spot coal is difficult to obtain, but the trade is not taking advantage of the situation by boosting prices further.

Car and coal shortages have lowered the Lake dumpings. The needs of the Northwest are fast becoming urgent and a few weeks more delay will spell a certain coal famine for that section next winter.

Cleveland

Domestic demand for coal in the Cleveland district is showing considerable strength. If it were possible for retail dealers to obtain coal, business in the fuel line could be maintained at a rate materially above that ordinarily prevailing at this season. Strike conditions, of course, have helped to strengthen the present demand. Some hope is seen by coal dealers and jobbers here in the priority orders issued by the Interstate Commerce Commission. It is believed that movement of loaded coal cars through the clogged Cincinnati and Columbus gateways will be speeded by this action.

The Chesapeake & Ohio and other railroads operating in Ohio report their sidings blocked with coal cars in Cincinnati and Columbus, while the Big Four yards are comparatively free. Belief is that through the enforcement of the priority orders much of this load will be shifted to the Big Four. This probably will expedite shipments of Southern coal.

An especially strong domestic demand exists here for Pocahontas and other West Virginia coals. Stocks in the retail yards are getting extremely low. One large jobber and retailer states that its orders are being filled from stocks of coal which have been left over. Pocahontas shoveled lump is being quoted at $9.50 a ton, and forked Pocahontas lump is being sold for $11 a ton, delivered. It is reported that the Cleveland Electric Illuminating Co. has just purchased 100 carloads of coal from mines around Pittsburgh which are now producing or are about to produce coal.

Columbus

Just prior to the issuance of priorities there was a hurry to get under cover by consumers not in the favored list. Buying was wild and prices ranged from the federal levels to as high as $7.50 per ton. It was not so much a question of price as of the ability of operators and jobbers to deliver the coal promptly. Anxiety is felt in all localities about future fuel supply. Then buying manufacturers have low reserves. Public utilities and railroads are in a safe position, but other industries have been scurrying about.

The lake trade shows a still further decline owing to car shortage and transportation disability. During the week ending July 26 the H. V. Docks had turned out 57,354 tons the previous week. The total handled by these docks to date is 1,503,705 tons. Up to July 23 of last year these docks had loaded 2,258,170 tons.

Pittsburgh

Operators state that miners went into four mines in the Pittsburgh district on July 27—Montour No. 4, Henderson No. 2, Atlas and Wilson, all in Washington County—while officials of District No. 5, U.M.W., assert that no coal has been produced at these mines.

The priority order for coal has not affected coal movement in this district thus far. The P. R. R. and the P. & L. E. roads announce that as they are operating at 100 per cent efficiency there is no occasion for them to modify their practice. The relatively small amount of Pittsburgh district coal available, and that from stripings, has been reduced by timidity of the workmen, and trading has been practically confined to Connellsville coal.

There was excited buying up to July 26, with the price advancing until the market was rather firm at $8.50 for steam grade. Then buying began to taper off, consumers expecting a fixed price, much lower, to be established soon. By the end of the week the market had become quiet, with the price down to $7.50. Buyers seem to expect that the set price will be $3.75 for lump, $3.50 for mine-run and $3.25 for slack, but Connellsville operators have already indicated an expectation of being able to obtain $1 more.

Eastern Ohio

Persistent rumors that a joint conference of operators and miners of a part of the old Four-State field is to be held in August and soon has given renewed hope to the coal trade that a coal shortage may be averted by the early resumption of mining operations.

Inquiries for fuel are increasing daily but there has been no appreciable interruption to industry because of fuel scarcity. The volume of non-union coal reaching this section is the lowest in years. Spot prices have stiffened materially during the past week, the range on any coal obtainable being from $8@9 per ton.

The Wheeling and Lake Erie Ry. is taking coal pro rata from each mine in accordance with the I. C. C. priority order.

Several blast furnaces in the Youngstown district were banked during the week because of fuel shortage. The Youngstown (Ohio) plant of the Trans plate & Co. is reported to be closing this week because of lack of coal. A strip mine near Steubenville where the workers quit because of intimidation and the fact that union miners had been supplying coal to this plant.

Detroit

Efforts to relieve the dangerous condition confronting Detroit as a result of rapidly diminishing coal supply are being made by a special fuel committee appointed by Detroit Board of Commerce.

Prices on bituminous at the mines have advanced to $8 and $10 per net ton, though jobbers say producing companies have not advanced the price of coal sold ahead are filing such orders on the Hoover price basis or in some instances at a lower cost to the buyer where coal is available for shipment.

Neither steam nor domestic coal buyers are purchasing coal except when necessary to meet current requirements, the present high cost, in their opinion, makes it undesirable to stock up at this time. Retailers fear they would be accused of profiteering in attempting to deliver such costly coal to their customers, while the steam plants do not seem to order coal in a way equal to the high cost in the selling prices of their products.

Northern Panhandle

The trouble at Cliftonville on July 17 has not affected production at other mines but the output of the field as a whole had been reduced approximately 20,000 tons a week owing to congestion on railroads. No new demand for fuel in all markets with prices steadily on the upgrade. The demand at the lakes is particularly strong.

Buffalo

The situation turns on the soaring price of coal, caused by delay in getting miners to go back to work. They have been able to get enough outside work men to keep them in production, but the shortage of coal to continue, for that shows what their hold on the situation is.

Care shortage caused by the shopmen's strike is causing most difficulty now. It is said that there is coal enough stranded in cars on the Baltimore & Ohio alone, in the vicinity of the lake region, to supply everybody. Mine owners in that territory report to Buffalo buyers of their coal that it is on track, but there is no motive power to move it.

As a rule the consumers have coal, but many are getting uneasy and bid up for it. Most of the sales are at $8@9 at the mines, but sales have been made up to $11. A little gas coal is offered here on track at $9 by a dealer who says he paid $8.50 for it.
Mississippi

Helpless But Composed
Northwest Faces Future

Stocks Exhausted, It Cannot Help End Strike Which Victimizes It—Holds Prices to Slow Rise—Industries Share Their Fuel Piles.

A ROUND the Upper Lakes industries and small consumers alike face a shivery situation. Nobody is absolutely certain that the government will be able to direct much coal to that region. Its stocks are about gone, the docks are practically empty of free coal and almost no shipments are arriving.

The only thing the Northwest can do, helpless as it is to play a hand in the settlement of the mine strike, is conserve what coal it has. This it is doing by various means including a general movement in which several "wise" industries are sharing their fuel with "foolish" but necessary plants. Prices are steadily rising in the face of this shortage, but the rise is not uncontrolled. The Northwest is keeping its head.

MINNEAPOLIS

The Northwest is in the desperate plight of being unable to do anything to help settle the coal strike. Neither miners nor operators are in intimate contact with this district, and there is no influence which could be brought to bear direct. Belated investigations, surveys and under way in different directions can collect information, but no fuel. They will be valuable in assuring the consumers of the exact status of things, so that there need be no worse alarm than the cold facts justify and they will aid materially in the equitable distribution of such coal as may be obtained.

As a result of the frequent reports of the desperate condition of things, people are approaching a panic. Premium prices could be readily obtained for prompt delivery, but profiteering is discouraged. Retail prices of prepared sized coke, heretofore selling at $14 in these cities, have been advanced to $15. The coking plant managers claim that the advance is still low and the coke is worth considerably more than this figure. Coke will have to be used rather freely as a substitute for anthracite. The needs of the Northwest are for 1,250,000 tons for the winter. The quantity on the docks, including everything down to anthracite dust, is less than 250,000 tons. The desirable sizes are also nearly exhausted. The tonnage needed is not so large and could readily be handled in the period remaining before the close of navigation. But when resumption of mining comes, it will come with the immediate urgent demand from all section for coal, and the Northwest will hardly have much chance for more than a minimum share. The soft coal requirements, while several times as large, have so many more sources to draw from, that they do not seem as desperate.

DULUTH

The situation here has become acute. Business as a whole is on tenterhooks. The most accurate estimates available place free stocks of coal here at but 100,000 tons and some of this is available only to regular customers. Only five out of the twenty-three companies at the Head of the Lakes are taking business.

The condition of anthracite is similar. There is none to be had in Duluth or Superior except a small quantity of egg. Dealers are taking orders for delivery when they get the coal, and it seems probable that many householders, who have not filled their bins, will pass a cold winter. Customers who contracted for large amounts some time ago are now actively moving this.

Companies are inducing concerns which laid in their stocks early to divide with less foresighted neighbors. This move is meeting with some success among public utilities. It is increasingly hard to keep the boats of the smaller independent lake steamer companies going, but $5.00—an advance of $2.50 in two weeks. Bituminous prices generally are up 50c. over last week.

MILWAUKEE

Like all other cities, Milwaukee is in the throes of coal agitation. A canvass of the receiving yards reveals the fact that the only hard coal available at this time is the short quantity of pea and buckwheat. Dealers are refusing orders for soft coal for winter use in homes, conserving it for industries. They hold that supplies for boilers and furnaces in apartments and houses can be obtained later.

Most supplies offered by this market use Eastern screenings. Pocahontas can be had without trouble and also to the high price of bunkers, which makes the operation of steamers unprofitable. Only two cargoes, aggregating 10,000 tons, were received last week, making the total receipts of soft coal 740,960 tons against 1,497,933 tons during the same period last year. Last year the hard coal receipts to date aggregated 45,708 tons. No hard coal has been received this year. These figures do not take into account receipts of coal by car-ferry, which mainly go through the port to their destinations.

New England

Threatened Coal Shortage Has Become a Reality

DEVELOPMENTS are so rapid that each day's news is history by nightfall. The strikes have so seriously affected the output in the non-union fields, notably in Pocahontas and parts of the New River district, that the threatened shortage of a fortnight is now a reality. Few of the agencies have coal in any quantity at Hampton Roads and the great bulk of contract coal has been effectually cut off. Railroad priorities are expected further to curtail the supply for normal uses, and the trade is wondering precisely what is to befall.

Sundry high quotations are reported, but the quantity of coal changing hands must be very small; $9, f.o.b. vessel has been rumored, and very likely will be much exceeded within a few days.

The transactions on the Roads have been of small tonnage for clearance purposes. High figures are also rumored on cars Boston, but in most cases realhands have little or none to spare.

The natural tendency here of both buyers and sellers is to stand pat for the present. Factors who ordinarily have large tonnages regularly arriving are now suffering a dearth of supply and on that account are trying hard to keep what they have. Some are closely interested in British coal and there is active canvassing now for orders against cargoes due to arrive early in August. So far the prices heard are around $9.50 on cars Boston and Portland.

At Hampton Roads the wholesale cancellation of charters because of the lack of coal at the piers has resulted in an accumulation in the coastwise freight. Coastwise freights are easy at 85c.@90c. to Boston, but tankers are quite as scarce as coal.

The few desirable grades available from central Pennsylvania are also commanding what would very recently have been considered high figures; $7@$7.25 per gross ton has been offered on Cambria coals, especially when available at New York piers. Screened gas coal has been quoted up to $9.50.
Price Situation Upset in Related Housecleaning

PRICE conditions for the past week have been badly distorted. As the government was about to step in there was a belated attempt at housecleaning and all firms that had car numbers on spot coal were disposing of them to the highest bidder. This, however, did not mean any wide range of profit to jobbers and wholesalers, for most of the coal was coming from small mines that exacted the last penny that buyers would pay. Industries placed low in the priority list were all caught in the rush for coal and with a prospect of waiting for a month for a new supply were disposed to pay any price asked.

Clarification of the situation was promised through the arrangement effected under Secretary Hoover at the Washington conferences. The Cincinnati trade has been disposed to stay within bounds and did so until forced into higher prices by the operators who had free coal and wanted the top of the market. Whatever arrangement is made in Washington will be followed here.

CINCINNATI

Lake business has been begging for coal for the past week and where tonnage was necessary to fill cargoes partially made up on contract stuff the high price of the market was paid. During the past few days—since it was shown that the government intended to take a hand—both the lake and the steel people have disappeared as buyers, though the railroads remained actively in the market until the last minute.

The railway situation seems much better at this writing. The Norfolk & Western worked 800 cars across the scales at Portsmouth in one day, as against 1,600 cars normal. Russell Ky. and the C. & O. scales there also report improvement. Movement of L. & N. coal likewise is better.

The local retail situation is unchanged. Prices that were established the first of the month still hold. An abortive attempt to advance the price of high-volatile and smokeless domestic was frowned upon and those who put up the prices up the latter part of last week had to get back in the traces.

Blocks of twenty and thirty cars that had passed the scales or were in transit, fetched the highest price, that about $9. Any siding of southeastern Kentucky coal that had been started to market was worth $8.50.

HIGH-VOLATILE FIELDS

KANAWHA

The effort of mines formerly in the union category to produce coal has been materially checked in this field owing to the growing inability of the carriers to keep the mines supplied with cars. Acting as a unit, have declared their intention of opening up throughout the field in response to the President's invitation, provided transportation facilities are furnished to move the output. Prices offered for coal range all the way from $4 to $7 and $8 a ton. Producers as a rule, however, are shipping to their regular customers at the Hoover prices. The lake demand is unusually strong and inquiries are heavy from Western markets. At the same time Eastern buyers are also seeking large tonnages.

LOGAN AND THACKER

A car shortage is making heavy inroads on production in the Kanawha Thacker district. Because of congestion on the Norfolk & Western, these mines are operating only three or four days a week. A strike of Norfolk & Western clerks has tended to make matters worse. Buyers are bidding as high as $5 and $6 a ton.

Not more than half the production possible during June is being reached in the Logan district owing to the difficulty being experienced in moving coal. Because of the conditions described the Logan output has been reduced from 250,000 tons a week or more to 180,000 tons, with mines not running more than half time. The whole situation in this district now hinges on the transportation situation.

NEORTHEASTERN KENTUCKY

Mines are being crippled by generally inadequate transportation facilities, which has cut production to 55,000 tons a week or just about 43 per cent of capacity. The demand is unusually heavy. Crippled transportation facilities are holding back movement to the lake.

LOW-VOLATILE FIELDS

NEW RIVER AND THE GULF

New River production would be virtually normal but for the rail strike, but the output is materially curtailed and miners experienced in moving it, as a result of the growing congestion on line. Unable to obtain empties regularly, mines are not working more than half time. As far as the coal situation is concerned it is no longer a serious factor. The market is extremely active and prices are soaring, although producers as a rule are not quoting the hedge price maximums. Consumers are willing to pay $5 and more a ton.

Production in the Winding Gulf region has been reduced to about 60 per cent of potential capacity by the rail strike. The demand is unusually heavy but can be met only to a limited extent since production has been reduced to between 100,000 and 120,000 tons a week. The scarcity of fuel is forcing prices up despite the fact that most producers are not quoting above the Hoover maximum.

POCAHONTAS AND TUG RIVER

Losses in production in the Poca- hontas region as a result of the rail strike are greatly outstripping outputs. Against a total production of about 100,000 tons a week about 100,000 cars and general railroad disabilities are causing a weekly loss now of about 320,000 tons. The strike of clerks on the N. & W. is doing the best it can to keep coal moving to markets, but connecting lines are experiencing difficulty in handling loads and getting empties to the N. & W.

SOUTH

BIRMINGHAM

The local market reached peak demand during the latter part of last week. Brokers and agents were deluged with inquiries from Virginia and other points. Their immediate interest was to get orders in and numerous representatives of industrial interests and foreign brokers were in the field buying everything in sight.

Prices for spot coal soared rapidly, ranging $4@6 per net ton mines for mine-run or washed, without particular attention to grade.

The strain has now eased off to some extent through the market is still strong and active, with demand in excess of supply. The sales agencies of the larger producers have no surplus and the spot supply comes principally from the smaller mines which have done no contracting and from operations which have temporarily resumed to participate in the active market. Coal of good quality for steam use is still available in twelve-month contracts at $2.25@$2.75 per ton mines. The output of domestic sizes is pretty closely sold up and spot coal is hardly obtainable, quotations and interest being in line with the figures on mine-run and other steam sizes.

Production is at the peak in so far as the car supply and transportation service will permit; the latter is improving.

VIRGINIA

Handicapped by a shortage of cars, mines in southwest Virginia are unable to produce as much coal as they did during June, the loss from a car shortage is approximately 150,000 tons a week during the latter part of the month, reducing the output of this territory to about 64 per cent of capacity. The car shortage is being most severely felt on the Interstate Railroad and the Norfolk & Western. On the C. C. & O. production is being maintained at nearly 90 per cent.
CONNECTICUT

The union wage coal mine a few miles east of Evansville, which was visited a short time ago by a body of masked men who damaged some machinery at the mine, will be reopened, according to a statement of H. W. Rice, president of the operators of the mine. Guards have been employed to watch the mine.

The City Coal Co., Jassowle, Ind., has contracted with Krellhiel Company, Chicago, III., for the tipple equipment for its new mine. The equipment includes a Jacobson horizontal screen with a loading box for the railroad coal, and a separate screen for preparing local trade coal.

KANSAS

A. H. French has resigned as district sales manager for the Midland Coal Co. at Pittsburg, Kan., and manager George J. Wulf, who became president of the company soon after the death of W. F. Hawkins, of St. Louis, several months ago, Holmes Wagner, for a number of years cashier, becomes general claim agent at Pittsburg.

Rustee Hamilton, dinky engineman for the Edlworth Coal Co., at Minden, Mo., has applied for a patent on a steam engine, the motive for which he spent eight years in developing. He asserts that his engine development more powerful with less bulk and fewer working parts than anything of the kind he has ever seen. The chief advantage he claims for it, however, is that it is foolproof.

KENTUCKY

Recent incorporations in Kentucky include the following coal companies: Bourneville Coal Co., at Minden, Mo., a capital of $100,000, and partners Charles Frost, John Frank and H. A. Steele, Copperas Cove Coal Co., at Bentonville, Ky., a capital of $100,000, and partners Thomas Porter and Logan Thomas East, Kentucky Coal Co., $25,000, and partners J. F. Auxler, N. C. Auxler and Paris Bouquet.

The Millers Creek Kentucky Mining Co., headed by W. B. Brunk, is installing an aerator across Big Sandy River at Auxier, and doing development work preparatory to producing as soon as the trains are completed.

IOWA

Coal production in Letcher County Kentucky has been decreased 99 per cent, account of the railroad strike. According to various estimates the present unemployment situation is reported to be serious.

The Prestonsburg Coal Co. has moved a large piece of equipment from the old company's coal mines near Prestonsburg to its new operation in Green River County. A narrow-shafting screen and a loading boom tipple and about two miles of railroad track from C. & O. have recently been completed.

MINNESOTA

The Big Mountain Coal Co., recently formed to operate a jobbing concern which has been re-organized by P. A. Coen and the Clyde Coal Co., has recently opened. New officers are P. A. Coen, president; S. C. Sharp, vice-president, and C. H. Auschild, secretary.

The following charters were recently granted to the Superior Coal Co., of Prestons- burg: Huether Coal Co., mining and preparing coal for the market. Has a capital of $500,000. Incorporators, H. J. Huether, B. A. Huether, and E. H. Huether.

The Huether Coal Co., Connellsville, $5,000; Philip Gallagher, Connellsville, treasurer. Incorporators, Thomas Howard, S. H. Galloway, and R. Galiardi, Connellsville.

The Valley Coal Co., has been supplying the City of Pittsburgh, under contract, with coal for industrial purposes, taxes, etc., during the strike period. For this purpose union miners were employed to dig out a number of tons of coal per day from one of the company's mines. It is reported that the new owners of these mines refused to work. The company, represented by Harry Kicklighter, of Pittsburgh, was the second party whereby coal was to be supplied for the city, the company paying a royalty of 15 per cent to the union and using some of the miners. It may be interesting to note that representatives of District No. 5 of the United Mine Workers of America gave their approval.

The Y. V. Coal, Gravel & Transport Co., Zanesville, has been incorporated with a capital of $250,000. The incorporators are H. B. Vincent, H. C. Stalher and others.

The Valley Coal Co., has been supplying the City of Pittsburgh, under contract, with coal for industrial purposes, taxes, etc., during the strike period. For this purpose union miners were employed to dig out a number of tons of coal per day from one of the company's mines. It is reported that the new owners of these mines refused to work. **WEST VIRGINIA**

Operations are to be conducted upon a far larger scale under the plans of the **Springdale Coal Co.**, which has recently been organized and chartered with a capital stock of $300,000. This company will engage in the coal business in Fayette County, and the offices have been located at Morgantown. Leading figures in this operation are Robert A. Pollard, H. C. A. Hawley, C. O. Dunn and E. L. Ellison, all of Beckley.

The **Centre Coal Co.** has been formed by Morgantown people with a capital stock of $75,000, with offices at Morgantown. Leading figures are Richard A. Pollard, Hudson Clinesey, Vision Mollott, Matt Fluttert and Huyck to all points in Morgantown.

The **Guyan Valley Fuel Co.** presages the development of property in the Logan region on a small scale, and the **Berkeley Coal & Coke Co.**, whose headquarters will be at Huntington, is also making preparations for the mining of coal.

**Traffic News**

The **Montana Coal & Iron Co.**, in a brief filing at Pittsburgh, says that it is possible the rate case requests the rates per ton payable by the coal from Beaver Creek, Mont., are applied to rail freight charged at Arlington, Minn., and Kirby to all points in Montana, Wash., Idaho, and Montana and the differential basis of rates on slack track lumber are illegal.

The **Indiana Power Co.**, of Vincennes, Ind., alleges unreasonable rates on coal switched at Evansville. The company requests the rates not in excess of those charged for other mines in the Finleyville, Moundville and Richland fields.

The **Lincoln Gas Co.** of Pittsburgh, has requested the rates on coal from its mine, which is at Selbyville, Del., Wheeling to points in the Eastern and Midwestern states are not reasonable. The company requests rates not in excess of those charged on other mines in the Finleyville, Moundville and Richland fields.

The I. C. C. has decided, in the case of **West Kentucky Coal Board**, that the rates on bituminous coal from western Kentucky mines on the Louisville & Nashville Railroad are unreasonable, and points in Georgia are unreasonable. It is held, however, that the maintenance of rates on bituminous coal from mines in Alabama, eastern Tennessee and southwestern Kentucky and port Wheeling, Ga., for export, while no export rates are charged on western Kentucky points from western Kentucky mines, is prejudicial to the western Kentucky mines.

The I. C. C. has made recommendations as to the following coal rates, which are unreasonable: from points near Evansville, Ind., to Zionsville, Ind., and Wheeling to points in the Eastern and Midwestern states from coal from a mine in the Illinois and Indiana coal field. The companies have been notified of the rates that are not reasonable. Rates on coal from a mine in Michigan are unreasonable. Rates on traffic charges on coal at Worthington, Minn., and Hammond, Wis., are reasonable.

The I. C. C. has made recommendations as to the following coal rates, which are unreasonable: from plants on the Illinois Central and Indianapolis Southern, and the Chicago, Rock Island & Pacific railroads on bituminous coal and briquettes from Illinois and Indiana to points on the South Side of Chicago.

The **Ballard & Thompsons Railroad Co.**, operating a line connecting the properties of the **Glass Works Co.** and the **St. Louis & Southern** R. R. at Thompsons, in Grand County, has applied to the Public Utilities Commission for permission to operate as a common carrier. It is held that both the needs of the coal companies and the residents at Sego make it necessary for the operation of the road as a public carrier.

Thomas W. Arnette, of Fairmont, president of the Antler Coal Co., has gone to Denver, where he will spend about two months in making necessary investigations. Mr. Arnette will visit the mines under his supervision and is endeavoring to improve the operations of the mines in the Morgantown field.

Toledo, Ohio, July 17 — The general manager of the **Massey-Tyler Coal Co.**, of which the co-partner is Mr. Hatfield, the latter has been in charge of the company since it took the lead in opening up one of its mines, has been open-shop on the belief that labor alone can not possible. Others finished as fellows: 2d; Michel; 3d; Holliveau; 4th, Blairmore, 5th, and 6th, respectively.

In the senior first-aid contest there were 28 contestants. The winners were: 1st, Drumbellier Coal & Land Co.; 2d, Coleman International; 3d, Canmore; 4th, Lethbridge, 5th, Lethbridge (No. 2); 6th, Calgary. The ladies first-aid event was won by a Calvert, Mrs. Frank Greeno, of Lethbridge, presented the awards.

**COAL AGE**

**Vol. 22, No. 5**

**ALBERTA**

Mine-rescue and first-aid contests were held at Canmore, July 10 and July 1 under the auspices of the Canadian Institute of Mining and Metallurgy. In the junior first-aid contest, the winners were: 1st, Mrs. N. A. L. Lambie, 2d, Mrs. C. M. Reader; 3d, Mrs. George R. Smith, 4th, Mrs. W. J. G. Gibson. In the senior first-aid contest there were six contest, the winners were: 1st, Mrs. J. E. B. P. Lambie, 2d, Mrs. W. J. G. Gibson, 3d, Mrs. C. M. Reader, 4th, Mrs. E. B. N. Ziler, 5th, Mrs. George R. Smith, 6th, Mrs. W. J. G. Gibson.

**WASHINGTON, D. C.**

For the year beginning July 1 the War Department has available, under Congressional appropriations for 1924 of the **National Army**, the President, $3,500,000 for the purchase of fuel during the year.

**Northwestern Dock Operators’ Association**

Henry F. Smith, of St. Louis, was elected president of the **Northwestern Dock Operators’ Association** at its recent meeting in Chicago. Mr. Smith is vice-president of the **Harold Coal & Coke Co.** of St. Louis, and the officers chosen were: Vice-president, J. L. Fish, secretary-treasurer, C. O. Lambie, secretary, J. O. Lambie, of the Toughenyohe-Northwest Coal & Coke Co.; secretary-treasurer, W. A. Prinsen, of Chicago.

**Coming Meetings**

**New York State Coal Merchants’ Association**

**American Institute of Mining and Metallurgical Engineers**

Will hold its next meeting during the week of Sept. 25 at San Francisco, Cal. It is proposed to meet on Sept. 19, stopping at different cities en route, and to have the meeting in conjunction with the annual meeting of the **American Society for Reinforcing Concrete Buildings**, New York City.

**American Chemical Society**

Annual meeting will meet at the **1924 annual meeting of the American Chemical Society at Carnegie Music Hall**.

**American Mining Congress**

Twenty-fifth annual meeting of the Association, and equipment will be held at Buffalo, Cleveland, Ohio, Oct. 9-14, Executive Committee, E. C. Porter, convention manager.

The **Rocky Mountain Coal Mining Institute** will hold its next meeting at Glenwood Springs, Colo., Sept. 7-8. Secretary, W. B. Whiteside, Denver, Colo.
A Substitute for President Harding's Proposal

CLEVELAND is staging a two-ring show this week. One is the Eastern Ohio operators' party with Mr. Lewis, to which we refer elsewhere on this page. The other is a horse of another color. It may almost be described as the "dark horse," for it was but announced on Tuesday with all details officially withheld until Wednesday. It is a plan to settle the present suspension of mining. It is not a settlement for the issues of the strike. Briefly, it is this—mine owners and mine workers are to resume operation with the status quo of March 31, 1922—wage scales, check-off, everything. They are then to go home and forget the controversy and cool off for 30 days. By Oct. 31 they are to elect an advisory committee composed equally of operators and miners, which committee is to make detailed, deep and complete study and investigation into the coal industry. It finally will report its recommendations, not binding on any one, as to the best way to conclude future wage scales, whether by districts, states, groups of states or nationally. This committee is to give equal consideration to the competitive relationships of the operators and the necessity for full compensatory wages for the men. A lot of other things are suggested.

The essential thing is that the moot point of HOW is put aside. Mr. Lewis does not get his four-state conference, nor the operators get their district agreements. Which it is to be will be recommended by this committee. Since neither side is called on to concede the point, and since the resumption for the winter at the 1920-1922 wages has already been discounted in most fields, made certain in fact by the proposal of President Harding last month, there is not much left to argue about. It may be, as some thus early would think, but another string in John Lewis' bow, but since he has the bow, what matters another string? It is a plan parallel to that proposed by the President on July 10, with the difference that John Lewis will accept it.

Negotiating a Truce

LAST February the United Mine Workers declared war on the American people. They said they would exert their full economic force to prevent the liquidation of their wages from the post-war peak. They have succeeded so far. In the face of economic conditions wholly opposed, contrary to every canon of sound industrial readjustment, the miners' union has stood off wage reductions, even consideration of wage readjustments, and when they go to work some time this Fall or this Winter, it will be for the most part at the wages they struck to maintain. This is not a concession in advance of the fact, but an actuality. It is a tribute to superior organization, unified command, better generalship and more efficient use of the common type of munitions, propaganda—if you do not object to the use of the word.

A war is not over until someone surrenders. Neither has surrendered so far. It is true that the principality that regards Cleveland as its capital and metropolitian center is treating with the union this week, but the bulk of the operators in that conference, the leaders at least, never were in the war. They had no quarrel with the union and have put no army in the field. The operators of Eastern Ohio have not capitulated to the union. Their course has been consistent from the start. They have been one of the neutral states in this strife. In the crucial test of 1921 that field suffered, by comparison, not at all from non-union competition. They could continue to pay the highest rates to their men and it would be no skin off their knuckles if the consumer had to pay them in accordance for coal.

Eastern Ohio in the last six months of 1921, when competition in the sale of coal was so keen that men ceased to be friends, operated at the rate of 32.6 per cent of full time. Her nearest union competitor, southern Ohio, managed to record 22.9 per cent in that same period. Pittsburgh all-rail mines ran at 41.2 per cent. The non-union fields of southern West Virginia, with lower costs both by reason of better natural conditions and liquidated wages could register no better than from 49.8 for Pocahontas to 24.3 for New River. Is it any wonder that Eastern Ohio has not been in favor of fighting it out with the union? How can anyone call a fellow a quitter when he never started? So it cannot be heralded as a victory for John Lewis that he has lined up that group of operators.

Where John Lewis has scored a triumph has been in holding his forces intact through the summer and until the public necessity for coal has driven first the hard coal producers and then a substantial portion of the soft coal operators to offer a resumption of work on the old and highest scale, for the winter. The question of supply of fuel for homes, transportation and industry for this winter has long since become so acute that the President has virtually taken charge of the situation. He is after coal production for the people. He asks the contestants to forget their strife for a while and give us the needed coal, and urges the submission of the points at issue to the third party, an impartial tribunal.

Plainly enough the policy of the administration at Washington in both the coal and rail strikes is to establish the principle of arbitration in these major industrial disturbances. Nothing can be fairer. The inhabitants of the east bank of the Rhine, however, never crowded the hotels at the Hague in 1914 and came somewhat reluctantly to Versailles in 1919. John Lewis surveys his ranks and states that the only council table he will put his feet under is one of his own
Choosing. So he calls in the few who have no quarrel with him and they bring some adherents and attrition of the operators' ranks begins.

Since March the various coal operators' local associations have regularly offered to meet their men, through the regular union representatives, in district conferences. Time after time they have called for conferences, set dates and opened the boxes of cigars, but nobody from the union came to the meeting. John Lewis had told the men that the only way to prevent a reduction in wages, to forestall the otherwise inevitable loss of some of the gains of the war and post-war inflation was to stick together; that district settlements foreshadowed less than district settlements and disruption of the union. He got the message over and no power of operator persuasion has been able to jar loose a single element of his membership. His ranks held.

Now, with coal stocks lowered to the point where cumulated demand insures full running time for all the mines and offers even the operators of the more sorely beset of the union operators a market for what they may be able to produce at such prices as will warrant any old wage scale, Mr. Lewis attempts to turn the flank of the enemy with some of the tactics he resisted for five months. Having successfully withstood the enticements of district settlements offering local enrichment to small groups of mine workers, he seeks to entice small groups of operators from their common policy of district settlements to participation in national wage conference.

### Congress Views a Hornet's Nest

Throughout the week the office of the Federal Coal Distributor has been busy day and night. It already has been demonstrated that H. B. Spencer and his associates have a comprehensive grasp on the situation and are entirely capable of carrying out the very remarkable plan which Secretary Hoover has worked out—remarkable particularly in respect to putting responsibility outside of Washington. The trouble is they are being called upon to make bricks without straw. Just how much of a success they will be able to make of the job, in view of the flimsy authority to which the Federal Government can lay claim, is questionable. One thing is certain, the coal operators are on trial. They have been put on their honor but if they yield too generally to the temptation of accepting prices above the maximum agreed upon, it is believed that nothing then can prevent regulatory legislation. This is not an argument for fixing prices, but a conclusion. Just now Congress regards the strike as something of a hornets' nest. The administration has won little commendation for its efforts. Because of the danger of being stung, Congress will keep away from the hornets' nest until after the strike.

### Two Hundred Thousand Dollars

High-sounding resolutions of horror at the Herrin massacre, in which a score of non-union men were murdered after they had surrendered to a mob—presumably a union mob—and resolutions calling upon the state and national authorities to bring the culprits to swift justice are easy to pass and put in the mail. But what do they accomplish? It is well for the public to express its opinion on such matters, but, unfortunately, the peculiar situation at Herrin and in the remainder of the solid-union south of Illinois makes it so difficult for state and government to enforce the authority of the law that the citizenry of the state and nation can better aid by lending assistance more concrete than words. Money is the answer.

In handling a situation such as that in Williamson County, where morals are no higher than they obviously are, one of the most powerful magnets to be used in search of the truth is cash offered to obtain evidence. State Attorney Edward Brundage, of Illinois, recognized that after his first visit to the troublesome region. He offered $1,000 cash for evidence that would result in conviction of the guilty. He obtained some evidence, but, apparently it is little enough. With a fund available two hundred times as large as that offered by Mr. Brundage a tremendous impulse should be given to the swift and sure apprehension of the men who instigated, abated, and executed the Herrin horror. Two hundred thousand dollars should encourage enough willing but fearful citizens of Williamson County to yield up facts at the risk of their lives so that that "bloody" section of the State of Illinois could be purged to a point where honest people there could once more tell the truth and law and order prevail.

### Interminable Roadways

Some are disposed to think that only in big mines are long roadways and a haphazard system of development to be deprecated. After all most of what has been said of these larger producers by Wilcox and Pleschner is true also of small drift mines.

When even a 1,000-ton mine is laid out with only a main entry and several interminable room entries there is bound to be excessive air resistance or excessive splitting and, what is as bad, much loss of air from leakage and much expense for maintaining stoppings and roadways. Development also is sure to be slow and must be run double shift.

Many small mines, especially in low coal, fail to be productive because of lost air, excessive road upkeep, frequent stoppings, repairs to brattices, too many poor communications, making supervision and management difficult; attempt to maintain several expensive drainage ways and too frequent night work on headings. Where a room heading supplies a full load for a locomotive the length of the heading may be of little consequence. The locomotive has to go as far whether the work is in panels or goes on indefinitely or to the crop. But where the locomotive has to haul from two headings to obtain a full trip it is a distinct disadvantage to have the headings long, for much time is wasted in running so far under partial load.

Unfortunately an elaborate layout serves often only to cause delay in the first stages of development. At that time one main entry (including, of course, a return airway) is all that is needed. The room entries are short, the resistance to the air is light, the leakage through the stoppings is negligible and the expensive layout necessary to guard the future is regarded as extravagant. But after awhile the simple method, adequate enough for early operation, becomes wholly unsuited to later conditions. Nowhere is coal enough removed, and a squeeze is likely to occur. With all the robbed portions of the mine cleaned out and entirely caved the newer parts are safe and may be relied on.
Methods and Practices of E. E. White Coal Co. 
At Stotesbury, W. Va.

By Alphonse F. Brosky*
Pittsburgh, Pa.

Track Device Tests Automatically Presence of Loose Wheels—Rebuild Locomotives Periodically According to Determined Schedule—Foundry Established at Mine—Tire Removals Facilitated—Larry Adapted to Steep Hillside Dump

A FREQUENT source of accident around coal mines is wheels that become loose and out of
gage by the loss or shearing of retaining pins or the loosening of bolts. No assurance can be felt that
wheels will not become loose even when they are of the
tight-wheel type, in which, of course, the axle revolves
with the wheel. Whether the wheels have plain or
roller bearings they are apt to become loose and the
so-called "loose wheel" that revolves on the axle is prone
also to loosen in the same undesirable sense. All wheels
therefore need inspection if derailments are to be
avoided.

*Bituminous editor, Coal Age.
Note—Frontispiece shows tipple of E. E. White Coal Co.

At many mining plants the mine cars are periodically inspected, particular attention being paid to the
condition of the wheels and axles. However, as such
cars are heavy and as the inspection usually is made
with the cars on the track, judgment is left to the eye
alone and not, as it should be, to some mechanical test.
Consequently a faulty wheel often goes unnoticed.
At other places the man who attends to the lubrication of
the wheels or axles is instructed to watch for any de-
fects, but, unfortunately, it is much easier to bend over
slightly and fill up the oil reservoirs than to get down
on one's knees and crawl around in the effort to detect
a faulty wheel or axle.

For this reason inspection is often omitted or else
made in such a haphazard manner that it might just
as well be dispensed with. In still other cases inspec-
tions are never made and defects are corrected only
when they assume a dangerous form and are readily
discernible by the eye. A greater tractive effort of the
locomotive is necessary when the wheels become loose.
This deficiency inevitably makes itself felt in higher
power bills.

At the Stotesbury mine of the E. E. White Coal Co.,
at Stotesbury, W. Va., an ingenious track device has
been designed which will make evident such wheels as
have too much play and will sound an alarm when they
are found. With this arrangement no one is required
to give up his time to inspection, as the action of the
device is automatic and, what is still more to its ad-
vantge, each car is inspected every time it passes
over the empty track at the tipple. Unlike a personal
inspection it is foolproof, for every car that passes
over the device is made to sound an alarm if the wheels
under test do not continue within the limits of the
track gage. One of the several men who work on or
about the tipple will hear the alarm and run the car
without delay on the track leading to the shop.

With the following description and the illustration
shown it will be possible for the blacksmith at almost
any mine to fabricate the rails of which the device is
composed. As may be seen by referring to the illus-
tration, the entire length of the deflecting track is no
greater than that of the standard rail—that is, about
30 ft.

It is inserted on the empty or return track leading
from the tipple, so that the cars pass through it by
The double rail on the right acts as a raceway, holding the flanges of the right-hand wheels against the inner guide rail. The tension spring at D should be strong enough only to pull back the latch to the position shown, after a normal car has passed. A spring with a tension of about 30 lb. should do this work.

The blacksmithing job required is easy, for the material needed is available at any mine. Even the small separating collars and the spring are likely to be found there. The cost complete is nominal, and the saving made by detecting a loose wheel before it has time to cause a smashup at frogs and switches will repay the expenditure.

We have been reading so much lately about mine locomotives and their care that we sometimes feel that the subject has been overstressed. But the E. E. White Coal Co. follows a policy regarding its locomotives that would increase the tonnage at any mine at which it was adopted.

The ideas which suggested the present policy came from two sources. One of these is the railroad. In the case of steam locomotives and, to a lesser extent, of other rolling stock the railroads have ever followed the maxim that "a stitch in time saves nine." As everyone knows, railroad locomotives are given a daily inspection and every evil is remedied regardless of the time or the extent of the repair job.

Run Mine Railroad as Railroads Are Run

Steam valves are replaced if leaky and all joints are made secure, and this is followed by attention to mechanical details, including a general tightening up of loose parts. Even though the steam locomotive is notoriously inefficient, it is truly remarkable how few are the delays on the railroads that can be attributed directly to the failure of the locomotive. The secret of this continuity of service may be found in frequent overhauls and inspections.

At the Stotesbury mine at least one locomotive is in the shop at all times. They are taken there in turn, not because there is something radically wrong with them but because it is thought that by so doing the interruptions due to locomotive ailments will be minimized. The policy is no longer an experiment, as gratifying results have justified its permanent adoption.

A new locomotive with a proper consideration for its limitations will run a long time without requiring much care. Gradually, however, it will run down; certain parts will have to be replaced because of wear and others as a matter of safety. Virtually this mine never has any old locomotives, as they are completely torn down, one at a time, and rebuilt, putting in new parts where advisable. The electrical features receive the greatest attention in these overhaulings, partly because they cause most of the trouble and largely also because their defects are not immediately apparent.

Gears, pinions, bearings and the like may be inspected and their real condition thus determined, but electrical equipment may disclose no weaknesses when inspected physically and yet may be found faulty when tested electrically. On the other hand, the opposite may be true—an electrical test may satisfy the observer whereas a physical inspection may show that the insulation is in poor condition. Armatures, controllers, resistors, coils, cables and so forth do not have lives of equal length, for the intensity of duty of each varies.
Under given conditions and with careful usage the average life of the part may be determined—the length of time, that is, during which the respective parts functioned satisfactorily. By allowing a life for each slightly shorter than that observed in use and making replacements and repairs accordingly the locomotives may be kept going for a long time without frequent and annoying trips to the shop.

In keeping costs an adaptation of the Indianola mine system is employed to cover the electrical equipment used underground. Each section of the mine is put in charge of an electrician, who is held responsible both for the upkeep and the cost of the electrical equipment in his section. In this way a check is made on the work done by the shopmen, as the electricians are willing to have their equipment overhauled at stated intervals, but do not like having a job that is not done properly charged up to their department.

The upkeep costs of locomotives, pumps, cutting machines and wiring per ton of coal mined are kept separately for each mine section, and it is the constant aim of each electrician to keep the cost per ton at the lowest possible figure. It might be said here that if the cost of new parts and the workmen’s time only is considered this system of renewal is much more costly than the old system where repairs are made only as needed, but if the greatly increased tonnage obtained under the new system as compared with that under the old is taken as a measure, then a saving is effected in favor of the new.

The loss of tonnage under the old method of not repairing until a breakdown occurs should be charged up against the old system. After the practice of making repairs before a failure occurs had been in force a year the tonnage coming from the mine in one month was increased from about 40,000 to 51,000 tons as compared with that attained when the new system had just been introduced.

Some mines in West Virginia, and for that matter in other states also, are situated in such isolated regions that only with great difficulty and loss of time are supplies obtained. A complete stock of repair parts cannot be carried without an excessive interest charge, but there are times when a gear or something similar is needed to complete an urgent repair job, and at such times the delay creates a perplexing problem for the management of the mine.

If the plant has been provided with a well-equipped machine shop, a small bronze foundry may well be added so that parts needed in a hurry may be molded, poured and machined in less time than would be consumed in placing an order for them at some distant point. A small bronze foundry, having a capacity of 400 lb. in one heat, occupies one corner of the blacksmith shop at the Stotesbury mine.

With the aid of a small furnace small pinions and gears may be cast, the latter of considerable size, in case of an emergency. Here the journal boxes of locomotives frequently are made and occasionally bushings are cast. But the foundry is most useful in the casting of metals having comparatively low melting points. Where mines are situated handy to a commercial foundry a job of an unusual characted may be completed under the personal supervision of the customer, who can see that just what he wants is constructed, but mines at a great distance from such a foundry are handicapped in this respect, and in such cases a foundry at the mine is more than justified.

No one can gainsay that where possible it is a wise policy to order all replacement parts from the manufacturer, as thereby a better product is assured. It would be foolish indeed to assert that workers at the mine can compete with a commercial house as to the quality and cost of one of its standard products. A small foundry is justified, therefore, only when installed for the purpose of insuring continuous operation of the surface

---

Jobs Completed in Foundry

This mine is located at some distance from custom repair shops and from supply houses, and consequently a foundry at the mine prevents delays that would otherwise be inevitable. Certainty of operation is one of the methods by which running costs are reduced.
plant. Because this is so the cost of the emergency job is a secondary consideration, so long as a normal coal tonnage is forthcoming as a result.

The furnace in use at Stotesbury utilizes coal as fuel, aided by a natural draft of a 24-ft. air column. The furnace proper is sunk below the floor line and is therefore of the pit type. For the benefit of those who might have need for it, a sketch of the furnace is shown on page 201. The retaining walls and the ash pit are constructed of concrete, the dividing wall and the grate being supported by old rail. The heating chamber is lined with firebrick and the fuel grate was supplied from a sand drier. It rests upon the rails embedded in the concrete. The mouth of the furnace is corniced by a cast-iron channelled collar covered by a cap of like metal. The lower inlet of the chimney is at least one foot below the floor line; consequently it should be protected by firebrick or plastic cement. The use of the latter to line both the furnace and the lower region of the chimney is desirable because of the ease with which it may be applied. The molding, heating of the bronze, pouring and the care of the furnace are placed in the hands of one experienced foundry-man, who, when occasion demands, enlists the aid of one or more of the blacksmiths.

The coal at the Stotesbury mine lies several hundred feet above the railroad track, so that all supplies must be raised up an inclined plane. At the foot of this plane and close by the railroad track stands the sand house, the construction of which has at least one feature of merit. It is elevated upon a foundation of wood posts so as to allow cars to pass under it, thus facilitating the loading of the dried sands. As the building is constructed of wood the two chambers in which the sand dryers stand are fireproofed by a cement lining and steel sliding doors. There are five compartments in the house; on the two extreme ends are located the storage bins for the green sand, and the two drying compartments adjoin these on the inside; between the two dryers is a storage bin for dry sand. The latter is provided with a trap in the floor through which the sand is discharged into a sand car spotted beneath. The layout is such as to eliminate all needless handling of the product.

At almost any mine the problem of removing flat and otherwise worn tires from locomotive wheels must be solved. This is accomplished in many ways, among which is the circular burner which circumscribes the wheel to be heated and consumes a mixture of gasoline and air under pressure. This method, while effective and quick, is dangerous and complicated as compared with the method employed at the Stotesbury mine.

The heating device in use at this mine is an adaptation of the gasoline air burner. A piece of 2-in. steel pipe is rounded to form a circle the inside diameter of which is slightly greater than that of the locomotive wheel. To complete the burner pilot holes are drilled at intervals.

A socket coupling connects the burner to a 2-in. line which connects up with a small motor-driven air blower. The burner is placed outside the machine shop directly under the hanging point of the boom of a swivel windlass derrick. The connecting air line supplies air from the blower inside the shop to the burner on the outside. Slack coal is used as fuel, heaped up about the burner and the wheel.

The second cut on page 201 shows a multi-groove split collar to take up play between an axle-suspended motor and the gear it drives. As shown in the figure, six ½-in. square-sectioned grooves are cut in the axle on 1-in. centers. Four square tongues of similar dimensions are cut upon the split collar to engage into four of the six female grooves on the axle furthermost away from the suspended motor.

With this provision any side play of ½ in. plus necessary clearance may be taken up simply by stepping the collar over one groove toward the motor. If the side play is great enough to be taken up but still less than ½ in. plus the necessary clearance, then the collar may be faced down to meet the correct dimensions. Every locomotive that comes into the shops at the Stotesbury
mine for the first time has its axles equipped with the collar. At few mines in West Virginia has an efficient system of slate disposal been installed. At several mines slate is actually hand shoveled from solid cars; at one mine at least horses and wagons are used; horn dumps and galloway dumps are resorted to extensively. One of the illustrations shows a refuse larry in use at the Stotesbury mine, having been built in its shops. It is nothing more nor less than a tilting container equipped with a lever-controlled end gate.

This box is mounted on a turntable on the upper half of which is mounted a 15-hp. motor which is used for revolving the slate holder and also for raising and lowering it by means of a worm and gear drive attached to a windlass-and-sheave hoist. The body of the larry is mounted on an I-section frame generously reinforced. The larry is driven through the usual pinion and gear attachment to the rear axle by a 15-hp. motor.

At many mines in this state the coal lies far above the railroad and the tramroads and slate roads are veritable shelves cut in the precipitous hill sides. Consequently a slate larry need only be self-propelling and self-dumping. It is not necessary to have it carry the slate away from the larry, for by merely sliding from the tilted bin large quantities of slate may be stowed without any necessity of barring the track over.

Will Neutralize Mine Water with Marl Before Pumping It to Surface

BY WILMER C. MASON
Columbus, Ohio

A TANK has been installed by the Triangle Clay Co., of Ulrichsville, Ohio, which apparently treats water from the coal mines so successfully that “sulphur” or copperas is removed and the effluent from the plant is made relatively harmless to pumps and pipes.

The installation consists of a wooden tank, 15 ft. long, 8 ft. wide and 2 ft. deep, divided by baffles alternately joining at the top and the bottom of the tank. The water flowing through the tank is thus forced upward and downward through the marl, a natural calcium clay, with which the tank is filled. This neutralizes the copperas, and the product, being insoluble, is caught on the cinders with which the last compartment of the tank is filled and which will be cleaned out from time to time.

The cost of the installation was $40. It is estimated that one charge of marl in the tank, which holds three tons, will last six months. Marl, at this rate, will cost another $40 a year.

An analysis of the untreated copperas water from the mine showed that it contained 17,800 parts per million of solids, of which 840 were in suspension. The solids in the treated effluent from the tank contained only 2,520 parts per million of solids, of which 60 were in suspension.

The solids in the water were largely sulphates of iron, calcium and magnesium, the iron sulphate giving a strong acid reaction in the untreated water, which expressed in terms of sulphuric acid, amounted to 446 parts per million. Although the other solids in the treated water, similarly expressed in terms of sulphuric acid, amounted to 87 parts per million, they were largely non-acid-forming calcium and magnesium sulphates, and indicators gave no acid reaction, either immediately after treatment or after the treated water had been allowed to stand a week with the purpose of determining whether the treated water would revert to acid.

Mine water has in the past so polluted streams that cattle and horses which drank it have died as a result. It has destroyed thousands of fish, rendering the streams unfit for use as a source of water supply for domestic or industrial purposes. Many companies have gone out of considerable expense in unsuccessful experiments to treat the water before pumping.

The Ulrichsville treatment tank, where the copperas

PLAY TAKEN UP BY GROOVED SPLIT RETAINING COLLAR

*Takes up any play that may tend to develop between an axle-suspended motor and the axle it drives. It will be clear that a shift of the collar from position A to position B will reduce the play the width between groove centers.*
is neutralized, was built outside the mine for experimental purposes only, but it will be moved to the sump, so that the treatment may accomplish its purpose of eliminating the cost of the present frequent renewals of pumps and pipes. The system was developed by the Stream Pollution Department of the Ohio Fish and Game Division. Several other mines in Ohio which have been watching the progress made with the preliminary experiments have intimated that they will install the system.

It should be added that the mine is not of large capacity, being worked only for the fuel supply of the clay company. The quantity of water now being pumped is about 500,000 gallons a day. When the strike commenced the mine was allowed to fill with water, which is now being pumped out. Under normal conditions about 100,000 gallons would have to be discharged daily.

**Illinois Mine Inspector Makes Suggestions For Greater Safety in Mining**

Too many accidents, fatal and non-fatal, occurred last year in the mines of Illinois. Falling coal alone, mostly coal that had been already undercut and shot, was the direct cause of thirty-two fatal and 412 non-fatal accidents. That is too great a number for one state, a single cause and a single year. When I come across an accident from falling coal I am always convinced that it was not really accidental, for it could have been avoided. Mine managers and superintendents contend that some men really die not from accident but from deliberate suicide, but the contention seems difficult to support.

All coal should be undercut or sheared and when undercut it should be snubbed for half the depth of the cut and at least one-third of the thickness of the seam. An accident by which four shotfiring in the Springfield district lost their lives on Feb. 22 of this year would not have occurred had the coal been undercut or sheared before the shots were fired.

We shall make more improvements in the next ten years in the mining and transportation of coal from the face to the surface than we have accomplished in the last thirty years. In the past we have greatly improved our mining machinery both below and above ground, but at the face improvements in mining methods have not kept pace with other developments. The faces of all cross and main entries should have two ways of ingress and egress to the surface, but when driving a single room entry it is not necessary to drive two headings—an intake airway and a return—provided that the mine is operated by the panel system of mining.

When the panels are 2,000 ft. apart a small booster fan can be placed at the mouth of each stub entry, and this will give the miner better ventilation at the face of the entry than he would receive if two headings were driven. The pipe from the fan can be kept within 10 or 15 ft. from the face of the entry until the headings hole through. Then when rooms are started air sent in at either end will go through without loss. In this manner one heading and several crosscuts will be eliminated, and a saving made in labor and yardage. And yet the mine will be better ventilated.

Some one has asked me: "With only one entry in operation, what if you should have a squeeze?" My reply is that I have never heard of a squeeze that did not close both entries and that in all my experience I have never known of anyone being closed in a mine by a squeeze. Furthermore, if coal were mined out in the proper way, no squeeze would take place in the advance workings, but only during the retreat or pulling of pillars. In my opinion a large part of our accidents, both fatal and non-fatal, are caused by taking out too much coal when driving our rooms up. The more tons of coal mined per keg of powder, the less accidents we have. The Lovington Coal Co. has been in operation for over ten years, mining 150,000 tons per year, or 1,500,000 tons in ten years, without a fatal accident at the face. In this mine an average of 150 tons of coal is produced per keg of powder.

Fifty or sixty per cent of the coal can be mined without the use of explosive. If we would drive up our rooms no more than 21 ft. wide, laying the road along one rib and leaving pillars sufficient to support the surface until the room is driven up to the boundary, and if when we start drawing back the pillars we would undercut the coal from crosscut to crosscut, the coal would fall down without the use of powder. This would increase the percentage of lump coal and reduce the percentage of screenings, causing the coal to bring a better price.

One mine in my inspection district, operating under the method just mentioned, produced from 80 to 90 per cent lump over 11-in. screens. While driving up the rooms the coal was shot with four drillholes instead of three, as in common practice. The first holes were drilled and fired about 3½ to 4 ft. above the bottom of the seam, and the coal below this was shot down and loaded out before the other holes were fired.

The coal was nearly all of lump size. No overhanging coal was left, nor did the ribs of rooms have to be squared up. Under this plan the number of accidents has been reduced, as the undermined coal all fell down on the floor of the room. With this plan also the miner had less work, for the coal was in fine shape for loading. Less powder was used in shooting and a better grade of coal was obtained.

Laws should be enacted regulating the use of electricity in mines, and no gasoline engines of any kind should be allowed below ground. Many mining accidents are due to mine cars, locomotives and hoisting machinery. I believe the time is not far off when belts will be the means by which coal will be transported from the inside parting to the surface. This also will add to safety.

*Abstract from paper by J. H. Haskins, state mine inspector for Illinois District No. 9, read at the annual meeting of the Illinois Mining Institute at its session June 3.
Steel Props Furnish Recoverable, Quickly Set and Self-Adjusting Supports for Mine Roof*

Designers Endeavor by Use of Sand, Dirt and Shot Beds in Telescoping Props to Provide for Taking Up of Initial Flexure of Roof Without Breakage and for Shortening of Props Prior to Removal

By John Roberts

In recent years, owing to the scarcity and consequent high price of timber, the use of iron and steel has greatly increased. This trend was particularly significant during the progress of the war. Many causes have contributed to enhance the cost of timber, the chief being labor and transportation charges and the gradual exhaustion of forests. There are indications that prices will remain at a fairly high level for some years to come, if not permanently, and that in the future mines will consequently use iron and steel more extensively than ever for the support of the roof.

Steel posts may be classified as follows: (1) Temporary supports, or those used at the coal face; (2) "semi"-permanent supports, or those used on branch roadways, and (3) permanent supports, or those designed to be used on main roadways.

One of the earliest metal props, if not actually the first, to be invented was that patented by W. O. Johnston in 1861. This consisted of a tubular prop made in two parts for easy handling, these being held together when in position by means of a retaining ring. The two parts were preferably inclined at the joints so as to facilitate their removal when the ring was released. Provision also was made to hold the parts together by a catch, if desired.

One form of this prop is illustrated in Fig. 1, the chain shown being used when withdrawing the prop. The objections to this type of support are: The retaining ring is apt to split if it is subjected to excessive pressure, and this tendency is increased when the joints are inclined; no provision was made for the gradual yielding of the prop to the pressure of the roof and although the prop could be withdrawn, the withdrawal was sudden, when it should be gradual. If instead of the ring the alternative catch was used falling stone or coal would be likely to displace it.

Collison Devises First Adjustable Props

Little appears to have been done in the way of introducing new metal props during the succeeding thirty-five years, but in 1896 Collison designed adjustable screwed struts (Fig. 2) for use in a horizontal position in trenches and like excavations. The struts were expanded and contracted by a nut which worked on a screw and bore against a washer. This design, however, never may have been applied to mining purposes.

In 1897 Cadman and Marshall patented a stop block for holding in position crossbars and side posts. The stop block was cast in one or two pieces and secured by a wedge-shaped bolt. It served to prevent the prop supporting a metal crossbar from being displaced. Later in that year Firth and Thompson brought out a metal prop constructed of H-iron, part of the web being cut away and the flanges being bent over to form a flat bearing surface, as shown in Fig. 3.

Several inventors seem to have directed their attention to pit props in the year 1899, about the time when W. H. Hepplewhite patented his system of tapered props, and the principles then first applied were followed by other designers in subsequent years. Green proposed the use of a metal box (Fig. 4) at the foot of the prop. The box was filled with sand, on which the prop rested, and this sand served as a cushion to take up the pressure. Doors at the sides of the box, which could be opened from a distance, allowed the sand to escape when the removal of the support was desired. Green's invention was followed in a few weeks by Baron Masham's adjustable prop (Fig. 5). The prop is made to rest in a hole in the floor, and was designed to carry a channel-iron girder that served to support crossbars. Adjustment was effected by means of a screw turned by a wheel. Security appeared to be a strong feature in this prop, as it could be fixed into both the roof and the floor.

Balmer aimed in his prop to cushion the weight by the use of a flanged and ribbed lower tubular member partly filled with dirt, which served to support the upper member. The adjustment or withdrawal of the prop (Fig. 6) could be effected by means of holes in the lower tube, which holes could be opened or closed at will, thus allowing the required amount of dirt to escape.

Gascoyne used a combination of wood and metal in

---

*First part of article entitled "The Development of Metal Supports for Mines," read before the North of England Institute of Mining and Mechanical Engineers, Newcastle-on-Tyne, June 9, 1922. The second installment will be published next week.
his supports. A vertical metal tube or a piece of iron of H-section (Fig. 7) was fitted with a moveable crown, which in turn supported a short auxiliary wooden block, on which rested a wooden cap. Wooden blocks also were used with tubular props. The auxiliary block, however, makes the prop less rigid, so that it would be easily displaced by falling coal.

Spencer and Chambers followed soon afterward with props of H-section in which the flanges were bent, as shown in Fig. 8 (a and b), which also illustrates the special form of cap used with this type of prop.

In the year 1900 Garforth, Sutcliffe and Buxton patented an extensible prop which had two extension screws and was specially designed to be used in conjunction with coal-cutting machines. This appears to have been the only important invention of its kind during that year, but in the year following Fowler set out to improve the Pirth prop by cutting away parts of the webs of the H-section and placing recessed saddles on them. The flanges were bent down over the saddles, and the latter tended to prevent distortion of the bent flanges. In 1902 Sommer, returning to the Johnston type of prop, used two tubular members, in which the lower tube was slotted at its upper end so as to facilitate clamping by means of a screw-collor.

Mounier in 1905 proposed the use of shot or other material in one part of the inner tube and devised means for allowing some of this to pass into a lower chamber either when setting up the prop or as the roof pressure came on. Mommertz (1906) employed a collar into which wedges were driven to secure both tubes together. Two forms of this collar are shown in Fig. 9. In a modification the wedges were replaced by a cam. In the same year Lowe used three tubes with a block of wood between the upper and middle tubes and wedges at the foot of the inner tube (Fig. 10). The first of many patents by Nellen was taken out in 1907 in collaboration with Voigt. These inventors suggested the use of cylinders of compressed stone in conjunction with metal.

Nellen subsequently designed a form of arch in which half tubes were held together by clips and filled with alternate layers of compressible material such as cork, straw and wood shavings, and this system was afterward applied in a modified form to props. Mounier developed further improvements in his prop, and used a rack and lever for adjustment. A cock was placed near the bottom of the tube to allow the shot to escape when necessary. The rack and lever would appear to be easily put out of action if handled roughly.

Noottaar, who introduced in 1907 a prop which possessed no very striking improvement, patented several binding devices for tubes in March, 1908. Later in the same month he brought out a tapered inner tube with wedges, similar to those proposed by Mommertz. He also devised a springhead to be used in conjunction with the wedges, but apparently made no provision for the withdrawal of the prop. Nellen again came forward, this time with two semi-tubes screwed together to form a hollow cylinder, which was filled with fine material. A rectangular opening in the lower tube is normally closed by a brace (Fig. 11), but on opening this the fine material escapes, allowing the head of the prop to sink and be withdrawn.

In the Eickershoff pattern (Fig. 12) the upper member rests on a shoulder of a cone-shaped body and is supported on sand, which is forced up through the cone when pressure is exerted. A hole near the foot of the prop allows the dirt to escape when it is desired to lower the inner tub. Normally this hole is closed by a rotary shutter. Caps and feet are placed on the props by means of bayonet joints, and these are fitted with lugs to engage with the levers used to turn them.

**DESIGNED PROP OPERATED BY SEPARATE TOOLS**

In a subsequent design by Sommer the upper member was raised by a mechanism which was independent of, and detachable from, the prop. This raising mechanism consisted of screw jacks, wedges and levers. In one form he adopted a rack and pinion, but in all his patterns the upper part of the lower member was slit so that the collar clamped the parts firmly together.

The year 1909 did not bring forth many ideas of importance, but it witnessed the entry into the arena of W. Reinhard, whose work will be referred to later. Binder devised shoes for holding props and bars in position. Schaefer proposed a form in which the upper member was secured in position (frictionally) by a divided ring placed upon the tapered upper end of the lower member. In this year Pittroff suggested the use of accordion-pleated tubes. The only development of note in 1910 was that of Sommer and the Mannesmannroehrenwerke, in which the sliding members were clamped together and provided with adjustable stop rings or pins. Possibly the Mannesmann weldless-steel prop shown in Fig. 13 is the outcome of the combined efforts of the inventor and factory just named.

In the few years immediately preceding the outbreak of the Great War several new principles were applied. Gruenewald and Gorich, for example, in 1911 introduced the system of holding the upper member by means of a series of balls and of adjusting the prop with the aid of an eccentric and lever at the bottom. Wild adopted the principle of right- and left-handed screw-threaded struts, which were held in contact by means of collars and end sockets, as shown in Fig. 14.

It was during this period that Reinhard developed his roof supports. In his earlier designs the feet of the props were made to receive tapered wooden plugs for yielding to the pressure, but these were replaced later by springs.

A prop of comparatively simple construction was in-
introduced by Humbles (1912). This is shown in Fig. 15. The prop was in one piece, with open tubular ends, in which internal diaphragms formed abutments for the floor or for wooden blocks. Flanged lids or beads were used to strengthen the ends, and the enlargements in the tube made it easy to attach chains and thereby to remove the prop.

Messrs. Mavor, Coulson and Mackay in 1913 encased wooden props in metal tubes, allowing parts of the props at the top and bottom to protrude so that they would yield on compression. In the same year Treinies used telescopic tubes filled with sand (Fig. 16). The upper tube was filled, plugged at the bottom, and held in position by a flange and collar. Means were provided for allowing the sand to escape, a device that is very popular with inventors.

Some of the foregoing supports were excessively simple in construction, but others were more complicated and necessarily expensive. The hallmark of refinement, however, was reached by Hodges and Smith, who, in order to indicate the movement of the mine roof, applied to props an electrical arrangement!

The war accentuated the demand for a substitute for timber and inventors continued their endeavors to obtain a suitable substitute. With the object of saving timber, Gainsford suggested using two metal tubes joined in the middle with a wooden plug and having a plug at the top and another at the bottom of the prop. Foggo also set out to save timber, and joined two short lengths of wooden prop by means of double-conical metal sockets provided with exterior strengthening rings (Fig. 17).

**Other Developments During the War Period**

Mills (1915) was responsible for a prop which in some respects resembled that of Reinhard, but he used a spring arrangement fitted within a special casing for holding the two parts of the prop together. The prop was adjusted by turning the casing. Verner supported the lower end of his tubular prop by means of a conical wooden block surrounded by a metal sleeve. The narrow end of the block was pointed upward, and yielded to pressure. Edwards and Beard and Slack and Williams also adopted the principle of employing wooden plugs at the foot of the prop for taking up the roof pressure, and the Butterley Co. and Bircumshaw have patented a means of readily removing these plugs.

Ericsson, who had previously devoted his attention to corrugated caps or lids, in 1915 devised the corrugated tube shown in Fig. 18. A suggested improvement on this type will be referred to later. The principle of the Wrighton and Ringquist prop will be readily understood on reference to Fig. 19. This prop consists of an inner and outer tube so arranged that the upper member rests on sand within the lower member. An aperture at the foot allows the sand to escape when necessary. When this aperture is closed, the sand passes up through a perforated plate at the lower end of the inner member as the pressure is applied. A perforated cap provides for the insertion of sand as required.

The form of prop shown in Fig. 20 was devised by J. S. Jones (1917), the chief feature of which appears to be the valve, which has two side apertures at right angles to a central one. In setting up the prop the side apertures allow the sand to fall around the lower receptacle until the prop is adjusted. These apertures are then closed and the central one opened, and this allows the sand to descend into the lower receptacle to a distance corresponding to the load on the prop. Robertson, in the same year, reinforced concrete cigar-shaped props with a spiral strip of metal. They were provided with end caps having serrated edges forming teeth, some of which were turned inward so as to penetrate the concrete.

Kearsley (1918) adjusted the inner member of the prop by means of pins inserted in holes in this bar. The whole appliance could be tightened by a screwed sleeve at the top of the outer tube. In the Sutcliffe and Sheppard type the lower member is hollow and is provided with teeth that engage in other teeth on the inner member and are kept in engagement by means of a gib-headed wedge so arranged that it may be loosened when desired without being completely disengaged.

A prop for mining purposes should possess the following characteristics: Strength, rigidity, resiliency, lightness, durability, adjustability, reliability, and simplicity of construction consistent with the foregoing qualities; it also should be easily withdrawable and comparatively inexpensive. With regard to construction and expense, where a prop possesses every other requirement, the cost, within reasonable limits, is not so important, because the props can be used repeatedly and recovered in safety, and although the original cost may be high, economies can be effected by their use.

In order that a steel prop may commend itself to a miner it should be capable of being set up easily and quickly, and when fixed it should be safe. When the preparation and setting up of supports entail much trouble there is often a strong temptation to the miner to delay the operation, and accidents have frequently occurred from this cause. To measure and cut a post and to prepare a cap, or "lid," takes much more time relatively than the actual setting up of the prop, and miners do not like to interrupt the process of filling a car of coal in order to put up timber.

When a workman sees that by removing, say, half a ton of coal he will have room to erect a necessary support he should in his own interest prepare the prop and cap beforehand. Many miners do this, but others omit the precaution and take risks. The temptation to do this is reduced where adjustable props that do not
require to be cut are in use. A prop which is considered to fulfill many, if not all, of the requirements of a handy and reliable support will now be described.

The underlying principle of the types illustrated in Figs. 21 to 23 is the employment of oval or partly oval and partly cylindrical tubes which can be adjusted longitudinally and be interlocked by partial rotation. The lower member, a (Fig. 21), is partly cylindrical and partly oval, the oval section being provided with horizontal ribs, b, which extend over part of the inner surface. The upper member, c, also is partly oval and partly cylindrical, but the major axis of the oval portion is slightly shorter than the minor axis of the lower member.

When the major axes of both members are parallel the upper member is free to move vertically within the lower member. The inner tube is provided with external flanges, d, which are adapted to engage in corresponding slots in the outer tube. On rotating the inner tube through 90 deg. it becomes tightened by friction as the flanges become engaged in the slots.

A clamp collar, e, is free to slide, within limits, on the upper member and is used to lock the two members in position, as shown in Fig. 21(d). This collar is provided with wedge-shaped or tapering slots that engage corresponding ribs, f, on the inner tube, this facilitating the turning of the inner tube as required.

The foot of the prop rests in a metal box, g, in which a spring is fitted to take up the pressure when the load is applied, and a similar spring, h, is fixed at the head of the prop. It will be observed that the bolt, k, which passes through the lower spring, is provided with a large head, which may be either round or square. This head serves to prevent the prop from being readily displaced after being properly set in a hole in the floor. The cup l (Fig. 21, d), carrying the head spring, is especially made to form a support for the cap.

The lower end of the inner tube also is provided with a cylindrical extension, m (Fig. 21, a), which constitutes a false bottom, and is provided with apertures for the passage of sand. In this type the sand is not used for supporting the upper member but simply to produce a cushioning effect during withdrawal and to prevent the sudden drop of the inner tube when disengagement takes place, as will be described later.

To set up a prop, a small hole is made in the floor to receive the bolt k; the inner tube is raised until the cup l touches the roof; it is then turned through 90 deg. and locked, being lowered if necessary an inch or so to enable the flanges to engage in the slots; the clamp collar is lowered into position, and the wooden lid is then driven in and tightened.

In order to withdraw the prop the clamp must be raised and fixed to the ribs; a chain should then be attached to the clamp, and the clamp given a partial turn from a safe distance. The upper member will then sink gradually on the sand, forcing it up through the apertures, and the prop will be loosened.

Fig. 22 shows a modified form in which a metal cap is used. It is so arranged that it can be secured by means of a wedge which cannot be withdrawn, whereas the cap may be removed on loosening the wedge. The final adjustment and securing of the prop is obtained by means of the wedge and cap, the box in which they are fixed being free to move vertically.

The principle of the oval interlocking prop may be applied to the corrugated type made by Ericsson (Fig. 18), for it will be seen that by using oval corrugated tubes (Fig. 23) advantage can be taken of the corrugations to facilitate adjustment and interlocking.

Another type for which I am responsible is shown
in Fig. 24. In this case sand is used for supporting the upper member, and the chief feature is the flat slidable plate valve, a, a plan of which also is shown. This valve is normally closed and prevents the passage of sand into the upper chamber. It is provided with a hole, b, for the insertion of a pin to keep it from being accidentally opened, and lugs, c, prevent its being completely withdrawn from the tube. Before setting up, the valve is opened and sand allowed to pass into the chamber d. The prop is then adjusted, the required amount of sand being run into the lower chamber for this purpose, and the valve is closed. As the load comes on, the sand in the middle and lower chambers is compressed, and a gradual yielding takes place.

In order to withdraw the support the valve is opened from a safe distance by means of a chain fastened at e and the upper member then sinks as the sand passes upward through the aperture f. The advantages claimed for this form of prop over somewhat similar types are the ease and comparative safety with which it may be removed and the fact that the sand is retained within the prop.

When Headframe Burns Colorado Shaft Mine Resumes After Thirty-seven Days

THIRTY-SEVEN days is a short time within which to see a disastrous fire destroy the top works of a mine, the construction of a new plant and the resumption of coal production, but thirty-seven days was enough time for that rapid series of events at the Monarch No. 2 mine of the National Fuel Co. near Louisville, Boulder County, Colorado. Today that mine is far better equipped than it ever was before and can produce 1,200 tons of sub-bituminous coal in eight hours when the whole operation is going full blast.

On the night of Nov. 15, 1921, the consuming flame did its work at Monarch No. 2. The structures over the shaft were all of wood and burned readily. The whole surface plant except the power house was reduced to ashes, and the wooden shaft lining was ruined to a point 65 ft. below the collar. Headframe, tipple, car loader, track scales, cages, trestles, chutes and practically all the top equipment of the mine went up in smoke.

It was a discouraging appearance the mine presented the next day. But the market for that particular coal was strong enough just then so that the National Fuel Co. could not afford to sit down and grieve. Rush plans for new top works were made, and the job of shipping material and equipment started at once.

A permanent headframe and scales were thrown up in a hurry, and a temporary tipple was ready for service as soon as the hoisting equipment was operative. On Dec. 22, exactly thirty-seven days after the fire, the mine began loading coal once more.

With more leisure the company chose equipment for the permanent steel tipple. Roberts & Schaefer, of Chicago, constructed the plant, which contains balanced picking-table screens, self-dumping cages, a belt-type box-car loader, scales and other modern equipment. Whereas the destroyed plant had but two tracks, the new one, which was finished April 1, 1922, has three, so that the mine can load every size of coal that may be required. The Monarch mine now uses electric power.

**MATERIAL FOR GEOPHONE DIAPHRAGMS.**—An investigation conducted by the U. S. Bureau of Mines to determine the most suitable material for geophone diaphragms showed that in mica diaphragms the thickness was not an important factor. Metal diaphragms were not only more satisfactory than the mica but their sensitiveness increased with thickness until a point was reached when a ringing tone was produced and the diaphragms therefore became useless. With the exception of Non Gran bearing metal, a material 0.025 in. thick was the maximum thickness that could be used. With Non Gran bearing metal, however, a diaphragm 0.035 in. thick was satisfactory. To determine the sensitiveness of the diaphragms, observations with the geophones were made on blows struck with a 52-lb. hammer swung as a pendulum against the coal at a distance of 400 ft. away from the observer. The swing of the pendulum was measured, and the shortest swing that could be detected with the geophones was recorded. The results obtained at the experimental mine with the different materials are given in Technical Paper 277, just issued.
Britain Leads Germany in Coal Resources: Foreign Production Figures for 1921

Before the war Germany had larger coal resources than any European country, with Great Britain second. All this has changed. Germany has a little more than one-quarter of the coal in Europe and Great Britain almost one-third. This, of course, has not arisen from any enlargement of the British resources but by the handing over of some of Germany’s coal areas to other nations. These facts are derivable from the third report of the Imperial Mineral Resources Bureau of Great Britain, which contains a general review of the principal mineral industries of the British Empire and other countries for and as of the year 1921.

Other countries have gained territory from Germany, Austria and Russia, and their quotas have been increased accordingly. Taking into consideration only the actual and possible reserves of true coal and lignite or brown coal in seams 12 in. thick and over within a depth of 4,000 ft., in accordance with the estimates obtained by the executive committee of the International Geological Congress held in Canada in 1915, the position before and after the war may be summarized roughly as follows:

**PERCENTAGE OF TOTAL RESERVES OF EUROPE BY COUNTRIES**

<table>

* Austria, 0.1; Hungary, 0.1.

Austria’s reserve was 41,377,000,000 tons. It is now only 388,000,000. Hungary had 1,718,000,000 and now has 619,000,000. Russia had 60,170,000,000 and now has 1,988,000,000. Germany had 207,030,000,000 and now only 148,248,000,000. The United Kingdom had, and now has 165,387,000,000. The whole of Europe has a reserve of 517,221,000,000 tons.

Whereas 31 per cent of Germany’s fuel production in 1913 was of lignite, in 1921 it was over 47 per cent. Taking into consideration the relative potentiality of coal, lignite as produced and lignite as marketed and converting the quantities of the several forms of fuel into their equivalent coal value, the following results are obtained:

**GERMANY’S DISTRIBUTION OF EARTH FUELS IN EQUIVALENT COAL VALUE IN MILLIONS OF TONS**

The United Kingdom in 1921 produced 168,000,000 tons, in 1920, 229,500,000, and in 1913, 287,000,000. Of this, 24,660,552 tons was exported in 1921, 24,931,853 in 1920 and 73,400,118 in 1913.

The average realized value of the coal mined at British mines in January, 1921, was 50s. 7d. ($7.44) and in December of the same year was 19s. 6d. ($4.75), the corresponding figure in 1913 being 10s. 11d. ($2.46). Wages were at their highest level in January, 1921, the average wage per person employed being £2 1s. 9d. ($10.49). For the quarter ending Sept. 30 the corresponding figure was £2 12s. 7d. (or $77-26 a month). Since that time wage rates have been much reduced.

The average f.o.b. value of exported coal in January, 1921, was 67s. 13d. per ton ($16.33), compared with 70s. 57d. per ton ($17.15) in January, 1920. The average value in December, 1921, was 25s. 2.2d. ($6.13), compared with 54s. 74d. ($20.59) in December, 1920. All the converted values given are at normal rate of exchange—namely, $4.865 per pound sterling.

France’s available production for 1921 is nearly equal to that before the war. True, the production of the areas in pre-war France is only 29,000,000 tons, but the Saar area added last year about 9,500,000 tons to the total, bringing the production roughly up to that in the pre-war period. Belgium’s coal fields are producing more than before the war, last year’s production being 21,700,000 tons.

India’s production is not definitely known at present. It may have fallen to 15,000,000 tons owing to the fact that with increased wages the men did not find it necessary to work steadily and a labor shortage consequently resulted. Furthermore the railroads were unable to supply enough cars.

South Wales and the Union of South Africa each export to India provided for this shortage in production. The output of the South African colony rose from 9,600,000 tons in 1913 to 10,160,000 in 1921 and exports from 800,000 to nearly 1,200,000 tons. The provinces contributed as follows:

10,168,764

The coal production of Australia, including brown coal, totaled 12,867,325 tons, compared with 12,968,285 tons in 1920. The Canadian production was about 90 per cent of that of the previous year—namely, about 13,250,000 tons as against about 15,000,000—the important decreases being in Nova Scotia and Alberta. The United States exported 12,250,000 tons of bituminous coal to Canada in 1921 as against 14,500,000 in 1920. The fall in the aggregate production and import in 1921 as compared with 1920 was 4,000,000 tons and resulted from the depression of industry, particularly in the steel trade of Nova Scotia.
Timber Frames in Headings

Use of Full-Length Posts to Support the Collars—Disadvantage in Liability to Being Knocked Out by Derailed Car—Another Plan Uses Short Legs Set in Hitches—Plan for Pitching Seams

In the issue of Coal Age, May 25, p. 886, appeared an inquiry regarding the manner of timbering a heading driven in coal 5½ ft. in thickness and overlaid with 12 in. of drawslate, above which was mixed coal and slate. The object sought was to reduce, as much as possible, the expense of cutting hitches, 8 in. wide and the same depth, in the coal and drawslate above, required for the short legs used to support the crossbars or collars.

One plan that I would suggest is to use full-length legs under the collars, as indicated in Fig. 1, widening the entry, if necessary, so as to give the desired clearance between the legs. As shown in the figure, I have made the entry 12 ft. wide, instead of 10 ft.

FIG. 1. TIMBER FRAME, LONG LEGS

and set the posts 10 ft. 6 in. spread at the bottom, with a width of 9 ft. between notches under the collar. An 8-in. collar should be used and 2 or 3 in. lagging laid over the collars to support the roof, which is described as a mixture of coal and slate and will probably need this support.

The collar shown in Fig. 1 is 10 ft. in length; but, if desired, a longer collar can be used and the posts given less inclination, as indicated by the dotted lines. The disadvantage of this plan, of course, is that the long legs are liable to be knocked out by a derailed car when hauling a trip.

Another and, perhaps, a better way is that shown, in plan and elevation, in Fig. 2, which eliminates the use of legs, the collar beams being supported by a special type of hitches cut in the drawslate. It is true the drawslate may prove hard cutting. If the slate is soft and crumbles on exposure to the air the hitches must be cut down to the coal, which appears to be firm, as the posts are shown resting in the coal, in the original inquiry.

As shown in Fig. 2, a simple box hole is cut in one rib of the entry, say 6 in. deep and large enough to receive one end of the crossbar. In the opposite rib, has been cut what should be styled a "slip hitch," which needs no further explanation than the illustration shown. When the crossbar is in place it is wedged with pine wedges.

STEEL TIMBERING MORE ECONOMICAL THAN WOOD IN THE END

Regarding the comparative cost of wood and steel for crossbars, if steel H-beams or other rails are available and the life of that portion of the mine is to extend over a long period, the steel will be more economical in the end than wood. The frequent renewals of timber will more than equal the higher first-cost of the steel. This is particularly true in the West where so much native pine is used in the mines.

Before closing, allow me to refer to a method of timbering entries in the empty carbide or powder can, which was first filled with concrete and set down firm on the bottom. As shown in the figure, each post on the low side of the entry was stood on such a concrete-filled can, which raised the foot of the post above water drainage and prevented its decay.

Mt. Harris, Col. Thomas Allen.

Solid Shooting

Actual dangers more important than possible dangers arising from the practice—Conditions in pick mining contrasted with those in solid shooting—Shearing versus center-top or bottom-mining—Reasons for condemning unregulated solid shooting.

The subject of solid shooting has been so well and thoroughly discussed, in the columns of Coal Age, it would seem that little of material interest can be added either in advocacy or condemnation of the practice, proceeding in the manner in which it has generally been considered and treated. It is my object in the present letter to discuss more particularly the dangers that actually result from the practice, rather than the one, on which so much emphasis is laid, as being possible through the practice.

For the last several months, I have read with care and much interest the various letters on this subject. Almost invariably those writers who have condemned the practice have assumed
that the greatest danger to be feared in solid shooting, or the shooting of coal on shots only, properly made, is the possibility of a blownout shot causing a coal-dust explosion. Again a few writers express their disapproval of the practice, without assigning any particular reason for their opinion.

**Pick Mining vs. Solid Shooting**

While not an advocate of solid shooting, I would not presume to condemn it solely for the reason just mentioned, as it has been clearly demonstrated, by both class, that mining men, such a possibility is as liable to occur in machine- or pick-operated mines, as in mines where solid shooting is practiced. Indeed, it is my opinion, based on observation and experience, that there is a greater possibility of a blownout shot occurring in a pick-mining operation than in a mine where shooting off the solid is practiced and even though the practice is not regulated either by statute or official supervision.

In pick mines, the miner is accustomed to go to the coal to a certain depth, drill a specified depth of hole and use a specific charge. This becomes routine work. If, for any reason, a hole is drilled on the solid the amount of explosive necessary to perform the work effectively becomes a matter of guesswork and the possibility, if not probability, is that it will be inefficiently handled.

On the other hand, a man when shooting off the solid has variable conditions of blasting to contend with, and this variability has cultivated his judgment to a degree that he seldom undercharges a hole. As a rule, where such shooting is practiced, the general tendency is to overcharge the hole. That such is the case may be readily perceived by any one who has worked in or inspected a mine of this kind. As a result, the coal is found scattered all over the working places and in some cases more or less finely divided condition. In such mines it is the more finely divided coal that is not utilized by the miner and, consequently, in every working place is found much of this fine coal.

**Coal That Is Properly Mined**

One of the conditions of "properly mined" coal, as defined by the Pennsylvania Anthracite Mining Laws is that the coal shall be properly cut or machine. In a former article on this subject, I endeavored to point out that the blasting of sheared coal differed in no respect from the shooting of coal from a loose end; also, that the miner took no part of the seam, created only a loose end by which the removal of the coal is more easily accomplished.

In center- or bottom-mining, the cutting, if properly done, should extend all across the working face before anything is sheared. In shearing, on the other hand, the cutting is confined to one, or not more than two, localities, the coal being cut through the thickness of the seam. Conse-

**Coal Age**

**Law and Justice**

Supremacy of the law—Authority of Courts—Confusion caused by mis-statements of leaders and the Press—An example and faulty education poisons the mind—Solution of the problem.

With pleasure and much satisfaction, I read the editorial entitled "The State, It is I," Coal Age, Apr. 20, p. 643. The writer of the article refers to the time when a French king made the bold declaration "The State, It is I," and there was some truth in the words he spoke. Today, in this enlightened country and generation, the conditions are far different from what existed under an absolute monarchy. There, the people were subject to the will of the ruler, whose word was law.

How many of us realize that the Law, here, is supreme. It is with reason, then, that we obeyed our intelligent men at times, sidestep the judicial branch of our government and attempt to set aside the law and replace it by suggestions of one kind and another that, in their opinion, would meet the present situation.

**Upholding Law Brings Condemnation to Judge Anderson**

Federal Judge Anderson is, today, the most despised man, in the opinion of a certain class of miners, because of his interpretation of the law bearing upon the 60 year old 6-hour day demanded by the leaders of the miners' organization, who claimed that it would give the men more steady work.

In this decision, the Court only upheld the supremacy of the law, and refused to permit the suggestion of the statesmen of citizens of the enactment of the lawmakers. It is not strange that, almost without exception, the attempts of propagandists of both parties to reconcile employers and employees result in driving them farther apart.

Confusion in the minds of the public, has been caused by the statements of leaders of both parties to the present controversy, through the daily press. Articles have been written, based on the suggestions of cabinet members and congressional committee men, that have no standing in the face of the law. On the other hand, we read how certain individual miners drew exceptionally large pay, at the end of the month, amounting to two or three times the average earning capacity of a miner. On the other hand, we read of extraordinary profits, amounting to millions, that are granted to certain companies to pay fat dividends.

Viewed from an unprejudiced standpoint, the present situation has grown out of the bad example often set by the luxurious living and faulty education of many who have accumulated wealth and are spending it wholly on themselves, while they manifest little regard for that class of workers on
which their activities depend. It is this condition that poisons the mind and makes it impossible for the two classes to work harmoniously together.

Time and necessity will bring the miner back to his work; but the problem will still be unsolved. Reduced wages cannot provide for him steady work, as has been argued. In this locality, out of a possible 300 working days in the year, one of our mines worked 88 days, at intervals of one or two days a week. Another mine did a little better, and worked 124 days during the year. The same conditions have prevailed practically throughout the entire competitive field.

Assuming the wages of miners are cut in half, can it be expected that they will work twice the number of days they worked previously? But, it must be remembered that double the working days will double the production of coal and, unless another system of mining and marketing is established, what would be the result?

It is a shame to think of the chaotic condition existing in this country at the present time when there is complete and utter lack of safety, which mankind, and discard only between men and men. In my opinion, the only solution to the problem is expressed in the words “Co-operative mining and collective marketing” of coal. This alone, I believe, can bring about a practical solution.

Staunton, Ill.

Testing a Safety Lamp

Every lamp tested by lampmen when given to miners—Tested again by fireboss—Habitual practice of an experienced fireboss—Two conditions that insure safety.

I HAVE been employed in many gassy mines worked exclusively with safety lamps. Naturally, the reference made by Joseph Cain, in his letter, Coal Age, July 13, p. 60, to statements of his firebosses regarding their practice in the use of safety lamps, interested me greatly.

It is hard for me to understand how any responsible fireboss could offer such an excuse as Mr. Cain says his men gave for failing to properly test their safeties, by blowing into their lamps after assembling them and before carrying them into the mine to make an examination.

The excuse these men gave was that they were afraid to tighten the lamp against the glass more, lest the heat of the lamp should expand the parts and break the glass. Of course, it was possible to blow out the light in a lamp so carelessly assembled.

In mines where I have been employed, when a miner got his lamp from the lampcar, he is in charge tested it by blowing into it, at both the top and the bottom of the glass, before giving it to the man. Each miner then had to take his lamp to the fireboss who made the same test and returned it to the man. Many of the miners would test their own lamps in the same way.

As mine examiner (fireboss) I always used my own lamp. Each shift, before going into the mine, it was my invariable custom to test my lamp, by blowing, to make sure the glass was tight. Every fireboss knows the lamps have asbestos washers and many have expansion rings besides to prevent the breaking of the glass by heat.

The answer given to a recent examination question asking what made a lamp safe, named two essential conditions: 1. The right construction and assembling of the lamp. 2. Proper handling in its use.

Inquiries Of General Interest

Self-Acting Gravity Plane

Having seen much valuable information obtained by inquiries through the columns of Coal Age, I desire to submit a proposition we have in contemplation in the near future.

At the present time, we are working a seam of coal that outcrops at the tipple. Overlying this coal is another, four-foot seam, outcropping about 900 ft. higher on the hillside. There are some six acres of this upper seam that we want to start to work out at an early date.

The plan that we are considering is to lower the coal from the seam above to the tipple where it will be loaded on the same tracks we are using in working the lower seam. We have in mind a single-track gravity plane extending from the opening in the upper seam down the hill to the tipple.

The grade is sufficiently steep to afford good haulage by the gravity system. What we desire to know, however, is whether it is practicable to use a single-track incline and provide a passing track at the middle of the plane. Or, is it necessary to build a double-track tramway. We wish to avoid that expense if possible.

Dora, Pa.  C. M. Shaffner, Supt.

Without more exact data it is only possible to reply to this inquiry in a general way. In the first place, regarding the choice between a single- and a double-track incline, the latter should always be adopted, unless the conditions are such as to entail a large additional expense. Two tracks are safer and more economical in the end than a single-track, where such construction is practicable.

The operation of a single-track gravity plane requires that a passing track be provided at the middle point of the grade so that the descending loaded trip can pass the ascending empties. In the accompanying figure, it is shown the portion of a single-track, self-acting incline, including the passing tracks at the half-way point. An automatic spring-pole switch at each end of this parting causes the descending loads to take the left-hand track, while the ascending empties pass to the right, as indicated by the arrows.

Much will depend on the inclination it is possible to establish. The grade over the main portion of the plane must be sufficient to provide a gravity pull that will move the trips. It is evident that there must always be an equal number of loaded and empty cars, and these will balance each other. Also, the unbalanced load is the weight of material (coal) being lowered and the net weight of the rope.

When a loaded trip is starting at the head of the plane an equal number of empty cars, forming the empty trip, is starting from the bottom. At this juncture, the entire length of rope is lying on the plane. As previously stated, the cars are in balance and it is clear that the gravity pull due to the weight of the coal must be sufficient to overcome the gravity pull of the rope and the frictional resistance of both trips and the rope.

To enable a gravity plane to operate successfully, the grade for a short distance at the top of the incline should be somewhat steeper, and that at the foot of the incline similarly lighter.
than the average grade of the plane. This will not only assist in starting but, likewise, help to slow down the speed of the moving cars and bring them to rest at the end of each trip. In other words this feature takes care of the inertia of the system when starting and when stopping trips.

Again, it must be observed that the rope balances itself when the two trips reach the passing tracks. From the time of starting till then, the net weight of rope is on the ascending side of the plane and acts to retard motion; but, after that, to the end of the trip the net weight is on the descending side and acts to assist motion.

Observe that during the first half-cycle the net weight, retarding motion, decreases from a maximum at the start to zero at the midtrip; and during the second half-cycle the net weight, assisting motion, increases from zero to a maximum at the end. The effect of this trend of the net weight of rope, from the ascending side of the plane to the descending side, is to uniformly accelerate the movement of the system.

In a perfectly designed self-acting plane, therefore, beginning at the head of the plane, for a short distance, there should be provided a slightly steeper starting grade, corresponding to an equal distance at the foot of the plane where the track is almost level. Between these two starting and stopping grades intended to overcome inertia, the grade of the main portion of the track should gradually and uniformly decrease from top to bottom, so as to offset the effect of the transfer of the rope from the ascending to the descending side of the plane.

The movement of the entire system is controlled by a strong brake applied to a brake-wheel mounted on the same shaft as the headsheave or attached to the latter. To allow for the fleeting of the rope on the drum and give the necessary arc of contact there are provided two headsheaves set tandem to each other. The rope is made to take as many half-turns about each sheave as necessary to prevent the slipping of the rope on the sheaves when the brake is applied.

be the same as that of a double-acting pump, per stroke. Therefore, since the given pump makes 340 / 3.4 = 100 strokes per minute, the single-acting pump must be run at a speed of 100 r.p.m., in order to discharge the same number of gallons per minute as the given pump.

**Question:** If the volume of air provided is insufficient when the fan is running at its full capacity what would you do, under such conditions, to improve the ventilation?

**Answer:** Clean up the airways; shorten the distance of air travel in every way practicable; straighten the air-courses, avoiding sharp angles and bends wherever this can be done to any advantage; and, finally, split the air current, at points where the velocity in the several splits will permit, remembering that the velocity of the air sweeping the working faces must be sufficient to carry away the gases that would otherwise accumulate. It is a matter of importance that all stop-pings are made air-tight so as to prevent the leakage of air through them. Again, wherever it is necessary to conduct the air to the faces of rooms or headings, or to cause the current to pass over falls or circulate through abandoned workings, the necessary brattices must be erected for that purpose.

**Question:** Name at least one dangerous practice that is frequently indulged in by the following persons: Miners, motormen, brakemen, brattice-men, trackmen, timbermen and wiremen. Would you allow these practices? Explain.

**Answer:** Miners are frequently prone to neglect to examine the roof in their working places and set the timbers needed to make it secure, before proceeding to work. They often omit to spray their coal when mining a shot, and will frequently cut too short a fan of brattice; or, in other words, the necessary brattices must be erected for that purpose.

**Question:** Are there any conditions under which it would not be safe to use a safety lamp? If so, name them.

**Answer:** A mine safety lamp is never safe when in the hands of an inexperienced person who does not understand the danger of its misuse. The lamp is not safe if defective from any cause, such as injury to the gauze chimney or the gauze protecting the openings for the entry of air; a dirty gauze owing to the accumulation of soot; or the improper assembling of the parts of the lamp. The lamp is not safe when the gauze becomes heated or the lamp is exposed for too long a time to a body of gas, or when exposed directly to the force of a blower of gas or a sudden rush of air, or carried unprotected against a strong air current.

The lamp is never safe when held in an inclined position, or swung backward and forward when being carried from place to place, or permitted to fall.

**Question:** State under what conditions you would consider a mine gaseous.

**Answer:** A mine should be classed as a gaseous mine when any portion of it is generating gas in sufficient quantity to be detected on an ordinary safety lamp of approved type. Such classification, however, does not imply that the mine must be worked with locked safety lamps. It would simply mean that necessary precautions must be adopted to prevent accidents occurring by reason of accumulations of gas. The tendency has largely prevailed, in the past, in coal-mining states, to designate a mine as "non gaseous," until sufficient gas is generated to require the mine to be worked with safety lamps, but the practice is a menace to safe mining.

**Question:** If you have a ditch 2 ft. wide and 2 ft. deep, running full of water, with a velocity of 15 ft. per sec., how many gallons is passing per minute?

**Answer:** The sectional area of the ditch is 2 x 2 = 4 sq. ft. Then, assuming an average velocity of 15 ft. per sec., the volume of the flow is (4 x 15 x 60 x 1,728) / 231 = 26,900 gal. per min.

**Question:** A pump discharges 340 gal. of water per minute and has a capacity of 3.4 gal. per stroke. How many revolutions would a single-acting pump have to make in order to discharge the same amount?

**Answer:** Assuming the two pumps are of the same size, the capacity of a single-acting pump, per revolution, will

**Examination Questions Answered**

Kentucky Mine Foremen's Examination, Lexington, May 30, 1922

(Selected, First-Class Questions)

**Question:** Are there any conditions under which it would not be safe to use a safety lamp? If so, name them.

**Answer:** A mine safety lamp is never safe when in the hands of an inexperienced person who does not understand the danger of its misuse. The lamp is not safe if defective from any cause, such as injury to the gauze chimney or the gauze protecting the openings for the entry of air; a dirty gauze owing to the accumulation of soot; or the improper assembling of the parts of the lamp. The lamp is not safe when the gauze becomes heated or the lamp is exposed for too long a time to a body of gas, or when exposed directly to the force of a blower of gas or a sudden rush of air, or carried unprotected against a strong air current. The lamp is never safe when held in an inclined position, or swung backward and forward when being carried from place to place, or permitted to fall.

**Question:** State under what conditions you would consider a mine gaseous.

**Answer:** A mine should be classed as a gaseous mine when any portion of it is generating gas in sufficient quantity to be detected on an ordinary safety lamp of approved type. Such classification, however, does not imply that the mine must be worked with locked safety lamps. It would simply mean that necessary precautions must be adopted to prevent accidents occurring by reason of accumulations of gas. The tendency has largely prevailed, in the past, in coal-mining states, to designate a mine as "non gaseous," until sufficient gas is generated to require the mine to be worked with safety lamps, but the practice is a menace to safe mining.

**Question:** If you have a ditch 2 ft. wide and 2 ft. deep, running full of water, with a velocity of 15 ft. per sec., how many gallons is passing per minute?

**Answer:** The sectional area of the ditch is 2 x 2 = 4 sq. ft. Then, assuming an average velocity of 15 ft. per sec., the volume of the flow is (4 x 15 x 60 x 1,728) / 231 = 26,900 gal. per min.

**Question:** A pump discharges 340 gal. of water per minute and has a capacity of 3.4 gal. per stroke. How many revolutions would a single-acting pump have to make in order to discharge the same amount?

**Answer:** Assuming the two pumps are of the same size, the capacity of a single-acting pump, per revolution, will
Federal Fuel Distributor Establishes Procedure for Getting Emergency Coal—Committees Named

FEDERAL Fuel Distributor Spencer has completed the organization of his administration by designating the following:

Samuel Porcher, in charge of railroad fuel; J. N. Snider, for New England and the East; George F. MacGregor, for the Western Le Fouston S. Willard, for tidewater coal; C. E. Tuttle for Lake coal. E. M. Durham, Jr., for the South-east; E. W. Thorneley, manager of orders; F. G. Tryon, of the Geological Survey; Lieut. Commander E. A. Cobey, of the Navy; M. J. Gormley, of the American Railway Association; J. C. Roth of the Interstate Commerce Commission; D. R. MacLeod, secretary of the Administrative committee.

District committees to be named in the principal coal producing districts east of the Mississippi River for the purpose of distributing orders from the Federal Fuel Distributor among mines will consist of representatives of the Federal Fuel Distributor, the Interstate Commerce Commission, coal operators and the railroads.

The Federal Fuel Distributor has designated district headquarters as follows:

**Norton, Va.:** All coal districts of Virginia except the Pocahontas.

**Thurmond, W. Va.:** covering New River and joint mines on the Virginian Railroad.

**Bluefield, W. Va.:** Pocahontas, Windng Gulf, New River, Tug River and Virginian coal districts.

**Huntington, W. Va.:** Kanawha, Logan, Williamson, and Big Sandy coal districts.

**Knoxville:** Coal districts in southeastern Kentucky outside of Harlan and Hazard, and all Tennessee mines.

**Louisville:** Harlan, Hazard and Western Kentucky on the Louisville and Nashville and the Illinois Central railroads.

**Birmingham:** Alabama.

The Federal Fuel Distributor announces that coal operators will continue their regular ordinary business, but that this will be gradually encroached upon by priority orders of the Interstate Commerce Commission and finally coal orders placed through the Federal Fuel Distributor for railway purposes and state committees will gradually absorb the total output of mines.

Under plans of the Federal Fuel Distributor, the governors of states will appoint fuel committees and orders from the committees will be sent to the Fuel Distributor at Washington, passed on, and then sent to district committees.

Duties of state organizations appointed by the governors are defined in regulations issued by the Fuel Distributor as follows:

Report at once the consumption of coal in the state, as to utilities, household, industrial and other uses.

Furnish statement showing a list of those who receive priority coal for current use, but not for storage, in the order of emergency of their need; character of coal required, including source from which consumer previously obtained supplies; name of coal operator with whom he does business if in the present producing field; weekly supply needed by such consumer; number of weeks stocks he has on hand.

To set up a single consignee in each state on behalf of all coal shipped into the state on orders from the governor’s committee, through the Federal Fuel Distributor. The governor’s committee will be responsible for the payment of all coal shipped into the state and will advance to a bank a deposit to cover it, which depositary will honor sight drafts with weight certificate, car number, etc., this being practically an f.o.b. sale.

The Governor’s committee will distribute the coal made available to it according to the respective states, and is at liberty to reconsign or move coal after it reaches points in the state.

The governor will distribute the coal according to necessity as follows:

Public utilities and public institutions, households, industries manufacturing public necessities, and industries in general.

The governors’ committee will be expected to secure the co-operation of wholesale and retail dealers in their states, and will be responsible for prevention of profiteering and extortion in the sale and distribution of coal in the states. They will furnish written orders to the Federal Fuel Distributor on forms to be prepared.

Government fuel orders will be given by the co-ordination committee and will pass through the Federal Fuel Distributor to the District Committees.

Shipments of coal by the Lakes to Minnesota, North and South Dakota, northern Wisconsin, northern Michigan and Canada will be through the Ore and Coal Exchange of Cleveland. Cars for such coal on contracts in existence will go through or be approved by the Federal Fuel Distributor to the District Committee. It is planned to establish a regular weekly movement of coal to this trade. The division of this coal between the states or receiving points must be approved by the Federal Fuel Distributor.

The Federal Fuel Distributor further announces that coal operators will continue to function individually with respect to filling their ordinary business or priority orders that may come under the Interstate Commerce Commission order of priority until orders are received by the district committee from the Federal Fuel Distributor supplanting their capacity.

On receiving orders for coal from the Federal Fuel Distributor the service agent of the Interstate Commerce Commission on the district committee will issue an order upon recommendation of the representative of the Fuel Distributor to the railroads to place cars for coal shipment. The order will be sent to the representative of the railroad on the district committee for transmission to the proper official of the railroad for execution. The district committee will specify the mines from which the coal is to be shipped. Representatives of the Federal Fuel Distributor will, subject to a guarantee of payment, which shall be satisfactory to the mine operator, but in keeping with the Hoover fair trade.

Representatives of the railroads on the district committee will report to the service agent of the Interstate Commerce Commission the number of cars shipped daily under the orders. The district committees will report to the Fuel Distributor at Washington the shipments made.

The distribution of fuel for railroads will be concentrated in the hands of a railroad coal committee composed of coal buyers from the different railway groups as given above. This committee will meet in Washington, check the needs of the railroads for coal, pass upon applications for emergency coal for railroad use and in other ways co-operate in the execution of the general plan.

**District Committees Named**

The personnel of the district coal committees has been announced by the Federal Coal Distributor, as follows:

**HUNTINGTON, W. VA.**

J. F. B. Conger, representing Federal Fuel Distributor

Coal Operators’ Representatives:

Williamson Committee:

L. E. Woods, Crystal Block Coal and Coke Co., Welch, W. Va.
G. S. Patterson, Sycamore Coal Co., Welch, W. Va.
L. E. Armestrong, Borderland Coal Co., Cincinnati, O.
Geo. Bauswine, Jr., Secretary, Operators’ Association of Williamson Field, Williamson, W. Va.

Northeast Kentucky Committee:

C. L. Casterl Jason, Mountain Stone Mining Co., Ashland, Ky.
W. M. Mooreman, Wells-Bkhorn Coal Co., Ashland, Ky.
S. Hand Consolidation Coal Co., Jenkins, Ky.
Geo. H. Archer, Prestonsburg, Ky.

**District Committees Named**

The personnel of the district coal committees has been announced by the Federal Coal Distributor, as follows:
COAL

Priority Plan in Middle West Makes Halting Start; Car Supply Continues Bad

The Middle West's hope for a flying start of the new federal system of coal distribution was brusquely defeated during the past week. The plan did not produce results. Priority orders did not absorb the whole flow of fuel, car supply was not much improved, and prices were not generally drawn down to the government level of $3.50. When the week opened cars made an improved showing. Many a Kentucky mine got more than 75 per cent of what they requested, and everybody felt fairly good. By the middle of the week, however, more than half the mines of the state were down and the same old condition of affairs prevailed. The L. & N. supplied 30 per cent of the demand for cars at the mines along its lines.

Practically all the coal that went to railroads sold at $3.50 but in many cases a jobbers' commission of 10 cent was added. The remaining coal, which was of larger volume than the market had expected, sold all through the Midwest region at widely varying prices. In the fields it brought $6.50@$10 and in the markets a shade more than that. Chicago, maintaining its reputation for top prices, saw coal from Kentucky selling above $11.

Illinois suffered a considerable flagging Friday when Robert M. Medill, state fuel administrator, announced that he interpreted the federal plan to mean that the state was absolutely cut off from all fuel from outside fields. At once the market got excited and Western Kentucky coal hopped from $9 to $12. There were all sorts of wild quotations made by greedy brokers running up to $14, but no sales were made above $12. The market quieted down to $10 the next day, however.

Mr. Medill, in a message to Coal Age Saturday morning set forth his understanding of the matter thus: "Illinois' supply of coal from outside producing points has not yet been cut off although we have been advised that we must not expect even a small amount of output so far as states which have no coal resources and which require longer periods of transportation must be afforded a larger ration of the national supply."

It is felt in some quarters that a few Kentucky operators, especially in the western end of the state, are doing what they can to avoid taking priority orders so as to extend the periods of $8 and $10 coal as long as possible. The first definite complaint of this sort in Kentucky was registered with the state railroad commission by Muscoee Burnett, general manager of the Paducah Water Co., who complained that he had tried to get coal from four or five western operators only to be told all their output was under contract and they could not send him a ton. The case is being investigated.

The new plan has not been in effect long enough yet for a thorough try-out. In Illinois, Mr. Medill is getting his county distribution boards appointed and will aid Governor Small or Acting Governor Sterling this week in the formation of a complete state committee.

In the meantime the coal trade not only of Illinois but of many of the surrounding states is anxious for the whole market of coal to come into gear. The general uncertainty of things wears on nerves already harrassed.

A survey of price situation made last week at the instance of Secretary Hoover developed the fact that 95 per cent of the coal now being produced is being sold within the maximum fixed.
Illinois Offers Last Year's Wages If Miners Will Agree To Abide By Impartial Arbitration

BY E. W. DAVIDSON

"Immediately upon resumption of operations, the whole matter of wages and working conditions will be submitted to a Board of Arbitration composed of citizens of high public standing and qualified to advise the President of the United States, no member of which Board shall be a contractor or a coal miner—the findings of such Board to be binding upon both operators and to continue for a period of two years from April 1st, 1922.

"As we have stated in our letter to President Lewis, we cannot believe that the Illinois miners will reject such an exceedingly fair proposal.

"Very truly yours,

"ILLINOIS COAL OPERATORS' ASSOCIATION.

"W. K. Kavanaugh, President.

"COAL OPERATORS' ASSOCIATION OF 5TH AND 9TH DISTS.

"H. C. Adams, President."

The Illinois refusal to attend the Lewis conference in Cleveland and the reasons thereof were set forth by the operators in this letter to Lewis:

"We have your invitation to meet you in conference at Cleveland, August 7th, to negotiate a basic wage scale for the country. You, the President of the State of Illinois as early as January, 1922, urged an immediate conference to discuss a new scale of wages to be effective April 1st, 1922. You continually refused to permit such conferences. You have heretofore issued two calls for joint interstate meetings, both of which calls we accepted; but prior to the date of these conferences you cancelled the calls.

"Subsequently, at the request of the Federation of the United States we met you and your representatives in Washington and requested in him a conference. We cannot understand why it is that the state of Illinois unanimously and without reservation accepted the President's proposition, and why it is that the State of Illinois refused.

"In public statements you seek to put the burden of the present critical position of the United States upon the operators, stating that you were responsible for the continued failure to produce coal. We believe that the international officials of the miners' unions entirely responsible for the present condition of the coal mines in the state of Illinois, where the operators have a definite contract with the miners which they agreed that there shall be a state negotiation of new wage contract prior to the expiration of the contract expiring March 31st, 1922. Through your refusal to allow this conference the present position in the state of Illinois has been brought about.

"The public, as well as you, are fully aware of the fact that so far as Illinois is concerned, your national and state organizations are in flagrant violation of your contract with the operators of this state.

"By reason of the published refusals from practically all other unions, districts to attend such meeting, we suggest that the conference cannot be in any sense representative, or even possible for determinative wage scales to apply throughout the country. It will be approximately the price charged by the operators of your state for dealing with a portion of the state of Illinois and possibly a few other districts, and wages fixed by the conference will be discarded as a practical method of determining wage scales; your own public statement in sending invitations to this meeting to a number of individuals not participating in the coal operators' field organization violates former Central Competitive Field procedure and acknowledges that you yourself recognize and are following a new course. For these reasons no representative of the Illinois Operators' associations will be present in Cleveland on Monday, August 7th.

"Recognizing the great seriousness of the present situation and the threat to public health and welfare that will be caused by further stoppage of coal production, and because of the failure of our former repeated acceptance of invitations to national or interstate meetings which have failed of results, Illinois operators are today offering to the President of Illinois the thought of a proper solution of the totally unwarranted deadlock in this situation. We cannot believe that the Illinois mine workers will reject such an exceedingly fair proposal as we have suggested and by their refusal continue to inflict great and needless suffering on themselves and on all other citizens."

"Illinois operators do not now and have not at any time favored even the temporary payment of the enormous wage rates now offered to their workmen. W. K. Kavanaugh, President.
Mine Fatalities in June Higher in Number
And Ratio to Output Than in May

Accidents at coal mines in the United States during June, the third month of the strike, resulted in the loss of 263 lives, according to reports received by the Bureau of Mines from state inspectors. Fatalities not resulting from the normal hazards of mining are not included in this number. Revised figures covering the present strike period show 78 fatalities in April and 79 in May. The increased number of accidents in June as compared with May was confined largely to the bituminous mines of Pennsylvania and West Virginia. Based upon a production of 22,593,000 tons of coal in June, as reported by the U. S. Geological Survey, the fatality rate for the month was 4.11, as compared with 3.89 for May and 4.04 for April of the present year and 4.03 for June, 1921.

During the past nine years (1913-1921) an average of 263 men have lost their lives by accidents at coal mines during June. The output of coal has averaged 47,280,000 tons, thus indicating a fatality rate of 4.29 per million tons as representative of the month of June over the 9-year period. It will be noted that the rate for June, 1922, while somewhat higher than that for May, was lower than the rate for April, the first month of the strike, and also lower than the average rate for June for the nine-year period between 1913 and 1921.

The first half of 1922 saw 899 men were killed by accidents at coal mines as compared with 1,001 during the first six months last year, a decrease of 172 fatalities, or 17 per cent. The output of coal has declined 14 per cent, the fatality rates for the two six-months periods being 4.13 for 1921 and 3.97 for 1922 per million tons.

Gas and dust explosions continue to be the only conspicuous class of accidents showing a higher fatality rate for 1922 than for the first six months last year.

No single accident in June killed as many as five men. The record for 1922 to date shows 7 major disasters in which 82 lives have been lost, as compared with 3 disasters and a loss of 17 lives during the first half of 1921.

Two Miners, Both Americans, Each Shoot And Load About Fifty Tons a Day

The Standard Island Creek Coal Co. has operations at Cora and Taplin in West Virginia, the two places being about fifteen miles apart. During the last half of June it conducted a loading contest between its Loma mine No. 3, at Taplin, and Cora mine No. 2, at Cora, offering a cash prize to the loader who produced the largest quantity of coal.

Jerry Dunn, an American miner, working at Loma No. 3 during the last half of June, 13 working days, loaded a total of 649 mine cars of a capacity of 1.4 tons per car—that is 656.4 tons, or a trifle over 50.5 tons per shift. He worked in a double-track room 36 ft. wide with coal 48 in. thick. The mine cars stand 27 in. above the top of the rail. The only assistance he had of any kind was the use of an electric coal auger to drill about 25 per cent of the coal loaded; otherwise he did all of his drilling by hand, shooting and loading the coal without assistance. Mr. Dunn is 6 ft. 2 in. tall, being thus decidedly above the normal height of men generally.

William Smith, an American miner, working at Cora mine No. 2, during the same period loaded 649 mine cars of capacity of 1.3 tons per car—that is 596.7 tons or 45.9 tons per shift. This coal was loaded from two entries each 18 ft. wide, the coal being 46 in. thick. Here also the mine car stands 27 in. above the top of the rail. The only assistance Mr. Smith had was the use of an electric coal auger for drilling approximately 25 per cent of the coal loaded; otherwise he drilled the coal by hand, shot it and loaded it into the cars. Mr. Smith also is above medium height, being 5 ft. 11 in. tall.

It will be seen that each of these men approximated a 50-ton railroad car per working day. F. J. Bailey is superintendent in charge of Loma Mines 1, 2 and 3, at Taplin, and E. C. Purrung is superintendent in charge of Cora Mines 1 and 2, at Cora. Our informant is A. W. Fay, the manager of the coal company. It will be noted that these miners received about 36 cars per day—some service.

Washington Puts Burden of Coal Distribution on States—Hopeful That Cleveland Conference Will Start Mines

BY PAUL WOOTON
Washington Correspondent of Coal Age

Washington, Aug. 8.—The pinch of coal shortage is becoming severe in several portions of the country. Spokesmen for the fuel distributor stated today that great pressure is being brought from the New England states and by states in the Northwest and in the Middle West. Senator Lenroot of Wisconsin saw the fuel distributor this morning and in no uncertain way said that something must be done to start shipments to northern Lake Michigan points, being out of reach of all-rail movement from Kentucky. One of the most active protests considered by the fuel distributor today came from the Middle Western states to look after their canning industry.

Large numbers of locomotives are being moved from the North to Southern coal fields, it was stated. Some railroad shortage of fuel is reported in the Middle Atlantic region. Secretary Hoover stated today that failure to observe the price maximum applied only to an insignificant portion of the tonnage being produced. No increases have been allowed in the maximum price, he stated, in those districts where the 1920 wage scale has been put into effect. He emphasized that the price agreement is for the period of the strike only, but he said the settlement of the strike will not necessarily take the lid off of prices.

Some further move by the President in the coal strike is expected. Events since he sent the operators home to produce coal are thought by many to have demonstrated that they will be unable to produce any appreciable amount of coal in the highly organized districts. On the other hand the mine workers have failed to accomplish anything constructive. In view of that situation many believe the President very shortly will take steps intended to force arbitration.

The failure on the part of the operators in the union districts to secure production has been a great disappointment to their sympathizers. It is true that there has been some increase in production in the Pittsburgh districts in the old non-union part of Pennsylvania, but the aggregate of that output is such as to have a very feeble influence on the situation. The small production coming from stripping operations in Illinois and Indiana has decreased. There is no production in Iowa and there has been no increase in the output of Missouri, Kansas, Oklahoma and Arkansas. Little is expected to result from state operation of mines and very little is being claimed as to the possibilities of production by such methods. As a result it is fully expected that the President will call in again the representatives of each party to this controversy and tell them that they have failed to make good and that the settlement must be placed in other hands.

A possible outcome of the Cleveland conference called by John L. Lewis, according to speculation here over the week end, is that an agreement can be reached whereby eastern Ohio can resume operations on the 1920 scale and with all the other demands of the miners put into effect. Such an arrangement might also be made at isolated operations in other districts in the central competitive field. If that should be done there would soon be a general resumption on that basis, some predict.

As the control over distribution progresses, it is very evident that the individual states under this plan have to shoulder most of the work and most of the responsibility. The task assigned to the Federal Government of apportioning current production among the states and among the railroads is easy in comparison. The thing worrying Washington is whether or not the states can measure up to the task assigned to them. To distribute coal in an intelligent manner in any state is a technical task of great complexity. Large organizations will have to be set up and heavy expenditures incurred. The fear is expressed that the states will not be equal to the task and the whole plan may have to be revised.

Despite the experience the railroads have had with service orders in the past, each road has put service order 23 in effect in its own way and as a result much confusion has been caused. This became so bad that the Interstate Commerce Commission on Aug. 4 was forced to issue an amendment to the order.

The matter of re-establishing restrictions on coal prices in Pennsylvania was the subject of a conference held at Washington on Aug. 7, between representatives of the operating mines of Pennsylvania and Secretary Hoover of the Department of Commerce and Federal Fuel Distributor H. B. Spencer. The purely voluntary price arrangement of June 1, of from $3.25 to $3.50 per ton, broke down two weeks ago, partially due to the fact that some coal producing districts refused to co-operate in the voluntary agreement at that time, and partially due to conditions brought about by the railways offering $1.50 per ton above the fair price for coal in the districts which did agree. Many coal operators in the districts where voluntary agreement was made have held to the fair price, but other districts are asking as high as $7 to $8 a ton.

The operators proposed that a new fair price should be fixed at a somewhat higher level than that of June 1, in order to allow for increased working expenses due to car shortages and partial operation of mines. It was considered by the administration officials that, inasmuch as the bulk of present production from Pennsylvania is consumed in that state and is, therefore, not a consequent export factor in interstate commerce, the Pennsylvania state authorities should participate in any arrangements. Moreover, while enforcement of price restrictions under the new plan approved by the administration has been made fairly effective in states whose coal predominantly enters into interstate commerce, any enforcement beyond purely voluntary action in coal locally produced and sold must rest upon the state authorities. A meeting between the Pennsylvania state coal committee appointed by Governor W. C. Sproul and the administration officials has been arranged for Wednesday to consider the matter.

While there has been an improvement during the last week in transportation service, there is a feeling that the bond of sympathy between the striking shopmen and the other railroad orders is sufficiently strong to make it certain that transportation efficiency is kept at a low ebb. Just at this time a shortage of power is beginning to be felt. Engine employees are in a position, without involving themselves, to contribute easily to further failures of locomotives. There is also the serious matter of boiler inspection. Strike sympathizers in high places are seeing to it that there is no laxity in the Government's inspection. There is now talk among men in the train service of refusing to take out trains on the ground that the state of the equipment makes it unsafe. The trouble with the workers on lake boats is said to have its real basis in the desire to contribute something to the success of the strike. Among the various labor organizations which have to contribute to the transportation of coal, it is very clear that they are in a position to keep transportation badly tied up for an indefinite period.

**Amendment No. 1 to Service Order No. 23**

At a session of the Interstate Commerce Commission, division 5, held at its office in Washington, D. C., on the fourth day of August, A. D. 1922, it is ordered, That paragraph numbered 7 of the said Service Order No. 23 adopted July 25, 1922, be, and it is hereby, amended.
and supplemented to read as follows effective on and after Aug. 1, 1923:

5. That in the supply of cars to mines upon the lines of any coal company or railways, the dispatch of cars for the purpose of place, furnish, and assign such coal mines with cars suitable for the transportation of coal, no precedence shall be allowed that will be required for the following classes of purposes, and in following order of classes, namely:

1. For special purposes as may from time to time be specially designated by the commission or its agent therefor.
2. For essential purposes under this order or class 1.
3. For transportation purposes by the coal company or railways.
4. For transportation purposes by any person, partnership, or corporation not engaged in the production of coal.
5. For transportation purposes by any person, partnership, or corporation engaged in the production of coal, but not engaged in the operation of the coal mines.
6. For transportation purposes by any person, partnership, or corporation engaged in the operation of the coal mines.

And subject thereto in order of priority:

Class 1.—(As to each coal-loading carrier which reaches mines in Pennsylvania, Ohio, West Virginia, Kentucky, Tennessee, and Alabama. For bituminous coal consigned to any other port for transshipment by water to ports upon Lake Superior.)

Class 2.—(As to all such common carriers by rail.)

Class 3.—(As to all such common carriers by rail.)

Class 4.—(As to all such common carriers by rail.)

Class 5.—(As to all such common carriers by rail.)

Class 6.—(As to all such common carriers by rail.)

Class 7.—(As to all such common carriers by rail.)

Class 8.—(As to all such common carriers by rail.)

Class 9.—(As to all such common carriers by rail.)

And subject to reclassification or diversion except for some purpose in the same class as a superior class in the order of classes, or as otherwise provided in the commission's rules and regulations therewith.

For the more prompt dissemination of coal, bituminous coal, and anthracite coal, to be shipped to retail dealers for household use.

For the purpose of boarding, and for the manufacture of containers therefor, for daily use not for storage, exchange, or sale:

For the more prompt and effective administration during the present emergency of the authorization, directions, and requirements of the commission. The provisions of the act shall be interpreted and applied as agents of the commission, with authority to make such regulations in regard to the matters are hereinafter defined in paragraphs (15) and (16) of section 1 of the Interstate Commerce Act, and referred to in this paragraph. The Governor, by and through Frank C. Crandall, Assistant Director, and thence through the proper officers of the commission and their agents.

The acts of the commission and their agents shall be for the purpose of making the work.

Detailed instructions have been sent to the state governors in the state whose railroads are to distribute the bituminous coal under the new plan. The governor of each state has prescribed a form which is to be followed by the governors in making application for coal. The form calls for the name of the applicant; the point at which the shipment is to be delivered; the name of the delivering railroad; the purpose for which the coal is to be used; the quantity requested; the average rate of consumption of the consignee; the tonnage for daily consumption; the consignee's present stock; the name of the firm with which the applicant has a contract; the district from which the coal ordinarily is supplied and the name of the bank which will guarantee payment when the coal is shipped.

Another form has been devised on which the district committees will report on orders placed. The governor of each state is requested to apply for coal produced in other states through the federal fuel distributor only, and to not order coal from district committees or from producers outside their own state.

Mr. Spencer emphasizes in his letter to the governors that there is no anthracite available for distribution; that essential purposes must be handled only for current use and not for storage; that emergency coal may be had only for the essential purposes outlined by the Interstate Commerce Commission and that all coal will be placed f. o. b. railway cars at the mines at the fair prices for that district approved by Secretary Hoover.

CONFERENCE WAS HELD DURING THE WEEK with the President, Secretary of Commerce Hoover and the Federal Fuel Distributor by Governor Miller of New York and E. H. Outerbridge and D. L. Cooke of the Governor's advisory committee, to acquaint themselves with the plans of the administration to distribute coal. The New York authorities expressed a willingness to co-operate with the government in the coal situation.

RAILROAD LABOR IS FINDING OUT that its goal is not within striking distance—Washington Post.
Illinois Refuses to Meet Lewis at Cleveland Under Any Pretext—Some Favor Crews’ Plan

Chicago, August 8—Operators in session all day Tuesday, Aug. 8, in Chicago reaffirmed their position favoring return to work of all striking miners at the old wage scale pending arbitration, which they were ready to accept either nationally or by states. This was set forth in a message sent to President Lewis of the miners at his Cleveland conference which at the moment was marking time under a pretense of waiting for Illinois and Indiana to come in.

The operators did not alter their firm stand to any degree but they did frankly ask Mr. Lewis whether he wanted them to talk with him on the basis of their proposal. Then they adjourned until Wednesday at 2 p.m. giving him a chance to answer. As an organization they have not been formally invited to Cleveland.

The main effort of Illinois was to secure arbitration of an unbiased effective sort and they were willing to agree even to the high wages of last year in order to get it.

The operators’ only statement at the end of the session was this: “The conference which Mr. Lewis so desperately seeks at Cleveland is not to negotiate a new wage scale or to accept President Harding’s recent offer of arbitration. It is only an offered opportunity provided by Mr. Lewis for the formal surrender of all those operators from any and every part of the country who desire to sign any kind of a contract that may be offered. “With only 49,000,000 tons or less out of an annual output of 500,000,000 willing to co-operate with Mr. Lewis in this further eleventh-hour effort to establish a national wage conference or to revive the discarded Four-State method of bargaining, Mr. Lewis is fully aware that he may not safely tempt public sentiment and welfare by attempting to arbitrarily take any official action with such a small portion of the whole tonnage, hence his anxiety to secure voluntary additional participation.

“This is clearly indicated by the fact that a substantial portion of the very limited tonnage represented at yesterday’s Cleveland meeting was recruited from fields not heretofore participating in the so-called Central Competitive conference.

COMpletely supplanting interest in the original meeting, called by John Lewis for Cleveland on Aug. 7, to negotiate a Four-State contract, the so-called Crews-Glasgow plan for settlement of the soft coal strike entered the arena on Tuesday morning. This plan, according to unofficial reports, the text not having been released when this issue of Coal Age went to press, provides for immediate resumption of mining at the wages and under the terms of the contracts in effect on March 31, just prior to the strike. This arrangement would continue in effect until the end of next March, and would reinstate the check-off and preserve the status quo of last year.

The second step in the plan provides for an advisory committee or commission, one-half operators and one-half mine owners, to be appointed in the last half of September to which is to be delegated the task of making a study of the soft coal industry and setting up recommendations as to the best way of negotiating future wage agreements. This committee, it is understood, would take the place of the commission that President Harding has been proposing to accomplish the same ends. The difference would be that in the one case the entire matter is retained within the industry and in the other the government would be a party. A further difference is found in the fact that the plan now proposed has no representative of the public, whereas the operators had made strenuous representations to the President that his commission should have nothing but public men on it.

This committee would be entirely advisory and its finding would in no way bind either party. This, it is pointed out, is desirable because the only finding that the miners ever accept are those of joint conferences, they having rejected at least in part the arbitration awards of the last two governmental commissions. The memorandum of the plan, it is understood, specifically provides that in making its recommendations the committee shall take into consideration the competitive conditions surrounding each producing district as well as the needs of the coal workers.

Wage rates would be recommended by the committee, it is reported, and the body would have authority from the signatories to make a complete and searching inquiry into all phases of the industry, looking to increasing the efficiency of operations and the betterment of working conditions. Particular emphasis is to be placed on the necessity of developing within the industry a proper spirit of responsibility to the public. Should the operators or miners not be able to agree on their respective members of the committee, the President will be requested to fill the vacancies.

The plan is reported to have the unqualified support of John Lewis and to be acceptable to Mr. Ogle, the president of the National Coal Association. The original draft was stated to have been prepared by Colonel Ralph Crews, a New York lawyer who has been prominent in coal matters for many years, and who changed the operators’ Four-State Competitive Field in the hearing before the Robinson Coal Commission in 1920. He enlisted the help of Mr. Glasgow, a Philadelphia lawyer who has been the general counsel for the United Mine Workers in recent months, and together they got Mr. Ogle and Mr. Lewis together for a consideration of the plan. It was the knowledge that he had this plan to spring on the meeting on Wednesday of this week that is reported to have moved the operators as the adjournment of the original meeting in Cleveland on Monday. The two meetings, those who are in touch with the situation are careful to point out, have no connection.

Commenting on the plan Monday night, Mr. Ogle stated to the press that it was of such character that all who were concerned would be obliged to give it careful consideration. As this issue of Coal Age goes to press there have been no official statements from the operators as to whether they would accept it. Illinois and Indiana producers met on Tuesday to give it consideration. The representatives of the Pittsburgh producers advised Coal Age on Tuesday afternoon that they would not participate and most certainly would not meet the miners in Cleveland. Others have informally expressed approval, while some are holding off.

Southern Ohio Operators Decline to Meet At Cleveland for Four-State Agreement

OPERATORS in the southern Ohio field affiliated with the Southern Ohio Coal Exchange have refused to join the proposed conference of miners and operators at Cleveland Aug. 7. This was made known definitely Aug. 3 when W. D. McKinney, secretary of the Southern Ohio Coal Exchange, sent a telegram to John L. Lewis, national president of the miners’ union. Among other things in the telegram were: “The method of negotiating a basic wage agreement in a four-state meeting has been challenged in the courts. Almost the entire coal industry has taken the position that it has proven entirely inadequate in meeting the changed economic conditions of the country. The coal industry is controlled by the states and every law relating to the production of coal has been enacted by the states. The federal authorities, recognizing this, have placed the responsibility of producing coal on the several states where coal is mined. Operators and miners in states and districts should meet and solve their own problems.”
LEWIS’ FOUR-STATE MEETING DRAWS SMALL ATTENDANCE
OUTSIDE OHIO—NO ACTION TAKEN MONDAY

THE original Cleveland conference, called by John L. Lewis, of the United Mine Workers, adjourned shortly after meeting Monday, Aug. 7, until Wednesday of this week. Operators not present were thus to be given time to reach the conference, it was stated. The real reason for the adjournment, however, it was generally understood, was to take under consideration the crews-Glasgow plan for settlement of the strike. The original meeting—the attempted Four-State conference—was held in abeyance to see what would happen to the proposed crews-Glasgow scheme.

Operators present on Monday, according to various estimates of the union leaders, represented about 30 per cent of the bituminous coal tonnage of the old Central Competitive Field. Among those also present were mine owners from northern West Virginia and a sprinkling from outlying districts. A joint body was organized, of which Michael Gallagher of the Pittsburgh Vein Operators Association was made chairman, William Greene, secretary of the miners’ organization was elected secretary, with W. L. Robison of the Y. & O. Coal Co., assistant secretary.

Mr. Gallagher and Mr. Lewis made this joint announcement following the meeting, which lasted but a few minutes:

“The situation of public distress so eloquently portrayed by Mr. Lewis is that which he forecasted early this year for calling this strike and at a time when coal throughout the United States was largely selling below cost of production.

“Nor is there any indication in his latest call of any willingness to recede from the original demands of his policy committee—a six-hour day five days per week, which reduces the physical capacity of the mines of the country 25 per cent. There is no acknowledgment that the arbitration offer of the President of the United States through an impartial commission is at all acceptable.

“The evidence of the extreme extent of the offer made by the Illinois operators to induce miners to resume work, and for them to establish and give definite evidence of their fairness in submitting to arbitration, we present herewith a comparison of the average wage scale paid in ten Eastern non-union fields now producing coal, and the scale posted on July 26th at the mines in western Pennsylvania, and on the basis of which tonnage is being produced to meet 40 per cent or more of the requirements of the country.

“Illinois operators do not now and have not at any time favored even the temporary payment of the enormous wage rates now offered to their workmen, but because of the offer of the President of the United States, we have accepted such basis of payment contingent, however, only upon the acceptance by the miners of a fair, impartial arm’s-length determination of a wage rate subsequently to be paid.”

Below is given a direct comparison by classification of wages paid since July 20, 1922 and to continue until January 1, 1923, at the Pennsylvania mines now being operated under the protection of the Militia of that state, also average wages paid by ten non-union coal producing fields, with mine wages demanded in Illinois.

No “checkoff” in behalf of the mine workers organization is being made by the Pennsylvania operators now operating under the scale here given:

Fairmont Not Invited to Cleveland

THAT northern West Virginia associations were not to be a party to the Cleveland conference was the announcement made during the first week of August. It was stated that the Monongahela Association had received no invitation to attend the conference and that if any northern West Virginia operators attended the conference, they did so as individuals and not as representatives of the association. The conference at Cleveland was regarded by many operators as more of an effort to strengthen the morale of the striking miners than as a bona fide effort to reach an agreement and of course it had its effect on strikers who were disposed to cry quits and go back to work.
DEMAND has eased off a trifle in the past week. There is, of course, no dearth of orders for all the coal that is being mined, but there has come an abatement in the rush as buyers prefer to await developments of the Cleveland conference between union officials and operators representing parts of the old Central Competitive group. The cessation of feverish buying has been accompanied in some instances by curtailed industrial activity and further efforts toward fuel conservation by utilities and carriers. In some sections the shortage is now acute; this is responsible for many Lake vessels tying up because of no bunkers and shortened operating schedules at steel mills in the Youngstown district.

Railroads are functioning better, production has increased slightly, and while congestion of loads is still the main bar to heavier non-union production, the accumulated tonnage on wheels is slowly being untangled and sent to destination.

SPOT COAL MOVES AT MORE REASONABLE PRICES

Coal Age Index of spot bituminous prices dropped 45 points to 511 on Aug. 7. This corresponds to an average mine price of $6.18, as compared with $6.73 on July 31. Buyers who must have coal are paying gilded prices for it, unless they are fortunate enough to be lined up with connections who are using the Hoover price as a basis of sale. The list of operators in this category is growing rapidly, however, and in the Midwest the Hoover level may be considered the minimum price of today, with the range continually narrowing as less and less coal moves at the high prices of last week. No seller wants to have high-priced coal confiscated at the Hoover level and there is also a growing feeling among producers that the wisest policy is to accept a reasonable return, especially as the car supply is to be contingent upon the observance of fair prices.

Contrary to expectations, priority orders have not swamped the mines now operating nor has the car supply improved materially, even for those producers who had accepted such preferential business.

Central Pennsylvania mines were the only ones to score advanced prices during the last few days. Somerset producers are now advocating $4.75 as a fair price for their coal during the present emergency. Smokeless agencies at Hampton Roads also kept their prices on the upgrade, mainly because the piers were unable to secure sufficient coal to accommodate the vessels awaiting cargo. On the other hand, smokeless firms in the Midwest were the foremost in observance of the Hoover fair-price list.

The feeling that a resumption of union mining is impending is reflected in this week's market for British coal in this country. Heavy orders had been placed in Great Britain for consumers in New England and the Atlantic seaboard but cancellation of some of these orders, amounting to many thousands of tons, followed the events of the week in the coal trade. As delivery of British fuel involves several weeks' time, no consumer wants to have much of this tonnage en route or on unfilled orders when there is a prospect of home-mined coal being available in the near future.

Anthracite consumers are now fully realizing that a shortage of coal awaits them this winter. Retail deal-
ers are being bombarded with orders and requests for early delivery, but can do little else than file these away with the promise of the earliest possible attention.

**BITUMINOUS**

"A slight increase in output marked the eighteenth week of the coal strike (July 31-Aug. 5)," says the Geological Survey. "Preliminary returns indicate a production of 4,250,000 tons against 3,933,000 tons in the week before. The increase is due to improved car supply in the middle Appalachian fields rather than to re-opening of mines hitherto closed by the strike.

"In spite of the increase in output, the eighteenth week finds production still about 1,100,000 tons short of the level reached before the shopmen's strike; in the week ended June 24, 5,337,000 tons were raised.

"Loadings on Monday, July 31, were 14,768 cars, an increase over the preceding Monday of 11 per cent. The following day they dropped to 11,783 cars, partly because of pay day. A partial recovery carried loadings on Wednesday up to 12,218 cars, and on Thursday 12,177 cars were loaded.

"Up to the present, mines responding to the invitation to resume operations have added little to the coal supply of the country. There has been practically no increase in output in any of the strongly organized districts, and the increase in shipments from Pennsylvania, and from the Fairmont and Kanawha districts has not been large.

"In the middle and southern Appalachians, production has been curtailed by the traffic congestion resulting from the shopmen's strike, but through Pennsylvania, the Central Competitive Field, and most of the districts west of the Mississippi, car supply has been adequate.

"In the strongly organized districts, Ohio, Indiana, Illinois, Michigan, Iowa, Missouri, Kansas, Oklahoma, and Arkansas, production is no greater than in the latter part of June before the Washington conferences were called. In

*Figures given in the preceding columns are net tons, F. O. B. mine. *\(^\text{†}\)Advance over previous week shown in heavy type, declines in italics. NOTE—Smokeless prices now include New River and Pocaenthalas.
the Rocky Mountain states, particularly Colorado and Utah, that there has been an increase, partly through more active demand, partly through return of striking miners to work.  

"Of all districts, Pennsylvania has been most closely watched to learn the response to the invitation to re-open mines. Preliminary returns indicate the shipments for last week (July 31-Aug. 5) will be 792,200 tons. In comparison with the week of June 24, before the Washington conferences, this is an increase of 24,000 tons or 3 per cent. (See preceding week. Resumed shipments from Pennsylvania show a decrease of 6.7 per cent. All districts except South Fork and central Pennsylvania have so far shipped less coal than two weeks ago. Up to the present time, therefore, mines that have responded to the invitation to resume operations have added but little to the coal supply of the country. The increased production has come instead from the middle Appalachians and is made possible by improvement in car supply."

All-rail shipments to New England were 436 cars during the week ended July 29, as compared with 445 cars in the preceding week. Most of this tonnage is on contract, as spot coal of the all-rail variety is more urgently needed elsewhere and New England is not yet feeling the pinch of the fuel shortage to the extent where it will pay the higher prices asked for coal.

Hampton Roads dumpings during the week ended Aug. 3 were 277,072 net tons, nearly 50,000 tons short of the previous week's figure. New England took approximately 200,000 tons of this. There is only a small tonnage at the Roads, but conditions are improving, as the railroads supplying these terminals are now moving cars more easily.

Low dumpings during the week ended Aug. 3 were 89,187 net tons; 73,294 tons cargo and 15,963 vessel fuel—compared with 153,890 tons in the preceding week. The season's movement to date is now 4,832,124 tons; last year it was 14,127,800 tons.

The Northwestern market is becoming skittish. Spot coal is so scarce that it is almost unobtainable and prices are strong. It is not yet too late to save the day if mining is resumed at an early date. Meanwhile, individuals are swapping coal supplies around to keep the wheels turning, although the shortage is daily closing down more plants.

ANTHRACITE

A few cars of hard coal were loaded during the week ended July 29, chiefly steam sizes dredged from the rivers, the only markets for them. Northern dealers and consumers are now anxiously interviewing their retailers in an effort to find out when they can expect coal deliveries. It is evident that when mining is resumed the distribution problem will be a difficult one to solve. Pea coal is still

Kentucky January-June Coal Output Exceeds
Same Period of 1921 by 5,000,000 Tons

KENTUCKY produced 17,267,132 tons of coal in the first six months of this year, in sixty-nine working days, according to the semi-annual report of the State Department of Mines, issued by L. E. Eldredge, chief inspector of mines. This was a daily output of 250,248 tons and is a net increase of 5,020,727 tons over the output for the first six months of 1921. The output during the first half of 1921 was 411 per cent.

"Assuming the mines were operated full time, or twenty-four days each month, the State of Kentucky would produce 72,071,425 tons of coal a year at this rate of production," said the chief inspector, speaking on the report.

Each of the eight districts in the state, except the fourth, composed of Knox and Whitley counties, showed an increase over the production for the first six months of last year. The increases ranged from 14 to 53 per cent. The net increase for the entire state over the tonnage for the first half of 1921 was 411 per cent. This increase in the fourth district was 49,237 tons, or 12 per cent under the tonnage for the same period last year. This decrease is accounted for by a decrease in the number of men employed in the district from 1,482 in 1921, to 767 in 1922, says the report.

COKE

Beehive coke output increased slightly during the week ended July 29, when 110,000 net tons were produced, as compared with 105,000 tons during the preceding week. The Connellsville output is at its highest mark since the strike began, having climbed slowly to a weekly figure of 72,700 tons. Coke offerings are still very light, however, as most of the increased production has been for furnace ovens.

The railroad strike is contributing to an increasing car shortage, which is cutting down the production about one day's output, or 250,248 tons, per week, according to production figures received recently, the report shows. The average number of days worked in the mines in the first half of 1921 was forty-five. This was raised to sixty-nine for the half year just closed, an increase of twenty-four working days.

Operators Restore 1920 Scale in Parts of Kentucky and Tennessee

A JTAIN arbitration board of the Kentucky-Tennessee district, meeting in Cincinnati, Ohio, reached a decision Friday, July 28, which will restore the wage scale of 1920 to union miners in the section around Pineville, Ky., to a few mines in the vicinity of Nashville, Tenn., and along the line of the Tennessee Central Ry. The award grants an increase of wages amounting to 24c. a ton to pick and machine miners; 20 per cent increase on yardage and deadwork, and $2.50 a day to day and monthly men.

It is contended by the operators that the award is not a recognition of the union but simply is a resumption of the 1920 wage scale with the miners as individuals. The award practically is said to be the scale of wages which is embodied in President Harding's coal-settlement proposition.
Orders for British Coals Canceled as Strike Settlement is Expected

COAL

The rapid supply of coal is one of the most important factors in maintaining the economy of any country. The situation in Großbritannien, as reported in the June 1922 edition of the British Coals report, highlights the impact of the strike on the coal industry. The strike, which was a significant event, led to a decrease in coal production and a decline in the supply of coal to various markets.

Hampton Roads Pier Situation

Coal Paragraphs from Foreign Lands

ITALY—Cardiff steam first quoted is 40s. 6d., according to a cable to Coal Age as compared with last week's price of 38s. 6d.

GERMANY—Production in the Ruhr district during the week ended July 22 was 1,800,000 metric tons, as cabled to Coal Age. In the preceding week the output was 1,760,000 tons.

*Advances over previous week shown in heavy type, declines in italics.

CANCELLATION of some American coal contracts, amounting to many thousands of tons, placed on the British market recently, has followed the belief that an early settlement of the United States coal strike may be expected soon. In spite of this, however, the Canadian and German calls are increasing and prices are at least firmly held. Production is well taken and new business is limited by the general scarcity.

Production in Great Britain during the week ended July 22 was 4,391,000 gross tons as compared with 4,227,000 tons, according to a cable to Coal Age. The somewhat sudden American demand galvanized buyers in Europe and South America, who had been holding off with the idea of forcing down price.

Coal Age's London correspondent, reading that the American miners had obtained the pledge of the British Miners' Federation not to supply coal for shipment to the United States, interviewed one of the British miners' readers, who says that no such pledge has been given. The British miners' view is that, when they were on strike, America sent as much coal as it was able to mine and British labor is now returning the compliment.
Government Plan of Control
Checks Ascent of Prices

Requests for Priority Shipments Fail to Exhaust Current Output—Non-Essential Industries Hustle Before Market Is Closed to Them—Buyers Cautious in Short Market.

GOVERNMENT action to control car supply at the mines has definitely checked soaring prices. Many requests for priority shipments have been filed, but as yet these orders have not taken up the full current production. Non-essential industries have been active in purchasing whatever tonnage is offering before the priority door closes the spot market to them. Buyers are proceeding cautiously, however, and refuse to pay the high figures quoted last week. Considerable bargaining has resulted, a strange feature in such an extremely short market. A feeling that the strike may be settled before much more British coal can be received here has caused several cable cancellations of orders this week.

NEW YORK

Anticipating the full functioning of the priority orders, buyers for non-essential industries invaded the market the last few days of the week and made heavy purchases. Some of these manufacturers were not actually in need of coal but did not choose to wait idly by and watch the railroads and other preferred classes pick up the available supply.

There is considerable uncertainty in the situation and the outcome of the conference held by union leaders and operators in Cleveland on Wednesday was closely watched. Some of the smaller operators are said to be willing to make contracts covering from four to six weeks or longer at prices much lower than the current market quotations.

Buying of British coal was quieter. The first cargoes are expected to arrive here about Aug. 10, although it was reported that three cargoes had already reached the harbor. It is not believed that any foreign coal will be shipped here unless it is already sold. Users of some British coal that has already been received say that the Atlantic seaboard are said to be complaining of its burning qualities. Local quotations ranged $9.50@$10.00 c.i.f.

SOME ORDERS HAVE BEEN CANCELED this week, apparently in the belief that the strike will be settled before the coal can be received.

Southern coal came here slowly and were quoted 9@8.50, Hampton Roads, and 11.50@12. New York. There were 304 cars at the local piers on Aug. 4, a slight increase over the previous week. Most of this was of Pool 11 quality. B. R. & P. coal were quoted locally $7.25@$8.25; Broadtop $8@$8.25, and Shawmut around $7.25.

CENTRAL PENNSYLVANIA

July production averaged 644 cars per day, a total of 14,075 for the month, a little below that of June. However, during the last 10 days of the month there was a big gain, the week ended July 30, showing loadings of 3,864 cars.

Shortage is beginning to be felt among the large public utility companies in the district. Prices on the spot market are a little lower, ranging around $7.50 at the mines.

Report from the leading operators in the district indicate that central Pennsylvania will not be represented at the conference in Cleveland. The district never was a part of the central concept of which the operators have always made their agreements with their employees as a distinct unit.

The Pennsylvania Railroad has announced that in order to take care of the railroad's current needs, it will be necessary to obtain from the producers 20 per cent of their output. The price is to be agreed upon later.

BALTIMORE

While a state commission for Maryland has been named in order that coal movement be regulated, it has not started to truly function, as complete instructions from Washington as to procedure are lacking. Meanwhile the plan of rationing, while making some industries hold out for better prices, is having no appreciable effect on quotations. Individual prices are being paid, and willingly, to get coal at all in many cases.

The Public Service Commission sent out a questionnaire in connection with the state plan of control, asking larger industries of the state whether they had much fuel on hand, and, as another thought, whether they would share with others some of the fuel they had. As a matter of fact few of the Maryland plants have large stocks ahead. The gas and electric light plant of Baltimore only has about twenty-five days' stock on hand. There is still some movement by barge from Norfolk to care for bunker needs and a small line distribution.

In July the total bunkers loading on foreign bound ships only amounted to 6,721 tons. The first ships bringing English coal to Baltimore are expected to dock about Aug. 15. Conditions in the local market at that time will have much to do with the distribution.

PHILADELPHIA

Higher arrivals have been noted during the past week. Any would-be purchasers, however, is deferring orders in the hopes of a quick settlement of the strike. Prices for spot coal are still high, still running from $7@$9, although there are bids in the $7 high figure recently.

If anything there is a slight decline in quotations, and a fair quantity of coal has been sold at $8. This may have been caused by the proposed priority orders of the I. C. O., which, while they have not as yet taken effect, have had a tendency to keep some purchasers in the background, believing that they will be able to get a more favorable price.

Good business with the large industries and utilities continues to go forward on foreign coals. Early in the week state handlers had some difficulty in arranging for boats, as the prices of charters have increased considerably. Orders placed now are mostly for September delivery, although it is quite possible some free cargoes are still afloat.

FAIRMONT

Although there was a rather marked increase in the number of mines in operation during the closing week of July, that was due more to an improvement in transportation than to any general response on the part of the miners to the proposed new settlement. As a result many of the operators are now back at work. Operators engaged in a general effort to put mines on an operating basis, secured injunctions, placed men on duty and cleaning up mines in general.

UPPER POTOMAC

A production of about 25,000 tons for the last week of July was being taken care of without any trouble by the Western Maryland, which was also furnishing all the cars needed. Approximately 40 mines in this district are not producing. Intimidation of men who want to return to work is the principal barrier to further operations.

KANSAS CITY

The coal shortage is being felt very acutely and prospects for increasing the production is not so bright as a week ago. Some of the miners that have been working right along have quit or at least failed to report for work and two large mines that have been producing are idle for the first time in several months. The rumor is that Howatt is responsible for this and his action is another slap at the industrial court law of Kansas.

The public is getting all "heat up," and feels that the strike should be settled right even if it takes all year to do it and there should be no temporizing.

SALT LAKE CITY

Although more coal is being mined than in 1921, operators are not able to properly take care of the demand. One prominent retail house is asking its customers to accept less than half what they order, believing that coal will be more plentiful by January. Reports from railroad cars, which are now running into the yards of the city, and about half of this is in the hands of one concern owned by a large operating company. It looks as if the independent dealer will have a hard time of it.
Anthracite

"When Can Anthracite Be Had?" Is Burning Question

Resumption Not In Sight, Dealers "Book" Orders or Substitute Pea Coal—Commercial Shortage of This Size Likely Soon—Distribution Problem Will Be Difficult on Resumption.

All in the trade now fully realize what a serious condition confronts the consumer of anthracite. The principal question addressed to retailers is when coal will be available. No tangible move is in sight to insure the resumption of mining and dealers can only take orders for future delivery or substitute at this time with shipments of pea coal. This size is moving fast and the request of the railroads that mine storage tonnage be held for their use will soon cause a commercial shortage. It is evident that when mining is resumed the question of distribution will be a difficult one.

River coals are very active and a large quantity of this fuel is being mixed with bituminous. Prices have risen, quotations ranging $2.75-$3 f.o.b. mines.

NEW YORK

The principal topic discussed by consumers nowadays is when they can expect shipments. There is practically no coal to be had.

With the situation becoming graver because of the trouble in the soft coal fields, the railroads began using pea and finally took in the available supply. The companies now have none to offer.

To most of the trade it is becoming more apparent every day that the movement of anthracite, after the mines resume operations, will be one of distribution and that well-laid plans will have to be formulated so that the coal will be evenly divided.

There are the usual orders on the books of local dealers covering the tonnage generally requested by regular customers. Dealers believe that owing to some "wise" buying in March and April house owners have a good supply on hand to start the winter.

The Western Independent Pea in the harbor that was quoted $12-$13, alongside. Stock buckwheat was $10.50 @$11, alongside; screenings, $2.25 @$2.75 at point of loading and river barrel, $2.50 @$2.75.

PHILADELPHIA

The present situation parallels the strike of 1902, at least in the matter of duration, although it will take a month yet before the present suspension equals that of the former year. However, at this time it seems altogether likely that the record will be reached, as no tangible move is in sight to insure the return of the men to work.

Each day shows a fast increasing concern on the part of the consumer. The dealers who ordered pea are in most instances delivering it as fast as it comes in, and the shippers are being pressed for shipment on the balance of the orders.

Some dealers have advised their customers that the time of resumption is still very uncertain and advising them to take a few tons of pea coal. In one instance only, the dealer bought the entire stock of pea being taken up and has refused to sell any more to transient trade. The price of pea at retail strengthens and most sales are being made at $11, the old winter price.

The trade in river barrel is active and a large quantity is being bought for mixing with bituminous coal. While no price is reported there is little chance that minimum and maximum quotations have shortened considerably. Most of the coal is now being moved from $2.60@$3.

BALTIMORE

With only a small quantity of pea coal left, hard coal dealers are at their wits' ends to advise regular customers. Some are suggesting the purchase of some soft coal to tide over the first weeks of winter. Dealers can see how everybody is to be supplied with even a little coal should the strike continue until Sept. 1. There is some new talk of using coal dredged from the bed of the Susquehanna River, but this fuel will not burn properly without a special grate and a special "blower" attachment.

The public is growing uneasy at last and the entire situation seems sure to grow tense in the next few weeks.

BOSTON

Retail dealers have now been reduced to minimum reserves of prepared coal for hotel, hospital and other current uses. Letters from the tentative distributors disclose stocks only for a few weeks at the most. Another month of mine idleness will force an active interest in wood and oil for household fuel.

The last available shipments of pea size are going forward. What pea is left in storage is being saved for locomotive fuel and there is little chance of augmenting supplies of this size for domestic use.

BUFFALO

The trade is practically dead and oddly enough nobody seems to be disturbed by it. Some consumers would put in a supply if they could get it, but nobody is in a hurry.

One reason for expecting a decline in price is probably because soft coal is pretty sure to drop as soon as mining is resumed. It is even expected to go down just as soon as the time is set for resumption of mining. So the consumers of anthracite are on the watch for something of the sort in their own trade.

The wise consumer has learned that substitutes, along with the steam sizes of hard coal, will be on the market at a reduction and they can be put in. In fact it seems likely that they would have to be put in to help out.

Coke

CONNELLSVILLE

Production is believed to be increasing constantly, but at a slow rate. The strikers seem convinced that they are going to win. Many operators are making constant efforts to attract labor to work and coke may be said to be pursuing anything like a strenuous policy in this respect.

In the open market, prices reached their top point Aug. 1, when the market was at $14.50 for furnace coke and $15.50 for foundry coke, with reports of some sales of good brands of foundry coke at $16.50, if not at $17.

Coal fumed on the market and favorite coke does not go to blast furnaces, the price being prohibitive, and is probably taken by foundries simply as a second or third grade material. The market has softened a trifle from the top point, being now quotable at $13.50@$14 for furnace and $15@$15.50 for foundry.

The Courier reports production during the week ended July 29 at 5,450 tons by the furnace ovens, an increase of 1,900 tons, and 14,220 tons by the merchant ovens, an increase of 2,130 tons, making a total of 72,700 tons, an increase of 4,050 tons.

UNIONTOWN

Much like the voluntary price agreement plan, the enforced coal price program through distribution of coal supply has so far proven entirely feasible on paper but not of sufficient strength to combat an acute need for fuel. It may be said, however, that the first slump in coal prices was in anticipation of the Hoover price plan being enforced immediately and when day after day passed without any effort to divert the tonnage produced here from its original channel, the market commenced stiffening slowly. Operators have definitely commenced to recruit their labor forces outside the region. With the local workers more determined than ever, after four months of idleness, to force recognition of their union hope of resumption with former employees apparently has passed. Many men are coming from the Southern fields but it is reported that a few men in miners coming from other districts for employment.

There is no troop protection in Fayette County, Sheriff I. I. Shaw having announced that the state police and mine guards were able to handle the situation. There is, however, a growing sentiment demanding that more positive action be taken to put a stop to outrages against men willing to work.

BUFFALO

The market is nearly blank. The ovens are asking $15@$16 for any good grade and consumers are holding off as much as possible. Operators have definitely commenced to take some banked coal and part of that goes for coke, but the supply is very limited.
Midwest Market Is Still Abnormal and Unsettled

Everybody from Operators to Dealers Holds Up Prices and Sits Back to See What Will Happen—Priority Scheme Starts Haltingly.

The whole region has been upset all during the week by the way in which the new priority scheme of coal distribution started into effect. Everybody expected a sudden and effective drop in prices of all Kentucky coals, a flood of shipments on priority and a fairly certain car supply to all fields. The drop started but never finished. The flood of priority orders was only a small stream and car supply, while starting well enough at the beginning of the week petered down on the St. Louis & Nashville to the same old 20 and 30 per cent. The general result on Saturday was that some coal was moving on priority orders at the government price of $3.50 from operators who were irate because there remained a good deal of free coal at prices ranging $6.50@10 or more.

Illinois particularly was upset during the week by the report of a shutdown of all coal from outside the state and west Kentucky, in Chicago, which had dropped to about $9, bounded sharply up to $12 and then down to $10 when rather uncertain assurances came that the shut-off would not be complete.

CHICAGO

All eyes and all minds in the coal industry during the past week were on Washington and on the fuel distribution system supposed to have taken full effect during that period. Prices on this market did not slide to the bottom, as some expected, for two or three reasons. They stayed up during the forepart of the week because it was anticipated at the outset that the coal then rolling and north of the Ohio River would be about the last fuel on the market here for awhile. Then, when Kentucky mines did not swamp under priority orders and when car supply did not rise much if any above former unsatisfactory levels, a little coal kept coming in at $9 or more.

Then when Robert M. Medill, state fuel distributor, stated publicly that Illinois could not expect any more coal from outside the state, the market, already skittish, suddenly vaulted again to $15 only to quiet down on Saturday to $10. It was generally said, by well-informed coal men, that the outside supply could not, in fairness be cut off from this state. Mr. Medill, in a message to Coal Age Saturday said the Illinois supply had not yet been cut off but that the state cannot expect to get "even a large part of our requirements."

Western Kentucky was about the only coal traded on this market during the week. A few cars of eastern Kentucky came in at $8.50 but that was all.

ST. LOUIS

With a week's supply of coal left, St. Louis faces a real famine, although this is not going to be as disastrous as might be expected, for all the larger plants have gone to using oil. The latest addition is the Illinois Glass Co., at Alton, and practically all of the big plants in the east side industrial district have gone to oil. St. Louis, every day sees new oil users, especially among those plants that would not be classified as essentials. The Union Electric Light & Power Co. has two weeks' supply ahead and nothing further in sight. The United Railways has gone to oil.

Kentucky coal is selling at $5@10 at the mine. All roads excepting the I. C. are observing the priority rules. Alabama is selling $5@8 at the mine. No West Kentucky is coming in and very little Missouri.

INDIANAPOLIS

There is no such thing as a coal market here. Business is big but orders are not being booked even by those who have West Virginia or Kentucky coal for sale because the car situation is growing worse. The utilities of the state, who can use Indiana bituminous coal are watching the efforts of state officials to mine sufficient coal to keep them going.

There is some coal drifting into the state from outside sources, but the supply is suffering and there is a positive shortage at the present time. Each day brings reports of more industries shutting their plants because of inadequate fuel. A survey of the situation shows hundred of plants burning their reserve supplies and dozens will be forced to close down the next week unless there is a change. Prices, naturally, are strong where coal is available.

SOUTHERN ILLINOIS

Quiet still prevails in southern Illinois, although the miners are restless and are finding it hard to make both ends meet. A few wagon mines are getting out coal for local purposes at a few points in southern Illinois but the tonnage is small. One of these is reported in the Carterville field and a few others in the Standard district. During the past week miners at O'Fallon prevented the loading of several thousand tons of slack that had been on the ground for a few years, which had been sold to the City of St. Louis for the waterworks. The union officials notified the drivers that until they wanted a repetition of the Herrin affair that they had better let the coal alone. They let it alone.

WESTERN KENTUCKY

A good deal of priority business is reported on the L. & N., while the L. C. does not appear to have very much of this business, so far, and with an almost full car supply has been able to furnish more equipment for commercial business than the L. & N. At Madisonville the L. & N. agent is refusing billing on cars unless on priority, or consigned to railroads and utilities.

On priority and railroad or utility business Hoover prices are said to command plus 8 per cent brokerage if buying is not direct. Prices on commercial business, where there is no priority, were reported sold at as high as $10 a ton this week though prices wavered from $8.50 up.

Operators are dying hard when it comes to acceptance of the Hoover prices, and are holding out for everything they can get, on the basis that priority will eventually take care of all production, and that there are not enough priority orders at this time to enable anyone to withhold cars where Hoover prices are in force. Western Kentucky has not accepted the Hoover price, except contingent upon satisfactory car supply. This it has not received.

LOUISVILLE

Tightening up of the market on open commercial coal is resulting from priority orders, and the fact that it is impossible to handle shipments over the L. & N.—that is from Kentucky mines—except to railroads, utilities or on priority orders.

Railroad reports at the end of the week that Chicago is offering $10@$10.50, where car numbers of coal rolling can be supplied. It is hard to determine a market on either eastern or western Kentucky, and reports are received of some $6@$6.50 coal, and of other coal sold at $10 in both fields.

It is reported that operators who are supplying tonnage at $3.50 are getting a bit wrought up over the fact that others are continuing the high quotations.

Canada

TORONTO

The public is now thoroughly aroused to the seriousness of the situation, indicated by a shortage in the normal coal supply, estimated at 300,000 tons. There is a anthracite now procurable except a limited amount of pea and buckwheat.

The Civic Board of Control has ordered $100,000 worth of Welsh coal for immediate shipment and has paid for an additional appropriation of $500,000, in order to have an emergency supply on hand during the winter.
Eastern Inland

Cleveland Conference Delays Buyers and Reduces Prices

Believe Settlement May Soon Be Reached—Spot Tonnage Exceeds Priority Orders—Lakes May Be Aided By New Government Fuel Committee.

EVENYONE is watching the Cleveland conference of producers and miners. The feeling is prevalent that a settlement may be evolved therefrom and this is quite a factor in delaying coal purchases. At the same time, operators have found that they still have free coal to offer, in addition to the priority orders for so-called essential industries and prices have softened from last week's peak.

Commercial coal is moving warily, as no one wants high-priced fuel consigned to Hoover levels. Lake business is still light, but the Northwest needs may yet be safeguarded by the efforts of the Lake branch of the Federal fuel committee.

CLEVELAND

Coal for retail distribution and for so-called essential consumption is considerably stronger, despite the priorities in the movement of fuel effective under orders of the I. C. C. Most of the open market coal is now coming from the Pittsburgh district, at $8@8.50.

Early this week, operators and sellers were unloading at $6, expecting a price of $3.50, or within the Hoover maximum. The B. & O. has started moving coal only on the priority list, but it is expected that enough orders are in to make the priority movement necessary. As a result, the rule has been lifted temporarily and coal again is being loaded for industries in general. This development has helped to strengthen the Cleveland market.

Applications are being filed by those who believe themselves entitled to coal under the priority regulations. The railroads serving the Southern coal producing territory still are clogged at the southern Ohio gateways. Sentiment is expressed that the government should divert locomotives from other roads to the non-union coal territory so that these roads could move out the coal accumulated on the mine sideings and railroad yards.

The total number of cars of soft coal received in the Cleveland district last week was down to 5,265 due to the 72-hour reduction in movements. Up to Saturday, five of the seven railroads running into Cleveland had brought in 682 cars of bituminous coal for all purposes. The best six days' receipts on these roads since the week ended July 8. Receipts for the week ended July 1 were 1,145 cars; July 8, 836 cars; July 15, 885 cars, and for the week ended July 22, 480 cars.

EASTERN OHIO

The quantity of coal available in this section increased slightly during the week because of accelerated operations by stripping mines and the release of more non-union coal from the congested strip. But tireless demand for steam coal is so intense that the sale of more apparent ten days ago seems to have subsided, somewhat due principally to curtailed industrial activities rather than the fulfillment of fuel requirements. Buyers of steam coal are holding off in anticipation of an early settlement of the coal strike. The position of the short-age is indicated by reports from various industrial centers in eastern Ohio. Blast furnaces are banked in the Youngstown district, and the Youngstown Chamber of Commerce has appointed a special fuel committee to solicit distribution of coal to domestic consumers and priority orders to manufacturers.

In the Lake trade bunker coal is difficult of procurement and many steamers are either being delayed or discontinued temporarily.

At a meeting of the Lake coal forwarders and dockmen, held in Cleveland recently, plans were made for securing a fair share of coal in order to take care of the railroads and public utilities in the Northwest.

NORTHERN PANHANDLE

An effort on the part of one large company to resume operations, even on the basis of the 1920 scale was attended with success, the 1,300 miners employed declining to return to work in the absence of any nation-wide agreement. Operations in the Northern Panhandle have been affected by the proximity of these open-shop mines to the Pennsylvania and Ohio lines. Notwithstanding this production continues on a fairly large scale.

COLUMBUS

Operators are playing a waiting game, scanning every effort made to settle the coal strike. The position of the operators, as expressed through the officers of the associations is unchanged, that is, to refuse to enter the four-state conference, but to negotiate either by states or mining districts.

Only a limited amount of coal is moving and a large part is going to railroads for fuel. Federal and state fuel commissions have been unable to function to a large degree and as a result some commercial orders are being placed, where priorities are not regarded. Stocks in Columbus are generally sufficient for 30 days on the average. So far no manufacturing plant of any consequence has been compelled to suspend operations. Public utilities are supplied for a time and the same is true of municipalities.

At the opening of the stripping operations at New Lexington a larger tonnage is being produced in Ohio, although no large mines have accepted the invitation of the President to reopen.

PITTSBURGH

While some men are reported at work in certain mines, there is no actual production reported. It is said that many of the miners believe that they practically won the refusal of the Pittsburgh and other districts to go to the conference at Cleveland called by President Lewis not having made an impression as yet.

Coal movement in the Pittsburgh district, involving non-union production from the Connellsville region, Westmoreland County, etc., has not yet been affected by the priority system or price regulations being formulated at Washington. Buyers are receiving coal they purchased a week or two ago if any consigning by the railroads.

From the top point of $8.50 for Connellsville steam coal, reached on July 26, the market declined sharply, owing to withdrawal of buyers, until on the morning of Aug. 1 the price was down to $6. Consumers then began taking hold again and prices stiffened, although they were not at the $8.50 mark of the past few days. Westmoreland gas has hardly been traded in at all. A little Youggheney gas has been in the market, at $8.50@8.75 last week. Recently paid $9@10 were paid.

Production in Westmoreland County is fairly heavy. In the Connellsville region there are almost constant gains.

DETROIT

Interest is centered on the state and county organizations which are being built in the effort to increase the supply of coal brought to Detroit and Michigan. Meantime, results of the present movement are reflected in reports of industries and utilities confronting suspension of operation unless their supplies are replenished within a few days.

Outlining his plans to the Board of Commerce, C. F. Dunn, the Detroit fuel administrator expressed a desire that he be given complete authority to act and said it is very probable if he is required to refer matters to the Michigan securities commission or the state fuel administrator. The present plan that the county fuel administrator will be directed toward getting supplies for the utilities and users of steam coal. The matter of replenishing supplies of domestic coal will remain in abeyance until needs are more urgent.

BUFFALO

The situation is a trifle easier, apparently because coal from many areas is moving faster than they were. The consumer is also helping out by refusing in a good many cases to buy at prices above the $5@6.50 mark.

Everybody is convinced that more mining is going to be done before many days.

All sorts of prices are now paid. If the basis is in a mining district he may pay $9 for it, but as a rule this section is holding off, in the hope, it appears, that something is going to be done. All prices for what is called good slack as low as $4.75 and there are prices all the way between.

The worst feature is the difficulty in getting Lake fuel. All prices up to $10 are asked for it, with the amount usually limited to 50 tons. For July the total was 57,700 tons and for the season 832,910 tons.
If Mining Resumes Now, Northwest Will Rejoice

Experts Figure Region's Needs Can Be Satisfied—Shortage Now Is So Sharp Northern Mines Are Closing—Market Gets Wilder.

THE Northwest is praying for a resumption of mining during the first half of this month—and is beginning to count on it. The general opinion is that if production starts within that period, enough fuel will penetrate this far to stave off suffering. Things are now at a serious pass, however. Many Northern mining industries are closing down, shipping is hampered not only by high bunker prices but by absolute exhaustion of coal at some ports and the coal trade is thrown into confusion here and there by the seizure by railroads of coal on its way to consumers.

A fuel census of Minnesota now going on shows that supplies are at the lowest ebb and that demand from many sources is going to be much heavier than has been anticipated. Freight rates on wood in Minnesota have dropped 20 per cent to help that fuel to reach market.

DULUTH

Many industries over the territory served from the Head of the Lakes docks will be compelled to close down within a few days on account of coal shortage. The sales manager of one of the dock companies had to refuse an order for 500 tons of lump from a mining company on the Mesaba Range. The mining company manager, who had received 14 turn-downs from dock companies, said the mines would have to close down. Other mining and industrial concerns are in the same boat.

Ivan Bowan, state fuel administrator, estimates Minnesota's small-town needs up to April 1, 1923, at 560,831 tons of soft coal and 142,958 tons of hard, a total of 703,782 tons. He believes Northwest threshers must have 1,000,000 tons. Well-informed men estimate the requirements of this market up to May 1, 1923, at 1,200,000 tons of anthracite and 3,500,000 tons of bituminous, allowing for approximately 3,600,000 tons of coal on the docks when the season of navigation opened on April 21, last. Dock operators think the necessary tonnage can be moved from Lake Erie ports if mining is resumed during the first half of this month and provided the railroads can do their part.

Docks with anything to sell are asking $8.50 for Youghiogheny, Hocking and splint lump, and up to $6.50 for screenings. Anthracite prices are unchanged.

MILWAUKEE

The coal market at Milwaukee is completely paralyzed. One coal company, which had a fuel contract with a railroad centering here, which it could not fill because of prior obligations, is having its coal on track confiscated by the railroad. Another company, which contracted to deliver 12,000 tons to city institutions, has defaulted on its contract. The company had been paying $7 per ton to secure coal to deliver at $5 as per contract. Another company asked to be relieved from a clause in its contract with the city covering the thermal units of coal.

State institutions and Milwaukee municipal buildings will be among the first to be benefited by priority orders to be issued by the Wisconsin fuel administration.

No cargoes have been received by Lake Thisis far in August. July's cargo receipts aggregate 167,799 tons of soft coal, making the season's receipts thus far 774,060 tons. About 700 tons of hard coal screenings represent the total receipts of anthracite thus far by Lake. Last year 503,158 tons of anthracite, and 1,515,293 tons of soft coal had been received up to August 1.

Following is the schedule of soft coal prices at retail put into effect Aug. 1; Pitts., Hock. & Yough., $7.25@ $10.25; West Va., $7.50@$8.50; Pocat-blows, $7.25@$11.75; Smithing, $11.25; Kanawha g splash; Illinos and Indiana, $7@$8.50; Coke, large sizes, $14, pea and nut, $10.

MINNEAPOLIS

Despite gloomy reports from all sources, this region persists in believing a relief from its fuel shortage is about to appear. It is difficult to present a report with certainty, but it is probable that the situation may be clearing up. Many wholesale coal dealers have received an order for 1,200,000 tons of coal.

The coal market is reported to be lively, but with many uncertainties. The break in the weather last Saturday cleared up the situation here. The threat of red tape was the chief worry at the time.

New England

Buyers "Wait and See" Before Entering Spot Market

THE market here has shown no material change since a week ago. Political gestures have had the effect of postponing buying and there is a general inclination to "wait and see," before negotiating purchases.

A few houses are dealing actively in British coal, especially for distribution Inland, but there is hardly enough pressure yet to force any very comprehensive business.

What coal is available at Hampton Roads is being applied almost exclusively on contracts and because the aggregate spot tonnage changing hands at the piers is relatively small there is little data on hand to gage current quotations. The smokeless agencies have apparently concluded to confine themselves exclusively to old sales, pending some clearer direction than has yet emanated from Washington. Meanwhile the railroad situation is much clarified.

Improvements are reported on the three roads terminating at Hampton Roads. Certainly if corresponding gains can be made next week on the N. & W. and C. & O. there will be enough increased flow of coal to strike a different sort of balance with respect to New England's supply. It will then be interesting to see whether representative operators will take a leaf out of the book opened for the rail managers or whether they will submit to distribution by novices regardless of their contract obligations. The far-sighted members of the trade are hoping that no developmert during the month will remove all possible excuse for the wasteful paraphernalia which some are so eager to erect. The lessons of 1918 and 1920 are soon forgotten.

Taking into account the inroads by oil, the textile strike, and reduced traffic generally, present reserves are larger than would justify hysteria, although of course, much will depend upon union output the next six weeks. No industry here has the fat margin to work on that was typical in 1918 and there is now every reason to look ahead, look and listen" before entering into blind obligations to accept any kind of coal on any old price. The trade, too, will be less likely to undergo extravagant distribution than was the case during the war period.

Householders who customarily use anthracite will not take kindly to bituminous as a substitute. If one reasonably uniform grade could be assured them, there might be some possible hope of replacing temporarily a certain tonnage, but without this the word that is being told "coal is coal" and in an already deep-seated prejudice against the industry will be unconscionably increased. To the dealer, whether wholesale or retailer, it looks like a joyous winter.
Cincinnati Gateway

Present Emergency Reveals

Queer Angles of Coal Trade

Uncertainty in Regard to Priorities—
Ruling Without Enforcement Ma-
chinery Called Fallacious — New
Dodge Evades Hoover Prices—
Smokeless District Holds to Hoover
Level.

BUSINESS in coal is full of all
sorts of queer corners, and, with
its pivotal position, the Cincinnati
gateway has developed a host of
them. At this writing it is difficult
to say whether priorities are on or
off. The fallacy of creating a ruling
without the machinery to back it up
is glaringly shown here. Right now
there is a large seepage through
of cars accepted by agents in the
mining districts on billing without any
strings attached to them. With these
coming through devoid of permits
they have given the jobbers and
wholesalers something to play with
—something that is marketable above
the Hoover prices.

This is especially true of L. & N.
shipments. The smokeless districts,
on the other hand, were holding to
the Hoover prices as the basis of
trade.

CINCINNATI

Billing and station agents on the C.
& O. are held to strict accountability
for the permits that are issued so that
there are few cars that can be snatched
out of the priority pot there. The
N. & W., too, have set the pace that
their method be systematized of the neces-
sity of watching priority orders, yet
here and there a few cars slip through.
On the L. & N., however, quite a large
number of tardy agents found their way
to the hands of the wholesalers and in
consequence these have been going to
industries and buyers far down on the
preferred list, providing that they will
pay the price.

Like all other dealers in surreptitious
quantities there is a wide divergence in
the price of this coal. The first of the
month and succeeding days saw the
range of $3.60 to $8, quality or prepara-
tion cutting no figure. It would appear
that those with the low price desire
now to move what they had before they
got their fingers burned.

Locally there has been another boost
at retail. Most of the concerns are
asking $8.50 for Pocahontas lump, $7.50
for mine run, $7.50 for bituminous
lump and $6.50 for slack. This ad-
vance was made because the slower
deliveries on contract necessitated get-
ing coal in the open market. A move
is being made to get a district order
to hold up deliveries of retail coal to
consumers upon the lower basis of
spring and summer.

HIGH-VOLATILE FIELDS

KANAWHA

With the C. & O. concentrating upon
the movement of coal to the Kan-
awha field, conditions began to improve
about the beginning of August, even
to a point where production in other and
adjoining fields was greatly curtailed as
the result. Thus, while Government
agencies were beginning to function
and prices were steadier.

LOGAN AND THACKER

The accumulation of 3,500 cars in the
Logan field is being gradually re-
duced. At the outset of August there
was a slight improvement in the car
supply and production began to move
upward again. There has been no ef-
fort to profit unduly by the emergency
and磋商 prices have been materially
reduced as a result of the warning as
to car supply where high prices are
exerted.

Until the end of July Kenova-Thacker
operators were not producing more than
half the output of June owing to the
inability of the mines to secure cars.
The irregular supply made it impos-
sible to go ahead at any time.
With embargoes against the movement
of all freight except coal, livestock
and foodstuffs, operators anticipate a
better movement of cars above the
shippers in the distribution of coal and prices
are approaching normal once again.

NEOESTERN KENTUCKY

After experiencing a shortage of cars
so serious as to reduce the output to
55,000 tons per week as against a po-
tential capacity of 288,000 tons, the
field is beginning to recover, although
producers are still handicapped by the
lack of an adequate supply.

LOW-VOLATILE FIELDS

NEW RIVER AND THE GULF

Although more New River mines are
operating, yet production has been
greatly curtailed as a result of the in-
ability to secure equipment promptly.
New River companies are lending their
full co-operation to the government in
the effort to get fuel to the market
promptly and to take care of needy
consumers, most of the tonnage shipped
moving at the Hoover maximum. There
was a decided slump in prices on all
grades during the closing week of July
and just as soon as the car supply be-
came dependent upon an observance of
fair prices.

Production in the Gulf, notwithstanding
a shortage of cars, entailing a heavy
production loss, remained at about
150,000 tons per week throughout
July, and as August was ushered
in there was a slight improvement in
the transportation facilities which had
the effect of enabling mines to increase
their output.

POCAHONTAS AND TUG RIVER

Serious inroads on the Pocahontas
output were experienced during the
closing days of July as a result of the
poor car supply, production being re-
duced from about 450,000 tons per week
to less than 250,000 tons per week,
with car shortage losses aggregating
almost 400,000 tons. Western connec-
tions of the N. & W. were slow in get-
ting cars back to that road. There
appeared to be a slight change for the
better by the beginning of August, how-
ever. There is a probability that the
Pennsylvania, under the proper con-
tractor, will secure the bulk of its fuel supply
from the N. & W. territory, including the
Pocahontas field.

The July came to an end the output
of the Tug River was not over
50,000 tons a week or just about half
of the total produced in recent months.
 Mines could produce no more owing
to necessity of cars and to an accumula-
tion of loads. Although the demand
was just as urgent as it had been, yet
prices were settled back to the Hoover
level after a brief period of soaring.

South

BIRMINGHAM

Demand continues strong although
the situation has eased some from the
tenseness of a week ago. Orders are
still to be had far in excess of the
supplies, and so far government control
of distribution has not functioned to
such an extent as to interfere ma-
terially with the normal movement. A
large tonnage is moving into the West.

The demand for smokeless is good,
the supply being somewhat short
of the needs at this time. Practically
all of the output of the Cahaba mines
producing domestic sizes has been con-
tracted for and the better grades are
scarce.

Operators have generally agreed to
abide by the Hoover price schedule
during the present emergency and ob-
serve priority orders placed at their
mines, it being the intention of the dis-
trict committee to so distribute prefer-
ential business as to interfere as little
as possible with outside customers.

Prices on the various grades under
the fair-price schedule will be about as
follows, f.o.b. mines:

<table>
<thead>
<tr>
<th>Mine</th>
<th>Run</th>
<th>Prepared</th>
</tr>
</thead>
<tbody>
<tr>
<td>Big Seam</td>
<td>6.00</td>
<td>8.50</td>
</tr>
<tr>
<td>Carbon Hill</td>
<td>2.50</td>
<td>2.80</td>
</tr>
<tr>
<td>Cahaba</td>
<td>3.20</td>
<td>3.50</td>
</tr>
<tr>
<td>Black Creek</td>
<td>3.20</td>
<td>3.50</td>
</tr>
<tr>
<td>Pratt</td>
<td>2.80</td>
<td>2.80</td>
</tr>
<tr>
<td>Coromia</td>
<td>2.50</td>
<td>2.50</td>
</tr>
</tbody>
</table>

Higher prices can easily be obtained
for all grades of coal than the schedule
and of course a majority is tak-
ing advantage of them, as is always the
case. Contract prices on domestic
coal for August range $2.45 to $4.50.

The situation is being interfered
with very materially by car shortage.
The railroads otherwise are furnishing
very much better service, as freight is
moving more promptly and regularly as a
whole.

VIRGINIA

Steam decreases in production marked
the course of July, and during the last
part of July, with a prospect, how-
ever, that there would be an im-
provement in transportation condi-
tions. Improved rates, however, were
producing at a heavier rate than others
in the field or at about 71 per cent. Prices
began to break as soon as it became
apparent that cars would not be fur-
nished to operators charging more than
a fair price.
COAL AGE

COAL AGE

NEW YORK

The Nashwalk Pulp & Paper Co., with headquarters in New York City, has purchased coal mining areas in New Brunswick. The coal properties inspected by officials of the company and it is expected that the work will begin in the next few weeks and will be resumed. It is believed that the property will show a fine grade of soft coal. The coal property being surveyed is located near the pulp land holdings of the company in the vicinity of Portage, Me.

Arkans a

A decree for foreclosure and sale against the property of the Arkansas Coal & Land Co., was made by the Federal Court, Ft. Smith, Ark. The property of the company in Johnson and Logan counties is involved. That public auction at Clarksville. The property to be sold includes the $300,000 judgment held by the Pennsylvania Mining Co. against the United Mine Workers, as an outgrowth of the labor troubles at James City, Pa., a few years ago. The Pennsylvania company's property was later transferred to the Fernwood Mining Co., and the two mines are now being operated as one. A part of that section of Johnson County, as known and shown on a map, the company placed a minimum price on the property of $100,000. The sale was decreed to be subject to the approval of the Federal Court.

KENTUCKY

The Boone Jellio Coal Co., of Pineville, has been formed by officers connected with the Boone Coal & Coke Co., and several residents of the Pineville district. The officers of the company are M. B. McDermott, president; John Emsloe, vice president; A. E. Wheeler, secretary and treasurer. Capital $20,000.

While state troops protected some of the interests in the mines in Bell County, with a total personnel of about 19,000 tons a year have merged the former United States Fuel Co. and the Consolidated Coal Co. The properties taken over are the assets of the American Coal Co., the Mingo Coal & Coke Co., Bennett's Fork Coal Mining Co., and Log Mountain Coal Co. The concern is capitalized at $2,800,000.

The Miners-Elkhorn Coal Co., F. P. Preston, Paintsville, general manager, has received an order from the Court of Appeals of the United States, which will develop a large acreage near Riceville on Big Sandy River. A quantity of coal has been sold and large tippie is being completed.

WILLIAM SCHROUCLIE, receiver of the Metropolitan Fuel Co., of Indianapolis, will sell the assets of the company at a receiver's sale Sept. 7. The concern, which was a receiver when suit was brought against it by the president of the big Indianapolis insurance agencies.

ILLINOIS

John M. Pooperling of the Jewel Coal & Mining Co., St. Louis, was in southern Illinois recently. While in the district he spent a few days at Du Quoin where the company has two mines located.

T. C. Keller, head of the Indiana & Illinois Coal Co., of Chicago, was on a business trip in the southern part of the state recently.

Reports have been confirmed of the purchase of a strip of ground near Mt. Vernon by the Wabash, Chester & Western R.R. The strip was the location of a strip that will be used for high-class purposes. The strip had too little storage room for loads during the three winters. The yards are to remedy this.

INDIANA

Coal production will be the principal business of the Dugger Martin Coal Co., recently organized at Sullivan, with a capital stock of $100,000. The company reserves the right to engage in any sort of mining business. The directors of the company are H. O. Martin, Oliver Steele and M. W. Dugger.

The White & Wright Coal Mining Co. has been organized at Clinton, for the purpose of doing a mining business. The organizers of the company are J. D. Wright, Charles J. White and O. T. Ray.

Morgan E. Greene, F. M. Goble, Russell Sullivan, Thomas Goble and Ray E. Greene are the organizers of what is to be known as the Greene-Goble Coal Co., recently incorporated at Shelburn. The company will do business.

Phebs F. Darby, an attorney of Evansville, has been named receiver of the Posey Mine Co., a coal mine in Warrick County, about two miles west of Boonville. The receivership grows out of the failure of Posey Co., which has been operating the Posey Ridge mine for some time.

William Schrourbc, receiver of the Metropolitan Fuel Co., of Indianapolis, will sell the assets of the company at a receiver's sale Sept. 7. The concern, which was a receiver when suit was brought against it by the president of the big Indianapolis insurance agencies.

KENTUCKY

The Boone Jellio Coal Co., of Pineville, has been formed by officers connected with the Boone Coal & Coke Co., and several residents of the Pineville district. The officers of the company are M. B. McDermott, president; John Emsloe, vice president; A. E. Wheeler, secretary and treasurer. Capital $20,000.

While state troops protected some of the interests in the mines in Bell County, with a total personnel of about 19,000 tons a year have merged the former United States Fuel Co. and the Consolidated Coal Co. The properties taken over are the assets of the American Coal Co., the Mingo Coal & Coke Co., Bennett's Fork Coal Mining Co., and Log Mountain Coal Co. The concern is capitalized at $2,800,000.

The Miners-Elkhorn Coal Co., F. P. Preston, Paintsville, general manager, has received an order from the Court of Appeals of the United States, which will develop a large acreage near Riceville on Big Sandy River. A quantity of coal has been sold and large tippie is being completed.

MARYLAND

Governor Ritchie has announced the membership of the Inter-State Coal Distribution Committee. Those appointed are Frederick T. specially the Board of Trade, A. Asbury Davis, president of the Merchants' & Manufacturers' Association, Clyde B. Martin, president of the United States Fuel Co. for Maryland, the United States Fuel Co. for Maryland, and Howard Adams, president of the Maryland Coalajobbers' Association. Hugh Ferris, president of the Exchange, William Miles Maloy, chairman of the Public Service Commission.

MISOURI

Henry Gibson, engineer, has come to Carrollton in the interest of the Big Four Mining Co., with a view of developing the local coal field. It is the plan of the company to open several mines here and start production. The leases secured are on the royalty basis and will net the owners of the land from $200 to $250 an acre.

The Callaway County Coal Co., which operates a coal mine near Carlington, has filed a petition in the Audrain County Circuit Court, asking for a dissolution of the company. If the petition is granted the company can no longer be profitably operated.

Robert O. Edings has filed suit against the Ray County Coal Co. for $40,000 dam-ages. The suit was received in Minn. Feb. 25, 1922. The plaintiff charges that while acting as the agent of the company without authority and to its damage and that he was caught between the choices of the company. He alleges that he was permanently injured and will suffer permanent disfigurement. The managers of the Clifton Hill Banking Co., with parties from Bevier and Macon, are interested in the proposed development of several thousand acres of coal rights in the western part of the county.

Pennsylvania

The fifth annual meeting of Cosgrove & Company was held at the Fort Stanwix Hotel, Utica. Seventy, or approximately 100 department heads and managers were present when the conference began. Bishop Carver, of Utica, delivered the address of welcome to the convention on behalf of the city, while Bishop Darby, Jr., welcomed the convention for the company. James and Greene county coal producers, in compliance to the request of Sec- tor, has been in attendance at this meeting at Utiontown, and affected an organization to be known as the Pennsylvania County Coal Association, as well as adopting without reserve Mr. C. P. Lingle, of Greene County, to fill the present coal shortage emergency. A committee, to be composed of the Audun, will be composed of W. C. Hood, of the H. C. Frick Co., John Sin- started work at Ming, Cooper, of Illinois, and C. Chezart, of Greene County, George W. Johnson, of Dawson, John B. Moore, and W. D. McGein of Connellville. This commit-tee will be changes.

The State will not await the decision of the Supreme Court of the United States in the constitutionality of the antitrust tax in dealing with appeals by antitrust pro- perly, up to the time the appeal is heard by the Attorney General, but will prosecute to the fullest extent. The law is in the hands of the District Court, Harrisburg. The appeals filed for the tax computed to be paid by the antitrust companies will be listed for disposer in court just as are other appeals. If the Attorney General has been notified of an appeal, the tax in the antitrust company which has been required to give adequate bond to the state tax courts, the law will proceed in the fall. The Attorney General will ap- pear in court in order to receive a certified copy of the appeal. The law is in the hands of the District Court, Harrisburg. The appeals filed for the tax computed to be paid by the antitrust companies will be listed for disposition in court just as are other appeals.

Frank Stirk, shaft sinking contractor, of Greensburg, has taken over the contract for the shafts of the large new operation of the Jeannine Coal & Coke Co., of Colorado. The purchase of the tract of land recently leased from the Thaw estate of Pittsburgh, near Utiontown.
Traffic News

The complaint of the Southern Ohio Coal Exchange and many individual coal shop- pers in that section has brought a decision from the Ohio districts to Toledo and other Lake ports following the reduction of freight rates from the East. The complaint was heard before the Ohio Utilities Commission late in July, and it was held that the full 10 per cent was not given to Ohio shippers in much of the effort of the carriers to preserve a balance in the differentials of pre-war times. W. D. McKinney, secretary of the Southern Ohio Coal Exchange was the principal witness for the complainants. The rate from the Ohio districts to Toledo formerly $2.10, has been reduced to $1.50, or about 19 per cent. The rate from the inner mines at West Virginia, formerly $2.86, was reduced to $2.29, while the rate from the frontier mines at West Virginia was reduced from $2.86 to $2.57. J. C. Vin- nying was the principal witness for the railroads. He claimed that the present rate arrangement had the sanction of the I. C. C.
Rates on coal mined in western Ken- tucky and moving to northern Georgia con- suming points and to Savannah, for export have been held by the I. C. C. to be too high in comparison with rates on coal from other points. The I. C. C. has ordered to fix charges on coal from the inner mines at about 7 cents a ton above the rates which they maintain at the southernmost points for coal mined in the Jellico-Middlesboro district.

The complaint of the Gulf Coal Co. has been upheld by the I. C. C. at Washington, Sept. 22.

The complaint of the Colony Coal Co. will be heard at an early date by the I. C. C. at Washington, Sept. 22.

In hearing in the complaint of the Tuba Fuel Co., assigned for New York Sept. 12, has been excluded.

COAL AGE Vol. 22, No. 6

UTAH

Michael Schennecter has received a per- mit to build a coal mine near Fish Lake, Filmore, Millard County. Coal has been found there and efforts are to be made to see if there is any bituminous coal in the area.

The Park Co-operative Coal Co. of Thompsons, has been organized to work the mines in Thompsons Canyon, owned by U. H. Clark.

WEST VIRGINIA

Increased valuation of coal property in West Virginia has resulted in a protest on the part of coal land owners in some sections. The protest is accompanied by an instance having announced that it would enter a strong protest against the value placed on its properties. It has been decided to make a general reassessment of property throughout the state and the West Virginia Tax Commissioner, D. G. Clark, has been given the authority by the state Tax commissioner, D. W. Ross, to organize a special staff at the direction of the state Tax Commis- sioner. The new staff will be equipped with the latest machinery and equipment in accordance with the statute books since 1908. The state Tax Commissioner, however, insists that coal land owners take the true and fair value in and value in accordance with such instruc- tions. There has been a general increase in the valuation placed upon smokiest and all other coal.

The Washington-Elkins Coal Co. Inc., has been formed at Elkins, with capital $100,000, incorporated by W. B. Maxwell, W. H. Russell, W. C. and Alverna Glueckner, all of Elkins.

The Mont-Saint-Louis Fuel Co., with headquarters at Morgantown, is inspecting the property of the Bear Mountain Gas Coal Co., near Philmont recently.

Supplementing recent news to the effect that Paul Hardy, a prominent coal operator of the Guian and Coal River territory had organized the Hardy Coal Co., for the purpose of developing large acreages of coal land on the Poor Pole of Todd County in McDowell County and was preparing to begin development work without delay, a coal miner reported recently to connect the Hardy company's property with a railroad, of which the N. Y. & Pennsylvania had been awarded to Harry Waugh, with head- quarters at Parkersburg.

The Hool Coal Co. has resumed opera- tions at its mine near Whet Shinning. This mine has been prepared for many weeks. It is owned by W. C. Wyatt and Frank A. Burnett.

Because of the application of unreasonable rates on anthracite from the Carbon- kopolis, the complaints of the Hool Coal Co. for delivery on the West Shore Railroad, the I. C. C. has ordered the General of Railroads to refund $17,733 to Frank A. Cookley and other shippers.

The Hool Coal Co. has been ordered to refund $734 to the F. Kogel Coal Co., for rates on coal from Ohio, Kentucky, West Virginia and Pennsylvania to Detroit.

COAL AGE Vol. 22, No. 6

Coming Meetings

New York State Coal Merchants Association will hold its annual meeting at Rich- mond, September 21-23, under the presidency of E. B. Blaine, of Albany, N. Y.

Industrial Exposition under the auspices of the Huntington Chamber of Commerce will be held Sept. 15-19 in the Chamber of Commerce Building, Huntington, W. Va. The West Virginia-Kentucky Asso- ciation of Electrical Engineers will again hold its annual meeting in the same building during the exposition.

National Exposition of Chemical Industries will be held at the Grand Central Palace, New York City, September 11-16. Manager, Charles F. Roth, Grand Central Palace, New York City.

American Mining Congress, Twenty-fifth annual convention and exhibition of mining and mining equipment will be held at Public Hall, Chicago. For further information, write offices, the Hollenden Hotel; E. C. Porter, Chicago.

National Exposition of Power and Me- chanical Engineering will be held at the Grand Central Palace, New York City, September 11-16. Manager, Charles F. Roth, Grand Central Palace, New York City.

The Duffin Coal Mining Co., Ltd., has been organized in Denver, Colo., to engage in coal mining and to deal in coal generally. The company is capitalized at $500,000 and the provisional directors are G. H. Seidewich, James Allanston, J. C. F. Bocock and C. C. Hugill, of Toronto.

Archibal Michelson, who is connected with a number of collieries in Wales, Yorkshire and Cumberland, has arrived in Toronto on a visit. He is president of the Davidson Porcupine Mining Co., of which the owner of the Hope strike is proving a big bon to the British collieries.

Senator W. R. Marshall, manager of the Standard Fuel Co., Toronto, has returned from a trip through the various coal fields of the United States, and he is looking into the strike situation and where he says he re- ceived a warm welcome. The strike would be looked after immediately work was resumed.

WASHINGTON, D. C.

Senator Cummins of Iowa, has presented to W. G. Block, of Davenport, urging the prompt shipment of coal for Iowa industries.

The District, with attorneys has de- tailed Walter C. Allen, secretary of the Senate, an investigation of the coal situation in Washington, in connection with the plans of the Senate Permanent Committee on the government's price system.

The constitutionality of the Lever fuel control law and regulations of the Fuel Administration during the war, restricting sales and prices of coal and attacking in an appeal filed in the Supreme Court, brought to the attention of Justice James N. Ford, its vice-president, who were each fined $1,000 and costs for charging that certain prices on the coal he sold in Cincinnati during September, October and November, 1917, and an order that the company's action was affirmed by the circuit Court of Appeals for the district of Columbia. The company and its vice-president was afforded by the circuit Court to reverse the decision of the lower courts the company argues that the act substituted executive for judicial processes and that it delegated to the President is not conferred upon him by the Constitution.

American Institute of Mining and Met- allurgical Engineers will hold its fall meet- ing at the North American Hotel, San Francisco, Cal. It is proposed to arrange the 18th annual session of the Institute for Sept. 16, stopping at different cities as the secretary, F. F. Sharpless, Engineering Societies, Chi- cago.

American Chemical Society's annual fall meeting will be held Sept. 4-9 at Pitts- burgh. Division of Chemicals will be held at Carnegie Institute of Technology and general meetings at Carnegie Music Hall.

The Rocky Mountain Geological Insti- tute will hold its next meeting at Glenwood Springs, Colo., Sept. 7-9. Secretary, F. W. White, Denver, Col.

Obituary

Robert M. Werreth, for 14 years Nor- folk manager for the Norfolk-Virginia Coal Mining Co., died recently at his home at Yorktown. He is survived by his widow and one daughter, and was 41 years of age.

Mr. Werreth was a mining engineer and mine owner, died suddenly of heart disease at the age of forty-eight at his home in Yorktown, Va., Butte, Ticonderoga, N. Y., and after working in the coal fields of Montana and made superintendent of the Clearfield Coal Co. of Clearfield, Pa., to which he belongs, studying mining and time mining engineering. After nine years as superintendent he became general field agent for the Norfolk-Virginia Coal Mining Co. in 1924 he came to Du Bois and entered the mining business as mine owner.
Time Always Befriends the Striker

At the Cleveland convention operators are agreeing to pay wages which only a little while ago they declared they could not pay. There will not be lacking those who will say that they could have paid them when the strike commenced had they only been willing. The reason for the operators' change of viewpoint is that now, after the strike has continued for nearly five long weary months, the stocks are almost exhausted, winter looms ahead, the railroads threaten to be congested and the public must buy from union mines and pay enough to make bituminous mining profitable no matter what the wage may be.

Mr. Lewis hoped to get the same result by unionizing the operators as against the public. He desired to form a big combination of mine operators so large as to be able to fix the price. In compelling them to pay a high wage he knew they must sell the coal at a high figure. They could do this only if they were numerous enough that the public could not sidestep but must buy from them. That is why Lewis wanted the Central Competitive field to bargain with him, and that is why, for a while, he sought to have the Washington authorities declare in favor of a uniform wage in the union and non-union regions alike. He was for unionizing the operators, forming them into a trust which could demand from the public what it would, and would be able out of excessive prices to pay excessive wages to the miners.

But the operators were afraid that such a union or wage trust was illegal. They avoided entering into it even though the President and Secretary Davis invited them, yes implored them to form it, and even though the public wondered why they lacked so greatly a proper sense of obligation that they failed to act in accordance with Federal suggestions.

Now at least there is no risk that the public will buy in the cheapest market because that market is too small for all to enter and is no longer cheap. Even in non-union regions wages have been increased. There is no longer any fear of the competition of non-union men, not at least before April, 1923. The union operators can now safely pay the wage that tended to bankrupt them before April, 1922.

It nearly always ends this way. A strike commences with strong arguments in favor of the operators and ends with conditions such as make the operators friendly and even anxious to concede, because there arrives a time when concession promises profit. Then the only fear is that a contract will be made of such duration that conditions will change before the contract expires.

The conclusion of terms between the union and scattered operators from 7 states does not settle the strike—it breaks the deadlock. The switch in policy on the part of the miners from four-state to district and individual settlements maintains the contention we have made from the beginning that what Lewis was really after was no reduction in wages; that his policy of no district settlements was designed for that and that alone. It was fine propaganda to hold the men in line from January to July but on Aug. 14 it becomes ballast to throw overboard.

Using the Public for His Own Ends

When the coal miners start work it will be with no reduction in wages and under no promise or obligation to arbitrate future wage scales. There is indeed but a slim chance that, as a result of nearly five months of strike, possible two months of sympathetic rail strike, and no one yet knows how much human suffering and industrial paralysis in the coming winter as a direct result of both, the public will have the least degree of insurance against a similar upheaval next year.

During the Cleveland conference John Lewis said to the public through the press "The miners have won their fight and it is practically over. There is no longer a thought in my quarter that wage reductions will be imposed on the mining industry. The question here is one of procedure without undue humiliation of the operators. We have no desire to humiliate them. We only want the immediate resumption of mining, the return to work of the men and the relief of the public." Again, "The miners have not deviated any degree from their original policy." And finally "The miners will never consent to arbitration." Thus from his present pinnacle speaks the head of the miners' union.

Cast your mind back to the early fall of 1919 when John Lewis fell heir to the presidency of the United Mine Workers through the retirement of Hayes. Hayes' legacy to Lewis, an untired leader, was a program so extreme as to shock the country. Lewis had to decide then and there between a policy of moderation and a policy of radicalism. He knew he was accused of being afraid to fight. He knew of the growing influence of the Farringtons, Howats and Brophys. When he set his compass toward "Fight" he took the most momentous step in the labor history of coal.

Taking up Hayes' crazy program of nationalization, 60 per cent increase of wages and the 30-hour week, and throwing it into the mine workers' convention in 1919, Lewis routed his opponents. Violating his contract with the operators, he called a national strike for Nov. 1, 1919, because to have waited until the contract expired on April 1, 1920, would have given the public an opportunity to build up coal reserves. The unlooked for forced resumption of mining by injunction and the forced acceptance of arbitration nearly upset John Lewis, but the 27 per cent increase in wages awarded was so much better than the miners expected that Lewis held his prestige.

Knowing full well that every force in the land was
driving toward liquidation of wages, Lewis in 1921 held to his 1919 decision to fight. To be a successful labor leader one must always be fighting for something more, demanding and never conceding, mindful always that the mine workers have more stomach for a fight than any one else in the country.

How Lewis has held his men in line, despite internal dissent, how he has defied in succession the operators, the President and the people of the country are part of today's realizations.

The burden of all this is that John Lewis is for the moment at the head of the most powerful labor organization in this country. He can hold that cherished position so long as he maintains the offensive and wins his strikes. He is no quitter, hence will have to pull another strike next year or the next. Which is another way of saying that John Lewis, strong as he has demonstrated he is, cannot control the miners. He leads in the direction they are going. The movement is bigger than Lewis—he cannot now put on the brakes.

Which brings us hard up against the problem of what is the country going to do about it? The framers of our government planned to prevent the usurpation of power by majorities. They saw to it that the minority might not be gagged. Little did they foresee the power of organized minorities. Less than 600,000 men of our population of some 20,000,000 workers have this year held the whip hand over all the remainder. The hundred million people who this winter will suffer for lack of the coal that the less than 600,000 refused to dig have not spoken yet. Public opinion is passive. No one in authority has told the people the trouble that lies ahead. What can the public say? It has said "Protect those who would work," but with the protection provided too few have been willing to work. The public can say—"Compose your differences without depriving us of fuel and transportation." If it cannot say that plain enough, forcefully enough, to reach and convince the most unheeding then we must wait till the union dis-integrates through its own super-aggrandizement, submitting in the meanwhile to its tyranny, or we must go on fighting it as best we may until it returns to reason.

None of the spectacles are pleasant—which will you have and what are you going to do to bring it to pass?

From those operators who are crawling to Lewis begging permission to mine coal, those he would not "humiliate," to those whose backbones are upright though their knees may tremble is a far cry, with every human motive ranging from mere profit-seeking to the highest ideals of public service.

Strength for the Next Battle

ALTOGETHER apart from the outcome of the passages at arms with John L. Lewis and his powerful organization of labor, it must be said that the coal operators of Illinois and some other sections of the country give signs of having learned a lesson. They have hung together as never before. That is a proud accomplishment even though it may be greeted by humorous sallies concerning separate hangings. In Illinois as in probably no other state, owners of mines have had thrust upon them painful subject lessons in the ultimate cost of past surrenders to the union. Every time they broke apart to make peace with the miners for immediate gain, they lost in the long run. Every capitulation added power and arrogance to the United Mine Workers of America. It is all very evident now, even to those operators who, for financial and other reasons, have been most keenly in need of producing coal.

It is so evident, in fact, that every operator knows there lies ahead in this country a battle that must be won. It will be a long battle and one requiring the utmost determination and sacrifice but it must be won if the coal industry is to attain the true normalcy so much desired by everybody but union labor. The skirmishes and heavy engagements of this summer have given the coal operators of the land opportunity to exert those forces for solidarity which are developing. Surely such forces have gained potential strength by this exercise. They certainly have in Illinois. Defeat without surrender in a fight for a just cause often is more stimulating to morale than victory.

It Is Up to Mr. Coal Man

EXERCISE of governmental control over coal distribution is producing the usual and expected crop of knockers. To some everything that is being done by the agencies at work in Washington is wrong. There is the customary blatant critical line of dope being written by the usual onlookers telling the country, or such as their tirades may reach, that it is all wrong. The thing to do, for instance, is to produce more coal and there will be no necessity for the government putting its hand on distribution.

In the first place those who take, or pretend to take, such a stand refuse to recognize that in this crisis the first essential step toward getting more coal out of the ground is to make what coal is being produced go as far as possible toward averting a shortage at points and with those consumers whose continuity of operation is essential to the nation. It is not too much to say that under present circumstances four million tons of coal per week reaching the proper consumers may be worth more than five million tons imperfectly distributed. To argue that Mr. Hoover is making bricks without straw is but partially stating the case—he is short of mud as well.

There isn't enough coal to go around and there isn't going to be enough. It's perfectly absurd for some coal men to complain about the government messing in the situation, because if it didn't, a thousand times as many people who are not coal men would demand it.

The old job of 1917-18 and of 1920 of spreading a thin supply of coal over a wide and persistent demand and need is here again. It must be undertaken with the best tools at hand. No one who recalls the difficulties that beset Washington in previous years when with wide-spread authority the control of coal distribution was undertaken can but appreciate what Mr. Hoover and his associates are facing.

It is useless to rail at the fact that Washington is putting its hand to the task—it had no alternative. It is childish to curse and growl at the methods, better take a hand in trying to improve them.

We are not at war with a foreign power, it is true, and a call to patriotism falls short on that count. But what is war but an effort to avert national disaster, and what less faces this country this winter with crippled railroads and short coal supply? The coal man knows this better than any one else and he can help or hinder as he wills.
Railroad Electrification
Will Make
Important Changes
In the Coal Industry

Roads Must Do More Work and Do It More Economically—
Byproduct Plants and Power Stations Will Be Operated Concurrently; Coke and Gas Being Used for Generation of Energy

BY CHARLES MEANS*
Pittsburgh, Pa.

COMMERCIAL development in this country seems to move in fairly well-defined cycles. Years ago we started in to build railroads and it now appears that we built them in plenty, although some were not well located with respect to the general requirements of the country. At a little later date telegraph and telephone lines were being constructed all over the land. In recent years we have been engaged in making one of these lines do as much work as several of them were capable of doing at the time they were constructed.

Just now we are engaged in building highways on a scale unthought of a few years ago. Whether our type of construction will handle future traffic is a problem that the next generation only can ascertain. We are engaged also in the construction of high-voltage transmission lines for the conveyance of vast quantities of energy over relatively long distances. It is reasonable to suppose that in time the wasteful burning of coal in small units will disappear and in its place will come large central stations where the coal can be consumed economically with full recovery of valuable byproducts.

ELECTRICITY FOR LOW-COST TRANSPORTATION

The railroads of the country are facing a problem that, if not solved, may materially affect the development of those regions remotely located with respect to water transportation. Their main problem is not necessarily lack of trackage but high cost of operation. Low transportation expenses and charges are essential for the free interchange of commerce, and the degree of economic development of any district is proportional to its transportation facilities.

As the situation now stands, with the railroads unable to handle successfully increasing inland traffic the next cycle would appear to be the complete electrification of railroads. The railroads we now have must do more work and do it more economically. A wonderful piece of apparatus is the modern steam locomotive, but it has well recognized limitations. Sufficient railroad electrification already has been completed to show us its possibilities, and with the development that will naturally come from increased work of this kind its success is assured.

Though the electric railway locomotive so far has been limited in its application to unusual or severe conditions, it has made good and will continue to do so increasingly as time goes on. This change in the manner of operating railroads will modify the coal industry profoundly. Coal is an expensive item in the operation of the common carriers, and the supply of railroad fuel is an important part of the coal business. Where it is available and conditions warrant its use, water power will be developed which will displace that part of the locomotive fuel that is now being hauled long distances, reducing the tonnage thus consumed not only by the quantity of coal thus displaced but also by that further quantity which is consumed in the transportation of such coal.

Coal that for various reasons is now considered unsuitable for locomotive fuel can be economically burned in large central stations. The firebox of a locomotive has certain well-defined limits, but the combustion chambers under stationary boilers can be designed to burn any kind of fuel having heat value.

This may mean the development of mines not now considered workable, as entirely new economic conditions will be brought about. It is reasonable to assume that the concentration of power-producing centers will admit of the recovery of valuable byproducts, only that part of the coal having no byproduct content being burned. Much of this content, though not suited to the needs of the chemist, has high calorific value.

BYPRODUCT PLANT AT EVERY POWER-HOUSE DOOR

The power plant of the future will embody a byproduct plant just as do the steel plants of today. This, however, will be built along somewhat different lines from those now in use, as the requirements will not be the same. The coke or residue after distillation need not possess metallurgical characteristics, heating value alone being the important consideration.

Coals now considered unsuitable for use at steel plants because their coke is not regarded with favor can be used at power plants after having given up their byproducts. Furthermore, lignites or low-grade coals that are not suitable for locomotive fuel or that cannot be transported profitably will then be of value, for they will be found to give satisfactory service when used directly under stationary boilers.

The ordinary steam locomotive necessarily is more
wasteful in the generation of power than the large central station because of high radiation losses and the inherent inability of the machine to convert any large percentage of the heat produced into useful energy. It is true that with electric currents certain losses occur in transmission, but the reduced cost of transportation, distribution and handling of fuel for locomotives more than compensates for these.

All these phases of railroad electrification have a direct bearing on the coal industry of the future. Because of the utilization of available water power, energy will be supplied in certain districts without resorting to the combustion of fuel. Because of the great increase in efficiency arising from the burning of coal in large central plants one ton in such a station will do the work of two when burned in a locomotive. Further, the burning of fuel in a central plant permits of the recovery of valuable byproducts not now available.

The entire aspect of the coal industry, in so far as railroad fuel is concerned, will undergo a marked change because of the centralization of coal-consuming plants in such locations as naturally offer lowest energy-production costs. Instead of coaling stations being distributed at many points throughout the country, coal used to supply energy for railroad operation will be centralized at a relatively few favorably located centers. Fuel that is now used exclusively by railroads may never reach any of the stations that in future will supply them with power.

While the changes outlined will, no doubt, be gradual, the time when all important lines of railroad will be electrically operated may truly be considered as being by no means remote unless some other now unknown solution for this problem should present itself. With this changed condition will come corresponding alterations in the marketing of a large percentage of the coal produced throughout the country.

Three-Part Pipe Wrench of Great Strength

Light Weight and Ease of Application

A NEW pipe wrench embodying a radical change in design from usually accepted standards as well as several original details in construction is known as the Little Giant. It has the end opening that has been so long and favorably known and utilized in machinists’ wrenches. This allows the tool to be utilized in much closer quarters than the side-opening wrench.

This new tool consists of three parts only: the frame, the movable jaw and the adjusting nut. The first two pieces mentioned are drop-forged and heat-treated. In the smaller sizes the combined handle and jaw is made with two pipe-gripping faces; in the larger sizes four such faces are provided. All springs, rivets, pins and the like have been eliminated, with the result that the weight of the tool is appreciably less than that of a wrench of the side-opening type.

Despite its comparatively light weight this wrench is unusually strong. The 14-in. size has repeatedly withstood stresses exceeding 4,700 in.-lb. without either slipping or bending. Government specifications for tools of this size require that they shall withstand only 2,800 in.-lb. The two or four sets of what might be termed stationary jaws or those integral with the handle may be engaged at the option of the user and lengthen the life of the tool almost in proportion to their number. The inner or secondary main jaws render the wrench highly efficacious on certain classes of work.

This new wrench is the product of the Greenfield Tap & Die Corporation, of Greenfield, Mass. The 8-, 10- and 14-in. sizes are already manufactured, and 18- and 24-in. sizes soon will be obtainable.

Stripping Methods That Afford Clean Coal

COAL is in general about as clean as the mining methods in use make it. Of course some coal is naturally dirty, but other coal is made dirty by negligent handling. There is no reason why strip-pit coal should be dirty. Unfortunately this type of working had its greatest development during a coal boom and in consequence even the most elementary precautions were not taken by some operators to keep the product clean, for quality then was less sought than quantity. The coal shovel was permitted to dig into the bottom; cover was allowed to fall down on the coal and was not removed from it before loading; the coal shovel loaded coal direct into the railroad car and no picking tables were provided. The result could not be in doubt. Stripped coal was in consequence regarded as being a poor purchase.

With care open-cut coal can be produced that is freer from impurities than that obtained underground. Not infrequently in a mine does the mining machine work its way into the coal bottom and the drawslate fall into the coal. Furthermore the cutting machine breaks up a large part of the coal and shooting tends to reduce what remains from lump to slack.

An open-cut mine like that of the Enos Coal Mining Co., in the Ayrshire coal district of Pike County, Indiana, illustrated herewith, avoids these difficulties of underground mining by lifting the overburden and cleaning the upper surface of the coal by hand shovels and wire brooms before the coal is disturbed, also by not attempting to shovel the coal down to the bottom clay, by shooting with due care and by running the coal over a picking table, where it is examined and cleaned by several men. The coal finally is delivered to the cars from the chute and an inspector watches it from a platform as it falls and certifies the coal as clean if it meets with his approval.

The screenings delivered at this mine are unusually large, about 65 per cent being 2-in. nut and practically none of it fine enough to be designated as "bug dust." This mine is typical of the newer operations in southern Indiana. It is connected with the Southern Ry. by ten miles of railroad owned and operated by the coal company. It will soon be connected also with the Big Four. The property was not acquired until May of last year and the first coal was loaded over the tipple in October. Before the strike the production reached 50,000 tons per month. This tipple can handle 3,500 tons in eight hours.

PIECE WRENCH PROVIDED WITH AN END OPENING

This wrench has only three parts—frame, movable jaw and adjusting nut. Springs, rivets and pins have been eliminated making the tool simpler and lighter.

Roadway and Other Permanent Supports in Coal Mines of Great Britain

Horseshoe Sets Coming Into Disfavor Owing to Weakness at The Crown and Often at the Ground—Methods of Stiffening Weak Points—Extruded Fireclay Often Breaks Invert Arch

By John Roberts

The steel "timbering" used on roadways, either alone or in conjunction with timber or masonry, may be termed semi-permanent supports. Steel rails and girders have been used in mines for many years, the simplest being a rail or girder stretched across a roadway and resting on wooden props or on masonry side walls, as illustrated in Fig. 1. The objection urged against these girders is that when repairs become necessary the girders are not so easily taken out as are timber "collars." On the other hand, they possess the advantage of greater strength and durability, and when once bent and removed they can be straightened for further service.

In Fig. 2 is shown a system in which a steel rail is supported on cast-iron posts. The posts are hollow and flanged at the ends, and cast-iron chairs fit into the upper ends. These chairs serve to support the horizontal rail on which the timber lagging is set. This system is, of course, suitable only where roof pressure along is expected.

To resist pressure from both roof and sides the steel sets shown in Fig. 3 have been adopted. The crossbar a is of I-section and is supported by legs, each of which consists of two channel-bars bolted together and resting on a cast-iron shoe, b. The legs and collars are provided with several bolt-holes so that the sets may be adjusted to suit roads of varying dimensions. The desired batter of the legs is obtained by means of the cast iron shoe b, the underside of which is curved and rests in a sole piece, c. In another form (Fig. 4) the legs and beam are secured by means of angle irons and bolts or rivets.

HORSESHOE LINING SET WITH FLOOR PIECE

Where the roof, sides and floor require support, the form shown in Fig. 5 has been applied. These sets consist of rails bent to the form of the roadway and fishplated as shown. With timber lagging, well packed behind with fine material, this device gives excellent support.

A type of steel set which has become quite popular in recent years, although first used many years ago, is called the "horseshoe" set, which consists simply of rails of uniform section bent to the form of a horseshoe and fishplated at the crown, as shown in Fig. 6. These sets are often used in conjunction with masonry and timber, side walls conforming to the rails being built up to a height of about 6 ft. and the upper sections lagged with timber.

When newly erected the construction presents a neat appearance, but the system can hardly be said to give satisfaction. In the first place, objection is taken to the weak joint at the crown of the arch, which is the point where great strength is required. Again the curved form of the sides has a tendency to cause the floor to "heave" or "puck." Generally speaking, the effect on the sets is either to cause the crown to be bent downward or to be driven up into the roof and to break the fishplates. Buckling frequently occurs also at the haunches.

Where a horseshoe set of uniform section is placed to withstand unequal pressures at different points, such premature buckling is only to be expected, and it is somewhat surprising to find that horseshoe sets have hitherto not been specially designed to offer increased support at the points where the maximum pressure is expected. If it is considered advisable to line a road with steel arches it should be worth while making a good and reasonably permanent job. The forms illustrated in Figs. 7 and 8 may, to a certain extent, overcome these objections.

Fig. 7 is a general design, from which it will be seen that the web of the H-section supports is expanded at the crown a, the two members forming a unit interlock at b. Specially-shaped and long fishplates are used, and these are secured by six bolts of suitable strength. At the haunches, c, a double flange and web provides additional support, which resists the tendency to collapse prematurely at these points.

The lower ends of the sides of each unit are so formed that the advantage of the arch-shaped structure is retained. The additional vertical struts or sup-

Fig. 2—Steel rail with the ball of the rail held by a chair which forms a cap to a hollow cast-iron post having flanged base; (a) side view; (b) end section. Fig. 3—Steel set with I-beam crossbar and two legs each of which consist of two channel bars bolted together and resting in an iron shoe (b), under which is a sole piece (c). Fig. 4—Steel set with legs attached to crossbeam by angle irons and bolts or rivets.
The holes so as to allow the structure to yield slightly to the load until settlement takes place.

It is realized that the manufacture of the suggested new designs will not be such a simple matter as that of plain horseshoe sections. There is, however, the alternative of using double-channel sections, held together not only by bolts but also by plates extending across the crown and haunches. These fishplates would give the necessary additional support to the roof (Fig. 11).

Other supports may be regarded as permanent. The distinction between permanent and semi-permanent is perhaps arbitrary, for in mines where little pressure is encountered the most simple form of timbering may last a lifetime, whereas in others elaborate and costly systems of reinforced concrete may have a comparatively short life. Speaking generally, however, masonry and "ferro-concrete" are regarded as permanent structures. The masonry arch reinforced with steel girders, illustrated in Fig. 12, has given good results. In this example ordinary masonry sidewalls were erected, and arched girders weighing 56 lb. per foot were placed in position about 6 ft. apart and resting on the walls. The masonry then was continued about and between the girders.

Ever since the introduction of concrete as a roof support for mines it has been the practice to reinforce it with metal in a more or less systematic manner. Formerly it was the custom to use old rails or any strips of metal to provide the necessary tensile strength. Reinforcement to be effective, however, must be carried out systematically, and this, as a rule, is now being done.

Engine rooms have frequently been constructed in the manner shown in Fig. 13, where old rails are bent to the required form and then fishplated. The concrete is well rammed behind the rails and the exposed surface is smoothed off to prevent, as far as possible, the accumulation of dust and to facilitate its removal. Such a structure possesses the advantage of having no inflammable material in its construction and com-

**HORSESHOE SUPPORTS WITH MODIFICATIONS**

Fig. 5—Horseshoe with steel base consists of three curved members with a fishplate at the crown and sides. This section is weak at the crown and haunches. Fig. 6—Simple horseshoe fitted at the crown, giving no resistance to thrust. This gives greater resistance to side pressures. If the floor heaves, less damage is done to arch. Fig. 7—An improved horseshoe set with better footing, stronger roof supports and more support at the haunches. The increased supports also strengthen the arch against side thrust. Fig. 8—Still stronger horseshoe with strengthening web. Holes are drilled for the web, and it is added only if the arch shows signs of failure. The web has no flange.

Ports provided are adapted to take the major portion of the stresses acting on the roof of the structure, while inwardly curved side members serve to resist the tendency to buckle. This will be obvious from the fact that by fixing the foot of each arm in a notch in the floor, as at a, each member is converted from a cantilever (viewed sidewise) into a beam fixed at both ends.

Failure usually takes place above the spring of the arch, while the sides often remain intact; therefore increased strength must be provided at the crown and haunches. The points near the ends of the fishplates will, at first sight, appear relatively weak, but it should be noted that the sharp arched flanges at these points offer much resistance to the pressure; in fact, this form closely resembles the five-piece set which in some fields is used to replace the more general set of only three pieces. When drawn diagrammatically, as in Figs. 9 and 10, the resemblance between the two systems of reinforcement is striking.

In Fig. 8 is shown a slightly modified form of horseshoe set in which a strengthening web (without a flange) is used. Holes are provided to enable a reinforcing strut to be bolted on as soon as the arch shows signs of failure. Cables or haulage pulleys may be suspended from holes lower in the web, thus obviating the fixing up of crossbars for this purpose.

It is highly important that the sets be well packed behind, so that the pressure may be distributed evenly. Particular attention should be paid to this requirement at the crown, otherwise the supports will be driven up into the roof. Failure often occurs also at manholes, as the result of improper packing, and to prevent this it is generally desirable to wall the sides of the manholes behind the steel sets. When the floor also requires support a tie may be stretched under the track and joined to the base of each member. The employment of wooden blocks under the feet of the supports is generally recommended, and where the feet are "stamped" some fine material should be placed in
Gasoline Locomotive with Tractor Type of Motor Having Clarified Air Supply

In order to meet the demand for a gasoline locomotive that would be dependable for light haulage service and that could be made at reasonable cost the machine shown in the accompanying illustration has been developed. This is a substantial locomotive built to withstand severe service. The motor is of the tractor type, the ruggedness of which has been thoroughly demonstrated. All engine parts in this design are thoroughly inclosed and consequently are well protected from dust and dirt, yet are readily accessible for inspection or repair.

Intake air to this engine is washed by being passed through a water clarifier which removes all dust and dirt. The usual simple and efficient splash system of lubrication is employed. All oil used for this purpose is introduced at one point in a central reservoir which supplies all parts of the motor and transmission assuring ample lubrication.

The clutch is placed behind and adjacent to the flywheel and the propeller shaft at its extremity carries a bevel pinion that is in constant mesh with two bevel gears, causing them to rotate in opposite directions. Forward or reverse movement is obtained by engaging either one or the other of these bevel gears by means of a sliding clutch. A neutral position, of course, is provided also. From the bevel-gear shaft drive is made through a spur gear reduction to a jack shaft on the extremities of which are mounted sprockets which connect with the axles through roller chains.

Changes of speed are obtained by throttle control similar in operation to that of a steam locomotive. All levers are grouped within easy reach of the operator. Cast-iron wheels are standard equipment but steel or steel-tired wheels as well as a cab can be provided. The weight is about 4,000 lb.; the minimum radius of curve that can be traversed is 13 ft. and the speed may be anything up to 8 miles per hour. The track gage is 24 in. or more and the height is 54 in. without cab. Assuming a car resistance of 30 lb. per ton of trip weight this locomotive, which is manufactured by the Atlas Car & Manufacturing Co., of Cleveland, Ohio, will haul a 25-ton trip on a level track, 9 tons up a 2-per cent or 2 tons up a 7-per cent grade.

GASOLINE LOCOMOTIVE FOR HAULAGE AT COLLIERIES

A 2-ton locomotive for light service, that can be used on 12-ft. radius curves and with a 24-in. track gage. It has hand brakes, renewable shoes and hand-operated sanders. The frame is of structural steel.
Can Mechanical Replace Human Energy in Underground Loading?

Human Effort in Coal Loading Costs $10,000 a Year per Horse-Power and Almost Ten Dollars per Kilowatt-Hour—Working Efficiency Roughly 2½ per Cent—Cars Changed in 1½ Minutes

A recent meeting of the Engineers' Society of Western Pennsylvania J. F. Joy read a paper on 'The Substitution of Mechanical Energy for Human Energy in Underground Mining,' of which an abstract follows:

"One of the largest items of expense in the production of coal is incurred in its loading out at the face of the workings. The annual production in the United States, which totals more than 500,000,000 tons, is loaded at the face by approximately 400,000 mine workers out of the 750,000 employed. It is evident, therefore, that this operation absorbs the greater part of the labor employed in the mining of coal.

"It is said that a man at work will through an eight-hour shift develop one-tenth of a horsepower, so that for 400,000 miners the power equivalent is 40,000 hp. Converting this value to kilowatt-hours and allowing 200 working days per year, the work equivalent resolves itself into 47,744,000 kw.-hr. With a daily wage of $5 it will be seen that the loading process costs the coal industry $400,000,000 per year or $10,000 a year for each horsepower.

"Pay five-hundred times too much for energy"

"Similarly the work costs almost $10 per kilowatt-hour, or four to five hundred times the cost of electrical energy. Because men can perform tasks like these only at enormous cost, engineers are providing means to convert electrical energy into mechanical work, in such a way as to effect greater economy.

"The question of efficiencies must be taken into account in making the comparisons. Assuming that the coal is loose the greater part of the 40,000 hp. is spent in raising it, let us say, 3.3 ft., which is a fair average for the difference in level between the mine floor and the top of the car. In lifting 500,000,000 tons of coal through this distance only 1,000 hp. is consumed, and the resulting efficiency is 2½ per cent. Most of the miner's time is spent in dislodging the coal preparatory to loading, in timbering, laying track, etc., but, regardless of the work incurred in these operations, the efficiency is lowered because he must stoop and erect himself for each shovelful of coal.

"The supplanting of hand labor at the face by machinery has been the aim of a number of engineers for a score or more of years. Progressive mining companies have encouraged this and interested themselves in the project and millions of dollars must have been spent in experimentation. As a result, many different machines, involving a variety of principles, have been devised and operated. Many of these machines work admirably when loading loose coal but have been unsuccessful in loading coal in the semidisturbed state as it exists at the working face after blasting. To meet this difficulty the man who loads by hand not only has a shovel to lift the coal but provides himself with two picks to loosen it, and excessive quantities of powder have been resorted to in some cases.

"Although it has the desired effect—that of producing an easily loaded coal—a loss results instead of a saving, inasmuch as the coal is shattered. Many of the machines were not designed in keeping with the prevalent system of mining. To make conditions more suitable to the handling of a particular type of machine the cry has been raised to supplant the room-and-pillar system by one of the many wall systems.

"It is safe to assume that 98 per cent of the yearly production of coal in this country is mined by means of the room-and-pillar system; the method of working has been adopted after years of study and experience on the part of the operators, so that today it is considered the most practical and economical means of winning coal. In the early development of this method many lives and much money were lost, so that it would be incongruous to consider a different system of working at this time."

A Loader Both Props and Runs Machine

In the discussion that followed E. H. Coxe, general manager of the Snowden Coke Co., inquired whether the runner of the one-man loader set the timbers as well as operated the machine, and Mr. Joy replied that it did. Some doubt was expressed as to the practicability of such practice.

Mr. Coxe then told of a loader that was developed and tried in one of the mines of the Pocahontas Fuel Co. several years ago. Mr. Newdick, who developed this machine, was in the audience. The loader was manned by four men in addition to the operative. The seam being mined was the Pocahontas No. 3, which varies in thickness from 8 to 10 ft. Two motors were used for pulling cars to and from the room face, two 3-ton cars to a trip. Breakthroughs were established at 100-ft. intervals, and in this way two motors could ply back
and forth without interference, one working on the straight and the other from the nearest breakthrough. In this manner it was said that a car could be loaded and moved in 4½ minutes, or at the rate of one ton per minute, allowing 1½ minutes as the average time for changing cars.

Mr. Newick afterwards stated that much time is lost in car shifting, even in the best regulated system; investigation at the mine mentioned proved that on the days of maximum loading the loader was in actual operation not more than 42 per cent of the time; with most favorable conditions and using two motors as cited, much time was lost. The time actually occupied in moving from one room to another with only 60 ft. between centers, traveling the nearest breakthrough, totaled approximately 4 minutes. This time did not allow for delays due to derailments and other accidents.

An instance was mentioned where a Meyers-Whaley loader disposed of all the coal from one cut in eight 3½-ton cars (loading time not given), with an average time of changing cars of 1½ minutes. This shifting time agrees closely with that given by Mr. Coxe, which was 1½ minutes.

The question was raised whether it is not disadvantageous to use a rigid conveyor on a machine mounted on a caterpillar tractor, in that the discharge end of the conveyor moves away from the car when swinging around for more coal. Mr. Joy was asked also whether his type of loader necessitated continual car spotting.

To the first question he replied that with the proper manipulation by a skilled runner the discharge point of the rigid conveyor could always be kept over the car and that the rigid conveyor means simplicity in both design and operation. In answer to the second question he said that the conveyor extends over practically the entire length of the car, loading progressively forward, so that the loader and not the car is moved.

To an inquiry made by Mr. Coxe as to the day-in and day-out output of the one-man loader Mr. Joy gave figures of a case where a 3-ft. seam was being worked. In two successive weeks one machine loaded an average of 52 tons in eight hours. In the two weeks that followed this period the average daily output amounted to 60 tons. The operator, he said, claimed a saving of 25c. per ton of coal loaded.

Mr. Eavenson asked if the loading could be reduced to man-hours per ton of coal, so that a person might figure out his own costs regardless of varying wage scales in the different fields. Such figures were not available at the time, but some interesting facts were given in reply. In the 3-ft. seam already mentioned approximately 12c. was allowed for cutting and 8c. for blasting per ton of coal. One loader operative, a mule and driver had an output daily of from 50 to 60 tons. The tonnage came from three working places; there were only nineteen working places in this mine at the time, and it is the ultimate object of the company to have not more than thirty working places throughout the life of the mine. The company asserts that the number of men on the payroll, exclusive of the men on the loaders, is lessened by one-third due to the concentration of workings.

Mr. Weldin asked Mr. Joy if he had decided to cease manufacturing the high-seam loader. The latter replied that in 1917 and 1918 the Pittsburgh Coal Co. used this type of machine in one of its mines, and produced 100 tons per day, loading slightly less than two tons in two minutes. However, he felt that the smaller one-man loader is more practical for the present at least and that the large machine was beyond the economic limit of present-day requirements.

Mr. Eavenson asserted that his observations led him to believe that the actual working time of a mechanical loader does not exceed 35 per cent. Consequently the greatest difficulty in the adoption of the mechanical loader cannot be ascribed to the loading machines thus far developed but rather to the inadequacy of the schemes of car handling. A successful method of car supply to the face must be worked out before the industry can hope for real success. He also asserted that with an adequate car supply, even a hand loader could almost double his daily output.

He was of the notion that pillars could be drawn more safely, more quickly and with an appreciable saving by means of mechanical loading. Because of the rapidity of mechanical loading the retreat would be so swift as to occasion little menace due to the roof, which would not cave so close to the rib end as it does in the present method of mining. Not only that, but there would be less slate to contend with and mining costs unquestionably would be decreased.
Mr. Joy said that there could be no doubt as to the advantages of the mechanical loader for pillar work. Returning to face loading, he said that in the mine of the Pittsburgh Coal Co. to which reference was made the roof was weak. An I-beam supported at both ends by wooden posts was maintained two or three cuts away from the face, being moved every other day. This provision and the practice of placing the regular timbering closer to the face greatly assisted in insuring safety.

He then mentioned an experiment made in a mine where the mechanical loader was used in wall mining. Entries were driven on 300-ft. centers. A wall cut to a depth of 7 ft. was made, with the track placed 7 ft. from the wall, or 14 ft. from the solid coal. Posts were placed on the opposite side of the track. With this arrangement the loader worked admirably.

At this point Mr. Coxe expressed his surprise that a flame-proof motor had not been developed for loading machines. Unless a safe motor were developed the mechanical loader seldom would be used in gaseous mines. F. A. Barry, of the Westinghouse Electric Co., said that manufacturers had given little thought to such a motor, inasmuch as the present demand did not warrant the cost of its development. Such a motor would require a marked change in design. Mr. Joy added that not only must a motor be developed to exclude gas from its interior but that the controller and the resistance must be protected similarly.

Healey River a New Coal Field in Alaska

With Seven to Forty-Six Foot Coal

THE Secretary of the Interior has authorized the immediate construction of trackage connections between the Alaska R.R. and the coal mines recently developed on the Healey River. By constructing a spur four miles in length cheap fuel will be made available to Fairbanks and the mining region tributary to it. The successful development of coal on the Healey River promises to stimulate mining in the Fairbanks region more than any other event in recent years. Even at present, without trackage connections, with all the expense entailed by having to haul the coal four miles to the railroad, unload it at the Nenana River, ferry it across and reload it on cars on the other side of the river, this coal is being laid down in Fairbanks at $8 per ton. With the completion of the Nenana River bridge this winter, and with the establishment of through traffic, Fairbanks will have all the advantages of cheap fuel.

Until the Healey River coal became available the Fairbanks district was dependent largely upon wood for its fuel. Prices last winter were as high as $24 a cord. Even the largest consumers paid $12 a cord on contracts. At such prices no serious efforts were made to thaw ground or even to operate dredges on a large scale. The cost of power prevented the development of large areas of promising placer ground of moderate value.

The coming of the railroad already has cut down the cost of miscellaneous supplies at Fairbanks by one-third. Now, with the assurance of a dependable supply of satisfactory fuel, it will be possible to undertake both lode and placer mining on a scale which costs have made impossible in the past.

What is true of the Fairbanks district will apply in a slightly different degree to all points along the inland rivers, as coal can be delivered by barge from Nenana at prices much below what hitherto has been paid.

Contracts have been let by the Healey River Coal Corporation for driving a 1,200-ft. main adit which will open a series of coal beds which vary from 7 to 46 ft. in thickness. The coal is a fair grade of subbituminous and already is being used extensively for railroad, industrial and domestic use. Steam-boiler tests have been made at Anchorage by John A. Davis, of the Bureau of Mines staff, which show that the Healey River coal has 90 per cent of the efficiency of that obtained from the bituminous coal of the Matanuska field. The corporation engaged in the mining enterprise is being financed and conducted by local men familiar with conditions in Alaska. Only within the last year has it been appreciated that this coal, which occurs near the lignite deposits in the Nenana fields, is not itself a lignite but is of a distinctly better grade. The failure to recognize its quality explains the delay in developing this resource which is expected to play an important part in developing the Fairbanks district.

Outcrops at Healey Forks, Alaska

Careful scrutiny will show a black dump with a coal chute resting on it to the left of the picture, the opening being in the thick bed. Another entry appears in the center at the foot of the same big seam, and on the extreme right is another chute, the drift in the coal which serves it not being visible. Here are apparently six seams, some quite irregular but one unusually thick. In fact the coal, which is subbituminous, measures in places 46 ft. in thickness.
Two-Unit Automatic Mine Substation Erected to Improve Service and Reduce Mining Cost

Surface Substation Runs Without Attendant — Second Motor-Generator Set Not Put Out of Operation Unless for Fully 10 Min. First Set Has Been Adequate, a Short Level Road Making 6-Min. Low Load Frequent

BY H. F. RANDOLPH AND C. E. H. VON SOTHEN

A REMARKABLE increase in the use of automatic substations in mining service has been noticeable during the last year. Motor generators and synchronous converters have been installed with control devices that permit them to operate with perfect safety even though unattended. Infrequent inspections only are necessary. Because of the elimination of the human element and the possibility of more advantageous location, such stations have been able to afford a quality of service better than that rendered by the ordinary manually-operated mining substation and as good as that of the best.

One of the most interesting installations recently put in operation is the two-unit synchronous motor-generator automatic substation of the Star Coal & Coke Co. at Red Star, W. Va. This company recently undertook a general electrification program which involved the installation of General Electric Co. transformers, induction motors for pumps, tipple and fans, an induction hoist motor with magnetic control, and the automatic substation just mentioned.

This substation is situated on the surface about a mile and a half from the mouth of No. 1 mine. Direct-current at 550 volts is taken down a boreshole a distance of 325 ft. to the trolley, which extends approximately 4,500 ft. into the mine in one direction and out through the mine mouth in the opposite direction. From the mine mouth it continues on the surface a few hundred feet, after which it enters No. 2 mine and extends about another mile underground. The present direct-current load consists of one 8-ton and one 10-ton locomotive in No. 1 mine, an 8-ton locomotive in No. 2 mine together with mining machines and gathering pumps.

In No. 1 mine the trips usually consist of twenty 2-ton cars each, except for a short distance where the grade is steep. Here the locomotives pull only eight or ten cars per trip. The loads are brought to the foot of the slope up which they are drawn by the induction-motor hoist over a 7-per cent grade to the mouth, a distance of 5,500 ft. The locomotive in No. 2 mine usually hauls out eight-car trips, the size of trip being such as to bring the full output of the mine to the tipple with as small a demand charge as possible.

Before the new installation was made the haulage system was supplied by two steam-engine-driven direct-current generators. These units have been replaced by the automatic substation, which contains two 150-kw. 500- to 550-volt generators driven by 2,200-volt 3-phase 60-cycle synchronous motors fitted with direct-connected excitors. By making the station automatic it has been possible to place it in the location that will give best voltage at the face, yet minimize attendance charges.

Power is purchased from the Virginia Power Co. Current enters the substation at 2,300 volts through iron conduit laid under the floor. Referring to Fig. 1 the incoming line panel is shown on the extreme left of the switchboard. In addition to indicating meters and overload protection, this panel contains integrating, graphic and demand meters. The alternating current bus connects this panel with the three adjacent ones, which are, in succession, a feeder panel and the two panels that control the synchronous motors. The line from the feeder panel goes to the outside through iron conduit.

Three transformers just outside the station deliver power to the pump motors at 440 volts, the lines being taken down the same boreshole as the direct-current.

FIG. 1.
Interior View of Substation

Two 150-kw., 500- to 550-volt synchronous-motor generators are installed with every detail of automatic control. Starting on the extreme left of the switchboard the first panel is for incoming current; to the right are a feeder panel, two panels that control the synchronous motors, two that give proper starting sequence and protection, a direct-current panel and one for the relays of the automatic reclosing feeder equipment.
lines. The 2,300-volt feeder continues over a pole line to the hoist, the fan, the town-lighting circuit, and to the transformers for the tipples motor and a second small fan. While the incoming line and feeder panels are not necessary for the successful operation of the automatic substation, it was considered desirable to combine them with the automatic switchboard so as to insure alternating current power for the hoist, pumps and fans when the substation is idle.

The remainder of the board consists of two control panels to give proper starting sequence and protection, a direct-current panel containing contactors and circuit breakers for both generators, and, on the extreme right, a panel on which is mounted the relays for the automatic reclosing feeder equipment. The feeder contactor is hung from the pipe framework behind the panel.

Oxide-Film Arresters Sidestep Lightning

Above the switchboard may be seen the six choke coils used in connection with oxide-film lightning arresters on the incoming line and the alternating-current feeder. The two motor field rheostats and the load-indicating resistor for the automatic reclosing feeder equipment also are visible above the board.

Though it is not the purpose of this article to present a detailed description of the operation and protection of this station a brief discussion of it may be of interest. Normally the station will run only during the day. An employee who lives nearby puts it in operation in the morning on his way to work by closing the two control lever switches on the base of the feeder panel or by closing the two oil circuit breakers. Only one motor-generator set starts at this time, however, a change-over switch determining which one shall lead. Provision has been made so that the station may be arranged for starting and stopping from the tipples office, should this be found desirable.

The starting operations are performed in the same order as in manual operation. In other words, half voltage is impressed on the motor until it reaches synchronous speed, then it is excited, and when the field current has built up to about one-half normal the machine is thrown on the line. The moderate starting peak thus obtained results in only a small demand charge and low cost for power.

In Fig. 1 the master control contactor for each motor-generator set is shown on the base of its control panel. When the incoming voltage is sufficiently high for proper operation and all protective devices are in positions showing normal conditions for automatic starting the master contactor of the first set closes immediately after the indication to start has been given. Fig. 2 illustrates the sets with their oil-immersed starting and running contactors. The starting compensator may be seen in Fig. 1, mounted on the end of the pipe framework that supports the starting and running contactors.

Closure of the master control contactor causes the starting contactor to connect the motor to the line through the starting compensator. Soon after the set reaches synchronous speed the exciters voltage builds up to a predetermined value, whereupon a relay picks up and closes the motor field contactor. This device is shown on the base of the synchronous-motor panel.

When the field contactor closes it opens the discharge resistance, which short-circuits the motor field during acceleration and connects this field to the exciter. As the field current reaches approximately three-fourths of its normal value it picks up a relay which opens the starting contactor and closes the running contactor. This connects the motor directly to the line.

Polarized Relay Assures Generator Polarity

When the voltage is sufficiently high a polarized relay, used to verify the generator polarity, closes its contacts. This completes the circuit to the generator line contactor through auxiliary relays. The line contactor closes and connects the machine to the direct-current bus. One section of the load-indicating resistor is next cut into the feeder circuit so as to bridge the feeder contactor. If no severe overload or short-circuit exists on the feeder its contactor closes after a short but definite time delay. The station is now ready to deliver current.

A current relay in the feeder circuit closes its contacts when the load on the first motor-generator set becomes slightly more than full. If this load is maintained for 30 seconds the second set is started, and in less than half a minute is equalized and on the line, helping out set No. 1. When the load falls off to a point
where set No. 2 is no longer needed and remains below this value for approximately ten minutes, this set is shut down completely, but is ready to come on again whenever required.

The reason for using a time-delay value of ten minutes is as follows: There is a stretch of track in No. 1 mine that is practically level, and while a trip is passing over it the total load on the station falls off appreciably. It takes a trip six or seven minutes to cover this stretch, and it would not be desirable to have the second set shut down, but will restart whenever required.

When the mine has finished for the day the station is shut down by opening the oil circuit breakers or the control switches, whereupon all devices return to the proper position for a restart.

In addition to the devices which insure proper sequence in starting the two motor-generators and putting them on the line, others are provided to protect the machines from any damage that may result from abnormal conditions that arise during operation. Two of these protective features have already been mentioned—namely, the relay to prevent starting on low incoming voltage and that for verifying generator polarity.

These protective devices may be divided into two groups: those affording protection in cases of temporary emergency, permitting resumption of service as soon as conditions return to normal, and those that shut the station down permanently when trouble arises of such a nature that the installation should be inspected or repaired.

In the first group may be placed those devices that protect against single-phase starting, undervoltage on the incoming line, overheated motor windings, overheat load-indicating resistor, direct-current overload and reverse power. The second group comprises the bearing-temperature relays and those devices affording protection against excessive starting time, wrong generator polarity, permanent field failure, overspeed and overload either on the incoming line or upon the two motor circuits. The alternating-current feeder also is provided with overload protection. The general arrangement of the bearing-temperature relays, flash barriers and speed-limit switch may be seen in Fig. 2.

Single-phase protection is so arranged that the station cannot start if one phase is dead, but as soon as three-phase power is available it will automatically go into operation. If single-phase occurs while the set is running it will continue to supply power unless the load is heavy enough to cause the motor windings to overheat. In such a case one of the temperature relays will open the main control contactor and shut the set down. It will restart automatically when the windings cool and three-phase power is supplied. The machine temperature relays are connected to the current transformers and have a heating characteristic similar to that of the motor. The automatic reclosing direct-current feeder equipment already referred to is designed to afford proper protection when either or both machines are running.

The service obtained from this substation has been highly satisfactory; all operations of the mine have been speeded up, delays greatly reduced both in number and in total time lost, and power costs have been cut beyond expectation. Other conditions remaining the same, it was found that for the first month of operation with the electric equipment the total cost for power was much less than it had been with the steam plant.

This includes the hoist as well as all other apparatus, but the saving in attendance charges on the substation made up a large part of the total. The results obtained clearly justify the increase in investment over that necessary for manually-operated substations.

Dangers Lurk in Unprotected Gears

This gear train was found unprotected, as shown, in a headframe of a big mine. Guards are still unusual in tipples. They are making their way in breakers, however. Our mine inspectors rarely examine tipples and would have little authority if they did. But dangers certainly exist in them from the moving parts of machinery, flying coal dust, lack of light and fire.

Fortunately the building itself is fireproof. Even

![Corner in a Tipple Where Protection is Needed](image)

then the exposed oil would in this case be no little menace, for the bearings are evidently bolted to wood stringers. With speed reducers the gears and the oil would be kept inclosed and space would be saved.

Gas Blows Out Coal in Granby Mine Faces

Blow-outs have been interfering with the working of the Cassidy, Vancouver Island, mine of the Granby Consolidated Mining & Smelting Co. These occurrences have been more or less frequent for months. Because of them the Minister of Mines some time ago prohibited the use of powder underground. Within the last few weeks they appear to have become more severe, for two miners have lost their lives at different times within this period. In each case they were buried under the fall of coal, and life was extinct before the bodies could be extricated. Coroners' juries have returned verdicts of death by misadventure, no blame being attached to any officials. The situation has developed into a problem of some perplexity both for the department of mines and the company management. The coal in the area now being worked is soft and conditions such that there is no assurance but that blow-outs will continue and that further lives be lost unless something is done to safeguard the workers. William Sloan, the minister of mines, has interested himself in the matter personally to the extent of prohibiting the use of explosives, taking up with the U. S. Bureau of Mines the question of the explosibility of the mine dust, and now, it is understood, has instructed his officials to make full investigation.
Practical Test Applied to Safety Lamps

Long-Standing Practice in Scotland—Lamps, at Times, Assembled Without Gauzes — Caution Taken by Firebosses to Avoid Danger of Cracking Glass — Need of Expansion Rings

REFERRING to the letter of Joseph Cain, Coal Age, July 13, p. 60, I want to congratulate him on the serious view he takes regarding the importance of testing every safety lamp before it is taken into the mine. Most of us will agree that sufficient attention is not given to this matter.

In Scotland, where I gained my early experience in mining, the Coal-Mines Regulation Act requires that firemen (firebosses) examine the safety lamps of all men employed in gassy mines. The examination is made at the fireboss station as the men pass in to their work. At the same time, each man is informed of his individual habit of working and the importance of making this examination of each lamp taken into the mine has long ago been impressed on my mind, through my experience in making such examinations as fireboss, and from the many accidents attributed to defective safety lamps.

PRACTICE IN SCOTLAND

The practice is of long standing in the mines of Scotland. It was the custom, there, to supply every fireboss with a small tin tube, for convenience in blowing down the top and bottom of the glass globe, if the working place was nothing unusual for a fireboss to reject as many as five or six lamps in every hundred examined, because of the test showing leakage past the globe.

If any reader doubts that this is an habitual practice in those mines, let him ask a Scotch miner, who has recently come over. Hand him a safety lamp to assemble and he will invariably blow all around the globe, after putting the lamp together lighted and ready for use.

Many a time I have been ridiculed, myself, for this habit, by those who contend that such a small hole would be no larger than those formed by the mesh of the gauze. They seem to forget that the glass globe has no cooling principle like that attributed to wire gauze. Not only would a loosely assembled lamp be unable to withstand a strong blast of air, but it would easily pass flame in an explosive mixture.

As further proof of the importance of examining safety lamps and applying this practical test before taking them into the mine, I have in more than one instance, discovered Marsaut and Mueseler lamps assembled without gauzes. These lamps are provided with slip bonnets that slip over and protect the gauze chimney of the lamp. When this slip bonnet was removed for the purpose of inspecting, the gauze would sometimes be found missing.

NEED OF GOOD EXPANSION RINGS

Now a word about the danger of the glass cracking when that has become heated, the lamp being screwed up tight and there being no expansion washers to allow for the expansion of the glass by the heat. I understand that comparatively few lamps have these expansion rings and in few of these is the ring really efficient.

When a lamp is tightened up on a hard-fibre washer that is non-resilient, there is no yielding to allow for the expansion of the glass. Even with a resilient washer, such as asbestos, the globe is sometimes cracked when the lamp becomes excessively heated in a gas-charged atmosphere.

Many experienced fire bosses with whom I am personally acquainted have long had the habit of not screwing the lamp tight against the globe, until later when the lamp will have become warm on the top and bottom. These men claim they are very particular about tightening up their lamps before leaving the main intake airway, by which time the globes have become fairly warm and expanded. The same men are emphatic in their claim of globes having been broken by tightening them up too soon.

LAMP GLOBES CRACKED BY HEAT

On more than one occasion, I have seen the globe crack when a lamp was hanging on a prop and had become overheated, perhaps by reason of the presence of more than the usual amount of gas in the air.

In a little book edited by L. S. Hawkins, chief of the Division for Vocational Education, in the trade-extension classes organized in coal-mining communities, occurs the following reference:

The expansion ring holds the glass sufficiently firm to prevent shattering and rattling and to keep tight joints, but it has given enough to allow for expansion, if the expansion ring is properly designed it will render it practically impossible to break the glass by screwing the font or lower ring up too tightly.

The United States Bureau of Mines has given much attention to the examination and testing of different types of safety lamps, several of which have been approved by the bureau engineers. One of these lamps, which has an efficient expansion ring, has stood fifty tests in a most explosive mixture of gas and air traveling at a velocity of 2,500 ft. per min., without a single glass being broken or cracked.

Bayview, Ala. JOHN WALL, Sr.

OTHER LETTERS

WITH much surprise I read the account of Joseph Cain, Coal Age, July 13, p. 60, where it is stated that three fire bosses, whose lamps he found to be improperly assembled, gave the excuse that they feared to screw up their lamps tight, believing that the heat would expand and crack the glass.

Such an excuse seems to me more like a grandmother's dream. It is strange to me that there are such fire bosses around. Every one looks to the fire boss as the man whose duty it is to warn them of walking into danger. It is hard to understand how they, themselves, would be guilty of doing the very thing they are supposed to keep others from doing.

HUMOROUS VIEW OF RECKLESS OR CARELESS FIREBOSSES

The fire boss who would prefer to enter a mine with his lamp in an unsafe condition, rather than to make it safe by screwing it up tight, ought not to be bothered with a safety lamp. Taking a carbide lamp, he should suggest to his brethren fire bosses, that they stay outside of the mine while he goes in to make an examination, doubtless, to his own suicide. Better that, than to have a number of men killed through his ignorance.

But, laying joking aside, let me say without hesitation that, in all the gassy mines, in the bituminous region of Pennsylvania, in which I have worked, no fire boss would ever make his second round with a safety lamp in the condition stated by Mr. Cain.

While I agree fully with his suggestion that all safety lamps should be examined and tested before being taken
into the mine, his method of making the test, by blowing around the glass of the lamp, is not the one that I would use to determine the safe condition of the lamp.

In my opinion, the blowing test is insufficient. If such a test should cause a lamp flame to flicker and possibly go out, we might all agree that the lamp was unsafe; but, to my mind, the security of a lamp, under conditions to be met in the mine, has not been proved by blowing against it.

In the blowing test, I would advise having an explosive mixture of gas and air, prepared on the surface at a place so arranged that the lamp could be subjected to such an atmosphere while its action is being observed. I consider the testing of lamps before taking them into the mine an important matter and hope to hear from others along that line. JAMES THOMPSON.

Mayport, Pa.

WHAT seems strange to me, in reading the letter of Joseph Cain, Coal Age, July 13, p. 60, is that he should condemn three lamps as being unsafe, when the cause of the light could be blown out with his breath.

The fact that Mr. Cain only made his special examination of the mine, once in three months, to ascertain its gaseous condition, would indicate that he had every confidence in his three firebosses, who asked to accompany him on this occasion.

HAS LITTLE FAITH IN BLOWING TEST APPLIED TO SAFETY LAMPS

It is well known that the breath from the human body contains carbon dioxide, which would have more or less of an extinctive effect on the flame in a lamp. As I look at it, it is not strange that the three lamps inspected by Mr. Cain could be blown out with his breath.

Let us suppose, for example, that the flame of each lamp was first lowered, as when making a test for gas. Then, if the lamp was grasped tightly with both hands, the fingers covering more or less the openings in the air-admission ring below the glass, it is easy to believe that the flame of each lamp could be blown out with his breath.

Our friend states that he blew hard, just below the glass cylinder where it rested on the brass ring supporting it. It is my belief that it is possible to blow out the light, in any Wolf safety lamp, by blowing hard against the lamp until the air-admission ring below the glass, it is easy to believe that the flame of each lamp could be blown out with his breath.

My conclusion is that this is not a proper test to determine the security of a lamp, and I think that most gas inspectors will agree with me in that regard. It is more important to make a close examination of every lamp and see that all parts are clean and properly assembled, just to make sure that there is no defect or injury apparent in the gauge. But when a lamp has been so prepared and lighted, its flame can generally be blown out with the breath, in the manner described.

OSCAR H. JONES.

Wilder, Tenn.

Heating of Gob Areas

Cause of heating—Use of salt as a preventive—Excluding air from the waste by different means.

I N THE issue of Coal Age, May 25, p. 886, a mining engineer asked for suggestions in regard to eliminating the trouble arising from the heating of gob areas, in longwall advancing. He stated that the primary cause of the heating is the mixture of fine coal, slack and clay cuttings containing pyrites.

It seems that a radialax machine is used for the mining, which was done in a clay hand in the coal, a foot from the roof. Under these conditions, there can be little doubt but that a large amount of fine coal and clay cuttings would accumulate at the working face and have to be either loaded out or stowed in the waste.

Owing to the presence of the sulphur, the stowing of this refuse in the gob would easily cause the waste to heat. To my mind, the suggested application of salt, unless used in excessive quantities, would keep the place moist and have practically the same effect as to saturate the place with water, which it is claimed would increase the trouble.

Not wholly knowing the conditions, it is only possible to make a few suggestions that may or may not be applicable in this instance. Where certain areas are giving trouble by heating, it may be possible to cover up the exposed portion with soil or clay taken from the surface into the mine. Mixed with some salt, this coating would probably remain moist and pack down so as to form an airtight covering, particularly if a light application of water was used.

To be brief, in my experience, there are two ways of fighting these conditions with any degree of satisfaction. The first is, to seal off the area so as to completely exclude the air; or, second, cause a sufficient air current to sweep the waste area to keep it cool by carrying off the heat generated.

Of these two methods, the last named is less practical than the first, because the noxious gases generated are liable to be carried into other parts of the mine. If permitted, I would suggest a combined panel system and modified longwall method of working, in order to eliminate gob-fire troubles.

As shown in the accompanying figure, this proposed method consists in driving the main developing entries three abreast, on a grade favoring the loaded cars. The seam is said to have a moderate pitch and these main entries are driven approximately on the strike but so as to afford a slight grade in favor of the loads. The driving of three narrow and the machine cuttings are loaded out from them.

At intervals of 1,000 ft., branch entries are driven up the pitch, in pairs and on 50-ft. centers, with 55-ft. barrier pillars on either side, leaving solid blocks of coal 1,550 ft. between them to be worked out as panels, in the longwall system. The panels are completed by driving cross-entries, at intervals of 1,250 ft., in pairs, parallel to the main entries and on 50-ft. centers, with 55-ft. barrier pillars on either side.

This makes the size of a working panel 1,500 by 1,000 ft. As these entries, the safest practice is to load out the machine cuttings rather than to gob this material, which will heat if stowed in the crosscuts, as is common practice.

Starting on the main headings, each panel is worked by driving three pairs of butt headings on 50-ft. centers and directly up the pitch, thus leaving 245 ft. of coal on each side of each pair of butt headings, which would be worked out as longwall-retreating facings. The butt headings are driven narrow, 10 ft. wide, through the gob area, which goes to make the working area after which they are widened out to 15 or 18 ft., depending on roof conditions. This extra width not only gives this panel a sufficient ventilation for the gobbing areas, but affords room for storing the cuttings, on the chain-pillar side, between the crosscuts. I want to say, however, that such practice is not recommended, it being advisable to always load out these cuttings.

When a panel is on the retreat system, starting at one end of the pitch, there would be practically six 250-ft. faces or, if worked in steps, thirty 50-ft. faces. Allowing four men working each 50-ft. face and assuming a machine cut of 6 ft., would give an output of, practically, 45 tons, per day, from each face, making the total daily output between 1,200 and 1,500 tons, from a single panel.

The concentration of work thus effected would enable all the coal in a panel to be taken out before much heating took place in the waste. Of course, the coal could be loaded up into the waste to a certain extent, the bottom of the gob being kept open to carry off the heat generated in the gob.
the chain pillars, in the headings, should be pulled as the work proceeds. In case trouble develops, however, the narrow openings, in the 95-ft. barrier pillars, will afford ample opportunity for the building of good airtight stop-

pings sealing off the district.

By making these stoppings sufficiently strong to withstand the pressure of the water, any panel or district could be flooded, if this became necessary. If a district is simply sealed off the usual pipes should be built into the stoppings for drainage and for testing the condition of the air within.

The method I have described, furnishes a means by which the gob-heating problem can be successfully handled. As the development of this system proceeds, the more newly turned branch entries can be used for haulage roads and airways, while pulling the barrier and chain pillars of the cross-entries. With the complete extraction of all the coal in each panel, and allowing for a 20 per cent loss on the barrier and chain pillars, this method should net a 95 per cent extraction of the seam.

Mt. Harris, Colo. Thomas Allen.

Making Americans

Illiterate Americans harder to manage than foreigners—Intimidation of for-

eigners by American leaders—Votes in meetings no criterion—New stand-

ard of Immigration needed.

Reading the excellent article of S. D. Hainley, Coal Age, Apr. 15, p. 619, I am reminded of numerous ex-

periences of my own in the coal fields of Pennsylvania, West Virginia and Kentucky.

While I am in hearty accord with every effort that should be made to edu-

cate the foreigner, in regard to his dilations to the nation, yet my ex-

perience has convinced me that the illiterate American is a harder subject to man-

age than the average foreigner, whom I have found more thirsty, energetic and religiously inclined than the igno-

rant American.

In practically every instance of misery standing with the men, I have found the foreigner always willing to do the right thing, except in cases where he has been intimidated by leaders, who are usually American born. It is these leaders who control the situ-

ation and it is their action that is re-

sponsible for the attitude of foreign mine workers. It is not the money, but the methods adopted that are the true questions of what they assume and believe to be to their interests as workers.

It is a common occurrence for a meet-

ing composed of a majority of foreign miners to be ruled by one or more indi-

viduals acting as their leaders. The votes taken at such a meeting are not the cri-

terion of the real feeling of the men, who are misled and blinded by the rep-

resentation of these leaders.

Taking everything into consideration, I believe it is going too far to expect every man entering our country to be able to read and write the English lan-

guage. This opinion is strengthened when we consider the hundreds of thousands American-born workers, who are illiterate and about whom we ex-

hibit less concern than the foreigner who migrates to our shores. I am speaking now educationally.

In my judgment, a far better standard on which to base our immigration laws would be one based on a higher moral and physical footing. The moral attribute, in a man's character, stands for more than his intellectual attain-

ments when we are striving for citi-

zenship and national ideals. Proceed-

ing on this plan, there will be little doubt but that the educational training required will follow.

Effect of Storage on the Heating Value of Coal

KINDLY permit me to ask a ques-

tion that, at the present time, has a peculiar interest. It relates to the storing of coal during periods when the production exceeds the demand. There has been a well defined prejudice against the use of storage coal, the claim being that the heating value has been impaired and that the coal does not burn as freely as when it is freshly mined.

The present state of the coal industry must impress everyone with the many advantages to be gained by storing coal. Not only is it true that the means of affording miners more steady work, during the dull season when trade is slack and the market demand low; but it would tide over such periods of de-

pression when industrial disputes have closed the mines and the supply of coal is limited.

With these thoughts in mind, I want to ask the question: If coal is pur-

chased and kept in storage for one year prior to its being used does it possess the same heating value as freshly mined coal? In other words, does coal depreciate in heating value and to what extent? Can a furnaces be worked as easily with old coal as with coal fresh from the mine?

New York City.

W. L. Jacobson.

The question of coal storage is, in-

deed, an interesting one at the present time. A large public is brought face to face with a condition that will be appalling if continued but a few weeks longer. As pointed out in this inquiry, the storage of large quantities of coal would have the ad-

vantage of keeping the mines running more regularly during a slack market, or when the supply of cars is wanting. It would eliminate one of the chief hindrances in the work of the miner, by giving him fairly constant employ-

ment. It would help to stabilize the in-

dustry, in the matter of the price paid by the consumer, and avoid the fluctua-

tion that is common to the present sys-

tem. With the guarantee of fairly steady work, the coal miner would not have the excuse he now offers for dem-

anding higher wages, and the present high price of fuel would more quickly become normal.

Referring to the question asked by the inquirer, it can be stated that the heating value of coal that is properly stored and protected to the same ex-

tent as is generally believed. Much depends on the size of the coal and the manner of piling. These factors are more important than the matter of ventilating the pile, which has often been urged as a necessary requirement, and can be overcome by proper glazing and spontaneous combustion.

The result of the experiments made along this line, by the Federal Bureau of Mines, as well as work of a similar nature undertaken by the University of Illinois, shows that the heating value of coal that is properly stored, does not ma-

terially decrease.

Attention has been drawn to the need of eliminating from the coal to be stored, the smaller sizes, including fine coal and slack. It is also needful to prevent the segregation of coal of different sizes, as invariably happens when the coal is dumped at the top of a conical pile. The larger sizes then roll down the sides of the pile, leaving the fine coal at the top.

In order to avoid this condition, the coal should be deposited in uniform layers over the entire area. There is less difficulty of fractional when it is stored under cover, but this is not al-

ways possible or practicable.

The prejudice prevailing more or less widely in respect to the use of stored coal arises largely from one or two sources; namely, the improper piling of the coal and the mixture of refuse gathered from the floor of the pile, in replacing the coal. Naturally, there is a greater loss in the storage of the softer and more friable coal, than occurs in the storage of anthracite and the harder grades of bituminous coal.

Little trouble is experienced in the storage of anthracite, owing to a less Inquiries Of General Interest

Size and Piling of Coal More Important Than Ventilat-

ing the Pile—Experience Proves Heating Value Not Materially Impaired—Prejudice Due to Various Causes

August 17, 1922
tendency to slack; and there is not the same danger from overheating in the pile and spontaneous combustion resulting therefrom. Coal containing sulphur (pyrites) is more subject to overheating and firing, by reason of the oxidation of the sulphur. For these reasons, all coals are not stored with the same degree of success; the softer and inferior grades requiring to be watched more closely than coal of better quality and harder.

When coal is to be stored a large level area should be selected and prepared by removing all refuse and vegetation from the surface. For a permanent storage plant, nothing is better than a concrete floor. Large storage bins, if properly erected, will greatly assist the reclaiming of stored coal. In any event, every precaution must be taken to reduce the breakage of coal in handling and eliminate its rough use of any kind.

Some difference of opinion exists in regard to the ventilating of coal piles. If this is done, however, sufficient air must penetrate the pile to carry off the heat generated. The introduction of a small amount of air only gives rise to oxidation, while not reducing the amount of heat that results.

Consequently, better results will often be obtained by excluding the air and moisture as far as possible. The floor of the pile should be well drained; but tiles, for that purpose, should not be laid beneath the pile, as that would give opportunity for the entry of air to the center of the pile. Every storage pile should be closely watched for the first evidence of heating, and space should be available for the removing of such portions of the pile before the trouble increases.

It should be stated, in closing, that stored coal loses some of its coking qualities and has not the same value for making gas. In storage, the coal loses some of its gas and, in firing, needs to be spread in thinner layers over the firebed. At the same time, its heating value, depending largely on the fixed carbon, is not depreciated.

**Examination Questions Answered**

**Miscellaneous Questions**

(Answered by Request)

**Question**—In a mine giving off 2,250 cu. ft. of marsh gas (CH,) per minute, the volume of air entering the mine being 70,000 cu. ft. per min., what is the percentage of gas in the air current at the outlet?

**Answer**—The total volume of air and gas, at the outlet, in this case, is 72,250 cu. ft. per min. The percentage of gas in this current is, therefore, 

\[
\frac{2,250 \times 100}{72,250} = 3.11\text{ per cent.}
\]

**Question**—What are the duties and qualifications of a shotfirer?

**Answer**—The duties of a shotfirer are determined largely by the company who employs him. In some cases, the shotfirer is charged with the duty of examining, charging and firing all shots prepared by the miners that are, in his judgment, safe. At other times, the miners not only drill their own holes, but charge and tamp them ready for the firing. But, in such cases, the shotfirer must examine every hole before it is charged by the miner. After the men have left the mine, it is the duty of the shotfirer to make his rounds and fire the shot in regular order, starting on the end of the air and proceeding against the air current.

The safest practice, however, is to make the shotfirer responsible for the entire work, locating and drilling all holes, and then charging, tamping and firing them, after the men have left the mine. In that case, the work of the miner is limited to loading the coal into the cars ready to be hauled out of the mine. In other words, the miner becomes a loader only and is not permitted to perform any of the work of blasting the coal.

The qualifications of a good shotfirer are the result of the necessary knowledge, experience and judgment that will enable him to break down the coal in the safest and most economical manner possible. In other words, he must be able to produce the largest amount of coal, with the least weight of powder consumed, and in the best marketable condition. He must be an active, industrious man, cautious and not given to taking chances.

**Question**—Blowout shots: (a) Under what conditions may a blowout shot take place? (b) What danger may arise from the same?

**Answer**—(a) A blowout shot may result from the charge of powder being improperly located or because the shot has not been properly mined or sidetrack, making the line of least resistance correspond more or less closely to the axis of the hole. Again, the hole may be overcharged, improperly tamped, or have too large a diameter; or different grades of powder may have been used in the same hole.

(b) A blowout shot always projects a large volume of flame from the mouth of the hole. If there is any dust accumulated in the place, this is blown into the air by the force of the shot and will probably be ignited by the flame of the burning powder and produce a local explosion of dust, which may or may not be extended throughout the mine, depending on the conditions existing in the workings.

**Question**—Describe how you would timber an entry where the roof alone needs support.

**Answer**—Assuming a fairly good slate or shale roof where the coal is hard, it is common practice to support the roof, at short intervals of, say five or six feet, with good crossbars, set in hitches cut in the top of the coal as shown in Fig. 1. When in position the bars are firmly wedged at each end. Where the roof is more frail and liable to scale off and fail between the crossbars, some form of lagging must be used above the bars.

Where the coal is less hard, the crossbars must be supported on legs, on one or both sides of the entry. If the hardness of the coal will permit, short legs set in hitches cut in the rib, as shown on the left in Fig. 2, are used to support the bars. Otherwise, the long legs, shown on the right of the figure, must be used. At times, in order to avoid the being knocked out by a derailed car, these legs are set back into the rib.

**Question**—Make a sketch of a set of timbers, showing how you would wedge them and give reasons for your method.

**Answer**—As shown in Fig. 2, in the last question, two wedges should be driven between the collar and the roof, near the top of each leg. The effect of this is to transfer the weight from the center to each side post and not permit it to bear on the center of the collar.

**Question**—What is the weight, in tons, of the air constituting the ventilating current of a mine when the combined volume of the several currents or splits is 2,240,000 cu. ft.?

**Answer**—We understand this question as referring to the weight of the entire air volume; therefore, to determine its weight, it is necessary, however, to know both the temperature of the air and the barometric pressure. Assuming a temperature of 60 deg. F. and a barometer of 30 in., the weight of a cubic foot of air is 0.0766 lb. The weight of the given volume, in short tons, is then 

\[
\frac{2,240,000 \times 0.0766}{2,000} = 85.8\text{ tons.}

Is Western Kentucky Lolling in a Bed of Wealth?

Many Coal Producers Reap Unheard-of Profits—One Lucky Striker Pays $1,500 for "Pot Hole" and Gets $2,200 for Four Carloads—But Car Shortages and Few Contracts Restrict Earnings in Feast-or-Famine Field

BY A. W. WILLIAMS
Louisville, Ky.

T

HE EYES of the coal industry have been turned on western Kentucky during the past few weeks, and few questions are heard oftener than the one concerning "enormous profits." However, giving the devil his due, it is necessary to look at both sides of the situation impartially. Some western Kentucky operators are making big money. Some are doing well. Some have been barel "skating along."

Western Kentucky for many years has been a field that failed to make much progress or any large amount of money. While West Virginia and Pennsylvania operators were looking upon us as "coal barons," western Kentucky operators were having a hard time in operating their mines and getting interest out of their investment. For years western Kentucky had a quite fair demand for domestic sizes in the Louisville, St. Louis, Nashville, Memphis and some Southern markets. Freight rates were against her in almost every port of the Ohio River. There was cheap coal in Illinois and Indiana, Ohio, Alabama, Tennessee and eastern Kentucky, and production was cheaper as a result of western Kentucky being a pit-mining section, while many other fields were using drift methods.

Old timers tell interesting stories of how they tipped scowlings into cars free of charge to railroads for use in building fills and grades. There was no demand to speak of for mine-run other than a little railroad demand. In producing lump coal at a low price in order to compete with other fields it was necessary to give away or bank the screenings. There were no big industrial cities that could take western Kentucky fuel profitably at a price that would allow the operators to make money. The fuel was consistently "knocked" by competitors because some of it was poorly mined and of poor quality. However, most of western Kentucky's fuel is of good quality—a little high in sulphur, a little high in ash, but also quite high in heat units.

The operators finally pulled themselves up by their bootstraps, so to speak. They put in a first-class traffic department and ended up in charge of a competent lawyer. They worked for equitable rates to the North, West and South, and were signal fortunate in improving their condition. During the war period Pittsburgh coal dropped out of the Ohio Valley and Southern markets as Ohio River transportation methods fell into the discard, and war activities took the entire production of the Pittsburgh district. Western Kentucky coal then moved into a wider area and made good.

Following the war there were periods of feast and famine. In 1920 the field made some money. It was not amenable to the efforts to enforce fair prices, as Federal Judge Evans, of the U. S. District Court for Western Kentucky, at Louisville, believed in the laws of supply and demand, and held that any effort to force a so-called fair price was unconstitutional. Western Kentucky asked her own prices and obtained them.

In 1921 between higher production costs and trouble in meeting competition some mines lost part of the profits they made in 1920. Then the eastern Kentucky sections, which were non-union, cut back to the 1917 wage scale, and offered western Kentucky a brand of competition that it was impossible to meet profitably, except in a few cases where freight rates favored.

However, back in the spring of 1920, when the old wage agreements had been up for renewal with the unions operating in western Kentucky, the operators were foresighted enough to hold out for a protecting clause when the strike came off. The strike lasted a short time, and finally an agreement was reached whereby the same general wage scale was offered as that in effect in Indiana, Illinois and elsewhere, but with one amendment concerning the question of returning to work. The so-called "strike clause," under which the workers would not go out on strike if the mine were in need of additional coal strike, provided the operators paid the peak wage, as called for in the contract, and continued paying this wage until the national strike was settled and a new general basis was arranged for mine labor.

The western Kentucky operators realized that a national strike was inevitable in 1922, when it was a foregone conclusion that the producers of the nation's coal endeavor to lower the wage scale which was forced upon the industry by war-time demand and conditions in the labor markets.

The consequence of the good work of the western Kentucky operators was that when the national strike came off there was no labor trouble in the field. However, Mr. Hoover in distributing that as a return basis of $3.50 a ton for all fields was equitable and fair. He told the operators to put the cart before the horse in the judgment of western Kentucky. Such a basis if fair for eastern Kentucky and West Virginia, operating on a 1917 wage-scale basis, was held to be unfair for western Kentucky, operating on the peak scale. Western Kentucky offered to accept $4.25 mine-run basis, but was turned down. That maneuver left the field under no obligation to the first Hoover conference.

SUPPLY AND DEMAND ONLY REAL PRICE BASIS

As demand for industrial and rail fuel increased and stocks in hands of public utilities, railroads, industrial concerns, etc., were reduced, prices began climbing. The old laws of supply and demand came into their own. Western Kentucky holds that there is no real price basis other than supply and demand, and any other effort to shape prices causes a fictitious market.

The operators proceeded to mine all the coal they could and sell it for the top price offered. Mine disability, some shortage of labor in a field that has not had opportunity to operate at capacity, some car shortage caused through poor service of equipment, and the fact that the physical capacity of the roads was not equal to the capacity of the mines prevented full-time production. However, prices hung at between $3 and $4 a ton until the walkout of shopmen resulted in severe car shortage, not only in the western Kentucky union field but in the non-union fields elsewhere.

Districts which had never purchased a pound of coal in western Kentucky began to demand it. Coal became coal, and there was no agreement concerning size, prices being the same for any size. Long freight hauls, which under ordinary conditions would prevent purchase of western Kentucky coal, were forgotten. In June many consumers held off and refused to buy while waiting for the freight-rate reductions of July 1, which resulted in a rush of buying after that date, along with the rail strike.

Why should western Kentucky coal sell at $3.50 a ton in districts where she had not had any previous business and no prospects of future business, if this same coal could be sold for $7 or $11 a ton? Seven and eleven were always triumphant numbers.

Buyers representing jobbers were active in the fields, searching for coal that could be supplied on demand or on announced tonnage. Buyers of concern of public utilities were in the fields, from the industrial plants and from every line of steam consumption. Retailers for a time were interested, but didn't buy much coal, figuring that if the strike broke right, they could obtain it cheaper later on.

As prices advanced jobbers demanded a larger fee for handling coal. In taking the financing of $7 to $11 coal the
jobber had to carry big credits, and at 15c. a ton couldn't get his interest out of investment. He demanded up to 50c. a ton and got it.

From July 1 forward car supply has been one of the most uncertain of all uncertain things. On one day there are no cars at many terminals. The next day there may be a supply of 33 per cent, or 50 per cent. Railroad figures showing cars asked and cars supplied don't always tell a true story. Operators assert that they haven't received nearly the percentage of cars asked. Many cars loaded with coal were days and even weeks in getting away from the mines, due to shortage of engines and to congestion in terminals. Other connecting roads were unable to handle cars turned over to them or to get empty cars back to the originating lines.

Getting down to cases, any mine producing full capacity and selling at $7 to $11 a ton would clean up. A mine with a daily capacity of 3,000 tons, produced at an average of $2 a ton and sold at an average of $5 a ton, would coin $18,000 a day, or something over a million dollars in sixty working days. However, there are not many 3,000-ton capacity mines or companies in western Kentucky and, unfortunately none of them has been able to run at capacity, or even 50 per cent of capacity as an average.

Production costs on full time operation, it is alleged, could be held at $1.90 or under even on the peak wage scale, although some operators argue that the lump costs is $2.25 a ton and that it runs up to around $2.50 a ton on only part-time operation. However, anything over $2@$2.25 a ton appears mythical, in view of the fact much lower prices were quoted in the spring, when mines were not busy.

Take, for instance, the week of Feb. 13—prices quoted at that time through jobbers showed lump, $2.25@$2.75; mine-run, $1.90@$2.00; slack, $1.60@$1.75. mines were charging the early spring sold at under a dollar, with no appreciable increase in lump. Operators asserted that they were losing money, but were forced to run to hold their trade and to take care of contracts.

PLAYING FAIR WITH RAILROADS INSURES CAR SUPPLY

Contracts—another feature overlooked by those who assert that western Kentucky is cleaning up—have been taking coal from more than one mine at prices ranging from $2.25 to $2.75 a ton. This accounts for a part of the small production that has been available in the market during the last few weeks and left less coal for the open market than the early figures show.

One operator without business last season was treated white by the Illinois Central R. R., which took his production at $2.60 a ton. Just recently the road is reported to have offered to take his production at $2.75 a ton, and the operator played fair and accepted the proposition at a time when he could have sold his production on the open market for much a higher figure. However, he is getting car supply.

So there have been all sorts of obstacles to getting rich quick. The big operators are not as likely to have been making big money as the "pot hole" operators. One small mine was sold a few months ago for $1,500, it being little more than an opening in the side of a hill. On Saturday, July 25, the operator offered $2,200 for the four-ton cars he had loaded, the average being $11 a ton. In buying the mine he took a chance, played his hunch, and made money.

Under ordinary conditions he would merely have a hole in the ground. As he couldn't hope to compete with the large mines, with fine equipment for producing at a low cost, his mine would be idle and he would be paying taxes on a hopeless investment. As it was his production cost for the four cars was much higher than at well-equipped mines, yet those four cars paid for the whole mine.

Railroads have been taking a great deal of the production in western Kentucky, paying all the way from $2.60 to $3.50 a ton where purchased by the line on which the mine is located. Outside railroads, such as the Rock Island, have not taken the market. The advantage in treating the originating line right lies in car supply. There have been some contracts at $2.25@$2.50, and in some cases agreements have been reached whereby the price was advanced and deliveries continued.

Throughout the period of high prices car supply on the Illinois Central R. R. to western Kentucky mines has been fair, running up to around 75 per cent most of the time. This would indicate that mines which have been fortunate enough to be located on the Illinois Central, are the ones that have been cleaning up. Of course the Illinois Central has been drawing the bulk of its tonnage from these mines, reducing the available supply for open market. However, on the Henderson and Ohio & Northern divisions of the Louisville & Nashville R. R., car supply has been rather steadily under 50 per cent average, running a little better than that on the Henderson perhaps, and down to 30 per cent on the Ohio & Northern.

Some production is expected to resume in two weeks without moving, Madisonville, Ky., reporting coal loaded on July 11 finally moving out on July 24. This is in the "interesting if true" category.

It is held that the potential capacity of the western Kentucky fields is around 1,900 cars daily. However, the railroads can't handle that amount of tonnage. In a recent big western auction you are bested prices we fuel in competition would show about 1,330 cars a day, although, generally speaking, operators assert that railroad capacity is around 1,500 cars a day. It is said that the Illinois Central R. R. on Tuesday, July 25, handled 878 cars of coal from its western Kentucky mines, but this cannot be verified. Total production of the field probably has been around 750 to 1,000 cars a day, according to some well-posted coal men.

FEEL ENTITLED TO CLEAN UP IF ABLE TO

Whether western Kentucky is cleaning up is a matter of conjecture. The field frankly enough feels it is entitled to do so if it can get away with it. As one coal man aptly expressed it: "There ain't no one that ain't going to sell when ever he is selling for all he can git for it." Another coal man remarked: "There isn't anyone that is going to buy our coal from us unless they can get better coal for less money from us than from anybody else. They are not going to pay us any more than they have to pay in some other field. They are not going to pay a higher freight rate to get our coal under normal conditions than they will pay to get a lower grade coal from another field. On emergency business if you are having a hard time getting it elsewhere, you can turn another crack at, it is the price is the governing commodity in ordinary fuel coal. If we can meet the price of the other field we can't always meet the freight rate. A lot of good it would do us to take care of a lot of buyers who have never been in the field before and who never will be in it again, merely for the hopes of getting some of their business when conditions round on the railroads that way.

"The western Kentucky coal man is being blamed for a lot of things over which he has no control. He is not given credit for being an intelligent business man. The old talk of the orphans and cold tenements is bobbing up, but it is still a long time before cold weather, and all immediate production is emergency production, which wouldn't go to the retail 30 cents. Coal is in a position in which it is going to reduce prices that the mine operator will pay for his blasting powder, for his picks, shovels, mine cars, etc. The cost is being paid by the utilities, which do a lot of gorging whenever they have the opportunity; by the railroads, by big industries, etc., and of course the consumer has to pay a little of the cost himself. However, the coal game is a deal of interest there is nothing in the world.

The general motto has been: "Get it while the getting is good." The coal trade in western Kentucky is generally described as one in which either a feast or a famine prevails. The leftovers from the feast take care of the periods of famine; otherwise most companies would be broke.

THE AMERICAN FEDERATION OF LABOR has discontinued its mining department which had been maintained at the Washington headquarters for special consideration of mining matters. James Lord, who has been president of the department, has taken the field as a labor organizer and will operate in the Pacific Coast region. It is said the abolition of the department was due to a large extent to differences which have arisen between Samuel Gompers, president of the American Federation of Labor and John L. Lewis, president of the United Mine Workers.
Washington Officials View Outcome at Cleveland As Makeshift Truce—Public the Loser

BY PAUL WOOTON
Washington Correspondent of Coal Age

EVENTS at Cleveland have progressed to the point where they foreshadow the beginning of the end, observers in Washington believe. The agreement promises to bear enough semblance to a national arrangement to save Mr. Lewis’ face. It is regarded here, however, as very evident that Mr. Lewis has lost his fight for a national agreement. It was regarded as a farce to follow out the old plan of two operators and two miners from each state where the votes from Ohio represented practically all of the tonnage covered by the agreement they proposed.

Federal officials are inclined to regard the result as something of a draw. The strength of the union has been clearly demonstrated. The mine workers have successfully resisted a reduction in their pay. The check-off will continue and working conditions remain unchanged. The operators at least have broken up the central competitive field. The prospects are that the union will lose the weakly-organized districts. No one of the fundamentalills of the coal industry has been remedied. Every issue involved in this strike must be fought out again. A truce now appears to be a certainty, but it will be a make-shift one.

The public is more concerned with the net effect of the strike. There has been a great industrial set-back. There has been widespread unemployment. The nation’s fuel bill for 1922 will be $300,000,000 more than it was in 1921. One-half of one per cent of the population has taken an advantage of its freedom to dominate the supply of a necessity of life. The interests of 99.5 per cent of the population have been affected adversely. There has been no humbling of the organization responsible. No industrial disciplining has resulted. Nothing of permanent value to the public has come from the strike.

While there is no doubt that many operators will not hold out long against the restoration of the 1920 wage scale, it is recognized that should Pittsburgh or any of the other individual districts refuse to become parties to the Lewis agreement, they must make up their minds to take severe punishment. They are certain to get it. With many union men working, strike benefits soon could be paid which would enable the men in those districts to hold out longer. It would be particularly difficult to reduce wages when even the non-union fields are pushing wages to the 1920 level.

As more and more is learned of the situation, it is being revealed that the United Mine Workers were on the ragged edge when they induced the President to call the conference in Washington. They appealed for arbitration as a last refuge. They knew that arbitration meant a reduction in the wage scale. But before the conferences had progressed very far, the railroad shop crafts went on strike and demonstrated unexpected strength.

This change in the situation put a new face on the whole matter. Mr. Lewis was quick to take full advantage of it, but he over-reached himself. He thought the operators would be forced to push themselves through the needle’s eye that he held up for them at Cleveland. In that effort there is evidence that he was bolstered and encouraged by coal operators in eastern Ohio. The response to his invitation was a great disappointment but the real need for a national agreement had passed so Mr. Lewis has been willing to negotiate with eight per cent of the country’s normal tonnage. His previous declarations that he would deal only with the bulk of the tonnage were abandoned without explanation.

One of the big factors influencing operators to get back to work is the fear that they will lose markets permanently to the non-union districts which have a better coal. Reports to Washington indicate that many industries, now that they have had a taste of high-grade coal, intend to use it permanently. Other companies fear the loss of business.

Interference of Priority with Contracts to Be Limited Except in Emergency

THE Federal Fuel Committee is giving serious attention to the problem of transporting coal supplies from Kentucky and the Virginias up the Great Lakes before navigation is suspended. It has been agreed tentatively that at present $25,000 tons per week will be allotted to this service, but this figure may be changed at any time as the daily coal production and movement varies.

The problem of the distribution of car supply between mines engaged in the shipment of coal classified under No. 1 priority and those shipping coal to public utilities and other consignees under previously-made contracts continues to demand the attention of the Fuel Committee according to a statement issued on Aug. 10. Though the committee desires to preserve the integrity of contracts as far as possible, its feeling is that general contracts must in a measure take secondary position to the meeting of particularly urgent coal necessities created under an exigency which has arisen since such contracts were made.

Present plans of the Fuel Distribution Committee are that orders for Class No. 1 coal shall be so distributed as not to disturb seriously the proper distribution of cars. All orders for coal considered to be within that classification will go to the district committees who will apportion the orders among the mines in their districts. In such apportioning of orders it is expected that contracts outside the area will be considered. In this connection, it is pointed out that many operators, having in mind the maintenance of their normal business relations, would prefer to devote their energies to filling their regular contracts.

The Fuel Committee is seeking a practical method of insuring that coal ordered through a retail dealer for the use of public utilities or hospitals will not be diverted to other channels. Where it is manifest that an order for coal comes
within a particular classification, no certification to the railroad will be necessary to obtain priority under order No. 23, of the Interstate Commerce Commission.

Where, however, the consignee of a shipment does not show the character of the coal and its uses it will be necessary for the shipper to obtain a certificate from the State Fuel Administrator that the coal is to be used in Class 2 priority, and a certificate should accompany the consignee's order to the mine. This will obviate taking matters of this kind to the Washington Central Committee, as it will give the mine operator the information needed to enable him to obtain from the railroad, cars to which he is entitled in making shipments of priority coal.

The Surveyor of the Virginia, which has been doing considerable amount of business in the Virginia, has been diverted to the Virginian Ry. Shipments of coal from southeastern Kentucky are being retarded to some extent by conditions at Corbin, Ky., where more than 300 railway mechanical employees are said to have left their employment because of threats of violence, but in the western Kentucky field coal production has been accelerated by a 100 per cent car supply.

The Department of Justice has rendered an opinion to the effect that priority orders for coal issued under Classification No. 1 of the Interstate Commerce Commission, have preference over other orders which operators may have on their books.

Washington, Aug. 12—After checking up ship charters, the National Merchant Marine Association estimates that imports of British coal during the next month will approximate 1,000,000 tons. Practically half of that amount will be carried in vessels flying the American flag. The rush to charter coal ships is welcomed by the Merchant Marine Association for the effect it is having on the idle fleet of the United States Shipping Board. In the course of its study of the situation, the Association found that 2,000,000 tons a month is the absolute limit of British exports at this time. The capacity was greater during the war, but much of the coal handling machinery at tidewater no longer is serviceable. Since Great Britain is not likely to neglect its regular export coal trade to look after the temporary needs of the American market, the Merchant Marine Association reaches the conclusion that exports from England to the United States are not likely to exceed 1,000,000 tons a month. Secretary Hoover states that the cancellations of orders placed in Great Britain, which have been mentioned in the press, only applied to orders which the British could not fill.

Fuel Distributor Spencer states that wholesalers are being allowed to charge the commissions provided under Dr. Garfield's regulations. This commission is not allowed, however, when railroad coal is purchased through a sales agency, Mr. Spencer stated. While weak spots have developed in the supply of coal for public utilities, Mr. Spencer states that谈恋爱 generally not filled by the State

Holbrook, of Bureau of Mines, New Head of School of Mines at Penn State

E. A. HOLBROOK, the assistant director of the United States Bureau of Mines, has accepted an appointment as dean of the School of Mines of Pennsylvania State College.

Mr. Holbrook frankly admits that he is leaving the government service with reluctance. He says that the work has been particularly congenial and that the opportunity offered to do valuable public service never was greater. He believes, however, that he has made all the contribution to the public service that he can afford and has accepted this new position because of the very material salary difference.

The resignation of Mr. Holbrook has been called to the attention of the congressional committees studying reclassification of government salaries and cited as an example of the loss of highly necessary technical skill which absolutely cannot be replaced at present salaries.

The salary of the assistant director of the Bureau of Mines has stood still for ten years. Formerly, salaries in educational institutions were on about the same level for comparable positions in the federal service. During the period that federal salaries have remained the same, college salaries have more than doubled.

Priorities Reduce Steel-Mill Operations

UNDER priority orders as well as under the system of car distribution now in effect steel mills in the Wheeling District and in the neighboring states of Ohio and Pennsylvania are suffering from a fuel shortage which has resulted either in restricted operations or in a complete suspension. It is next to impossible for many of the mills to obtain fuel owing to the preference given the railroads and utilities. Other industries are also suffering from a lack of fuel, but the shortage is making itself felt to a greater extent in the steel industry than in others where there was not as much activity. Steel mills had already been adversely affected by the rail strike but with their fuel cut off and with open-tops being given to the mines to the exclusion of other industries, steel mills have found it impossible to transport their products to market.
Illinois Operators Determinedly Hold Out at Chicago When Lewis Refuses Arbitration

BY E. W. DAVIDSON

ARBITRATION was the one important issue which prevented President Lewis of the United Mine Workers of America from drawing Illinois into his Cleveland conference last week. For four days from Tuesday until Friday, the operators of Illinois remained in session at Chicago, burning up the telephone and telegraph wires to all points of the compass making suggestions and proposals that would have opened the way to their taking part in the Cleveland conference—a basis of straight-out arbitration. That state even sent a delegation composed of Andrew J. Maloney, J. W. Needham and H. C. Perry to Toledo to meet W. A. Glasgow, attorney for the miners, but it refused to approach Cleveland unless arbitration was agreed to. This Lewis refused. So Friday at noon the operators adjourned sine die and went home saying Lewis might sign up a string of operators in some sections but that their job was to keep Illinois men out of it.

Before the Illinois men adjourned, they cast a heavy bomb into the labor camp by publishing a letter from President Harding endorsing their position. All week long they offered to deal with Lewis, sending the miners back to work at the 1920 wages and conditions provided he would agree to arbitration. He failed to practically Lewis made out. They wired Frank Farrington, Illinois miners' president, who was talking at the Cleveland conference, that their previous one-state offer to him to reopen the mines at the old scale for the winter pending arbitration still held. It was a week of determined refusal to surrender. Illinois said it would not go to Cleveland to deal with Lewis on his terms and it didn't.

During these days of the split of the operators there was a strong sentiment in favor of capitulation. There were operators who said there was no use kicking any longer against the price, and that the attainable price of coal this fall and winter would justify Illinois in surrendering. But stern stuff prevailed. The majority clung to the belief that if Lewis would not agree to arbitration when all his other points were conceded to April 1, 1923, then he would be hanging himself if he were allowed to go ahead and make a wage scale with as many operators as he could line up.

"It's a fight to a showdown," was the final word of W. K. Kavanaugh, president of the 5th and 9th District Operators' Association as he started for his home in St. Louis at the end of the week.

"There is nothing we honestly could to produce a strike settlement out of this occasion," said an operators' official. "Having been in great doubt as to just exactly what Lewis was willing to do since he was trying to reach us through outside parties—and being unable to find out any other way, we sent our delegation of three to Toledo to meet Mr. Glasgow and find out. We found out Mr. Lewis had nothing to offer that we could accept. Mr. Lewis cannot say hereafter that we did not give him very opportunity to meet us on the fair basis we proposed."

There is no doubt but that the action of Alfred M. Ogle, president of the National Coal Association helped to strengthen the unity of the Illinois men against Lewis' conference basis. When it became known that Lewis had met Ogle in Philadelphia previous to the Cleveland conference, and that Ogle had tried his best to bring Illinois and Indiana into the meeting, the feeling against Ogle in Illinois was bitter. There is much discussion about withdrawals of western groups from the National, as a result.

All week long there were preparations being made at many of the Illinois mines clearing the works for production. Boilers were fired, mules were taken from pastures down shafts and pumps and fans were speeded up. Officially the operators denied that this meant any weakening on their part. Certain owners believed they might have opportunity to dig coal all of a sudden, and they were getting ready; that was all. Union officials throughout the state prophesied they would all be back at work soon.

"If they are," commented an operator at the close of the week in Chicago, "then it will be because we have made a separate state agreement with Farrington. That, it seems to me now, is the most likely outcome of this whole case."

The letter of President Harding to the Illinois operators, addressed to Dr. F. C. Honnold, written Tuesday, Aug. 8, follows:

"I am writing to make acknowledgement of your telegram of Aug. 4, in which you convey to me the proposition made to the mine workers in the State of Illinois. I am frank to say I do not see how your workmen can refuse such a proposal. If terms can not be settled on so liberal an offer it is manifest that the mining situation is very badly tied up, and the government must find for itself some way of extrication."

The final message to President Lewis on Friday noon was this:

"The operators of the State of Illinois have today adjourned their conference. They are willing to reconvene to consider any proposal of the miners of the State of Illinois that carries with it a final and unconditional the most liberal arbitration proposal recently made by the President of the United States, carrying old scale of wages and conditions. We regret exceedingly your arbitrary position and your refusal to consider any plan except the unfair and unreasonable one you have offered. The people of the United States must now draw their own conclusions and we are willing to have our hands cast in the ballot box."

The telegram to Farrington renewing the Illinois offer to reopen the mines at the old wages and fix a new scale and set of working conditions by unbiased arbitration was:

"The operators of the state of Illinois have adjourned their conference today subject to the call of the three presidents. They are prepared to reconvene at any time to discuss with the miners of Illinois the proposition of resumption of mining along the lines heretofore submitted to you as their president. We will not attend the conference at Cleveland as Mr. Lewis has refused to discuss the propositions submitted by the President of the United States, and that provided arbitration points on which we will be unable to agree.

"We ask you again to carry out your contract with us to provide a contract to settle the mining scale in Illinois, and we again renew our proposition to open our mines at once on the old scale and conditions with an agreed submission of all disputed points to a board of arbitration composed of fair-minded citizens of the state of Illinois who are not in any way connected with the coal industry, their findings to be accepted without reservation by both sides and to be effective April 1, 1923."

The Illinois case as it stood at the end of the week is set forth to the public thus: "The adjournment of the meeting of Illinois operators who have been constantly in session here throughout the last four days, and their repeated refusal to attend the present meeting at Cleveland, Ohio, which was called by Mr. Lewis, is due to the following facts. The question involved is the right of the public to have a voice, through arbitration in the determination of industrial disputes, thereby preventing the abusive use of power by labor leaders."

2. The four state conference method of determining wage scales and working agreements in the coal industry has proven its ineffectiveness, its lack of fairness as a method of determining scale of wages and working conditions has been challenged by the courts as being an illegal and improper procedure.

3. The mine workers' plan of a national conference of operators and miners is open to the same objections; and in addition thereto would practically guarantee a country-wide monopoly of mine labor such as that now prevailing in the state of Illinois.

4. The Illinois operators have submitted to the mine workers several very fair proposals for a settlement. The operators have given the most careful and thorough consideration and reply to every proposal by the mine workers, or submitted by public officials or public spirited citizens.
They have accepted without reservation the proposal of the President of the United States and have continually offered to confer or negotiate, provided that, in the event of failure to agree, there should be public arbitration of disputed points and thereby avoidance of a repetition of the present tie-up. Mr. Lewis has constantly declined every proposal which carries bona fide arbitration of disputed points, and has always refused to meet except after acceptance of his own conditions. Four solid weeks.

"The Illinois operators, after twenty-five years' experience, are convinced that joint collective bargaining such as now prevails in the coal industry, is not only unsatisfactory but inimical alike to the coal miners, to the coal operators and to the coal consuming public, and that for such procedure negotiation supplemented by fair arbitration must be substituted."

"The present meeting in Cleveland is in no sense representative of the coal industry. Operators producing possibly 30,000,000 tons of coal per annum, out of about 500,000,000 for the country and 225,000,000 tons for the former Central Competitive field, are there. The states of Illinois and Indiana, producing more than half of the old Central Competitive field tonnage are practically unrepresented."

"We have renewed our demands that the Illinois mine workers honor their contract obligation to meet us in State conference—and have also renewed our offer of Aug. 4 to re-open the mines on the old wage basis until March 31, 1923, pending negotiation and arbitration of a new wage scale."

Ford's Plan to Run Corbin Shops Fails
L. & N. Says It's "Unthinkable"

HENRY FORD'S efforts, aided by Governor Groesbeck of Michigan, to obtain control of the L. & N. shops at Corbin, Ky., regarded as the key to the coal supply of the Northwest, has so far failed. Governor Morrow of Kentucky, who was understood to be lined up for the Ford proposal, did not come to Louisville for the conference between the L. & N. and Ford's representatives, but went to Corbin, the "railroad neck" between Kentucky coal fields and the Northwest, to investigate rumors of disorder. Mr. Morrow said the Ford proposal would not be accepted by the men.

Several representatives of Mr. Ford held a conference with President Mapother, of the L. & N. last week, after which Mr. Mapother made "cable" telegrams that Mr. Ford be allowed to take over the Corbin shops and operate them with his own men. Mr. Mapother pointed out that Mr. Ford would institute a wage scale which the L. & N. would not maintain when the emergency had passed.

Peabody Predicts Failure of Priority System

"The government's system of priority distribution of coal is bound to fail this fall and winter," F. S. Peabody, chairman of the board of the Peabody Coal Co., told 300 members of the Chicago Association of Commerce last week. "It is to be operated on entirely the wrong basis and will lead to such confusion that the railroads will be hampered rather than helped in distribution."

Mr. Peabody said the Hoover plan thus far has operated to keep coal down to $3.50 where cars are short and to hoist prices out of sight wherever cars are numerous. In L. & N. territory the supply of cars has been much less than even 10 per cent of the mines where the $3.50 price has been prevailing generally, whereas the Illinois Central has been giving nearly 100 per cent car service and the coal that road has hauled to the commercial market was selling at $10@$11 on the day Mr. Peabody spoke.

"We have a mine down on the L. & N.," said Mr. Peabody. "One day recently we were allotted 15 cars. Every single one of the 15 was shipped out on a different priority order. That illustrates what is happening and will continue to happen under the Hoover system. Imagine the tremendous and complicated work of billing and switching and juggling of cars under all the priority orders that will be issued!"

He declared the mines of the country would be working within two weeks and that if they were enabled to work their limit they could produce a billion tons of coal in the next eight months. However, he said railroad service will be so hampered by one thing and another that the country will be able to get just barely enough coal to prevent industrial and domestic distress.

Mr. Peabody freely lambasted the national administration, declaring that governmental delay and interference in the strike situation had delayed a possible settlement by five weeks.

State Prods Williamson Officials—Sheriff Makes a Few Motions

GOVERNOR LEN SMALL of Illinois, under fire at a conference in Chicago late last week with important business organizations, promised he would do something about the Herrin massacre in which 19 non-union workers were killed and 30 wounded June 22 after they had surrendered to a mob which attacked them at a strip mine. He said he would not declare martial law in "Bloody" Williamson County to hasten the administration of justice, however, until he had given the county officials another chance. On Friday the sheriff and county attorney announced they were doing some sleuthing but that no arrests would be made until the September term of the county grand jury. That is all that has happened. Every instigator and participant in the Herrin horror remains as free as he was the day of the slaughter.

At the Chicago conference the governor was urged by the Illinois Manufacturers' Association and the Chicago Association of Commerce to throw troops into the county at once and make a thorough and complete job of gathering evidence and pushing the administration of justice. He was also urged to call a special session of the legislature and recommend that it create a state constabulary. He did not take kindly to the idea.

The public clamor for a special session to repeal the coal miners' qualification act so that non-union men can get into the mines to dig on the Hendricks mines will have been nothing short of a form of hood treatment by the governor. He has done nothing about it and gives no sign of doing anything. Members of the legislature have said they doubted whether a quorum could be assembled because the representatives have already drawn their annual salary of $2,500 for this year and probably nothing would get them back to Springfield this year except extra pay.

Coal Retailers Make Survey of Stocks, Regional Reserves Compared

A survey of the stocks of anthracite and bituminous coal on hand in various sections of the country as of July 8, 1922, has been made by the National Retail Coal Merchants' Association, Philadelphia, the information being collected for the use of Secretary Hoover. Based on consumption during the preceding thirty days, stocks of hard coal ranged from 60 days' supply at Albany to practically nothing in the Middle West, the tonnage tapping off as the result of the supply of coal grew greater. Bituminous coal stocks, on the other hand, were more adequate throughout Ohio, Michigan and other Middle and Central Western states than in the Eastern centers. Exceptions were New York City, with three to four weeks' supply, and New England, with 60 days' stocks.

The Southern Appalachian Operators' Association, in a public statement, has charged the Kentucky-Tennessee Operators' Association with trying to "break up the arrangement brought about by the government to hold down the price of coal," in that the Kentucky-Tennessee operators have made a deal with union officials raising wages $2.50 a day for day workers, 24c. a ton to tonnage men and 20 per cent extra on dead work and yardage. The Southern Appalachian Association reiterated its intention never to deal with the miners' union again.
NEGOTIATIONS between the United Mine Workers and several groups of soft coal operators, in session since Monday, Aug. 7, were brought to a conclusion on Tuesday, Aug. 15, when Lewis abandoned his policy of a four-state contract or nothing and opened the way for individual producers to sit down with the miners.

All through the first week of the negotiations at Cleveland the union fought to gather in a skeleton representation from the old Central Competitive Field, but when the skeleton was erected it refused to stand, for a few of the more prominent of the Ohio operators, although supporting the idea of the interstate contract, refused to sign at the high wage scale demanded by the miners unless they in turn would agree to arbitrate the scale to follow after April 1 next. The conference had sufficient semblance to the real thing to hold back Farrington from delivering the Illinois miners as a district.

Late on Monday, Lewis opened the doors to any and all coal operators in Cleveland to participate in the meeting. On the Thursday previous he had ordered them out of the room, where none were allowed save from the old Central Competitive Field. For a week T. H. Watkins and a group from Central Pennsylvania had been waiting that opportunity. They had reached a tentative understanding with the union that it would give consideration to their plan, adapted from the Crews-Glasgow plan, providing for compulsory investigation and a fact finding commission. Substantial tonnages from other outlying districts and smaller towns, along the route not represented in the conference, were lined up to back Mr. Watkins' proposal. When Mr. Gallagher and Mr. Robbins broke away from the negotiations because they could not force arbitration on the miners, Lewis opened the doors to the others.

AGREEMENT REACHED AFTER MIDNIGHT, MONDAY

On the basis of the tentative plan prepared by T. H. Watkins, this new conference began negotiations at once and by 1 a.m. on Tuesday had reached a temporary agreement. This was referred to the policy committee of the miners on Tuesday morning when the assembled operators also took it under advisement.

Tuesday afternoon the joint conference ratified the agreement and extended an invitation to the operators not present to come out as shown by the dotted line, and the strike in the soft coal fields was considered broken if not ended.

At the end of the first week the situation at Cleveland may be summed up as follows:

The cut and dried program laid out by Lewis and announced from Philadelphia the previous week had been wrecked by delay. The program provided that the Ohio operators, with sufficient tonnage from the other three districts making up the old Central Competitive Field to give semblance to its continuance, were to march up and sign a new four-state contract.

The first delay was caused by the sudden interjection of a substitute plan by Ogle, known as the Crews-Glasgow plan. This stalled the conference on Monday, held it over until Wednesday with no action, and delayed the final settlement until Thursday. On Thursday morning the miners were in a high ferment and the miners and their leaders were there, and it was in the hope that they would decide to come to Cleveland on the terms of the Ogle plan.

The second important delay followed the sudden and determined resistance of certain of the more important eastern Ohio operators to any settlement that did not include arbitration of the next wage scale. The demand was made further on Friday that the miners had understood that no such question would be raised by the producers. President Harding's message to the Illinois operators released on Friday was important in developing this situation. In fact it was this particular matter of arbitration and the division in the ranks of the Ohio producers that finally broke up all hope on the part of the miners for their long cherished desire for an interstate wage agreement.

A day was lost getting the legal aspects straightened out and thus a week passed with no contract, with the miners' delegates becoming impatient and the strength of the operators gaining perceptibly.

As hope of even a skeleton four-state contract was fading, Lewis had in the background a substantial tonnage of outside tonnage assembled in Cleveland ready to make terms with him. The terms they would accept were acceptable to Lewis personally, it seems, but it was essential for him to prepare the ground in advance with his own people before advocating their acceptance.

UNION POLICY DEMANDS INTERSTATE CONTRACT

To grasp the significance of the meetings at Cleveland it is essential to review the events leading up to it. The United Mine Workers have been maintaining their policy of not meeting with the coal operators unless they are permitted to do so through the medium of an interstate conference, that is a conference with the four states comprising the old Central Competitive Field. To this program the miners were finally agreed, and the operators of Illinois and Indiana, willing at first to take up the old form of conference have since been reluctant to engage in such an undertaking. Eastern Ohio has from the first been willing and it might be said, anxious to participate in that form of conference, but the Mine Workers could not meet with this group alone and be considered for any settlement.

On the first of August John Lewis, then in Philadelphia, announced that he had assurances from operators in the four states comprising the old Central Competitive Field that they would answer a call for a meeting to negotiate a new scale and bring the strike to an end. He said that he had some 75,000,000 or more tons of annual production in hand and he called a conference at Cleveland for Aug. 7. He stated that the miners would not have to take any reduction in wages and that the mines would be in operation within a week or so. It was generally admitted that if he should in fact succeed in getting a bona-fide four-state contract he would have won the strike.

In accordance with schedule the meeting was convened at Cleveland on Monday, Aug. 7. The entire official roster of the miners was present and A. M. Ogle, president of the National Coal Operators Association, was a member of the policy committee of that organization. Many Ohio operators and a scattering representation from other fields were on hand, but it was not clear how many of those who were there purposed to participate in the conference and how many had come there simply as observers. The meeting that day was of short duration. It selected officers and adjourned to meet on Wednesday. The news leaked out that a new plan had been proposed that bid fair to bring in all the outstanding tonnage. The meeting would wait a day or so to give those not present opportunity to come.

The plan that was hopefully expected to do this was not officially given out. It was known as the Crews-Glasgow plan. It was reported to have the approval of John Lewis and A. M. Ogle, president of the National Coal Operators Association. The general terms of the agreement were as outlined in last week's issue of Coal Age. Nothing came of this effort, for, according to Mr. Ogle, it "was killed by too much premature publicity." Mr. Lewis stated on Thursday that it was definitely out of the running.

The miners and operators assembled on Wednesday at 3 o'clock. According to them, nothing was accomplished, for they were still playing for time, waiting, in the hope that Illinois and Indiana would agree to come to Cleveland.

Thursday morning the policy committee of the miners met and in the afternoon the joint conference convened. By that time the miners had been notified that Illinois and Indiana were not coming. It is true that a ray of hope was held out by the fact that Mr. Glasgow, the chief legal ad-
visor to the miners suddenly left Cleveland by automobile bound for Toledo late Wednesday night, his purposes being to meet representatives of the operators from four states, one from Illinois, who had refused to put in an appearance at Cleveland. The Illinois men were headed by Andrew Maloney, vice president of the Chicago, Wilmington & Franklin Coal Co. They were generally understood to represent the sentiment from their state that opposed making any settlement with the miners that does not embrace arbitration. No announcement of what transpired at Toledo has been vouchedsafe from a waiting public. Mr. Glasgow returned to Cleveland on Friday evening and reported, but John Lewis said, nevertheless, that he could tell nothing of what had transpired. It is fair to assume that the Illinois men were told that the miners were unalterably opposed to arbitration, and that Mr. Glasgow was informed that the Illinois operators were joining the four-state operators who have been invited to the meetings, but that there was no assurance that anything the miners want. They were known at the Cleveland Conference as the “tonnage-hungry crowd.” They were not in harmony with any move to hold back a settlement for such little matters (so they viewed them) as an agreement to arbitrate or investigate. They said, “Let the next contract take care of itself.” Time enough for that when the time comes. The debate over the operators’ ranks has been going on all week to the impatience of the miners, who think that they have won and want signatures on a contract so that they can go to work. This sentiment is expressed both at the mines and at the Cleveland Conference.

The position taken and so firmly held by the Illinois operators against settlement without arbitration, has had a profound influence on many of the operators of Ohio and western Pennsylvania who are attending the meeting. Publication Friday night of the letter from President Harding to the Illinois operators sustaining their stand put heart in those who are holding for that kind of settlement and made the miners furious.

Another of holding a joint scale meeting, the miners and operators met separately on Saturday morning. It was quite apparent to the small army of observers about the hotel corridors that something was wrong, that things were not going according to schedule. Ohio interests substantially responsible for the bringing of the meeting together suddenly developed a powerful desire to force arbitration on the miners. To persist in that stand meant a break-up of the conference.

Conference Disposes of Legal Complications

Another question loomed large when Friday night word was received that the government would look on an interstate agreement as possibly illegal; that is, in contravention of the Sherman Law. This complication was taken up by some of the operators as a means of stalling the proceedings, if appeared, but John Lewis got around the trouble by saying that the Illinois state district and the operators would be between the United Mine Workers, and the operators as individuals. On this point the conference, on adjourning at 5 in the afternoon, issued the following statement, signed by Lewis and Gallagher:

“In order to allay the misapprehension which exists in some quarters as to the purpose of the meeting of operators and miners now in session in the City of Cleveland, Ohio, this statement is issued.

“We are assembled for the purpose of negotiating, if possible, a new wage agreement between the representatives of the United Mine Workers and the individual operating interests represented in this meeting. The conference is in no sense what may be termed a four-state conference and does not undertake to represent the operators of any particular state or district or interests not represented herein. Its sole purpose is to promote a mutuality of understanding as between the operators participating and the representatives of their employees.

“This statement is the joint action of the meeting assembled.”

Justice interpreted, despite the assertions of the labor leaders that it bore no such significance, as a distinct concession on the part of the miners. It said in so many words that there was no longer a Central Competitive Field. It was explained that the miners could and would agree on a base scale for that district and that this would preserve the form of the old contract, and that the operators would simply be called on to sign as individuals. This legal hurdle having been surmounted, the conference adjourned until Monday morning.

Illinois and Indiana Hold Back

“It still appears that Indiana and Illinois associations are sharply divided and engaged in prolonged debate about the advisability of entering this conference. We will be glad to have you continue their arbitral refusal it will make no difference. We will proceed with the work of this conference. In any event, we have assurances—the definite assurances—that if a scale is reached here important producers will break away from Illinois and Indiana associations and sign the scale.

“I confidently predict that when a scale is made here, that 75 per cent of all bituminous tonnage now on strike will sign the scale in one week. A settlement in the anthracite fields will naturally follow.

“The miners have won their fight and it is practically over. There is no longer a thought in any quarter that wage reductions will be imposed on the mining industry. The question here is one of procedure without undue humiliation of the operators. We have no desire to humiliate them. We wish to have immediate reumption of mining; and the return to work of the men and the relief of the public.”

After the meeting on Thursday afternoon Mr. Gallagher, chairman of the convention stated that “progress had been made.” The names of a committee on credentials and rules were given out. This committee was as follows: S. H. Robbins, Ohio; Jas. Paisley, western Pennsylvania; F. O. Parker, Indiana, and Judge Campbell, Illinois, for the operators; and P. T. Fagan, Lee Hall, Peters, Hessel and Frank Farrington for the miners. It was stated that over 40,000,000 tons of annual production from the old Central Competitive Field was in the meeting divided as follows: Ohio, 27,000,000 tons; Pittsburgh and Freepoint, 9,500,000 tons; Illinois, 1,500,000 tons; Indiana, 2,000,000 tons.

Outlying Field Operators Thrown Out

The most significant move at the meeting Friday afternoon was the ejection from the conference, on demand of the miners, of all operators not in the old Central Competitive Field, and the statement of John Lewis, after the meeting that the miners had not deviated in any respect from their original policy. It was to be no wage reductions and a four-state settlement, just that and nothing else.

Friday was devoted to a scale-committee meeting. The representatives for the operators on the scale committee were five from eastern Ohio, S. H. Robbins, T. K. Maher, R. L. Wildermuth, W. H. Haskins, A. A. Augustus; one from Indiana, W. A. Satterlee; one from Illinois, Richard Carver; and one from western Pennsylvania, Jas. Paisley. There were eight representatives from Pennsylvania, H. F. Greer, and Geo. Savage from Ohio, Farrington and Fishwick from Illinois, Hessler and Roberts from Indiana and Fagan and Hargrett from Pittsburgh. John Lewis, William Green and Van Bittner for the miners, Michael Gallagher and W. L. Robison for the operators were included in the group.

The scale committee had two meetings on Friday and got nowhere. To the surprise of many and perhaps of the miners who had gained an idea that the agreement was all cut and dried, the operators registered a demand for the 1917 wage scale and arbitration of the scale for 1923. Quite naturally the miners would not consider this. There is nothing they can gain by the demand except what the operators’ ranks has been going on all week to the impatience of the miners, who think that they have won and want signatures on a contract so that they can go to work. This sentiment is expressed both at the mines and at the Cleveland Conference.

The position taken and so firmly held by the Illinois operators against settlement without arbitration, has had a profound influence on many of the operators of Ohio and western Pennsylvania who are attending the meeting. Publication Friday night of the letter from President Harding to the Illinois operators sustaining their stand put heart in those who are holding for that kind of settlement and made the miners furious.

Another of holding a joint scale meeting, the miners and operators met separately on Saturday morning. It was quite apparent to the small army of observers about the hotel corridors that something was wrong, that things were not going according to schedule. Ohio interests substantially responsible for the bringing of the meeting together suddenly developed a powerful desire to force arbitration on the miners. To persist in that stand meant a break-up of the conference.

Conference Disposes of Legal Complications

Another question loomed large when Friday night word was received that the government would look on an interstate agreement as possibly illegal; that is, in contravention of the Sherman Law. This complication was taken up by some of the operators as a means of stalling the proceedings, if appeared, but John Lewis got around the trouble by saying that the Illinois state district and the operators would be between the United Mine Workers, and the operators as individuals. On this point the conference, on adjourning at 5 in the afternoon, issued the following statement, signed by Lewis and Gallagher:

“In order to allay the misapprehension which exists in some quarters as to the purpose of the meeting of operators and miners now in session in the City of Cleveland, Ohio, this statement is issued.

“We are assembled for the purpose of negotiating, if possible, a new wage agreement between the representatives of the United Mine Workers and the individual operating interests represented in this meeting. The conference is in no sense what may be termed a four-state conference and does not undertake to represent the operators of any particular state or district or interests not represented herein. Its sole purpose is to promote a mutuality of understanding as between the operators participating and the representatives of their employees.

“This statement is the joint action of the meeting assembled.”

Justice interpreted, despite the assertions of the labor leaders that it bore no such significance, as a distinct concession on the part of the miners. It said in so many words that there was no longer a Central Competitive Field. It was explained that the miners could and would agree on a base scale for that district and that this would preserve the form of the old contract, and that the operators would simply be called on to sign as individuals. This legal hurdle having been surmounted, the conference adjourned until Monday morning.
Contract Negotiated and Signed at Cleveland Conference

Following is the scale report approved at the Cleveland conference Aug. 15, 1922:

Report of the sub-scale committee Aug. 14, 1922:

The operators represented here in this joint conference which are now on strike, are to be opened immediately upon the execution of supplementary contracts extending to March 31, 1923, in all instances of strikes which are now pending or affecting such mines are to be as they respectively existed on May 14, 1922, except as to renewal of continuation clauses in such contracts.

The participants of this conference agree to send and this conference invites the bituminous coal operators of the United States to send representative delegates from coal producing districts, or from substantial groups of coal operators which delegates shall as far as possible be representative of the bituminous coal industry of the district, or groups, to meet with the operators, to be appointed in joint conference in Cleveland, Oct. 2, 1922. This joint conference shall appoint a commission of equal numbers of representative operators and miners, which commission shall be deemed a joint committee of inquiry, to be followed by the bituminous coal industry in the negotiation of agreements which may be justly and peaceably assembled in joint conference in Cleveland, Oct. 2, 1922. This joint conference shall appoint a commission of equal numbers of representative operators and miners, which commission shall as far as possible be representative of the bituminous coal industry of the United States, such delegates to meet in joint conference Oct. 2, 1922, at such place as may be determined to by joint conference held Oct. 2, 1922. This joint conference shall receive the presentation of the committee of inquiry and shall be furnished by the committee of inquiry and such committee shall be furnished with all information desired and aided in every manner deemed necessary by the operators and miners.

In the event such joint conference shall fail to agree upon the method of settling of the dispute, the parties may at any time petition the President of the United States to appoint the members thereof in his discretion and the President of the United States shall act as such by appointment. The cost of such committee of inquiry shall be paid by the Industry, one-half by the operators and the other half by the United Mine Workers of America. Such committee after developing all the facts shall make such recommendations as it may deem proper and advisable and shall so far as possible embody these recommendations in a report to be submitted to the joint conference to be convened Jan. 3, 1923, as hereinafter provided.

In order to reach a final and proper determination of the controversies in the bituminous coal industry, joint conferences of miners and operators and the public as well, the following principles are presented for consideration by the committee of inquiry: The wage rate in any district shall, as far as reasonable, be competitive within the mining industry and shall at the same time be fully compensatory to the miners being sufficient to afford not only a living wage but also to allow reasonable opportunity for accumulating savings. The encouragement of a proper spirit of obligation and responsibility on the part of all parties will be sought by the adoption of proper machinery, both local and national, for promiss determination and settlement of any points of dispute and of any local, state, district or district adjusted by the joint conference.

The determination of a proper policy to encourage efficiency of operation, not only on the part of mine management in the maintenance of the mines and operation of the mines, but also on the part of individual miners in the performance of their daily work.

The participants in this conference agree to send, and this conference invites the bituminous coal operators of the United States to send representative delegates from coal producing districts, or from substantial groups of coal operators which delegates shall as far as possible be representative of the bituminous coal industry of the United States, such delegates to meet in joint conference Aug. 14, 1922, at such place as may be determined to by joint conference held Aug. 14, 1922. This joint conference shall receive the presentation of the committee of inquiry and such committee shall be furnished with all information desired and aided in every manner deemed necessary by the operators and miners.

In the event such joint conference shall fail to agree upon the method of settling of the dispute, the parties may at any time petition the President of the United States to appoint the members thereof in his discretion and the President of the United States shall act as such by appointment. The cost of such committee of inquiry shall be paid by the Industry, one-half by the operators and the other half by the United Mine Workers of America. Such committee after developing all the facts shall make such recommendations as it may deem proper and advisable and shall so far as possible embody these recommendations in a report to be submitted to the joint conference to be convened Jan. 3, 1923, as hereinafter provided.

WATKINS PRAISES CLEVELAND CONFERENCE

Reason Restored. He Says

At the adjournment of the conference on Tuesday T. H. Watkins said: "As the result of conciliatory efforts inaugurated by President Harding at the Washington conference, the situation in the anthracite area consequent to the recent Cleveland meeting, the Central Competitive Field conference to which we attribute most of our past difficulties was definitely broken up and abandoned yesterday and the meeting was thrown open to operators and miners from every district in the United States. The formation of new contracts expiring March 31, 1923, is left to a joint committee of operators and miners which will report on Jan. 3, 1923. All parties have engaged themselves to make a most exhaustive investigation of the whole industry and to lay down recommendations on which voluntary agreements can be negotiated on sound economic lines between the operators and the miners. For the first time in the coal industry important labor leaders and employers have joined together in a crisis and voluntarily set up the machinery not only for a resumption of work but for the establishment of a public tribunal before whom they engage themselves to appear with all the facts of the industrial activities of both parties. The recommendations of this commission are to be the guide for necessary steps toward a permanent settlement without further strikes. We are all agreed that we want to negotiate without interference or compulsion except as both sides may bow to the powerful influence of opinion of a well informed public. The document means that reason has been restored. The exercise of force whether through strike, compulsory awards, or arbitrary procedure, has no place in the program upon which we have agreed. Compulsory arbitration has failed too often in recent industrial crises to offer a fair and effective solution which requires a basic solution, not merely a reconciliation of immediate differences. We believe that the door has been opened to a new era in the coal industry in which the coming public as well as those producing coal will have access to the essential facts of the industry and will be an influence in guiding it into more peaceful channels.

Anthractitie Negotiations To Be Resumed on August 17 at Philadelphia

EVIDENCE that the union is slowly yielding to the pressure of public opinion is found in the sudden interval taken in the anthracite situation. On Friday, Aug. 14, Lewis wired the operators of the important coal region saying that the miners were ready to again meet the operators to discuss a new contract. He said: "Replying to your wire, representatives of the United Mine Workers are not making anthracite negotiations secondary to bituminous negotiations, despite all reports to the contrary. We have understood attitude of anthracite operators to be that they would refuse to make any settlement in advance of bare being made in bituminous. If this is not now true, and it is developed that anthracite operators are ready to go into direct negotiations with the United Mine Workers on the basis of the old wage scale and demands of the Shamokin convention, we will be glad to attend a joint conference on any date designated by the anthracite operators' representative.

Mr. Warriner lost no time in making reply, asking Mr. Lewis to meet the anthracite operators in Philadelphia on Wednesday, Aug. 16.

The meeting has been postponed until Thursday, Aug. 17, to give the union officials time to finish their business at Cleveland.

NEARLY ALL IMPORTANT Operations in Nova Scotia were closed on Tuesday by a strike of more than 12,000 miners. Five thousand Cape Breton workers at a mass meeting at Glace Bay and another large meeting at New Waterford repudiated the agreement which their officers made with the operators and declared the strike. Other fields joined, thus tying up a source of supply that has been utilized by the United States since early in the present strike.

The companies' offer raised wages from $2.85 to $3.25, and contract rates 10 per cent, about 29 per cent below the wages of 1921, which the miners are asking.
Coal Price Legislation May Supplant Voluntary Control, Hoover Asserts—Lake Shipments Speeded Up

Forecasting legislation aimed to control the price and distribution of coal during the emergency this winter, Secretary Hoover, on Tuesday, Aug. 15, said: "If the control over prices and distribution is maintained, Congress must provide legislation." It is impracticable, he said, "to try to continue the control indefinitely on a voluntary basis." While 60 or 70 per cent are always willing to do the square thing, in the flush of the prosperity, this was fair for them to have the remainder in a position to profit by taking advantage of the situation. The legislation necessary has not been worked out. A number of alternatives are under consideration but no decision will be reached until the depth of the problem is known.

In discussing the co-operation he had received in the control of prices and distribution, Secretary Hoover said he had been given a few days' time for co-operation in the smokeless field, and almost as good a performance in Virginia and other parts of West Virginia.

Advices reaching Washington are that British gas coal arriving in New York is not readily salable. It also has been found that no coal rates are in effect from New York to Inland points.

The possibility of expediting coal shipments to the Upper Great Lakes region in order to attain the necessary total movement to that territory before the close of navigation is a problem being given the serious attention of the Federal Fuel Distribution Committee. The Federal Fuel Distributor expects shipments aggregating 250,000 tons of coal will be made to the Lakes in the present week as compared with an estimated shipment of 147,000 tons for last week. A figure of 400,000 tons has been set for Lake movement during the week beginning Aug. 21.

The ability to supply urgent Lake requirements depends largely upon the coal production situation in Pennsylvania. Mines in Pennsylvania that ordinarily ship Lake coal are at present closed and the question of whether Pennsylvania coal will be available in considerable quantity for early Lake shipment has largely on the question of the various coal tonnage produced in Pennsylvania will be sufficient to take care of that state's own urgent needs and to allow of a supply for diversion to the Lake country. A partial solution to the problem may be found by replacing Pennsylvania Lake shipments by importations into that state of Tennessee coal from the southern Appalachian district.

The move of 60,000 cars to be made for coal mined in the various Pennsylvania districts is expected to be definitely settled at a meeting in Harrisburg, Tuesday, Aug. 15, between the Pennsylvania Public Service Commission and a committee of coal operators. This meeting is a continuation of the session held in Philadelphia Friday and Saturday of last week, at which sessions the matter of definite price fixing was deferred for a few days for further investigation. The Pennsylvania Public Service Commission, which is acting as the State Fuel Administration is engaged in making an inventory of the urgent fuel requirements of that state.

A total of 13,528 cars of coal were loaded throughout the country, Friday, Aug. 11. This represents an increase of 769 car-loadings over the same day of the previous week. Loadings of 60,000 cars were reported for the first five days of last week, an increase of 5,800 cars over the corresponding number of days of the previous week. Loadings on the Chesapeake and Ohio system Friday amounted to 1,319 cars; on the Norfolk and Western, 2,115 cars; and on the Louisville and Nashville system, 1,609 cars. Coal loadings on these three lines represent an increase of more than 100 cars over the figures for Friday of the previous week.

An estimate of the fuel requirements for public utilities and domestic consumers in the District of Columbia has been submitted by the board of commissioners of the district.

Governor Hardwick of Georgia has designated the Georgia State Railroad Committee to act as the State Fuel Committee. A fuel distribution committee for the city of St. Louis has been appointed by Governor Hyde of that state to function under the general direction of the State Fuel Committee. This committee will co-operate with the St. Louis Chamber of Commerce.

The necessity for giving preferred classification to smithing coal has been presented to the Fuel Distribution Committee. Various organizations representing the steam laundry trade have set forth the fuel requirements of the various districts. They have been informed that each laundry should take up with its state fuel committee the matter of fuel needs.

Inquiries from Kansas and other trans-Mississippi states relative to the obtaining of coal supplies from producers in the Rocky Mountain region are being referred by the Central Fuel Committee to the coal distribution agencies in the states now producing coal in that territory.

Representatives of a large industrial concern owning its own coal mines conferred today with the fuel distribution committee relative to placing the entire coal production of this mine, subject to the orders of the fuel committee for use by essential industries.

Senator Swanson and representatives Harrison and Blund of Virginia, accompanied by Maj. Alexander Forward, State Fuel Administrator, reached Norfolk, and a delegation of prominent citizens of the state, called upon Fuel Distributor Spencer today to ask that a specific allotment of coal be turned over to the Virginia committee for distribution among essential industries in accordance with the plans of the federal organization.

The suggestion was made by the central committee that an organization for the distribution of fuel supplies be formed in Virginia similar to organizations in other states, to co-operate with the state fuel administrator.

Fuel supplies of the various branches of the federal government have for some time been fairly well assured and no special efforts to safeguard these supplies are required just at this time. Naval fuel reserves are said to be in especially good shape.

A South Carolina delegation conferred with the fuel distributor relative to its situation in that state. The delegation declared that the matter of fuel distribution was progressing satisfactorily in South Carolina and that available fuel supplies were being distributed to those industries where the need was the most keen.

The I.C.C. on Tuesday reprimanded the carriers for controlling the coal loads under priority orders. Calling attention to the increasing frequency of this practice, the commission declared it tended to defeat the efforts of the government to insure equitable distribution of the curtailed supply of coal. The roads were ordered to refrain from such action.

National Coal Directors Meet in New York

Peace and harmony prevailed at the meeting of the board of directors of the National Coal Association in New York on Monday, Aug. 14, despite predictions to the contrary from several quarters. About 20 directors were present, mainly from the East and South. Those from the West were not able to attend because of the acute labor situations in their respective districts.

The meeting lasted all day, during the course of which many routine matters were considered and matters of policy of the National Coal Association were considered at length. After the meeting A. M. Ogle, president of the Association, said:

"It always has been and is now the policy of the National Coal Association not to interfere in any way with wage negotiations of the directors under the existing policy within any district in the bituminous coal fields. The Association does not undertake to settle strikes. This is a matter which must be determined by representatives of the several districts involved. It does undertake, however, to properly represent the bituminous industry generally in all its phases before the public."
A peculiar situation exists in the spot coal market. Prices are high but are not soaring, for coal is even more limited than a week ago, but the demand has declined apace with the amount of tonnage offering.

Procrastination has ruled the coal buyer. The Cleveland conference gave hope of resumption of mining, and consumers pared their purchases to the quick in order to be able to take advantage of the easier flow of coal when union-mined tonnage is again available. The diminution of demand has been accomplished in many cases by the curtailment or complete shut-down of plants by those who feel that this is preferable to paying the high premiums now being secured by spot coal shippers.

Priorities Rule on Bulk of Tonnage Moving

Those who must keep in operation, and this class includes the railroads and "essential" industries, are actively bidding for the meager current production that is available to the spot buyer. Priorities rule on the bulk of the tonnage moving but there is much confusion as yet in carrying out these orders and railroad confiscations are heavy. The situation is further complicated by the rail trouble and consumers on the preferred list are often forced to pay the going price to replace delayed shipments of coal.

There is little of this spot coal available, for, although production is increasing, most of it is needed on priorities. Spot coal prices have risen to an average of $6.66 per net ton at the mines, Coal Age Index on Aug. 14 going to $5.50 as compared with $1.50 for the previous week. This is a rise of 39 points for the index and 48c. in the average price for the week. The coal commission at Washington, recognizing unusual expenses of certain operators now producing, has sanctioned an increase from the original $3.50 Hoover level to $4.50 for New River and $4.75 for Kanawha.

Railroads are functioning better but the traffic congestion is still acute and lack of motive power is hampering dispatch of loads and the placement of empties. The roads are gradually enforcing the priority orders but State and Federal committees have not yet clamped the lid down on high prices. The fear, however, that a settlement of the strike may find them with a large tonnage of high-priced coal en route is causing jobbers to be extremely cautious. Orders are taken on a day-to-day basis now, and there is less tendency to exact all that the consumer might pay. Quick turnovers are the rule and the desire for large premiums and commissions are not allowed to delay present sales.

The edge is off the market for British coals. Cargoes are arriving daily but consignees are for the most part essential industries who will be the first served after the strike. As this British coal is relatively higher priced than our own fuel and the British market is sold well into September there will be few additional orders placed since mining will be resumed at an early date.

The situation at Hampton Roads is slowly improving, as the railroads are able to clear their lines. An embargo has been placed on exports, and bunkers are due for a slump as priorities leave little tonnage for vessel fuel. The accumulation at the piers is running down and tonnage awaiting cargo is heavy.

Shippers are being deluged with requests for quotas.

tions and the prospect that coal mining is to be resumed has brought many orders for delivery "immediately after the strike." The price question is being carefully left open and shippers are accepting orders on that basis, promising delivery at the earliest possible moment.

BITUMINOUS

"The nineteenth week of the strike (Aug. 7-12) opened with a decided increase in production," according to the Geological Survey. "Returns so far received indicate an output of soft coal of about 4,800,000 net tons, or 500,000 tons more than the week before. The increase is due to gradual improvement in traffic conditions on the railroads serving non-union fields and also, but only in a very small way, to increased production in fields hitherto throttled by the strike. Despite this increase in bituminous coal output the nineteenth week finds production still about 550,000 tons below the level reached before the shopmen's strike.

"The total output of all coal, anthracite and bituminous, in round numbers is 7,880,000 tons in the corresponding week of 1921, 7,771,000 tons of bituminous coal and 1,772,000 tons of anthracite were produced.

"Detailed records of shipments from each district indicate that the increase to the coal supply from mines that have reopened is small, although four weeks have elapsed since the invitation to resume production was extended. There have been only very small gains in a few of the stronger organized districts.

"In the middle and southern Appalachians, which have been the principal sources of supply, production has been curtailed by the shopmen's strike but has gradually increased during August. The unorganized districts of this territory has gained, by relief from traffic congestion, about 200,000 tons over the output of last week. The non-union and partly organized fields of this region are now furnishing about 41 per cent of the total output in the United States, whereas they furnished 54 per cent in the week of July 17.

NOTE—Smokeless prices now include New River and Pocahontas.
ended June 24. The districts in Pennsylvania and the central competitive field and those west of the Mississippi have been less affected by the coal curtailments. Changes in shipment rates measure better the direct influences of efforts to overcome the strike. In Pennsylvania the output since the last week of July has increased somewhat. Union districts in West Virginia also reported slight increases.

The Northwest is in desperate need of coal and the coal distribution committee has issued priority orders on cargo and vessel fuel in an effort to get a supply to the upper lakes. It is hoped that this will be possible. Dampings at Lake Erie ports during the week ended Aug. 14 recovered from the extreme slump of the week before. The total dumped was 147,358 net tons—123,121 tons cargo and 24,237 tons vessel fuel—compared with 92,747 tons during the week ended Aug. 7. The total movement for the season is only 4,776,684 tons; last year's figure was 14,789,941 tons.

Tidewater dampings at Hampton Roads increased during the week ended Aug. 10 as the carriers have been able to clear up some of the congestion between the mines and piers. The dumpings were 306,258 net tons as compared with 277,072 in the previous week.

July witnessed a decline in Tidewater dampings. In comparison with June the total dropped 21 per cent, principally caused by decreased movement from Hampton Roads to New England.

Because the strike has curtailed shipments to the three Northern ports—New York, Philadelphia and Baltimore—the cumulative Tidewater movement from Jan. 1 to July 31 was much below normal. Shipments during the first seven months of 1922 were 29 per cent less than the average for the corresponding period in the three years preceding. The chief element in the decrease was a sharp decline in exports. Shipments to New England were greater than in any of the 3 years preceding, because of the effort of New England consumers to obtain water-borne coal to replace dwindling all-rail shipments.

ANTHRACITE

The hard coal situation is unchanged. Production is nil except for a weekly output of less than 30,000 tons of steam coals dredged from the rivers. Pea coal is all that is moving and even this is slowing down as railroads are reserving tonnage at the mines for their own use.

Anthracite wage questions will be discussed in the coming conference which follows the Cleveland soft-coal negotiations. An early resumption of hard-coal production is likely to result therefrom.

COKE

Production of beehive coke continues to increase slowly. During the week ended Aug. 5, 116,000 net tons were produced, 4,000 tons in excess of the previous week. There is less spot coke offering, however, demand is lighter and there is more dickering over price as users are forced to close rather than pay any further premiums. Only those foundries with most pressing business are attempting to remain open.

The growing scarcity of coal was reflected in a decrease in the output of byproduct coke in July. The total production for the month was 2,486,000 net tons against 2,580,000 tons in June.

In spite of the decrease as compared with June, the July rate of output was within 3 per cent of the average for 1920, the year of maximum output. The byproduct plants of the country continue to run, but curtailed by the strike in the Connellsville region and elsewhere. The beehive ovens produced only 450,000 tons in June.

The coal consumed in the manufacture of coke in July is estimated at 4,281,000 tons, of which 3,571,000 tons was charged in byproduct ovens and 710,000 in beehive ovens. That this rate of consumption cannot be continued long unless the production of coal is greatly increased over the previous rate, will be apparent from the fact that the coal used in the manufacture of coke in July was only 28 per cent of the coal mined that month. This was possible because the byproduct ovens were able to draw upon coal held in storage.

Foreign Market
And Export News

American Orders Have Bolstered British Prices
And Quieted Threatened Labor Troubles

The advance of British prices as
a result of the American demand
has been little short of miraculous.
Recently, in the closing down of
steam coal sales in America, the
prices of steam coal in Wales are
now nearly 10s. higher. The extent
of the American demand in Wales is
do not known, as no figures of much value
are disclosed. It is evident, however, that
steamers were sent to Cardiff and
were ready at Cardiff to be off before Aug. 17.
The American buyers were able to
obtain their coal comparatively cheaply
because they arrived on the market
at a time when colliery owners were
in no mood to keep their pits open and how to dispose of their accumu-
lated stocks.

Production during the week ended
July 29 was 4,989,000 gross tons as
recorded by "Coal Age." This is a consid-
erable increase from the previous week's
figure of 4,391,000.

Coincident with the demand from the
United States there sprung up a brisk
trade with South America, which had
disappeared since 1914. At the same
time merchants on the Continent, who
had been delaying getting their autumn
requirements in view of the fear of a
further fall in price, hurried their orders,
so that they got them before the Ameri-
cans were able to cause a further rise.

There is no sign of any labor trouble.
The miners do not know the destination
of the particular coal they are pro-
ducing, and, apart from that, they are
not at all anxious to find any cause
for stopping.

Some hundreds of thousands of tons
of gas coal and coking coals have been con-
tacted for in northern England, and the
total output field is operating at
full pressure to cope with the orders.
As a result Northumberland and Dur-
ham pits are entirely booked up until
the end of September. European
contracts include one of 20,000 tons of
gas coals at 22s. 3d. for Bergen and 60,000
tons of special gas coals at 26s. for
Amsterdam.

On the whole, the attitude in North
England has been transformed from
 pessimism into optimism. The present
position is that business is restricted
only by the need for further shipping
facilities.

French Production During May

Production of coal in France in May
was divided as follows between the
various coal fields:

Inland Demand Cuts Supply at Roads

The market was quieter last week
than during the earlier period of the
strike, although quotations remained
firm at advanced levels. From the
spectacular point of view, emphasis
was shifted from the inland to the
inland demand on account of the numer-
ous appeals for fuel which have be-
sieged shippers at Norfolk since the
lack of coal in Virginia and North
Carolina became acute.

The movement has been in about the
same proportion as in the previous
week on all three railroads. Stocks
at Tide have contracted slightly, but
have hovered very close to 100,000 tons
for the greater part of the time.

Coal Paragraphs from Foreign Lands

Italy—The market is dull. Imports
during May totaled 1,043,000 tons,
of which 52,000 tons were from the United
States, 5,362,000 from the United King-
dom, 318,000 from Germany.

Cardiff steam first is now 42s. 6d.,
according to a cable to "Coal Age." Last
week's quotation was 40s. 9d.

Germay—New coal prices, caused
by the increase in miners' wages which
had come into force on July 1, show an
addition of about 30 per cent. Pat
coln now costs about 1,200 m. per ton
at the mine, which is about 100 times
above the pre-war figure. Before the
war the price was 12d. 12s. per ton.
Other coal has advanced relatively.

Price in the Ruhr district for the
week ended July 29 was 1,802,000
metric tons, according to a cable to
"Coal Age," 2,000 tons in excess of the
previous week's output. The Inter-
national Miners' Congress is urging
members to the Reparation Commission
to request a modification of the spa
coal commission.

(Advances over previous week shown in heavy type; declines in italics.)
Non-Essential Industries

Hot After Meager Tonnage

Production Increases, but Little Coal Left for Spot Market—British and Southern Territories Aid—Impending Strike Settled. Loosed Flood of Orders and Inquiries.

Non-ESSENTIAL industries are active bidders in the spot market. Demand is exceedingly strong and receipts are heavier, but quotations are not soaring as there is more of a tendency to observe fair prices. State committees are securing a few cars for needy points, railroads are taking much of the current output and the remaining spot tonnage is exceedingly light. Cargoes of British coal are now arriving. Southern coals, via water from Hampton Roads, are also moving better, filling a few gaps in the market.

Coal houses are being deluged with inquiries and many orders are being placed, for delivery after the settlement of the strike, but the question of price is being left open.

NEW YORK

The arrival of the first cargo of British coal in this harbor during the present strike was the feature of last week's market. This arrived in an Italian vessel and was reported as having been sold to a public utility corporation. It was followed a couple of days later in the week by another vessel which docked in Brooklyn. Other cargoes of foreign coal are expected almost daily.

Offers of British coal are being made to local dealers, and one house received an offer of Scotch coal at about $11, c.i.f., or about $12 alongside in small barges. Quotations for British coal, c.i.f., for late August or September delivery, ranged about as follows: Durham, first class, 42s.; Durham, second class, 40s.; Northumberland, un-screened, 40s., and Admiralty, 49s.

While the demand was strong and coal moving in better shape, there was a tendency to keep prices nearer the Hoover schedules, although no quotations were available as low as those figures. There were 429 cars at the local piers on Aug. 11, and it was estimated that less than 25 per cent of these were available for spot buyers.

The state fuel commission is busy formulating plans for seeing that all public utilities and essentials secure coal. The railroads are heavy buyers. Demand along the line is much stronger than at Tidewater. Southern coals are coming forward in slightly heavier volume, with quotations around $13, this harbor, in small barges. B. R. & P. coals are quoted $7.75@8, with similar quotations for Pittsburgh.

UPPER POTOMAC

Virtually all mines in the Upper Potomac region on the West Virginia side of the river between Thomas and Piedmont, are now in operation. On the Maryland side fewer mines are at work owing to the lack of co-operation of Maryland. Production is being steadily increased and is averaging about half of normal. A few mines in the Georges Creek region also are operating. Railroad fuel is moving at about $3.50 a ton but the quotation generally on coal in the various pools is about $6.

PHILADELPHIA

That reserves of consumers are being fast eaten into is shown by an increase of direct inquiries to shipping houses. Many of these concerns have April contracts of 5,000 tons which is it with the greatest reluctance that they make small purchases at the current figures.

Prices have not materially deviated from last week's quotations. Generally, though, when no grade is specified the price has been about $8, with Pool 10 classification taking the top figure. August orders are yet to become effective, although it does seem to have had the effect of automatically giving better shipments to utilities. Usually such concerns having contracts have been in receipt of more coal. While this has been of considerable help, yet it has not been sufficient to permit the larger users of coal to keep out of the priority market, and many of them have recently paid the maximum prices to keep a margin of safety in stocks.

The edge, at least temporarily, seems to have been taken off the foreign coal market. Of course rising prices of coal and freight on the other side of the river has had something to do with it, but no doubt purchasers are also desirous of having some of the coal in hand to make certain that it will meet their requirements.

FAIRMONT

By the end of the first week of August there had been so much improvement that conditions were better than they had been at any time since the beginning of the strike. More mines were at work—200—more men were at work and production was larger. About 550,000 tons were now producing coal. Transportation conditions are also proving to be conducive to a larger output.

CENTRAL PENNSYLVANIA

There are approximately 1,000 more men at work than before troops and state police were sent into the field. A noticeable increase in production is reported. The company has gone from 600 to 700 cars per day.

No important developments marked the progress of the strike last week. A 100 per cent car distribution is reported on all railroads entering the field. On the South Fork branch of the P. R. R. 392 cars were loaded during the first five days of August, with the number slightly on the increase each succeeding week. The first week of July showed 113 cars on the first five days.

The Pennsylvania company is repairing freight cars as fast as they are turned into the shops at Altoona. Coal operators and officers of the Central Pennsylvania Coal Producers' Association attended the conference with Governor Sproul in Philadelphia at the end of the week.

BALTIMORE

With the Maryland coal committee beginning to function the market remains stiff and rather acute in spots. The commission is headed by W. M. Malloy, of the Public Service Commission, and the practical director is L. Eaton, of the B. & O., who arrived this week to act as vice-chairman. He found calls from a number of Maryland towns which claimed to be without fuel for industries or hotels, etc., and this was taken care of through some operators who could spare a car or so of coal here and there.

Governor Ritchie appealed by wire to John L. Lewis, president of the United Mine Workers, to attempt to settle the Maryland situation immediately after the Cleveland conference. He received a reply that action would be taken in the case the situation following the Cleveland conference warranted such a move for the Maryland field. Despite union statements to the contrary, the B. & O., the Pennsylvania and Western Maryland officials continue to report more than enough cars in all producing territory to remove all difficulties.

Prices remain high. Consumers are entirely willing to pay $6@8 a net ton, f.o.b. mines, for the coal that is offering. At that the coal is cheaper than the Pennsylvania coal which commands $10@12 at the piers. West

SALT LAKE CITY

Utah needs no fuel administration. Governor, Chas. R. Smith, retiring, Hooper, Utah is producing 73 per cent of the normal output of coal. Domestic consumers are asking for coal. There is, however, no rush. There appears to be enough cars and the strike situation is about the same. The soldiers are still in charge.

July production was 374,854 net tons. In July last year the figures were 273,092, but in 1920 they were a round half-million.

KANSAS CITY

The peaceful situation that existed in the Kansas coal field a short time ago has taken wings and the lamb-like demeanor of Howatt followers has changed. Very little coal is being produced in that state. The long continued strike is causing steam plants to turn to oil and a great many are installing oil burning equipment. The Kansas City, Mo., municipal plants will change over to oil at once and a great many manufacturing plants are also changing to oil.

Coal is hard to obtain that at any time since the strike and the price is anything the seller asks. Some Kansas mill coal sold for $7 f.o.b. mines this week.
COAL AGE  Vol. 22, No. 7

Anthracite

Early Scarcity Is Inevitable
Substitute Fuels Are Urged

Household Consumer Fully Awakened
to Gravity of Situation—Retailers
Besieged With Orders—Stocks Being
Rationed—Pea Coal Disappears as
Railroads Take Mine Stocks for
Steam Substitute.

The public is now thoroughly
aware of the serious aspect of
the situation for the winter. Retail-
ers are besieged with orders, but are
doing little else than file these for
attention at the earliest possible
moment.Domestic stocks are being
rationed out only to hospitals, hotels
and other urgent points of consump-
tion. Even pea coal, which has been
in plentiful supply, is disappearing
from the market, as mine stocks are
being held for the hard-coal burning
railroads.

Substitution of other fuels is now
being urged in the East, for the first
part of the season at least, as it is
realized that even if mining is
resumed in the near future the needs
of the Northwest would take much
of the current production well into
the time when domestic coal fires
are lighted.

NEW YORK

With the naming of a fuel commis-
sion to look after the distribution of
coal the public is thoroughly aroused
to conditions and consumers are realizing
the mistake they made in the early
spring by not putting away their next
winter's coal.

It is possible that coal will be doled
out in bags by some retail dealers,
whose yards are in the poorer sections,
the consumer taking it away himself.
This system has been followed in some
instances during previous coal short-
ages. Retail dealers' books are carry-
ing many orders but no one knows when
to expect delivery.

A few loaded boats of pea were re-
ported as afloat in the harbor but their
number was so negligible as to amount
to practically nothing. The companies
have nothing to offer to the trade and
most independent operators are keep-
ing their supplies for their own use at
the mines.

Some river barley was offered here
toward the end of the week at
$2.50@2.75.

BALTIMORE

The situation continues to cause
much worry. Many consumers will un-
doubtedly have to face the early weeks
of cold weather without hard coal, no
matter how soon mining begins. Some
dealers are advising consumers to take
lump soft coal, or the English coals
coming in. Few of the household heat-
ing plants are adapted to use soft coal
without great trouble.

The State Forestry Division is en-
deavoring to get rural users of hard
coal to take wood, offering to see that
thistles are washed. If it was successful in
full it would save a consump-
tion of about 600,000 tons of an-
thracite. At last the public is awaken-
ing to the real dangers of a coal short-
age. As the cold weather during the
both consumers and coal men grow
nervous. It is far from a healthy
situation.

PHILADELPHIA

The appointment of a fuel commis-
sion by Governor Sproul seems to have
brought home to the consumer the ex-
treme shortage that is likely to prevail.
When it is voted, but that wise days
will bring us into general coal burning
weather, the wonder is expressed where
the coal is going to come from, even
though mining could be resumed at once.

Consumers begin to realize how help-
less the dealer is to assist them, even
though he does promise to make de-
liveries when coal is received.

The movement of pea coal into the
cellars goes on actively, and shipments
from the companies are somewhat
light, although heavy ton-
ages on order, in fact it is believed
that the amount actually ordered will
exceed the tonnage in stock. A good
deal of this coal is going to distant
territories, who, while they do not or-
dinarily use much of this size, yet be-
gan placing orders for it somewhat
earlier than local retailers.

There seems new something more
definite than mere rumor upon which
to base a decision to have but two sizes
of family coal when shipments are re-
sumed. It is believed that the larger
companies have already adjusted the
screens at the breakers with this idea in
view.

In steam coal, which means river
barley, the quotations are still very little
changed, $2.50@3, although a small
quantity of low-grade material has
been moved at $1.85, being coal with a
larger percentage of pebbles than usual.

BOSTON

A few last clean-up cargoes of pea
are being received, but as a result of the
recent movement, they are practically nil.
Retail dealers are reduced to extremely small
reserves of prepared sizes, but coal is
still being distributed through usual
channels and there is no dealer of any
size has yet thrown up his hands.

The wholesale trade feels that when
mining is resumed prepared sizes will
be distributed by representatives of the
producers, much as in 1918, and
that no effort will be made by the
administration to supplant the usual
channels of supply. The subject was
gone into in great detail during the
war, and it would be hard to believe
the experience of that period would
be thrust aside.

BUFFALO

One jobber reports some hundreds of
carloads still held in storage, which he
will sell at a premium of only 75c, a
ton. It must be that his company has
the hoarding habit in a very marked
degree, or this coal would have been
gone long ago. Still the consumer
appears to be reconciled to the indefinite
waiting.

It seems to be the idea that nothing
is to be done until the bituminous
miners are at work. The indifference
of the men and their readiness to
remain idle indefinitely at the command
of their leaders is still as hard to
explain as ever.

SOUTH

BIRMINGHAM

The strong demand which has pre-
vailed for some time past is still well
sustained and there is a scarcity of all
grades. The bulk of the output, as
anticipated, has been pretty well sold
up for some weeks ahead, with several
hundred cars moving daily to Western
railroads and to lines operating in the
district. The industrial demand and
the call from Municipal plants and
smokestacks in every direction is large in
the aggregate.

Prices are generally a matter of elec-
tion of the seller, and mine run and
washed range $4.50@5.50 mines, with
little or no regard to quality. Spot
domestic is equally as scarce as com-
mercial coal and dealers generally are
manifesting activity such as has not
been shown in a long while, but are
making little progress in placing
orders.

Despite the car shortage and crippled
transportation conditions, record pro-
duction is being maintained, running to
375,000 and 380,000 tons during the
last three weeks. With an ample
supply of equipment for loading and
hauling, service could be increased easily 50,000 to 75,000 tons
per week. The lines are showing steady
improvement in service.

VIRGINIA

Not much more than 50 per cent of
potential capacity is being produced.
Any increase in production has been
limited to the mines on the N. & W.
and the Southern, mines on the former
road having increased their production
to the extent of 15 per cent and on the
Southern by 5 per cent.
Abnormality Is Normal

Now in Midwest Region

THE Midwest is getting hardened to upset conditions. Uncertainty in everything to do with the coal trade has calloused coal traders to a point of calmness. Prices remain high and coal is almost impossible to get for open market except from western Kentucky, whose output sold at the end of the week for more than $8 in most cities hereabout. Buyers are now so confident of the end of the strike that they are buying only where it is absolutely essential. Jobbers are declining to sign up with producers for any more coal except on a day-to-day basis.

The machinery of controlling distribution of coal from the Kentucky fields has not got well into its stride. The result is a large part of the output is still going into the open market. Priority orders are growing more numerous every day but even this is uncertain because of conflicting efforts of those supposed to grant priority. Coal supply continues to be limited.

A good deal of the coal produced by the eastern Kentucky fields is going to railroads and utilities at the Hoover prices. West Kentucky continues recalcitrant and while its committee wrangles with Washington to get an increase in the Hoover maximum, most of that region’s coal sells higher than $8 at the mine.

CHICAGO

A state of uncertainty has prevailed so long on this market that it now is accepted as normal. Hence its continuance during the past week while the strike gave signs of ending at the Cleveland conference, upset nobody. A little coal from Kentucky was traded here every day at prices that preceded around $8@9 all week, closing Saturday at $8@8.50. At no time was there any heavy trading nor was the market level. Wild quotations were quoted from time to time to unwise buyers, resulting in an occasional sale at $11 or even $12.

Practically no coal other than a small volume from western Kentucky moved through this market except one batch of Pittsburgh No. 8, which was offered on Wednesday first at $9 and finally as low as $7.50 before it was cleaned up on Friday. A scattering few cars of West Virginia high-volatile also appeared and sold at the same levels. Practically no smokeless or eastern Kentucky figured in the week’s business.

A great deal of interest was stirred up by various business organizations who raised their voices over the approaching fuel famine in the city. Dealers ended a canvass showing practically empty yards and a survey of shipyards showed the supply of coal was left. Chicago is pleading with Washington for freer shipments to this region.

SOUTHERN ILLINOIS

Mules are going down the mines, presumably for the purpose of cleaning up, but it is likely they will stay down. At least, that seems to be the impression among the miners. Several mines are in first-class condition to produce coal in the event of a settlement but others may need several weeks to get in shape. Everybody is optimistic. There is no trouble in the Carterville or Du Quoin fields. There is some activity in the Mt. Olive and in the Standard districts toward cleaning up.

The shippers of Madison and St. Clair counties have been busy trying to prevent clashes between striking miners and the loaders of coal from the slack piles. Belleville loading has been stopped by the miners. Loading continues at one Collinsville pile, protected by a U. S. District Court injunction.

INDIANAPOLIS

The call for coal in Indiana is increasing but there is no coal. The demand is due to indications of an end to the strike and to the fact that the industrial plants which have been skimping along on low reserves for weeks, wish to get in on the ground floor. No contracts are being written as high as they likely will get.

During the past two weeks there has been a revival of business in some of the staple lines in the state and this is calling for more fuel. Many plants have had to close down during the past week because of lack of coal. Utilities appear to be suffering, but not to the point of shut-downs. Some are burning cobs. The state operation of strip mines has resulted in a total of only eight cars, a disappointment to Gov. Meriwether, who expected a larger production in the eight days the State has had control.

WESTERN KENTUCKY

Although priority orders are controlling the movement, use and destination of coal, and billing is refused by the producers, except when shipped on such orders, the price question is not being policed by the railroads, with the result that about the lowest quotations for Western Kentucky coal are around $7 and ranging upward to $8 and higher. This is a drop from $9@10 from July 5.

Western Kentucky has never agreed to Hoover prices. For several days past an effort has been made to secure a $4.25 maximum, and press reports from Washington, indicate a favorable consideration, but no definite action. It is claimed that Washington has been countermanded $3.75 as the maximum. Production is somewhat better. There is a ready demand for all coal that can be produced at $7@8 a ton, and the industry is showing much inclination to accept $3.50, believing now is for railroad and industrial use principally, and does not represent much domestic fuel.

LOUISVILLE

Regardless of conferences this week of representatives of Kentucky, Indiana, and Chicago (H. A. Hoover and of the Kentucky Fuel Commission along with railroad officials, about the only change noted in the general situation is that all coal produced is moving on class 2, priority orders. Prices continue at $7@8 in both eastern and western Kentucky, although a few producers may be maintaining the $6.50. Jobs are taking orders, enforcing priority rulings, but the State and Federal boards are not controlling distribution.

Railroads and railroads are paying the $7@8 asked, without much argument. Michigan is raising a lot of noise concerning inability to move Kentucky’s production direct to Detroit, but Governor Morrow, of Kentucky, argues that Kentucky comes first. Jobbers report that they are not buying any coal or taking any chances on orders that may be countermanded if the strike blows up at Cleveland.

Discussion locally indicates that if any effort is made to refuse cars to customers which can afford to pay the freight but who charge over the Hoover price, there may be an effort to secure Federal court injunctions to force equitable car distribution, on the basis that no state or Federal department has the right to endeavor to regulate prices, and that such action through misuse of the powers of the Interstate Commerce Commission are unconstitutional.

ST. LOUIS

St. Louis is almost out of coal. A little is moving into the city but the situation is critical. Several small plants are running on short time and some have suspended, and it is estimated that about 5,000 tons of coal per day are being displaced in the St. Louis district by oil burners. Oil transportation is beginning to get serious. A peculiarity about it is that the oil companies are paying $8@10 a ton at the mine for the coal and are selling oil to non-essentials.

The domestic trade is easy and patent waiting, but the dealers are out of coal for small essential plants and railroads are beginning to feel the pinch in a severe way. The fuel commission has set mine prices on Missouri coal but no retail prices were set. The prices quoted at the mines on Kentucky coal range $8@9, $10, and 88c@$1, and at those of $7@8, and no other coal are available.

The general impression here is that the strike will be settled within a week, and the market should take advantage of it. St. Louis will begin to get any commercial coal and the situation is such this winter that the average supply of coal will not be normal in St. Louis unless the market is springing on account of the depleted stocks.
Eastern Inland

Buyers Reduce Orders, Awaiting Strike’s End

Cut in Consumption Necessary With Lowered Spot Demand—Priorities Leave Little Free Coal—Lake Trade Will Be Assisted by Issuance of Preferential Orders.

Priorities rule on the bulk of the coal moving. The buyer is not bidding up the market, preferring to await the early resumption of union mining which has been assured. Demand is off, but in many cases this has been accompanied by a curtailment or complete industrial shutdown as buying had lately been largely for day-to-day consumption. Prices are a trifle softer than last week.

The Lake trade has been hard hit by the scarcity and rail congestion, but the latter is clearing slowly and the issuance of priority orders for vessel and cargo coal is designed to remedy the situation.

Columbus

Operators and shippers are marking time, waiting for the results of the Cleveland conference. There is a good deal of optimism shown in producing circles and a general feeling that matters may be straightened out by the conference. The state fuel commission is functioning and only a small amount of coal is available.

Prices are erratic at the extreme. Some free coal is selling around $6.50@$6, and in some cases higher. Shippers asked by the fuel commission are made generally at Hoover levels. So far no large user has been compelled to close down because of lack of fuel although quite a few are close to the bottom of their bins. Railroads are taking the main bulk of the production.

Quite a few Lake shippers are in the market. Offers of $4@$4.75 have not been taken up and producers are content to await developments. The H. V. docks at Toledo loaded 55,911 tons during the week ended Aug. 9, as compared with 42,101 tons the previous week. The Northwest is clamoring for coal and some priorities to insure shipments to that section are being issued.

Buffalo

The situation here is just as quiet as ever. Jobbers have regular understandings with reliable mine owners, and are doing a ragged sort of business, with some cars one day and perhaps none the next. Others hold off, with the idea that prices will go down fast as soon as the mining settlement is made.

The more determined of the operators say that mining at former wages merely means another fight next April. It will not answer to go on in this way indefinitely.

The price situation is as unsteady as ever. Now and then a car comes out that was bought at $3, again one sold for $9. Between these extremes a good average is $7.50@$8.50.

The company getting Lake fuel continues, but the fleet manages to obtain it somehow. With new crops heavy the Lake activity will need to continue.

Cleveland

Hope of an early settlement of the strike has caused a peculiar situation in the Cleveland market. Buying is not as strong as it was two weeks ago and consumers who are not forced to take their supplies on a day-to-day basis are delaying in the hope that they will soon be able to place orders for union-mined coal at more reasonable prices.

Industrial plants are steadily losing time through individual fuel shortages. The danger point has been reached by railroads and public utilities, and these industries are most active in seeking tonnage. Pressure is being taken on an increasing volume of the non-union output and the Lake situation is being given some attention by the issuance of preferential orders for the movement of bunker coal, as well as the placing of a priority on cargo coal shipments.

Prices show a wide range, but have little significance as rail congestion and priority orders allow but little tonnage to seep through.

Eastern Ohio

Even though the supply of available coal in the market has averaged prices at a minimum, steam users are purposely procrastinating as to any steps looking toward replenishing their stocks because of renewed hope that mining will be resumed soon.

Inquiries are not so numerous as several weeks ago, notwithstanding that many large industrial plants as well as railroads and public utilities are nearing the danger point of fuel scarcity. Likewise, confiscations by the railroads are becoming more frequent, evidenced particularly by the inability of consignees to get non-union coal consigned to them from West Virginia and eastern Kentucky. Congestion at Ohio River gateways continues to be the main barrier to a more rapid volume of arrivals. Receipts of bituminous coal at Cleveland during the week ended Aug. 5 slumped considerably, total arrivals being but 62,000 tons. This registers a decrease of 21,616 cars under the receipts for the week ended July 29.

Eastern Ohio stripping mines continue to produce between 30,000 and 40,000 tons daily, probably being unable to attain the former maximum output, which some six weeks ago was averaging a little above 50,000 tons.

Spot prices have varied during the week, quotations on eastern Ohio stripping and West Virginia Panhandle, any grade, ranging $7@$7.50. Eastern Kentucky and West Virginia were quoted $4.50@$8.00, but information in the trade is that these latter quotations were not without some signs of impossibility to get this coal through. Considerable shifting as well as delays in Lake shipping are reported because of inability to get bunker coal and in isolated cases as much as $10 has been paid.

Detroit

With only about 300 cars arriving daily to meet requirements amounting to 45,000 to 50,000 tons, Detroit is steadily reducing reserve stocks.

Efforts of the D. T. & I. R., controlled by Henry Ford, to arrange an agreement are still above the underas the former might send motive power and train crews to move several hundred loaded coal cars, held back on the Benedum & Western Pennsylvania, being of Corbin, Ky., have been unsuccessful, the management of the L. & N. taking the attitude that it would be an injustice to other parts of the country to permit this excessive movement of the coal to Michigan.

Word comes from Washington that Michigan’s fuel administrator, who presented priority orders for more than 300,000 tons, has been promised the immediate shipment of consignments amounting to 8,750 tons.

So far the various fuel administrators have taken no steps to obtain coal to supply the needs of household consumers, all efforts being for the relief of utilities.

Pittsburgh

The Pittsburgh Coal Producers’ Association, as a body, refused to have anything to do with the Cleveland convention, representation at the convention being merely of a few scattered mines. The evident intention of the district as a whole is to resume operations when feasible on an open-shop basis.

The remark that the districts represented at Cleveland were moved by financial considerations. A similar incentive, it is said, does not obtain with the typical Pittsburgh district operator.

The only important market in the past week has been in Connellsville steam grade, the price of which has ruled steady at a range of $7.75@$7.50, being a shade stiffer than a week ago, but easier than late in July, when the top price of $8.50 had been reached.

Occasionally a little Connellsville by-product coal is bought at $8.50 but there is little demand, consumers considering the price prohibitive. More coal, however, $8.50@$9, being taken chiefly by gas companies.

While reports continue to be made of gains in coal production in the Connellsville region, it seems to be beyond question that the offerings in the open market are lighter than 30 days ago.

Northern Panhandle

Although production is not as large as it was before the rail strike, it is being maintained at about 40,000 tons a week. Additional mines have not been able to resume operation, however. The Ohio, however, but appear to be declining somewhat, the general average being about $6 per ton.
Upper Lake Region Is in Desperate Need of Coal

Hopefully Awaits Coal Now on Way From Kentucky—Survey Shows Supply on Hand Is Gone—Propaganda Works Well—Prices Are Climbing.

WITH docks swept almost clean and with supplies everywhere down to a few days' life, the North-west anxiously awaits the arrival of the first cargoes which the government's new distribution system is going to deliver. Already 530 car-loads are ordered for it under the first priority for the Upper Lakes states. These 530 cars are beginning to come out of the Harlan, Hazard and other Kentucky fields for shipment through the Ore & Coal Exchange at Cleveland.

The Northwest needs it. Surveys by sections show the region is in a desperate plight which good propaganda and much activity by politicians have described effectively to the country. Prices are climbing to $8@$9 but there is practically no free coal and contract orders are being filled in small dribs.

DULUTH

Dock operators and dealers on this market are being besieged on all sides for supplies when they have no free coal. What little remains is being held for consumers entitled to priority. They are endeavoring to supply 1,000,000 tons to threshing outfits over the northwest. That, with bunking coal for the steamers, the railroads and other consumers in the favored class will have to come from allotments to be furnished the northwest.

A survey taken by a committee of the Duluth Chamber of Commerce showed that fuel supplies of many industrial consumers are nearing exhaustion. The report of the committee set out that seventeen mining companies operating on the Minnesota ranges are short 1,000,000 tons. The hard coal situation at Duluth and over the northwest was claimed in the report to be desperate. Record shipments for the season were made from Duluth and Superior docks during July, the total being 27,069 cars. Last year 26,664 cars were loaded out in June and 13,448 cars in July. Only 105,474 cars of coal were received at this harbor this season, being 27,069 cars. Last year 26,664 cars were loaded out in June and 13,448 cars in July. Only 105,474 cars of coal were received at this harbor this season, being 27,069 cars.

Compared with the same period last year, anorth coal receipts decreased 788,461 tons and bituminous receipts 8,445,174 tons. Shipments of 19,000 Hampton Roads because priorities have been placed on new factory installations, have been planned according to the principle that coal is to be used when it is needed and not when it is surplus. With the future uncertain, a small supply of coal has been gained, but it is known to be extremely short.

MINNEAPOLIS

Political propagation on behalf of the coal requirements of the Northwest may help win priorities and real service for this section. The governor of this state urged the government to take over the coal-carrying roads from the non-union fields to the lower Lake Erie ports. Whether a sequence or coincidence immediately after the governor's statement was made came a Federal promise of concentrating on these coal-carrying roads to get service.

Members of the coal trade insist that regardless of the settlement of the miners' wage situation, the big difficulty will continue to be the failure of the railroads to perform their functions. Senator Kellogg and Governor Preus, both of Minnesota are campaigning for coal. Nothing is being neglected that might possibly serve to bring about fuel deliveries. A coal survey is being made throughout the state. A great many large users and public service concerns are reported very low on fuel, some with less than three weeks' store.

MILWAUKEE

Milwaukee's coal market is at a complete standstill. Only two cargoes have been received thus far in August, and the docks are about swept clean. Everybody clamoring for coal, space is rare. The state fuel administration is functioning and strenuous efforts are being made to bring about urgency consigning of coal. One priority shipment of forty cars to the Milwaukee Gas Co. was confiscated en route by an eastern railway. A small cargo of soft coal is on the way here from Quebec, and other small steamers plying in the wheat trade to Montreal may bring additional cargoes.

Receipts of coal thus far in August aggregate 7,500 tons of soft coal, making the season's receipts to date 781,560 tons, against 1,604,424 tons during the same period last year. Up to this time last year 547,400 tons of anthracite had been received over the docks. Not a cargo has been received this year.

The price list on hard coal has not been changed as yet, as none is to be had. What the present rates will be when coal commences to move is a matter of conjecture. An offer of anthracite from Vancouver, B. C., at $18 a ton has been refused. Soft coal prices continue at the 50c. advance noted last week.

New England

Receipts from Hampton Roads Cut by Priorities

High Quotations Rumored for Coal Diverted from New England—Only Slight Interest Shown in Market—Buyers Profess Ability to Await Lower-Cost Coal.

A SIDE from diminished receipts on contract there is practically not a thing doing in this market. Sundry quotations are rumored, as high as $13 having been asked for small lots on cars Boston or Providence, but in most instances there is so little free coal that no one is much interested. Rehandlers are applying coal on orders entered into some weeks or months ago, and at this end thus far there has been no attempted interference.

Buyers have reasonably comfortable reserves and are by no means panickey over conditions. There is talk of replacing anthracite prepared sizes with bituminous for household use, and the public is now being advised to buy soft coal enough for two months.

Fewer transactions are possible at Hampton Roads because priorities have been placed on new factory installations, and it is not to be expected that the output will soon be increased either through some understanding reached with the unions or that the operators will themselves resume operations regardless of union leaders. So long, however, as meetings and conferences are continued such action will be very difficult for not only do such "negotiations" tend to hold operators back but they also influence mine workers themselves to hold out further in the hope some arrangement can be made on the peak wage basis.

COAL AGE
Growing Effect of Priorities Reduces Spot Offerings

Prices Are Lower as Free Tonnage Has Moved Out—Lakes Hampered by Priority Orders—Walkout Cripples L. & N. Service.

The movement of coal through this gateway the past week was a little heavier, despite the confusion of establishing priority plans for the distribution of fuel. Under anticipated priority conditions but little coal was placed for Lake shipment, the L. & N. refusing to set cars for loading for the Lakes, although inconstant operators with contract orders besieged the offices in desperation. Harlan and Bell counties are tied up by a walkout of the Big Four brotherhoods employed by the Cumberland Division of the L. & N.

Prices have been depressed by the growing effect of priority orders. There is, however, some coal now coming through, loaded before the issuance of these orders, and delayed by the transportation trouble. This is regarded as the last of the high-priced product.

CINCINNATI

For the week ended Aug. 5 the rail movement into and through Cincinnati was better and showed considerable recovery on the part of the coal roads. Total interchange of cars was 13,481, of which 5,842 were coal loads, a matter of 534 cars increase over the movement of the preceding week for coal. Of this increase the L. & N. contributed 375 cars, a fine record, taking into account handicaps. The C. & O. contributed 156 cars and the N. & W. 3 cars.

Congestion at distributing centers is being gradually overcome regardless of strike conditions and this is freeing some coal loaded before the issuance of priority orders. This has turned into the market some coal which has sold from $7.50@$9, which is regarded as the last of the high-priced product.

It is understood that the fuel committee organization is taking into account production costs and is permitting an additional charge in some cases, notably the New River district, of $1 additional to counter overhead costs, and that a few bituminous producers are advanced $1.25 over Hoover fair prices for the same reason.

HIGH-VOLATILE FIELDS

LOGAN AND THACKER

Logan mines are not getting more than one-tenth of the car supply wanted. The trouble is not local but is due to the difficulty in getting empties back from Western connections. Market conditions are highly conducive to a large production in this territory if the coal could only be moved. Many contract customers have been deprived of a supply; this is especially true of the steel industry.

Transportation conditions are being gradually improved in the Kenova-Thacker field. Mines are now averaging about 40 per cent improvement is due in part to the increased number of shopmen at work on the N. & W. and to a larger flow of empties back from the West. Priority orders are interrupting the usual flow of coal.

NORTHEASTERN KENTUCKY

Unfavorable transportation conditions are still barring many mines from operating at a time when market conditions make it necessary to produce a larger tonnage. The first few days of August, however, saw a slight improvement in conditions. Labor is available for a large output if mines can only secure an adequate supply of cars.

KANAWHA

Although mines are still laboring under transportation difficulties, yet the output remains at about 60,000 tons per week, with more than half the mines in the region still in operation and with a prospect that additional mines will resume under more favorable transportation conditions. The market is most urgent and inquiries cannot be taken care of owing to priority orders.

LOW-VOLATILE FIELDS

NEW RIVER AND THE GULF

Although all New River mines are operating, it is only after a fashion, owing to the difficulty experienced in getting cars and in getting coal moved. This is holding production down to a little over 100,000 tons a week. Production is gradually getting back to a normal basis, however, owing to the increase in transportation facilities. The movement to Tidewater has been small. With tonnage still so low prices continue on a rather high level, although government regulations are having a tendency to force a decline.

The Virginian has been handicapped by lack of motive power and production in the Winding Gulf for a time was reduced to a point below 100,000 tons a week, but with a slight improvement in transportation facilities mines are managing to increase the output. Tidewater shipments have been greatly restricted.

POCAHONTAS AND TUG RIVER

With transportation conditions on the N. & W. somewhat improved, it is possible for the mines in this field to increase its output, the increase within a week amounting to about 60,000 tons. Shopmen from other roads are now at work on the N. & W. and that is making it possible to use more motive power.

Coke

UNIONTOWN

Miners in the Connelsville region face the prospect of seeing at least a portion of the union miners returning to work under a patched-up agreement with themselves no nearer their goal than the day they walked out.

Meantime production is increasing steadily as is also the number of dynamite outrages. Labor, mostly negroes from the Southern fields, are arriving and these miners are distributed at the various plants, apparently carrying out a policy of reorganizing labor forces. The condition of the striking miners in some cases has reached the point of a crisis. At the Palmer tent colony an epidemic of typhoid fever broke out which resulted in a score being sent to the hospital.

The market remains high with no attempt yet made at restrictions of price or diverting of tonnage to priority consumers. Railroads are now the buyers, and regular rates are being made at $7@$7.50 for all tonnage offered. The coke market remains a missing quantity.

CONNELSVILLE

Coke offerings in the open market appear to be somewhat decreased, as compared with a fortnight or a month ago, although in many quarters it is thought that the market is more active than ever before, and this is the mark of good business. The market is high with no attempt yet made at restrictions of price or diverting of tonnage to priority consumers. Railroads are now the buyers, and regular rates are being made at $7@$7.50 for all tonnage offered. The coke market remains a missing quantity.

BUFFALO

Jobbers are hardly able to get anything with a little more competition from the beech districts. A little coke can be had now, though, where there was none formerly. The figures run up to $15 and $72. Connelsville foundry coke is $9@$10 for chestnut size, adding $.38 for freight to Buffalo. Mines are working approximately three days a week. The Tidewater movement has been slow.

All Tug River mines are running, but only at a full-time basis, owing to the difficulty in securing cars. Production is limited to about 62,000 tons per week, with signs pointing to an increase as lines are opened for the movement of coal, and as cars are moved into the field more freely from the West.
COAL AGE

August 17, 1922

271

*NEWS ITEMS*

From Field and Trade

ALABAMA

Forty-nine applicants for mine positions took the semi-annual examination before Chief Mine Inspector C. H. Neibitt and his assistants held at the Alabama State Mines Department. The examinations were issued to eighteen who successfully stood the examination for positions as first-class mine foremen, twenty-three for second-class mine foremen and three to men who wished to fill positions as miners.

Roy R. Con, of Montgomery, has been appointed fuel administrator for Alabama. At a recent meeting of Alabama operators to discuss and take action on the plan of the government for the operation of lands in Jackson and DeKalb counties. It is understood that the company is making an attempt to bring the adjoining counties with an acreage of approximately 100,000, and plans to build a railroad a distance of about four miles to strike the natural gas in these blocks to be constructed at the terminus of the line. The capital stock is said to be $500,000 and the location is in the counties of Montgomery and Crenshaw. Sheridan W. Baker, Santa Rosa, Cal., is said to be the principal stockholder.

COLORADO

Much criticism has arisen because the new advisory coal committee fixed coal prices higher than did the fuel administration during the Gardner and Collings, and with the approval of the committee, refused to approve the sale. Other members are James Dalywraith, state fuel commissioner; Fred W. Bennett, T. C. Hitchings, Harrington, W. R. Childers, and William R. Russian. The committee's report will be $3.50 per ton. The Colorado Fuel Commission's report will be $3.80 per ton. It is expected that the prices will be about $3.50 per ton.

ILLINOIS

The Sangamon County Coal Mining Co. is installing improvements at its mine near Lindon during the entire strike. The entire plant is to be electrified with the exception of the switchboard. Many of the improvements will be possible by the extension of a power line. The improvements will be made at the expense of the company.

Gordon Mason purchased the Morgantown property of the Producers' Coal Co., at considerably lower prices than the mining company's offer of $6,000.

The Harrisburg Coal Mining Co., Harrisburg, III., has completed the installation of three Krueger engines, loading booms at the Blue Bird mine.

The Donk Bros., Coal & Coke Co., with main offices in St. Louis and sales offices at Calumet, Chicago, A. H. Speulda, for sometime sales manager for the company, has been put in charge of the new office.

An announcement has been made by the West Virginia Coal Co., St. Louis, Mo., of the purchase of the New Marilla mine near Marion. The newly acquired property is an up to date mine with an output of from 3,000 to 5,000 tons a day. The equipment of the mine is considered to be worth approximately $1,500,000. In addition, the company has control of additional mines in the area.

H. A. Requa, sales manager for the Columbus Mining Co. at Chicago, spent the first six months of the year in Wisconsin, receiving the so-called observation that the stories of fuel famine now gnawing Wisconsin from door to door are simply not true.

C. S. Peabody, chairman of the board of the Peabody Coal Co., has returned to Chi-
cago after a trip to New York and to Eastern markets. He is expected any day to announce a large purchase of new coal from the west. The coal is in demand by Eastern industries which need it more keenly than Western householders will see to it. He said the last coal

bank has been cleaned up and the last anthracite rail below Big Foot.

Joseph Harrington, well known as the designer of the Harrington stoker, has been named chief engineer of the Dillon Coal Co., as combustion engineer.

DIANA

The discontinued branch of the C. & E. I. Railroad, known as the "Coal-Road" in western Indiana, has been bought by a number of business men living along the line, and, according to report, will soon be in operation to the great benefit of a number of small industries that have been cut off from railroad service.

KENTUCKY

Better market conditions have resulted in new mining companies beginning to spring up again. Some of these are small companies which will only operate the mines and others will operate mines which have been previously abandoned. No large

new developments are being reported.

Among recently chartered companies are the Toco Mining Co., Providence; Thomas O. Long, George W. Williams; Mrs. O. L. Smith, and E. C. Hollingsworth, Lemon King, all of Providence.

The Hazel Coal Co., a new company at the meeting in Cincinnati, approved the plan of the committee, and with the approval of the members of the distribution committee. The members said that the Hazle coal would soon be offered to the public at a price of $3.50 per ton.

MICHIGAN

Charles F. Dunn, wholesaler in Detroit for some years, has been selected as Wayne County fuel commissioner, following the their announce- ment of the Michigan Central freight de-

r. in connection with the work.

Ivan Bowen, of the Minnesota railroad fund, has been named a member of the distribution committee. He has started a canning of the 2,500 retail dealers with the request to ascertain how many there have been on hand, what they have been assured they will get and what their absolute needs to serve the winter, are.

MISSOURI

The El Dorado Springs Development Co., reported by news personal, has been placed under a large contract for the composition of a new coal mine. The company has been given a five-year extension of the contract to ascertain how many there are on hand, what they have been assured they will get and what their absolute needs to serve the winter, are.

The Mine of the Liberty Coal Co. of Mo., has been reopened under agreement with the local union of the United Mine Workers of America and will mine enough coal to keep the plant of the Liberty Light & Power Co. going.

NEW YORK

The Floradale Equipment Co. has been organized by C. H. Floradale with offices at 150 and 152 West St., New York, to handle the Conveyors of America, Chicago, a manufacturer and distributor of high grade, steamjet ash and conveyor the American transit company.

The Buffalo Chamber of Commerce has appointed Charles. L. Couch, president of the Buffalo Coal Co., as a member of the committee to look after coal supply and distribution. A preliminary meeting has been held at which a sub-committee was appointed to be the supply and needs of Anthracite will be locked away.

W. P. Smith and W. Denny, of Buffalo, have been appointed by the organization of a new company, to be operated under the name of the Smith Denny Coal Co. Mr. Smith was the representative of W. C. Stone & Co., of Uniona, Pa., until the office was closed. The company is supposed to be in the coal business in Toronto.

E. M. Host, of Inverness, Coal & Coke Co. for the three months ended June 30, shows a

ports gross earnings of $320,742 against $321,533 for the same period last year. The earnings totaled $56,519, after allowing for all charges, including interest and taxes. After allowing for the regular preferred dividend, the balance was $17,555. The annual dividend is $2 per share, to be paid on January 15, 1923.

Pennsylvania

Governor Sprout on Aug. 8 announced that he had named a State Fuel Commissi-

on to operate with the Federal Fuel Commission. There are seven members of the Pennsylvania Fuel Commission, in addition to a special committee upon distribution. The Pennsylvania Fuel Commission has been appointed a number of special agents to do the work.

The following bituminous coal companies have been granted state charters recently: Washington Coal Co., of Altoona, capital $300,000; treasurer, Edward K. Cook; directors, Paul F. Min. Missouri City Coal & Coke Co., of Kansas City, capital $100,000; treasurer, Samuel E. Cook; directors, George H. Min. The companies are the incorporators.

Edwin E. N. Young, of Detroit; E. E. E. N. Young, of Detroit; E. E. E. N. Young, of Detroit; E. E. E. N. Young, of Detroit; E. E. E. N. Young, of Detroit; E. E. E. N. Young, of Detroit; E. E. E. N. Young, of Detroit;

The School of Mines of the Pennsylvania State College has over 1,900 students enrolled this year. The college is in residence on the campus during the four regular residence courses in mining engineering, mining geology and mining mechanics.
that the School of Mines, in common with other schools of its kind, may take in a larger number of students making application for admission, and that a number of the companies in the State University with accommodations for 10,000 students.

UTAH

J. T. and E. L. Raines, A. H. Jenkinson, R. V. Wing, J. J. Geer, W. M. Strong, Lake City, and Wm. Stevens, Cedar City, have been granted permits to mine coal in this state.

The Carbon County R. R. has been organized, with offices at Casper, Wyoming. The company was recently formed with a capital of $150,000, and has purchased 2,000 acres of land in the county for a terminal.

The companies of the railroad company will be head of the railroad company.

WEST VIRGINIA

It has been necessary to institute suits of ejectment against most of the sixty-two miners occupying houses owned by the B. D. Nealy & Co., in Monongalia County, in view of the failure of the miners to move out, and their eviction has been ordered.

The company promises that if they are not able to pay the outstanding accounts, they will be required to vacate the premises. The suits have been filed.

The Coalburg Collieries Co., of Eldora, on Cabin Creek in the Kanawha County field, has filed in the Court of Common Pleas of Kanawha County application for a mandamus injunction to obtain possession of the coal rents and interest coupons and receivers' certificates of the Monongahela & Monongahla River Coal Co., and to prevent them from interfering with the company's operations.

The orders are necessary, as the company has been unable to pay the rent due on the coal.

The coal deposits in this area are valuable, and the company wishes to continue its operations.

Traffic News

Deciding the complaint of the Lehigh Valley Coal Co. against the Director General of Railroads, the Superior Court of Pennsylvania, in Monongalia County, has ruled that the rates are not unreasonable.

The complaint of the Lehigh Valley Coal Co. against the Director General of Railroads in Pennsylvania, has been dismissed.

Rear rates from the Pittston Coal Co., at Scranton, to other collieries in the Lehigh and Wyoming regions of Pennsylvania to breakers in the same region, have been reduced.

The rates have been reduced from $1.50 per ton to $1.25.

Unreasonable rates on coal from various points to Omaha are alleged in a complaint filed by the Metropolitan Utilities District, of Omaha.

The operation of a line of railroad already constructed has been requested in an application for franchise, made by the Thompson & Thompson Railroad, the line being from Thompson and Thompson Co., and to provide service for coal mines in the vicinity.

The “eastern” coal case, in which Indiana shippers are seeking a reduction in rates, has been decided. The railroads to the East, and the Blackfoot & Thompson Railroad, the line being from Thompson and Thompson Co., have also been ordered to reduce their rates.

The price of coal has been reduced from $2.50 per ton to $2.00.

Coming Meetings

New York State Coal Merchants' Associa-
tion will hold its annual meeting at Rich-
field Springs, N. Y., Sept. 7-9. Executive
secretary, W. F. Woodside, Arkay Blg.,
New York City.

Coal and Industrial Exhibition under the auspices of the Huntingdon Chamber of Commerce, will be held in the Chamber of Commerce Bldg., Huntingdon, W. Va. The exhibition is sponsored by the National Association of Mine, Mechanical and Electric Engineers, and will be held in the same building during the exposition.

American Mining Congress will hold its national meeting at the Grand Central Palace, New York City, July 10-15. President, Charles H. Kott, Pittsburgh, Pa.

National Safety Congress will hold its eleventh annual Safety Congress at the Mayflower Hotel, 11-15. President, W. F. Whitaker, Denver, Col.

American Chemical Society's annual fall meeting will be held in the Grand Country Club, Pittsburgh, Pa. Divisions will be held separately, with general meetings at Carnegie Music Hall.

The Rocky Mountain Coal Mining Institute will hold its 11th annual meeting at the Grand City, Salt Lake City, Sept. 7-8. Secretary, W. F. Whitaker, Denver, Col.
Quixotic Sacrifices

At CLEVELAND the United Mine Workers announced the terms on which they would go back to work. The terms are now well known. The miners did not ask for further conferences. The matter was settled. All that was therefor required was for the operators as individuals, or as groups if they preferred, to step up and sign the contract—one the dotted line.

Some persist in referring to the outcome as individual settlements. It is anything but individual settlements—for all it is individual signatures. There is no point in trying to cover over the extent of the defeat suffered by the operators. The only feature to which they can point as a gain is the breaking up of the old Central Competitive Field. Lewis did not get that treasure restored, and, as we have said before, it was, after all, not an essential to him.

Large groups of operators have not signed the Cleveland agreement. Some are trying to effect outright district agreements as such and thereby establish the fact of district contracts, for which they have been contending. To accomplish this they are finding that they are being called on to concede more than even the terms imposed by Lewis at Cleveland. Illinois at this writing is endeavoring to wrest from the union a contract more favorable to the Illinois mine workers than that offered by Lewis last week. They are still pinning their hope on Frank Farrington, who has delivered nothing as yet. It is an admirable enterprise in which they are embarked—that of breaking Lewis' hold by re-establishing Farrington to power through their sacrifices. So might a shipwrecked, starving mariner, clinging to a log, resist the friendly wind blowing him toward shore whilst he carved his log to a stately ship that he might ride to port in style.

Guerilla warfare annoys and hinders, it does not overcome an organized enemy.

The President's Message

To PRESIDENT HARDING the coal industry owes a debt for his message to Congress on Aug. 18, the theme of which was the present disturbed industrial conditions of the country and the major subject of which was coal. Like every student who writes a thesis as a result of his first study of an interesting subject, the President has discoursed at length on coal. He has found it an absorbing if disturbing subject.

Going back to last October, when the administration initiated its efforts to forestall the coal strike by seeking an agreement in advance between the miners and operators to arbitrate their differences—an agreement, by the way, that the operators were then wholly willing to make but which the miners refused—the President carries the narrative down to the present. His remarks on the rail strike are really supplementary because to the government at Washington the early settlement of the rail strike has been considered of first importance because of its influence on the coal strike.

Those Americans who read Mr. Harding's message with even casual care will be impressed with the hopelessness he expresses. After telling of his efforts to get the disputants together this summer he says with respect to his proposal of July 10: "Appraising correctly the hopelessness of the situation I again invited both operators and workers to meet with me, and tendered a means of settlement so justly inspired that it was difficult to see how anyone believing in industrial peace and justice to all concerned could decline it." Yet, he notes, "the mine workers refused to resume work under the arbitration plan" and "a considerable minority [of the bituminous coal operators] declined the proposal." The cause of his despair, as it has been of the despair of the coal industry since the Cleveland meeting early this month is summed up in his highly significant words:

"The simple and significant truth was revealed that, except for such coal as comes from the districts worked by unorganized miners, the country is at the mercy of the United Mine Workers." Merciful heavens! How John L. Lewis must have swelled to bursting with pride in his kingship when the President of the United States admitted so much!

Pointing out that at every stage the government has been a neutral regarding wage scales and working contracts and that there are fundamental evils in our "present system of producing and distribution which make the wage problem difficult," Mr. Harding, believing that the "public interest demands the investigation and the finding of the facts" for the public, asks Congress for authority to create a commission of investigation of the whole coal industry "with provision for its lawful activities and bestowal of authority to reveal every phase of coal production, sale and distribution."

In speaking thus he rightfully says that he is speaking in the interest of the mine worker, the mine operator and the public.

Praising the coal operators who have scrupulously held to the maximum prices set by Mr. Hoover, the President glories in the "revelation of business conscience stronger than the temptation to profit by a people's misfortune," and makes "grateful acknowledgment to those who preferred to contribute to national welfare rather than profit by a nation's distress."

It is not because Mr. Harding offers solutions for the problems of the coal industry or sets out to get a commission to assemble facts that we are grateful for his message on coal. It is because to an intelligent public his words will carry the knowledge of a troublesome and difficult problem and conviction that when a chief executive throws up his hands in despair over the strike there is perhaps after all something more than plain hardheadedness on the part of the coal operators to explain the duration of the strike and the loss of the fight to the miners.
Coal and the Tariff

IN THE boom year of 1920 the spot price of bituminous coal rose to unheard-of heights, passing in some isolated instances $20 per ton at the mines. Throughout the greater part of the year prices were high, yet the official figures of the Geological Survey show that the average for all soft coal produced was but $3.74, an increase of $1.25 over the average for 1919. On a normal output of 500,000,000 tons this would mean less than two-thirds of a billion dollars added to the cost of coal one year over the other. This increase was in fact taken in part by the advances in wages to the miners and in part went to the coal operators as profits.

A strenuous effort has been made this year to reduce the wages of coal-mine labor in consonance with commodity prices, the cost of living and wages in other industries. It has signally failed. The President in his message to Congress tells us why—the unconquerable United Mine Workers. Coal will therefore be no cheaper this winter; for many it will be higher than last year. The fight within the industry has resulted in a decision calling for more money from the public. For this the industry will be lambasted from one end of the country to the other, and—here is the point—from one wing of the Capitol to the other. Congressmen and Senators will lay the lash to the coal industry for robbing the people, for depriving it of coal and for profiteering in a commodity that is essential to keep people warm.

At the same time these same Congressmen have passed a tariff bill that adds more to the cost of necessary clothing for warmth—that is to say, for wool—than all the coal industry will exact. Sober-minded citizens are saying that were any set of men outside of Congress to have conceived and carried out the plundering of the people of the country for the benefit and profit of the few—some of whom, it appears, sponsored the bill—that this tariff contemplates, those men would be subject to indictment for conspiracy under the anti-trust law.

Wool, sugar and thousands of articles and commodities necessary to the everyday life of the common people are to suffer tribute to these organized plunderers in Congress. The President is proud of his neutrality in the coal and rail strikes. But where is neutrality between the builders of this unprecedented and unholy tariff and the consumer?

Is This Unionphobia or What?

ABOUT three weeks ago Donk Brothers Coal & Coke Co., of St. Louis, obtained permission from Frank Farrington, president of the United Mine Workers of American in Illinois, and from district officers of the union to proceed with construction of the main shaft at the company's new mine near Edwardsville, Ill. This was entirely according to Hoyle under the terms of the 1920-1922 contract—a contract which the International union was struggling to maintain. With all the necessary preliminaries completed, the company and the contractors started shipment of tools and machinery toward Edwardsville, ordered superintendents and job foremen to that town and placed considerable orders for electrical equipment and material. Work was to start with a rush and be pushed to completion as quickly as possible, thus providing immediate employment at union wages for a good many striking union men—some of them hungry after four months of layoff—and future employment to a good many more as fast as the mine was developed.

It was reasonable to suppose that the men of Edwardsville, fully authorized by their own leaders, would go to work forthwith and gladly. But did they? They did not. Instead they held a local meeting, decided their state and district officers were incompetent to pass upon their case, and proceeded to take the matter into their own hands. They delivered an ultimatum to the mine owners and to their own officials. No construction on that mine should start until the strike in Illinois is over. Construction on other mines in Illinois was proceeding under the contract, but it did not at Edwardsville. So energy expended in getting ready to finish the mine was wasted. Shipments were stopped; orders cancelled. Hungry union men continued hungry.

The whole trouble was that union men refused to obey their chosen leaders. There is no use searching for some devious method of reasoning by which the men reached their peculiar decision. In all probability reason played no part in the case whatever. The International miners' union does not preach reason into its members. It has spent years diligently instructing them in dogmatism and the infallibility of unionism. It has so successfully instilled within them a mental attitude of disregard for authority and the rights of others that today, becoming an irresponsible rabble, the membership sometimes does not hesitate to disregard its own constituted authority. When mine unionism reaches that point its foundations are cracking. The drunkenness of power may bring it down in ruins.

How Much Strength in the Law's Arm?

OUT in Illinois public and private pressure is slowly compelling officers of the law to do something about the Herrin massacre. There have been one or two gestures before. Now we see a circuit court judge issuing a summons for a special grand jury to meet Aug. 28 at Marion, 10 miles from the scene of the June 22 horror, to begin an official investigation. The law has been slow in the Herrin case.

Those who hopefully study the case in its present status are able to perceive certain indications that the call for a special grand jury is not to be merely a gesture. For one thing, the judge declined to permit the county sheriff to serve the summonses. The sheriff may be one of those upon whom painful justice will be meted out when justice finally prevails. For another, it is known that a quiet effort is to be made eventually to take the case out of "bloody" Williamson County, even at the cost of a change in the state constitution, if it becomes evident that a fair and fearless jury cannot be impanelled from among the citizens of that county. And finally, the plea of the state that it has not sufficient funds for a proper prosecution of such an elaborate case may be met with private funds in plenty. Already the Illinois Chamber of Commerce has begun accumulating them and other agencies may do likewise.

It remains highly doubtful whether justice can be done in the "bloody" county. But if it cannot, the sooner the people of the United States find it out the better. It will remain then for the world to learn whether a small community can successfully defy the will of a sovereign nation.
Low-Cost Methods Enable Thin-Seam Mine in Montana To Compete with Thick Coal Found in That State

Semi-Automatic Equipment Eliminates Hoist Engineer and Pumper—Five-Car Tracks Paralleling the Faces Aid the Loading Of Coal—Low Cars Prevent Much Breakage and Save Labor

By C. M. SCHLOSS
Denver, Colo.

The mining fraternity of the Rocky Mountains, accustomed as it is to operations in thick beds, views dubiously the possibility of economically mining the thinner seams. Most attempts in this direction have been unsuccessful. It is difficult for the thin-seam operator to compete in production cost with his neighbors mining beds ranging in thickness from 5 to 65 ft. It is difficult, but that it is not impossible is proved by the success of the Keene mine of the Bair-Collins Co., four miles west of Roundup, Montana, on the main line of the Chicago, Milwaukee & St. Paul R.R.

Keene, originally a wagon mine, was opened by a slope. When the Bair-Collins Co. became owners in 1920 they immediately sank a shaft and began to develop the mine to produce a daily output of 600 tons, which they do not expect to exceed. The superintendent, Albert Griffin, says, "With an output of only 600 tons a day we can keep down our investment in equipment and the consequent interest and depreciation on that equipment; we can keep our workings concentrated and our expense for supervising bosses low. With us, a production of 600 tons a day is the point where the economic law of diminishing returns begins to act."

The 34-in. coal bed lies from 80 to 130 ft. below the surface on a uniform pitch dipping 4 per cent slightly north of east. Immediately superimposed on the coal is an 8-in. layer of drawslate and a thick stratum of sandstone; the floor being entirely of the latter material. The excellent roof and floor and the light overburden make possible wide rooms and entries with narrow pillars. Squeezes are rare. A few props are used, more as a precautionary measure than because they are actually needed. The operation is on the lower half of the Roundup bed which is here split by 11 ft. of rock.

FIG. 1—BUTTS AND MAIN ENTRIES CROSS AT 20 DEG.
Keene mine has a layout plan that seems to have been pushed over from the vertical. All the right angles of the ordinary mine are 90 or 130 deg. The arrangement makes the faces abnormally long and unusually easy to approach with a curved rail. In consequence no difficulty is met in placing a line of five cars at the face at one time for the men to load. This saves double shoveling or worse.
FIG. 2. CAR WHICH NOT ONLY CAN GO INTO LOW PLACES BUT, WHEN THERE, CAN BE EASILY LOADED FROM THE SIDE

At 1 will be noted a small angle iron which runs all along the side of the car. Its function is to prevent the wood from being "chewed away" by the loading of coal and to lock the coal in place after it is built up on the side of the car. The back of the car is made low as at B so as to make it easy to load at this point. The top of the board B is 131 in. above the rail, and the top of the angle A, 161 in. Note also the heavy brace C which supports the flare of the car which is in this instance merely a level shelf. D is a check hook on the front band of the car, well protected by the angle brace.

From the shaft bottom the mine spreads out in a fan-tail as shown by the map, permitting easy grades into the rooms. Main entries are driven 30 ft. wide and over the haulage roads they are brushed to a height of 5 ft. for a width of 12 ft. Rock shot down from the roof is gobbled on both sides of the track forming walls to protect the entries from squeezes, or heavings of the floor, should they occur.

Cross-entries are brushed to a height of 4 ft. 6 in. Rooms are driven at an angle of 30 deg. with the butt entries and are 50 ft. wide, on a grade of 1 per cent in favor of the loads. The room faces parallel the butt entries.

A track is laid in each room paralleling the inclined face and at a short distance from it. A curved section connects this standing road with the track laid along the rib. The face track is thrown over as the room advances. By this means five cars can be spotted along the face at one time and filled with coal as they stand. This saves much extra shoveling. When the only track in the room parallels the rib and when under those circumstances more than one car is spotted at a time much effort is wasted in reshoveling such coal as is not lying convenient to the cars.

Steel ties are used in the rooms so as to keep the track as near the floor as possible. To increase the height in rooms the 8-in. layer of drawslate above the coal is removed but no other brushing done. The room centers are 70 ft. apart and a 20-ft. pillar is left between rooms.

The illustration of the Keene car is worthy of attention. The wagon is unusually and purposely low, for two valid reasons, the first being obvious—the restricted height of the working places—and the second one, not so readily recognized—a reduction of the height to which large lumps must be lifted. Lowering this lift decreases the work of the loaders.

“We have made it easy for the men to load large lump coal,” says the superintendent “and showed them that it is less laborious than breaking the lumps up before loading; 54 per cent of our product is lump.” The car is built essentially on labor-saving lines for it weighs only 1,200 lb. and is equipped with roller-bearing wheels.

The mine buys alternating current from the Montana Power Co. transforming it down to 440 volts for the two alternating-current cutting machines used at this mine and for uses other than those met by the 50-kw. motor-generator set.

Up to the present, mules have hauled all the coal from the room necks to the bottom; but a combination trolley- and storage-battery locomotive, which can be charged from the trolley, is about to go into service. At night, when little work is being done, it will be used throughout the entire mine for the hauling of coal. During the day it will handle merely main-line movements, the mules gathering the cars from the rooms and hauling them to partings, ready for the locomotive. The Bair-Collins Co. believes that operating costs can be greatly reduced by semi-automatic machinery without the large investment necessary to purchase fully automatic equipment. One example of this is the main hoist with push-button control, operated by the weighman upon a signal.
from the bottom, thus eliminating hoisting engineers. The weighman touches the button, the contactor panels connect the motor to the line, accelerate it, decelerate it, and a limit-switch and electric brake stop it when the cage has reached its dumping position in the long-radius dumping guides. A second example is the centrifugal pump at the shaft-bottom, which dewater the mine.

A float in the sump is connected by a system of levers to the motor starter; when the level of the water rises to a predetermined point the float closes the starter and the pump becomes operative; vice versa, when the water drops to a second point the motor and pump are stopped by the same means.

The shaker-screen is started or stopped by a push button operated by the weighman; it can be stopped by a remote-control button below, operated by the yardman under the tipple. He cannot, however, start the screens himself, but must signal the weighman to start when the latter is ready, using an 110-volt electric vibrating bell for the signal. The automatic idea is incorporated in the induction motor-generator set supplying direct current for the locomotive. This has features which make it practically automatic.

Keene coal is classed as sub-bituminous and its analysis is as in Table I.

At the Keene mine the superintendent keeps a daily cost sheet which enables him at the close of the day’s work to analyze the expenditures for the day and cut down thereafter any item which is excessive, before it has been magnified twenty to thirty times as it would be if the excessive cost were not made manifest before it reaches the monthly cost sheet. A copy of this daily sheet appears as Fig. 6 in this article. It is simple and short, but effective—a moneysaver.

One can check off on the fingers of one hand the reasons for the financial success of this property: (1) Small investment and overhead, (2) small supervision expense, (3) an economical system of mining, (4) reduction in “non-productive” or company men, and (5) most important of all, good management.

"IT’S AGAINST THE RULES to smoke in this mine, but t’ell with th’ rules. I got to smoke.”

He smoked—and went up in it.

DON’T WORRY ABOUT WHO WILL LOSE THE COAL STRIKE. You’ll find out when you price a ton of coal next fall—Wall Street Journal.
A Screen That Imitates the Effective Way In Which a Hand Sieve Is Manipulated

For many years the reciprocating or shaking screen has been used almost exclusively in sizing coal both anthracite and bituminous. True, the revolving screen has been employed to some extent, but as it was extravagant in its consumption of power and degraded the coal excessively, the shaking screen with spring-board or rod suspension and with elastic wooden or rigid steel connecting rods was generally adopted.

Recently, however, H. W. Falkner of Ashland, Pa., through the Tamaqua Manufacturing Works, of Tamaqua, Pa., has introduced a type of shaking screen that differs more or less radically from any that have preceded it. This new device is known as the Economy Gyrating Screen. As may be seen in the accompanying illustration, the screen or screens, for there may be almost any number, are mounted on a suitable inclination and hung by rods provided at the top with a joint permitting movement in two directions. As a matter of fact this latter usually takes the form of an eyebolt or its equivalent, connecting with an eyed rod. On one side of each screen deck or set of decks near either end, an eccentric strap is rigidly attached. These encircle eccentrics upon two vertical shafts. The two eccentrics actuating a single screen or deck are set at 180 deg. from each other and the shafts revolve in opposite directions. The screen deck as a whole is thus given a peculiar half gyratory half oscillating motion and “shakes” as much sidewise as it does endwise. Building the machine with decks to the number of two or some multiple of two permits balancing of the screens to a large degree.

It will be apparent from the above description and the accompanying drawings that one point upon each screen surface will have a simple reciprocating motion
equal in amount to the throw of the eccentrics. All other points on the screen will have not only this oscillatory movement but a side shake as well, the amplitude of which will vary from zero at the center to a maximum at the ends.

As a result of its construction several advantages are claimed for this machine as compared with the ordinary shaker. Among these might be mentioned: The material treated spreads itself evenly over the screen area; the efficiency of the screen is greatly increased; far less tendency is present for the holes to wear elliptical; little unbalanced “shake” is transmitted to the building in which the screen is housed or by which it is supported.

Cherokee-Crawford Field of Kansas Has Prospective Rival in Linn County Coal

BY C. M. Young* Lawrence, Kan.

Throughout all but the first years of the history of coal production in Kansas the principal output has come from near the bottom of the Cherokee shales, which outcrop in the southeastern corner of the state. By far the larger part of the output comes from Cherokee and Crawford Counties, but coal is also mined from the same horizon in Leavenworth County, though the Leavenworth or Beaver coal has never been definitely correlated with the Weir-Pittsburg coal of the southeast part of the state.

At the present time somewhat more than half of the known available acreage of the Weir-Pittsburg field has been mined out. At the general rate of production of recent years about 50 per cent of the remainder of the coal will be exhausted in 10 years. The date of final exhaustion cannot be predicted.

Though the Weir-Pittsburg field has been quite thoroughly prospected in the southeast corner of the state, the remainder of the coal area of the state has not been thoroughly tested. It is known that the occurrence of coal is a possibility over an area extending from

*Professor of Mining Engineering, University of Kansas.
Doniphan County, the extreme northeast County of the state to Montgomery County, on the south line of the state about 70 miles from the Missouri border. The boundary of the coal district is very uncertain, but the strike of the coal-measure rocks indicates roughly such a line as is suggested. Coal has been mined in a small way at Troy, near the center of Doniphan Country, and quite recently some large areas of coal land have been acquired by prominent coal producers south of Coffeyville, which is near the south line of Montgomery County where coal may be found in the lower coal measures. There is a larger area, extending considerably farther west in which the upper coal measures occur and may produce coal, as they do in Osage County.

Because of the importance of Kansas coal to the district which it naturally supplies, future developments are of interest. The probable scene of greatest activity in the future is Linn County, which lies half way between Kansas City and the southern line of the state, and roughly 70 miles south of Kansas City. This is sometimes known as the Pleasanton district.

Coal was found in this district at about the same time as in the south part of the state, and was worked extensively in 1903 and 1904. Work was nearly abandoned about 1908 to 1910, though work at one mine, the Thurwell, later called the American Eagle, and now the King Coal Co. mine, was never entirely abandoned.

The extent of the Pleasanton district is not definitely known. The coal being mined there is apparently the same as that being worked on a small scale at Worland, just across the state line in Missouri, which is the Mulberry coal of the Missouri State Geological Survey. The coal outcrops at various places and has been worked to some extent on the outcrop by stripping. It is known that the coal is found at Prescott, about 8 miles south of Pleasanton, and that it is found to the northeast as far north as 8 miles north of Worland. The extent to the west is doubtful, as the field has not been thoroughly explored in this direction. One report is that the coal outcrops in the hills just west of Pleasanton, being upturned there. Another report is that this is not the same coal but that the coal being mined at Pleasanton persists to the west, though growing thinner. The geological conditions indicate that the latter view is the correct one, and that this bed is not upturned, though the extent to the west and the thickness are not known.

At the present time coal has not been traced to the south beyond Prescott. About 3 miles south of La Cygne, which is about 12 miles to the north and a little west of Pleasanton, the Kaw Valley Coal and Mining Co. is operating a seam from 3 ft. to 3 ft. 4 in. thick with a good top. About one half mile west of La Cygne the coal is being mined at a depth of about 140 ft., the thickness of the coal being 3 ft. and the top being good. This same coal is being mined at a short distance to the east of La Cygne, and again 5 miles east of La Cygne, where it has a thickness of 3 ft. with a good top. It occurs at a depth of only 50 ft. Another bed of 3-ft. coal has been found by drilling over an area of about 1,100 acres in the area just mentioned.

At Boicourt, about half way between Pleasanton and La Cygne, coal has been found at a depth of about 70 ft. This has a poor "soapstone" top. Whether this is the same coal found at La Cygne is not known, but the character of the top and the facts that the coal with a good top is found at a depth of 50 ft. 5 miles east of La Cygne and that this Boicourt coal is at a depth of 70 ft., give some indication that the latter coal occurs at a lower horizon than the former.

It is also reported that records of drilling show four seams of coal at Fontana, which is near the south edge of Miami County, and about 6 miles northwest of La Cygne, and 18 miles north and a little west of Pleasanton. It is said that there are two 3-ft., one 4-ft., and one 5-ft. bed, the last occurring at a depth of about 480 ft. with a limestone top. None of these beds has been exploited, and the report of their existence is based on the rather uncertain evidence of boreholes sunk with churndrills.

There is however sufficient probability behind these reports to justify prospecting, and to make it likely that extensive developments may follow if the coal proves to be of good quality. It is possible that this coal may be the same as the lower Rich Hill coal which has been quite extensively mined near Rich Hill in Bates County, Missouri. If so it occupies approximately the same horizon as the Weir-Pittsburg coal of southeast Kansas, and the Bevier or Leavenworth coal of the northern part of the state.

As has been stated already coal mining in this district has been almost abandoned for some years, but rather recently has been revived. At the present time, early summer of 1922, the mines of this district are being operated non-union though not to their full capacity, most of the mines of the remainder of the states being closed because of the strike.

The earlier mines were operated by stripping, where they were located near the outcrop and by a few shaft mines where the cover was heavier. The shaft mines were worked on the longwall system, most of them by hand mining, though in one case a longwall machine was tried, and in another case a compressed air-puncher. Difficulties were encountered in working the coal by longwall, although this seemed at first to nearly all observers the proper method to be employed in this seam. Unfortunately the character of the top is such that it will not stand well at the face, though this method might be applied if operations were continuous.

Quite recently one of the operators has been trying the longwall method using a machine with a 3-ft. bar. Though the coal was propped and sprayed after cutting and props were placed less than 12 in. from the face the roof would sometimes break. The next time the
cutting was made the roof would not bring sufficient weight on the coal for it to fall without shooting. The next cut would sometimes give another break of perhaps 6 ft. This experience has convinced the operator that the longwall method cannot be satisfactorily applied at his mine, and it is being converted to the room-and-pillar system. Similar experiences have convinced most other operators that the method cannot be successful, at least so long as operations are intermittent.

In general the coal of this district varies from about 27 in. to about 3 ft. in thickness. In most places the roof will stand well in the entries, though there are some places where it occasionally falls. Most of the mines are dry, though some of them are troubled with surface water. There is little gas, but in some places a small quantity comes from the top.

Up to the present most of the mines have been opened on a small scale, most of them having an output of only 50 to 100 tons per day. The largest of these smaller mines, that of the Pleasanton Coal & Mining Co., can produce possibly 250 tons per day. The Douglas mine, about 6 miles east of Pleasanton, has been planned for an output of about 1,000 tons per day, but it is still in the development stage.

The illustration shows the tipple of the Pleasanton Coal & Mining Co., which though simple is one of the most elaborate in the district. Most of the tipples are provided only with gravity screens, and make only two sizes, lump and mine run.

A few notes on the operations of the Pleasanton Coal & Mining Co. will give an idea of the plan followed at the mines of this district. Entries are driven from 16 to 20 ft. wide, and gobbled on one side. The entry pillar is 12 ft. wide. Entries are driven to a height of 5½ ft. above the rail. Rooms are propped where necessary, with props 32 to 34 in. long. Three holes are drilled per room, and about 6 in. of black powder used per hole. The powder used has been FF and FFF; in future the latter will be used.

Though these operations, which are in a way pioneering operations, are on a very small scale, it seems probable that work will be continuous in this district and that it will increase in importance. This field is much nearer to Kansas City, which is a natural market for it, than the field in the southeast corner of the state. Railroad connections are satisfactory, the district being traversed by both the St. Louis & San Francisco, and the Missouri Pacific.

I am indebted for much of the information given in this paper to James A. Sherwood, chief mine inspector of Kansas, whose wide experience gives weight to his opinion that the future of this district will be important.

As to the character of the coal, it may be said that in general the coals of the Kansas field decrease somewhat in value from the Weir-Pittsburg bed upward, and the coal of Linn County, so far as known, is not quite equal to the Cherokee coal. Two samples cut at the face by Mr. Sherwood which I was enabled to examine, show an average heat value of 12,123 B.t.u., which is only a little below the average value of Cherokee coal. However this determination of the heat value of the coal in the Linn County field is the result of analyses of only two samples. This is too small a number to form the basis of any definite opinion as to quality of the fuel.

Dabney Mine Before Coal Strike Stored Coal to Maintain Steady Output

IT IS indeed unfortunate that the producers of coal took such an optimistic view prior to April 1 that they stored little or no coal in anticipation of the strike. The buyer and retailer for the most part put in stocks almost to capacity and seemed to sense the coming storm. But the coal producer, realizing that storage would require larger equipment than he possessed would not venture his money or was awakened too late to the possibilities that the protracted shutdown offered.

It has been stated and is generally realized as a fact that a steady run pays better than one that is discontinuous and that it is better to run at a small loss than to shut down entirely. For both these reasons it would have seemed well to have done, like some West Virginia mines, put coal in storage when orders were insufficient or cars were not available. The fear that coal would be produced cheaper after the strike than it was before held back union mines, but it had no effect on those in non-union regions which had already made the reductions anticipated at union mines.

Not all coals are of a nature favorable to storage,
and probably only those bituminous coals may be stored that are low in sulphur as, for instance, the Eagle seam of the Kanawha Group that is mined at the Dabney mine of the Thurmond Coal Co. This operation is located on Rum Creek, five miles west of Logan. The coal attains a thickness of 5½ ft., and has as an average less than 0.6 per cent of sulphur. It is clean except for a 4-in. cap of dirty coal near the roof which is of slate. The nature of this coal commends it as suitable for storing, and advantage is taken of that fact at the Dabney mine.

The present output is only about 600 tons in eight hours. However, since January, 1921, it has been operating at two-thirds capacity or 400-tons per day, without losing many working days. During all this time there were other mines in the field working part time. The Dabney mine was enabled to operate continuously solely because coal was stored on the surface when the demand fell off. On both ends of the tipple on either side of the track mine-run coal was piled to a depth of 25 ft. and to a width of 60 ft. The dump extended for a total length of 600-ft. In the process of storing coal was loaded in the ordinary manner into railroad cars; these were dropped down the track and unloaded by means of a steam shovel having a 1½-yd. bucket on a 48-ft. boom. In this manner as much as 20,000 tons of coal was strewed over the yard at one time, only to be loaded out again when orders have to be filled which in aggregate exceed the tonnage that the mine is able to supply from its daily output.

In order to load the coal from the piles a smaller shovel, weighing 30 tons and having a 3-yd. bucket, is utilized to sweep the coal within reach of the larger shovel. This is necessary because the large shovel is mounted on a railroad truck which travels on the same track as the cars that it loads and, consequently, the limit of reach of the shovel is equivalent only to the length of the boom. The main shovel is manned by three men, an engineer, a fireman, and a helper. The latter drops the cars, trims them when loaded, and removes lumber and other debris such as may find its way to an exposed coal pile. Only two men, the engineer and the fireman, are needed on the small shovel. As many as twenty-one railroad cars have been loaded out by these five men in eight hours, although the average loading during the months of May and June was ten cars per day.

Coal was not stored at the Dabney mine with a view of making money; an “even break” was all that was desired. The venture was made only to keep the miners employed, possibly not at full time but to an extent that would insure a living. It might be said that the present output of 600-tons is loaded out by 35 to 45 loaders; the average output per loader is 17.8 tons per shift. It is obvious that having such good men, something had to be done to keep them on the job. It is true that the loaders in this mine, who have this large tonnage record, are not required to lay their own track or set their own timbers, but the time occupied in these duties would not subtract many tons from the average output per loader even if he were asked to perform these tasks.
Fuel and Refractory Materials

After many years W. B. Davidson has essayed to bring A. Humboldt Sexton's masterly book on "Fuel and Refractory Materials" up to the minute, and the revised work has been published for American circulation by Van Nostrand Co. In its 382 interesting and authoritative pages, missing in minutest detail and authoritative books, will be found articles on combustion, heating power of fuels, and solid prepared fuels such as coke. This book is doubtless regarded as entirely up to date, but what book really is? You will look in vain for the Piette or the Roberts oven. The treatment of coal washing in this volume is so inadequate that it almost would have been better if the author had left it out. The Robinson and the Luhrig washer are the only two to be found. Reference to other washers is made in a short paragraph which includes a word or so on the froth flotation process and nothing as to table washing, the chance system and the air washer. The author admits the incompleteness of this section, and it need not be proved.

Articles follow on liquid fuel and gaseous fuel (combustion gas producers). One rarely sees so long an array of these devices in the author has assembled. By-products and low-temperature carbonization follow. These subjects are treated in a manner neither up to date nor adequate. The subjects following are furiances for metallurgical processes, smoke and its prevention, pyrometry, calorimetry and testing fuels.

The closing chapter, being on refractory bricks, blocks and tiles, justifies the last part of the title "refractory materials."

The book is a substantial contribution to the literature of fuels. Its failure to treat washing adequately is not a fault and it cannot be held blamable in that it does not treat complete combustion in a detailed manner. It was not the original purpose to give either detail or attention. It follows from the most modern practice is a common fault of all books and the little attention paid to foreign development, American and other, is a fault not peculiar to this book or to British books alone.

It must be remembered that the first edition was written for steel makers by the past president of the West of Scotland Iron & Steel Institute, and consequently is said in it and according to modern practice as a common fault of all books and the little attention paid to foreign development, American and other, is a fault not peculiar to this book or to British books alone.

What a Visitor to Non-Union Mines Found

Forecasting the present attempt to organize the non-union coal fields of Pennsylvania, the Bureau of Industrial Research recently issued a pamphlet by Powers Hapgood entitled "In Non-Union Mines." Powers Hapgood is described as a member of the United Mine Workers of America and as one who left Harvard in 1920 to work in the coal mines of Montana and Colorado. This booklet is his diary of wanderings in 1921 through the non-union coal fields of central Pennsylvania, in and about Johnstown in Cambria and Somerset counties.

The chronicle itself is the story of a man who worked a few days in this mine and then moved on to another, doing various sorts of mining under a variety of conditions. He tells us in minutest detail the things as they happen, and when he lights his carbide lamp, when he goes underground, to how the fireboss' alarm clock woke him early in the morning. An itinerant, a few days at each mine, he was put to work at odd jobs, here cleaning up rooms, there loading pillar coal.

Being a "human" document it must needs have a touch of suffering, so we are told of the poor mine rat found "torn and bleeding in the middle of the track," where a shot had caught him. "We felt sorry for him. Down in the darkness one appreciates all forms of life."

Everyone who at any time in his life has plied pick and shovel knows that such labor is unusual and that the mine is a dangerous place. There is little added to one's knowledge of the coal industry by this recital, which withholds every evidence of being a true narrative of what the Harvard man encountered on his travels. We would suggest, however, that he study his Pennsylvania mining law somewhat more carefully.

One can but wonder, however, what would have been recorded had the Bureau of Industrial Research delegated this task to him, saying that the book would have visited mine after mine that recognized the scale that the Harvard man failure but not working at that or any scale, and upon inquiry he would have learned that the mines had been closed by the unequal competition of the mining plants visited by the man from Harvard. The union is such a good thing that many union men are working in mines where the union is unrecognized.

Colliery Fireman's Pocket Book

Hardly a month passes without an elementary textbook on mining appearing in Great Britain, and they are all good books, painstakingly written, prepared for beginners but carrying the reader well forward in the subject discussed. Some—indeed most—see anxious to tell too much for the particular class of men to which they are directed. This colliery fireman's manual, for instance, might be entitled "Colliery Superintendent's Pocket Book," and would less belittle its name than it does now, not to say that everything can be understood by all who understand English as "she is spoke" in the British mines.

The book comprises 230 pages, contains 88 illustrations and diagrams, measures 5x8 in., and is published by Thomas Wall & Sons, Ltd., of Wigan, England, the firm that issues "The Science and Art of Mining." It is written by Thomas Bryson, who is a lecturer in mining and has been an examiner for the certification of mine firemen.

Much about mine gases and ventilation, coal dust and safety lamps, supporting of roof and sides, explosives and blasting, may suit the fireman, but methods of working, haulage and haulage appliances, mine drainage, surface and leveling are hardly firemen's subjects.

Coal-Mining Costs

A. T. Shurick has compiled a book bearing the engaging title "Coal-Mining Costs." We are sorry to find that he has failed in almost all cases to credit the sources of his information except in a general statement of the various types of authorities. Gracefully and truthfully he avers that "the technical press has been drawn upon liberally." Apparently it is not necessary to name the papers drawn on or the authors who contributed the original articles. Such articles as are there are marked, "Author's name.

The name of the author of the book should have shared the fate of the other names and the book should have appeared without that record.

Truth to say, the authors thus shorn of their glory have done quite well. They prepared these data partly that the mining world might be grateful and recognize, and partly that the service, if ill required, has been well done. The book contains many things that the reader will want. Some parts are deficient, some difficult to apply owing to changing labor prices and material costs, but the work is valuable even if it demands some knowledge of past wage and material scales and some good judgment in its use. It could not be otherwise than of value, containing as it does a cross-section of the work of the best engineers of the country. The volume contains 515 pages, measures 5x9 in. and is issued by the McGraw-Hill Book Co.
Enlisting the Turntable in Mechanical Coal Loading

Turntable Is Located on Room Track Opposite a Line of Crosscuts Which Intersect Five Consecutive Rooms and Give a Storage Road for Cars Near the Loading Machine

By E. N. Zern
Pittsburgh, Pa.

It is generally conceded that before mechanical loading can be successfully applied to coal mines some method of co-ordinating the processes of loading and transportation must be found. For twenty years experiments with various types of equipment have been made for the purpose of finding some means of displacing labor in the work of transferring coal from the mine floor to the car.

During this period machines have been evolved that have developed and maintained capacities of a ton per minute. It is true that in the testing of these devices weaknesses in design and structure have been revealed, but where the principle of operation has been proved correct parts can be strengthened without difficulty.

The validity of the statement that coal-loading equipment, practical from the standpoint of mechanical construction, is today available, will hardly be questioned. On the other hand the assertion that a practical loading machine has been taken into a mine and successfully operated would be generally disputed—and with good reason. This adverse opinion admittedly must be correct for it is based on the failures which litter a score of years. The cause of this distrust is therefore of lively interest to all mining men, and, stated briefly may be said to lie in the neglect of the mine management to so arrange haulage facilities that a loader may be worked at something near its possibilities.

The failure to realize this essential point is astonishing to those who, within recent years, have witnessed loaders being placed in mines where not a single preparation for their reception was made in advance of their introduction. The inevitable result, of course, was failure, and coincident with failure the condemnation of all such "ornery contraptions." Many, perhaps all, these disappointments might have been averted had one of the lessons of the late war been applied.

What quality of military leadership would a general possess who would urge on his troops without first making sure that transportation in the rear was well arranged so that supplies and reinforcements could be immediately brought to hand? The success of a mine is no less dependent upon proper transportation facilities than is the success of an army. To bring the analogy up to the present day, it is just as reasonable to expect satisfactory results from a radio receiving set that is

FIG. 1—METHOD OF WORKING SUITED TO MECHANICAL COAL LOADING

Among unusual features are the turntables T, the car house X, the line of crosscuts intersecting four or five rooms, a few curved room necks and crosscuts and the bypass entry. Otherwise it is hard to realize that this is not a room-and-pillar design for a mine operated without the use of machines for loading.

Groups of five rooms are formed, and each has a loading machine and a locomotive apportioned to it. The turntables are moved up as often as the five-room crosscuts are completed. In order to meet the difficulty arising from the instability of having five crosscuts in a row, each five-room section can have its crosscuts in a different line from those in the adjacent five, thus staggering them.
FIG. 2.
Method of Working

This shows twenty rooms to a panel. These may be made 360 ft. long, but with conditions as here laid down little reason can be found for not making the rooms 400 ft. long. Every fifth room has a curved neck and crosscuts fitted to receive rails turned to a radius of 40 ft.

without the range of a broadcasting station as it is to look for favorable returns from a loading machine that lacks the benefits of adequate haulage.

So much for the location of the difficulty; the important question is what is to be done about it? The problem resolves itself into two parts, first, to evolve a system of haulage usable in connection with mechanical loading or conveying in longwall workings, and, second, to evolve a system usable with room-and-pillar workings. The first problem mentioned is fairly easy of solution, but as so little of American mining is done by this method, most attention naturally will be given to devising haulages that are applicable to room-and-pillar development.

In our search for a solution we are obliged to face five unalterable conditions: (1) The room-and-pillar method of working is here to stay (at least, for a long time) and no radical changes in working methods should be attempted, (2) the haulage system should be such as will insure the rapid and unrestricted movement of loaded and empty cars, (3) abundant storage room must be provided for trips both loaded and empty, (4) trackage arrangements must be such that cars can be loaded at different parts of the entry without interference in the movement of trips, (5) the method must be practicable, conducive to large output and economical in operation.

**Turntable Is a Simple and Effective Device**

The method of haulage herein described is suited to all the usual procedure characterizing the panel system of working and also fulfills the five conditions just outlined. Room work is begun at the last necks on the entry, and pillars are drawn on the retreat although the advance method of working may be used. In the plan of entries, Fig. 2, twenty rooms are shown. These, for purposes of operation, are divided into groups of five rooms each. Four rooms of each group, (see Fig. 1) are provided with a turntable. Possibly this is the one and only peculiar feature of the entire plan.

The use of turntables may appear like a reversion to the obsolete. Such a feeling can, perhaps, be best explained by borrowing an expression from the same country as has furnished the idea, "Such things are not done with us." A little investigation of turntables, however, reveals the fact that they are not as formidable as they might appear. In reality they are extremely simple devices and can be supplied by several manufacturers fitted with either ball or roller bearings; they are capable of carrying as great a weight as ten tons, are not over 6 in. high, weigh about 1,200 lb., and sell at a price varying from $150 to $175. It will be noted from the description which follows that rotation on the turntable is restricted to the empty wagon, for the loaded wagon and the locomotive merely cross it. They are easy to operate, are strongly built and compact, so that moving them ahead from one to the next line of crosscuts, as is intended, offers no unusual difficulty.

For the purpose of explanation we will assume that the coal being worked is 6 ft. thick, that the rooms are 300 ft. long and are driven on 60-ft. centers, 20 ft. of which is ascribed to room width and 40 ft. to the width of the pillar. The length of room, though assumed as being 300 ft., in view of the ability of the modern locomotive justifiably might be extended to twice this distance, thus effecting many economies. An undercut of 61 ft. in this coal will produce about 32 tons, or 16 car-loads if these are figured at 2 tons each. All cutting is to be done on the night shift, except that in starting room work on group No. 4 (the last group) rooms Nos. 18, 19 and 20 may be started at the same time and cut as frequently as possible. After these are driven in a sufficient distance, room No. 17 is started, then No. 16, and so on. As the rooms advance their faces should be brought in step as is customary with this system even when operating without mechanical loaders.

A strict adherence to system is a *sine qua non*. After rooms are under way on the entire entry, the order in which they are loaded out becomes a matter of the greatest importance, as the success of the method depends upon this detail. It has already been stated that there are four groups, each containing five rooms.

**Loading is done simultaneously in each of the following rooms, reading across the column:**

<table>

It is apparent that full working will be attained only after a certain period of time has elapsed, but the grouping is correct, no matter at what stage the work may be. Thus, when one-half the number of rooms is working, the last two columns in the table indicate the proper order of loading, when three-fourths of the number are working, the last three columns indicate the order and when all rooms are being driven all columns apply.

It should be stated here that this grouping is based on sixteen-car trips for each room, as well as upon other data already given on the coal bed, such as widths of
room and pillar, undercut, etc. If 3- or 4-ton capacity cars were to be used, there would be allowable one to two room variations in the order given. Changes in dimensions can be calculated in advance of laying out the work, but these will not affect the method. We will now follow the actual operations which take place in coal loading and removal.

Let us suppose that the gathering locomotive has pushed sixteen empty cars into room No. 16 and from here to the storage crosscut. Curves of 40-ft. radius are provided in this room and also in rooms Nos. 1, 6, and 11, which likewise lead to storage cross-cuts. The first car is placed on the turntable, T, in room No. 20 (see Fig. 1), rotated into proper position, and then drawn to the face by a winch attached to the loading machine. In order to minimize labor in pushing, all cars either should have roller bearings or be fitted with an easy-running type of plain bearing. After the car is loaded it is promptly withdrawn by the locomotive and as soon as the loaded car has passed the turntable, the process of supplying an empty is repeated.

After several empties have been taken from storage, the remainder can be drawn close up to the turntable by a small room-hoist located at point X, or the same service may be performed by the winch on the loader or a crab on the locomotive, with the help of a sheave or snatch block, placed between the rails. The loads from room No. 20 are stored on trackage provided on the entry, and thence may be pulled out to the main entry, either by way of the butt or by the bypass entry.

No Time Need Be Lost

The empty cars for room No. 15 are placed as described above, the procedure of moving both empties and loads being also similar. The sixteen empty cars needed for room No. 15 are pushed in by the locomotive belonging to this group of rooms and halted on the entry, a few feet from the switch points at this room. While the locomotive is cutting loose, passing through the motor chute at room No. 10, and proceeding thence to the front of the trip, an empty car may be detached and drawn to the room face by the winch on the loader. This car, and all others subsequently loaded from this room, will be placed on the butt-entry tracks between rooms Nos. 16 and 19. An inspection of the plans will show that this position of the loaded cars does not interfere with the passing of trips to and from the group beyond—in short, there is no interference either with the movement of cars within a group of rooms or with those in any other group. Also it will be noted that the loads from either group can be taken to the main entry by means of the bypass at any time desired.

The procedure for room No. 20 is as already given. By the time room No. 10 is ready for loading, the crosscut entry which serves the third group of rooms may possibly be connected up so that empties for room No. 15 can be stored on it by passing them through room No. 11. If, however, the storage crosscut is not available, sufficient room will be found on the butt entry between rooms Nos. 10 and 15 to accommodate both loaded and empty cars. The procedure in either case for room No. 15 is similar to that already explained, the loads being placed, as before, between rooms Nos. 16 and 19. The method of supplying cars to room No. 10 is the same as described in the previous paragraph for room No. 15, the loads, however, being stored on the butt entry between rooms Nos. 10 and 13.

For the purpose of showing the ready adaptability of the track arrangement, it may be assumed that loading is taking place in the mid-group rooms. The empty cars for room No. 18 are stored on the track in the storage crosscut, on both sides of the room, and the loads are placed on the butt-entry storage beyond room No. 20. The empty cars for room No. 13 are placed to the left of the room switch, as heretofore described, and the loads are split, six being placed on the butt-entry track between rooms Nos. 16 and 18 and ten between rooms Nos. 13 and 15. This leaves a way open at all times for empties passing to the fourth group of rooms.

Each group of rooms is to have its own locomotive, loading machine and undercutting machine, and its own working force, which, counting all machine operators, a timberman and a trackman, makes a total of eight men. A few foremen, drillers and shotfriers will take care of the needs of the four groups, the grand total for the entry not exceeding 36 men.

As all rooms are driven on sights, standardized lengths of track can be used in the crosscuts between all turntables. The use of steel ties will make it easy to assemble and dissemble such sections.

In driving a crosscut it is possible to reap the benefit of machine loading by placing a turntable in the room track at the position it will ultimately occupy when all crosscuts in the line are completed. As the crosscut advances into the rib, a temporary set of rails leading from the turntable will enable the car to follow the machine.

One of the striking advantages of this proposed system lies in keeping the empty cars close to the loader at all times. This is particularly emphasized if the rooms be driven to a length of, say 600 ft. The empty cars will be, as always, within 100 ft. of the loader. The loaded wagons are relatively far away from their storage, but it is not necessary to take each car out of the room when loaded. The motorman, by merely coupling up the loads and pulling the train past the turntable, so that an empty car may be released, can cut down to two, three or four the number of trips from the room to the loaded-car storage.

An objection may be raised against the weakening effect on the roof of the continuous line of crosscuts running across five rooms. Any possible injury from this source could be brought within limits by placing the crosscuts in one group 10 to 20 ft. beyond the line in an adjacent group, or, in other words, the crosscuts can be staggered by groups.

The inevitable question will arise, what tonnage can be expected with such a system? The oft-repeated capacity figure given for loading machines, "one ton per minute," is no doubt realized where coal is loaded on the outside from a storage pile, but when applied to underground coal piles it breeds mischief. But such a capacity is not necessary for success. A few minutes with figures will show that in the case here assumed, sixteen wagons, or 32 tons, are presumed to be loaded from one room, which figures multiplied by five rooms makes 80 wagons, or 160 tons, from the group. The loading time for each wagon in an 8-hr. day is, therefore, 6 min. Considering the neatness and abundance of empty cars in each case, this time allowance per wagon appears to be reasonable. The four groups on the entry will produce 640 tons with a total working force of about 36 men, making an average of 18 tons of coal per man per day.
Safety Man Car Which Will Not Run Away
On a Steep Incline When Rope Is Severed

Men familiar with mines seldom object to riding on a man hoist or plane any more than they hesitate about doing any one of a hundred other dangerous things. They have been educated to danger and believe that their calling demands that they take a chance. Many, if not most, mines are literally covered with signs cautioning safety, yet because mining men have been educated to danger they continue to face an obvious risk. Therefore as men will jump on board the cars traveling up or down a plane regardless of the danger and notices forbidding such action it becomes necessary to provide means to assure safety and preserve the life that the average mine worker so freely jeopardizes.

The accompanying illustrations show a man car for use on slopes and inclines. The principle upon which the operation of this car is based is that of friction. Two extra ropes are laid throughout the entire length of the incline. At the top these are attached securely to a concrete foundation; at the bottom sufficient tension is applied to make them operative at a given load in the car. Within the mechanism of the car these ropes are guided around a V-grooved pulley provided with a brakeway upon which pressure may be applied either by means of a governor or through the medium of a handwheel.

In operation, therefore, the grooved wheel may be either tight or loose, depending upon whether or not the brake is applied. Any desired degree of tightness may, of course, be obtained. The proper tension to be applied to the lower end of the ropes is determined from dynamometer tests made when the car is fully loaded.

In construction the mechanism is solid and substantial. The sheave wheel is a steel casting and in addition to the brake carries a ratchet, which, in conjunction with a pawl, provides an extra assurance of safety. A governor of the flyball type furnishes automatic actuation of the brake band.

The accompanying photographs show the making of tests on a car of this kind on the plane of the Amherst Coal Co., at Amherstdale, W. Va. This plane is 850 ft. long, and the grade varies from 25 deg. at the bottom to 38 deg. at the top or just below the knuckle. In his report to the chief of the Department of Mines J. F. White, a state mine inspector, says: "First a short manila-roping hitching was made from the hoisting cable

**FIG. 1. SAFETY MAN CAR ON AMHERSTDALE PLANE**

Grade varies from 25 to 38 deg. In the illustration the hoisting rope is shown disconnected and the car with its load of human freight is being held by the brakes, which cause the car to become firmly hitched to the two ropes visible in the part of the plane above the car.

**FIG. 2. MAN CAR DESIGNED TO ACCOMMODATE THIRTY-SIX MEN ON STEEP PLANE**

It will be noted that the ropes travel around three pulleys much as in the arrangement that is sometimes used in lowering cars from rooms in mines where steep pitches are encountered. The brake can be put into operation either by a governor or the operation of a hand wheel. Where the hoisting rope was cut with two men in the car the latter traveled down the hill only about 3 in.
to the car. This was provided so that the rope could readily be severed. The car was hoisted about two-thirds of the way up the plane, at which point the rope was cut. It traveled back down the hill not more than 3 in. The car contained two occupants, one of whom cut the line. It did not seem to make any appreciable movement when the rope was severed.

"As a second test men were stationed on the incline at approximately 100-ft. intervals. The car was hoisted to the top of the plane, the hoisting rope was disconnected, and with one man operating the hand brake the car descended the hill, stopped at the different points and picked up the entire party, bringing them to the bottom of the plane.

"The next demonstration was conducted entirely at the top of the hill. Two thousand three hundred pounds of dead weight was loaded onto the car, after which it was turned loose over the knuckle. This was accomplished in the following manner: A short manila-ropa hitching was made as before, this being severed with a knife as the car came onto the steep grade. The car with its load started down the hill but stopped automatically 25 ft. 7 in. from the top at a point where I would say the pitch was 35 deg."

After the above-described tests the Amherst Coal Co. was given permission to carry as many men per trip on this car as it would hold. The dimensions of this particular car are shown in the accompanying line drawing. It will be observed that these dimensions are greater than those of the ordinary mine wagon, but the size of the car need by no means be limited to the measurements given.

The fact that this car is much heavier than the ordinary mine wagon used for hoisting men on planes and inclines brings up the question of rope stress and cost of operation. Computations based upon assumed conditions closely paralleling those existing at Amherstdale show that although the maximum rope stress resulting from the use of the new man car is almost three times that encountered with the ordinary mine car, yet because the new car holds many more men than the old and consequently makes fewer trips, the power consumed and the cost of operation are appreciably less.

This device, known, after its inventor, as the Proctor safety car, is being built by the Safety Appliance Co., of Huntington, W. Va.
Problems of Operating Men

Overcoming Difficulties in Working Low Coal

Low Hard Roof Debars Both Trolley and Reel Locomotive — Storage-Battery Locomotive Employed

Scheme to Increase Hauling Capacity of Locomotive

Reading the interesting article entitled "How Locomotives May Be Made to Gather More Cars," by F. C. Cornet, Coal Age, June 1, p. 921, has struck a responsive chord in my mental cogitations. The subject is one to which I have devoted much thought, in general as well as in specific instances.

In the planning of mining operations, time, and again, I have tried to work out some scheme that would reduce the innumerable trips that a gathering locomotive must generally make to the working face where a single car is set in and loaded at a time.

Recently I was confronted with a situation that required driving the rooms up an 8 per cent pitch. The coal was low and the state mining laws forbade the installation of trolley wires, unless they were guarded by boards or hung in trenches channelled in the roof. Both of these measures were impracticable, the former because of the small headroom and the latter owing to the expense of cutting the hard roof, which was a tough sandstone.

Storage-Battery Locomotive for Use in Low Coal

These conditions automatically eliminated the use of both trolley and reel locomotives from further consideration, in the proportion solved itself, therefore, into selecting a low type of storage-battery locomotive, which was adopted forthwith.

Here again, however, difficulties confronted us, both natural and artificial, so to speak. First, the 8 per cent grade made it necessary to drive the rooms across the pitch, or at such an angle with the entry that would enable the locomotive to handle the cars to and from the faces of the rooms.

Second, a single track being laid against the rib, in each room, the management rightly decided that it would work an overburden on the men if the locomotive was to set in more than one car at a time, in each room. This would increase greatly the number of trips the machine would have to make in gathering and placing cars at the faces of the rooms. Investigation showed that it would be impossible to get sufficient battery capacity, even with two sets of cells in the locomotive.

After carefully studying the problem, it appeared to me that the only possible solution was to adopt the plan described in the article of Mr. Cornet, to which I have referred. That was to drive wide rooms that would permit of setting in two or three cars along each face of the time, by curving the track at the head of the room and extending it along the face, as shown on the left in the accompanying figure.

If the roof conditions would not permit driving such wide rooms the necessary length of track along the face each be secured by cutting the face at an angle with the axis of the room, as shown on the right in the same figure.

It will interest the readers of Coal Age to know that a similar method is being employed at the Keene mine of the Bair-Collins Co., located four miles west of Roundup, Montana, on the main line of the Chicago, Milwaukee & St. Paul R. R.

This mine has an output of only 500 or 600 tons a day. It is working a seam of sub-bituminous coal that pitches 4 per cent to the northeast and lies at a depth of 130 ft. below the surface. The seam, which is but 34 in. thick, is overlaid with an 8-in. drawslate, above which is from 8 to 9 ft. of sandstone.

In working, the drawslate is taken down and gobbled. Under the strong sandstone roof and light cover, it is possible to drive wide openings with narrow pillars between them. The entries are 30 ft. wide and braced to 4 ft. 6 in., in the butts and 5 ft., on the main roads, for a width of 12 ft.

The rooms are driven 50 ft. wide, at an angle of 30 deg. with the entry, which makes a 11 per cent grade in favor of the loaded cars. The face of the coal is cut parallel to the entry, for the full width of the room.

The curved section of track, at the head of the room, is advanced with the face. In this arrangement, it is possible to place from four to five cars at a time along the face. The cars each have a capacity of 2,300 lb. and are loaded over the sides, being very low. At present, the cars are pushed to the mouth of each room, by the men; but a gathering locomotive is being installed, which will greatly simplify the work.

Denver, Colo.

Unsafe Roof Conditions Often Develop Suddenly

Conditions in roof strata vary widely—Danger may develop in a short time after examination.

One writer, discussing the question of how a fireboss may prove that he examined a place, when his marks made at the face and on the side of the coal have been destroyed by a roof fall before the miner enters for work, says such a fall could hardly destroy both marks.

Another writer claims that if the face was driven in the solid coal and had been properly examined by the fireboss that morning, it could hardly happen that a fall of roof would occur in the short time that would elapse before the men entered for work.

Now, it is clear to my mind that men who will make such statements as these have always worked under good roof. Either that, or they have had little or no experience in the work of firebossing. They do not realize that conditions may and often do exist that make both of these occurrences possible.

From my own experience, I recall several instances where places driven in the solid coal, as well as others where pillars were being drawn, caved badly shortly after those places were examined by mine officials and mine inspectors.

Instances Recalled Where Roof Has Caved Suddenly

Even now, I could name at least a dozen places that caved in between the early examination made by the fireboss and the time for the men to enter for work. Many of these places still showed the marks made by the firebosses on the face of the coal, the sides and often on the roof and timbers. At times, it would happen that the marks were destroyed by the fall.

By way of illustration, let me assume that this fall occurred in the first pair of entries examined by the fireboss and found safe for work, and
perhaps he may have eight or ten more entries to examine if his territory is large.

No one will deny that four hours may pass between the time the first pair of entries were examined and the men entered their places for work. Nor can any one fail to realize what might happen in that time. All practical miners will agree that it does not take hours for roof conditions to change or a place to cave.

Many miners have left their places and run for their lives, without stopping to pick up tools or dinner pails, and these men will tell you that it took but a few minutes for a roof that they supposed was safe to give signs of imminent danger.

PROVING A FIREBOSs' WORK

Now a word in reference to a fireboss proving that he made his examination and marked the place as required by law, the same morning when those marks had been destroyed by a fall that occurred between the time of his examination and the entrance of the men for work.

As has already been mentioned by other writers, any fireboss who performs his work carefully should have the confidence of his employers and all who are associated with him. His marks in adjoining places should be evidence that he had examined the place where the fall occurred.

One would be remembered that the marks of a fireboss do not prevent a fall taking place but a short time after the examination. If it was possible for a fireboss to look into the strata and know its real condition, there would be fewer accidents from falls of roof in our mines.

MINE FOREMAN.

Seal Panels in Pittsburgh Seam When Abandoned

What experience teaches—Peculiar features met in working the Pittsburgh seam—Panels must be sealed as soon as worked out and abandoned.

The discussion of how best to deal with the problem of safeguarding abandoned areas, in mines, has been both interesting and instructive. In reading the several letters that have appeared on the subject, one cannot but feel that the variance of conditions, in different localities, must determine the question of sealing off or ventilating areas that are worked out and abandoned.

Speaking from experience in the Pittsburgh district to which my remarks must be confined, I must say that it is almost impossible and quite impracticable to properly ventilate the abandoned panels that characterize the working of coal seams in this locality.

When all the coal in a panel has been extracted and the pillars and stumps robbed, it is found to be practically impossible to circulate the air over and around the falls that have taken place within the territory. The whole area has caved badly and any one familiar with the working of the Pittsburgh seam will realize the truth of my statement.

The little air that would seep or creep through the labyrinth of falls that occur within the area of an abandoned panel, in this seam, would be just sufficient to render more dangerous what otherwise might be given off on the falls. It would have no effect to sweep away these gases or dilute them to an extent that would render them harmless.

SEALING COMMON PRACTICE IN THE PITTSBURGH DISTRICT

In the most modern mines in this district, it is the common practice to seal off these panels, at both ends, by building solid 9-in. brick walls in the openings, as soon as the extraction of coal is complete in that area. At each end, there is left in a seal an opening of sufficient size to permit a man to crawl through and make a regular examination of the panel. These openings are closed with tightly fitting double doors.

The examination of abandoned panels has shown that they fill up with black-damp, which prevents spontaneous combustion taking place and helps to render explosive the firedamp mixture that would become very dangerous if diluted with air, but, in its present condition, is harmless with reference to explosion.

In closing, let me endorse the statement emphasized by Ostel Bullock, in a recent letter, to the effect that the success of any plan depends on the manner in which the work is carried on.

Mine Foreman.

DIFFICULTIES IN SUPERINTENDING

Things the superintendent must know—His numerous perplexities—His life a burden.

It was interesting to read the remarks of S. D. Hainley on "Ideals in Superintendence," Coal Age, June 8, p. 967. Evidently, Mr. Hainley knows a little of what a mine superintendent must endure.

One cannot think of a single subject that the superintendent of a mine is not expected to understand and be able to explain, from the growing of panspins to telling the size and shape of the moon.

To my mind, these things are only preliminary to his duties in opening up a mine. He may be a college graduate and have a sound of information, but what will not make him a successful superintendent of a coal mine.

THE SUPERINTENDENT BESET

The superintendent of a large mine has a thousand and one things to occupy his thoughts that the public know little or nothing about. It would be useless, if not impossible, to enumerate the numerous difficulties and perplexities that are the inheritance of the man who fills the office of superintendent.

If a piece of machinery breaks down and is thrown out of commission for a brief period, for the reason that a small repair part that should have been kept on hand in the supply room is found lacking, the superintendent must explain the cause of the accident and why the repairs are not quickly made.

Again, he is liable to be called out of a comfortable bed, at any hour of the night, because the fire boss cannot get water into the boiler; or the basin pump has lost its water and the pumpman is unable to start the pump, being a new man; or the fireboss, making his early rounds has found a fire in a heading; caused by a shot the night previous, there is trouble with the generator in the engine house; or the fan is running hot; and other things too numerous to mention.

DOMESTIC TROUBLES

Worst of all are the many domestic difficulties brought to the superintendent for solution. For example, Angelo Pronco's boarder threw up his rooms, claiming Mrs. Pronco's cooking was terrible; the fireboss's wife is throwing both Anglo and his wife out of the house and, "Would the superintendent please come down at once?" Mrs. Sudisky, burning a lot of rubbish, has started a fire in the flue of her chimney and it is feared that the house might take at me as I go by, bedad me and me man will git out and take our boarders all with us.

Then, Mrs. Murphy is on hand at the office to greet the superintendent with the information that the two Refalysky boys broke a pane of glass in her front window. She is always talking, in walks John Labio and tells the superintendent that Mike Melisky is moving out and could be, himself, move in. "Mike has built a pighouse and I have bought it and want to move in today." "Not in the pighouse, I hope," remarks the superintendent blandly.

THE PIT COMMITTEE

Answering a 'phone call from the tippie, telling of a broken horn at the dump, the superintendent orders another horn from the supplyhouse and hastens out, only to be met by the pit committee, who bring a complaint from the men about the scales, which they want tested and a new tare put on the cars.

To meet the demands of the company, the chain of command, the children's playground and the welfare organization, the purse of the mine superintendent is always empty. He is lucky if he can keep out of politics in the town, but in ninety-nine times in a hundred that is out of the question.

There are two churches in the place and the superintendent attends one of them regularly, he must be sure that none of its members hold too many of the good jobs in the mine; he
will be accused of favoritism. Having a son, if he gives him a fairly good job, it is reported around that the boy "gets his money for nothing." Indeed, a volume could be filled regarding matters that perplex and worry a superintendent, until his life is a burden often times.

THOMAS HOGARTH.

Indiana, Pa.

Gaining the Confidence of Men

Confidence the first essential in getting results—Men will work for bosses whom they trust.

SPEAKING of getting results in the work of mining coal, I find that different writers, and even different writers on different days, write in different ways of treating their men. My experience as a mine foreman has taught me that there is only one way to deal with men and that is to treat them as you would like to be treated if in their place.

The first thing that a mine foreman must do if he hopes to succeed, is to gain the full confidence of the men in his charge. Gaining the confidence of one's men is, indeed, the first essential in getting results. Today, the boss who fails to gain the confidence of his men will not be able to handle them successfully in the interest of the company.

KIND TREATMENT WINS WHERE OTHER METHODS FAIL.

It is frequently the case that the failure of a boss along this line means much to the company who employs him. In other words, in order to get work done, numerous concessions must often be made and favors granted, by a boss who has failed to win over his men; and these add materially to the cost of operation. Where a foreman deals squarely and kindly with his men, it is not necessary for him to throw away his company's money to get work done.

When I was assistant foreman, it was part of my duties to fire the shots, see that the timbers were properly set and look after many other details of the work. Of the fifty-live men under my charge, there was not a man but that would willingly do anything I asked.

My rounds were made every thirty minutes and, such was the confidence of the men, they would wait for my advice to tell a hole, get to point it, and what weight of powder to use. This information was always given thoughtfully and carefully.

FAMILIAR WITH HIS MEN.

Observing the roof in a place, I would say, "Jack, you need a timber here," and the man would jump for his ax at once. If there was slate to be moved there was never any trouble to get a man for the job, knowing that he would be paid what was promised and would make good money at the work.

It was pleasing, one day, to overhear a new man asking an old miner why he had set so many timbers in his place, which was more than the rules of the mine required. The reply was, "Well, George, my boss told me to set them while I had time between cars. He said it would make my place safer and the work easier for drawing back the pillars and he knows." In closing, let me say that men will work for a boss in whom they have confidence. When a company has confidence in its manager, the manager confidence in the superintendent, the superintendent confidence in the mine foreman, and the foreman has gained the confidence of his men trouble will end and harmony prevail.

THORPE, W. Va.

G. W. BREEDEN.

Inquiries Of General Interest

Method of Working to Reduce Danger from Sudden Outbursts of Gas

Outbursts More Frequent in Disturbed Areas—Occurrences Often Give Little Warning—Numerous Attempts to Drain Gas Prove Futile—Pillar-and-Stall Method Safest

BELIEVING that the danger from sudden outbursts of gas, in mines, can be greatly reduced by adopting measures for their prevention, I am taking the liberty of asking the opinion of the editor of Coal Age and its practical readers, on this subject. I am particularly anxious to know what is generally regarded as the safest method of working to employ in working coal subject to these conditions.

In this district, there have occurred a number of outbursts of gas that have thrown down much coal, and many of them have given little warning of their coming. In a few instances, miners have been caught and buried under tons of fine coal broken down by the pressure of the gas in the formation.

The coal we are working is soft and friable, with occasional harder faces. While the surface is practically level, the seam has a pitch of about 20 deg.; and we are now working under about 1,500 ft. of cover. Shotfiring is strictly prohibited in the mine.

On previous occasions, it has been estimated that outbursts of gas have reached 1,000,000 cu.ft., in four hours, and that as much as 800 tons of coal have been displaced by the pressure of the escaping gas. Frequent attempts have been made to drain off the gas, by keeping boreholes ahead of the working faces; but the flow of gas from these holes appears to be little more than in ordinary workings.

In view of these facts, the plan has been suggested of shooting the coal with permissible explosives, after the men have left the mine. Electric firing would be employed, all shots being connected in series and fired from the outside of the mine.

The purpose of this plan is to invite the occurrence of an outburst at a time when the men are not in the mine. It is thought that the shock of blasting would have the effect to precipitate an outburst that might be imminent. The question arises, however, regarding the danger of fires being started in the mine if the coal is blasted in this manner.

I would like to ask if there is danger to be feared from fires being started from blasting with permissible powder. Has the practice been followed, in any mines in the United States, of firing all the shots from the surface when no one is in the mine? What, if any, danger may be anticipated in employing that method of firing?

It is understood, of course, that a thorough inspection of the mine would be made by the firebosses, after the shots have been fired from the surface and before the men are again permitted to enter the mine for work. I shall appreciate very much what information may be given or any suggestions offered that will minimize the danger from the source I have mentioned.

— B. C. Canada. MINE MANAGER.

The mining of coal, in districts where the formations have been much disturbed, is always more or less hazardous. Probably no danger to which a miner is exposed presents a more difficult problem for solution than that due to the imminence of sudden outbursts of gas to which this correspondent has referred.

The subject is one that has long baffled the ingenuity and experience of many of the most practical mining men in the Northwest, where the phenomenon has been most developed. After an experience of eight years, in the development of the Morrissey mine, in British Columbia, the Crows Nest Pass Coal Co., was compelled, in 1902, to abandon its further working.

Probably the safest method is that known as the "pillar-and-stall method," in which narrow openings or stalls, 8 or 10 ft. in width, are driven up in the first working. These stalls are separated by pillars of somewhat greater width, which are then drawn back after the usual manner.

The disturbed condition of the strata, geologically, affords every opportunity
for movement and slipping in the formations. This is undoubtedly accompanied with the working of the gas confined in the strata, and the action increases as the mine workings are developed. Such movement and settlement of large rock masses causes an ominous pounding, which the miners term "bumps."

In an interesting article on the "Outburst of Gas in Crowstone Field," Coal Age, Vol. 14, p. 443, Mining Engineer James Ashworth, draws attention to the analyses of gases from that field, as showing the presence of gases of the higher hydrocarbon series. Mr. Ashworth there expresses the belief that some of these gases are in the liquid form in the coal; and that, on the pressure being relieved, they volatilize and break down the coal in the finest dust. The conditions, however, outreach our present knowledge of the subject, which renders our conclusions mere speculations at the best.

In regard to firing the shots in a mine electrically, from the surface, it can be stated that as far as permissible explosives are concerned, their use practically eliminates the danger of fire being started in the mine by blasting. While this practice of firing is by no means universal, there are instances where it has been followed. At one time, the Stag Canon Fuel Co., at Dawson, New Mexico, used this method of hoisting the mine when no one was underground, the firing of the shots being accomplished by means of an electric battery at the surface.

**Examination Questions Answered**

**Miscellaneous Examination Questions**

(Answered by Request)

**Question—To what extent does the pressure in a boiler exceed that in the cylinder of an engine? A boiler pressure of 60 lb. per sq. in. would be how much in the cylinder of the engine, and where is the difference employed?**

**Answer—The steam-cylinder pressure is always less than the pressure indicated by the gage on the boiler. The amount by which the boiler pressure exceeds that in the cylinder depends primarily on the distance the engine is located from the boiler, the size of the steam pipe conducting the steam to the engine, kind of valves and type of engine. For an ordinary slide-valve engine located a short distance from the boiler and with fairly good pipe connection between the two, it is customary to assume a cylinder pressure 2 or 3 lb. less than the gage pressure in the boiler. This, of course, has reference to the full cylinder pressure before the cutoff valve closes. The mean effective pressure in the cylinder is considerably less than this initial pressure depending on the point at which the engine cuts off steam, amount of clearance and other data.**

**Question—What kind and size of hoisting engine would you install to hoist 1,200 tons of coal from a shaft 400 ft. deep in 8 hr., with a steam pressure of 70 lb. per sq. in., the weight of coal in each car being 3,000 lb. and allowing 20 per cent for resistance of engines, ropes, and pulleys, and making due allowance for the time consumed in caging the coal?**

**Answer—Assuming a double-compartment hoist in which the two cars and cages balance each other, and adding 20 per cent to the weight of coal hoisted each trip, to allow for frictional resistances, gives for the load on the engine, 3,000 × 1.20 = 3,600 lb. Hoisting 3,000 lb. of coal each trip will require (1,200 × 2,000) ÷ 3,000 = 800 hoists, in a day of 8 hr. or 8 × 60 = 480 min. Again, assuming a speed of hoisting of 20 ft. per sec. and allowing, say 13 sec. per hoist, for caging the coal and starting and stopping each trip, gives 400 ÷ 20 + 13 = 33 sec. as the time required for making a single hoist. The total time of hoisting is, therefore, (800 × 33) ÷ 60 = 440 min. This will allow 420 ÷ 440 = 0.90 min. for unavoidable delays each day. To hoist a load of 3,600 lb., at a speed of 20 × 60 = 1,200 ft. per min., will require (1,200 × 3,600) ÷ 33,000 = 130.9 effective horse power. Then, assuming a cutoff, giving a mean effective pressure of, say 60 lb. per sq. in., in the steam cylinder, and taking the ratio of length of stroke to diameter of cylinder as 1.5, the engine making, say 450 strokes per minute and having an efficiency of 90 per cent, the required diameter of the cylinder is

\[ d = \frac{80}{\sqrt{130.9}} \times \frac{0.90 \times (60 \times 1.5 \times 450)}{60} \]

say 12 in.

The length of stroke is then 1.5 × 12 = 18 in. and the size of engine required is 12 × 18 in.

**Question—It is required to raise 800 loaded mine cars a distance of 98 yards, in a two-compartment shaft, 400 yd. deep. Give the general dimensions of the engine, drum, diameter of rope, etc., necessary to properly perform the work. Assume the weight of the coal to be 33 tons, the weight of the cars 14 tons, the weight of the cage 11 tons and the steam pressure 50 lb. per sq. in.**

**Answer—The load on the rope when the cage is at the bottom of the shaft is: coal, 31 tons; cars, 13 tons; cage, 11 tons; total, 6 tons; to which must be added, say 500 lb. (1 ton) for friction. In estimating the size of rope required, allowance must be made for the weight of the rope itself, based on the weight of a 1-in. rope (1.5 lb. per ft.), the weight increasing with the size of the diameter of the rope. The breaking strain of a 1-in., cast steel, 6-strand, 19-wire hoisting rope is 39 tons. Then, using a factor of safety of 8, in this deep shaft (1,200 ft.), the diameter of the required rope will be given by the formula

\[ d = \sqrt[3]{\frac{8 \times 61 \times 2,000}{39 - 1.58/2,000 (8 \times 1,200)}} = 1.26, \text{ say } 11 \text{ in.} \]

The weight of this rope is 1.58 (14)\(^2\) = 2.15 lb. per ft. and the total weight of the rope hanging in the shaft is 1,200 × 2.15 = 2580, say 3,000 lb.

The next step is to compute the unbalanced load on the engine. In a double-compartment shaft, the two cages and two cars balance each other, which makes the unbalanced load on the engine: coal, 31 × 2,000 = 65,000 lb.; rope, 3,000 lb.; friction, 500 lb.; total, 68,500 lb.

In order to avoid an undue bending strain on the rope, the minimum diameter of drum, for a 11 in. rope of 6 strands, 19 wires, should be 50 times the diameter of the rope; or 50 × 11 = say 60 in. or 5 ft. When hoisting at a speed of 2,400 ft. per min. in a 5-ft. drum must run 2,400 ÷ (3.1416 × 5) = 152.8 r.p.m. A direct-connected engine will therefore make 2 × 152.8 = 305.6 strokes per min.

Now, assuming a maximum speed of hoisting, for this depth of shaft say 40 ft. per sec. (2,400 ft. per min.), gives for the time of making a single hoist, allowing, say 13 sec. for caging the coal, 1,200 ÷ 40 + 13 = 33 sec. But, in order to hoist 800 cars in 8 hr., the total time consumed in hoisting is (800 × 33) ÷ 60 = 440 min. This allows 8 × 60 = 440 ÷ 40 = 11 min. for unavoidable delays in a day. A slide-valve engine, cutting off steam at 8 stroke, the mean effective steam pressure in the cylinder, corresponding to 90 lb. gage pressure, is, say 70 lb. per sq. in.; and assuming the ratio of length of stroke to diameter of cylinder as 1.5, the diameter of steam cylinder required is

\[ d = \sqrt{\frac{808}{70 \times 1.5 \times 305.5}} = 24 \text{ in.} \]

The length of stroke is then 1.5 × 24 = 36 in. There will be, therefore, required for this hoist a direct-connected 24 × 36 in. slide-valve engine, running at a speed of 152.8 r.p.m. and winding on a 5-ft. drum.
Draft Legislation for President’s Plan for Coal Agency; Hoover Price Raised to $4.50

BY PAUL WOOTON
Washington Correspondent of Coal Age

Washington, D. C., Aug. 22.—Legislation intended to carry into effect the President’s plan for a national coal agency, which is “to purchase, sell and distribute coal which is carried in interstate shipment,” is being drafted in the Department of Justice. Two or three alternative propositions are being formulated, all of which will be submitted to the President’s coal committee for criticism and suggestion before they are sent to the Congressional committees.

Secretary Hoover stated this morning that he anticipated that the Governor of Ohio would have no difficulty in arranging price matters with Ohio operators at the conference called to meet in Columbus to-morrow.

On the recommendation of the Governor of Tennessee the maximum price for coal being produced in that State has been increased to $4.50. This action was taken when the Governor certified that increased wage and production costs justified the higher maximum. Since the $4.50 price had been granted in West Virginia and Kentucky as well, it also was extended to Virginia.

The Fuel Distributor states that everything possible is being done to speed up the Lake movement and that the volume of coal moving to the Northwest has been increased materially by the new production from Ohio. Arrangements are being perfected to supply Michigan with a considerable tonnage of emergency coal. The State fund of $1,000,000 should be made available, the Fuel Distributor has advised the Michigan authorities, in the form of a bank deposit, so as to facilitate certification for the handling of coal orders.

Requests have been received from Missouri and Kansas asking that Service Order No. 23 be extended to the territory west of the Mississippi River. It is stated that the price of coal is being boosted in those states by competitive bidding, particularly on the part of railroads. Fuel Distributor Spencer, however, is of the opinion that the situation can be corrected through co-operation with the railroads operating in those states.

Advices reaching Washington are to the effect that all operators are on the point of signing the Cleveland agreement. It is fully expected here that all coal mines in the union field will be producing by next week.

A TRUCE, with the contestants retaining their arms and preparing for a resumption of hostilities on a larger scale, describes the situation in the coal industry. It is an opinion in Washington almost unanimously held that all the operators eventually will accept the Cleveland agreement. So far as government officials are concerned, they will have little patience with any other course. Their position is that the public’s need of coal is more important at this time than any issue involved in the strike. The viewpoint of government officials and members of the Congressional bodies is important not so much from any law the government can invoke as from the fact that they are assured complete publicity for their opinions on this subject and in that way can crystallize public opinion.

The public does not recognize that this is a fight between an arrogant labor union and mine owners who want to manage their own property. On the other hand there is acute public consciousness that it is going to be difficult, if not impossible, to get enough coal. There was public support for the operators’ position early in the strike, based on the belief that it would mean cheaper coal if the operators were to win. Now it is recognized that for the operators to hold out longer would simply mean additional shortage and higher prices. The argument that it would result in lower prices at some future time is too vague to be impressive as winter approaches.

Despite these facts there are some who would like to see no further signatures affixed to the Cleveland agreement. If they have the courage to hold out, it is argued, and offer to take back their men at the 1920 wage scale, but without signing the Cleveland contract, it will not be long until the leaders cannot hold their men and a hole will have been kicked in the bottom of Mr. Lewis’ boat. In some cases it might be possible, it is said, for separate contracts to be made with the men. Such a contract need differ only slightly from that adopted at Cleveland to keep the Cleveland settlement from becoming a national one.

The men might give their leaders trouble were they to be held out of employment for technical reasons after nearly five months without work. Since only 40,000,000 tons of production are represented by the Cleveland agreement today, there could be no large amount of strike benefits paid were the remainder of the operators to stand pat. Mr. Lewis has staked everything on the operators giving in before the men. It may be said, however, that those favoring such a course are in the minority. Even among the operators the majority seem to favor the resumption of work at the earliest possible time.

If the entire Central Competitive Field can get under way within ten days, it is believed that the situation can be tidied over so that industry can be kept going. It is realized that the country’s coal reserves are about gone. Widespread stoppage of industry will show itself soon unless capacity production is attained quickly. The ability of the country to produce coal is well known, therefore holding would soon cease. Such reserves as remain will be used up first with the knowledge that better prices are more likely to be obtained the longer purchases can be deferred.

The non-union fields are in a position to produce a record tonnage. Not only have many new mines been opened but it is predicted that all non-union operators will be paying the 1920 wage scale before Labor Day. All of this is on the assumption that normal transportation facilities will be available.

The suggestion has been made that since there will not be enough anthracite to go around, such supplies as become available should be allotted in a way that each community will know how much of that kind of coal is to be available. The average domestic consumer, secure in the knowledge that the strike is settled, is passing more probably to have a sign of relief and expect to obtain his full quota of anthracite. Even those who realize that there must be extensive substitution will expect his neighbor to do the substituting and as a result a real attempt to obtain fuel for the winter may be delayed too long.

Secretary Hoover is outspoken in his praise of the large percentage of coal operators who have continued to sell coal at the agreed price when they could have had $8 or $10 for the asking. At the same time he deprecates in no uncertain terms what he refers to as “bootlegging in coal.” He points out the impossibility of continuing such an arrangement indefinitely, especially when it must apply to a large number of additional districts.

To Restrict Prices at Reopening Mines

THAT the mines reopening in the union fields will be subjected to price restraint is foreshadowed in the following message from Secretary Hoover to Governor Davis, of Ohio:

As you will note from the President’s message, the proposed federal legislation will fix a maximum price for anthracite at $8.50 per ton for shipments at the mine or $8.00 per ton for shipments at a point nearer to the consumer. The $2.50 differential is intended to provide for transportation from the mine to the point of shipment, plus an additional $2.00 allow for handling and revenue. As such prices are based on the principle of relative value and under the conditions of the mining and transportation business today, such a price is not high, but as you know, it will be limited to interstate movement of coal. But if we are to have proper protection of the public on mine prices for intrastate production and margins made on resale of coal wholesale and retail
it must be accomplished through agencies established by state governors. Moreover, we need immediate action pending any legal proceedings.

I am informed that coal mines now opening under the Cleveland agreements in Ohio are demanding from $7 to $10 a ton for coal. In the meantime the public utilities of Ohio are asking us for priority orders against Southern fields where the price is $3.50. You will observe that this situation is the same as in Tennessee. It was not just to either the operators or to persons in great need of coal, but the public utilities and the State of Ohio in particular must be considered. The situation is not only urgent, but it is necessary to believe what you are told. The situation exists in Ohio.

I have had communication with operators in Ohio who are anxious to do the fair thing by the public and I believe you will welcome from you some sort of voluntary arrangement for establishing fair prices in Ohio. The rates made under the Garfield scale you will find in the Pittsburgh News to be $10, the average price of coal to run-of-mine was about $3.50. The recent signed wage scale is a large increase over the basic in use at the time the Garfield prices were made. The situation warrants a general understanding between the operators and the public to the effect that any increase in the prices of the operator shall be an enormous saving to the public over prices now being paid from Ohio mines.

I cannot make any more than that if the people of Ohio and surrounding states are to be protected, there should be a voluntary arrangement, with the necessary committees to enforce it under the direction of your fuel committee, by which some fair manner of running and similar voluntary arrangements and enforcement is set up in respect to wholesale and retail handling of coal. The Federal Fuel Distributor would gladly co-operate in making such an arrangement as this.

Governor Morrow of Kentucky after an examination of the situation, has written me that the public utilities and similar voluntary arrangement and enforcement is set up in respect to wholesale and retail handling of coal. The Federal Fuel Distributor would gladly co-operate in making such an arrangement as this.

Governor Davis asked Secretary Hoover to name Ohio coal profiteers.

In answer to a telegram of Mr. Hoover's on Saturday, Aug. 19, which had been said he had informed that some Ohio operators, under the Cleveland agreement, were asking $7 to $10 a ton for coal, and that "coal operators would welcome some sort of a voluntary arrangement to establish a fair price for coal in Ohio," Governor Davis asked Secretary of Commerce Hoover on Aug. 21 to make known the names of Ohio coal operators who are profiteering, if he knows who they are, that "they may be dealt with as they deserve." The 'serious nature of your Saturday's telegram, both in its charges and in the grave effects on the Ohio public of such as you outline, compels me to ask you for more specific information," the Governor's telegraphic reply to Mr. Hoover declared. "If there are coal operators in Ohio who are so utterly calloused to every principle of fair play in dealing with the public as to seek to extort exorbitant prices such as you point out, the people of Ohio want, and I believe they have a right to know who these concerns or individuals are. I request, therefore, that you make public the names of these operators that they may be dealt with as they deserve."

Middle West Keen for Coal as Negotiations Progress Toward End of Mine Strike

The Middle West looked anxiously as negotiations progressed in Chicago and Terre Haute late last week for the end of the mines' strike in those states. The facts are that practically every user of coal is seriously worried and some, including many a necessary industry, are suffering. The strain through the past summer has been too much for the country. It didn't turn out to be a case of the union mines supplying all the summer needs of the land—thanks to transportation that did not transport. And while coal users are strong for an immediate resumption of mining, the miners of the region, especially those in southern Illinois, have been giving every encouragement to their exultant cockiness by hounding coal trains and causing local coal to seek out cars of coal for them to destroy. This bit of tactics supplanted sniping at train crews, which was the order of the day in the week of the Lewis Cleveland conference.

In St. Louis and surrounding Missouri territory the coal famine is as painful as anywhere. Some industries have closed down, public utilities are up against it for fuel, the Terminal Railroad is working from day to day on the day's supply, and the new state fuel committee which determined that 50 cars a day were necessary for only the essentials of the St. Louis region, could buy and deliver only 15 or 20 cars. When Kentucky shipments consigned to St. Louis were set out and dumped in southern Illinois by miners, E. J. Wallace, of the fuel committee, protested to Governor Small. Adjutant General Carlos Black, of the state guard, at once notified the operators of the mines involved that if they could not stop that sort of thing, state troops would appear on the scene to do it for them.

In Wisconsin, public utilities have been wound up by the recent announcement of the state railroad commission that no matter how necessary the industry, it would not get a coal priority order issued to it unless it had coal under contract. The railroad commission is handling the question of priority in that state to relieve the present situation.

The railroad commission has sent out questionnaires to all big fuel consumers asking for stocks on hand as of July 31 and estimates of fuel needs for the next few weeks. Unless these are returned at once, the commission says, those who fail cannot get priority orders. On the whole, with stocks dwindled down to next to nothing, Wisconsin is in a bad way.

Illinois manufacturers are scraping the bottoms of their coal bins, the Illinois Manufacturers' Association announced in Chicago Friday after completing a survey of its members. Out of 499 replies received by the association, coal supplies on hand average but 18 days and that average was based on figures which in some instances were a week old. The report that the actual coal supply at the time the report was issued was good for little more than a week in some cases.

The total tonnage for the 499 manufacturers was but 351,025. The best supplied plant was good for 40 days. More than 100 were out of coal and running on only what they could get from day to day. They all protested at having to pay $10 and $11 for "dirt" and for low-grade fuel which contained 25 per cent ash and as little heating value as 9,000 B.t.u. and which was bought last winter for $1.50 and $1.60.

Confusion has arisen in many quarters over the priority plan. In Kentucky it is working better, probably, than anywhere else, and even there men with priorities cannot get the coal allowed them and when they do get it they often pay the top price of $8 or $9 instead of the Hoover level. In Missouri the commission has had exactly the same difficulty. In Indiana very little coal has been handled by the state's martial law scheme. In the northern states, where not a ton is coming out of the ground, about all the state committees could do was to holler and in Illinois everything is at loose ends because, after appointing R. L. Medill as state food administrator, Governor Small did not name the committees with Mr. Medill and there were no funds for the committee's work.

Mr. Medill has set up an office in Chicago with volunteer aids and is receiving requests for coal priorities. But he doesn't know what to do with them when he gets them. So he merely forwards them to Washington, hoping they will do somebody some good. The Governor does not complete the fuel organization because he doesn't know yet what it will have to do or what its powers may be. He is waiting for development.

After all this the difficulty which coal consumers—even those with government priority ratings—have been having in getting coal because strike-crippled railroads cannot haul it out of the fields, because railroads have confiscated fuel in terminals and because unscrupulous jobbers have worked all sorts of trickery and treachery out of the business. It is easy to see why the people of the Middle West want the strike settled at once and coal mined on any old terms. The pressure they have been bringing to bear upon the operators was calculated to hurry proceedings.

Coal Age Index

The indexes to "Coal Age" are furnished free to all who ask for them. The index for the first half of 1921 is now ready for distribution, and a copy can be had by addressing a postcard to the subscription department of "Coal Age."
Watkins Deprecates Compulsory Arbitration

A TELEGRAM to President Harding under date of Aug. 29, has been made public by W. H. Watkins, president of the Pennsylvania Coal & Coke Corporation, who attended the Cleveland conference in company with two of the large central Pennsylvania producers—F. E. Herriman, president of the Clearfield Bituminous Coal Corporation, and D. C. Morgan, president of the Pittsburgh & Shawmut R.R. and the Allegheny River Coal Mining Co. According to Mr. Watkins within 24 hours after his telegram was dispatched, the Cleveland Commission, a body composed of one representative from each of the three coal fields involved in the dispute, was formed to look into the cause of the quarrel, was disrupted, and machinery established for the immediate resumption of mining and an exhaustive public investigation in the industry prior to April 1 next. The miners' policy committee with the operators present agreed unanimously on the principle set forth in the telegram, which reads as follows:

It is my judgment that a prompt settlement of the coal strike must depend upon compulsory arbitration as against compulsory inquiry applicable to the fixation of a scale of wage to become effective April 1, 1923, when the apparent over inflation of visioned scale wages will expire.

It is admitted by both parties to this dispute that a method must be found not only to procure a prompt resumption of mining but to prevent a recurrence of this deplorable crisis.

The commission of operators that the only effective way to guarantee the peaceful settlement of the wage scale question, thereby securing to the United Mine Workers at this time a commitment to submit their case to arbitration and to bind themselves now to accept the award of such an impartial commission.

An agreement to accept arbitration for April 1 next cannot be secured without the report of an impartial commission. An agreement wrung from an unwilling party is dangerous and not for the future peace of the industry which is now bought by all parties concerned. The whole principle of compulsory arbitration is at variance with the traditions and spirit of the Free enterprise institution. Some of the present national strikes which deprived the public of the necessities of life, the triumph of the spirit of civilization and fair play.

An impartial compulsory arbitration in future disputes was exhaustively studied by the Roosevelt Anthracite Strike Commission of 1902, of which I had the honor to be a member. The seven years previous reports of President Roosevelt as follows:

"...if the present peace hold, a public against long-contested controversy and to make a coal famine or a famine in any other direction practically impossible we deem it essential that there should be a neutral authority to conduct just such investigations as that you called upon us to make."

The operators have urged the commission to recommend the adoption of compulsory arbitration, so-called, as the means of this desired result, but we cannot see our way to recommend any such drastic measures. We do not believe that in the United States such a system would meet with general approval, nor would it be possible for such a commission to be established by a most of the American people in any similar controversy.

"...the chief benefit to be derived from the suggestion herein made lies in placing the real facts and the responsibility for such condition clearly upon the heads of the coal operators, who have long been crystals and make it their full worth.

A thorough experience in the coal industry I have had no occasion to doubt the wisdom of this award, and on the other hand I have had ample evidence of the turmoil, the ill-feeling and the breach of faith that are the atmosphere of compulsory awards.

The proposed compulsory inquiry advocated by the Roosevelt commission of 1902 leaves both parties free to negotiate willing on the basis of the recommendations of an impartial commission which has had access to all the facts and whose findings will have the force of law, so far as necessary and of democratic society.

The fact is that the limited conference to which I am not a party, now in session in Cleveland, should shun and that the whole industry, and not the parties, should immediately assemble and call on the national scale commission of the United Mine Workers to meet them and any other operators, and to bring an agreement containing the apparent desire of all parties, and submit this agreement containing the apparent wish of all parties, and submit this agreement to the members of the commission to recommend the fixing of a scale effective until April 1, 1923, together with a provision for the fixing of a scale at monthly intervals for the period of compulsory arbitration, or if more than seven impartial citizens of commanding public reputation have been agreed by a thorough examination of the whole industry and on the return to you as the president of the Senate of my recommendation, not only in the report of this informal commission to the Governor but to make a study of the whole industry, and on the return to you as the president of the Senate of my recommendation."

Keeney Says Friendly Operators May Clean Up Mines Preparatory to Resumption

FEELING absolutely confident that whatever settlement might be effected at Cleveland, northern West Virginia operators as a whole would fall into line, C. F. Keeney, president of District 17, let it be known while the Cleveland parley was in session that operators who have been friendly to the union and had made no effort to operate their mines on an open-shop basis or on any other basis, since April 1, might begin the work of cleaning up the mines preparatory to operation. The statement made by Keeney was as follows:

"Operators who have been favorable to the United Mine Workers since this suspension began, April 1, 1922, have permission to clean up their mines, provided they pay the former scale with the check-off dues and assessments, with the understanding that they will not try to dump any coal until the settlement is effected between the operators and the United Mine Workers of America. This does not, however, apply to the operators who have been unfair with the United Mine Workers of America since this suspension took place and have attempted to operate their mines on an open-shop basis. If after the mines have been cleaned up for the operators who have been favorable a contract has not been reached we will ask our men to again cease work until further notice from the United Mine Workers of America.

As for the operators listed as unfair most of them are now operating their mines so that refusal of permission meant nothing in their case.

Miller Calls Special Session of Legislature To Name Fuel Administrator

GOVERNOR MILLER issued a proclamation Aug. 21 calling the New York State Legislature into extraordinary session for Monday, Aug. 28. The primary object of the call is to create a fuel administrator, clothed with sufficient authority to regulate equitable distribution and fair prices of fuel in this State during the coming winter. A few weeks ago Governor Miller, without any particular authority of law, named a state fuel commission consisting of a number of representative people, of which Eugene H. Outerbridge was making chairman. Mr. Outerbridge has been forced to resign because of ill health, however. Prof. Charles E. Locuck, of Columbia University, will take Mr. Outerbridge's place.

This commission has been making an informal survey of fuel on hand in the State, the sources of supply and the extent of distribution and it is upon the basis of the report of this informal commission to the Governor that the Legislature will be asked to clothe officially a state fuel administrator with legal authority over distribution and price fixing.

Quiet in Utah; One Guard Troop Withdrawn

THERE is little change in the strike situation in Utah. All is quiet on the surface. One troop of the National Guard has been sent home, but at the request of the community from which it was drawn and because it was feared the crops were in danger of going unharvested. The withdrawal of the troopers gave the public the impression that the strike was collapsing. A correspondent of Coal Age inquired of a state official if it was the intention to recall all the members of the Guard, and he replied "Very far from it!"
Borah and Winslow Coal-Commission Bills Reported Favorably; Early Passage Forecast

The Senate Committee on Education and Labor and the House Committee on Interstate and Foreign Commerce both ordered favorable reports on Aug. 22 on bills to create a fact-finding commission to investigate the coal industry. The Senate committee adopted the Borah bill with modifications and the House committee adopted the Winslow bill, which was introduced only Monday.

Efforts will be made to speed action on each measure in the respective houses, the first reading was today. The Borah bill, which was introduced several weeks ago, provided for, a commission of five members to be named by the President without restriction as to personnel. As originally drawn this bill provided a commission of three—one from the coal operators, one from the union miners and the third from the general public. The salary to be paid was reduced to $7,500 a year today from the original figure of $8,000. The committee modified the provision calling for a report on the "necessity" of nationalization of the mines to read the "wisdom" of such a step. The time for submission of a report was reduced from nine months to five. The commission would report on a standardized day's work as well as a standardized cost of living.

The Winslow bill, introduced in the House by the Massachusetts member, who is chairman of the Interstate Commission committee, is agreed to by the conference committee only after six hours' debate Monday and Tuesday. The House bill was drafted after Representative Winslow had had a conference with President Harding. Some of its provisions were rephrased but there was no material change made in sense from the original text, which is as follows:

"That for the purpose of securing information in connection with questions relative to interstate commerce in coal and other questions and problems arising out of and connected with the coal industry, there is hereby established a Governmental agency to be known as 'The United States Coal Commission,' to be composed of not more than nine members to be appointed by the President of the United States. No member of the United States Senate or of the House of Representatives or person who has any interest in or is connected with the coal industry shall be eligible to serve on said commission. Each member of said commission shall receive a salary of $10,000 a year. Said commission shall cease to exist one year after the taking effect of this act."

"It shall be the duty of said commission to investigate and ascertain facts in the coal industry as to ownership of coal mines, prices of coal, wages, wage contracts, conditions of employment, distribution, waste of coal, profits realized by owners or operators of coal mines or by other persons or corporations having to do with the production, distribution or sale of coal, and any other material facts in connection with the coal industry generally and the organizations and persons connected with it. Said commission shall report to the President and to Congress its findings of fact and such recommendations as to methods and measures as in its judgment will promote continuity of production and efficiency in mining and distribution and maintain the uninterrupted movement of coal in interstate commerce and safeguard the interests of the workers, operators and the general public. Said commission shall submit its first report not later than Jan. 1, 1933.

"The said commission shall have power to administer oaths, subpoena and examine witnesses and to compel the production of any book, paper, document or other evidence, and to take the deposition of any person before any person having power to administer oaths. In the case of a deposition, the testimony shall be reduced to writing by the person taking the deposition or by persons under his direction. No person shall be exculpated from so attending and testifying and depositing or from producing any book, paper, document or other evidence on the ground that the testimony or evidence, documentary or otherwise, may tend to incriminate him or subject him to a penalty or forfeiture; but no testimony, deposition or evidence taken under this act shall be elsewhere used in any prosecution of any person who has testified, deposited or produced any such book, document or other evidence. But no person shall be exempt from prosecution and punishment for perjury committed in so testifying and, and this act shall not be construed as exempting any person from attending and testifying elsewhere or as denying the right to compel the production of any book, document or other evidence elsewhere in any action or proceeding."

"Any member of the commission or agent of the commission duly authorized in writing shall at all reasonable times for the purposes of examination have access to and the right to copy any book, account, record, document, correspondence or paper relating to any matter which the commission is authorized by this act to investigate."

"Any person who shall willfully refuse to attend and testify or depose or to produce or permit access to any book, account, record, document, correspondence or paper as herein provided for, or who shall testify or depose falsely in any material particular, shall upon conviction be punished by a fine of not more than $5,000 or by imprisonment for not more than one year, or by both such fine and imprisonment."

"The commission may appoint, remove and fix the compensation of such employees, make such expenditure and make such rules and regulations as may be necessary for the efficient administration of this act. The necessary expenses of the commission shall be allowed and paid upon the presentation of itemized vouchers therefore, approved by the chairman of the commission.

"There is hereby authorized to be appropriated out of any money in the treasury not otherwise appropriated, the sum of $500,000, or so much thereof as may be necessary, to be available until expended, for carrying out the provisions of this act."

It is the administration's plan, it was revealed at the White House on Tuesday, to constitute the fact-finding commission, if Congress should authorize one, entirely of representatives of the public. To attempt partisan representation on the commission would be difficult, it was pointed out, because of the different elements within the industry which would have to be taken into consideration. Particular reference was made to separate representation on the part of the non-union and union industries, the central fields and the non-union fields. The chief duty of the commission, it was agreed, is to create a committee in the interest of the American public, particularly since the coal operators and mine workers are creating their own machinery for a study of the situation.

The following telegram was sent by A. M. Ogle, president of the National Coal Association, from New York, Aug. 18, to President Harding:

"The strike in the bituminous coal fields emphatically has demonstrated the immediate need of a non-partisan tribunal that will thoroughly investigate, in the interest of all parties, every phase of the industry and make public at an early date its findings with such recommendations as it may deem proper and advisable. Coal mining is an involved and intricate industry and great confusion exists concerning it not only in the public mind but within the industry itself. The immediate resumption of mining may be most important in the minds of many but if we are to avoid further conflict in the mining industry, beginning April, 1928, resulting in inconvenience to the consuming public and in hinderance with industrial progress, all the existing bargaining fields and the non-union fields. The chief duty of the commission, it was agreed, is to create a committee in the interest of the American public, particularly since the coal operators and mine workers are creating their own machinery for a study of the situation."

"The immediate resumption of mining may be most important in the minds of many but if we are to avoid further conflict in the mining industry, beginning April, 1928, resulting in inconvenience to the consuming public and in hinderance with industrial progress, all the existing bargaining fields and the non-union fields. The chief duty of the commission, it was agreed, is to create a committee in the interest of the American public, particularly since the coal operators and mine workers are creating their own machinery for a study of the situation."
Wage Increases in Non-Union Fields

Cause Price Advance of $1

Acting upon recommendations set forth in a telegraphic communication from Governor E. F. Morgan, of West Virginia, the Federal Fuel Distributor on Aug. 19 instructed district fuel committees that the recommended fair price for coal from all West Virginia districts has been raised to $4.50 per ton. The previous price prevailing in most West Virginia districts was $3.50 per ton. Governor Morgan's telegram was as follows:

"In view of the relationships between operators and United Mine Workers providing for resumption of work on the scale effective when the strike was declared, they will soon make an announcement of a new scale of prices. This would benefit coal producers in West Virginia, as it is expected that the miners will now work to the scale agreed upon." This new scale of prices is expected to increase the coal sold under the fair price in the smokeless fields as compared with the profitter coke from those districts.

The raising of stock prices in the West Virginia districts in the latter part of July started a buying panic and it became necessary to take further action. To this end the various districts, through their committees, have been given the authority to lay down a schedule of prices under the fair price act, under which they hope to continue a fair price for coal. The committees were instructed to do so in order to make sure of the distribution of coal under these prices and the necessary administrative machinery was put into operation. In the various districts, the operators have been notified that they must carry their orders for coal on the fair price list, and that they must fill their orders for coal on the public on prices. This plan was being made effective in maintaining the fair price of coal in the state. It was not effective, however, where there were ample supplies on hand.

While the coal industry is generally healthy, there are still many areas in which the coal industry is not enjoying prosperous times. In many cases, the coal industry is faced with declining prices, and the operators are forced to lower their prices in order to remain competitive. In some cases, the operators are forced to accept losses in order to keep their businesses afloat. This is particularly true in the case of the coal mines in the eastern United States, where the competition from the southern and western coal fields is intense.

The operators have been faced with the problem of maintaining a fair price for coal, but they have also had to contend with the problem of maintaining a fair price for coal. The operators have been forced to accept lower prices in order to maintain a fair price for coal, and this has resulted in a decrease in the price of coal. In order to maintain a fair price for coal, the operators have had to lower the price of coal, and this has resulted in a decrease in the price of coal.
Accepting Cleveland Agreement, Illinois Operators
In Part Sign as Individuals

BY E. W. DAVIDSON
Western Editor of Coal Age

ILLINOIS made peace with the miners late Tuesday afternoon in Chicago, on the exact basis laid down at John L. Lewis’ conference with operators in Cleveland. No arbitration is provided for. Illinois did not sign solidly as a state, however. After a final fight among the operators, President Frank Farrington for the union accepted the signatures of the Fifth and Ninth District Operators’ Association as a unit, the Illinois Operators’ Association as a unit except the Peabody Coal Co. and the Old Ben Coal Corporation, both of which signed individually, and of all the members of the Central Illinois Association as individuals. The agreements, all identical, were signed late in the afternoon and before dark mine-plant whistles all over Illinois were sounding the three joyous blasts which meant work the next day—work the first time since April 1—and a complete union victory.

Of the eighty million tons represented, about twenty million tons signed individually, led by the Peabody interests and the Old Ben Corporation, which made a mighty fight on Tuesday, the last of five perspiring, hot-worded days of conference. They argued that group signing of any contract with the miners would expose the operators again to indictments such as they suffered after the 1919 contract was made.

Thus the fight in Illinois ended with defeat of the operators who were holding out so solidly for arbitration. That issue was lost in the struggle early at Chicago. During the five hard days Farrington spent a lot of time trying to get a contract at the old wages for nineteen months and finally everybody quit struggling to overdo the Lewis plan and went back to it in its entirety, signed both collectively and individually and rushed plans for getting coal out of the ground.

The momentous Chicago conference, full of possibilities for unexpected things because both Farrington and the operators were dead against signing a Lewis-made agreement, convened Friday morning at 10 o’clock. Wise operators went into that session predicting under their breaths that not quite all the surrendering was going to be done by their side. Indiana eyes and Indiana ears were trained on the meeting, for the Indiana men had already met John Hessler, Hoosier state union president, over in Terre Haute, and had adjourned until Monday in order to see what Illinois would do beginning at the zero hour of 10 Friday. Little enough was done. A process of taking plenty of time to this serious business was adopted. At the request of Farrington, the conference adjourned from 10 until noon and then from noon until Saturday morning in order to give Farrington a chance to get his scale committee together and talk to them, he said.

The operators had met on Thursday and had announced that it was to be arbitration or nothing so far as they were concerned. Farrington, hearing of this, said it would have to be nothing, then, for he could sign no agreement that varied from the detested one prescribed by the Lewis meeting in Cleveland.

Nevertheless he and his scale committee took occasion to pay their respects to Lewis and the plan they said he compelled them to abide by. He said Lewis had "deserted Illinois miners" in the sectional scheme decided upon. They passed a resolution unanimously approving of the stand Farrington had taken at Cleveland against the Lewis nation-wide program of contract making. Farrington stood there against Lewis had been that he would not sign any national agreement because to operators of his state were there and therefore the document, so far as Illinois was concerned, meant exactly nothing.

That was about all that happened in formal session Friday. After the noon adjournment both sides took themselves into shirt-sleeve sessions here and there and began the struggle to find a way to make a deal in Illinois that would meet three conditions: (1) Come near enough to Lewis’ plan so that the International could not prove it to be in violation; (2) embarrass Lewis to the utmost degree possible under the conditions; (3) embarrass the Illinois operators as little as possible.

Saturday morning the conference got away to a good start. It organized for its future meetings, both sides stated their case—the miners for the Cleveland plan though they condemned it, and the operators for arbitration—and then the conference went into executive session behind doors that were by no means soundproof against some of the positive, full-blast articulation which ensued.

Farrington, speaking the miners’ piece, recited the terms framed at Cleveland, repeating that the union in Illinois is compelled to come to an agreement with the operators only on those terms. W. K. Kavanaugh, of St. Louis, president of the 5th and 9th District Operators’ Association, stated the operators’ case, declaring for arbitration—"the American way" of settling industrial disputes—and renewing the operators’ peace offer of Aug. 4 calling for a return to work of miners at the old scale while a non-partisan commission decided what the scale and working conditions should be after March 31, 1923. Farrington replied that arbitration would spell, for the union, the loss of a large part of the ground it has gained in recent years, and therefore could not be considered.

Long debate followed in which some sulphurous language was touched off. It ended at noon with the decision to take the matter out of the hands of the big and unwieldy conference for the time being and lay it in the hands of a committee of six to produce a plan of agreement and then to put the conference up to the contract of six consisted of the three operators’ association presidents, W. K. Kavanaugh of the 5th and 9th, Rice Miller of the Illinois Operators, and Harry C. Adams of the Central Illinois Operators, and three union officials, President Frank Farrington, Vice-president Harry Fishwick and Secretary Walter Nesbit.

The one outstanding and vital declaration of the day by Farrington was that he absolutely would not sign any contract with individual mine owners of six. All Illinois miners would. Farrington then added that he and his individual mine owners of six would go back to work together or none would go, he declared. This firm position by Farrington meant a good deal to the closely knit factions of operators who were making the fight for the state. It meant Farrington would do some of their own work for them by holding wobbly operators in line for a general state settlement whether they wanted to stay in line or not.

Saturday night the Congress Hotel, where the committee of six was working, was full of operators from all over the state who were hanging around the conference keen for the first chance to sign the dotted line and wire their mine superintendents to blow the whistle. More than one of them said flatly that they would have signed with Farrington then, as fast as they could have on the arbitration plan. Moreover, they added, they were pulling strong for a quick decision. The idea of the conference stewing along in Chicago for a week or more trying to make an agreement was highly distasteful.

Nothing, however, came out of the committee of six all day and all evening Saturday. This morning the committee settled down to it again and wrangled all day and well into the evening. The only thing that leaked out was that Farrington was proposing and the operators counterproposing all sorts of shifts and changes in a settlement of the Cleveland type but that nothing definite was determined.

The hope of Farrington seemed to be to obtain a contract to run nineteen months to April, 1924, at the old wages instead of running only to next April, as Lewis
Big Association Groups Slow to Accept Cleveland Pact

PROGRESS, slow but apparently sure, is being made over the country in the resumption of mining in the union coal fields that have been on strike since April 1.

In addition to the substantial increments to output furnished by the three large producers in central Pennsylvania, the Pennsylvania Coal & Coke Corporation, Clearfield Bituminous Coal Corporation and Allegheny River Mining Co., a number of the smaller operators have signed up and started their mines.

Meanwhile approximately 200 association coal operators of the central Pennsylvania field met at Clearfield on Aug. 17 and rejected the Cleveland agreement as a working plan and arranged with the United Mine Workers' leaders for a joint conference in Altoona on Aug. 21.

Following a meeting in Cumberland, Md., on Aug. 18, at which representatives of coal companies and individuals operating coal mines decided to refuse to recognize the miners' union, Maryland operators in the Georges Creek region, on Saturday, Aug. 19, posted notices at the mine openings that they would reopen on the 1920 wage scale.

At a meeting last week of the Southern Ohio Coal Exchange action was taken leaving the question of signing the Cleveland scale to the individual operators. The meeting was long and a good deal of opposition to the scale developed.

The central fuel committee at Washington was advised on Aug. 19 by George T. Poor, chairman of the Ohio Fuel Committee, that the production of coal in Ohio is expected to be practically on a normal basis by the first of this week with an anticipated possible output of 5,000 cars per day.

Numerous breaks from a policy of non-acceptance of the Cleveland agreement are reported in the ranks of the Pittsburg and the Lehigh Basin. The coal operators have indicated that union membership will not bar them from employment here but it also has been made clear that there will be no recognition of the union.

The first material break in the ranks of operators in northern West Virginia came when fifty coal companies operating in that part of the state signed an agreement with the United Mine Workers on Aug. 17 to operate on a union basis under conditions prescribed in the Cleveland agreement. Among the larger concerns which signed the contract was the Consolidation Coal Co.

The agreement was entered into after a meeting of the Northern West Virginia Association at which it was decided to take no association action. Despite this action most of the mines now operating in this field are on an open-shop basis.

As this issue of Coal Age goes to press on Tuesday night no announcement has been received from the meeting of Indiana operators at Terre Haute, where acceptance of the Cleveland agreement was being considered for several days pending the outcome of the Illinois conference described elsewhere in this issue.

Ogle Disavows Attempt to Deliver Illinois And Indiana at Cleveland

PERSISTENT reports from Illinois that A. M. Ogle, president of the National Coal Association, had exceeded his authority and had misrepresented his constituents when he held a conference on Aug. 6 with John L. Lewis, president of the United Mine Workers, at Pittsburgh, are discounted in the East. It is being pointed out that what Mr. Ogle did was to deliver a plan of settlement to the coal operators' attorneys representing both sides and to offer to put it before the union coal operators. It is reported that the Indiana operators are indignant over the insinuations from Illinois and are backing Mr. Ogle. By some it is charged that certain Illinois influences are at work to disrupt the National Coal Association.

Following the meeting of the directors of the association in New York last week Mr. Ogle sent the following word to the operators: "Reports and rumors going out from Cleveland last week to the effect that I had agreed to deliver Illinois and Indiana into the meeting called by Lewis at Cleveland are completely without foundation. It seems strange that anyone with intelligence would make a charge so palpably absurd on the face of it and almost equally strange that anyone should give it credence. That such groundless rumors have been so readily accepted is probably due to the strain under which everyone has been laboring during the tense and trying situations that we have been compelled to meet almost daily. It is fortunate that our National Association has developed sufficient strength to stand steady against the shocks caused by such temporary dissensions and misunderstandings."

By this time tension in the committee had grown severe and nerves were rasping. For an hour the committee talked sharply back and forth. Then the door flew open and out tramped Farrington clamping on his hat. "If I can't get a chance to talk in this meeting, I'm through," said he.

It appears the controversy had grown quite heated. However, before he got far away he was pacified by an operator commander and so the subcommittee merely adjourned until evening to cool off. That night if anything was decided by the committee that fact did not leak out. But a level best effort was made because a separate meeting of the miners' whole scale committee was slated for Tuesday morning at 10, an operators' meeting at 11 and the reconvening of the joint conference at 12, and if no final report was ready for that noon session nobody knew how serious a crash might ensue.

The Tuesday struggle became hopelessly tied up during the middle of the day when, with arbitration and the nineteen months proposition both scrapped, there remained only a battle among operators as to whether they would sign in a group or individually, and whether the miners would sign them both ways. When the committee of six could not pull the operators together, Farrington got permission of his men to sign them both ways. The final general conference was called, the two-way plan was agreed upon and the agreement was signed, thus ending the strike in Illinois.
HESITATION continues to mark the progress of the industrial coal buyer. Those, like the railroads and utilities, that must have coal as they go along are getting it with the help of the government. They are not confining themselves to the Hoover prices either, but are paying premiums as they go. Current production is just about equal to the current consumption of the essentials, as transportation and utilities, with perhaps a little left over for such as hospitals. Everyone appears to be waiting for the union mines that have signed up with John L. Lewis to begin work. Last week there was little evidence that these long idle union mines furnished much coal to the country, but the indications are that more will be forthcoming this week. Estimates place the total output this week a little short of 6,000,000 tons.

RESUMING MINES NOT YET OUT OF TROUBLE

So far none of the large operators' associations has signed up as a group. This has not prevented individuals from putting their names on the dotted line and many mines in Ohio and Pennsylvania have started work in the past few days by this route. But those who attempt to start up find their troubles are not over, for men are scattered, some having left the country and others being away on other jobs, and it is going to take more time than many anticipated to get normal output from those mines that start, and much longer to get them all started.

Thus the consumers who are sitting back waiting for a flush production are going to have to wait for some time. Their holding back is the factor mainly responsible for the continual staggering march of coal prices. It requires a stiff demand to hold prices at some of the high levels recorded in recent weeks and when a portion of that demand is withdrawn the market sags. This is what happened during the past week: The result is that on Monday of this week Coal Age Index of spot prices of bituminous coal dropped 20 points to 530 from 550 a week ago. The corresponding average price was $6.41. One curious feature of this figure is that while the high range on Kentucky coal dropped $1.50 to $3 last week, the low range was raised a dollar by the change in the Hoover price from $3.50 to $4.50.

The government program of priorities is not working with all the smoothness that might be hoped for. In fact it seems to be functioning with some difficulty. Plainly the trouble is lack of complete co-operation and lack of understanding all around—even in Washington—of what it is designed and desired to accomplish. Certainly it has not operated so far as a price controller. The railroads are following orders as regards distribution but apparently have no influence on prices when it comes to placing cars.

A desperate effort is being made to get coal started up the Lakes and it is here that the real test is coming. Priorities have put coal up the Lakes before and doubtless will do so again.

Hopefulness prevails with respect to early resumption of mining in the hard-coal region and there is little more to be said on the subject. There is no hard coal to distribute and consumers have not become urgent for supplies. Coke is being turned into domestic fuel channels in order to get it moved under favorable priorities.

BITUMINOUS

This is the first full week that any of the union coal miners have been at work and it will be some days before it can be ascertained how much they will add to the current coal output. According to the report of the Geological Survey for last week the best that was hoped for in the few days following the Cleveland conference was a few hundred thousand tons, mainly from Ohio and Pennsylvania. Illinois and Indiana were still holding out and but few mines had started up in the Southwest. Northern West Virginia was getting under way.

Great anxiety was being experienced by many operators about getting their mines to work now that they were willing to sign the pact that the United Mine Workers drew up at Cleveland, for every day at the high spot prices means many dollars of profit. Furthermore these operators are anxious to be the first to get to work, as they anticipate a decided car shortage when the districts as a whole get going.

Loadings on Monday, Aug. 14, according to the railroads, were 15,722 cars, a decrease of 3 per cent as compared with the week preceding. Thereafter they declined steadily to 12,530 cars on Wednesday. The loadings on Thursday, 15,469 cars, gave the first indication of shipments from mines reopened under the Cleveland agreement.

Car supply improved in certain districts of southern West Virginia and Kentucky, but in Harlan County and adjacent fields of southeastern Kentucky and Tennessee.

The following statement shows the number of cars on all railroads loaded daily:

Coal Age Index 530, Week of Aug. 21, 1922. Average spot price for same period $1.41. This diagram shows the relative, not the actual prices on fourteen coals, representative of nearly 90 per cent of the total output of the United States, weighted in accordance with respect to the proportions each of slack, prepared and run-of-mine normally shipped and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913-1914," published by the Geological Survey and the War Industries Board. (Pittsburgh District, Indiana and eastern Ohio prices not included in figures for last week.)

19th Week in Vol. 22, No. 8

*Cross tons, f.o.b. vessel, Hampton Roads.

**Advances over previous week shown by blue type, declines in italic.

NOTE—Smokeless prices now include New River and Pocahontas.
transportation was for a time almost completely blocked. Western Kentucky also reported acute transportation loss.

There was no compensating increase in shipments from the non-union fields of Pennsylvania, according to the Geological Survey.

Final returns show production of all coal in the nineteenth week of the strike as 4,605,000 tons, including 29,000 tons of anthracite. In the corresponding week of 1921, the output of bituminous was 7,770,000 tons and of anthracite, 1,770,000 tons, a total for all coal raised of 9,540,000 tons; the year before that the total was 12,280,000 tons. Considering anthracite and bituminous coal as a common source of supply, the present weekly output is five or six million tons below normal.

Lake dumpings increased last week to 162,162 tons, of which 104,112 tons were cargo and 58,050 tons were bunker fuel. Lake dumpings are disturbing as the owners of the Federal Fuel Distributor all coal loaded on Monday, Wednesday and Saturday of this week in the Kenova-Thacker, Logan and Kanawha on the C. & O., Big Sandy, Hazard, Elk Horn and Harlan fields is to be consigned to the Lakes. The loadings from these fields on the corresponding days of two weeks ago were a little short of 400,000 tons. Lake shipments are now about 10,000,000 tons behind last year.

Not only is the movement of Lake coal behind past season's but the distribution of the coal actually dumped has differed from other years. Shipments to Canada have decreased much more sharply than those to American destinations. Of the total dumped, only 11.7 per cent went to Canadian ports as against 28.5 per cent in 1920. There has been a great increase in shipments to Buffalo and other Lake Erie ports, with over 14,000 tons of a total of 89,000 tons being shipped to Lake Erie ports on the American side as against 12,550 tons in 1920.

Still more striking has been the increase in the proportion moving to Lake Michigan, to which 43.1 per cent of this season's dumpings has been consigned in comparison with 25.5 per cent two years ago. In like manner the sharpest decrease has been in the movement to Lake Superior by 15.5 per cent of the total—had been consigned to American ports on Lake Superior up to July 31. Yet these ports absorbed 51.4 per cent of the movement in 1921 and 36.5 per cent in 1920.

The reserve of coal on the commercial docks at the head of Lake Superior decreased sharply during July whereas it normally increases at this season. According to the Northwestern Coal Dock Operators' Association, the stocks of bituminous coal at Duluth, Superior, Ashland and Wabush dropped from 1,498,000 tons on July 1 to 601,000 tons on Aug. 1. Stocks of anthracite declined during the same period from 364,000 to 170,000 tons.

In comparison with last year the present reserve appears very small, but it must be remembered that in 1921 stocks were above the average, says the Geological Survey.

### Stocks on Lake Superior Docks

- **Anthracite:**
  - July 1, 1922: 367,771
  - July 1, 1921: 400,395
  - Aug. 1, 1922: 417,254
  - Aug. 1, 1921: 3,513,539

- **Bituminous:**
  - July 1, 1922: 1,498,276
  - July 1, 1921: 4,342,467
  - Aug. 1, 1922: 668,858
  - Aug. 1, 1921: 2,355,624

According to the Geological Survey mines in Pennsylvania, Maryland and northern West Virginia shipped less coal during the week ended Aug. 19 than during the previous week.

The all-rail movement to New England increased to 688 cars in the week ended Aug. 12 from 437 cars the week before. In addition to this figure 226 cars were reported to have been shipped from Rouses Point, up near the Canadian border. In the same weeks of last year the movement was in excess of 2,000 cars per week. Anthracite movement to the same territory was 226 cars during the second week of August, mainly of steam sizes. A slight gain in tidewater dumping at Hampton Roads was recorded in the week of Aug. 17. In that week the total was 307,182 tons compared with 306,258 tons in the previous week. Many vessels are reported waiting for cargoes and the supply at the piers is gaining. Lambert's Point the N. & W. piers gained but Sewalls Point lost. The
North American Orders Strain British Export Facilities; Production Nears Record

The British market is very active. Prices are strong and the emergency demand from Canada and the United States is straining the exporting facilities of the country. Spanish demand is showing unexpected strength.

Exports to North America are expected to reach 200,000 tons per week and may soon exceed the pre-war record. Some American business extends into October, although most of the orders are for delivery within the next 30 days.

Production reached 5,122,000 gross tons during the week ended Aug. 3, according to a cable to Coal Age, the heaviest since early in April. The preceding week's output was 4,898,000 tons.

There is a slight lull in the north of England industry due to the fact that the entire output during August has been booked up, and shipping facilities beyond the end of this month are not certain. The Scottish coal market is disappointed at the non-materialization of American orders. It appears that Scotland was on holiday when the English pits were working, and were taking their time over filling the orders to America which they believed were ready to their hand. When the Scottish pits prepared to deal with the American requirements they discovered that no orders were coming their way. England and Wales had got busy, with the results that inquiries gravitated south.

The June audit in Wales, on which August wages are based, shows the worst figures since the National Agreement, and the proceeds were not enough to cover the standard costs. During this month revenue was £3,136,000 and costs £3,243,000. The owners have had to surrender £283,000. In these circumstances wages will remain on the minimum. The July audit will show little improvement, so that wages will remain about the same until October when the results of the American demand during August will be felt and wages will rise in sympathy.

The miners have is the regularity of employment.

French Feel Effects of U. S. Strike

Important purchases of British coals by the United States have been felt on the French market, which has materially improved since about the middle of July. Arrivals of British coals in France are decreasing. Pithead stocks are still so high that French collieries would particularly welcome a few substantial orders from America. The collieries of the Nord and Pas-de-Calais have a joint selling agency. Le Comptoir d'Expansion Commerciale des Mines du Nord de la France, 26 rue Saint-Jean, at Douai (Nord), and this organization could certainly arrange for coal exports to America as it did last year to Great Britain during the miners' strike in that country.

Other facts just now concur in improving the French market. A strike of river craft personnel on the Lower Rhine hinders the arrival of German coals; good deliveries are being made abroad of Sarre coals, which sell now in south Germany to the extent of 170,000 tons per month.

At a meeting of the Nord coal field miners' union, a resolution was adopted deprecating any reduction in wages.

Coal Paragraphs From Foreign Lands

ITALY—The price of Cardiff steam first was quoted at 42s. 6d. Aug. 19, according to a cable dispatch to Coal Age.

GERMANY—The production of coal in the Ruhr district for the week ended Aug. 5, according to a cablegram to Coal Age, was 1,731,000 tons.

Prices Soften at Hampton Roads

Vessel requirements registered at the piers expanded slightly during the past week, but there was no further tightening of the market here in consequence. Perhaps in keeping with the general relaxation of the market, prices declined, although there is that there is so little free tonnage in the market made the quotations nominal. Movement at the piers grew larger at Lambert's Point and at Newport News, but declined at Sewalls Point. Some delays to steamers calling for cargoes were reported. As a whole the bunker demand has not cut much figure in the market, however, as foreign trade vessels are taking their fuel on the other side. Among the vessels chartered or awaiting charter in the coal trade here is the largest fleet of sailing craft that has been anchored in Hampton Roads for several years.

Demands for tonnage for use in manufacturing plants and at public utilities appear to be following a more orderly and composed course, following the strike conference. Earlier in the month shippers here were beset with frantic appeals for small tonnages to avoid what the vessel-purchasers described as serious crises.

Foreign Quotations by Cable to Coal Age.
Trade Tastes Dose of Optimism; Prices Soften

Output Gains in Pennsylvania and Northern West Virginia Help Market

—Southern Coals in Bigger Volume—

British Fuel Disappoints—Priorities Absorb Most of Available Product.

INCREASE in production in Pennsylvania and northern West Virginia is proving a great help to the market along the northern Atlantic seaboard. These gains in output are small as mining is first resumed, but absence of car shortage and an evident purpose on the part of the miners to return to work again as soon as the individual mine owners sign the Cleveland contract has given the trade a dose of optimism and softened prices.

Demand is not insistent, but rather is holding back awaiting more production. Southern coals are in better volume at Northern ports. The first experiences with British coals, now flowing in, are not particularly happy. Some of our equipment is proving to be not adapted to this coal.

Priorities continue to absorb most of the coal available for the market.

NEW YORK.

The outcome of the Cleveland conferences and the probability that many mines that supply this market would soon reopen put a damper on the local demand last week. Quotations softened at various times during the week.

The enthusiasm which prevailed over the possibility of believing the situation by the introduction of British coal was not so pronounced toward the end of the week when it became known that one of the public service corporations had experienced some difficulty in using it to advantage. During the first five days of the week there were 67,026 tons received here in eleven vessels, all of it apparently on order.

Southern coals are coming forward in good shape and with quotations at Hampton Roads ranging $10.25@10.75, quotations, c.i.f. New York, having ranged $11.25@$12.55 in big bottoms and $13.00 in small barges.

The railroads are heavy buyers, although they have priority rights. Some dealers continue to buy and have their coal conspired. It was said that some railroads have been able to buy B. & O. coals at around $5 f.o.b. mine.

There is no indication of lowering their coal quotations and it is not believed that operators will be willing to bind themselves for the balance of the coal year. While some believe it will be possible to get at least $5 at the mine, others believe the minimum figure will be around $6.

FAIRMONT

Although the Cleveland conference created more or less of a feeling of uncertainty, operators not knowing to what extent the conference might affect the mines already operating on an open snap basis, nevertheless producers continued to increase the output. About 220 mines were in operation, the largest number since the beginning of the strike. Prices were still on a high level, the maximum being about $7.25.

PHILADELPHIA

The general run of consumers seem to have taken it for granted that the Cleveland conference ended the coal strike and as a result they have ceased to inquire for coal. Some plants with barely enough coal to keep them going for a few weeks are taking the stand that by waiting prices will be much easier.

The indications are strong that the rail strike will soon be settled, and this being the case there will be a greatly increased movement of coal to the consumer and considerable reduction in prices.

There has been some softening in prices, although the cuts have not been deep. Indications are that there will be still further recessions during the next week.

CENTRAL PENNSYLVANIA

Operators pretty generally have agreed to the settlement and already many mines are working. The operators of th Pennsylvania Coal & Coke Co., thirty-five in number, are at work. The Stineman mines at South Fork, the Miller Run Coal Co. and the Clark Coal Co., at Hastings, the Barnes & Tucker Co. and the Maderia Hill Co., at Barnesboro, with mines in good condition, were ready to start operations at once.

Word from every mining community in the field is that the effect of operations will be gotten under way as fast as the equipment permits when they are gotten back into the mines. It is predicted that practically all mines in the district will be in operation before the end of the present week.

There is not likely to be a shortage of cars. The railroad shopmen's strike did not affect the repair shops in Altoona and all equipment is in good condition for handling the increased output of coal that will now be called upon to handle.

BALTIMORE

Prices for soft coal have not fallen as a result of the impending strike settlement and in the face of the general transportation situation and the deploration of stocks it is impossible to make much headway in cutting down prices. The railroad situation is such that all the coal moving is on priority basis, it has not broken down the situation in which coal consumers readily pay high prices to get immediate supplies.

Fairly high grade gas coals are still being offered at this time around $7.50 per net ton f.o.b. mines. What little steam coal is offering is taken up rapidly at $7.50@8.

The Baltimore industries have been running on narrow margins of reserves and therefore the receipt through a local concern of nearly 100,000 tons of Virginia coals by barge proved a real boon. The same is true of /importing between 75,000 and 100,000 tons of British lump coal of high grade for the Baltimore trade. The first of this coal is expected this week and a considerable demand for it already in evidence from householders to replace anthracite.

Both the Virginia coal and the British coal have been placed on a price basis that is not prohibitive.

UPPER POTOMAC

The number of mines operating in the Upper Potomac region is increasing from week to week and about the only plants not producing now are those on the Maryland side of the Potomac where little or no protection has been accorded by local authorities. No trouble is being experienced in securing all the cars necessary. Prices are ranging $6@$7.25.

SOUTH

VIRGINIA

Under improved transportation conditions, the field is showing further signs of recovery from the slump caused by a break-down in car and coal supply and movement. Improvement has been more marked on the N. & W. than in any other section of the state. Notwithstanding this increased production there is an acute shortage in the state and some industrial plants have found it necessary to close down.

BIRMINGHAM

Relief from the stress in demand on this field by forward consumers is already evident. The Missouri Pacific placed a large tonnage a day or so prior to the strike settlement affecting a portion of the Local Competitive Field and almost immediately canceled some. A priority was recently granted the Rock Island in the matter of car supplies to mines at which contracts had been placed for fuel in this district. The road not having been able to secure sufficient coal otherwise on account of shortage of equipment.

It looks as though the buying movement in normal Alabama territory has now received sufficient impetus to warrant assurance of further advance. A steady weekly production will be easily absorbed when shipments to outside territory are cut off.

The strong pressure in the coal market continuing through the past week maintained prices at high levels, ranging $6@$6 per ton, and like figures are expected to continue through the coming week. Continued pressure from emergency orders prior to the inauguration of Hoover schedules ranged $2.50@$3.50 per ton.

Production for the period of Aug. 5 reached 400,000 tons, although some orders were held at mines on all lines on account of shortage in the car supply.

Anthracite

Trade Concerned at Task of Spreading Short Fuel Supply
Sees Possibility of Trouble in Accumulated Demand—Dealers Dole Out Stocks Only Where Need Is Urgent—Householders Optimistic.

No ALARM is manifested over the Eastern anthracite-coal consuming territory as the end of summer approaches and production of hard coal continues at a standstill. The trade itself—retailers, wholesalers and producers—is greatly concerned and fully recognizes the possibility for trouble when it comes to spreading out a short supply over an accumulated summer and early fall demand.

Dealers are holding to their stocks—quite scanty in most yards—and are doling out supplies only where urgently needed. Pea is the only size that is moving at all and that now is very difficult to get. River coal, size and quality not guaranteed, but at stiff prices, is available to meet the demands of particularly needy consumers.

Substitution of bituminous coal for anthracite is not in evidence to any marked extent as yet. Not until people really feel the pinch of a shortage of hard coal will they turn to soft coal. There is yet abundant optimism among those householders who give next winter’s coal supply a thought, that the mines will soon start and that they will then have all the coal they want.

PHILADELPHIA
Retail dealers take it for granted that the miners and operators will get together, and are prepared to resume deliveries. Of course, in formulating their plans the dealers are going ahead without taking into consideration any rules that might be decided upon by the fuel commission. The hope is strong that the commission will continue to itself the distribution of fuel to the dealers, allowing them to work out their own method of placing the coal to the best advantage.

Due to the fact that there is no probability of a wage reduction it goes almost without saying that prices will be about the same as they have been during the past year, unless the dealers will pass along the entire freight reduction, which amounts to about 25c. a ton.

Pea coal continues to come in, and retailers are making immediate deliveries, with the result that when winter comes there will be a lack of the usual reserve yard stocks of pea.

There is still a plentiful supply of river barley and if anything prices are a trifle easier, running $2@2.75. Some concerns, in fact most, have found that the mixture of fine anthracite with soft coal generally works out advantageous, and this, combined with a promise of better bituminous shipments, is responsible for the easier prices.

BOSTON
Dealers are holding their small reserves of egg, stove and chestnut for such emergency needs as may develop, and are doling out what pea coal is available. Only small and scattered lots of bituminous are being delivered in place of anthracite, most housekeepers having elected to take pea as long as it lasts.

At whatever the trade has been much encouraged over the prospect for settlement. It is realized, however, that an agreement has not been reached yet and that several weeks may elapse before such a settlement is reached. Meanwhile, what pea is in storage is being saved for locomotive use until the bituminous situation has improved sufficiently to justify its release.

NEW YORK
Outside of small tonnages of pea, buckwheat and river barley producers and wholesale dealers have nothing to offer. Pea coal is being used largely by the railroads, who find it more economical to burn than bituminous coal at the current quotations.

There is almost none of the larger sizes in the local retail yards. Demand for buckwheat and the smaller river products was easier last week, due to the conferences in Philadelphia, and the resumption of mining in some of the bituminous areas. No apparent change in quotations, however.

Buckwheat was scarce and was quoted by some dealers at around $12 along with. Buckwheat was quoted $36@3.25 at point of loading.

Some independent buckwheat was offered here at $9 f.o.b. mine and during the week a stray lot of rice was quoted at $7 f.o.b. mine. Independent pea coal was quoted at around $14, f.o.b. piers.

BALTIMORE
Hard-coal dealers are not particularly disturbed at the thought that British lump soft coal will be used in a number of homes hereabouts during the early winter. They believe that the advantage of anthracite over any class of soft coal for household use is such that hard coal will become once more the exclusive, fuel for the home as soon as it is available.

No delusions are entertained that the entire hard-coal demand for the early autumn and winter can be met, no matter how favorably the situation at the hard-coal mines may develop within the next few weeks. The Maryland Fuel Distribution Commission is allotting priority orders in cases of emergency, all of which are reported as being filled fairly promptly.

BUFFALO
As a rule the handlers of hard coal do not look for a supply for some weeks yet, even if the men go to work soon, as is supposed to be the program. The output is so much more slow and difficult than in the case of soft coal that no shipments of account will be made right away. So far as this market goes the situation is just as it was.

The consumers will be glad when the Larkin housewives can get coal. After all, the coal dealer can be turned in here and there will be coal enough. It is doubtful if the old close adherence to anthracite and certain sizes at that for certain purposes, will ever be returned to. It is found that with the regulation sort and sizes as a foundation it is easy to use something else as a filler with good results.

SALT LAKE CITY
The domestic consumer is buying more coal now than he has done in any August for two or three years. This is due to the prices and the published reports of the Commercial Club’s offer to help the state executive to distribute coal when necessary. Further, there is some talk among coal operators of increasing the price of lump and stove coal and although nothing has appeared in the papers about it, it is presumed dealers are making it known to their customers.

Producers are all a long way behind on their orders and dealers are finding it difficult to obtain sufficient coal for immediate delivery, that filling up of their yards being out of the question.

KANSAS CITY
Better feeling prevails in the market here with the approach of the end of the strike. Production in the fields near here will be at full tide soon and that—baring a complete collapse of railroad service—enough coal will be shipped to satisfy immediate demands. During the week that closed the main business of the coal man was pacifying consumers who demanded coal he could not get for them.

Union officials assert that 1,200 men have gone back to work in Arkansas and Oklahoma within a week. A conference for Tuesday, Aug. 22, was slated between union officials and Harry N. Taylor, president of the Southwestern Interstate Operators’ Association. It is possible that a general resumption of mining will follow.

DENVER
Demand for coal from almost all classes of consumers grows heavier daily. Production is a little better to match and as a sort of background for the local markets the Pueblo steel mills closed down last week, thus removing a large consumer from the market. Peace reigns in almost every mining region. Troops have been sent home from Frederick.
Entire Region Awaits
End of Strike Parleys
Prices Tend Downward, as Resumption of Mining Is Expected Daily—Supply of Cars Keeps Most Fields in Hot Water—Indiana Coal on Market.

All the Midwest region sits on the edge of its chair awaiting the outcome of the conferences going on at the close of last week and the first of this week between operators and miners in Indiana and Illinois looking toward a resumption of mining. Since general operation of mines is expected almost hourly, buyers have largely withdrawn from the market and prices are on the downgrade. Kentucky, West Virginia and wagonmine Indiana coal sold in various marts in this territory at figures ranging from $7 to $8.50 Aug. 18 and 19. Nobody bought save those compelled to by circumstances and most buyers demanded more than car numbers. There has been too much juggling of them lately.

The shortage of fuel in consumers’ hands is even more acute than last week because of poor car supply and the hampering influence of the railroad shopmen’s strike. Especially is this so around St. Louis.

The priority system of distribution continues to function haphazardly in this territory. Nobody thoroughly understands it, nobody appears to enforce any provision of it, and the railroads serving the mining fields make no efforts to shut off car supply to those who ship on priority orders regardless of the price.

CHICAGO

An expectant calm and downward prices characterized this market during the week just closed. Buyers rushing madly after anything black were not to be seen. Their days appear to be gone forever—until the next time. Such confidence was felt that coal would soon be produced in Indiana and Illinois that by the end of the week prices on Kentucky coal had reached $7.50 a drop of at least $3 for the week before, and were going down. Very little of it was available. Only a few cars of West Virginia fuel got here. It was traded in abundance at the same price as Kentucky.

For the first time in months Indiana coal reappeared here in sizable shipments. Practically all of it was from wagon mines and was of doubtful quality and preparation. But it sold on Saturday for as high as $7.50, though a good deal was offered at varying figures under that.

Great uncertainty as to priorities and price regulation exists here. Robert M. Medley, appointed Special Fuel Administrator, came to Chicago a week ago and set up an office but no state fuel committee has yet been appointed by Governor Small, and the chances are that none will be.

SOUTHERN ILLINOIS

Some excitement in the southern Illinois field arises over the differences between Lewis men and those in favor of Farrington. The different gaits of outlaws in the places that have always caused trouble in the past seemed to be for Lewis, and the quieter and more reserved district will be lined up for Farrington. The Farrington men seem to be far in the majority. There is a desire on the part of all miners to get to work. Operators continue to request miners in shape for operation. Much the same condition prevails in the Mt. Olive and the Standard fields excepting that nearly everybody there is ready.

There has been considerable trouble in the coal fields caused by mobs of miners intimidating and threatening the trainmen on the Illinois Central and Mohawk & Ohio railroads. It is reported that there is no interference with coal moving on the Southern and the L & N.

ST. LOUIS

The situation here is extremely critical. The City Hall is without electric power for lighting or elevators and many factories, including the rolling mills of the American Car & Foundry Co., have been shut down on account of no coal. The essential priorities that are furnished by wagonload through the dealers require 35 cars a day and in the last five days not more than 10 to 15 cars have been released. Some of these small plants that are highly essential are in a critical condition. The Union Electric Light & Power Co. is running from day to day and its load is increasing because the water at the Keokuk power plant is too low to give its normal electric power. The householder in St. Louis is still taking things easy.

The railroad situation here has been bad. The Terminal has been running on less than a half supply of coal every day for several days. It depends upon getting a few cars in each night. For five days the Illinois Central brought no coal through, it all being held up south of Coulterville by the Illinois striking miners. On the 18th a couple of hundred cars came in in four trains.

The country districts are in a serious condition at many points and those who are running have begun to use wood. Kentucky coal sells anywhere from $8 to $9 at the mine, with Alabama ranging $6-$8. No coal has arrived here yet at the Hoover price. Byproduct coke is selling wholesale at $10 per ton f.o.b. St. Louis, and gas house sold at $9.25 until it was exhausted. Byproduct coke retail is $13 and gas house at $12.25.

WESTERN KENTUCKY

Operators report that loaded coal has been on tracks for days without moving and that they are not getting cars to load, and the trainmen’s strike has been only partly settled and traffic conditions are very poor.

It is reported that some mines in Western Kentucky haven’t had more than a day or two of full operation this month. For the first ten days of the month it is reported that on the Illinois Central car loading equaled 93 per cent of total capacity, and on the L & N 68.8 per cent. Normal average for the field being around 63 per cent. However, conditions on the L & N have been no worse for the past week. Washington had $475,000 paid for a fair price for Kentucky. Machinery supplied by the state and federal governments to handle priority orders is beginning to be utilized, but slowly. It is reported that railroads are looking for prices in putting in or pulling cars, it merely being a question of priority and right to ship. It also is reported that priority buying is not making any real effort to buy at Hoover prices. Sales were reported until the end of the week at around $8 a ton. Then the price started down.

LOUISVILLE

Although there is a great deal of talk of severe fuel shortage, it appears as if Louisville industries are fairly well taken care of. The Louisville Gas & Electric Co. has received some contracts from mines in Echols, Ky., and its own fleet of freight cars. The Louisville Railroad Co. has received service from its contract mines without much trouble. The Louisville Water Co. has now bought all the coal it has gotten. Some small companies here and there in southern Indiana and Kentucky are ranting about not being able to obtain fuel, but Kentucky men think that wherever a utility has been forced to close down it has been through refusal to pay the price asked or through bad management in buying ahead of actual demand.

Locally it is believed that the Cleveland agreement will soon begin to have effect on the prices in Kentucky fields.

INDIANAPOLIS

State operated mines in Indiana are a thing of the past, at least for this strike. On Monday the Governor ordered all guards home and announced that he would not longer attempt to run the strip pits. He said that the newly opened shafts and wagon mines will guarantee ample supply to utility and state institutions.

Such Kentucky and West Virginia coal as is being obtained here costs $6@7. Indiana coal is being quoted at from $5.75 to $6.50, depending upon the grade. Anthracite is priced at from $15.50 to $16.75 to the retail consumer and Pocahontas from $8 to $8.50 with forked lump at $9.
Approach to Normal Still Some Weeks Off in Ohio

Much Repair and Cleaning Up Required—Car Shortage Predicted—Many Pittsburgh Operators Refuse to Sign Cleveland Agreement—Lake Situation a Vexing Problem.

It will be several weeks before anything like normal conditions prevail in the coal fields of Ohio. Mines are starting up, but the operating organizations are disrupted, men scattered and mines in need of much repair and cleaning up after nearly five months’ shutdown. Car shortage is predicted almost simultaneously with the resumption of the work. In the Pittsburgh area some mines are resuming work, but a majority are hanging together in a refusal to accept the Cleveland settlement.

The lake situation is the main problem in this region, for until the lake trade is taken care of coal for local users will be scarce. Priorities are being used to force coal to the Northwest, but with little effect so far.

Prices softened some on the news of the Cleveland settlement, but urgent buying has held them firm since then.

EASTERN OHIO

Each day adds signatures of operators to the new Cleveland wage agreement. It is predicted that by the close of the week all Ohio will be signed up. In Ohio it will add three and one-half million tons per month at 1921 rates and will exceed that with maximum car and labor supply.

Prevailing prices on every grade of coal from most any producing district range from $5 to $7.25 per ton f.o.b. mines, the minimum figure indicating a decline of $1 per ton during the last 22 days. It is also reported that there were 10,000 tons of Eastern Ohio No. 8 lump for lake shipment offered at $5.75 per ton f.o.b. mines. The volume of market coal from the South continues to be negligible.

It is reported that, following telegraphic instructions, local unions in Ohio No. 8 started machine men cutting coal on the 17th. Not over 200 cars were loaded on that day, however.

In the lake trade the prediction is made that a pooling and movement similar to that made by Service Order No. 10, issued by the Interstate Commerce Commission during the lake season of 1920, will be made operative soon.

PITTSBURGH

Opinion in Pittsburgh is practically unanimous that the members of the Pittsburgh Coal Operators’ Association will hold out for a district settlement with the miners, or the establishment of a regular open-shop condition. The chief doubt is as to how long this will take, some guesses being that the district will not be running well until two or three months have elapsed.

In some quarters, apparently well posted, coal operators predict that the Connellsville strikes will be ended by about Sept. 1, it being intimated that there will be a moderate wage raise for the miners of Aug. 1, 1921, which was the regular scale of the region last March although some independents were paying less. The new strike is expected to persist for a month, but some semblance of recognition of any union is expected.

The railroads practically dropped out of the coal market for a few days in the past week but are back again in a moderate way and there is now buying by other interests. In the interim the market declined Connellsville steam coal being $6.75 and Westmoreland quiet at about $7.50. There is now a little production in the Pittsburgh district, but not enough to make a market.

BUFFALO

This market is now trying to square itself, with the new state of things, though as yet they are to us only on paper.

As might have been expected there is on the market quite an amount of coal that the owners appear to have been holding for nobody knows what prices. If there is any real distress here it seems to be monopolized by the jobbers.

As a rule the city jobbers refuse to give out prices. They say there are none, for the consumer will not buy. Morning’s mail is almost a blank so far as any communication from consumers is concerned. The price has been about $7.50 to $9 per ton, but a decline is looked for at once, unless some hitch develops. So far only one of the Allegheny Valley companies has announced a time for resumption, which is at once.

The Lake situation does not change. Fuel is still $10 or more and hard to get at that.

NORTHERN PANHANDLE

Operators are keeping production up to more than half full-time capacity, but far from full for regular operation. Much of the tonnage, however, is being utilized for railroad fuel purposes. A little is going to the West, and to Northern markets. Although much of the output is being delivered on contract and at the Hoover maximum, as high as $7.25 is being offered.

COLUMBUS

Active preparations are being made by operators to start work, following the agreement signed at Cleveland. The position of the Ohio coal is stronger than ever. The exchange was against signing as an organization, but the exchange adopted a resolution leaving the matter of signing to the coal operators.

With the Ohio fuel commission functioning, practically all of the coal coming into this territory is under priorities, but the receipts are not up to current requirements. No price has yet been fixed on Ohio coal and consequently it is moving at considerably higher levels than the Hoover figures. Pocahontas and other smokeless grades are selling around $4@$6.50 with the Hoover levels generally maintained.

Lake trade is now attracting a good deal of attention.

The retail trade is at a standstill as dealers’ stocks are pretty thoroughly cleaned up. Retailers, in many instances, are booking orders to be delivered later, with the price question held in abeyance.

DETROIT

So far the functioning of various fuel administrators has been productive of no substantial change for the consumers of bituminous coal in Detroit, and the situation is becoming more acute as existing stocks are reduced without corresponding receipts of coal.

The Detroit Edison, Detroit City Gas and the Ford Motor companies have been hard hit by the strike of trainmen at Corbin, on the Cumberland division of the Chicago, Milwaukee & Nashville. The companies have mines in this field.

After organizing an auxiliary committee to assist Wayne County’s fuel administrator, the positive receipt of coal has been confirmed that the fuel administrator, lacking the support of law, is without authority to control or regulate coal prices or distributors’ coal. The price of coal is reported selling at about $6.75. Retail prices on domestic bituminous range $11.50@$12.50 a ton delivered at the buyer’s sidewalk.
Everybody Feels Better With Strike About Over

This Region Fairly Confident Now That It Will Get Enough Coal, but Promised Shipments Have Not Arrived—Hope for Late Freeze-up.

The Northwest, practically destitute of dock coal, feels great relief at the news that the coal-mining strike is about over and that mines will soon be able to dump great quantities of fuel over the lower lake docks consigned to upper ports. The only question that greatly worries this region is: Will the railroads be able to handle it? If they do, and if heavy shipments begin not later than Sept. 1 and if the freeze-up this winter is a little later than usual, then surely enough coal will reach the Northwest to take care of all its necessities until next summer.

Prices here have been steadily climbing. They have attained such heights, in fact, that one or more protests have been registered at Washington charging profiteering. The Northwest cannot stand $9.25 mine quotations on coal that sold for $3 and $4 before the strike. The latter is more nearly a proper retail price. However there are buyers willing to pay almost any price under protest, so long as they get some coal. Many industries throughout this region have already succumbed to emptiness of coal bins and most public utilities are about to scrape bottom.

MILWAUKEE

Prices of bituminous coal in Milwaukee were advanced 75c. per ton to the consumer, effective Aug. 15. This makes a total advance in soft coal of $1.25 per ton since Aug. 1. The trade is now paying $7.50 at the mines instead of the Hoover rate of $3.50 per ton.

The car supply also is vital. Unless the present shortage is relieved many industries will shut down. Priority orders that are not backed up by recognized authority are of little avail. Coal directed to Lake Michigan ports has been sent elsewhere or has been confiscated by railroads. Until government agencies begin to function reliably the coal trade is bound to continue in a state of demoralization. Electric utilities in Wisconsin, which consume from 60,000 to 10,000 tons of coal per month and gas companies using 30,000 tons are facing suspension.

Five cargoes of soft coal, aggregating 26,802 tons, were received by lake steam last week's report, including 1,500 tons of Nova Scotia coal by way of Quebec. This makes the season's receipts up to this time 890,162 tons of soft coal with no anthracite. Last year's receipts as of this date aggregated 757,079 tons of anthracite and 1,672,155 of soft coal.

The following are the retail prices of soft coal according to the latest advance: Pittsburgh, Hocking and Youggheny, $11; pile run, $9; screenings, $8; West Virginia screened, $9.50; pile run, $9; screenings, $9; Pocahontas screened, $12.50; mine-run, $10.50; screenings, $9; smithing, $10.50; coke, large size, $15; pea and nut, $19.

A carrying in charge of 75c. is made on all except coke. The market is bare of Illinois and Indiana coal and Kanawha gas mine-run.

DULUTH

Duluth and the Northwest generally has heaved a sigh of relief at the news of the termination of the coal strike. The Northwest is in a bad way. The 530 cars from Kentucky allotted last week have barely started but shipments are promised soon.

There were only 632,483 tons of bituminous on the docks Aug. 1 and that quantity was 258,000 tons oversold. The docks at Ashland, Wis., had only 28,500 tons of soft coal and were 68,000 tons oversold. Six cargoes of coal arrived here last week. This was non-union coal sent as a stop gap, and filled a great need of vessels and public utilities. It is the opinion of dock men generally that arrivals of heavy shipments will resume at this port about Sept. 1.

In view of the unusually severe winter last year it is thought that the freeze-up will be long in coming this year. If this proves true it will mean that there will be sufficient time between Sept. 1 and the close of navigation to get the docks replenished.

However, the resuming of the refueling of the Northwest depends to a large extent upon the country dealers and the celerity with which they order stocks. If the tendency is to hold off and trust to a possible break in prices the Northwest will be cold next winter, in spite of the termination of the strike. The docks will become full and the close of navigation will see insufficient supplies. If the country dealers are prompt in their part there is no reason why sufficient coal should not be brought up the lakes to satisfy all demands.

Prices are firm at $8.50 for lump, 50c. less for run of pile, and no market on screenings, of which there are none available.

New England

Midsummer Lull On; Trade Confined to Spot Shipments

There is very little change in the current market. Trade is in a quiet mid-summer state and transactions are confined to limited quantities for spot shipment. The larger consumers have comfortable reserves, considering the almost uniform light business they are doing, and receipts for the present seem to be in sufficient volume to relieve them of any immediate anxiety.

News dispatches the last few days have taken such a favorable turn that buyers are more optimistic than a fortnight ago. No one in the trade really expects much increase in the volume of coal for New England during the next thirty days, but there is an undeniably easier feeling among buyers that probably reflects better reserves than were being counted on. Even users of high-grade gas coals are inclined to await developments, hoping there will be enough increase in output to modify current prices.

In practically every direction there are quotations far above the Hoover level. Inland from rehandling points like Boston, Providence and Portland $10.50 is still the standard coal, while f.o.b. Norfolk and Newport News $10.50 for $11 are the spot quotations on the same grades.

While commercial coal is still reaching Hampton Roads buyers and quite an amount of tonnage is waiting against its arrival, there is increasing confusion over the practical working out of Service Order No. 23. As between the Washington committee and those in the several states requisitions are being round in circles while priority coal is being confined almost exclusively to railroad fuel needs other than in New England. Attempts are made to get coal for various state consignees, but so far as reported at this writing there is none available through such channels.

It is recognized here that Washington labors under great disadvantage, for apparently no one acting on behalf of the President's committee is in position to assume responsibility for anything that under court review might turn out to be discrimination.

Meanwhile, trade agencies continue to distribute as much of their own coal as may be available, and with varying policies as to the "fair price." Shipments on contract are coming forward in good volume, and there is some expectation that they will continue about on the same basis.
Cincinnati Gateway

Market Is Badly Muddled
By Government Restrictions
Quotations Show Wide Range—Increasing Number of Sellers Disregard Hoover's Price List—Peace Efforts Bear the Market—Car Shortage Acute.

A DOZEN divergent angles have done their part to disrupt even a semblance of normal transactions of business through the Cincinnati gateway. Some firms have thrown themselves entirely upon the mercy of the coal permits that have been issued and are sticking strictly to the Hoover prices. Others are taking advantage of the 8 to 10 per cent allowed to wholesalers and are packing on all of the sail that such will stand. Others have resorted to the usual openings that have been left to put their coal on the market at the top prices and it is rather surprising to find that more and more firms that stood solidly back of the Hoover proclamation are beginning to chafe under the restrictions that have been imposed through the permits, privileges and priorities.

The Cleveland conference, followed by announcements of mine reopenings, was a bear to the market and prices have slipped down a peg.

CINCINNATI

Probably the most rasing occurrence of all that have come up in the past three months is the exposé of the fact that over 800 cars from Hazard, Harlan and southeastern Kentucky, as well as a large number from the West Virginia fields, have been moved to the Lake under Permits No. 1. granted to the Pittsburgh Coal Co., which has not been a factor in the Cincinnati trade for years and yet has taken precedence over firms with offices here who have handled this fuel since the fields came into national trade.

The Cleveland negotiations had their effect in lowering the prices. The news that Fairmont intended to start up by the end of the week also was a softening factor.

Smokeless prices seem to be held pretty generally to the Hoover schedule with the exception of some Dry Fork and New River offerings. Cars supplies are short with the N. & W. declaring that they are in the worst position in years. The C. & O. and the L. & N. are resorting to embargoes to get coal moving.

Retail prices have not changed. Some of the companies are having trouble in making deliveries and holding their customers off to a later day when the strain will not be so great.

LOW-VOLATILE FIELDS
NEW RIVER AND THE GULF

Although New River mines are gradually rerelivering from the acute car shortage, production is still at a low ebb, averaging a little over 110,000 tons a week. The market is in rather an unsettled condition owing to the heavy demand and confusion attendant upon the establishment of the priority system which is diverting coal into new channels. So far as the general feeling of the trade is being moved at Hoover prices.

Gulf mines are managing to speed up a little in view of a somewhat better car supply from the Virginian and the C. & O. which were so seriously crippled for a time by the strike of shopmen. Railroads are handling more coal to the piers and much of the congestion has been relieved. Supplies for the general market have been somewhat curtailed as a result of the state of things. The market is still high despite the fact that most producers are not charging more than the Hoover price agreed upon.

POCAHONTAS AND TUG RIVER

Conditions in the Pocahontas field are beginning to assume a semblance of normal once again as mines find it possible to secure the fact that the bulk of the operators are not departing from that list.

HIGH-VOLATILE FIELDS
KANAWHA

Tonnage is gradually increased, especially in view of a more adequate car supply. Much of the coal originating in this region is being applied on priority orders under Class 1 and 2 so that railroads and utilities have been getting the lion's share of the output. Spot prices range $6@ $7.25, despite the fact that the bulk of the tonnage is moving at the Hoover prices.

LOGAN AND THACKER

Under improved transportation conditions, Logan production is once again on the up-grade. Owing to the curtailed output mines have not been able to furnish large tonnages and with a steady supply and priority orders are absorbing much of the coal needed to take care of these customers. Less tonnage is going to utilities and more to the railroads and utilities, with some to the Lakes. Government distribution agencies are functioning, but that the miners have brought prices down appreciably.

Although all the mines in the Williamson field are in operation the point has not been reached where it is possible to work full time, owing to the restricted car supply.

NORTHEASTERN KENTUCKY

The supply of cars is still so short that the output is not over 20 per cent. The field is unable to fill the needs of regular customers or send a very large tonnage to the Lakes. Prices of $6@ $7.25 are being offered in the open market.

COKE
UNIONTOWN

Resumption of some union mines through acceptance of the Cleveland settlement caused a drop of $1.50 per ton in the price of coal in the Connellsville at $15.50 for foundry, $13.00 for rail and in the Tug River at $12.50. A conference the market here was quoted at $7.50@$7.75 per ton. The week closed with a drop to $6 with sufficient orders at that figure to absorb the tonnage produced.

It is now conceded that production is at the highest point since the strike started and is increasing each day. Prices of shipper of shipments for the week are not yet available but railroad officials report an average of 1,000 cars of coal a day and 230 cars of coke per day being delivered by all lines. In most instances the orders at Frick, Rainey and other independent operations are increasing daily with mines being added to the active list each day.

CONNELLSVILLE

The principal change in the strike condition in the past week is that the Frick company is producing considerably more coke and is also shipping coal. Among the independents the operators a slight increase in operations is reported.

The market has continued very narrow, both demand and offerings being light. For many weeks past the demand has been very restricted by the high prices ruling, and has been narrowed down almost to a few foundries, these foundries buying only in a limited way, from hand to mouth. Regular foundry coke is as high as ever, being quoted at $150@$160, while so-called "furnace coke" is easier, at about $13.50@$14.

Reports have become much more definite that the strike in the Connellsville region are disposed to go back to work. The Cleveland settlement, whereby about 15 per cent of the coal operators involved in the agreement with the United Mine Workers, did not help the Connellsville strikers and it is expected that they will shortly realize that they can hope for nothing coming from the company. It is now generally assumed that in due course a moderate wage advance will be posted in the region, above the Frick scale of Aug. 1, 1924, and that in a short time the Connellsville strikes will all be over.

BUFFALO

The price continues strong. The supply is as light as ever. The big coke centers are still depending on a few side ovens and keeping their regular others idle for want of coal. Prices remain $15.50 for foundry and $6.55 (very scarce) for domestic, chestnut size, adding $2.28 for freight to Buffalo.
News Items
From Field and Trade

ALABAMA
C. C. Copperstone, of Carnegie, Pa., has been transferred to the Chicago Title & Trust Co., 10,000 acres of mineral lands in Marshall and DeKalb counties to secure a mortgage of $1,500,000, which will be used in the development of its coal and ore lands in that section.

COLORADO
All coal mines in Colorado with the exception of three Colorado Fuel & Iron Co. mines in Franklin county operated during the week, according to announcement of the commandant of the Colorado Rangers.

Robert Turner, superintendent of the Turner mine in Huerfano county, was arrested on charges of forgery. The miners there that went to the mine to work and that Turner interposed that they would not be safe unless they had a guard of fifteen men. Mr. Turner was charged with妨害公務罪 and released immediately on bond.

KENTUCKY
Troops were sent to Isley on Aug. 15 to protect the Coal & Coke Co. property, after snipers had started firing on civilian guards.

The Morris has named Fred M. Sackett chairman of the State Fuel Commission, which has opened offices at 161 Republic building, Louisville, as food administrator during the war.

The Frederick & Black coal mine at Dublin has filed amended articles increasing its capital stock from $200,000 to $1,000,000.

The Frankfort Elevator Coal Co., which handles and transacts connection and Kentucky river transportation of coal, has been awarded a contract of 5,000 tons, at $5.50 a ton, for transporting rock salt under plans for contract award being made by the Sink Fuel Co.

A. Wallet & Co., grain elevator operators, have filed suit for $37,800 alleged for damages caused by the Owen coal Co., for alleged mining of coal under property owned by them.

The Louisville & Nashville R.L. has opened a few days ago that it had brought its shop forces up to 7,750 men.

The Dutchess Fuel Co., of Milton, Knox County, coal capital $10,000, has been chartered by the Secretary of State. Incorporators are William Evans and William Leofence, all of Knox County, for development purposes.

The Eastpoint Block Coal Co., of Evansville, has been chartered by J. F. Auxier, Faris Bowling and N. C. Auxier, all of Auxier, for development of a mine.

MICHIGAN
John Kraft Coal Co., of Detroit, has increased its capital stock from $5,000 to $125,000.

The Owosso Coal Mining Co., Owosso, has been authorized a capital stock of $350,000. Incorporators are H. A. Bacon, C. D. Bell, C. C. Fitch, J. M. Otter, of Flint, and C. C. Fitch, of Lansing. The company will be managed by J. F. Auxier of the Michigan Securities Commission, has been appointed its attorney and administrator.

The Ford Motor Co. of Detroit was one of the first seekers of a priority order from the fuel commission. The company was a manufacturer's priority order for 7,500 tons daily with an additional 309 tons daily on its representation that it is under contract to deliver 15,000 tons per month to the Detroit City Gas Co. with 2,000,000 cu.ft. of gas daily.

The Zap Coaly Co. has been incorporated at Zap, N. D., to operate a lignite stripping mine. The Pratt interests of Minneapolis are the incorporators. This operation requires removing about 15 ft. of earth to reach a deposit of 15 ft. of lignite. Several other open pit mines in North Dakota.

Ivan Bowen, of the State Railroad and Warehouse Co., has resigned as assistant superintendent of the Berwind Fuel Co. docks at Duathlon.

Missouri
A petition in equity has been filed in the Macoupin County circuit court asking for a dissolution of the partnership in the Star Coal Mines. The petition recites that the parties have had a dispute and that the defendants have stopped the payment of funds to the plaintiff, and seeks an order for the division of the business. The company's property at stake is estimated to be worth from $60,000 to $70,000.

The stockholders of the Callaway County Coal Co., with headquarters at Carrington, are to meet to vote on a resolution to dissolve the company and close up its affairs and dispose of its assets.

Governor Hyde has appointed Hugh J. Macpherson of Joplin, a member of the state public service commission, for the succeeding term, members of a commission to supervise the development of power. The Macpherson commission will be made of either five or seven members and other members will be named by such five or seven members.

Incorporation papers have been granted to the Central Missouri Mining Co., at Centralia. The company plans to mine in the city on an extensive scale, by strip mining.

NEW YORK
The Pond Creek Coal Co. for the six months ended June 30, 1922, reports total production of 94,864 tons and net profits, after all expenses, of $91,343, an increase of 22 per cent over that of the same period last year. Net profits, after all expenses, of $91,343, an increase of 22 per cent over that of the same period last year. Net profits, after all expenses, of $91,343, an increase of 22 per cent over that of the same period last year. Net profits, after all expenses, of $91,343, an increase of 22 per cent over that of the same period last year.

The J. P. Burton Coal Co., Cleveland, has opened an office at Buffalo, with A. F. Meister residing there.

Scheid Engineering Corporation, New York City, has been appointed as the agent for the Fenlur Moore Coal Co., Winnetka, Conn., manufacturer of mining and handling machinery for industrial plants.

OHIO
No bids were received Aug. 11 by the Columbus Board of Education for the purchase of 10,000 tons of lump coal for the various school buildings of the city. This was attributed to the unsettled conditions incidental to the strike. The board re-advertised for bids.

The United States Coal Co. has just announced the initiation of extending its coal mining operations at Bradley, Jefferson County, to Smithfield, where two new shafts will be opened. The company will build a new town near the center of the mining district to extend its road from Bradley to Smithfield and put on passenger service. The Wheeling & Lakeville Railroad, headquarters of the company are located at Wheeling, and H. E. Willard is the general manager.

Sim Buku, who has been with the American Steam Coal Co. for three years, has severed his connections and opened an office on the X. R. Dgegan Coal Co., of Huntington, at the Dixie Terminal Bldg., in Cincinnati.

H. F. Idlett, of the Riddle Coal Co., Chattanooga, and Clyde Palmer, Cincinnati, manager of that company, spent ten days going over and inspecting the mining properties of the company in southeastern Ken-te-tuck and northern Alabama.

K. C. Slupe, president of the Elkher Coal Co., recently returned from a recent visit to the Cincinnati market. Other mining men there were J. H. Roberts, C. G. Cook, Frank Pineville, Ky., J. C. Callihan and W. R. McRae, all of Pineville, Ky., and Safi Allen of Prestonsburg, Ky.

Pennsylvania
N. S. Greenfelder, mining engineer of the Herron Coal Co., Huntingdon, has been attending the summer courses in coal mining at the Carnegie Institute of Technology, Union college of the University of Pittsburgh. His subject was the selection of explosives for the mining of coal. E. T. Stodol is in charge of the summer school at Carnegie Institute, and these courses are given by the Pennsylvania State College.
WEST VIRGINIA

Under arrangements just consummated between the Robinson Coal Co. and the Con-
nington Coal Co., the former company is acquiring the northern West Virginia, the former com-
pany to acquire the Connington Coal Co. operation, better known as the O'Donnell mine on the east side of the Carnegie coal field. This mine has been out of commission for some three months.

One of the largest deals of recent months has been consummated at Fairmount, inter-
state, in the purchase of the Fairmount-Chicago Coal Co., having acquired 2,000 acres of Sawickley for $120,000. Terms of the sale were largely negotiated by the Jefferson Coal Co., a concern in which the Edward Hines coal and lumber inter-
state had a dominating interest.

The understanding is that the purchase price of the property was actually purchased by the Fairmount-
Chicago Coal Co., which is capitalized at $100,000. The company has already perfected arrangements to increase production on a plant near Fathercille and to expend about $280,000 in in-
vesting the new plant. Twenty-five old mines for miners to be 8,800 new mine cars have been ordered and the cars direct from railways. The coal will be handled exclusively by the Fair-
mount-Chicago Coal Co., both having the same offices.

The tipples of the Mutual Coal Co., at Middletown, in the Monongalia field has
been destroyed by fire and two mine locomotives valued at about $20,000 have also been
destroyed. The mine is said by county authorities to have been of inscond-
able importance, and is being operated as an open shop mine since April 1.

ONTARIO

J. A. Ellis, vice-chairman of the OntarioRGB. Board, has been appointed con-
troller for the province with wide powers for regulating the purchase and dis-
tribution of coal and for exercising supervision over coal dealers over the situation and has held a meeting recently in Toronto. The company assigned last July to the Trusts & Guarantee Co., for the purposes stated, now stands with assets of $8,319.75. It is hoped to realize about $6,900 on the assets.

QuebeC

Sir Bertram Chadburt, M. P. for Barrow-

Ontario, England, is in Canada investigat-
ing the coal situation with the view of finding a permanent market here for British coal. He states that it is chiefly a matter of the Canadian market and a reason-
tory price and does not think that the situation can be solved. He feels that the col-

the situation can be solved. He feels that the col-

in South Africa and Britain with all the slides is not worthy of the high price.

Traffic News

Eleven coal companies operating in the

Whiteburg-Honibrode county of Kentucky on
the L. & N. have appealed to the State Rail-
way Commission on the ground that rates from that section to other points in the
state are too high, and that as a result the rates from the Hazard district.

The I. C. C. has decided the following coal rate cases on coal from bituminous
coal from St. Leonard, New Brunswick, to Quebec, Que., is unreasonable. The Re-
quested rates of the stow coal from Bessemer and Lake Erie, Ohio, to stations on the
Rochester, Buffalo 

and Pennsy-"lvanian railroads have been reduced. Rates on bituminous coal from mines in the Bouvier, Ind., district to stations in the adjoining states of Ohio and Ind., during Federal control, were un-
reasonably high. The reduce the complaint of the Cannelton Sewer Pipe Co. Rates on bituminous coal from Century, W. Va., to Pump Station, Ohio, are unreasonable because of the reduction of rate from Strongsville to Pump Station on the New York Central.

Jeffrey Single-Roll Coal Crusher.

The Jeffrey Mfg. Co., Columbus, Ohio, Catalog No. 525, describes Jeffrey Single-Point Crushers. This crusher is illustrated. The coal is fed into the crushing chamber and by the single point of crushing force is reduced to the desired size. It is large enough to meet all conditions of crushing but small enough to meet the demand for a uniform and consistent coal.

The Jeffrey Crushers are used for reducing the classifier of the crusher in service and table of capac-
ity. The Jeffrey Crushers are equipped with crushing various grades of bituminous coal.

What of the Business Revival?

PRICES and wages are going up. Every indication is for a busy and prosperous winter. Talk of business revival is in the air. The Steel Corporation has increased wages 20 per cent, making the pay of unskilled labor $3.60 per day, in an effort to hold the men that might be attracted to the coal mines, where the wage is again to be $7.50 per day. Liquidation of wages and prices has been estopped for the time being. The big question remaining concerns the permanence of the boom that appears to be on us. This is of interest to the coal industry because of what it portends after March 31, 1923.

It may be premature to speculate on next summer, and quite likely fruitless, but for coal it is important. The industrial storm this year may be largely traced to the effort made to liquidate wages in the unionized coal mines, and the end of the general movement due to the failure of the struggle in coal—that is, failure for all except the coal miner. Whether or not there will be a repetition of the effort next year and whether that effort will be accompanied by a coal strike will depend on the strength of the industrial revival, so called, and on the outcome of efforts yet to be fully inaugurated for preventing open breaks in coal wage negotiations in the coal industry.

The most important and at present the most apparent factor in the quickening of business is the absence of stocks of coal and of iron and steel products, traceable directly, of course, to the shortage of coal. As is noted in the monthly survey of business by the Department of Commerce, production has been descending for some time and prices have been going up. The twin strikes are held accountable for this state of affairs. Iron furnaces have been banked by the score, foundries are without pig, and a huge demand for iron in all forms is backing up on the manufacturers. Deliveries cannot be promised, for the furnaces are actually short of coke and but now are getting the supplies they need.

The railroads have been making a fine showing despite their strike, but they have not met all the demands placed on them and he would be shortsighted who would not anticipate still further and important shortages of transportation as the crops are offered to the rails and as coal mines get back to operation. Prices of coal are dropping from their peak—$8 coal was followed by $7 coal and that in turn by $6 coal. The trade is unsettled but a cross section of opinion seems to hold to the belief that the market will settle down to around $5 for the winter.

Will business function on a boom basis with coal at that figure? Just how sturdy is this revival? If it is predicated only on the making up of shortages caused by the strikes, then it will not be longlived. If it is that and something more, then it will live through. No one thinks that the demand for coal in the coming months will be as insistent as during 1920, that the country can or will absorb as much at as high figures as then. Theoretically stocks of coal in the hands of consumers are reduced to zero, and in fact they are lower than ever before recorded. The demand will be strong until that hole is filled, but beyond that point the strength of the coal market will depend on the persistence of general business activity.

The soft-coal requirements of the United States during the first six months of this year were very close to an average of 8,000,000 net tons per week. Consumption has declined since July 1. The two largest consumers, the railroads and the iron and steel industry, have used less, largely because they could not get it. The coal strike actually caused plants to shut down and fewer trains to move. It is not unlikely that a sum of 8,000,000 tons per week consumption has fallen to nearer 6,000,000 tons in recent weeks. As production gains and prices recede that figure will increase.

If the present revival is the beginning of a secondary period of inflation, to be followed by another effort at deflation, and very competent opinion holds to that view, then we will experience a second effort to lower coal-mine wages after March 31, 1923.

King Lewis I

CREDIT without stint is given the United Mine Workers as the greatest labor organization in the world. On every hand the press and private comment confess to the remarkable victory of the miners in the soft-coal strike. Recorded history, we are told, has no counterpart for the struggle in the coal industry this year. With every factor dead set against the union miners, they pulled themselves out of the hole—even though they may have pulled the shopmen in—and they now stand the acknowledged victors, conquerors alike of the mine management and owner, of the government and of the people.

And John L. Lewis is crowned the hero of it all. He is the mighty force that held the army of 600,000 together, held the bucking bronzes, Farrington and Brophy, in line, encouraged the line force and inspired the heavy artillery of propaganda, pulled the wires in Washington, confounded the administration and walled the operators. Like the boy wonder, the chess player from Austria, he lone-handed moved his pieces on a score of boards, outfitting a score of separate individual operator groups each electing to play its own game. They are all cleaned up now, save one that he has stalemated and one that is not quite played out.

By the editors of the country John L. Lewis is hailed as King, Dictator, and with other equally choice and endearing encomiums. Some refer to the conclusion of the strike as unionism gone wild. Some class him with the renowned and redoubtable George Baer of 20 years ago. His loyal followers flock about him and do lip service, telling him how mighty and how wonderful he is.
It is not necessary, however, to quote the press on the greatness of John L. Lewis. He admits it. We wonder what the public that is getting excited over the revelation of power held by this one man would say were they to hear Mr. Lewis tell how mighty he is. Picture him pacing back and forth across the room where he is supposed to be negotiating a contract with operators—let us say, for instance, in Philadelphia last week with the anthracite producers. Hear him say, for instance: “You ask me why I will not accept arbitration; why I will not accept even recommendatory arbitration with freedom to accept or reject the findings. Why, gentlemen, because I know that by any comparison made, with the cost of living, earnings, wages in other industries, however arrived at, the miners lose. We will not have our wages and earning compared with others to our disadvantage. That method of adjusting wages is out of date for us.”

Or perhaps the subject was the life of the contract, the little matter of wages having been settled in advance as the highest ever recorded. Perhaps the operators have said that they could not agree to pay those wages beyond next April, because they did not know what the price of bituminous coal would be, an important factor in selling steam sizes, comprising from 30 to 40 per cent of their output. Mr. Lewis demands in the hard-coal region a contract to run until March 31, 1924. To the objection of the operators he perhaps said: “Let that not worry you. The price of mining bituminous coal is not coming down. I have the soft-coal men wrapped around my little finger.”

Or as a peroration: “They told me I could not do it. College professors, economists, business men, my best friends and advisers said it was folly to undertake a strike this year, to try to hold coal miners’ wages up to the post-war heights. But, gentlemen, I have done it.” Can’t you just hear the rumble of that basso voice and see the shake of that magnificent mane? What an autobiography John L. Lewis would write today!

**Choose an Able Commission**

Coal legislation in three forms is being considered in Washington. Just plain inquiry heads the list in popularity, some method of controlling prices follows and outright seizure of the mines is latest and last.

The first, a commission of inquiry, is favored on every hand. As to the form of the investigation there is little discussion but the character of the commission has provoked much argument. The miners’ union wants to have some of its people on that body, arguing that unless it is represented the commission cannot get the facts and will not know what to do with the data when it gets them. This argument has much merit, but is completely overshadowed by the counter argument that were they to have representation the commission would have to agree with their contentions entirely or there would be a minority report. The country wants no minority report and it therefore is saying keep both miners and operators off.

We earnestly hope an able commission will be appointed, that it will have ample powers, ample funds and ample time to make its study and report. In its anxiety to save the country from freezing Congress will, it is hoped, come to some better method of getting coal out of the ground than taking over the mines. It is not the ownership that is holding up production of hard coal and laws cannot make the men dig coal.

*British Miners and Coal for America*

*VARIOUS* attempts to restrain the British miner from producing coal for America failed, as they were bound to fail. The fact that the proposal was vetoed at the recent Miners’ International Congress held at Frankfurt-on-Main may be regarded as conclusive evidence that the miners’ leaders desired to abstain from interference in the matter. It has been pointed out that the miners in Great Britain were justified in the course they have taken, owing to the American miners’ refusal to co-operate during the coal stoppage in Britain last year. This seems an excellent reason why the British worker should retaliate, but there is a still more practical one. It is obviously impossible for the miners to stop producing coal for America without ceasing production altogether, since it is not within their knowledge to which of the overseas markets the coal they produce is sent. Furthermore, it was mainly the non-union miners in this country who produced the coal for export that helped to break the strike in Great Britain last year.

British exporters are not reaping a financial harvest from their business in this country. American buying has been judicious in the main and carefully executed. Owing to the dull state of the export trade when the inquiries from this country first began the purchasers were able to obtain what are now considered by London as remarkably favorable terms. As a matter of fact the charter market has been as important an influence in determining the c.i.f. price of British coal in New York or Boston as has the price f.o.b. Cardiff.

It is clear that the British miners are doomed to disappointment in so far as they have been anticipating high wages later resulting from high prices and substantial margins over costs by the British export trade from the American business.

It will be remembered that last year in less than three months Great Britain bought and imported from this country some three million tons of soft coal at her own price. There was no perceptible increase in the market as the result of the British purchase of our coal in 1921. Under similar circumstances of dull market, low prices and idle mines, British coal men selling America not over two-thirds as much coal as we sold them last year record a market rise of 5s. or more in a month.

**Some of the Operator Groups** are reported in the press to consider that they emerge partial victors from this strike. Central Pennsylvania producers, for instance, announce that inasmuch as they negotiated a “district” agreement with District No. 2 of the United Mine Workers in so far as they deviated from the Cleveland contract by omitting provision for a gathering in October they beat John L. Lewis, who held out for no district settlements. These operators are just fooling themselves if they really think that way. Their victory is akin to that of the prisoner in the late war who was permitted to retain his trousers, although his suspenders were removed. Illinois operators, signing exactly similar terms, openly announce that they have been compelled to surrender.

**Kin Hubbard, Hoosier Humorist and originator of Abe Martin,** had this to say of the coal strike settlement: “Th’ coal strike has been all settled fine an’ dandy an’ temporarily.”
Cambria Steel Co. Drops Coal Down Well, Loads It at Bottom and Hauls It to Ovens*

Coal Is Passed Down a 110-Ft. Shaft from an Upper Bed to a Lower and Is Reloaded for Two-Mile Run to Rosedale Ovens—Electrically Actuated Gates Load Through Measuring Hopper

BY GEORGE A. RICHARDSON†

THE excellence of the iron ores in the vicinity of Johnstown, Pa., and the abundance of timber for the manufacture of charcoal fuel resulted in the development of many small iron furnaces in the early part of the last century. The presence of large coal deposits, in turn, aided in stimulating the business and maintaining it after local ores were no longer used.

The inception of what ultimately developed into the Cambria Steel Co. dates back to the year 1842 but it was not until 1855 that the first rolling mill was completed and put in operation. At the same time what is known as the Rolling Mill mine was opened. This mine, with the exception of three years (1888, 1889 and 1890), during which time natural gas displaced coal at the works of the Cambria Iron Co., has been in continuous operation ever since.

ONE SEAM YIELDS 20,000,000 TONS IN 67 YEARS

An excellent idea of the extent of the operations is to be gained from the figures that follow. In the sixty-seven years that have elapsed since the opening of the mine more than 20,000,000 net tons of coal have been produced from the C' seam alone. Despite the large amount that has been removed there is still remaining in the C' seam in the territory allotted to this mine an unmined tonnage of nearly 40,000,000, or twice the tonnage that has been removed since the mine was opened.

The record yearly production for this mine was made during 1905, when 804,188 net tons of coal was produced. The record production for any one month was made in May, 1907, when 79,875 net tons was dumped, and the daily record was made as recently as May 31, 1921, when 3,872 net tons was extracted.

This mine has worked over the largest territory of any single opening in the country, covering an area of approximately 10 square miles. The distance to the farthest working face is 5 miles.

From these figures it will be seen that the transportation problems at this property are unusually difficult and that the tonnages to be handled are larger than those in most single coal-mining operations. These drawbacks make imperative the introduction of the most modern

---

*First part of an article on the Rolling Mill mine.
†Midvale Steel & Ordnance Co., Cambria Steel Co.
methods if production is to be maintained and to be performed economically.

At the Rolling Mill mine two seams are workable. Both are in the Allegheny series. The upper, known locally as the Cement seam, is sometimes called the C', but is more generally designated as the Upper Kittanning. From it the Rolling Mill mine has obtained all its tonnage. It is a bright, horizontally bedded coal, the height of which averages about 3 ft. 6 in. At an average depth of about 110 ft. below this seam lies the Lower Kittanning bed, known as the Miller or B seam. The roof is exceptionally good, in general being of black slate. It requires little or no timbering. In the new development which is to be described the main heading in the Miller seam has a length of more than two miles, and throughout its length no timber is used.

Until quite recently this coal was transported by six different kinds of haulage before it was finally dumped on the tipple. These consisted of mules, storage-battery locomotives, trolley locomotives, head-and-tail rope, grip-rope and chain haulage.

Until 1881 all the coal produced in this mine was handled entirely by mules, which hauled it from the mine across the Conemaugh River and directly into the steel works in small mine cars. The coal was all mined by hand.

In 1881 small steam locomotives were introduced to haul the coal from the main sidetrack, which is about a mile and quarter back in the mine, this being a system of haulage that has seldom been attempted in the mines of this country. The coal was delivered to the main sidetrack with mules, and the dinkeys, or

**PLAN SHOWING MINES OF CAMBRIA STEEL CO. WITH PARTS OF THE CITY OF JOHNSTOWN AND SUBURBS AND CROSS SECTIONS OF THE SHAFTS.**

Note the long underground roadway from the Elk Run shaft on the right, at which point coal is dropped down a well from the Cement seam to the Miller seam. The section of this shaft, or coal well, is shown in the upper right-hand corner. The roadway passes under Westmount Borough and under the Conemaugh River on its way to the hoisting shaft of mines Nos. 5 and 6 in Rosedale. This shaft is located on the far side of Hickston run, near the Rosedale coke ovens. At that point a well passes coal from No. 5 mine, Cement seam, down to No. 6 mine in the Miller seam. The section of this shaft is shown in the second illustration in the upper left-hand corner. Had the coal been taken above ground to the Rosedale plant in accordance with the original plans it would have interfered with operations of the Cambria Steel Works and the cost would have been excessive.
steam locomotives, hauled it outside and distributed it directly into the mills.

This method was again changed in 1890, when the present tipple was built and a rope was installed. The mules continued to be used for gathering the coal to the main sidetrack.

As the mine developed further and further under the hill, the need for additional haulage facilities arose. In 1898 a compressed-air plant was installed in the Mill Creek valley, the mine was piped for compressed air and a number of air locomotives were installed and used for hauling the coal from the different sections to the main sidetrack, where it was picked up by the rope haulage. Mules were still used to gather coal from the working faces.

In the same year (1898) compressed-air coal-cutting machines were installed for undercutting the coal, greatly adding to the number of tons per miner.

The development of the mine over a still larger area made necessary the installation of five electric storage-battery locomotives in 1916-17. Until this time the gaseous condition of the mine would not permit of the installation of trolley locomotives and electric coal-cutting machines, but in 1918, owing to the excellence of the mine ventilation and the improvement of the gas conditions, the management and the state mine inspector considered it safe and in keeping with the state mining code to electrify a portion of the mine.

As a result the electric trolley motors were put in use in this mine for the first time in its history, and in January, 1919, this was followed by the installation of a modern electric coal-cutting machine, the first that the Rolling Mill mine has ever used. The introduction of electricity eliminated the use of the compressed-air locomotives, many mules and several air-cutting machines and air pumps. Hence, despite the fact that the mine has been in use practically without a break for 67 years, the equipment is among of the most modern in the country.

WITH NEW OVENS CAME NEW MINE EQUIPMENT

The practice of conveying the coal from the mine to the tipple, located in the Cambria plant, by means of rope haulage was continued until April, 1922. In 1916 what is conceded to be one of the best and most modern byproduct coke-oven plants in the country was designed for a location in a deep valley near the Cambria plant, through which flows Hinckston Run, the new installation known as the Rosedale plant. The carrying out of this design was commenced in 1917 and completed in 1922. Here care is taken of the entire output of the Rolling Mill and Rosedale mines.

One of the most important problems to be solved was the conveyance of the coal from the Rolling Mill mine to the Rosedale shaft. Several plans were considered and in explaining these it will be helpful to refer to the diagram which shows the relative location of the various openings.

The first plan considered involved the construction of an eight-track viaduct over the Conemaugh River from the Rolling Mill mine and the Miller seam into the upper end of the Cambria plant, the building of a new tipple, etc., at an estimated pre-war cost of $1,500,000, which would have meant three to four times as much during the war and the period immediately following. This plan had serious disadvantages. To begin with, the cost was high. More important, however, was the fact that congestion would be increased at a place that was already congested. Johnstown lies in a narrow valley between high, steep-sided hills, and the level space so necessary in steel-plant operation is always at a premium. Lastly, it would be necessary to haul the coal from the tipple to Rosedale, necessitating additional trackage through the plant and the use of still more space that was valuable for other purposes.

The diagram the location of the entrance to the Rolling Mill mine, the space occupied by the rope-haulage system, viaduct, tipple, etc., are all indicated.

The second plan proposed involved a radical departure from the first and there was some question of its practicability. It was finally adopted, however, and brought to a successful completion. This new plan involved the entire abandonment of the old system of rope haulage, the viaduct, tipple, etc., and the introduction of direct communication with the Rosedale plant through a heading from the Elk Run shaft of the Rolling Mill mine driven in the lower coal bed, which is known as the Miller, or B, seam.

The greatest difficulty with this plan and the one which gave rise to a fear that it was impracticable lay in the fact that it was necessary to drive the heading under the Conemaugh River and at a level which allowed
only about 70 ft. or cover. The diagram clearly shows the new route. It was expected that the water encountered in passing under the river would give much trouble.

The total length of the new heading is a little more than two miles and except in the section under the river gave no trouble of any kind. In driving that section drillholes were carried 16 ft. ahead of the gangways for fear that water would enter the workings in unmanageable quantities. Due to crevices in the strata large inflows were encountered on four separate occasions. The crevices, however, were filled with cement and no further difficulty was experienced with them. Today the plan adopted is in successful operation, and it is interesting to note that it was completed at a cost practically the same as that estimated on a pre-war basis for carrying out the first plan.

As might be expected, equipment of the most modern type has been used at this new operation and many new ideas originated by the mining department of the Cambria Steel Co. have been successfully developed. These will be described step by step in connection with the account of the methods used in getting coal to the Rosedale plant.

It has been mentioned already that the operations in the Rolling Mill mine are in the upper, or Cement, seam. Under the new arrangement coal, instead of being taken to the old opening which comes out at the Conemaugh River, is brought as far as the Elk Run shaft, located in the Borough of Westmont and about one-half mile back in the mine. Here a coal well has been sunk to the Miller seam, which at this point is 115.4 ft. below the Cement seam and about 342.6 ft. from the surface.

The equipment for handling coal at this point includes one trip feeder, a car stop, a rotary dump and a trip maker in the Cement seam, with automatic power-driven gates, trip feeder, etc., in the Miller seam. Coal from the Cement seam is weighed in cars before being dumped.

The equipment provided for the Cement seam is capable of handling loaded mine cars in trips not exceeding 110 cars each, advancing and dumping at the rate of six or seven cars per minute and remaking into trips of the same size. The trip feeders at this point are of the chain type with hooks and have a speed of about 65 ft. per minute. Trips of the size mentioned, the number of cars being based on an average load of 3,000 lb. each, can be handled on a 1-per cent favorable grade, enough cars being spragged to keep them from running forward.

A standard car stop is provided at the dump so that the operator has position control of the delivery of cars. This consists of a pair of heavy steel horns seated on heavy steel coil springs. These horns the operative controls by hand with the aid of a system of levers.

The rotary dump is operated by a 10-hp. 250-volt direct-current motor with automatic electric control. It requires no attention other than to start and stop it by the pressing of push buttons. Spring-seated car
The control of the loading machinery is entirely automatic. As each car approaches the gate a contact is formed and the lower gate is set in operation. It opens and discharges its contents into the car while the latter is in motion and then closes automatically. As the lower gate closes the upper gate starts its cycle of operation and the hopper is refilled. When the hopper has been filled both gates remain at rest until the next approaching car forms the contact which starts the apparatus in motion again.

With apparatus of this character cars can be loaded with great rapidity, the average rate being six cars per minute. The trip, both empty and loaded, is moved forward by a chain haul of the same general construction as that used for the feeder in the Cement seam but modified in some details. The speed is 80 ft. per minute instead of 55 and the spacing of the hooks is different. This chain haul can handle 130 cars, the grade being 1 per cent and favorable to the load. The average weight of the loaded cars is 5,000 lb. Enough cars are spragged to keep the trip from running forward.

**Proposed Danger Sign Divided Diagonally**

In the report of the thirteenth annual meeting of the Mine Inspectors Institute of America appearing on page 133 of Coal Age for July 27 last, the description of the proposed underground danger signal was in error. The recommended signal is intended to be arranged as shown in the accompanying illustration. It will be seen at once that the proposed board is divided by diagonal lines into four quarters—an upper, a lower, a right and a left. This arrangement will be less confusing than that described. Had the drawing here presented been at hand when the description referred to was written no such mistake as was made would have been possible.

The personnel of the U. S. Bureau of Mines Car No. 2 recently conducted first-aid and mine-rescue training at Dawson, N. M., and at Cameo, Somerset and Gilman, Col. The city firemen at Trinidad, Col., were given a course in first aid. The crew of Car No. 3 has conducted training at Heelwood, Frugality, Fallen Timber, Blundburg and State College, Pa. Car No. 4 was one of the attractions at the King Coal Carnival recently held at Henryetta, Okla., which was attended by approximately 40,000 people. G. T. Powell, of the Evansville (Ind.) safety station, gave first-aid training in June at Seco, Millsboro, Blackey, Sassafras, and Wico, Ky. K. H. Chisholm, of the Norton (Va.) station, conducted first-aid training at Moss, Va., for the Clinchfield Coal Corporation and at Roaring Fork and Pardee, Va., for the Blackwood Coal Corporation. First-aid Miner Reid, of the Norton station, conducted first-aid training for the Stonestake & Coal Co., at Stonesta and Dunbar, Va., and for the Clinchfield Coal Corporation at Crane's Nest and Clinchfield, Va. J. G. Schoning, foreman miner of the Seattle (Wash.) safety station, conducted training at Issaquah, Burnett and Black Diamond, Wash.

"These safety guys make me tired. It's too much trouble testing out this breathing apparatus."

Well, he didn't care much about breathing any longer, anyway.
By raising 8,218 tons of coal in a single shaft on March 25, 1922, the Orient mine of the Chicago, Wilmington & Franklin Coal Co. established a one-day single-balanced-hoist record that has so far never been beaten. The Zeigler mine of the Bell & Zoller Mining Co. during the same month established the one-month hoist record, producing 164,109 tons, its maximum production in any one day being 7,537 tons.

It will be said doubtless that there are single breakers in the anthracite region that not only handled but actually prepared more coal than the Orient and Zeigler shafts lifted and the surface plants prepared. That is true. Truesdale breaker of the Glen Alden Coal Co. put out in 1921 1,550,014 tons of fresh-mined coal, which would average, it is true, only 129,168 tons per month but the output in the record month of that year was 162,000 tons, and in March, 1922, when Orient and Zeigler made their big record, its production was 202,000 tons. The greatest quantity of coal shipped in one day from Truesdale breaker was 10,314 tons.

Note—The illustration at the top of the left-hand page shows the Orient and that at the top of the right page the Zeigler mine. These plants are only five miles apart and are located in the Franklin County field, where some of the largest producers in the United States are to be found, that county having been left undeveloped for many years owing to the depth of the coal, not one of the mines in that district being mined by drift or slope.

Conditions Under Which Made Wonderful

Orient Dumps a Mine Car Every Three-Eighths Million Tons in One Production—Output per Man per

On March 31 of this year the Truesdale plant mined, hoisted and prepared 12,000 tons, of which 9,500 tons were shipped, and 2,500 tons of coal were held for the boiler plant and in pockets for retail trade. Truesdale has been for many years a consistent producer. Since and including 1913 it has not failed once to ship more than a million tons of coal a year. It has no culm banks or strippings to help it maintain its output, but its coal comes from two shafts, five slopes and two tunnels—nine openings in all.

Plymouth No. 5 also, one of the plants of the Hudson Coal Co., commonly known as the Loree colliery, which has five coal shafts, a slope and three tunnels, put out 1,502,071 tons of fresh-mined coal in 1921 and 1,580,000

Truesdale Breaker

A preparator that for nine years has never failed to produce a million tons yearly and has shipped in a single day 16,314 tons. Tributary to the mammoth breaker are two shafts, five slopes and two tunnels. In 1921 1,550,014 tons of fresh-mined coal was produced. On March 31 this plant mined 12,000 tons, but 2,500 tons was held back to keep the mine free of water during the impending strike.
Orient and Zeigler Mines
One-Hoist Records

Seventeen Seconds—Loads One and Year—Zeigler Has Biggest Monthly Day Six and Three-Quarter Tons
tons including coal from culm banks. These are plant outputs and are not obtained through the handling of a single shaft hoist.

It is useful, however, to recall the gigantic operations of the anthracite region in sizing up and in considering the importance of the records made in the Orient-Zeigler contest and to realize that the tonnage of each of the Illinois shafts all came to one landing and was hoisted up one shaft by one hoist. There was a concentration not only in regard to time but in regard to facilities of operation. This is really the important fact. We might attain the output of the Orient mine by putting in two plants each of which could produce 4,000 tons and get the result desired—an output of 8,000 tons—but the essential point is that the greater cost of two plants was avoided and that one gang of men produced the whole tonnage.

Still it would not have been a particularly creditable performance if to obtain so much coal through the shaft it was necessary to use an undue number of men. After all, economy of operation is the main consideration. Thus Zeigler produced on its best day about 8.1 tons per man and during the whole month averaged 6.78 tons. The average output per loader per day for the whole month was 11.7 tons and per machine man 95.9 tons, the bottom laborers handling 27.9 tons per man and the top laborers 63.3 tons. These records are exceptionally good.

TONNAGE PER MAN EXCEEDS AMERICAN PRACTICE

Is it necessary to call attention to the fact that in the United States the average tonnage per man-shift in whole years, when idle days interspersed among working days made men more anxious to do their best, ran during the period from 1890 to 1918 between 2.56 tons and 3.91 tons and that even in Utah, where coal

Cleansing nut coal at Orient Mine

The method of suspending the shaking chute is interesting. Note the evenness of the product. There is a close analogy between the anthracite and Illinois coal shipments, despite the difference in the degree of mineralization of the fuel. The Illinois coals are more carefully prepared than most bituminous coals, the domestic fuel market being fostered with unusual solicitude.
tonnages per man are unusually high, the output in 1918 was only 4.79 and in 1917, 5.40 tons per man per day.

The showing certainly compares favorably with those that Professor Henry Lewis gives for the British mines in 1921—namely, 177.2 tons per year per person. The men in the Zeigler mine beat that record in a single month of twenty-seven working days.

It must be remembered, however, that the coal in Illinois is not so uneven in thickness, so irregular in level and so wet as in Great Britain. Illinois coal is clean. Several true faults are found in the Orient mine but the displacement is relatively small. The grades in sections run to 5 or 6 per cent and in Zeigler even 8 per cent, but there are stretches of half a mile or more where the seam lies practically level or with only a gentle dip. Regular workings with headings driven in any direction without trouble from water give Illinois an advantage over Great Britain and most of the United States. The southern Illinois mines have not failed to take advantage of the favoring conditions. The operating staff has with long experience learned to install such equipment as will render the best account of every opportunity. It must also be remembered that the assurance of a strike on and after April 1 made every man paid by the ton anxious to do his utmost so as to obtain the largest possible cash reserve for the long period of idleness which was in view.

The attached tables will give some idea of the relation between the tonnages and the number of men at work at both mines.

At the Zeigler mine it was an easy matter to handle the coal up the shaft because it was provided with two 8-ton skips. Its main difficulty was getting enough coal to the landing. The interesting methods by which this problem was overcome may be found described in Coal
Thirty-Day Free Storage Given at the New Government Terminals, Mobile, Ala.

BY DAVID HOLT
Mobile, Ala.

ARGES of rough-hewn lumber first brought Alabama coal to Mobile in the early fifties. This could be done, however, only when the rivers were at high stages. The boats usually were sold with the coal and were broken up for the timber they contained. The bargemen returned by steamboat to Tuscaloosa, and thence traveled overland to their homes in Walker County.

No large quantity of water-borne coal ever moved to this seaport. Frequently the coal and barge were sold at Tuscaloosa to save the long drift down the Warrior, Tombigbee and Mobile Rivers. With the extension of railroads through the coal fields this limited use of the natural waterways for coal transportation gradually came to an end, and it was not until after the canalization of the Warrior River was completed in 1915 that the water traffic in coal was revived. Even then lack of facilities for handling water-borne cargo coal at Mobile retarded development of this commerce.

Floating equipment for bunkering steamers long has been ample for the needs of the port. Such equipment can place fuel aboard a vessel as rapidly as it can be trimmed and stored in the bunkers. The Southern Ry. built a tippet with which to handle coal from cars to ship and the Louisville & Nashville RR. did likewise. Then the government built a coal- and ore-handling plant. This was completed last May and now forms an important link in the Mississippi-Warrior service.

A survey of the port compiled by the Mobile Chamber of Commerce for publication in June, 1922, shows that the present coaling facilities exceed 12,000 tons per day of 8 hr., or more than two average ship cargoes. This equipment includes the government tippet, two railroad tipples, five derrick barges of from 50 to 100 tons hourly loading capacity; one collier capable of placing 150 tons of coal aboard ship per hour, and a locomotive crane designed to transfer coal from barge to ship.

Mobile did not advertise itself as “the cheapest coal port on the Gulf of Mexico” until it was prepared to “deliver the goods.” The Mississippi-Warrior service has published and placed in effect its tariff for the delivery and storage of coal at its Mobile plant, which has a capacity of 400 tons per hour from barge or storage pile to ship or other carrier. This publication shows that coal for export or coastwise movement via ocean

At the Orient mine 825 dips aggregating 4,100 tons were made in the morning and 815 dips totalling 4,118 tons were made in the afternoon. Three railroad trains of fifty-eight cars each, or a total of 174 cars, were needed to handle the day's production, the coal being screened into seven sizes over tippet and re-screeener.
vessels, will be handled at the Waterways tipple under the following conditions:

"Delivery will be made directly from barges of the Waterways or from the stock pile into ocean vessels, or from barges to stock pile, the Waterways reserving the right to unload barges immediately upon arrival at Mobile, placing the coal on the stock pile. No charge will be made for delivery of coal into ocean vessels from barges of the Waterways or from stock pile or from barges of the Waterways to stock pile or for storage, provided delivery is completed within 30 days after the arrival of the coal at Mobile. The period of 30 days will be computed from 7 a.m. of the day following the arrival of the barge at Mobile, Ala., Sundays and holidays excepted.

FIFTEEN CENTS PER TON AFTER THIRTY DAYS

"If delivery is made, or if coal is held in storage after the expiration of the 30-day period a charge of 15¢ per ton of 2,000 lb. will be assessed. This charge includes the transference of coal from barge to stock pile, from stock pile to vessel, or from barge to vessel, as well as storage at the tipple. This charge must be paid immediately upon the expiration of the 30-day period referred to in the preceding paragraph."

Under present regulations, no coal will be handled at the tipple by the Waterways except in line service. No railway connects with the plant, which is located on the east side of the Mobile River. The storage capacity of the bins is 40,000 tons, which will permit the accumulation of sufficient coal for several ships' cargoes.

As the plant was placed in commission in June, the greater part of the coal handled by it has gone to Texas ports by ocean barges. One Mobile shipping firm, Page & Jones, has handled four cargoes of coal and coke, or approximately 24,000 tons, from the port of Mobile within as many months. Further exports are anticipated in the near future. The greater part of the cargo coal handled was loaded at the railroad tipples and all of it came to the port by rail. The latest shipment, composed of about 5,000 tons of coke and coal, was made to Callao, Peru, on the Danish S.S. "Nordfarer." This is said to be the beginning of a large movement of Alabama coal and coke to that Peruvian port.

Shipment of pig-iron, iron pipe, steel rails and other manufactured products of the Birmingham district to the Orient and to Pacific coast ports of the United States, via Mobile and the Panama Canal, with return cargoes of wheat, flour, fresh, dried and canned fruits and canned fish, has shown a marked increase during the present year. It is not an uncommon occurrence on the Mobile water front to see a steamer taking metal products from cars on one side and steel rails from Warrior barges on the other. The distribution of freight brought in by these steamers inbound gives the Warrior barges the return cargo that is needed for the successful operation of the line.

The commerce of the port of Mobile is in a flourishing condition and will be further improved after the passage of the proposed Seaport Amendment on which a vote will be taken on Nov. 14, the purpose of which enactment is to permit the State of Alabama to lend $10,000 on its credit for the further improvement of the seaport, by the building of self-supporting terminals, to be owned and controlled by the state, through its harbor commission.

Telegraphic advice from Alaska are to the effect that the Naval Collier Jason is en route south from Alaska with 5,000 tons of washed coal from the Chickaloon mine and 600 tons from the mines of the Behring River Coal Co. This coal is to be given a battleship test. An ingenious application of gold-mine practice has been resorted to in washing the Behring River coal. Gold sluices have been put in for this purpose and are giving splendid results. They are built in parallel, so that while one is being cleaned the other is in service. The plan is so effective that even the fine coal which settles in the bins shows no more than 4 per cent ash. Much of the coal thus far mined has run only 2 per cent in ash. The coal is sacked at the foot of the sluice and there transferred by truck to a canoe landing four and one-half miles away.

"Cap chimpers are toys for kids. I'll use my teeth."
He did. But he has no use for them now.

"This must be a missed shot. I'll dig in and find out." Wham!
Laws Compelling Use of Telephones at Mines and Provisions that Make Them Safe and Durable*

Several States Provide for Their Compulsory Installation—Severe Conditions Imposed Require Specially Constructed Devices—Reliable Transmission and Signaling, Prevention of Burn-outs, and Safety to Users Essential

By D. E. A. Charlton†

A mine not a shift passes in which the usefulness of the telephone fails to be made manifest, and it hardly seems necessary in these days of enlightenment to enact laws making the use of the telephone in mines compulsory.

In June, 1921, the U. S. Bureau of Mines issued a compilation of state safety regulations pertaining to the use of telephones at mines prepared by L. C. Ilsley and R. A. Kearns. This shows that sixteen states have rules or enactments relating to telephones, and I understand that no new state regulations have been enacted since then, although changes may take place at any time. It is of interest that the Federal Leasing Act of Feb. 25, 1920, has the following reference to mine telephones: In each mine where more than 100 men are employed underground on any shift the lessee shall provide and maintain a telephone system between the hoisting-engine room, the ground landing of the shaft or slope, the principal mine exit of drift mines, the fan building when same is located 1,000 ft. or more from the power house or main exit of the mine, and such other points on the surface as the safety of the employees may dictate. The telephone system shall also extend into the mine and telephones be placed on each shaft or slope landing in use and at the inside siding of each of the main haulage roads. The underground telephones shall be so placed that no body of twenty men shall be more than 1,000 ft. from the nearest telephone station. Telephones shall also be placed in each refuge and first-aid chamber.

What Laws of the Several States Require

The following is a résumé of the various state regulations with regard to the use of telephones at mines: The rules of California provide that telephones be maintained in all mines over 500 ft. in depth. Colorado orders the maintenance of an adequate telephone system in all mines, extending from the surface to the bottom of the shaft. Illinois requires that a system of party-line telephones be installed that shall include one telephone at the bottom of the hoisting shaft or, in slope or drift mines, at the first cross entry, and one at each inside parting. Iowa demands that in all mines where the workings extend more than 3,000 ft. from the foot of the slope, shaft, or the mouth of the drift a telephone system shall be installed and that this shall be extended as the works of the mine progress 3,000 ft. therefrom. Kentucky specifies that in any coal mine where more than fifty men are employed underground, one or more telephones shall be installed communicating with the surface. In Kansas it is unlawful to operate or permit any coal mine to be operated not equipped with a party-line telephone system. The New Mexico law apparently exempts metal mines, for it is stated that it shall be the duty of the operator to install and maintain a telephone system in every coal mine. The North Dakota legislation also relates to coal, and specifies that in any coal mine where more than fifty men are employed underground, one or more telephones shall be installed. The Oklahoma laws provide that a telephone system shall be furnished in every coal mine where as many as fifteen men are working.

Pennsylvania, Tennessee, Utah and Wyoming

In the anthracite mines of Pennsylvania means of communication must be provided by telegraph or telephone between mines and collieries, and in the bituminous region of that state the law relates more specifically to communication between the surface and the bottom of the shaft or slope. Tennessee specifies the maintenance of a metal tube from top to bottom of shaft, or a telephone system. Texas also requires that a metal tube or telephone be maintained. The Utah laws provide that in all mines in which ten or more men are working more than 2,000 ft. from the entrance, or in which there are ten or more working places more than 2,000 ft. from the entrance, an underground telephone system shall be installed. Washington specifies that a telephone or metal tube shall be maintained from the top to the bottom of every shaft or slope, and at each alternate working level. Wyoming orders that a system of party-line telephones be provided at each coal mine in operation. In addition, several of the regulations of the various states contain clauses relating to the installation and maintenance of mine telephones.

The severe conditions to which mine telephones are exposed make it necessary to construct them more ruggedly than is necessary in ordinary installations. Underground, the device frequently must be exposed to moisture, gases, acid water, and mechanical sources of injury. Of these, the last, which include falls of ground, blasting concussions and rough handling, are the most frequent; moisture is probably the next. Gas and acid water are in general restricted to coal and copper mines.

Mine telephones are in general housed in a moisture- and rust-proof iron or steel case, of sufficient thickness to provide ample protection from injury. The edges of the case are well rounded, so that water and falling objects will easily slide off, and strong mounting supports are provided to insure rigidity when the telephone is installed. An outer door on the case, provided with a rubber gasket, serves, when closed, completely to protect the mechanism from any disturbing elements.
When this is opened, only the transmitter, receiver, receiver cord, and generator handle are exposed, as an inner door effectually conceals and protects all of the delicate mechanism of the telephone. When necessary, locks or padlocks may be placed on the outer door, the shift bosses or foremen being provided with keys. Binding posts for the line and ground wires are placed in a terminal box, which is either mounted on the underside of the case proper or included as a part of it. The bells, bell mounting, and clapper rod assembly are housed in a dome-shaped casting on the top of the case.

The talking apparatus of the mine telephone consists of a standard long-distance transmitter and receiver, slightly modified for underground service. In the design of these the manufacturers have considered carefully the hard usage to which the mechanism will be subject, and waterproof windings and special insulation are used throughout. The ordinary form of gravity-controlled hook switch is not sufficiently rugged for mine service, and one manufacturer, at least, has devised a positive spring-concentrated hook switch in which the force of gravity is not employed. The receiver, instead of being suspended from a lever which terminates in a fork-shaped yoke, normally rests between the jaws of a special holder. When the receiver is taken out of the jaws a trigger depresses a small plunger which passes through the door and actuates the contact spring of the hook switch.

Mine telephones are usually supplied with ringers of 1,600 or 2,500 ohms resistance and five-bar hand generators. Under average service two standard dry cells will furnish talking current for a year or more, as the transmitter has a fairly high resistance and therefore a low current consumption.

Frequently it is desirable to supply loud-ringing extension bells so that the telephone signals may be heard at some distance or above the noise in that particular place, which may be a shaft station or a pump room. In this event gongs of 6- to 8-in. diameter are supplied, the ringer coils usually having the same resistance as those used in the telephones.

It is customary to protect mine telephones against lightning discharge and accidental crossing with high-tension lighting or power circuits, and for this purpose a protector, consisting of mountings equipped with fuses and carbon-block type open-space cutouts, is used.

**LARGE CHOICE OF TELEPHONE CONDUCTORS**

Conductors of many kinds may be used for mine telephone lines, and many different types of brackets and insulators are available. No one type of installation can be recommended for all conditions. The following kinds of conductors are in general use for wiring mine telephone systems:

**Surface**:
- Triple braid weatherproof copper or iron wire (No. 12 gage);
- Bare copper or iron wire; bridle or drop wire for short runs.

**Underground**:
- Practice greatly differs as to sizes and types of wire used underground. One manufacturer recommends armored cable, Ferrin cable, or twisted-pair drop wire (40-per cent para insulation).
- From a questionnaire which I sent out the replies varied greatly, but in general Nos. 12, 14 and 16 copper wire, rubber-covered and armored, also No. 12 iron wire, tinned, were specified. In some instances, the wires down the shaft are included with the signaling wires, the whole consisting of a single cable with individual strands for the two functions. Where conduits were used, 3-in. metallic carriers were specified.

Not infrequently much trouble is experienced from the breaking of the line by falls of roof and similar happenings. In the installation of wires, particularly in haulage drifts where trolley locomotives are used, it is essential that care be taken in the placing of wires.
so that there shall be no connection between the two circuits. Unless the telephone wire be well insulated, a wooden or insulated conduit should be provided where it crosses over trolley wires.

The location of mine telephones depends of course upon the extent of the operations. Not infrequently a group of mines will be connected from a central switchboard which will serve all important points above and below ground. In most installations, however, it is customary to maintain a single circuit at each mine, connecting the surface with the underground workings and signaling to the different stations by means of code rings. The following buildings will usually be included in such a circuit. For metal mines (surface): Office, engine room, boiler room, shops, change house, first-aid room, and top of shaft; (underground): shaft stations, pump stations, powder magazines, loading pockets, and transmitting levels. For coal mines (surface): Office, engine room, shops, tipple, top of shaft or slope, and first-aid room; (underground): shaft or slope bottom, pump stations, main partings and first-aid rooms.

In a tentative draft* prepared by the U. S. Bureau of Mines the following general requirements have been stated to be used as a basis in establishing a list of telephones which would be permissible for installation in gaseous mines:

**WHAT A PERMISSIBLE TELEPHONE SHOULD EMBODY**

The apparatus shall be so designed and constructed that under no circumstances can its normal operation cause ignition of surrounding explosive mine atmospheres. All parts of the apparatus shall be adequate for the service for which they are intended.

The construction of permissible apparatus shall be especially durable. This requirement shall be applied consistently to all the details of the apparatus under test in order that with proper care and maintenance the permissible qualities of the apparatus will remain unimpaired under the severe conditions imposed by mining service.

All terminals and contacts, and all wiring, shall be adequately protected, and all leads shall pass through the casings of the apparatus by means of adequately insulated devices of approved design.

All parts of the apparatus, such as the magneto, the hook switch, etc., which are capable during normal operation of igniting explosive gas and air mixtures, shall be placed in permissible compartments.

All openings in the casings of permissible compartments shall be tightly closed and it is desirable that such openings shall be as few as possible. All joints in the casings of a permissible compartment shall be metal-to-metal, so designed as to form a path not less than 1 in. long from the inside of the casing to the atmosphere. All bolt holes in the casing shall be bottomed or so arranged that the accidental omission of a bolt will not give an opening through the casing. The compartment shall be provided with an adequate lock or seal to prevent any person from tampering with the apparatus inside the casing.

Battery cells shall be placed in a permissible, or in a locked or sealed adequate compartment, and their terminals and the connections thereto shall be arranged so as to preclude the possibility of anyone meddling or tampering, or making electrical connection with them. The short-circuit current of the battery measured as close as possible to the terminals shall not exceed the following limits: For batteries giving 2.5 volts or less, 100 amperes; for batteries giving 2.5 volts but not more than 4 volts, 85 amperes; for batteries giving more than 6 volts but not more than 6 volt, 45 amperes.

The manufacturer shall permanently attach to the case of the apparatus adequate instructions for the installation and connection of the telephone, so that the safety and efficiency of the apparatus and the system to which it is connected shall not be diminished by its installation. He shall also attach to the instrument an adequate wiring diagram of the apparatus.

Correct wiring and proper installation and maintenance, combined with sensible usage, are essential to the success of mine telephone systems. The telephone is a prime necessity in every mine, for without it today safety and efficiency are impossible.

In the preparation of this paper I am indebted to L. C. Ilsley, electrical engineer of the U. S. Bureau of Mines; the Stromberg-Carlson Telephone Manufacturing Co., the Western Electric Co., and to the several safety engineers and superintendents who have given me specific information concerning telephone installations and various other details of practical operation at their mines.

J. J. Rutledge, superintendent of the Central District experiment station of the U. S. Bureau of Mines, Urbana, Ill., is devoting much time to the study of improved methods of underground work in coal mining which result in increased recovery of coal. Mr. Rutledge recently conferred with operators of Iowa mines regarding a method in use there which recovers 90 per cent of the coal in the bed when conditions will permit its use.

**NUMEROUS TESTS HAVE BEEN MADE at the experimental mine of the U. S. Bureau of Mines near Pittsburgh, Pa., to determine the resistance offered to given quantities of air by placing mine cars in different sections of the air passageway, including timbered sections with timber sets spaced respectively at 5-ft. and 10-ft. centers. Tests were made to determine the equivalent straight-entry lengths corresponding to a right angle turn, respectively without vanes, with one vane, with two vanes, and with two vanes and a Venturi vane. A program of 30 tests was completed in July.**
Inborn Superstition Regarding Mine Accidents

Fatal Accident Starts Men Thinking—Superstitution of Large Class of Mining Men—Death Rate Shown by Statistics—Prevailing Indifference of Workers

In his article entitled "Importance of Checking System," Coal Age, July 20, p. 96, J. W. Powell expresses his deep regret on reading the reports of fatal mine accidents, recorded from time to time, in Coal Age and the public press.

When investigating a recent fatal accident in a mine, I was impressed with the lack of consideration given to these sad occurrences. There seems to be a widely prevailing feeling that accidents will happen in coal mines, in spite of all that can be done to eliminate them.

A remark commonly made is, "When a man takes a job in a mine he assumes his own risk," and Providence only knows how great is that risk. Such an attitude on the part of the worker, it must be acknowledged, does not tend to lessen casualties.

My visit to the mine just mentioned has altered my thinking. The foreman spoke of this accident as "Number one," adding, "We will sure have two more soon." He said that, in all his experience, he had never known it to fail; but when one accident occurred two more were sure to follow.

The remark of the foreman, I have learned, is inborn in a large class of mine workers and mining men in general. It is a superstition that pervades their minds. Many mine workers have come to look on an accident as something mysterious and beyond the comprehension of mortal man and, beyond a small circle of friends and neighbors, the incident goes unheeded. There is not the community interest that the occurrence should awaken in the hope of making labor more safe.

Instead, what do we find? A serious or, perhaps, fatal accident occurring awakens nearby workers to a sense of danger. For a time they are more alert and cautious. But the sense of danger grows less, as time passes, and when a second accident occurs many are hardened and the effect is far less than on the first occurrence.

Again, time passes and a third accident occurs. Then the old indifferent manner of performing their work returns. With evident relief a worker explains, "Well, that is Number three. We are safe now, for a while, anyway."

Importance of Investigation

It is my belief that this attitude of mine workers, call it superstition if you will, is responsible for the great indifference displayed by the average miner, regarding his own personal safety. It explains why an accident out of the ordinary is required to bring men to a realization of the hazards about them and make them, for a time, more careful in their work.

Reflections such as these should bring to our mind the fact that there is much need for improvement in this direction. The proper way to approach the matter is to make every fatal accident the subject of a thorough and immediate investigation. It is important that this should not be delayed, or the impression to be made on the minds of the men will be lost.

At once, on the occurrence of an accident in or about a mine, the superintendent or mine foreman should appoint a committee of three to make a thorough and careful investigation and report the facts to him for submission to the highest official in charge. Throughout the investigation, the aim should be to fix the blame for the occurrence on any one found to have neglected a duty, and make recommendations to avoid a similar occurrence.

The investigation made by the committee, in addition to those made by the state mine inspector and the coroner if the accident is fatal, should make a deep impression on every one connected with the undertaking.

In other words, every one should be made to feel that an accident, be it only a minor, serious or otherwise, is not a thing to be passed over carelessly or lightly set aside. Cause for the occurrence must be found and the responsibility placed on the shoulders where it belongs. Bulletins and pictures strongly emphasizing the fact make a lasting impression on the mind.

Pikeville, Ky.

The Certificate and Safety

The mine symbolized as a ship—Mine officials are the captain and officers of the ship—Knowledge required to insure safety—Responsibilities of the fireboss.

Permit me to offer a few words in addition to what has already been said regarding the employment of certified men in responsible positions in coal mines. Arguments have been advanced on both sides of the question, but it stands to reason that a certificate of competency honestly gained is an evidence of the holder's intelligence and acquaintance with the principles of mining.

Without doubt, we have many good men who have gained experience through long years of practice and, yet, it cannot be denied that some of these are dangerous men to be given charge of a mine where the conditions require a knowledge that cannot be gained through practical experience alone.

Must Know More Than Practice

Consider for a moment a foreman given charge of a very gaseous mine where the coal is highly inflammable and makes much dust. His previous experience does not guarantee that he will be able to handle successfully the problems that will arise under these conditions. He must have a knowledge of the nature and behavior of gases beyond what practice has taught him.

What is true of the foreman is true, to an even greater extent, of the fireboss in whose hands are placed the health and safety of the men employed in such a mine. Like the foreman, his knowledge must be greater than what one can learn in the practice of firebossing alone.

Let me liken the mine to a great ship voyaging the ocean. The miners and daymen are the passengers and the mine officials, from the superintendent down, are the captain and officers, to whom are entrusted the safety of the ship and its precious burden.
Coal mining, piled is will in practical is within fireboss, safe dilute the gob, cope build knowledge mining, to the accurate thoroughly have reduce eliminate official Oscar may. Then, it mine heating gain am a man it all. As which matter my generated. longwall mining understanding every among motion. Another dust, putting is with the practice. No man with an education would do this. Instead, he will see that sufficient air is used to sweep the place where the gas is accumulated, in volume sufficient to dilute and render harmless the gas.

Another danger requiring a higher knowledge than that gained in practice is the dust menace in mines. Where the fine dust of an inflammable coal is allowed to accumulate on the timbers, roof and sides of the roads and air-courses, or in the working places, it is extremely dangerous. It becomes the prime factor in propagating an explosion throughout the mine that would, for the dust, have had only a local effect.

Mine Officials Require Knowledge Gained Only by Study

The study of appliances to which I have referred gives both the mine foreman and the fireboss a knowledge of the dangers present, and enables them to avoid all conditions that make the mine unsafe. It is up to every mine official to gain this knowledge in addition to his practical experience.

Let me say, in closing, that I am of the opinion that there has been and still exists a close relation between the certificate of competency and mine safety, which every man should recognize. The holder of a certificate should be employed, in any official capacity, in preference to a man who holds no certificate, provided both are practical experienced men.

The certification of mine officials raises the standard of excellence, giving to every such man a knowledge of gases, ventilation, pumping, drainage, timbering and other subjects, including the geology of the coal formations that define him familiar with this. Hence, mine officials will be better able to understand the cost-sheet and reduce the accident list and insurance.

In the last examination, in Kentucky, out of 126 applicants, 114 passed a successful examination and gave evidence of their practical intelligence.

Heating of Gob Areas

Referring to the question of the heating of the gob, as the result of mining a seam, in a clay parting containing sulphur, allow me to give a little of my own experience in keeping the waste cool under similar conditions.

In the first place, let me say the mine should be well ventilated. From the conditions described in this place, there is little doubt but that much fine coal is mixed with the clay cuttings thrown back in the gob and every opportunity is afforded for heating to develop that will create trouble and should be prevented.

Use of Salt in Blasting Advocated to Reduce Heating

In the reply to this inquiry, mention has been made of the use of salt, as a means of countering the tendency to combustion in the waste. This, to my mind, is a good plan; but let me suggest that, before this request is brought into the mine, the face for the purpose of cutting, a layer of salt should be sprinkled broadcast on the bottom rock along the face.

By so doing, there will result a more intimate mixture of salt with the clay cuttings and fine coal. Then, before the refuse is used, the salt should be repeated sprinkled salt. Indeed, the salt should be used without restraint if it is to prove effective. Again, when throwing the refuse into the waste it should be distributed in thin layers and not piled in heaps, in order to reduce the heating, by giving the air current a better opportunity to carry away the heat as it is generated. Also, the gob should never be piled against the coal rib, which should be kept clear and free. This will also prove an advantage by giving cleaner coal when removing the pillars.

Wilders, Tenn.

As has already been suggested, the best way to eliminate the trouble caused by the heating of gob, in the longwall-advancing method of mining, under the conditions described as "Mining Engineer," in Coal Age, May 25, p. 886, is to load out the clay cuttings mixed with fine coal and containing some sulphur. This should not be stored in the gob if trouble is to be avoided.

The suggestion of the use of salt, in an attempt to reduce the tendency of the gob to heat is, in my opinion, well worth trying. We are taught that coal absorbs anywhere from 11 to 3 times its volume of oxygen and the resulting oxidation of the hydrocarbons in the coal develops heat, which if allowed to proceed will eventually fire the coal left in the waste.

Excluding Air from the Gobes Practice in England

My method for preventing this action is to exclude the air from the gob, as far as that is practicable. The gob, in longwall working, should be stored as closely as possible and confined by well-built packwalls. The building of these packwalls, shutting in the gob and reducing the air, is of great importance in longwall advancing, under the conditions named. In some districts in England, the coal seams are subject to gob fires; and it is the custom, there, to build the packs, along the roads or "gates," as they are called, very solid so that they are impervious to air.

At times, these packwalls are made of blocks of clay 9x9x18 in., in size, sent down from the surface into the mine, and these are built up as walls on each side of the goaf. The result is that little air can reach the gob, except at the working face; and, at times, such a wall is built across the face when it becomes necessary to seal off the area because of a fire started in the gob.

WILLIAM DICKINSON.

Lochelly, W. Va.

Some Facts in Coal Mining

Higher accident rate among American miners--Employed in more dangerous work--Causes of waste of coal and materials.

In HIS address before the Clarksburg Mining Institute, a short while ago, R. M. Lambie, chief of the Department of Mines of West Virginia, made one or two statements to which it will be well to refer by way of explanation.

As reported in Coal Age, May 18, p. 825, Mr. Lambie is said to have remarked that "the percentage of accidents among employed Americans is greater among foreigners, claiming that in 1921 there was one fatality for every 342 American miners employed, while the rate among Hungarians in the mine was one for every 645 miners.

A statement is anything but flattering to the American miner, unless the reason for its truth is explained. The speaker went on to say that Negroes, Italians and Spaniards were among the most careful men in avoiding accidents.

A simple statement giving the ratio of fatalities for so many persons employed, it will be generally agreed, is
no criterion by which to judge miners of different nationalities, in respect to their relative freedom from accident.

It is well known that the foreign miner must perform the most dangerous work, in the mine, more often than falls to the lot of a foreign miner. From the very nature of the case, as a class, foreign miners are employed on the less hazardous kinds of work. Few of this class of miners are to be found drawing pillars, timbering high falls and doing other dangerous work.

In one mine where I was recently employed, of the 200 men engaged in loading the coal cut by machines, only 20, or 10 per cent, were Americans and most of these were so employed, temporarily, because of a lack of pillar work and other more hazardous undertakings.

In the same mine, from 75 to 80 per cent of the men employed in the pillar workings were American miners. It is clear from these conditions, and the fact that any ratio of fatalities to the number of men employed has no national significance and must be unfair to American miners to whose lot it falls to perform the more hazardous work.

Waste of Material Due to Large Areas to Be Inspected

In the course of his address, Mr. Lambie referred to the deplorable waste of both coal and material manifest in a large number of mines. Unquestionably, this is true, but the responsibility for this waste is attributed more to the fact that underground officials are given, generally, more territory to supervise than these men can look after efficiently.

Much of the waste can undoubtedly be avoided by giving each foreman and assistant foreman jurisdiction so that he will be able to visit each working place several times a day, instead of having to hurry around in order to visit every man once a day.

More frequent inspection of the working places would have the advantage that the foreman or assistant foreman would be able to see that his orders, given on a previous round, were obeyed and not put over till the next day with the chance that, in the meantime, accident would befall the man.

Large Amount of Coal Lost in Crushing of Pillars

The largest loss of coal occurs in places where the pillars are so badly crushed that work on them is too dangerous and must be abandoned. This condition often results from pillars being left standing for an indefinite period; or because of a haphazard system of working, in respect to driving the rooms and drawing back the pillars.

For example, where the line of pillar work is to parallel the entry, a sufficient number of rooms should be driven up together and, on reaching the limit or boundary, the pillars between them must then be drawn back together. On the other hand, if the rooms are turned in regular order, one after another, the work should be so arranged that they will reach the limit or boundary in regular order and the line of pillar work should then be kept straight and make an angle of about 45 deg. with the entry.

Any delay, either in driving the rooms forward, or pulling back the pillars in regular order, will throw an excessive load on these rooms or pillars that are delayed. This will cause the roof to cave in the rooms and pillars will be crushed. Proper attention to these matters will avoid a very large waste of coal in our mines.

Thomas Allen, Mt. Harris, Colo. Safety Instructor.

Inquiries Of General Interest

Estimating Calorific Value of Mine Feeder Gas

Heating Value of Any Combustible Depends on Its Composition—Heat of Combustion Calculated From Chemical Reaction—Composition of Feeder Gas Variable

Recently my thoughts have dwelt much on the great loss we permit in allowing large volumes of feeder gas to escape into the atmosphere, without making any attempt to utilize its heating value. I believe attention has been drawn to this matter, at different times, in the columns of *Coal Age* and other mining publications.

Lately, the subject has impressed itself strongly on my mind, in connection with the draining of gas from abandoned panels and other large areas that have been sealed off in mines. The gases generated in these areas have been drained to the surface through boreholes sunk for that purpose.

Now, why would it not pay to conduct this gas, by pipes, to the boilerhouse and burn it under the boilers. There may be practical reasons why a system of this kind cannot be used, but that the saving of the heating value of these waste gases would more than compensate for the expense of installing the necessary piping system.

If there are objections to introducing the gas under the boilers, could it not, at least, be conducted to the main flue or base of the stack where it would be ignited and create a motive column that would increase the draft in the stack? Such an arrangement would also greatly assist the drainage of gas from the sealed portions in the mine. If these gases were allowed to escape, they would be converted to carbon, and the chief combustible is the fixed carbon; but the heating value is greatly modified by the amount of volatile combustible matter contained in the coal. The best results are obtained by estimating the heating value of each constituent, in proportion to the percentage present, as determined by the ultimate analysis of the coal.

In the combustion of a gas, the heat of combustion is equal to the excess of the heat of formation of the several products of the combustion, over the heat of formation of the combustible itself. This can only be estimated by means of a thermochemical equation. For the purpose of such a calculation, reference must be had to a table giving the heats of formation of the different mine gases. Such a table is given on page 68, "Mine Gases and Ventilation"—Beard, Eighth Edition.

The entire subject of calculating the heating values of substances and gases is fully treated in those pages. For example, the molecular heat of formation of pure methane (CH₄) is given as 39,060 B.t.u. The products of combustion of this gas are carbon dioxide (CO₂) and water (H₂O) and their respective heats of formation, as given.
in the table, are 174,600 and 126,288 B.t.u. The reaction is shown by the chemical equation.

\[ 2 CO + O_2 \rightarrow 2 CO_2 \]

Their being but one molecule of carbon dioxide and two molecules of water formed in this reaction, as shown in the equation, the total heat of formation of the products of combustion, less the heat of formation of the methane; is 174,600 + 2(126,288) = 39,050 = 388,116 B.t.u., which is the total molecular heat developed when methane is burned. But, the molecular weight of methane being 16, the unit heat of combustion of this gas is 388,116 / 16 = 24,257 B.t.u., which is the theoretical amount obtained by calculation. The experimental heat of combustion of methane, however, is 23,513 B.t.u.

A must be remembered, however, that the composition of the gas is very variable. An analysis of natural gas, in the Pittsburgh district, is given as follows (percentage of volume):
- Methane, 67.0;
- Hydrogen, 22.0;
- Olefines, 6.0;
- Nitrogen, 3.0;
- Carbon monoxide, 0.6;
- Carbon dioxide, 0.6;
- Total volume, approximately, 100.

The heating value of the same gas, as determined by experiment, is given as 892.4 B.t.u. per cu.ft. of the gas at 64 deg. F. An interesting problem is to calculate the heating value of this gas, as a check on the experimental value just given.

**Examination Questions Answered**

**Alabama Mine Foremen's Examination, Birmingham, July 24-27, 1922**

*(Selected First-Class Questions)*

**Question:** If the ventilation of a mine is insufficient, how may it be increased without increasing the power?

**Answer:** Clean up all air-courses, removing every obstruction to the free passage of the air; enlarge all break-throughs and shorten the course of air travel, as far as that is practicable, avoiding all sharp turns in the airways. Wherever the velocity will permit of further dividing the air, this should be done in order to reduce the mine resistance.

**Question:** When coal is shot off the solid how should the holes be drilled and what kind of powder should be used?

**Answer:** The axis of the drillhole should make such an angle with the face of the coal and the charge be so located that the line of least resistance, extending from the charge to the face of the coal, will be less than the depth of the hole. The hole must be well tamped and only permissible powder should be used in charging.

**Question:** Where coal is undercut by machines, is it possible to have a wind or a blowout shot? If so, what would be the cause?

**Answer:** In machine mining, a wind or a blowout shot may result from the hole being drilled beyond the depth of the coal, and making it a shot on the solid. If an undue accumulation of fine cuttings is permitted at the working face, the fine coal and dust will be blown into the air by the force of the shot; and the explosion of the dust clouds thus formed will have, more or less, the same effect as a wind shot. In order to avoid such an occurrence, the fine cuttings of the machines must be removed before any shots are fired.

Much will depend on the soft friable nature of the coal and its inflammability.

**Question:** In a faulting heading where the sides are showing weight and the roof in the face bad, how would you timber to hold the side squeeze and make progress and safe work in the face? Give sketch of timbering.

**Answer:** As shown in the accompanying figure, heavy timber frames should be used, from 10 to 12 in., either round or square. The legs should be well notched into the collars and lagging used above the collar beams and behind the sideposts or legs.

**Question:** How would you timber a room that had bad roof and a soft fireclay bottom? How would you keep your roadway safe?

**Answer:** Under these conditions a systematic form of timbering should be adopted in the room, the posts being set in rows parallel to the face and three or four feet apart, center to center. The posts should be set on footboards or stringers to avoid their sinking into the soft bottom, and long cap-pieces, booms or stringers should be used above the posts to support the frail roof.

On the roadways, the timber frames should be set from 2 to 4 ft. apart, center to center, depending on the depth of cover, and lagging should be used above the collars to prevent the fall of small pieces of slate that would block the roads. The legs of the timber frames should be set on stringers, on each side of the track.

**Question:** If you were firing fire shots in the face of a room, with one shot depending on the other, what precaution would you use to prevent a windy shot?

**Answer:** If five shots are to be fired consecutively, one depending on the other, the only safe method to pursue is to fire each shot separately and in order, starting with the first free shot. Dependent shots must not be fired with fuse, on any condition; neither should they be fired electrically, causing practically the simultaneous explosion of all the shots. In firing the shots separately, as stated, time should be given for the smoke and gases produced by each shot to be carried away, before a succeeding shot is fired; otherwise, a local explosion of these gases and dust may result.

**Question:** In timbering pitch seams, would you underset your props or place them at right angles with the top and bottom? Explain fully with sketch.

**Answer:** In setting post timbers in a pitching seam, the posts should be inclined slightly up the pitch from a normal line. By so doing any slip or movement of the roof down the pitch will tend to tighten the posts. On the left of the accompanying figure, is shown a post set normal in the seam, or in line with ac drawn perpendicular to the strata. Again on the right of the figure is shown a post set inclined up the pitch from the normal line ac, or bd. It is quite evident that any slip or movement of the roof down the pitch will loosen the post on the left, while the same movement would tighten the post on the right of the figure.

**Question:** How and in what parts of a mine is coal dust produced?

**Answer:** In a machine mine, the greatest portion of the dust is produced in cutting the coal. The same is true, but to a less extent, in pick mines. Much dust is produced, in all mines, by coal falling off the cars in transit and being crushed to fine coal and dust by travel on the roads. In mines where blasting is performed by black powder, much dust is produced by the miners using excessive charges of powder. Overcharging the holes is not as common in the use of permissible powder. Generally speaking, the largest quantity of dust is produced at the working face.
Sentiment for Control of Coal Prices Bolstered by Unsettled Conditions on Railroads

BY PAUL WOOTON
Washington Correspondent of Coal Age

WASHINGTON, Aug. 29—The hope that Mr. Ford will not find it necessary to close his plants on account of coal prices was expressed today by Secretary Hoover. He called attention to the fact that Mr. Ford has signified his willingness to pay $4.50 for coal. Mr. Hoover expressed the opinion that the price would not be greatly in excess of that prevailing in the coal centers of the State. The government is said to be in favor of keeping the situation as it is.

That the administration has at no time favored putting the government in the coal business was indicated when Secretary Hoover declared emphatically today that the Cabinet never has seriously discussed the seizure of either anthracite or bituminous mines. Mr. Hoover stated that no less than 25,000 cars loaded with non-union coal are awaiting movement. None of the coal mined under the drastic priority requiring one-half of all non-union coal sent to the Lakes has reached the lower Lake ports as yet, he declared.

Principal emphasis is being placed by those opposed to legislation looking to the control of coal prices and distribution on the argument that such control no longer is needed. Many lawmakers are of the opinion that the situation is such that it can take care of itself. Those who favor the legislation might be willing to accept the argument that they will require that railroads 'move' coal at a high rate of efficiency. With the uncertainty as to railroad operation, however, they contend that this control must be established.

They point out that the emergency will not have passed until coal starts moving to the Northwest at the rate of one million tons a week; until prices show a definite downward tendency; and until the anthracite mines are in operation and careful attention has been given the problem of substitution for that portion of the anthracite production which cannot be made up.

Theoretically at least all stocks of coal now have been wiped out. Whatever stocks there may be in fact are known to be negligible and too low to enter the winter with safety. The market cannot be expected to tranquilize until a considerable amount of coal is to be put in storage. How soon such a point can be reached depends entirely on the service which the railroads can give. The American Railroad Association makes the ambitious estimate that the carriers can transport 9,000,000 tons weekly. At the National Coal Association it is thought that 8,000,000 tons is the maximum. Disinterested traffic men, however, point out that if coal shipments reach 5,000,000 tons of bituminous, in addition to the anthracite that is expected to be moving, and at the same time the usual volume of other freight is handled, the railroads will have performed an extraordinary feat even if there were no strike and if the equipment all was in good condition.

There is an increasing feeling among officials in Washington, however, that the railroad management are not being entirely frank with their employers. They seem to think that the situation with regard to railroad equipment is much worse than the railroads are willing to confess, to say nothing of the question of their ability to attain a high degree of efficiency with the morale of its employees in its present state. The attitude of the railroads is negative in contrast to that of the coal operators when they declared the strike would be terminated by July 1.

Within a week after the Cleveland conference 250,000 tons of production had signed on the dotted line. In no case has anyone of the district settlements departed from the Cleveland contract, unless the action of one district in central Pennsylvania in refusing attendance at the Oct. 3 conference be termed a reservation. Western Pennsylvania, part of northern West Virginia and the Chesapeake & Ohio tonnage in Kanawha are still holding out as this is written, but it is believed here that their effort to get the men back at the 1920 rate, but without signing the contract, will be futile. It seems quite certain that no contract will be signed in western Pennsylvania that does not include the check-off. The operators, officials here believe, have saved nothing out of the wreck, except that they have not gone through with the old-time Central Competitive Field agreement.

In the meantime the United Mine Workers have threatened to call a strike in the New River district with the idea of forcing a contract there. This action is regarded as significant as foreshadowing a series of strikes in the districts formerly organized but lost to the union in 1921. Even in the Central Competitive Field probabilities point to sporadic local troubles, for in many places the men are reported to be returning to work in an arbitrary and arrogant frame of mind.

Fair Price for Pennsylvania Bituminous Fixed; Name Regional Fuel Committees

The Pennsylvania Fuel Commission has established a fair price for bituminous coal but has not as yet attempted to fix a fair price for anthracite. At its meeting on Aug. 22 it fixed bituminous prices according to the type of veins in the coal region, $4.50 a ton, $250 per thousand tons. The price of coal in District No. 1, including the thin-vein mines, and $3.75 a ton, f.o.b., for coal at the mines in District No. 2, containing the thick-vein mines. The districts are those designated in 1918 by the Federal Fuel Administration. A commission not exceeding 25c. a ton was also fixed by the commission.

The commission of itself, has not the power to enforce the rules, but through co-operation with the Interstate Commerce Commission and the Public Service Commission of Pennsylvania holds it can make them effective. Commissioner Clyde Aitchison of the Interstate Commerce Commission will soon confer with the Public Service Commission relative to naming a joint representative of the two commissions as a member of each of the six regional fuel committees represented by the State Fuel Commission. These representatives will be the agents of the Fuel Commission throughout the bituminous districts.

It was originally intended by the State Fuel Commission to name seven regional fuel committees, but the number was reduced to six when the personnel was announced. These committees, to which will be added the joint representative of the Interstate Commerce Commission and the State Public Service Commission, are:

- Western Pennsylvania—Thomas Fisher, Philadelphia; T. W. Guthrie, Pittsburgh, and Thomas Lewis, Johnstown.
- Northwest Pennsylvania—Edward Speidel and Fred Stover (besides S. B. Siller, Samuel Sillars, R. M. Dickson, P. F. Riehle, T. F. Diefenderfer, F. R. Callan, and J. C. Forsyth, Clearfield.
Anthracite Deadlock Blocks Peace in Coal Fields

Although the government has continued to exert pressure to bring the two sides to an agreement, the anthracite operators and miners refuse to recede from their respective positions. Secretary of Labor Davis held a two-hour conference in Philadelphia on Aug. 20 with John L. Lewis and then returned to Washington, where it is understood that he will make a report to President Harding concerning the situation. Anthracite remains the stumbling block to more or less complete peace in the coal fields. Every effort so far has been made to break the deadlock in the negotiations between the operators and miners. The union on the one hand is holding out for a contract at wages and with working conditions that extend until April 1, 1924. The men ask a continuation of the high wages for two winters, as compared with their victory in the soft-coal fields that gave it to them for one—that is, until next April.

The operators have agreed to extend the expired contract until April 1 next, but refuse to commit themselves to paying the maximum wage beyond that date. They say they are willing to make a contract for any number of years covering working conditions, but ask that the wages after April 1 next be subject to arbitration, either by a board appointed by the President or some other outside party and the award to be either binding or to be merely recommendatory.

The miners refuse to agree to the interjection of any outside party or influence in the determination of their wages, either now or at any future date. It is not the wages that are to be paid this winter that is holding up the resumption of hard-coal mining but the matter of how the next scale is to be determined and when.

Many and powerful influences on the outside are being brought to bear on both parties to reach a settlement. The President has used his persuasive powers and Senators and others have been in conference with John Lewis to no avail. The pressure from public interests over the hard-coal-burning East is daily growing stronger. Congress is being flooded with protests and is being urged to do something. With the soft-coal strike largely out of the public mind, attention is rapidly being focused on the deadlock in anthracite.

Samuel D. Warren, spokesman for the anthracite operators, made the following statement Aug. 23, reviewing the steps that have been taken in conferences between the operators and representatives of the anthracite miners:

"Our conferences with the representatives of the anthracite miners, which began on Aug. 17, were brought about in response to the request of the President of the United States, communicated to us by Senator Pepper. The hope was expressed by the President that there might now be found some 'fair basis' on which the suspension of operations in the anthracite fields might be terminated.

"In the proposals we have made to the miners' representatives in the course of the conference we have had in mind not merely the bringing about of a resumption of production, although we think that is most important. We have endeavored to accomplish this, and at the same time to establish a basis looking toward permanent peace and continuous working in the future.

"It was our belief that this could be best secured by a long-term contract with a provision for periodic revision of wages by arbitration, which should be binding upon both parties. We were entirely willing to accept as a board of arbitration a commission or tribunal to be appointed by the President.

"The covering being refused by the miners, we proposed to utilize the existing organization of the Conciliation Board, which in the anthracite field has been adjusting disputes between operators and miners satisfactorily for the past twenty years. In case the Conciliation Board, which is composed of equal numbers of operators and miners, should not be able to agree, we proposed that the presiding Judge of the United States District Court of Appeals for the Third Judicial District should appoint three umpires whose decision should be final and binding upon both parties.

"Unfortunately and, in our opinion, unwisely, the representatives of the miners rejected this proposal.

"In a further effort to meet their opposition to binding arbitration, however impartial, we made the following proposal:

"(a) On Jan. 3, 1923, the Anthracite Board of Conciliation shall meet in conference and determine wages and working conditions in the anthracite field effective for a period of one year beginning April 1, 1923. On Jan. 3, 1924, the board shall meet in like manner to determine wages and working conditions for a period of two years beginning April 1, 1924.

"(b) In case there has been no agreement prior to Feb. 15 in the years 1923 and 1924, the Presiding Judge of the United States Circuit Court of Appeals for the Third Judicial District shall appoint three disinterested citizens of outstanding character and ability, who shall sit with the board to hear the argument and make findings with respect to the matters in dispute. These findings shall be rendered on or before March 15, shall be recommendatory in character, and shall be subject to acceptance or rejection by either party within ten days thereafter.

"This proposal, representing the extreme of concession by the operators, was met by the miners' spokesmen on Aug. 22. We have offered to consider any practical modification of these plans which would not sacrifice the ends sought. The miners' spokesmen declined to make any such suggestions. They can speak for themselves as to their attitude. To us their plan seems to be indefinitely to retain war-time wages regardless of any other considerations.

"It will be noted that the proposal embodies the use of the Conciliation Board instituted in the anthracite field by the Roosevelt Commission in 1903. The board's personnel includes the three district presidents of the miners' organization in the anthracite field in conjunction with three operators. Matters in dispute which the board finds itself unable to adjust are referred to an umpire appointed by the Presiding Judge of the Circuit Court.

"Our suggestion only embodied by way of change, therefore, the appointment of three umpires instead of one, in order that a matter so important as a general contract might receive that impartial consideration necessary to a proper acceptance on the part of those interested, including the spokesmen of anthracite operators.

"While we realize that the proposal now made may be considered defective in that the findings of the umpires are not binding, it is nevertheless hoped and believed that the findings arrived at under such circumstances would afford the basis for a peaceful and orderly settlement and tend to avoid suspensions of mining hereafter.

"The necessity for some method by which recurring periods of idleness in our industry may be avoided, in so far as possible, is conceded by all. The mutual responsibilities of the operators and the miners demanded the most serious consideration and prompt acceptance of this proposal. These responsibilities require that the production of anthracite shall be resumed at the earliest possible date, and that we shall at the same time remove the menace of another suspension next year.

"We are hopeful, in spite of the rejection of our last proposal, that wiser second thought will bring about its acceptance. Continued opposition on the part of the miners to any plan which seeks to avoid another suspension carries with it a heavy responsibility. It means that the officials of the United Mine Workers must assume responsibility for the suffering on the part of the public and the miners themselves that may result from further delay in resumption of production. It means that rather than agree even to an advisory finding as to future wages the miners' representatives are willing to deprive the people of a large section of the United States of essential fuel. We cannot believe that this stand will be maintained. If it is, there can be no question as to where the responsibility lies for the consequences that may follow."
Central Pennsylvania Signs Agreement and Goes to Work; May Be Only a Truce

Central Pennsylvania—that is, the strictly union part of that field—has reached an agreement with the United Mine Workers and gone to work. It took three days of fighting, arguing, and the usual scale-meeting stuff to put it over, but in the larger coal fields and among both sides and the miners were ordered back to work. Prior to this there were several large companies, including the Pennsylvania Coal & Coke Corporation and the Clearfield Bituminous Coal Corporation, that had signed with the union at Cleveland as individuals and have been at work for more than a week.

The operators in the field are going. There are those operators who have both non-union and union mines. Several large companies are in this class, part of them with both kinds in Pennsylvania and some with union mines in other states or fields and non-union mines in this field. The union has adopted a policy of offering such operators the same contract for all their mines, thus forcing them to unionize their open-shop mines or leave the union mines idle.

The agreement is between representatives of the United Mine Workers of District No. 2, the Association of Bituminous Coal Operators of Central Pennsylvania and the Central Coal Association. In accordance with a plan adopted early in the week, a sub-scale committee was appointed to take up all questions, on the part of the operators, that committee was composed of Charles O'Neill, J. Webb Shillingford, J. R. Caseley, C. B. Maxwell, Rembrandt Peale and J. William Wetter. The personnel of the United Mine Workers was President John Brophy, Vice-President James Mark, Secretary Richard Gilbert, Harry Crago, Stanley Hudzinski, Herman Carletti and Rene Godlowski.

Agreements and counter agreements were presented. The sub-committee would meet jointly and then separately and vote down proposals. The whole question finally settled down to a reduction of the Cleveland agreement and the check-off system, which was vigorously attacked by the operators and just as vigorously upheld by the U.M.W.

The end came after a series of sessions lasting for six hours. The final agreement, accepted and signed by both sides, was presented by Charles O'Neill, secretary of the Central Coal Association. The agreement follows:

It is hereby agreed and by between the officers of District No. 2, United Mine Workers of America, the Association of Bituminous Coal Operators of Central Pennsylvania and the Central Coal Association that the working agreement terminating March 31, 1922, is hereby renewed and extended to March 31, 1923, and the agreement as amended and except that part of Rule 25 reading as follows:

"It is hereby agreed and by the officers of District No. 2, United Mine Workers of America, the Association of Bituminous Coal Operators of Central Pennsylvania and the Central Coal Association that the working agreement terminating March 31, 1922, is hereby renewed and extended to March 31, 1923, but that the provisions of the agreement as amended and except that part of Rule 25 reading as follows:"

The scale agreement not having been signed or renewed before March 31, 1922, then that in that event the U.M.W. of A. of District No. 2 will continue all men in mines regularly at work under the wages and conditions of this agreement for the additional thirty days after the date on which the scale committees of the operators and miners hold their first meeting for the purpose of negotiating a scale to succeed this present scale. On reaching an agreement to succeed this present contract the wages paid by the operators to the miners dating from April 1, 1922.

The strike in District 18, which is composed of eastern British Columbia and Alberta, has been settled and the miners were ordered for work Monday, Aug. 28. The terms of settlement practically mean that the Cleveland agreement has been accepted and that the men go back without a reduction in wages.

Miners and operators of western Canada have signed an agreement by which the miners will return to work at 15 per cent wage reduction from 1921 rates, it was announced by the Department of Labor Aug. 25. The operators had asked for a 20 per cent reduction.

Wage Increase for Alabama Miners

Wages of coal miners in the Alabama field will be increased 20 per cent on Sept. 1, according to an announcement from Birmingham Aug. 26. About 26,000 men will get the increase.
Coal-Commission Legislation, If Passed, Likely to Be Combination of Winslow and Borah Bills

Unless displaced by emergency legislation, it is believed that a bill to create the United States Coal Commission with authority to investigate the coal industry and report conclusions and recommendations to Congress and to the President will be enacted into law before another week has passed.

The administration has not indicated a preference between the Winslow bill, passed by the House, and the Borah bill, pending in the Senate. It is said that the President would be satisfied with either. It is probable that in its final shape the law will be a combination of the two bills, put together in conference.

The principal points of difference are that the Winslow bill provides a commission of not more than nine members, while the Borah bill provides for five; the Winslow bill carries an appropriation of $300,000 and the Borah bill, $100,000; the Borah bill goes further than the Winslow bill and instructs the proposed commission to report recommendations on standardization of wages and working conditions, standardization of work to be done for a living wage, standardization of mine efficiency looking to closing of those mines having low efficiency and high productive costs and the advisability or wisdom of nationalization of the mines together with advisability of governmental control and regulation.

The Winslow bill, favorably reported to the House the day after its introduction by Representative Winslow of Massachusetts, chairman of the Committee on Interstate and Foreign Commerce, which considered the measure, was launched with a stormy future due to the rules committee getting out of hand, but through quick work of administration and Representative Mondell, the Borah committee and the committee on rules the bill was passed the same day by the House. The vote was 219 to 55, with four Republicans opposing it and 24 Democrats voting for it.

The bill was amended before passage on motion of Representative Bankhead, Democrat, of Alabama, to reduce the salaries of the commissioners from $10,000 to $7,500 annually and on motion of Representative Moore, Democrat, of Virginia, to reduce the appropriation for the commission from $500,000 to $300,000. Otherwise efforts to amend were rejected, excepting a perfecting amendment to make the intent clear.

In order to report a special rule setting the bill for consideration, the rules committee was called Wednesday morning. This committee, instead of voting a special rule for the Winslow bill, voted 5 to 3 to report a special rule setting the bill in the committee as a special order of business. The Byrd bill was reported favorably by the labor committee some weeks ago, after extensive hearings. The administration objected to some of its features. Floor Leader Mondell, of the Republicans, had announced that the Winslow bill would be called for special order before he was informed by Minority Leader Garrett of the action of the rules committee. Representative Bland, who had the amendment of the majority leader make the point of no quorum and while the roll of the House was being called another meeting of the rules committee was summoned and a larger attendance was drummed up. At this meeting the earlier action was rescinded and a special rule was ordered out, setting the Winslow bill for consideration. Meanwhile, however, other administration leaders had succeeded in getting the Winslow bill reported in regular order, so it was under consideration when the special rule was brought out.

Representative Bland, Republican, of Indiana, made three separate attempts to substitute his bill for the Winslow bill, without success. He objected to the new bill mainly, he declared, because it had no "teeth" while the labor committee had given careful consideration for weeks to his measure. In the final vote Representative Bland voted for the Winslow bill.

Representative Denison, Republican, of Illinois, declared that the Winslow bill was not wholly satisfactory and made efforts to reduce the number of commissioners from nine to five, but without success.

On the floor before the stamp of approval of President Harding, declared Representative Winslow, having been submitted to the President less than two hours before it was introduced. Minority Leader Garrett opposed the bill, declaring it to be "useless."

While the Winslow bill was being passed by the House the Senate Committee on Education and Labor was busily considering the Borah fact-finding bill, and reported it favorably to the Senate. With various modifying amendments. The rewritten Borah bill provided for a commission of five members, with salaries of $7,500 each; the commission to exist a year and to report first within five months. An appropriation of $100,000 was provided. The Borah bill followed the same line of instructions as to the duties of the commission as contained in the Winslow bill, but went further in instructing the commission to report recommendations relative to standardization of mines upon productive capacity; standardizing cost of living for mine workers; standardizing the amount of work a man shall do for a reasonable wage, this latter having been put into the bill by Senator duPont; standardizing a basis of arriving at overhead cost of production and distribution of coal to the consumer; advisability or wisdom of nationalizing the coal industry, and feasibility or necessity of governmental regulation and control.

When the Winslow bill came from the House to the Senate it was referred to the Committee on Education and Labor, of which Senator Borah is chairman, which promptly struck out all after the enacting clause and substituted the Borah bill, with a favorable report.

On the floor the Borah bill was amended on motion of Senator Reed, Democrat, of Missouri, to provide that not only members of Congress be excluded from membership on the commission but that all federal government officials be debarred. This would exclude any members of the Cabinet.

Lively debate on the bill took place in the Senate. No Senator declared himself directly in opposition to the fact-finding commission bill, but many argued that additional legislation, to meet the immediate needs of the situation, was necessary.

Senator Sutherland, of West Virginia, assailed that part of the Borah bill directing the proposed commission to report on the advisability of nationalization of the coal mines. Senator Edge, of New Jersey, also criticized this same provision, while Senator Stanley, of Kentucky, attacked it caustically. Senator Borah declared that information on this question should be in possession of Congress and that no one should object to having information on any subject.

Senator Reed, of Missouri; Shields, of Tennessee; and Fletcher, of Florida, declared the fact-finding commission would "get nowhere" with the problem and while they did not directly oppose passage of the bill they characterized it as useless legislation and not what should be brought forward in the emergency.

Guard Remains in Pennsylvania Fields

No change in the location of the Pennsylvania National Guard units now in the bituminous field are contemplated by Governor William C. Sprout. It is held that the resumption of work, urged as a reason by union men for the withdrawal of troops, is the best reason why the troops should be retained at their present stations.

A detail of state police was sent last week to Valley Camp Coal Co., where the captain of the Valley Camp Coal Co. started operation recently under the Cleveland agreement. In a poll of the employees, according to word received by the state police, 180 voted to accept the agreement and return to work and 160 voted against resuming work.
Illinois at One-Third Full Speed in Four Days; Surrender Not Complete, Some Feel

On Saturday, Aug. 26, four days after the signing of the Illinois mine peace—a peace based on the Lewis terms as laid down by President Lewis' commission—87,000 miners in the state had attained only about one-third their normal rate of production.

The first day or two of work in the mines was devoted to getting tools and machinery down into the ground and cleaning up and inspecting. Actual mining of coal did not get under way until Tuesday. On Saturday the best report from any mine in the state showed that on the previous day—the last full day of the week—a 60-car mine had loaded and shipped 42 cars. Other reports ranged down to two or three cars and some mines failed to make a turn-in. It was estimated by experts that the output of the state was close to 30 per cent of normal. Railroads were able to supply cars in plenty at most yards, but the inevitable shortage was said to be hampering a few mines near St. Louis.

A good deal of opinion is expressed as to the strength of the tactical position which the Illinois operators assumed when they framed up their peace with Farrington in Chicago, Aug. 22. It was authoritative stated that the omission of clauses binding Illinois to take part in the Lewis plan for making the new wages practically amounts to a blank in the Cleveland plan. It is said to put that state in a better position to assist in a possible federal investigation of the coal industry and that if enough union and non-union tonnage throughout the land is in a similar position, then an outside authority could more readily arrive at constructive conclusions that might be at variance with the autocratic ideas of John L. Lewis, president of the miners' union. It is calculated that about 320,000,000 tons of production might take the Illinois position, making the estimates thus: Illinois, 90,000,000; Pennsylvania, 50,000,000; West Virginia, 90,000,000; Kentucky, 31,000,000; Alabama, 19,000,000; Colorado, 12,000,000; Virginia, 10,000,000; Kansas, 7,500,000; Tennessee, 6,500,000; Missouri, 5,500,000; southern Ohio, 10,000,000. If this formidable total of $2,500,000,000 were to line up in full and free co-operation with such a coal commission as may be created under the Winslow bill, that commission might arrive at the facts about coal in such a way as seriously to hamper the Lewis program of wage making next winter and spring.

But there is a variety of opinion among Illinois operators as to the defensive value of their freedom from obligation to meet Lewis officers in Cleveland. Some say that they were glad to see an opportunity to make peace without having the entire Lewis program shoved down their throats and that the form of Illinois peace at least gives them a little time to spar with the union before the next clinch but that they suppose when Oct. 2 comes around they will see that nothing better remains for them to do than attend the Lewis meeting and write to the men in the new game as a matter of plain self-defense. Even W. K. Kavanagh, president of the 5th and 9th District Operators' Association, said after the Illinois agreement had been signed that he supposed Illinois would take part in the Lewis conferences.

The form which was signed at Chicago follows:

It is hereby agreed by and between the officers of District No. 12, United Mine Workers of America, and John Lewis, president, and the operators of the mines of Illinois, that the working agreement which terminated March 31, 1922, is hereby renewed and extended to March 31, 1923, in all of its provisions as to wages and working conditions, excepting that the 32d clause is to be stricken therefrom in accordance with the policy adopted by the policy committee of the United Mine Workers of America, Aug. 15, 1922.

The 32d section, referred to, is as follows: "The joint executive boards are authorized and instructed to arrange for negotiations for the formation of a new contract to begin at a date not later than the expiration of this contract."

Indian Signs Cleveland Fact, but Refuses To "Approve" It in Peace Document

Most of the 30,000 striking union coal miners in Indiana are back at work again under the old terms and conditions, just as the men of Illinois are. The Indiana operators signed with their miners in Terre Haute on the basis laid down at Cleveland by President Lewis of the international union but they did refuse one demand of their men. The peace document as first spread on the table by John Hessler, president of District 11, called for the operators not only to "accept" the plans of the Lewis and Cleveland plan. The operators shied away from the dotted line until the offensive word "approve" had been scratched.

In its final form, the Indiana peace was made thus:

"That the terms, provisions and conditions of the Terre Haute agreement, which was in effect in District No. 11, United Mine Workers of America, on March, 1922, be hereby extended to April 1, 1923, and that the miners of the supplementary agreement shall be opened immediately upon the execution of this supplementary agreement. The signers of this supplementary agreement and those whom they represent accept the policy adopted by the joint conference of miners and operators held in Cleveland, Ohio, Aug. 15, 1922."

This agreement was signed by the Indiana Bituminous Coal Operators' Association and the Indiana Coal Producers' Association, which is the strip-mine operators' group.

Probe of Herrin Massacre Under Way

A grand jury in "bloody" Williamson County, Illinois, convened Aug. 28 to begin action against those responsible for the Herrin massacre, June 22, in which nineteen non-union men were killed and thirty wounded after they had surrendered to an attacking mob at a strip mine. It is a special sitting called by Judge Dewitt T. Hartwell, of the Williamson County Circuit Court, at the instance of Attorney General Edward Brundage. The session is in Marion, 10 miles from the scene of the butchery.

The court made it plain that there are two sets of killings to be investigated. The first is the shooting of three union miners by the strike guards at the Southern Illinois Coal Co. plant on June 21. The Cononer's jury put the blame for this on the coal company officials.
