*Total passing the "Soo" (west bound) and therefore covers the Duluth district and shipments to Canadian ports.

1 Figures marked * not included in totals.
2 Including car ferries.
3 Including ore ferries.
4 Incomplete, port at City of Detroit not reported since 1920.
5 About 11 per cent of annual requirements for the Northwestern district.
Price-Control Bills Favorably Reported in Both Houses; Hoover Urges Enactment of Winslow Measure

Regulation of the sale price of coal through denial of car supply to those who charge unreasonable profits and control of distribution of fuel are provided in similar bills introduced in Congress last week by Senator Cummins and Representative Winslow, chairmen of the interstate commerce committees of the two houses. It is said that the bills in general have the approval of the administration and that they were drafted with the co-operation of the Department of Justice and the Department of Commerce.

During consideration of the Cummins bill by the Senate Interstate Commerce Committee the question was raised as to whether the bill would be effective in controlling the retail price, and suggestions were made for an additional section to cover this point more specifically. Demand also was made that before legislation of such drastic nature be enacted, or recommended, parties at interest be called to give their views.

Both bills would amend the Transportation Act to enlarge the powers of the Interstate Commerce Commission to include authority to issue orders for priority or embrargoes for or against any carrier or regroup or corporation or person, to assure equitable distribution of fuel and to prevent the purchase or sale of coal by any person, corporation, partnership or association at "prices unjustly or unreasonably high." There is to be created a Federal department of Fuel Distribution, with a Federal Fuel Distributor to be appointed by the President, who may appoint assistants and who shall determine whether and where shortages of fuel exist, fields of production and markets, nature and location of consumers, prices normally charged and whether current prices, with fair profits, are just and reasonable, and make recommendations to the Interstate Commerce Commission.

Under the Cummins bill the act would expire whenever the President declares by proclamation that the emergency has ceased. Under the Winslow bill, the act would become suspended by Presidential proclamation at the end of the present emergency but remain on the statute books so that it could be invoked again should a similar emergency arise in the future.

Both bills carry an appropriation of $250,000. The Winslow bill would make not to exceed $50,000 of this sum available for payment of expenses incurred by governmental agencies and federal or state agencies in connection with the act.

Without a record vote, the Senate Interstate Commerce Committee Monday ordered a favorable report on the Cummins bill, after it had been decided definitely not to hold public hearings on the measure. The bill was amended to provide that it shall expire at the end of a year and to make specific the fact that its provisions apply only to interstate commerce.

A favorable report on the Winslow bill was ordered by the House Interstate Commerce Committee Monday evening, with slight amendments in phraseology, and after four witnesses had been heard by the committee Republican Leader Mondell announced that he expected the bill to pass with two days' debate.

Appearing before the House committee, Secretary of Commerce Hoover urged enactment of the bill into law. He declared that the powers of the federal authorities are not sufficient to meet the situation despite the improvement by reopening of many bituminous mines. He declared that from 90 days to six months would be required to relieve the existing "coal famine." While the majority of the operators have held prices within reason by voluntary agreement, the Commerce Secretary declared that some operators are defying the government and force fair prices upon those who would profit from the situation.

J. D. A. Morrow, vice-president of the National Coal Association, informed the committee that he believed most of the operators would oppose the bill. He did not believe it would accomplish any good purpose, he said, but would hamper operations by governmental interference with legitimate channels of trade.

C. B. Aitchison, member of the Interstate Commerce Commission, urged adoption of the bill as he said the commission needs added authority to accomplish what is now expected of it.

Edgar Wallace, a representative of the American Federation of Labor, told the committee that generally the bill was satisfactory to labor, but that price-fixing in principle is regarded as dangerous.

A bill giving the President authority to take over and operate mines during any emergency was introduced in the Senate on Aug. 25 by Senator Edge, of New Jersey. Meanwhile, other bills, according to the ideas of individual members, are making their appearance. Representative Dickinson, of Iowa, has introduced a bill to create a coal commission of four members to fix wages and working conditions in the industry in the event of a disagreement and with broad powers to regulate prices on the basis of cost of production plus not more than 10 per cent profit. This bill was referred to the Senate Commerce Committee of the House, where it is expected to die.

Representative Brennan, of Michigan, has introduced a joint recommendation authorizing the Interstate Commerce Commission, Department of Commerce and other agencies to take steps to conserve coal by denying fuel to non-essential industries, by closing electric signs, and other means.

Ends Federal Control by Federal Agencies

"Because of the general resumption of bituminous mining, no more coal will be directed by the Federal Fuel Distributor to the different states—except the Upper Lakes—under emergency orders under class No. 1, and no more shippers holding priority No. 1 orders placed through the Federal fuel distribution agencies are expected to complete shipments on such orders unless by mutual agreement between shippers and the consignee. The issuance of emergency priority orders of class No. 1 for railroads will continue until such time as the Interstate Commerce Commission shall have provided other plans for caring for the railroad requirements. A new plan is being worked out under the Interstate Commerce Commission to secure an assurance of reasonable lake movement up to the capacity of lake transport. The agreement as to price restraint with the non-union operators expires today with the resumption of the union bituminous mines. The various states and the Federal Fuel Distributor now have the authority to fix prices of coal for their jurisdiction. Whether the same result is achieved is earnestly hoped by the operators and dealers will conform.

"The legislation before Congress can only control the price of coal moving over state lines—that is, in interstate commerce. The price of coal produced and consumed in a state, together with the charges which wholesalers and retailers within the state may make, the latter including even interstate coal, should be controlled by the state authorities. Therefore, there can be no real control of profiteering unless the state authorities act."
Drastic Fuel Bill Presented in New York Legislature and Quickly Passed

Under the urgent insistence of Governor Miller that there exist an emergency directly affecting the public health and welfare requiring governmental regulation and control of the supply of fuel during such emergency and its equitable distribution to consumers at reasonable prices, the New York State Legislature on Aug. 28 introduced a measure intended to solve the fuel problem in New York State. The measure, known as the Hewitt-Jesse bill, was passed without change on Aug. 29.

The measure creates the office of state fuel administrator "to continue until by proclamation of the Governor the emergency requiring its creation is declared no longer to exist." It provides for general supervision over the receipt, transportation, distribution and allotment of fuel to various sections of the state; price fixing of fuel by the administrator; seizure and sale of surplus stock of fuel held contracted for or arranged for in excess of the average requirements of any individual, manufacturer, wholesaler or dealer, with a provision for the immediate payment therefore after its sale to the person from whom such coal is taken; the creation of a revolving fund for the purchase and sale of fuel by the state administration, if "the Governor by a certificate filed in the office of the Secretary of State shall declare that the emergency be so acute that the exercise of such powers is required."

For the purpose of creating the revolving fund and paying the expenses of the administrator the sum of ten million dollars is appropriated.

Other features of the bill include the right of municipalities to curtail the use of gas and electric signs, the right of the administrator to prevent the waste of fuel, the right of the administrator to adopt rules and issue orders with the same force and effect as law, the temporary suspension of that provision of law which calls for the purchase by municipalities of fuel after advertising for bids, etc.

A measure was also introduced authorizing the city of New York to increase from two to five million dollars the amount of money the city may borrow in one year on certificates of indebtedness and allowing such city to engage in the business of buying and selling fuel.

Southwest Also Settles on Cleveland Basis

The mines of the Oklahoma and Arkansas fields are resuming work following a settlement reached at Kansas City, Aug. 16, based on the Cleveland agreements. The wage scale and working conditions of 1920-22 are extended to April, 1923. The operators insisted upon writing into the agreement a clause aimed to guarantee that all miners who have been working in certain of the mines shall not be discriminated against. It will be several days before production reaches full speed in the field.

F. S. Peabody, Chicago Operator, Dead

Francis S. Peabody, chairman of the board of the Peabody Coal Co., and long rated as one of the ablest men and most striking figures in the American coal industry, died suddenly of heart disease Sunday, Aug. 27, while on a fox hunt on his estate at Hinsdale, Ill. He was 63 years old.

Mr. Peabody, who was born in Chicago, educated at Phillips Academy and Yale ('81), first was a bank messenger boy in Chicago and then, in 1883, a partner in the small retail coal firm of Peabody, Daniels & Co. This concern later became the Peabody Coal Co., which developed swiftly into the largest retail coal business in Chicago, out of which the present Consumers' company evolved. Branching out into coal mining, the company spread its network of mines until today it owns or operates for others a string of forty-six soft-coal mines from the Sheridan field of Wyoming to the newly controlled Erie mines of Pennsylvania. The stronghold of the company is in the central and southern fields of Illinois. The remarkable success of the Peabody Coal Co. and its subsidiaries is directly to be credited to the genius and resourcefulness of Mr. Peabody and of the group of men with which he surrounded himself. His only son, Stuyvesant, is president of the company.

Mr. Peabody was long active in Democratic Party politics nationally, once having been boomed for U. S. Senator from Illinois, and was chosen by President Wilson to direct the financial end of the party's 1916 campaign in the Western states. In 1917 he served in Washington as chairman of the Coal Production Committee of the Council of National Defense. He was decorated by the King of Italy for his war work, which included strong support of the Salvation Army. Of recent years Mr. Peabody had been withdrawing by degrees from the more vigorous business activities and had been spending all the time he could on his model farm enjoying his hobbies, which were dogs, horses and the collection of original Robert Louis Stevenson manuscripts. The funeral was arranged for Tuesday, Aug. 29, with burial in Hinsdale.

U. S. Steel Corporation Advances Wages 20 Per Cent Beginning Sept. 1

An advance of 20 per cent in wages, to become effective Sept. 1, was announced Aug. 22 by the United States Steel Corporation. This is the announcement:

"The wage rates of day labor at the manufacturing plants of the Steel Corporation have been increased about 20 per cent, to become effective September 1. Other rates will be equitably adjusted."

Other wage announcements by the Steel Corporation have been as follows, according to the Iron Age:

<table>
<thead>
<tr>
<th>Date</th>
<th>Wage Rate Increase</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aug. 29, 1921</td>
<td>Decrease to 30c. per hr.</td>
</tr>
</tbody>
</table>

The following table shows the wages of common labor after each advance or decrease in wages by the United States Steel Corporation:

<table>
<thead>
<tr>
<th>Date</th>
<th>Wage Rate Increase</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aug. 1916</td>
<td>8-hr. day abolished</td>
</tr>
<tr>
<td>Aug. 29, 1921</td>
<td>8-hr. day abolished</td>
</tr>
</tbody>
</table>

Independents generally have announced that they will meet the advance made by the Steel Corporation.
As production increases with mines opening under the Cleveland wage agreement more coal is beginning to flow in its accustomed grooves. Much of the output is still going on priority orders but the heavier production has permitted contract shippers to again supply some of their regular trade.

Spot offerings also have increased, but the rank file of consumers are less anxious to buy. Railroads, utilities, steel plants, etc., are the heavier takers of spot tonnage but the high-priced demand has fallen off rapidly with the partial resumption of union mining.

Recession in Demand Only Temporary

Prices of spot coal reflect the weakened demand. Coal Age Index of spot bituminous prices dropped 93 points to 437 from 530 a week ago. The softening was most apparent in central Pennsylvania and in western Kentucky, while Pocahontas stood firm. The market range is gradually narrowing down to the Hoover basis, although a full dollar over the fair price is still a representative spot figure. The smaller consumer is badly in need of coal, but as he sees the market softening, is delaying entering his order from day to day. He has skated on thin ice for several weeks and is willing to take a chance for a while longer. As soon as improvement in production appears permanent he is bound to replenish his reserves and this buying rush will more than keep prices from dropping below fair-price levels.

Meantime no-bills are appearing in Illinois and Indiana, where union mines have resumed, and it is evident that a four-day week is the best that can be expected, even were transportation facilities more adequate. The St. Louis fuel committee has ceased to function and the situation has lost its serious aspect. Throughout the Middle West the general steam demand is light, domestic call is leading, and Kentucky coals, caught en route by the heavier union mining, have sold off. There is much Kentucky and Alabama tonnage rolling and this must be absorbed before a healthy demand can develop for Illinois or Indiana coals. Ohio No. 8 mines are rapidly getting into operation but are hampered by the lagging demand and a car shortage on the B. & O. and W. & L. E. roads.

North Atlantic markets are easy. Heavier receipts via water and rail have taken the top off the market. British coals are flowing in, but are going at lower figures to meet domestic competition. There is little likelihood of a runaway market in New England. Re-
COAL

Vol. 22, No. 9

and already the shortage fears of Northwestern consumers have been somewhat allayed.

All hope of any August resumption of hard-coal mining was blotted out last week when the Philadelphia conference deadlocked. There is no surface indication of any early settlement and consumers are eagerly taking pea coal, the only size available, or are turning to substitutes such as coke.

BITUMINOUS

Additional production of mines opening up under the Cleveland agreement has caused a sharp upturn to the daily output as shown on the chart on the preceding page. According to the Geological Survey, an output of at least 6,000,000 tons for last week (Aug. 21-26) is assured by early reports, and additional tonnage from other mines that are known to have signed the agreement may raise the total to 0,250,000 tons.

On Monday mines in eastern Ohio and parts of central Pennsylvania were shipping coal, and the loadings for that day were 19,043 cars, an increase of 3,340 cars over the preceding Monday. Loadings on Tuesday declined somewhat but on Wednesday and Thursday increased again, and were somewhat on the corresponding days in any week during the strike. These increases were due to first shipments from Illinois and other Western districts, which carried the total up to 18,748 cars on Thursday.

</tbody>
</table>

The increase came almost exclusively from mines formerly closed by the strike. In the middle and southern Appalachians transportation difficulties still limited output and shipments were but little larger than the week before.

It is not possible to estimate shipments from producing districts for the week ended Aug. 26, as published in preceding issues of the age. No measure of the coal output which has been produced from mines beginning production after Wednesday. The average shipments during the first half of last week exceeded the average for the preceding week by 33 per cent and that for June 19-24 by about 15 per cent.

The increase in production is chiefly in central Pennsylvania, western Pennsylvania, the Fairmount and Panhandle districts of West Virginia, and Ohio, in which districts, collectively, the daily rate of production exceeds by 156,000 tons, or 150 per cent, that of the week before. The increase in central Pennsylvania is about 90 per cent, in western Pennsylvania, 50 per cent; in northern West Virginia, about 170 per cent and in Ohio, 15 per cent.

The middle and southern Appalachian districts show slight change. The region as a whole is producing a little more than last week but has not again reached the level of production attained before the shopmen’s strike. The eastern Kentucky districts are still greatly handicapped by traffic congestion. While production there increased about 32 per cent it is still less than half of the quantity mined weekly during June.

Even with an output of 6,250,000 tons of bituminous coal a week, present production is still below normal. In the preceding week of 1921 the country raised 9,640,000 tons of coal, of which 1,890,000 tons was anthracite and 7,750,000 tons bituminous coal. The year before that the total raised was 13,250,000 tons. In comparison with these figures the present weekly output of all coal, anthracite and bituminous, is from four to six million short of normal.

Tidewater dumpings at Hampton Roads increased to 350,537 net tons during the week ended Aug. 24 from 307,182 tons in the preceding week. The tonnage at the

pier is heavier and railroads are functioning better. Coastwise prices are somewhat softer, as receipts from other sources are more adequate at Northern points.

Michigan non-essential industries have been unable to obtain priorities for an adequate fuel supply. It is understood that Detroit consumers may form a pool and send buyers into the field in an endeavor to augment their receipts.

</table>

Lake dumpings reflect the governmental activities in behalf of the Northwest. During the week ended Aug. 28 the lower ports handled 258,024 net tons—223,361 tons cargo and 29,663 tons vessel fuel—as compared with 176,640 tons in the previous week. The season's dumpings to date are 5,208,479 tons; in 1921 they were approximated 16,000,000 tons. The Northwestern docks are bare of coal and are eagerly awaiting the arrival of these cargoes. From Aug. 1 to 15 the reserve of bituminous coal dropped from 661,000 to 305,000 tons, and of anthracite, from 170,000 to 92,000 tons. A year ago, when stocks were above the average, the dock operators had on hand between 5,000,000 and 6,000,000 tons of bituminous coal and about 600,000 tons of anthracite.

ANTHRACITE

Production remains at a standstill. The Philadelphia conference of miners and operators, while deadlocked, is still the center of interest and hope persists that an early settlement may be effected, although there are no indications of it at this writing. River coals continued to be dredged at the rate of 30,000 net tons during the week ended Aug. 19.

Pee coal is about all that is moving, either from mine storage or retail yards. Consumers are eagerly accepting this, as they realize the seriousness of the situation. About two weeks more will see the exhaustion of the companies' reserves of this size. North Atlantic centers are urging the use of coke or bituminous coal as substitute for anthracite. New York City has taken steps to abolish temporarily the smoke ordinance prohibiting the use of bituminous coal.

COKE

Beehive coke production increases slowly. The output for the week ended Aug. 19 was 115,000 net tons, as compared with 112,000 tons in the week preceding. Demand wanes however, as coke buyers adopt the same waiting tactics as those in the coal market. Prices are softer but are by no means too high to worry the operators of blast furnaces.

In the Connellsville region the H. C. Frick Coke Co., subsidiary of the U. S. Steel Corporation, has posted notices of an increase in the scale, offering a return to 1920 wages—the highest on record. The notice provides for an open-shop basis of work and while organizers are attempting to hold the union ranks firm it is now expected that the strikes will wane rapidly.

Kentucky Governor Drafts County Judges to Help Enforce Fair-Price Regulations

In anticipation of an early termination of the railroad strike, Governor Edwin P. Morrow of Kentucky has perfected an organization to prevent profiteering in coal in that state. The Governor has appointed every County Judge in the state a member of his Fuel Distributing Committee and sent letters requesting each one to inform him promptly of any individual paying more than $4.50 a ton in carload lots and of any local dealer charging more than a fair price. He also will write to chambers of commerce and boards of trade requesting them to advise him of any manufacturing plant or public utility which is charged more than $4.50 a ton at the mines.

"I intend," Mr. Morrow said, "to enforce the regulations by the fullest publicity and also by refusal of priority orders by withholding cars from anyone who charges more than the Hoover price and by withholding priority orders from local dealers who profiteer. The cars will go to the dealers who charge fair prices."
British Hold European Orders to Fill Strike Gap; Exports Equal Pre-War Record

British exports are still equaling pre-war records. The pressure at the ports is acute as emergency tonnage increases. The North American orders are strong but tonnage is being diverted to fill the gap made by the strike in the United States. The exception of Best Admiration large, however, export prices are showing softening tendencies. Production during the week ended Aug. 12 was 3,023,000 gross tons, according to a cable. This shows a marked curtailment being due to holiday interruptions.

So far no agreement has been reached on the question of trimmers working three shifts instead of two so as to relieve congestion at the British coal shipping ports. The operators and shippers have asked the unions to work three shifts so as to be able to employ more trimmers and also to permit of greater coal output, thus giving more employment to more men.

Welsh coal fields are now operating at top pressure. Orders from the United States and Canada continue to arrive. A recent report states that Wales, at any rate, will continue at top speed well into October even if no further orders are forthcoming.

As a result of the American demand steam coal prices are strong but the best Admiration coal is not above 30s. with other varieties in proportion. As a rule the colliery operators in Wales are taking the long view of the present revival, in that they are endeavoring to prevent undue inflation of prices.

Practically the same position is found in northern England. American and Canadian inquiries continue to arrive and the pits are operating at top pressure. At present, however, the north of England pits are finding difficulties in getting their coal shipped owing to the congestion at Newcastle.

French Mine Costs Still Too High

The French market is moderately active, but, with the huge mine stocks still existing and an increasing output from the gradually restored devastated mines, no true improvement of the situation is to be hoped for before a reduction in costs permits French collieries of the Nord and Pas-de-Calais to meet British competition. The difficulty of this task will be fully grasped if it is considered that, while their wages are three times higher than before the war, French workers are now individually mining 20 per cent less coal.

The miners are now said to be in a rather conciliatory mood. It is therefore to be hoped that they will voluntarily agree to extend their effective underground working time from 61 hr. to 71 hr. and thus enable the collieries to effect a saving of at least 10 f, per ton of coal mined. Already now, collieries of the Nord and Pas-de-Calais are accepting forward contracts with a provision providing for an eventual revision of the selling price.

Germany, who was under an obligation of supplying to France, Luxemburg, Belgium and Italy a monthly quantity of 1,916,000 tons had asked the Commission of Reparations, under the fallacious pretext that she was importing coal from Great Britain, to reduce this quantity to 1,340,000 tons. The commission decided that from August to October Germany will have to deliver to these four countries a monthly quantity of 1,725,000 tons.

Coal Paragraphs from Foreign Lands

ITALY.—The price of Cardiff steam first is still quoted at 42s. 3d., according to a cable to Coal Age, unchanged from last week.

GERMANY.—Production in the Ruhr district for the week ended Aug. 12 was 1,778,000 metric tons, according to a cable to Coal Age. The preceding week's output was 1,731,000 tons. Miners are demanding an increase of wages amounting to 130 to 140 marks a shift.

SWITZERLAND.—British supplies of coal, which constituted 15 per cent in 1920 and 19 percent in 1921 of the total coal imports of the country, are falling off, owing to the keen competition of German, French and Belgian coal on the Swiss markets. Out of a total importation during the first quarter of 1922 of 266,000 tons with a value of 20,000,000 fr., Germany's share was 108,000 tons, France 56,000, Belgium's 55,000 and that of Great Britain only 31,000 tons.

Better Receipts at Hampton Roads

Business was more brisk at Hampton Roads last week, all piers increasing their dumpings. Supplies were slightly increased, due to a temporary increase in transportation on the Virginian and N. & W. Prices showed a downward tendency, due to reports that larger supplies were being received from overseas ports. Demand remained strong, however.

The outlook was somewhat more encouraging, although dealers did not have much relief from the stringency in the near future. Railroads were holding their own in coal movement, all reporting a slight improvement in condition of their equipment.

COAL

Consumers Seek Bargains
As Coal Prices Recede

Offerings More Plentiful — Though
Users’ Stocks Are Low, Shipping Prices Temp B隅ors to Delay Further
— Resumption of Buying Not Far Distant.

Buyers are hunting coal bargains as spot prices slip. Offerings are increasing as production has improved in the fields resuming under the Cleveland agreement. Priorities have taken a goodly tonnage but the remaining spot coal is not being snapped up as eagerly as before. Consumers’ supplies are dangerously low but buyers have gone on a hand-to-mouth basis for so long that they are inclined to take a further chance and are delaying replenishing their stocks as prices slip gradually downward.

As soon as the buyer is satisfied that the improvement in production is permanent he is bound to enter the market and this buying rush is certain to stimulate staggering prices.

NEW YORK

The market was on an up and down basis last week. Quotations as well as demand changed frequently. Selling figures are gradually getting down to normal and buyers are bargain hunters. The failure to bring about a settlement of the railroad difficulty caused some uneasiness but it was not believed there would be any serious delay in shipments. Continued idleness in the anthracite mines has already created increased demand for bituminous and with the suspension of the Board of Health law prohibiting the use of bituminous in this city still greater will be the demand.

During the last seven days there were nearly 125,000 tons of British coal reported as having arrived in this port in 22 vessels. Demand for foreign coals receded somewhat during the latter part of the week. Quotations for British Admiralty coals were around 42s.

Southern coals came forward in good volume. There was considerable free coal here at the end of the week, quotations ranging $11@$12, New York harbor.

Local users are satisfied they will be able to get coal at much lower than current prices. There were 558 cars at the local piers on Aug. 25 an increase of 158 cars over Aug. 21. Most of this consisted of Pool 11 quality.

Quotations for mine shipments were lower than on the Tidewater basis. Industries included in Class 2 of the priority orders were given quotations from $5 up on Morgantown district B. & O., coal, B. R. & P. coals were quoted around $5.50, West Virginian and Latrobe coals holding about the same range. High-volatiles were quoted $5.50@$5.75 and Pittsburgh steam coals, Pool No. 34 quality, around $5.50.

FAIRMONT

A number of companies having signed the Cleveland agreement, northern West Virginia coal is now being handled, but the open-shop, mines in operation greatly exceed the union mines in number. Naturally production has increased, but the bulk of the output during the week ending Aug. 19 was coming from non-union mines, most of which are adhering to the policy of the open-shop contracts during recent months. Much of the coal is going to the railroad, the open market price ranging $4.50@$6.50 a ton.

PHILADELPHIA

There has been a little freer offering of spot coal recently, but it seems that the more coal available for the market the less anxious the consumer is to buy. There are more miners for low prices, and each successive drop recently only seems to have encouraged the consumer to hold off longer.

Frequent reports are heard of small operators signing up on the basis of the Cleveland scale and the number accepting grows each day. However, it is a foregone conclusion that the big concerns and most of the non-union, will continue to do so.

Prices have fallen close to an average of a dollar all around and even lower figures are looked for yet there is also a likelihood that there will be a considerable rebound. There is not the least doubt that the moment the consumer is convinced that mining has resumed at a greatly improved degree there will be a rush into the market, with only one result—increased prices.

Foreign coal is now arriving almost daily. Inasmuch as there have been some sharp price recessions in domestic fuels this has had the effect of slowing down orders for overseas fuel. In addition, this is also a fair tonnage of Southern coal coming in, and many of the barges formerly in the anthracite trade are now being used for Southern loadings.

CENTRAL PENNSYLVANIA

As far as the union mines in central Pennsylvania are concerned, the strike is at an end for the present. Influenced by the settlement, prices have sagged. Spot quotations are $5@$6, but it is expected that the price will soon reach the fair-price level of $4.50 established by the agreement, despite the competition, as mining progresses, should bring it to the figure prevailing prior to April 1.

Before leaving Altoona following the agreement with the union operators, President Brophy declared that the entire force of the union will be concentrated on the fields remaining out of the organization. Production in the non-union districts has steadily increased, the peak being reached last week when 1,020 cars were loaded in one day. It is apparent that the union has a task before it, as the non-union fields are mostly paying a higher rate than the agreement with the union calls for.

Baltimore

With the increased production of soft coal prices have fallen off so that at this writing gas and steam coals are in the market at prices ranging $5.75@$6 a net ton f.o.b. mines. These prices apply in the majority of cases to both Pennsylvania and other fields.

There is talk of the Hoover price of $4.50 but in most cases this is not an active binding figure even for priority. The demand from consumers, at least that kind of demand which was willing to pay up to $8 for quick deliveries, fell off rapidly with the reopening of the mines in the Cleveland agreement.

The question of profit-limiting is the principal one now agitating the Maryland Coal Commission and the solution is apparently not reached through the conference so far held with official Washington. In sales for domestic use, especially, there is great difficulty in arranging a price, as the cost of handling varies greatly.

UPPER POTOMIC

All but about 15 plants are now in operation and production is increasing daily. All the mines are running open-shop, the owners having refused to sign with the union though paying the 1920 wage scale. The tonnage now being handled by the Western Maryland is larger than at any time in recent months. There continues to be a strong demand from eastern markets, prices ranging $4.50@$7 a ton.

West

SALT LAKE CITY

Operators are still behind on their orders but prices have not increased. The car situation is satisfactory. A few more men have gone to work at the mines and production is holding up well. The strike situation is unchanged.

Prominent operators at Ogden, who have never been in Wyoming, have left for Rock Springs where they will be present at a meeting to consider the question of reopening the mines in that state.

KANSAS CITY

In spite of the settlement Aug. 23 of the strike in the Southwest field, the outlook for both operators and miners seems bright. Competition of the strongest kind from Illinois coal on the East and Colorado coal on the West, and with fuel oil from all directions will cut heavily into the mines and production will sag. Shortage, prior to set in about the middle of September, may interfere with the flow of Illinois and Western coal, but it will be largely handled by the companies already has established itself well both locally and throughout the South, which is counted on normally to absorb about all the black coal shipped from Kansas and Oklahoma fields.

A little new Kansas coal reached Kansas City by Saturday and was quoted as follows: Lump, $6.50; nut, $6.50; mine run, $5; slack $2.50@$3.

North Atlantic
Substitutes Sought as Hard-Coal Famine Looms

Coke Being Used and British Coal May Be Pressed Into Domestic Service—Depletion of Pea Stocks in Sight—Stimulus to Output of River Barley.

Hope of any August resumption of anthracite mining has been blasted by the deadlocked Philadelphia conference. In the meantime the retail situation is being given much publicity by the daily press and all consumers now realize the gravity of the fuel outlook for this winter.

Coke is being substituted as an emergency fuel. There is some talk of using British coal for domestic purposes along the North Atlantic seaboard. Pea coal is still actively moving out, both at retail and from the mines, but at the present rate of distribution two weeks will see mine storage piles of this size fairly depleted. Production of river barley is stimulated by the steam shortage.

As it becomes certain that anthracite will be impossible to procure at the start of the winter, steps are being taken by New York City authorities to abolish the ordinance prohibiting the use of bituminous coal.

Philadelphia

Just as everyone had begun to be hopeful that there would be some anthracite production in August, the miners and operators came to a deadlock, with absolutely no sign of their resuming negotiations.

Receipts of pea coal by the retailers have been up to the tonnage of the last few weeks, and it is believed that the next two weeks will see the entire exhaustion of the companies' storage piles. Consumers of all classes are now eagerly seeking this size, as it is the only coal now left on the market. Dealers are fully convinced that they will have to handle bituminous coal this winter in order to serve the people, and in the meantime are seeking sized coke. They have found that the market is already sold up, as much of the product is going to iron furnaces. Their only hope in case of stress would be by the fuel commission ordering this fuel into domestic use.

One of the coal associations, in order to assist in the equitable distribution of such coal as comes to market, has suggested some rules to the fuel commission, as follows: The maximum gross profit on retail sales not to be in excess of that in March, 1922; delivery to consumers to be limited to 60 days' supply; operators shall not make sales to other than retail dealers; the commission shall do all possible to have coal kept up to the standard of preparation.

NEW YORK

The seriousness of the situation is being realized more each day. Hard coal is becoming scarcer and bituminous is being recommended for use as a substitute by a number of administrators. Since the breaking off of negotiations between the mine owners and the Board of Aldermen of this city has asked the Board of Health to suspend the ordinance prohibiting the use of bituminous coal in the city. Leave also has been asked of the State Legislature to issue bonds which will enable the city to go into the coal business.

There is little hard coal about the retail yards and none being offered for sale by producers and wholesale houses. What is left of certain sizes there are to be had are being doled out in small lots by retail dealers. Orders are filled and it is apparent that those houses owning large bins are empty are likely to have some sleepless nights soon.

About the only anthracite available is river barley which is being offered in small lots. Quotations range $2.50 @ $4 at the point of loading.

BOSTON

The retail price on pea has been lifted in Boston to $15 per net ton, sidewalk delivery. Prices on larger sizes are only nominal, no dealer having more than a very small quantity on hand.

Stray lots of pea are still coming forward from a few producers. The tonnage available, however, is very much less. The local operators will not be able to meet the demand for industrial and utility use but are taking what is coming. A few of the larger companies will have practically none in stock when mining is resumed.

Baltimore

Dealers are keeping one eye on the possibility of a settlement of the anthracite trouble, although they are not so much impressed with the thought that the government will actually operate anthracite mines, and the other on the class of distribution which they will undertake as an emergency pending the first receipts of hard coal. In this latter connection some will avail themselves of the domestic soft coal which is now offering, while others will take supplies of the English coal already in port.

In 1902 some English coal brought to this port in ballast was sold to local consumers at a price of $11, as a relief from the prevailing conditions at this time. A price of $13.50 at this time would certainly be considered conservative. Some tests of substitute by the coal just brought in, a Welsh product, show that it burns with a good flame and with very little smoke or residue. Hard coal dealers, however, predict that as soon as anthracite begins to run again the demand for even the best kinds of soft coal for household use will come to an end.

BUFFALO

With the failure of the operators and the union authorities to arrive at an understanding all hope of a coal supply right or of a sufficient output for the winter disappeared. The question now is what will answer as a substitute.

It is believed that natural gas will be in much larger supply than during the past few years. Still the problem is not an easy one. The city has about 110,000 families living in single houses to four family flats, of which it is estimated that 75,000 have no coal of account.

Meanwhile an enterprising Scranton coal man sends in an offer of coal "as soon as mined" at $17.50 for stove and chimney, $10 for pea and $12.50 for washing, to which add $3.25 for freight.

South

BIRMINGHAM

Though the market is not as active as a week ago, business being offered is more than sufficient to take the comparatively small amount of free coal that will be had. Inquiry from Western points has fallen off with the resumption of operations at mines in the union fields and other districts on the strike. Strikes have been declared and demand for industrial and utility use is good. The railroads and other contract consumers are taking the bulk of the output and the larger companies have little or no free coal to offer on the market.

Pressure has not been sufficiently relieved to restore differentials as to quality and preparation, and mine run and washed steam is selling at $4.85 per ton mines, while spot domestic is reported around $5 and hard to obtain at this figure.

Mines on the Southern Ry. especially have suffered serious delays this past week account of shortage of cars, operation being all the while off for a few hours to as much as two days in the week. Conditions in this respect are not as bad on other lines, but all lines are short on coal-carrying equipment. Production for the week of Aug. 12 was approximately 300,000 net tons. Withdrawal of a large amount of equipment from foreign lines which have been taking coal in this district for some weeks pending the settlement of the strike, has been seriously felt.

VIRGINIA

Mines have not been able to reach higher than 50 per cent of potential capacity owing to lack of adequate transportation facilities, production not being above 150,000 tons a week. That section of the field covered by the Norfolk & Western is producing about 75 per cent of capacity. C. & O. mines are producing at the rate of 64 per cent. Coke production remains at about same rate, viz, 400,000 tons a week, or approximately the same level, with much of the output moving under contract. One hundred out of the 115 mines in this territory are in operation.
Chicago and Midwest

No Joyous Welcome for Fresh Midwestern Coals

Many Spot Buyers Withdraw from Market Hoping Prices, Now Seeking a Firm Level, Will Drop—Illinois Mines Reach 30 Per Cent Production.

If anybody expected the Midwestern market to get out the band and the town "hack" to welcome the return of Illinois and Indiana coal, they were disillusioned before the mines of the states had been producing four days following the end of the strike. Efforts to feel out the market at $6 were coldly received after the first day and by the fourth the recession in price had driven quotations below $5. Steam demand was light except among railroads. In the markets the main interest was in prepared sizes. Steady customers in the retail trade got most of the first coal shipped. This situation is expected to reverse itself after a few days when it is definitely determined what the bottom price is to be.

A good deal of coal from Kentucky, en route for Midwest markets was caught by the end of the strike and is selling as low as $3.50. At certain Illinois mines, there were no bills on the track the second day of operation.

INDIANAPOLIS

With the resumption of operations in Indiana, the retailer has come into the market and he wants coal badly. Prices show no change at the mines outside of Indiana.

The coal executive board of the state administration is arguing for a $3.50 price at the mines. Most of the operators believe when quotations are finally made, the price will be more nearly $4, at least for the time being. The governor, however, has authorized the payment of $5 for coal provided on a guarantee to the state institutions.

It is generally believed by operators in Indianapolis that a four day a week program will be all that will be permitted because of the rail situation. The rail officials here say they can provide cars for every pound of coal the operators produce, but as one aptly put it, "they never have."

WESTERN KENTUCKY

Although demand has slumped a little as a result of production starting north of the Ohio and the Chicago market is weak and only bidding about $4.50@$4.75 for western Kentucky coal, it is claimed that the field will continue as busy as car supply will permit, as priority orders are taking production just now, and there is the great demand to be supplied through the retailers, and restocked at the ports, along with railroads, before any let-up is in prospect. Prices are working down to around the allowed figure of $4.50 a ton, but may remain firm at $4.50@$5, which will never cover brokerage in the latter instance.

Whether Chicago, Detroit and other Northern markets continue buying in large quantities or not will make a great deal of difference for the time being, as St. Louis, Louisville, Nashville, Memphis and many other towns are needing considerable tonnage, and retailers do not expect to accumulate much stock.

LOUISVILLE

During the week prices have worked lower until there is but little coal quoted at more than $5@5.25 for any size, from any Kentucky field. The allowed price of $4.50 a ton is being approximated at last. But it is reported that some producers are passing their coal through brokers, so that the latter may have an opportunity to collect their 8 per cent brokerage.

There are rumors to the effect that some producers are billing their output through newly organized brokerage offices, prices being at the $4.50 maximum, thus keeping their own records clear while these subsidiaries rake in big profits.

It is feared that an already poor car supply to Kentucky will become worse now that Northern fields are producing again.

SOUTHERN ILLINOIS

Nearly every mine in the Carterville district started to work on Aug. 25. Some of them did not get any coal, however. Those mines that did not open began cleaning up preparatory to starting.

When it became known that Illinois had signed up there were parades in the mining camps all over southern Illinois, especially at West Frankfort and all Franklin County fields. There was general rejoicing everywhere, for the miners, it now develops, were practically convinced they were going to have a job this winter.

Somewhat similar conditions prevailed in the Duquoin and Jackson County fields, with the exception that several of the smaller mines are not ready to open. In the Mt. Olive district coal was produced the first day, but no shipments made.

Railroad buying was easy in the Standard and Mt. Olive fields, practically no railroad coal being loaded except that on overlapping contracts. The Carterville prices seem to range around $6@$6.75 for domesti sizes, including No. 1, 2 and 3 washed. No. 4 washed is $4.75, No. 5. $3.90, 2-in. screenings, $4.50, 1-in. screenings, $4.35 and mine run, $4.65. Railroad coal seems to range $4.50@$4 for mine run on contracts.

Mt. Olive shipments to the country and Chicago range about $5 on domestic sizes down to $4.60 on steam. St. Louis prices on Mt. Olive domestic are $4.50 down to $4.25 on steam. Big Mt. Olive and Murphysboro ranged around $6 for everything at the standard, although opened up at $6 for lump and down to $5 for mine run, but this rapidly declined until the latter part of the week saw coal going as low as $2.75 for screenings, $3 for mine run and $4 for prepared sizes.

CHICAGO

No liveliness of markets here followed the resumption of coal mining in Illinois and Indiana. Spot coal appeared to withdraw with the expectation that if they stayed out for a few days coal could be down to $2.50. As it was, Illinois coal on the market brought the above $5 but did not move in any quantity at prices above $5 for lump, $4.50 for mine run and $4.25 for screenings, which was the bulk of the demand for domestic.

Indiana coals were offered at figures above the Illinois levels. In the price jugglery which is now going on and may continue for a week or more until a firm level is reached, it is natural to suppose that most Indiana coal will drop below what from well-known Illinois fields. A good deal of Kentucky coal on the way here was caught short by the end of the strike, so that quotations on it dropped suddenly from around $6 to $5 a ton a day of the settlement to less than $5. Very little smokeless coal reaches here.

ST. LOUIS

The end of the coal strike was not as haphazard an affair as might be expected in St. Louis. All buyers seem to figure that they have an unlimited quantity of Kentucky and Alabama coal in transit that is going to drag on for the next three weeks. As a result they are not in the market for Illinois coal. There seems to have been some sort of a well-formed plan not to buy Illinois coal when the mines started up, although the day before they started up these same buyers were paying $7@8$8 for Kentucky coal. The result is that the Illinois Standard market is pretty well broken up and quotations range from $4 down to $2.75 and shipments are being diverted to the north. The same is true of Mt. Olive. On such Carterville as is coming in the price is being paid, but the tonnage is light.

The St. Louis fuel committee has ceased to function, but the State fuel commission will continue to keep in touch with the situation. A meeting was held in St. Louis on Aug. 24 in regard to this and it was decided to keep the operators apprised of the care of the situation until it developed that they were unable to cope with it.

Canada

TORONTO

Fuel Controller Ellis strongly advises coal dealers to purchase Welsh coal, but so far there has been no move in that direction as rumour has it that plenty of anthracite will be available before winter, though the Controller is of the contrary opinion. J. Sanderson, representing the European and Asia Committee of Commerce, has come into the market with the object of opening up a market for British coal. He states that his company could supply the needs of a large city and has at present over 100,000 tons ready for shipment from Cardiff.
Output of Resuming Mines
Hampered by Car Shortage

Large Consumers Now Buying; Smaller Users Holding Back for Lower Quotations—Shrinkage in Demand Softens Prices—Closing of Ford Plants Important Market Factor.

No. 8 operations have cleaned up and are resuming work under the Cleveland agreement. Production is seriously hampered, however, by a car shortage on the B. & O. and W. & L. E. railroads. The major portion of the output is going to the railroads, steel plants and other large users. Smaller consumers are awaiting lower prices, and the recession in demand has caused a softening, temporarily at least. The announced intention of Henry Ford to close down his plants Sept. 16 will have a pronounced effect on the market.

Ohio operators have refused to enter a state conference on price regulation, fearing the federal law on the subject.

PITTSBURGH

Operators now offer the men the 1920 scale, without union recognition or the check-off, and the men show little disposition to accept the common belief is that the Pittsburgh Coal Co. will hold out indefinitely, but there is doubt as to some of the smaller operators. Published reports of Pittsburgh operators being disposed to sign the scale refer chiefly to operators in the Freeport vein.

Some observers are confident the Connellsville region will be fully at work in a few days and that this will shortly cause a break among the strikers in the Pittsburgh district.

The trading market in coal continues to be confined almost wholly to Connellsville steam, which has declined fully a dollar in the week, being now available at $5. Offerings have increased somewhat, but the decline was due chiefly to decrease in buying. The railroads seem to have been instructed to stay out of the market. Pittsburgh strip-mined coal has been offered down to $5 and experiences a limited demand. Westmoreland gas stands at about $5.

CLEVELAND

With the announcement of the acceptance of the Cleveland wage scale by additional important groups of operators, demand has eased off somewhat. Consumers apparently are convinced that supplies soon will be greatly increased. This view is not held by some operators, who depreciate stories that production will reach normal levels soon. Their experience is showing them that a shortage of cars at the mines is already seriously hampering the resumption of production. In the meantime prices have dropped. Threatened regulations may have had some influence in bringing this about.

At a meeting of the members of the Ore & Coal Exchange in Cleveland a few days ago, practically the same rules and regulations governing the period prior to 1920 were adopted. The price arrangement, as in 1920, probably will provide for a settlement of balance price fixed by the committee at the end of the season, applying to all balances outstanding.

For the season to Aug. 20, shipments of coal up the Lakes to the Northwest amounted to 4,057,524 tons of cargo coal against 14,962,793 tons in the same period of 1921, and 9,055,834 tons in 1920.

COLUMBUS

Most of the mines are now getting down to business with a fairly good force of miners and output is growing daily. Car supply has been quite good up to the present.

The state fuel administration is functioning and priorities are taking care of practically all that is produced in the state. Railroads and utilities are still getting the bulk of the tonnage, although some is going into other channels. Retailers have not been able to get much coal up to date and are looking orders for delivery later on. Lake trade is showing some life although the movement to the Northwest is still small in comparison with previous years. Lake shippers have closed a few small contracts at $8.50.

DETROIT

With bituminous receipts averaging about 200 carloads daily, while between 50 and 600 are necessary to meet requirements, Detroit is steadily running behind on coal supply.

Priority orders for about 150,000 tons of coal for Michigan, which were sent forward to the Federal fuel administrator by the Michigan fuel administrator, have been approved only to the extent of about 50,000 tons.

The apparently ineffectual outcome of the drive to recompense the Chicago coal administration has caused a revival of the previously discussed plan of organizing a local pool among Detroit coal men for the purpose of sending in coal to the producing districts in an attempt to get coal without assistance of the federal authorities.

Owing to diminishing coal supply, 85,000 employees of the Ford Motor Co. will be laid off Sept. 16. The company's Highland Park plant is reported to have installed oil-burning equipment in its furnaces. Whether the use of oil will be continued permanently is not announced.

BUFFALO

The trade has reason to feel that the worst is over. This market is not getting any new coal yet and some that was promised has been ordered to the Lakes, but there will soon be enough if things go right. There is little likely to keep prices up, but consumers are waiting for them to come down.

Supply has been pretty good. Jobbers were active and their advice was needed. Today there are plenty of consumers, large and small, with months of coal ahead of them. So there will be no statistics.

Bituminous prices now run from $7 for Youghihoghey gas, $6.75 for Pittsburgh lump and slack to $6.50 for the northwest. Allegheny Valley and $2.24 to other points have freight to Buffalo. So far mining reumption in the Allegheny Valley is more general than in the districts further south.

NORTHERN PANHANDLE

So many companies are operating on an independent basis that the contract made with the union has not practically increased output. At mines where there has never been an agreement with the union, production continued at about the same rate, the field is as a whole having an output of about 50,000 tons during the week ending Aug. 19. There is a heavy demand at the Lakes and in northern markets, with large tonnage from the region being utilized by the railroads.

EASTERN OHIO

Operations have been slow in reaching capacity output because of transportation disability and preliminary cleaning up in some of the mines.

During the three days ended Aug. 19, the number of users has increased somewhat, but there is little foreign trade. For these three days of 309,750 tons of the 140 mines comprising the field. While a greater number of mines have been sending coal ever since for greater production, car shortage has been a considerable factor in the situation.

The number of users is at a low ebb and buyers for the rank and file of industry are still in a position to withhold orders, anticipating that prices will react further when coal becomes more plentiful. Larger users such as railroads, steamship lines and steel plants are very much in need of coal and the major portion of current output is going to these. Many of the producers have succumbed to reactionary tendencies and quotations are now $1@$1.75 less than a week ago.

Bituminous coal at Cleveland during the week ended Aug. 19 agglomerated 636 cars and were approximately the same in quantity as receipts during the two weeks immediately preceding.

Arrangements have been made to pool Lake cargo coal effective Sept. 1, similar to the plan inaugurated during the season of 1920 when total movement up the Lakes exceeded 22,000,000 tons, of which 16,000,000 tons were floated after July 31. At a meeting of shippers, an executive committee was formed to formulate rules and regulations to expedite the handling of this important traffic to the Northwest.
Northwest

Upper Lakes Region Now
Frets About Anthracite

Most Coal Men Believe Adequate Soft
Coal Supplies Will Be Shipped Up
from Erie Ports but Lose Hope on
Hard Fuel—Prices Flighty.

The Northwest is now morally cer-
tain it will get enough bituminous coal to meet all its crying wants. While cargoes have not yet begun to arrive under the new distribution plan in any great number, they are expected to begin this week. In spite of a good deal of bleating for prior-
ities which may not be granted, it is generally felt that the North-
west's plight—even though partially brought down by Northwestern fail-
ure to conserve the dock coal it had early in the summer—will draw tre-
mendous shipments from now until the freeze-up. But as to hard coal the feeling is different. Coal men are confident that the strike settle-
ment in the anthracite fields will come so late that not a ton of output
from those fields will reach here.

The Northwest's propaganda sys-
tem is still working effectively. It
has been so successful in setting forth the region's desperate plight that it may have had something to do with recent hoists in price on
what little coal there is available.

DULUTH

The Northwest now feeling sure of plenty of bituminous coal for public utilities and industries is centering its interest upon the anthracite situation. Coal men here think the hard coal strike will not be settled until it is too late to ship much up the Lakes. This
will mean that the Northwest will burn smokeless in its house furnaces.

Bituminous is steady and there is little quotation of prices as docks are
busy filling past orders. It is said that 75,000 tons, outside of bituminous, still
remain on the docks but this has been taken already.

Five cargoes came into port within the last week. This is Kentucky coal and is selling for around $9 for lump, with 50c. off for run of pile. It is ex-
pected that one or two cargoes will
arrive daily from now until the first of the month, and that after that ship-
m ents will resume in force.

The order to pool coal at Lake Erie ports is causing dissatisfaction among
dock men and dealers. Much money has been spent in advertising certain
varieties of coal and the pooling will make this advertising ineffective. It is felt though that it is the only way to handle the situation, by the consumer
generally.

MILWAUKEE

Watchful waiting is the order of the day. The settlement of the strike in the soft coal fields has eased the tension to some extent, but until coal begins to move and there appears to be some organized system of distribution both dealers and consumers will continue to worry.

Nobody has any idea as to how the apportionment of coal is going to be
made, but everybody expects higher prices to American demand. Many have switched from coal to coke to make sure of getting some kind of fuel.

Eleven small cargoes of soft coal were received here thus far in August, making the season's receipts of soft coal to date 827,212 tons, against
1,799,943 tons during the same period last year. Car-ferries brought 1,564
tons of anthracite and 54,273 tons of soft coal from the East thus far in August. The bulk of this coal goes direct to the interior, only a small per-
centage remaining here. Last year up to this time 618,007 tons of anthracite
had been received here. Not a cargo
of anthracite has reached port thus far
this year.

MINNEAPOLIS

The problem of getting an adequate supply of some kind of coal into the Northwest before the close of naviga-
tion promises to be the hardest job yet encountered by the coal industry in this region. The fact that the Northwest had a good supply of coal on the docks last spring and did not take advantage of it, is working against all arguments as to its present and future needs. Minnesota state institutions are now low on fuel and authorities are wonder-
ing where they will get some within the next few weeks.

When Central Western railroads came to the Lake Superior docks during the summer and bought a big tonnage, shipping it down to Chicago and vicin-
ity, Northwestern roads were utterly indifferent. True they did buy some tonnage, but far less than their neigh-
bor to the South. Now these same Northwestern roads plead for the same priority that the North-
west will simply have to go into the market for coal in competition with other buyers,—pay whatever price they have to pay in order to get what fuel is available.

New England

Tension Is Lightened
As Inquiry Slackens

Panic Demand Disappears—Comfort-
able Position of Railroads Will Facilitate Movement All-Rail—
Large Output Expected in Next
Thirty Days.

This week shows very much less
tension. In contrast with a fort-
night ago there is apparently no panic demand whatever and current
inquiry is notably less than last week. The railroads are in very comfort-
able position as to supply and it is expected that coal on contracts will begin to flow all-rail as well as by
water.

Most buyers are building large
upon production the next thirty days, and while there might be danger in this if reserves were low, the fact is that stocks in this territory are adequate for some time to come. Con-
sumers who have deliveries due them
on contract are expecting that their
September quotas will be filled, and apparently there is small chance now
of any runaway market.

Several Pennsylvania operators are
diligently seeking spot orders, and to such extent is this true that already
quotations are lower than was the case a few days back. Grades roughly
described as “Pool 10” that were offered at as high as $7.50 have been quoted recently at $6.50, and with the smoke-
less coal also losing off in price the trade looks for still lower figures in
central Pennsylvania.

While Pocahontas and New River are
much involved with priorities, and coal intended for New England has been
diverted to railroad use elsewhere, the Hampton Roads agencies are ex-
pecting the situation to change mate-
rially by the early part of September. There are still spot sales reported at around $10.50 f.o.b. vessel, usually for
small tonnages to clear boats, but ship-
ners will have their own coal restored to them in increasing volume and will be expected to resume shipments on contract.

The trade generally is much relieved
over current news from Washington. Ordinaries have been so upset and many sales have been made, the situation having been created that everybody, the lay distributors included, are happy to see coal beginning to flow in accustomed
groups.

The New England railroads have
made such good progress in replacing striking shop craftsmen that there is less anxiety here over equipment than is doubtless the ease in other sections of the country.

Meanwhile, cargoes of British coal arrive from day to day and are likely
to continue arriving for the next 60
to 90 days. Heavy purchases were
made while the labor situation looked serious and doubtless there will be
some shrinkages to be absorbed.

Already, British coal is quoted lower than a week ago.

DELAWARE
The duPont Company announces that effective Sept. 1, 1922, the smokeless pow-
ders department will be placed in the hands of an independent department, known as the Explosives department, and will be operated as an independent industrial department, known as the Explosives, to be managed by the President of the whole company.

ILLINOIS
Havens A. Requa, sales manager of the Columbus Mining Co., Chicago, is spending the latter part of his vacation in Philadelphia, under the guidance of Vice-President A. Felix duPont, as general manager.

MISSOURI
The Big Four Mining Co., is opening mines near Carrollton. It is reported that three of these will be opened up at once, and the first one will be on a shaft east of town.

NEW YORK
The Island Creek Coal Co., for the first half of the year, has net earnings of $1,916,548, after charges and taxes, of $1,578,427, equal to $1.43 a share. Total earnings for the first half of the year were 119,739 shares of common stock.

OKLAHOMA
The Texas Pacific Coal & Oil Co., of Fort Worth, Texas, has been granted a permit to construct a pipeline from the Texas Pacific Oil Co., with an aggregate capacity of $5,000,000, with the understanding that the company is capitalized at $5,000,000 with R. D. Hunt, of St. Louis; E. I. Norton, and Horace K. Thurbur, of New York, as in-
corporators.

Pennsylvania
The North Western Mining & Exchange Co. is about ready to start the development of property at Clermont, near Dubois. There are a number of claims including the Jesse property, which, with its 1,000 tons daily, is to be analyzed as a coal mine, in the meantime being prospected for oil. The operation represents an outlay of $2,000,000.

The construction of the coal-loading docks in the Lehigh Canal, near Northampton, six miles north of Allentown, by the Lehigh Coal & Navigation Co., preparatory to abandon-
ing the railroad service, is progressing. The construction of the basin at Mauch Chunk, has been started. The company has spent $500,000 on the new undertak-
ing. The docks will be built on the boats from Coalport to Philadelphia has been placed on the market, officials say, by spring freshets.

The dock will compel the coal, said the building of immense yards at Northampton by the New Jersey Central, which will bring the coal on the place instead of at Coalport.

TENNESSEE
The West Virginia-Tennessee Coal Co. has been incorporated with capital of $15,000 by T. O. Busbee, Thomas Lockhart, W. H. Worthington and Julius Kernst, the company will develop properties near An-
napolis.

Kentucky
The Kentucky Coal Lands Co. is incorporated as a joint-stock company, with an authorized capital stock of $100,000, divided into 100 shares of $1,000 each. The purpose of the company is the purchase, lease, and development of coal lands, and the sale of coal. The company is capitalized at $60,000, with the following officers: A. D. Thompson, president; H. S. Marston, vice-president; J. W. Cooper, secretary, and C. A. B. throttle, treasurer.
Traffic News

Coal companies operating in the Me Roberts region of Kentucky have asked the Interstate Commerce Commission for a hearing on rates paid by mines in the Hazard group. It is contended that these mines are geographically and geologically a part of the coal region embraced in the Hazard group, and that the same rates should apply from the Roberts group to Cincinnati and Louisville and points in Central Fraternal Association territory and to points in certain of the Western States. The complaint is signed by the Commercial Coal Co., Blackey Coal Co., Marian Coal Co., Dudley Coal Co., and Consolidated Fuel Co. The traffic case of the West Kentucky Coal Operators’ Association versus the American & Rockfish R.R. will be the subject of a hearing at Louisville on Sept. 15 before Examiner Fleming.

The traffic case of the Virginia Coal Operators’ Association versus the Atlantic & Pacific R.R. will be considered as a hearing at Washington Sept. 21 before Examiner Gentry.

The case of the Gulf Coal Co. versus the Virginian Railroad Co. will be considered as a hearing at Washington Sept. 22 before Examiner Gentry.

Oral argument in the case of the Clay County Operators’ Association versus the C. & M. R.R. will be held at Washington Oct. 21 before Division 3 of the Interstate Commerce Commission.

In a complaint to the I. C. C. the Sewell Valley Railroad alleges unreasonable and unjustifiable divisions of rates on coal by the Chesapeake and Ohio.

WASHINGTO...

D. C. Botting, for many years connected with the coal-mining industry in this state, returns on Sept. 1 to become manager of the Pacific Coast Coal Co., Seattle. He has for three years past been general manager of the Vandalia Coal Co. Mr. Botting was born in California fifty-one years ago, and when a boy worked in the mines at Nortonville. In 1901 he was appointed state mine inspector for the county in which capacity he served until 1912, when he resigned to take charge of the mining end of the government party which went to the Alaskan coal fields to determine the suitability of those coals for naval purposes. His return he became commissioner of the Washington Coal Operators’ Association and manager of the Producers’ Association. During the latter end of the war party he was appointed acting manager for the state under the U. S. Fuel Administrator.

WEST VIRGINIA

Preparations are being made by the Ace Coal Co., of Shinnston, to develop coal lands in Harrison County, this concern having only recently been organized with a capital stock of $50,000. Offices of the company are at Shinnston. Leading figures in the new concern are: Basil H. Lucas, president; H. W. Simpson of Johnstown, Pa.; L. C. Cricle and A. M. Leonard, of Clarksburg. The strike cut down the enrollment for the miners’ short course of six weeks at the West Virginia School of Mines, in an attempt to strike, however, there were sixty-nine students enrolled. A committee of forty-six was organized in the Kanawha By-Product Coal Co. for the purpose of operating in the Kanawha region, the offices of the company to be at Charleston. This company has a capital stock of $45,000. Harry W. Jenkins, of Comb, W. Va., is organizer of this company. George K. Guthrie, T. C. Parrott, W. E. Orth, T. C. Patterson and R. R. Circle, all of Charleston, have organized the Rosehill Coal Co. by Philadelphia capitalists preposing the further development of the coal in Talcott County. This company has been chartered with a capital stock of $100,000, but quarters to be at Newroz. Principally interested in the new concern are J. H. Roberts, J. E. Johnson, J. F. McAlpin, James W. Birch, L. G. Ball and Stewart Frazer, Land Title Building, Philadelphia.

George S. Brackett has been named as the government’s agent for West Virginia. Mr. Brackett is the secretary of the Northern West Virginia Operators’ Association and manager of the Producers’ Association. During the latter end of the war party he was appointed Acting Manager for the state under the U. S. Fuel Administrator.

BRITISH COLUMBIA

The Chin Chinn Coal Co., a Seattle concern, has restarted the development of its property in the North Shore mining district. It closed down at the end of last year, after producing small quantities of coal. The company has done a considerable amount of tunneling, drifting and diamond drilling. The coal field is described by Professor U. L. Uglow in Part A of the summary report of the Canadian Geological Survey for 1921, which has just been issued.

ONTARIO

The Black Diamond and Coal Co., Ltd., has organized with headquarters at Toronto. The charter just issued authorizes the company to engage in the wholesale and retail coal business. The authorized capital is $10,000 and the directors are J. L. Ross, L. Y. Sutton and E. M. Carruthers, of Toronto. J. E. Ryan, vice-president of the F. A. Fish Coal Co., Ltd., Toronto and Pittsburgh, has resigned his position after seven years of service.

The government peat plant at Alfred, which was tried out last season, is in full operation. B. F. Haanel, of the Federal Mines Branch, the government’s peat expert, has been appointed general manager.

The Coal Operators’ Association of the U. S. Bureau of Mines, is visiting the experimental stations with the idea of improving their work and standardizing office clerical procedure.

C. E. Augustine, a fuel engineer of the Bureau of Mines and of the Veterans’ Bureau, will visit all hospitals in the United States and small town institutions to make reports and recommendations on the equipment that may be used in fuel-heating equipment and in the selection of fuel.

The Grand Trunk Pacific has for many years as an assistant to the Director of the U. S. Geological Survey, has resigned to undertake the practice of mining law.

George S. Bire, chief mining engineer of the U. S. Bureau of Mines, is making a tour of the large producing districts, and will visit British Columbia before his return to Washington.

The West Virginia-Kentucky Association of Mining Engineers and Electricians, of the United States, will hold its annual meeting in connection with the annual meeting of the National Mining Association at the City Hall, Huntington, W. Va., Sept. 19-22. Secretary, H. Smith, 312 Robinson Building, Huntington, W. Va.

National Exhibition of Chemical Industries will hold its eighth national exhibition at which 200 concerns will be represented. The meeting will be held Sept. 18-21 in the Hall of the International Exhibition Hall.

American Mining Congress, Twenty-fifth annual convention and exhibition of mines and mining equipment will be held at Pittsburgh Sept. 28-30. President, H. B. Porter, convention manager.

American National Exhibition of Power and Mechanical Engineers will hold its fall meeting the week of Sept. 25 at San Francisco, Cal. It is proposed to arrange for the meeting to be held Sept. 16, stopping at different cities en route. The meeting will be held at the Carnegie Institute of Technology, Pittsburgh, Pennsylvania.

American Chemical Society’s annual fall meeting will be held at Pittsburgh, Pa., divisional meetings will be held at Carnegie Institute of Technology, and in the Pennsylvania State Hall.

The Rocky Mountain Coal Mining Institute will hold its next meeting at Glendale, Calif., Sept. 7-9. Secretary, F. W. Whiteside, Denver, Cal.

American Institute of Mining and Metallurgical Engineers will hold its fall meeting the week of Sept. 25 at San Francisco, Cal. It is proposed to arrange for the meeting to be held Sept. 16, stopping at different cities en route. The meeting will be held at the Carnegie Institute of Technology, Pittsburgh, Pennsylvania.

American Chemical Society’s annual fall meeting will be held at Pittsburgh, Pa., divisional meetings will be held at Carnegie Institute of Technology, and in the Pennsylvania State Hall.

The Rocky Mountain Coal Mining Institute will hold its next meeting at Glendale, Calif., Sept. 7-9. Secretary, F. W. Whiteside, Denver, Cal.

American Institute of Mining and Metallurgical Engineers will hold its fall meeting the week of Sept. 25 at San Francisco, Cal. It is proposed to arrange for the meeting to be held Sept. 16, stopping at different cities en route. The meeting will be held at the Carnegie Institute of Technology, Pittsburgh, Pennsylvania.

American Chemical Society’s annual fall meeting will be held at Pittsburgh, Pa., divisional meetings will be held at Carnegie Institute of Technology, and in the Pennsylvania State Hall.

The Rocky Mountain Coal Mining Institute will hold its next meeting at Glendale, Calif., Sept. 7-9. Secretary, F. W. Whiteside, Denver, Cal.
Wanted—A Policy

DAZED with the overwhelming defeat they have suffered, operators are asking each other: How in the world did it happen? How did Lewis do it? Look back over the past six months, check up this generalization. Lewis fused all the issues raised by the operators—the check-off, wage reductions, district vs. other forms of settlements, open shop, broken contracts—and made one issue to put before his men. He told them that all these things meant one thing and only one thing to them—disruption of their cherished UNION. He was on the defensive on every issue save one, that of the broken contract, yet by selling the idea to his members that the whole strike was precipitated by the operators for the purpose of tearing down the miners' defense, their organization, which alone stood between them and "poverty, suffering, degradation," he unified his ranks and won his fight.

The operators, on the other hand, scattered their fire. They divided at the start on the matter of whether to meet in a Central Competitive Field conference. Some posted notices of one wage reduction, some another, some none at all. Some stressed the issue of the check-off, others did not. A few groups of operators handled their own situations with finesse. They built up records that standing alone were unassailable. But no two built the same structure, and but the flimsiest liaison was maintained. There was no unity of action. There was not, and is not now, a leader among whom the operators could or would rally. No rallying cry was raised to hold them.

The story is not complete without mention of the very obvious fact that what has been said about the lack of unity among the operators can be said with equal truth with respect to the administration at Washington. Taken as a whole the administration offered no help. Of course it could not have been expected to take sides, but it might at least have been so led that it could have clarified the issues for the public whom the government represents. Instead there has been a policy of in and out and in again.

If the operators are dazed over the final outcome, the public is amazed. Slowly—only during the past few weeks—has the realization of what it means to the man on the street been dawning on that individual. The public is but now coming to appreciate what it portends to this country to have such arrogant power in the hands of one man. It is not that he is a labor leader—the reasoning and the attitude would and should be the same were that man on the other side. Therein lies the chief danger to Mr. Lewis. He has overstepped the bounds and it will be his undoing.

History has recorded more than one victory gained at the peace table by a contestant defeated on the battlefield. The peace table for the bituminous-coal industry is set for Cleveland and the date is Oct. 2, next. The program is that the United Mine Workers and operators from all organized soft-coal fields will there and then assemble to consider ways and means of negotiating their next working agreements and contracts. This much is specified in the arrangement to which Lewis fixed his signature at Cleveland on Aug. 15 and to which some of the coal operators have agreed.

Not all the operators have signed these terms. Illinois, central Pennsylvania and others have not so obligated themselves. Nevertheless they may attend, and to this end they have been careful not to go on record to the contrary. This much may be said for this prospective conference, the purpose of which is ostensibly to insure future peace in the industry—the operators may as well stay away as attend in their present disorganized state of mind. Unless the soft-coal producers at Cleveland next month present a solid front, unless they can match organization with organization, they go but to listen to terms.

Clearly enough if attendance among operators is confined to the few who actually signed a "Cleveland" agreement, Lewis will give it scant attention. To some among the operators this meeting offers high hope of constructive action, but to Lewis, an opportunist, it will be just what the developed circumstances may afford.

Should a substantial majority of soft-coal men elect to participate, and they doubtless will be encouraged to do, the result will be a fiasco for them unless they go there united on a program, sufficiently cowed by their present defeat to accept national leadership. There is small chance that the operators can dominate the situation, but there is a chance to divide the honors.

Less than a month remains before this opportunity is opened. In a struggle of force, Lewis won hands down. Can he repeat in a battle of wits?

The Last Stronghold

WHEN last week the Pittsburgh Coal Co., signed the Cleveland agreement with the United Mine Workers the last of the opposition to the union in this strike was crumpled. The contest between these two has been a contest of force from the beginning, with the odds all on the side of the union. Fighting force with force is all right when the opponents are of comparable strength, but when the United Mine Workers matches strength with one coal company, even though it be one of the very largest, the ultimate end is never in much doubt.

The world loves a fighter, and it respects a fighter who knows when he is beaten. The Pittsburgh Coal Co. could have held out to the limit of its financial resources and the country have had all the coal it required this winter, since coal supply and not mines and miners will set the total output. We will wager that the victorious union has a wholesome respect for the company that stood it off until there was no point in further fighting, even though the union deserves little credit for this particular victory.
Potentiality of the Anthracite Situation

NOTHING could be plainer, in the light of recent events, than the dynamite concealed in the anthracite situation. It required a sudden awakening on the part of the East to the hopelessness of the anthracite situation a few weeks ago to really arouse the public and Congress to the real facts of the coal strike. Hard coal goes to the homes and when their security is threatened the public wakes up and speaks.

Whatever form the wrath of the public may take and whatever legislation may be aimed at coal, the main-spring of motive may be traced back to hard coal. Immediately the majority of the bituminous-coal mines resumed operation and the hard-coal mines remained idle, the public grasped the significance of the situation. It was able for the first time to see behind the big talk of the union, which has pushed the anthracite controversy into the background for five months, and then to get a true perspective.

No single group of coal operators this year has kept its case so well in hand and the issues so clear as have the hard-coal men. The circumstances of the strike and the willful misrepresentation of the union have until recently prevented them from realizing the deserved benefits of their well-conceived efforts. When they narrowed the controversy down to an admission of defeat on the matter of wages and asked only that they and the public be protected from future disruptions to mining and be assured of continuity of household fuel supply, the public saw the point and rallied to their side. In a clear field, unencumbered by a nationwide soft-coal strike, the anthracite-coal operators could have won this year. But then had there been no soft-coal strike it is a fair assumption that the union would have refrained from a trial of strength in the hard-coal regions. They used anthracite as a sympathetic strike to help win the other.

What Will Happen in April

FORECASTS always are dangerous, and it would not be well to attempt to say just what will happen next April. Most persons are disposed to believe that by that time the market will be glutted with bituminous coal and that wages in the non-union regions being lowered will be impossible for the operator in union districts to offer the 1920 scale, for without contracts and with lower wages in competing districts which are fully able to supply at least a large part of what coal is needed there will be no possibility of running the mines in union regions more than a day or so in each week.

Increasing business may by that time have modified the situation so that the prospects will be brighter for greater activity than has been outlined. Car and locomotive shortage and severe winter may prevent the accumulation of stocks by consumers. Business activity may prevent the non-union fields from cutting wage scales as low as in 1921, and the increased cost of living may make less forcible the call for deflation in mine wage scales.

The operators who have been calling for arbitration doubtless are perfectly willing to have the issue based not on present conditions but on those prevailing about the time of the proposed award. Arbitration of the bituminous scale is now, however, unlikely. The best we may expect to have is a report on the subject at issue, but when it comes it will give utterance as to later conditions than those now confronting the industry, and they, as has been said already, may be more favorable than those now being faced. The operators' proposal has been entirely equitable even if it should be found in 1923—which is perhaps not likely—that we are on the crest of an inflation wave as high as that in 1920.

Some increase in the demand for bituminous coal undoubtedly will arise from the displacement of hard coal with soft during the coming winter. British coal will hardly come here in quantity, as the price is likely to rise to such a height as to prove a deterrent. Efforts to place the domestic coal of Great Britain in the American market as a substitute for anthracite should and is likely to fail. The coal used for house heating in England is a fuel that will burn in an open grate. It is not what we would term anthracite, for among other qualities it has that of giving a plenitude of smoke. It also cooks like the bituminous or semi-bituminous coal that it is.

Unless the bituminous coal supply fails it is useless to bring coal from Wales or Durham to make up for the anthracite deficiency, except perhaps coal from Pembrokeshire. Better coal than most of it for domestic heating can be found in the New River, Pocahontas and central Pennsylvania regions. It must be remembered that more than 12 per cent of the coal in the United States other than anthracite—that is, that which in a broad classification is known as bituminous—is used for domestic heating. In fact large areas of the country have never used any other coal for that or any other purpose.

Is Henry Ford Learning?

IN THE boom year of 1920 the greatest scandal in coal prices was raised by the indiscriminate, wild bidding for coal, particularly in the eastern Kentucky fields, by the agents of Henry Ford. As many as five or six buyers representing this manufacturer were in each field, unknown to each other, commissioned to get coal and get it at any price. They bid against each other, and because they were after almost unlimited tonnage they put the price to the sky for other buyers. Coal producers will long recall the orgy of buying that Ford staged in that memorable year. For the heights reached then the responsibility is generally placed on Ford's practice of buying before the coal was dug and over the head of every other user.

Now comes the same Mr. Ford with the announcement that he will close his plants before he will pay the robber prices the coal men are asking, that he will cease the production of flivvers rather than take coal away from the needy people of the Northwest. Such compassion touches the heart. For one who has never hesitated to bolster the labor market with wage increases and who has hitherto been the support of high coal prices this change of heart is noteworthy.

One cannot help wondering whether the sagacious Mr. Ford has not again sensed a slump in demand for his product and is not taking this method of letting down from peak production. He has never been known to permit a matter as small as $1.50 in the cost of a single car to interfere with his operations.

Too much of the energy of the business revival seems to be concentrated at the mourners' bench.—Canton Repository.
Haulage, Hoisting and Dumping Practices At Rosedale Mine

BY GEORGE A. RICHARDSON

Largest Mine Locomotives Made Haul 145 Cars, Each Holding 1½ Gross Tons — Hoisting Shaft Has Coal Well Carrying Coal to Skip-Loading Level — Shaft Capacity 10,000 Tons Daily — Steel Guides — Hilted Sprags

A previous article† has described how trips of coal in the Rolling Mill mine of the Cambria Steel Co. are discharged by rotary dumps into a well in the Elk Run shaft which carries the coal from the Cement seam to the Miller bed, where a hopper delivers it in measured quantities to a trip of mine cars for delivery to the Rosedale coke plant.

From Elk Run shaft the coal is hauled directly to Rosedale through a heading 7 ft. high and about two miles long. An interesting feature of this heading is its wonderful roof, which is self-sustaining throughout its entire length. Not a piece of timber of any kind is used from one end to the other including the section under the Conemaugh River. It is one of the longest headings in the country to be maintained without the use of timber.

FROM Elk Run shaft the coal is hauled directly to Rosedale through a heading 7 ft. high and about two miles long. †Midvale Steel & Ordnance Co., Cambria Steel Co.
‡"Cambria Steel Co. Drops Coal Down Well, Loads It at Bottom and Hauls It to Oven," Coal Age, pp. 313-315.

Note—The illustration which forms part of the title of the article shows the "bottom," or hanking, of the runway-supply shaft at Rosedale No. 5, which is 159 ft. deep. The roof is so exceptionally good that it stands unsupported over two tracks as adamant as if arched with concrete.

The track is laid with 70-ft. rail, and, as the loads are heavy, it is supported by wood ties. In every other part of the mine including the working faces steel mine ties are used. It is interesting to note that the latter were developed originally largely to meet the needs of the company's own mining operations. They are used wherever rail sections not heavier than 60 lb. per yard are required.

The trips are hauled by electric locomotives, two of these being the largest of their type that have been built to date. They are of the following general specifications: Weight, 35 tons; gage, 45 in.; motors, three 250-volt, each of 125 hp.; height over all exclusive of trolley, 4 ft. 1½ in.; wheelbase, 10 ft.; length over all excluding bumpers, 22 ft.; width overall, 6 ft.; driving wheels, cast iron with steel tires, 36-in. diameter; wheel tread, 3½ in.; wheel flanges 1x1 in.; gear ratio, 15 to 74; control, pneumatic-electric and arranged for dynamic braking; brakes, hand and "straight air"; ventilation of motors, forced. Each of these two 35-ton locomotives will haul a trip of 145 cars, all of which have a capacity of 1½ gross tons.

At the Rosedale end of the heading are two shafts.

ROTARY DUMP IN MILLER SEAM NO. 6 SHAFT. Here the cars from the Elk Run shaft are dumped in a ttipple of the pneumatic rotary type at a speed of 8 cars per minute, in one hour 480 cars can be discharged. Each dump holds two cars. The dump is tilted to the dumping position and back in 6 seconds, the stroke being cushioned on air. Four pneumatic cylinders actuate this dump.
known as Nos. 5 and 6. No. 5 shaft is the man-and-supply shaft. No. 6 is used for hoisting coal. The dumping equipment at the latter shaft is of the pneumatic rotary type, the specifications being quite different from those at Elk Run. Before considering them, the first or upper one in the Cement seam dumps into a coal well which allows the coal to drop down into a storage bin below the level of the Miller seam as shown in a cross-section of the shaft. The dump in the Miller seam discharges directly into another storage bin on the opposite side of the hoisting shaft.

These dumps hold two cars and are designed to operate at such a speed that 8 cars per minute can be dumped continuously, or 480 cars per hour. The actual time necessary for dumping the loads and returning the empty cars to an upright position is 6 sec. Air is used to operate these dumpers, four pneumatic cylinders being provided which permit of the rapid and positive operation of the dump. They are so constructed that each stroke is cushioned on air.

The car hauls used for delivering cars to these dumps are designed each to handle trips of 120 loaded cars. They are able to start a trip from rest and bring it to a speed of 72 ft. per minute, maintaining that speed on a 1 per cent favorable grade. They are operated by a 20-hp. motor. Similar equipment is used for handling the empty cars when they leave the dumps.

The coal from the dumps goes into two weigh pans, one for each dump, each consisting of two units, and is weighed by automatic recording scales. Cut-off gates control the flow of coal into the measuring pockets. Each dump has two of these. They are

THIRTY-FIVE TON ELECTRIC MINE LOCOMOTIVE
This is the largest locomotive of its type ever built for mine service. It is used for hauling trips of 145 cars holding 3,360 lb. each from Elk Run shaft to the Rosedale shaft. It runs on 76-lb. rail, the weight being distributed over six wheels. The gauge of the locomotive is 45 in., the wheelbase 16 ft. and the over-all width 6 ft.

however, it is well to mention the conditions at the point of discharge.

Provisions have been made for receiving coal from both the Cement and the Miller seams in the Rosedale field. Hence two rotary dumps have been provided.
Skip-Filling Arrangements

Coal comes to the skips from two sources, the rotary dump on the left and the coal well on the right. The former is fed by cars filled for the most part at the Elk Run shaft (Rolling Mill mine) and also from the workings in the Miller seam at Rosedale (Rosedale No. 6). The latter takes care of coal from the Cement seam at Rosedale (Rosedale No. 5). Arrangements are made to weigh the contents of each car separately. For this purpose weigh hoppers or pans are placed under half of the rotary dump.

Operated by air, the controls being at the mine level. Each dump has also two loading gates to control the flow of the coal from the measuring pockets into the hoisting skips, which have a capacity of 8 tons. These gates are of the safety type and so designed that they stand open only when the skip is in the loading position at the bottom of the hoisting shaft. The weight of the skips and counterweights operate the gates automatically so that each skip loads itself when it lands at the bottom. If by any chance the counterweights should become loosened, the gates would drop to the lowest position, closing the openings.

No. 6 shaft is 232 ft. deep. Over it stands a steel headframe 175 ft. high. The coal is hoisted up this shaft and dumped into a large storage bin at the top of the building which houses the coal-washing apparatus. The handling of the coal from this point on will be treated in a separate article to appear at a later date.

The shaft has two compartments so that the hoisting is balanced, the empty hoist aiding in the raising of
The full skip. The hoist, itself, having a cylindro-conical drum is located in a building at one side of the shaft and is operated by a 1,000-hp. motor working on a 2,200-volt 3-phase 25-cycle current at 370 r.p.m.

The original specifications called for equipment to handle 17,000 lb. (8 long tons) of coal per trip at the rate of 36 sec. per trip, or 100 trips per hour, totalling 750 tons. The delay allowed for dumping and loading was 10 to 12 sec. This capacity has been greatly exceeded, and the skips are able to handle 20 tons per minute, or nearly 10,000 long tons per day of eight hours. The level of the skip dump is 125 ft. above the ground, making the total approximate travel a little more than 350 ft.

The man-and-supply cages operate in a double-compartment shaft, 170 ft. deep. The hoists each have cylindrical drums 7 ft. in diameter driven by 250-hp. motors operating on a 2,200-volt 3-phase 25-cycle current. The cages have been designed to handle a load of 11,000 lb. and can raise 600 cars of rock per day. The hoist will also lower approximately 11,000 mine props daily (25 in a car) in addition to rails, men and miscellaneous supplies.

One of the most interesting features at these shafts is the installation of 100-lb. standard-rail steel guides. This may be said to be a revolutionary development, for up to the present time it has been thought that it was not safe to use steel for this purpose.

In the past it was believed that safety catches could not take a tight grip on the guides if made of steel, and this objection was raised when the use of them was first broached by the Cambria Steel Co. It was only after exhaustive tests had been made which showed conclusively that a cage could be stopped on steel guides in a distance of 1½ to 2 in. that the installation finally was approved. These guides have given absolutely no trouble, and they have never failed. Any mining man knows the heavy costs of replacements where wooden guides are used, whereas steel guides will last as long as the mine opening itself. Another interesting feature in the construction of this shaft is the use of steel buntions.

At No. 5 shaft, rock cars are landed about 30 ft. above the level of the ground and are discharged by a hand-operated rotary car dump. The car runs into a spring-operated mechanism which clamps it against the bumpers or horns that are permanently attached to the ends of the rails. After a car is dumped and restored to the upright position, a trip releases the spring clamp, and the car is backed out to make room for the next one.

The rock which is brought up out of the shaft at this place is dumped into railroad dump cars and taken to the slag dump. The rotary dump just described is not
FEW IF ANY SHAFTS HAVE STEEL GUIDES BUT STEEL GIVES GOOD RESULTS AT ROSEDALE.

Many have declared that safety catches will not hold heavy cages effectively unless wood guides are provided into which the sharp edges of the clutch would effectively enter. Experiment has shown that catches can be installed that will grasp the 100-lb. railroad-iron guides at this shaft with such force that the cage detached from the rope would stop in 1½ to 2 in. without fail. The rails once placed will give unimpaired service as long as the shaft remains in use. The use of steel buntons also is shown.

much used as little rock is brought out of the mine, most of it being stored inside.

The mining methods at this colliery are much the same as those in general use, room-and-pillar methods being employed. Owing to the exceptionally good top, falls of roof give no trouble.

Drainage likewise presents no special problems. A pump house and sump are located near the bottom of No. 5 shaft. This sump will hold 360,000 gal. of water. Under present operating conditions a three-stage centrifugal pump of horizontal type with direct-connected motor is used, the pump being operated only about 2½ hours in every ten to eleven. Another pump is being installed to be used in case of necessity.

Steel sprags of ½ and ½-in. pipe are used almost exclusively. These are of two types, one plain with a ring on the end, the other with a hilt. Where the hilt is used it is shrunk and welded on the pipe.

Hoisting Engine

This is the main hoist by which all the coal produced in the Rosedale and Rolling Mill mine is lifted. Coal from the Cement bed at Rosedale is dropped down a coal well to a point at which the skips are filled. That from the Rolling Mill mine is dropped down a well at Elk Run shaft to the Miller seam and is hauled to the Rosedale shaft, where it, with the Miller seam coal removed at Rosedale, is also dumped down to the skip level.

HEADFRAME AT NO. 6 SHAFT, ROSEDALE MINES.

This tower is 175 ft. high and is located with the coal washery, a short distance from one end of the coke ovens. The shaft is 282 ft. deep. The coal is dumped into a large storage bin at the top of the building.

Steel sprags are a safety provision as they eliminate many thumb injuries. They are especially suitable for use in rooms but are not so necessary where the cars are spragged by men who are experienced in the work, for, owing to their experience and skill, regular spraggers seldom have accidents of this kind.

The motor barn is a large brick structure built in the
Rotary Car Dumper Used at Surface for Discharge of Slag into Railroad Cars.

Only coal is brought up by the main hoist and it is raised in skips. The rock is brought up in the car by the cage hoist in the manway-supply shaft and is elevated to a point only 30 ft. above the level of the ground. The car is run into a rotary dump which is actuated by springs. Bumpers, or horns, attached to the dump hold the car when it reaches the right place on the rails in the tippler, which then revolves enough of a revolution to discharge the rock. The dump is on an upgrade of 15 per cent so that the car when released will run out of the dump toward the shaft switch by gravity. A 15 per cent grade leads down from the shaft landing to the switch so that the loaded car reaches the dump at some speed, running thereto by gravity. Much of the rock is stored in the mine, and the dump therefore is not kept very busy. What is dumped is taken to the slag pile.

Miller seam, near No. 5 shaft. It is sufficiently large to house the 35-ton electric locomotives. It contains a drop pit and a chain fall and a trolley capable of lifting any motor up to and including the 35-ton size.

A separate room adjoining the barn is used as a supply room for motor parts. It is provided with steel bins, racks and other conveniences in accordance with the best modern practice.

Sand for locomotives is dried at the surface with the aid of steam. It is then passed down boreholes that have been drilled through the overburden to both seams.
The skids which on heavy grades are used under the cars are in many ways original, though the basic idea has been used before. The illustrations clearly show the way in which they are made and applied. They have been used with the greatest success, and they are especially needed where trips of the length of those in this mine have to be handled.

Where timbering is necessary steel mine timbers with wooden legs are used. These are made up of a pair of 4-in. 10-lb. I-beams riveted at the ends to short pieces of channel which serve as caps for 8x8 in. posts. The I-beams are separated by spacers and bolted together. These are known as double cross bars. The diagram shows further details. By this arrangement most of the advantages of all-steel timbering are obtained. Wood posts can be fitted more readily than steel legs as they can be trimmed to the required length by a saw.

The cars at the mine are of unusual construction. They were designed by the general superintendent of coal-mining operations of the Cambria Steel Co., who has patented the form of construction used. The main claim for these cars is that they are unusually strong particularly in a longitudinal direction which is that in which the greatest shocks are usually sustained. In case of accident the wood shock absorber and the method of its reinforcement make it practically impossible to telescope the cars.

An inverted channel section is pressed in the bottoms of these wagons so that it projects upward into the car. On the underside and in the channel section is placed the wooden shock absorber which is a piece of plank 3x9 in. and 9 ft. long. When bolted in place it is flush with the bottom of the car. The ends of this plank are capped by bumpers. The plank cushions any shock the car may receive, and the channel section by its stiffness provides the wood filler with the required strength. Tests have been made which show the greatly increased strength obtained by this method of construction. Two types of cars were tested with identically similar impacts. One of these, an ordinary car, was practically destroyed whereas the other, one of the type just mentioned, received practically no injury.

From the foregoing descriptions it will be seen that these mines are excellent examples of modern and advanced coal-mining practice. Every effort has been made to increase production and at the same time add to the safety and economy of the methods used. Even laymen who visit these mines are conscious of the fact that they are well equipped.

The Cambria Steel Co. operates its mines solely to take care of its own needs and most of the coal produced is converted into coke. The coal from the mine described does not, of itself, coke readily, and it is necessary to mix it with coal obtained from other of the company's mines. This will be taken up in greater detail in a future article dealing with the Rosedale coal washery and the byproduct coke oven equipment, which represent the last word in equipment of this kind.

In conclusion it may be said that one is at no time more struck by the tremendous strides that have been made in coal-mining methods than when one compares the present plant at this mine with those that preceded it. From the days when hand drills, mule-drawn equipment and manual labor sufficed to the present time with its improved methods and tremendous production is indeed a far cry.
Pulleys Having Cork Inserts Set in Face Are Used to Keep Belt from Slipping

A SLIPPING belt on a heavy drive makes trouble, which may be of several different kinds. In the first place the driven shaft or machine is not operated at its calculated speed; second, the belt is subjected to heavy wear and, third, the squeak or squawl developed is likely to be highly objectionable. Various palliatives may be applied. Many belt dressings have been placed on the market that are said to work wonders. Particularly if the drive be at high speed, drilling holes in the face of the smaller pulley (drilling out from 10 to 25 per cent of the area is usually sufficient) may accomplish the desired result and stop slippage.

Still another means of increasing the adhesion of a belt to a pulley is to cover the pulley face with a strip of belt, which should be neatly lapped and riveted or cemented in place. If the emergency is dire and requires immediate correction, even though this be only temporary, sifting powdered rosin between the belt and the wheel usually will stop slipping at least for a time.

All of these expedients, however, are open to many objections. The time to prevent a belt from slipping is when the machinery is first installed—before slippage has had a chance to start. On straight belt drives—that is, those where the belt is not crossed—other things being equal, slipping will take place at the smaller pulley, as this has the lesser arc of contact. The logical method of preventing slippage is to increase the adhesion of the belt to this pulley to such an extent that it will at least equal its adhesion to the larger pulley.

The accompanying illustrations show a 300-hp. belt drive installed in the Coaldale breaker of the Lehigh Coal & Navigation Co., where an attempt has been made to obtain the results just outlined. Here a 44½ in. diameter by 38 in. face split steel pulley provided with cork inserts is mounted on the shaft of the driving motor. This machine has a rated speed of 365 r.p.m. and drives a 12-ft. line-shaft pulley, also of 38 in. face. The motor shaft, as may be seen, is extended to an outboard pedestal bearing mounted on the same bedplate as the motor and moving on guide rails with it. This makes an extremely simple and "husky" drive and one that should give both extreme positiveness and a minimum of trouble. At first sight it would appear that the cork inserts would not be durable but it is said that they wear indefinitely and are practically unaffected by dust, oil or water.

The breaker in which this drive is installed, it may be said in passing, is one of the largest and most modern in the entire anthracite region. The former structure occupying this site burned, and to prevent a recurrence of such a loss the new building has been made as nearly fireproof as possible. Approximately 2,500 tons of structural steel has been used in its construction. It is seven stories high and has about 50,000 sq.ft. of concrete floor and 200 ribbed wire-glass windows in steel frames each 11x12 ft. in dimensions. Pipe coils spreading 30,000 sq.ft. of radiating surface will heat the building in cold weather. Ample toilets, lavatories and drinking fountains also have been installed. These are somewhat of an innovation in breaker construction. All jigs and other machinery are driven electrically, and a central control station has been provided.

A BUSINESS OPPORTUNITY of unusual promise has opened to the byproduct coke industry. Substitutes for anthracite coal must be found. Were production to start immediately, there would not be enough anthracite coal available this winter to go around. Large stocks of byproduct coke are available, thus offering that industry an opportunity to prove that coke is as satisfactory a fuel as is anthracite and can be had at less price. It remains to be seen whether the industry can resist the temptation to exact the highest possible price and sell its product at a small margin of profit with the idea of popularizing the fuel. Under present conditions the industry can get fancy prices for its product. The hope is expressed by federal officials that the industry will show enough collective sense to sell coke at the lowest possible price and will send out a large force of men to show how coke may be burned to the greatest advantage.
By Uniting Two Collieries and Building a New Breaker Operating Cost and Degradation Will Be Reduced

On an Output of 430,000 Tons per Annum Madeira-Hill Interests Expect to Reduce Their Operating Force by Between 150 and 255 Men Exclusive of Eight Pumpers

By Dever C. Ashmead*
Kingston, Pa.

In the early days of anthracite mining a breaker was built at almost every mine opening. Originally these structures were of small size and when their capacity reached 200 tons per day they were considered large installations. It was found, however, that much labor was required to operate these many small plants and when this became expensive and difficult to procure consideration was given to the consolidation of the many small breakers into a few of much larger capacity.

By building larger and more efficient breakers it was possible not only to make one new breaker take the place of two or more, simultaneously reducing the number of men employed in actual preparation, but also to cut down the outside force. A specific example will illustrate this general principle.

Two anthracite companies, known as the Greenough Red Ash Coal Co. and the Colonial Collieries Co., are each subsidiary to the Madeira-Hill Co. The breakers of these two firms are now about 5,600 ft. apart. The two properties under operation were separated by a tract of land 1,400 ft. wide, controlled by another company. The Madeira interests accordingly obtained possession of this piece of ground, and the two properties were thus consolidated.

Double Plants and Forces Necessary

The annual output from one of these collieries totals about 250,000 tons, and that of the other reaches approximately 180,000 tons. Under present arrangements two breakers are required to prepare this coal. Consequently two distinct forces of breaker and outside employees as well as two breaker and two outside forces are necessary. In addition to this, six pumping stations are required underground to handle the water produced each day.

All told, about 400 men are employed in and about these surface plants, 145 of whom are used in actual coal preparation. Furthermore, the breaker at the Greenough colliery is somewhat behind the best modern practice, and although the resulting product is of good quality, breakage and waste is excessive. At Natalie the breaker is more modern, but it is located well away from the center of the property as now constituted.

After careful investigation of existing conditions and the savings made possible through a consolidation of preparation operations, a point approximately midway between the present breakers was selected as the site.

Note—The frontispiece shows the surface plant of the Greenough Red Ash Coal Co. colliery at Marion Heights, Pa., which will be abandoned as soon as the new plant is completed that will combine the workings of this mine with those of Natalie.

*Anthracite Editor, Coal Age.
of the new shaft and preparator. This shaft will be sunk to the coal bed, a distance of 450 ft., and from its foot tunnels will be driven to connect with the present workings of both the Greenough and Natalie collieries.

This arrangement will present many advantages. All the surface haulage with which the present plants have to contend will be eliminated. By the time the new plant is completed the two or three small slopes now tributary to these breakers will be worked out and the roads leading to them will no longer be needed. Difficulties incident to transportation on the surface during the winter will be overcome, and the haulage, being entirely underground, will be conducted under more nearly uniform conditions. The six pumping stations now in operation will be consolidated into one. At present eleven men are required to take care of the pumps whereas under the new arrangement only three will be necessary.

In order to make the requisite underground connections it will be necessary to drive approximately 6,300 ft. of tunnel exclusive of the sixth lift in the Lykens bed. At present three slopes and one shaft are employed, requiring the services of eight hoisting engineers. Under the new scheme only one shaft and one slope will be used, for the operation of which only four hoistmen will be required.

At present the existence of two collieries signifies that two complete outside and two office forces must be maintained. Combining these plants will permit a similar combination of these organization units with a corresponding saving in expense. It is possible that the services of as many as 150 men will be dispensed with, as at present 260 employees are required for this work. Breaker, or preparation, forces might also be reduced as the result of such a consolidation. At present an aggregate of 145 men is required to prepare the coal. In the proposed new structure on account of improved equipment and processes now developed and available, forty to fifty men will be enabled to prepare the mine product effectively.

From the above estimates it will be seen that theoretically at least the services of 267 men may be dispensed with. It is hardly to be anticipated, however, that this saving will be realized fully. If, however, the consolidation of operations results in a saving of necessary labor amounting to the services of only 150 men and that their average wage is only $3.50 per day, the total saving in wages would be $525 daily. Assuming that these men normally would work for 265 days per year, an annual saving would be made in labor alone totaling approximately $140,000.

In addition to this labor saving, the cost of preparation could be lowered, for in a new breaker of this kind better design and improved methods of treatment will reduce the degradation of the coal. The figures presented above are not actual as will be promptly recognized by all those familiar with the conditions existing throughout the anthracite region. Thus the rate of $3.50 per day is too low but is here presented to show the obvious possibilities involved.

The new headframe and breaker will be of steel and as nearly fireproof as they can be made. The rest of the new buildings about the plant will be of hy-rib steel lath covered with stucco. This building group will consist of a combined machine, blacksmith and carpenter shop, a supply and office building, a house over the mine hoist, a motor-generator set and a compressor, a substation, a boiler plant (used for heating only), a locomotive barn, an oil house, a magazine, a local-sales scale house, and a modern timber yard. Of course a thoroughly modern wash house also will be provided. This building will be of sufficient size to accommodate 350 to 400 men.

Preparation within the breaker will be of the "wet type, and all sizes of two distinct kinds of coal will be prepared. That is, the Red and White Ash coals, both of which will be produced at this operation, will be prepared separately. All machines will have individual motor drives, but these will be controlled from a central switchboard.

The advantages to be derived from the proposed consolidation are manifold. They may be stated as follows: (1) Several miles of surface transportation now necessary will be entirely obviated; consequently no delays can be caused by inclement weather. (2) One breaker employing forty or fifty men will replace two requiring 145 men. (3) One outside

**COMBINED PLAN NATALIE AND GREENOUGH COLLIERIES SHOWING NEW DEVELOPMENTS AS PLANNED**

A shaft will be sunk and a breaker with all the structures essential for the operation of an anthracite mine will be erected. Gangways will be extended and two large turnouts provided. A long tunnel will take the water from a low point in the Natalie mine to the surface along the course of Coal Run Creek.
How to Find Economical Size for Airshaft

BY M. H. HALL*

When determining the size of an airshaft to serve a proposed mine it was customary until recently to make it conform exactly with the two hoisting compartments of the main shaft. These latter are usually designed to accommodate the mine car to be hoisted or are made similar to similar shafts operating satisfactorily under like conditions in the same region.

Such airshafts are not in accordance with good engineering. In many cases openings so proportioned have to be enlarged after a few years in order to decrease the pressure necessary on the air current, for a sufficient volume cannot be forced through the mine without an unreasonable expenditure for power.

The factors governing the economic size of an airshaft are as follows: The estimated life of the mine, the cost of sinking and lining, unit power cost, volume of air required and the interest rate on money invested.

The following table has been computed, assuming a depth of shaft of 100 ft., a coefficient of air friction \( k = 10\) and the following assumptions concerning costs, life of property, etc.: The estimated life of the mine is taken as 50 years, the cost of excavation at $15 per cubic yard, the cost of concrete lining as $30 per cubic yard in place, the volume of air required as ranging from 100,000 to 600,000 cu. ft. per minute, the unit power cost as 2c. per kilowatt-hour, and the interest rate on the investment as 6 per cent.

In the left-hand column the sizes of the assumed square shafts are shown, in the second column is placed the sinking or first cost. This includes the excavation and the concrete lining, both at the rates assumed. The third column contains the annual interest charge at 6

</table>

Per cent on the first cost of the shaft, plus the sum that must be placed yearly at 6 per cent compound interest in order to amount to the first cost of the shaft at the expiration of 50 years or the life of the mine. This sinking fund or extinguishment charge is absolutely necessary in order that the original capital be not impaired.

The next and succeeding columns showing the assumed volumes of air to be circulated per minute are double. The left-hand half shows the power cost per year. This is the cost of maintaining the ventilating current continuously for one year at the assumed rate of 2c. per kilowatt-hour, based on an over-all mechanical efficiency for combined fan and drive of 66½ per cent. This is probably somewhat higher than is commonly attained even in first-class installations.

The total annual cost will obviously be the sum made up of the figure shown in column 3 plus the power cost for a given volume. This sum is tabulated in the second or right-hand half of the double column under the subhead "Total Cost, Year." Inspection of the total annual costs set forth in this column shows that a small shaft entails a high annual expense. This gradually decreases as the cross-section of the shaft increases until a size of maximum economy is reached, the increased fixed charge of which equals the decreased power cost.

In each total yearly cost column a horizontal line is drawn below the minimum cost for each assumed volume, making a broken or stepped line across the table. Following any horizontal portion or step of this line back to the first column the most advantageous size of square shaft to pass any assumed volume of air will be found.

The process involved may well be illustrated with an example. Suppose that it is desired to ascertain the economical dimensions for a shaft to pass 500,000 cu. ft. of air per minute. In the column subheaded "Total Cost, Year" under the volume heading of "500,000 cu. ft. per minute" the lowest cost is found to be $3,225 for a shaft 100 ft. deep. Following the line below this figure to the first or left-hand column the cross-section of the shaft is shown to be 20x20 ft.

Again suppose a comparison is desired between the relative economies of shafts of correct and incorrect cross-sectional areas. Assume that the proposed shaft will be 600 ft. deep and that 500,000 cu. ft. of air will pass as before. From the table, under the volume heading of "500,000 cu. ft. per minute" and the subheading "Total Cost, Year" a minimum of $3,225 for each 100 ft. of shaft depth is found. As the shaft is to be 600 ft. deep the total expense obviously will be six times this amount or $19,350. Now suppose that an attempt is made to ventilate the mine with a shaft that is 10x10 ft. in section, involving, of course, a greatly decreased
first cost. Under "500,000 cu. ft. per minute" and opposite a 10x10 ft. shaft a total yearly cost of $30,416 is found for each 100 ft. of depth, or a total cost for the shaft in question of six times this amount or $182,496. Subtracting the total yearly cost for the 20x20 ft. shaft from that of the 10x10 ft. shaft we have $182,496 — $19,350 = $163,146. This sum represents the annual loss chargeable to lack of knowledge or to failure to apply the principles of engineering economics.

This sum if placed at interest at 6 per cent and compounded annually will amount at the expiration of 50 years to approximately $47,367,800. On the other hand the saving effected by sinking a 10x10-ft. shaft in preference to one 20x20 ft. in dimensions, or $140,160 if also placed at interest at 6 per cent and compounded annually will amount to approximately $2,581,800 at the end of the 50-year period.

Evidently the ultimate economy obtainable from the larger shaft will amount to $47,367,800 — $2,581,800 = $44,786,000 at the expiration of 50 years or the estimated life of the mine.

All figures here set forth are the results of slide-rule calculations. They probably are sufficiently accurate, however, for all practical purposes.

Speed-Reducing Gear Lowers Headroom
Needed for Loading-Boom Hoist

NECESSITY, in a low-roofed machine shop exercising her well-known maternal instinct toward invention, has produced a new type of electric hoist which conserves room, is rapid in operation and readily spots a loading boom or other load. The machine is expected to reduce the degradation of coal during loading for those who supplant hand power with mechanical for the raising and lowering of loading booms. For two years this machine has been in everyday use, several sizes having been employed for various purposes in shops and foundries. Some months past three units were installed by the Sincerity Coal Co. at Marion, Ill. This hoist, known as the McCollum, is now being formally introduced to the coal industry by Roberts & Schaefer, engineers and contractors, of Chicago.

The Sincerity Coal Co. has three double-chain hoists of this type, attached to an equal number of shaking loading booms. The capacity of each of these hoists is 2 tons but machines are made in 2-, 3-, and 5-ton sizes. They are applicable to either the shaking or the apron type of loading boom; the double-chain hoist (Fig. 1) is especially adapted to the shaking type, and the single-chain machine (Fig. 2) to the bottom of apron type.

The new hoist is simple, compact and rugged. All these desirable qualities are made possible by the use of a special annular gear reduction interposed between the motor and the chain sheave. By the use of this gearing a high ratio of speed transformation is obtained efficiently and in a small space. This makes it possible to employ a high-speed motor, one of 1,800 r.p.m. being generally used. Such a motor is lighter, less cumbersome and cheaper than one delivering the same power at a slower speed.

This speed-reducing mechanism can be driven only from the motor end. As a result the torque produced by a suspended load has no tendency to cause the mechanism to rotate and allow the load to descend. This feature makes it possible to do away with the strong electrical and mechanical brakes heretofore essential in hoisting apparatus. A small friction brake is employed to check the momentum of the motor rotor when current is shut off. This permits accurate placing of the load.

FIG. 1. DOUBLE-CHAIN BOOM HOIST OF SIMPLE DESIGN

One chain is attached to each side of the boom or chute and passes over a suitable sheave on the main shaft. Thus as this shaft is revolved both sides of the car-loading device are raised or lowered evenly. Motor control is obtained by means of a rope hanging within easy reach of the car trimmer.
Safety-First Instructions Much Needed In Mining

Disregard for Safety-First Rules Causes Accidents—Miners Not Wholly to Blame—Safety Instructions Needed to Reduce Accident List

Reading the interesting letters that have appeared in Coal Age, discussing the accident that occurred when a miner was burned by going over or around a fall of roof, in his working place, in attempting to see if the fireboss had marked the face of the coal, I have been impressed with the thought that there must have been a lack of suitable safety instructions in that mine, either that or the miner wholly disregarded the instructions given him.

In the first place, let me say that I do not approve of a fireboss marking only the face of the coal to indicate that he has examined the place and found it safe for work. That is not to say, however, that a fireboss should not mark the coal face; but I contend he should also leave a mark at the last breakthrough, unless it is understood that the miner, not finding any mark back from the face, can assume that the place is safe for him to proceed to his work.

Lack of Safety-First Teaching Responsible for Accidents

In my opinion, the lack of safety-first teaching in that mine, had more bearing on this accident than anything else. I feel that if men are properly taught, along the right lines, they will not attempt to go over a fall to hunt a supposed mark made by the fireboss.

Finding a mark on the face of the coal, beyond the fall, would only show that, either the fireboss had made a very hasty and careless examination of the place, or that a condition had developed since and the fall had taken place after the fireboss had gone.

Taking all into consideration, I cannot say, as many have already claimed, that this miner was wholly to blame for the injury he received when he went beyond the fall. My thought is that some blame attaches to all concerned. It seems to me that there could not have been sufficient interest taken by those in charge and whose duty it was to give the men the necessary safety-first instructions.

After an accident has happened, it is always easy to tell how it might have been avoided. I wonder how many mine officials, who have read these letters, have similar conditions now existing in their own mines and, yet, give the matter little further thought, passing this warning by as of little importance.

That, to my mind, is our worst trouble. We read an account of what happened in the other fellow’s mine; but it does not occur to us that the same thing is liable to happen in our own place. If the same thing should occur with us, however, we would at once get busy and do what was necessary to avoid its recurrence.

There are roof conditions that make it impossible for any man to examine and say with assurance that it will not fall within two or three hours, though there may be no signs of weakness apparent at the time the examination is made.

For this reason, I do not feel that a fireboss can be held responsible for such an occurrence as the one mentioned. However, to make myself clear on the situation, I believe that should such a thing happen—it ought to make a fireboss more cautious and thorough in his future examination of places. In other words, the lesson should not be without its moral effect.

My observation proves to me that many accidents in mines result from the lack of interest on the part of both the men in charge and the workers; and this applies to other industries as well as to coal mining. The men in charge too often pose as leaders while their acts belie their claims to leadership.

Certified Men Mistaken Who Think They Know It All

Speaking of certification, I cannot but think that many of our certified men feel as if they knew it all, and have done and are doing all that is required of them as officials. Here, let me say, is where they are all wrong. When a man receives his certificate he has only just started; stopping there, it will certainly prove a failure.

When a man is placed in charge of a mine is the time he should start to study and train others in regard to the meaning of safety-first. He should organize safety-first meetings, with the aim of giving instruction along lines that will make work safer for the men and more effective.

Any mine superintendent or foreman who regards such efforts as a waste of time is unworthy of his calling and unfit for the position he holds. A good rule for any man to follow is to try to teach other men what he has been taught and what has helped him. It is no waste of time for a man to be a booster of safety-first. It pays.

It has always been a surprise to me that mine officials, whose companies are spending large sums of money for safety, rarely talk safety to their men, or give them needed instruction along that line. Let us hope that a deeper interest will be taken by mine officials everywhere in starting and maintaining safety-first and institute meetings, for the benefit of their men.

Teach Rudiments of Mining in the Common Schools

Decrease of American Miners—Cause found in lack of early education—Effect shown in accident list.

One of the outstanding features in the mining of coal that is apparent to even the casual observer is the rapid decrease of American miners employed in our mines. Other writers have drawn attention to this matter and numerous remedies have been suggested, such as courses of training for miners and other incentives to the study of mining.

It is generally conceded that the employment of so large a class of foreign labor, ignorant of the principles of mining and unable to speak the English language, is responsible for the high accident list. Closer supervision of the work has been advocated as a means of eliminating many preventable accidents. It appears to me, however, that we have not as yet gotten at the root of the matter.

In seeking to ascertain the cause why young men, born and bred in mining communities, drift into other occupations, I am led to conclude that the underlying cause for their choice is the lack of early education in mining and its allied subjects.

In our school system, even in mining communities, it would seem that little, if any, attention is given to the teaching of the rudiments of mining in the common schools. Children are taught almost everything bearing on other callings and industries. But those subjects that deal with underground conditions, the study of the coal for...
Firebossing

Time and distance important factors in firebossing—Full may occur in a place examined shortly before—Fireboss foolhardly to attempt to pass beyond a fall.

Speaking of firebossing and the possibility of a fall taking place after the examination is made and before the men enter for work, I am of the opinion that such a thing is liable to happen at any time and when the fireboss is a conscientious and careful in his work. It must be remembered that time and distance are two important factors in the work of a fireboss. In many of our large mines, it is not uncommon for a fireboss to have to travel a mile or more underground, before he can reach his section of the mine where his work begins.

Firebosses Ordinarily Given Too Large a Territory

Perhaps, the section in his charge may include two series of headings 450 ft. apart. We will say there are twenty places, ten pillars and ten rooms driven to an average depth of 200 ft. on 50-ft. centers, in the first pair of headings and the entries are advanced, say 400 ft. beyond the last room. It is easy to see that by the time this fireboss has reached the main entry again, he will have traveled at least one mile. He must then go 450 ft. to the mouth of the second pair of headings where, we will say, he has ten more places to examine. The rooms, here, may be driven to an average depth of 150 ft. It is clear that by the time the man has returned to the shaft bottom, he will have traveled between four and five miles.

Fireboss Must Enter Report in Book After Examination

Even walking at the rate of 6 ft. a second, or four miles an hour, more than half his time will be consumed in walking. In the meantime, he has examined for gas and other dangers between thirty places in his section and is fortunate indeed if he gets back in time to enter his report in the book kept for that purpose, before the men enter the mine for work.

In many instances, a fireboss' work is harder and his route longer than what I have mentioned, and he is often obliged to save time by passing through the breakthroughts, at the faces of the rooms, which is a common practice.

Let me say, in closing, that it would be foolhardy for a miner, on entering his place and finding a fall had occurred, to attempt to pass beyond the fall. A miner would deliberately do this and be burned by the gas ignited by his lamp, would deserve all he suffered by reason of his foolhardiness.

Gans, Pa.
R. W. LIGHTBURN.

Explosibility of Gaseous Mixtures

Experiments of Bureau of Mines show explosive range of methane and air in presence of carbon dioxide—Influence of other gases not determined.

Kindly allow me to express my opinion in reference to the explosibility or non-explosibility of the mixture of gases, described in a question given in a recent firebosses' examination, in Indiana, and which was answered in Coal Age, Feb. 9, p. 252.

The question stated that a chemical analysis of mine air showed the following composition: Nitrogen, 80 parts; oxygen, 12 parts; marsh gas, 8 parts; carbon dioxide, 3 parts; carbon monoxide, 1 part; hydrogen sulphide, 1 part. The answer given to the question states that this mixture is highly explosive.

In the issue of March 16, p. 455, in reply to a correspondent who expressed doubt as to the mixture being explosive, the editor says that eight volumes of oxygen are required to consume the three volumes of methane and one volume, each, of carbon monoxide and hydrogen sulphide; while there are twelve volumes of oxygen present in the mixture, or half again as much as is needed.

Explosion Determined by Trial

My belief is that the question as to a mixture of gases being explosive can only be fully determined by experiment. Not having the necessary equipment for doing this, I have examined results of similar experiments performed by the Bureau of Mines, as published in Technical Paper No. 43 entitled "The Influence of Inert Gases on Inflammable Gaseous Mixtures," by J. K. Clement.

The paper describes a series of experiments performed to determine the explosive range of methane when mixed with varying proportions of oxygen, carbon dioxide and nitrogen. For that purpose, mixtures of these gases were introduced into a Hempel explosion pipette and its ignition tested by an electric spark.

A similar series of experiments were performed, on a larger scale, in a steel explosion cylinder, with the result that a wider explosive range of the gas was determined in this manner. With pure methane and air, no carbon dioxide being present, explosions ceased when the oxygen content fell to 14 per cent, the methane ranging from 6.5 to 6.9 per cent. Under the same conditions in the steel cylinder, explosions ceased when the oxygen content fell to 13 per cent, the gas then ranging from 6.3 to 7.1 per cent; while a 14 per cent oxygen content gave an explosive range of the gas from 6.2 to 8.2 per cent.

Influence of Carbon Monoxide on Explosion of Firedamp

My conclusion is that with an oxygen content of 12 per cent, as stated in the question to which I have referred, there would be no explosion of the mixture. As to the influence of the other two explosive gases, carbon monoxide and hydrogen sulphide, in this mixture, I may refer to Technical Paper 134, published by the Bureau of Mines and entitled "Explosibility of Gases from Mine Fires."

In that paper, page 13, speaking of the influence of carbon monoxide on the inflammation of methane, after showing that, as the percentage of methane decreases, an increased percentage of carbon monoxide is required to produce inflammation in the mixture, the authors state: "When about 3 per cent of methane is present, there is needed about 6.5 per cent of carbon monoxide to produce an explosion."

Calculation shows that such a mixture contains (100 - 9.5) 90.5 = say 19 per cent of oxygen. No experiments are shown with a lower oxygen content; but I am sure that with only 12 per cent oxygen, as in the question to which I have referred, no explosion could occur.

No Reports on Influence of Hydrogen Sulphide

No experiments are available showing the influence of hydrogen sulphide, in mixtures with reduced oxygen content. Although I realize, as stated in the question to which I have referred (page 455), that both carbon monoxide and hydrogen sulphide are more readily ignitable than methane, and both of these gases are present in this mixture; I fully believe that, while the mixture may be inflammable, it will not explode.

Many factors will modify the ignition and explosion of a gaseous mixture, which depends on the chemical heat of the reaction, the pressure, the source of ignition and its duration, as well as the velocity at which the mixture is moving and other items. Our
technical literature is extremely poor on mine matters. Max Suter.

Herrin, Ill.

[Experiments under the conditions that prevail in the mine must always throw much light on the question of the inflammation and explosibility of gaseous mixtures. The laboratory experiments referred to by this correspondent have value, but they fail to even approach the conditions that prevail in practice in the mine. As the correspondent has stated, many factors modify the results obtained.

Referring to Technical Paper No. 43, it should be remembered that the experiments there described relate to mixtures of methane, air and carbon dioxide. The author states (p. 21) as follows: "The results apply to mixtures of these four gases only and not to mixtures containing appreciable quantities of carbon monoxide." It must be remembered, also, that besides carbon monoxide, there is also present hydrogen sulphide, both of which gases materially widen the explosive range of methane, which makes this reference not applicable to the present mixture. The fact that there is 50 per cent more oxygen in the mixture than is required for the complete combustion of the explosive gases present, inclines one to the belief that the mixture is explosive.—Editor.]

Analyzing the Foremen

Need of disinterested inspection of mines—characteristics of good and bad foremen—Protection of company interests.

Among the many interesting points brought out in the discussions that have appeared in Coal Age is a remark of George Edwards, in the issue, May 18, p. 845, to the effect that a competent and disinterested person should be employed to inspect the mine and report direct to the management regarding its condition.

I am in sympathy with this writer's suggestion that such an inspection and report is important in order to maintain a uniform production at a mine. The smaller mines, in particular, have only the report of the mine foreman, and if that is biased the mine owner may be in total ignorance of the true condition existing underground.

Characteristics of Different Types of Foremen

As is well known, there are foremen and foremen; and the problem of the operator is to know that he has the right man—one on whom he can depend. My impression is that there are three classes of mine foremen, namely: good, medium and bad.

Each of these types or classes have their characteristics. A good foreman is a man who knows how to develop a good mine for the company. Naturally, he meets with difficulties that increase the cost of production. He does not pretend to hide or misrepresent the facts.

This foreman is not noted for his ability to make things appear better than they are. He is on the job to work and not to spend time and effort in an attempt to deceive or mislead his employers. His thoughts are given to the improvement of the mine and for this he works hard.

In contrast with this type of official, there is the foreman whose chief characteristic is the regard he has for his own interest even to the neglect of the welfare of the company who employs him. His only thought is how to make things appear well to the company as long as he is with them. He gives less attention to maintaining roads and air-courses in good condition, because these items increase the showing on his cost-sheets. His chief efforts are expended in putting out the coal, which he thinks will please the management best.

The report of conditions in the mine, by this type of foreman, is flowery indeed. He always dwells on how much lower he can make the cost-sheet the next month. He continues in this course of deception as long as he feels it is safe and then begins to look for another place where he can play the same game and get away with it, which he always hopes to accomplish.

Midway between these two types of foremen, there is a third class, best described as plodders. They are not particularly dishonest and, perhaps, do not intend to deceive. But, they are wholly unsuccessful in their management of the mine. In a few words a man of this type is not fitted for the position he holds.

Know Your Mine Foreman

In the foregoing, I have attempted to analyze typical mine foremen as we find them in charge of mines. With larger coal companies, the problem of knowing the exact condition of the mine is not as acute as with smaller operations. Many large companies employ private inspectors, besides having other means of knowing the progress and condition of the work underground through their engineers.

Employment of private inspectors is, of course, out of the question with the small operator, which makes it one of the more important that he should select and hold the right man in the position of foreman. It goes without saying that such operators should be more than ever cautious in the selection of the foreman; or be, themselves, thoroughly familiar with the conditions inside of the mine. On that, more than on anything else, depends the ultimate success of the operation.

Of General Interest

Increasing Ventilation in a Drift Mine

Drift Mine Opened on Hillside—Main Entries Driven Nearly a Mile—Ventilation Becomes Poor—Shaft Sunk One Thousand Feet from Head of Entry

Some time ago we opened a drift mine on a hillside. The main intake entry and haulage road is driven 12 ft. wide and 6 ft. high. The air-course is 9 ft. wide and 6 ft. high. These entries have now been driven a distance of 4,200 ft. The mine is ventilated by a fan, which produces 40,000 cu.ft. of air per min., at an expenditure of 8 hp.

In order to improve the circulation of air in the mine, it has been proposed to sink an air shaft at a distance of 1,000 ft. from the face, on the 6x9-ft. air-course. This shaft will be 8x8 ft. in section and 120 ft. deep, measured from the surface to the coal. The question I want to ask is the following: Estimating on an outside temperature of 54 deg. F., and a mine temperature of 60 deg. F., what horsepower will be required to produce a circulation of 60,000 cu.ft. of air per minute in this mine after the change is made?

In replying to this question, we will assume that the two main entries 6x12 ft. and 6x9 ft., in section, respectively, are driven into the hill a distance of 4,200 ft. and practically level. Though not so stated, it is assumed that the fan is located at or near the mouth of the main return air-course and operated on the exhaust system.

We understand that it is proposed to sink an 8x8-ft. shaft, 120 ft. deep, at a point 1,000 ft. from the head of the air-course, as indicated in the accompanying diagram. When this change has been made, it is assumed that the fan will be moved to the top of the air shaft and operated, as before, as an exhaust fan.

The new arrangement will cut out 3,200 ft. of the 6x9-ft. airway and the resistance of the shaft will be added, which is very slight. It is not clear, however, how a circulation of 40,000 cu.ft. per min., can be produced in this.
mine by an expenditure of 8 hp. Calculating the power on the air in the usual manner, using the modified Atkinson co-efficient (0.00000002), the horsepower on the air is

\[ H = \frac{4,200 \times 40,000}{0.00000002 \times 33,000} = 46.7 \text{ hp.} \]

Then, assuming the combined efficiency of the fan and engine as 60 per cent, the indicated horsepower of the engine driving the fan is 46.7 - 0.68 = 80 hp., which the correspondent may have intended to state, instead of 8 hp.

In order to ascertain the power required to increase the circulation from 40,000 to 60,000 cu.ft. per min., by sinking the shaft and cutting out 3,200 ft. of the old air-course, as stated, it is necessary to calculate the potential factors of the main intake, 4,200 ft. long; the return air-course, 1,000 ft. long and the shaft 120 ft. deep, as explained under "Tandem Circulations," Mine Gases and Ventilation, Second Edition, p. 214. The summation of these potential factors gives for the corresponding relative mine potentials, before and after the change, \( X_i = 0.9397 \) and \( X_f = 1.179 \).

Then, since the power on the air varies as the cube of the quantity and inversely as the cube of the potential factor; and taking the original power as 80 hp., the power required after the change is made will be

\[ H_f = 80 \left(1.179 \times \frac{0.9397}{1.179}\right)^{3/2} = 136.7 \text{ hp.} \]

In other words, in order to increase the circulation from 40,000 to 60,000 cu.ft. per min., in the manner proposed, will require, say 140 hp.

**Examination Questions Answered**

**Alabama Mine Foremen's Examination, Birmingham, July 24-27, 1922**

*(Selected First-Class Questions)*

**QUESTION**—Give your ideas fully as to how and in what parts of a mine sprinkling and spraying should be done and state what are the comparative advantages of each plan.

**ANSWER**—Much will depend on the character of the mine, method of working and means employed for mining the coal. In a large mine, particularly when mining a soft, friable coal and using machines for that purpose, an effective spraying system should be installed throughout the mine. This is more important where the coal is highly inflammable and blasting is performed. All roads, travellingways and working places should be thoroughly sprinkled, or sprayed by installing a pipe system extending throughout the mine. Under less dangerous conditions, water cars or lines of hose can be used in place of installing a pipe line. The use of water cars and hose has the advantage of requiring but a small outlay, while a pipe system for spraying is more efficient and water is then always available where it is needed.

**QUESTION**—What gases are found in bituminous coal mines? Give the symbol, specific gravity, composition and properties of each gas, its effect on combustion and state where you would expect to find it.

**ANSWER**—The principal mine gases are methane (CH₄), specific gravity 0.559; carbon dioxide (CO₂), specific gravity 1.529; carbon monoxide (CO), specific gravity 0.967; hydrogen sulphide (H₂S), specific gravity 1.1912. Besides these, there are the heavy hydrocarbons, olefinic gas (C₄H₈), specific gravity 0.978; ethane (C₂H₆), specific gravity 1.0366. The composition of each gas is made known by its symbol.

Methane, carbon monoxide, hydrogen sulphide and the heavy hydrocarbon gases, associated with methane are all combustible and form explosive mixtures with air. Carbon dioxide is an extinctive gas, half again as heavy as air, at the same temperature and pressure. Both carbon monoxide and hydrogen sulphide are extremely poisonous when breathed. Carbon dioxide, though not a poisonous gas produces a strong toxic effect on the system, causing headache, nausea and finally death.

In mining practice, these gases are found mostly where they are generated, the hydrocarbon gases issuing from the pores of the coal and in damp places in the strata adjoining; carbon monoxide being generated wherever slow combustion is taking place in abandoned workings, or produced by mine fires or the explosion of powder or gas; and hydrogen sulphide resulting from the disintegration of pyrites in damp places in the mine. The gases lighter than air tend to accumulate at the roof and in other places, while those heavier than air, chiefly carbon dioxide, are to be found accumulated in dip workings and on the floor or other low places in the mine.

**QUESTION**—What dangers may arise from the use of electricity in mines? Give your recommendations for avoiding each.

**ANSWER**—Mines equipped electrically present the danger of possible contact of men and animals with live wires; possible ignition of gas by the sparking of wires, blowing out of fuses and breaking of incandescent lamps. The first danger mentioned should be avoided by employees being carefully warned by the instructions given them and the notices posted where danger exists; also by properly safeguarding all live wires at points where men and animals must pass under them or near them. The danger of fire, by reason of electrical installation, could be avoided by all such installations being made by a competent engineer and electrician who understands mining conditions and has every regard for the safety of the men employed in the mine and the security of the property.

**QUESTION**—What general conditions would determine the size of pillars and what points should be considered in the removal of pillars?

**ANSWER**—In general, the size of pillars in mines is determined by the depth of cover, character of the roof, floor and coal, thickness and inclination of the seam, method of working employed, presence of gas or water in the strata and the other factors which may result in damage on the surface due to the extraction of the coal.

Before the robbing of pillars is commenced, its effect on the future development of the mine must be considered; also, what effect the drawing of pillars will have on adjoining workings and the inflow of water or gas from the overlying strata or from the surface, and what damage, if any, will result on the surface.

**QUESTION**—How should the ventilation of a mine be arranged to reduce friction and gas explosion to a minimum?

**ANSWER**—A large mine should be divided into separate ventilation districts. Each district should have its own separate circulation, taken from the main intake airway and discharged into the main return. In each district the air current should be made to sweep the working faces in such a manner as to keep them free from any accumulation of gas. Splitting of the air current in this manner will reduce the friction in the mine to a minimum and afford the least danger of an explosion of gas or dust.

**QUESTION**—What method would you recommend for timbering working places, keeping in mind the safety of the workmen and the recovery of the greatest amount of coal?

**ANSWER**—A method of timbering should be employed that is best suited to the conditions at the working face. Where these conditions are more or less uniform, it is well to adopt a systematic method of timbering, the posts being stood in rows parallel to the face and at specified distances apart, the posts in each successive row being staggered. All timbering must be promptly done in the manner described and violations of this rule should be suitably punished.
Million-Ton Duluth Dock Tells Northwest's Coal Story

A "before and after" view of the Pittsburgh Coal Co.'s dock at Duluth, showing the amount of coal carried at the dock in normal times and the long, bare expanse of dock at present. The few piles of coal are for bunker purposes. Some idea of the desperate condition of the Northwest at the end of the coal strike may be gathered from the pictures.

Empty Barges at a Big Fuel Terminal in New York Harbor

Fleet of coal barges lying empty at the Susquehanna R.R. coal pier at Undercliff, N.J., opposite New York City.
Pittsburgh Coal Co. Signs Cleveland Pact; Bringing Peace to Pittsburgh Field

With the signing of the Cleveland conference agreement, Aug. 30, by officials of the Pittsburgh Coal Co. peace again reigns in the Pittsburgh district. The reconciliation was effected suddenly, not as in other sections of the bituminous fields, where indications of the willingness of the operators to meet with the miners made apparent a lost fight.

Late on Tuesday, Aug. 29, the Pittsburgh Coal Producers' Association, acting for operators other than the Pittsburgh Coal Co., signed an agreement with the union to resume operations practically under the Cleveland plan. It was the following day that Pittsburgh Coal Co. signed up independently.

The Cleveland agreement as accepted was slightly modified, omitting "approves and" from that section of the agreement, which reads: "the signer of this supplemental agreement approves and accepts the policy adopted by the joint conference of miners and operators held in Cleveland Aug. 15, 1922."

One of the members of the operators' committee had this to say regarding the modification: "We signed because we were forced to, and those who know us would question our veracity if we appended our names to an agreement approving the articles of this one."

The supplemental agreement was signed in the offices of the Pittsburgh Coal Co. by John A. Donaldson, president, and J. H. Armstrong, general manager of the Pittsburgh Coal Co., and P. T. Fagan, acting president, and William Hargest, secretary-treasurer, of District 5, United Mine Workers.

Governor Sproul announced Aug. 29 that approximately 350 of the 1,050 National Guardsmen, on duty in the bituminous coal region in the southwestern part of Pennsylvania since July 21, would be called back to their homes Friday, Sept. 1. The units are those of the 104th Cavalry and the troops are B, stationed at Woodvale; D, Burgettstown; E, Heilwood; F, Clarksdale, and a machine gun company at Jenners. It was planned to reduce the headquarters outfit of the field and also the service troops of the medical detachment.

Livingstone New President of District 26; Osborne Conclialion Board Reports

Robert Baxter, for the past three years president of District 26 of the United Mine Workers, comprising the provinces of New Brunswick, Nova Scotia and Prince Edward Island, has been buried under an avalanche of votes in his fight for re-election. Dan Livingstone, of Westville, whose home, by the way, is not in the Cape Breton district, defeated Baxter easily, the majority being very large. The elections were held by mail, Baxter losing at every poll. Silby Barrett, international board member, also was defeated, and this means the end of the opposition among U. M. W. officials of the district to the tactics of J. B. McLachlan, district secretary. McLachlan was victorious by a wide margin over W. P. Delaney, who has been vice president of the district U. M. U., and in sympathy with the policies of President Baxter and Barrett. The new president, Livingstone, was formerly an international board member, being defeated last year for that office by Mr. Barrett.

The Osborne conciliation board, appointed to adjust the differences between the miners employed by the Inversness Railway & Coal Co. and that company, has made a report recommending that wages for section foremen be $3.70 per day; all other section employees to be admitted as union men and paid as such; bank headsman 5.5c. per ton for coal and 4.5c. per ton for stone; weighman, a minimum of $100 per month; hoist engineers of category 1, $3.90 per day, and category 2, $3.70 per day.

Late on Aug. 25 the British Empire Steel Corporation and the union came to an understanding, after four days' discussion. The matter was then submitted to the men in a referendum and the outcome was votes of nearly three to one for acceptance. In fact, Phalen local of Glace Bay, which was the most active in the strike, accepted the agreement by a large majority. But the Springhill local defeated the agreement by a large majority, and asked for the recall of the recently elected district officers.

The men will return to the mines in the course of ten days. No date has been set but the men will surely not return until the troops are withdrawn from the mining districts. This will take several days and perhaps a week, as the troops came prepared for a lengthy stay in the mine fields.

Minimum datal rates are to be increased to $3.25 per day with a minimum increase of 40c. daily and adjustments of higher rates according to a schedule attached to the agreement. Contract rates will be increased $0.07. More than one-half cent will be added to machine rates except at Sidney mines, where the increase will be 2c. The contract will terminate not sooner than Jan. 15, 1924.

Independent Connellsville Operators Vote to Stick to Open Shop

Independent coal operators of the Connellsville coke region will never recognize the union but will stand firm on the open-shop policy, declared W. W. Parshall, vice-president of the Fayette County Coal Operators' Association, in a statement issued at Uniontown, Pa., Aug. 31. He denied reports that certain of the independent owners would sign union agreements.

Representatives of fifty companies, at a meeting held Aug. 29, voted unanimously against recognizing the union. One of the features of the meeting was a definite and emphatic announcement that none of the Hillman mines in the Connellsville region would sign the union scale. This was the attitude, also, of the other large operations in the region.

The increase in output from non-union mines in the Connellsville region continues at about the same rate as in recent weeks. During the past week three additional large operations, the Republic plant of the Republic Iron & Steel Co., the Revere plant of W. J. Rainey, Inc., and the Brier Hill Steel Co., resumed work with small forces of strikers who have returned to work with men they have brought in. Throughout the various working plants in the region over 100 strikers have returned to work since the posting of the advanced wage scale.

Will Not Fix Coal Prices in Ohio

The Ohio Fuel Commission, of which George M. Poor is chairman, after a long session Aug. 31, announced that it would submit its report to Governor Harry L. Davis, who appointed it several weeks ago. The commission has been hearing a series of meetings on the subject of possible fixing a fair price for coal in the various Ohio fields, but has not arrived at any decision. It is unofficially announced, however, that the commission will permit the law of supply and demand to prevail, following the example of the Federal Fuel Commission. A number of operators were heard on the subject and it was believed best to permit the ordinary trade developments in the belief that prices will soon decline to what might be considered a reasonable level.

In a recent statement Governor Davis announced that a fair coal price for Ohio will be established even if it was necessary to call a special session of the Ohio General Assembly to enact the necessary legislation. Attorney General John C. Price has been called upon for an official opinion of the power to enact laws for that purpose and he is now looking into the Constitution. Governor Davis wanted to know what, if any, powers the state has under the Constitution to establish or regulate prices of necessities of life under what constitutes a public emergency; what existing legislation there is dealing with such a situation; what new legislation would be possible under the Constitution to make effective such inherent authority as the state has.

Some operators have urged the following provision in the Constitution: "Laws may be passed to provide for the regulation of methods of mining, weighing, measuring and marketing coal, oil, gas and all other minerals."
Coolness of the Industry Toward Coal Legislation Seen As Shortsighted Policy on Capitol Hill

By Paul Wooton
Washington Correspondent of Coal Age

While the coal operators have maneuvered themselves into a position where they must support, outwardly at least, the fact-finding legislation which has passed the House and is now before the Senate, it is quite evident that their support is not wholehearted. Their opposition to the price-control and distribution bill is particularly active. In this they are joined by the American Wholesale Coal Association.

There is a feeling on Capitol Hill and among some of the executive officers of the administration that the course of the coal operators shows a lack of vision. They are moving toward a greater struggle in 1923 than they had in 1922. If prices are high this winter, they will enter the 1923 strike bereft of support from the public and in fact will have to contend with an embittered public opinion. For that reason some argue that they should recognize that this is an emergency and tender their honest advice as to the plan which distribution should follow to get the best results.

In some quarters the attitude of the operators and the wholesalers is referred to as typical of their inability to unite on anything other than a policy of opposition. This policy in the past has alienated many of their friends. Senator O'Byrne, of Missouri, is cited as an example. If any member of the Senate is sympathetic to business it is he, yet his opinion of the coal operators, when expressed privately, would infringe on the postal regulations if it were printed.

In the same way this policy has antagonized other members of the Senate and of the House of Representatives, which, combined with a hostile public opinion certain to be engendered by high prices, means that the operators will enter 1923 struggle as an handicap.

The position of the operators is that the administration is making the same blunders as did the Wilson administration in 1917 when attention is centered on prices rather than on transportation. The drastic Lever law, it is pointed out, resulted in only a few score of indictments for profiteering. The experience with that legislation, the operators contend, has shown that wholesale prices cannot be regulated satisfactorily by law. It matters little if the price of coal be $1 a ton if coal cannot be obtained. The situation was even worse in 1921, the operators point out, because there is much less coal above ground now than was the case then. It can be said that the direct opposition to the control bill is not limited to operators and wholesalers of coal. A large number of consumers, particularly the ones on long contracts, are also in opposition to the measure from Senators who do not believe it good policy to vest such power in the federal government.

Evidently the tactics of the opposition to the pending coal legislation will be to secure delay. Every day that final action can be deferred will diminish the pressure behind the legislation. The rate at which coal will be distributed until the surplus of cars is exhausted will do much to allay public apprehension. The public will not realize that the spurt of production made possible by the surplus of cars cannot be maintained. As the legislation progresses there probably will be a demand on the part of the Pennsylvania Senators for separate machinery to handle anthracite. This will tend to complicate the situation and make it easier to sidetrack the legislation.

The American Wholesale Coal Association also voices determined objection to Senator Reed's (Missouri) amendment to the coal commission bill wherein the wholesale cost of coal would be required on the 1st and 15th of each month to report to the Secretary of the amount of coal purchased and the prices paid for the various grades; the amount of coal sold to retailers and the prices received for the various grades, and the amount of coal sold directly to consumers and the price received for each grade. They also are required to show whether the coal was spot or contract and must cite the date of the contract.

The transportation situation is much more encouraging, although there is doubt, as this is written, as to the effect of the Attorney General's injunction proceeding. Evidently the railroad brothers are much displeased with the shopmen because they did not settle when they had such a favorable opportunity. As a result the bond of sympathy between the shopmen and the brotherhoods has been weakened materially. It also is known that the brotherhoods are entirely out of sympathy with the resort to sabotage.

Official reports by the Interstate Commerce Commission covering the five serious wrecks which have taken place on the railroads during the strike show four were due to the carelessness of train crews and one was caused by wreckers. In no one of the cases did defective equipment constitute a contributing cause.

Western Kentucky Signs Up with Union on Cleveland Basis Until April 1923

After meeting for three days an agreement was signed up by the Western Kentucky Coal Operators' Association and District 23, United Mine Workers of America, in which the Cleveland agreement contract was agreed upon. The operators objected to the Cleveland conference in October, feeling that as they had never been included before it was an effort to bring the field in to strengthen weakness caused by defection elsewhere. They finally capitulated, however. The new agreement runs until April, 1923.

There was no strike in western Kentucky, as the old agreement carried a no-strike clause, under which the workers continued on the job. It is reported that the new agreement calls for $6.79 for inside workers for an eight-hour day. Under the original priority order open-top cars with sides less than 36 in. in height were exempted. That order left 62,000 open-top cars for loading with building and road materials. In a letter to General R. C. Marshall, director of the Associated General Contractors, Commissioner Atchison stated that this action should not be taken as the final word on the subject. Due to the present demand for coal, it is believed that more cars could be released just at this time, but it was stated that the decision will be relaxed still further just as soon as the situation warrants.

New Order Releases 34,000 Open-Top Cars

Thirty-four thousand additional open-top railroad cars have been released from preferential loading. This was accomplished by amending the existing priority order so as to exclude open-top cars with sides 42 in. or less in height. Under the original priority order open-top cars with sides less than 36 in. in height were exempted. That order left 62,000 open-top cars for loading with building and road materials. In a letter to General R. C. Marshall, director of the Associated General Contractors, Commissioner Atchison stated that this action should not be taken as the final word on the subject. Due to the present demand for coal, it is believed that more cars could be released just at this time, but it was stated that the decision will be relaxed still further just as soon as the situation warrants.

Fifteen Killed in British Columbia Mine

An explosion in No. 4 mine of the Canadian Collieries (D) Co., at Cumberland, B. C., Aug. 30, caused the deaths of fifteen miners, three white men and the remainder orientals. All the bodies have been recovered. There were sixteen injured. The cause of ignition is unknown.
Pocahontas Operators Revive 1920 Scale; Wage Increase Was Unsolicited

An announcement has been made by the Pocahontas Operators Association that effective Aug. 15 wages have been advanced to the level of the 1920 scale, such action having been taken at the conference held in Pocahontas. The conference was attended by representatives of the coal operators in the Pocahontas region, the advance amounting to more than any ever before granted at any one time.

The increase made by Pocahontas operators came without the knowledge of miners and was a voluntary act upon the part of the operators, employees not having solicited the increase. It was deemed necessary by the Pocahontas association, however, to restore the 1920 wage scale because of the fact that such a scale was being paid in the Winding Gulf and New River districts, and there was a possibility that such a wage might be adopted by the labor forces elsewhere by virtue of higher wages paid elsewhere unless the rate was increased. Mines in the Bluefield, and similar territory, are paid the same wages as those in the Pocahontas region.

The operators' committee pointed out at the conference that the adequacy of transportation facilities was the big factor in the price of coal at the present time. Mr. Moor- man said he believed the majority of the operators would give the public a square deal and that they would co-operate with the state coal committee in preventing any possible small minority from attempting exorbitant prices.

Mr. McCord said that inasmuch as the state coal commit- tee had no authority to enforce a price on coal it would leave the determination of prices to the judgment of the public and to the operators. It was pointed out that the committee would have the authority to distribute cars only to operators who gave evidence of trying to do the right thing. Mr. Moorman reported the operators were not receiving many orders for coal. Mr. McCord recommended that all consumers who were expecting to receive coal from Washington cancel their orders and place their orders with Indiana coal men.

Amend Service Order 23 to Limit Class 1
Priorities to Extraordinary Cases

Official action of far-reaching importance to the country's public utilities was taken on Aug. 29, when the Interstate Commerce Commission issued amendment No. 4 to Service Order No. 23, which restricts Class 1 priorities on coal to such extraordinary cases as may be designated from time to time by the Commission. Coal intended for emergency uses generally is included in Class 2 priority. Owing to the limited time during which lake transportation will be available, shipments of coal from the Northwest to the lower lake points will be made under Class 1 priorities.

The issuance of this amendment brings the situation back to that which existed when J. W. Lieb issued his first circular to the public utilities. It is expected to correct the evils arising under federal fuel distribution, which was cut off a large number of public utilities from their regular fuel supply, leaving them in an emergency class and compelling them to buy coal at prices greatly in excess of their contracts.

Reports reaching Washington indicate that the public utilities are getting their share of the increased volume of coal being produced, but owing to the fact that reserves have been so generally used up, the situation of a large number of public utilities will continue to be serious for some weeks to come, particularly since they are not allowed to build up stocks and because of the uncertainty of transportation.

Priorities Extended to Cover West, but in Modified and Limited Form

The Interstate Commerce Commission on Aug. 31 issued its Service Order 24, which directs all common carriers by railroad west of the Mississippi River to give priority and preference to the movement of food for human consumption, feed for live stock, live stock, perishable products and fuel, and to the return of empty cars intended to be used for the transportation of such commodities.

Utah Troubles About Over; to Recall Troops

Governor Charles R. Mabey of Utah has under consideration the advisability of recalling the National Guard from the Carbon County coal fields, where they have been on duty for the past few months, following clashes between strikers and the civil authorities. The situation has been quiet for some weeks and the public is getting a little impatient on account of the money needed to maintain the Guard on duty. It is expected that the soldiers will have been sent back to their several communities before these lines appear in print.

Indiana Trusts Coal Men but Commission Will Deny Cars to Profiters

Failing to obtain an agreement with Indiana coal operators to fix a price on coal, the state coal committee has turned over to the operators the responsibility for the establishment of prices that will be accepted by the public as fair. The decision was reached at a conference in the offices of the Indiana Public Service Commission between the state coal committee and the operators' committee. John W. McCord, chairman of the utilities commission; Edward S. Bessin and David Matthews, of the commission represented the state, and William M. Zeller, Jr., and J. T. Moor- man the operators.

The operators' committee pointed out at the conference that the adequacy of transportation facilities was the big factor in the price of coal at the present time. Mr. Moor- man said he believed the majority of the operators would give the public a square deal and that they would co-operate with the state coal committee in preventing any possible small minority from attempting exorbitant prices.

Mr. McCord said that inasmuch as the state coal commit- tee had no authority to enforce a price on coal it would leave the determination of prices to the judgment of the public and to the operators. It was pointed out that the committee would have the authority to distribute cars only to operators who gave evidence of trying to do the right thing. Mr. Moorman reported the operators were not receiving many orders for coal. Mr. McCord recommended that all consumers who were expecting to receive coal from Washington cancel their orders and place their orders with Indiana coal men.

Amend Service Order 23 to Limit Class 1
Priorities to Extraordinary Cases

Official action of far-reaching importance to the country's public utilities was taken on Aug. 29, when the Interstate Commerce Commission issued amendment No. 4 to Service Order No. 23, which restricts Class 1 priorities on coal to such extraordinary cases as may be designated from time to time by the Commission. Coal intended for emergency uses generally is included in Class 2 priority. Owing to the limited time during which lake transportation will be available, shipments of coal from the Northwest to the lower lake points will be made under Class 1 priorities.

The issuance of this amendment brings the situation back to that which existed when J. W. Lieb issued his first circular to the public utilities. It is expected to correct the evils arising under federal fuel distribution, which was cut off a large number of public utilities from their regular fuel supply, leaving them in an emergency class and compelling them to buy coal at prices greatly in excess of their contracts.

Reports reaching Washington indicate that the public utilities are getting their share of the increased volume of coal being produced, but owing to the fact that reserves have been so generally used up, the situation of a large number of public utilities will continue to be serious for some weeks to come, particularly since they are not allowed to build up stocks and because of the uncertainty of transportation.

Priorities Extended to Cover West, but in Modified and Limited Form

The Interstate Commerce Commission on Aug. 31 issued its Service Order 24, which directs all common carriers by railroad west of the Mississippi River to give priority and preference to the movement of food for human consumption, feed for live stock, live stock, perishable products and fuel, and to the return of empty cars intended to be used for the transportation of such commodities.

It is expected that the soldiers will have been sent back to their several communities before these lines appear in print.

Indiana Trusts Coal Men but Commission Will Deny Cars to Profiters

Failing to obtain an agreement with Indiana coal operators to fix a price on coal, the state coal committee has turned over to the operators the responsibility for the establishment of prices that will be accepted by the public as fair. The decision was reached at a conference in the offices of the Indiana Public Service Commission between the state coal committee and the operators' committee. John W. McCord, chairman of the utilities commission; Edward S. Bessin and David Matthews, of the commission represented the state, and William M. Zeller, Jr., and J. T. Moor- man the operators.

The operators' committee pointed out at the conference that the adequacy of transportation facilities was the big factor in the price of coal at the present time. Mr. Moor- man said he believed the majority of the operators would give the public a square deal and that they would co-operate with the state coal committee in preventing any possible small minority from attempting exorbitant prices.

Mr. McCord said that inasmuch as the state coal commit- tee had no authority to enforce a price on coal it would leave the determination of prices to the judgment of the public and to the operators. It was pointed out that the committee would have the authority to distribute cars only to operators who gave evidence of trying to do the right thing. Mr. Moorman reported the operators were not receiving many orders for coal. Mr. McCord recommended that all consumers who were expecting to receive coal from Washington cancel their orders and place their orders with Indiana coal men.

Amend Service Order 23 to Limit Class 1
Priorities to Extraordinary Cases

Official action of far-reaching importance to the country's public utilities was taken on Aug. 29, when the Interstate Commerce Commission issued amendment No. 4 to Service Order No. 23, which restricts Class 1 priorities on coal to such extraordinary cases as may be designated from time to time by the Commission. Coal intended for emergency uses generally is included in Class 2 priority. Owing to the limited time during which lake transportation will be available, shipments of coal from the Northwest to the lower lake points will be made under Class 1 priorities.

The issuance of this amendment brings the situation back to that which existed when J. W. Lieb issued his first circular to the public utilities. It is expected to correct the evils arising under federal fuel distribution, which was cut off a large number of public utilities from their regular fuel supply, leaving them in an emergency class and compelling them to buy coal at prices greatly in excess of their contracts.

Reports reaching Washington indicate that the public utilities are getting their share of the increased volume of coal being produced, but owing to the fact that reserves have been so generally used up, the situation of a large number of public utilities will continue to be serious for some weeks to come, particularly since they are not allowed to build up stocks and because of the uncertainty of transportation.

Priorities Extended to Cover West, but in Modified and Limited Form

The Interstate Commerce Commission on Aug. 31 issued its Service Order 24, which directs all common carriers by railroad west of the Mississippi River to give priority and preference to the movement of food for human consumption, feed for live stock, live stock, perishable products and fuel, and to the return of empty cars intended to be used for the transportation of such commodities.

Utah Troubles About Over; to Recall Troops

Governor Charles R. Mabey of Utah has under consideration the advisability of recalling the National Guard from the Carbon County coal fields, where they have been on duty for the past few months, following clashes between strikers and the civil authorities. The situation has been quiet for some weeks and the public is getting a little impatient on account of the money needed to maintain the Guard on duty. It is expected that the soldiers will have been sent back to their several communities before these lines appear in print.
Winslow Price-Control Bill Passes House; Senate Debates Cummins Substitute

With Democratic Senators voicing disapproval on the grounds that it is unconstitutional and useless, joined at times by Republican Senators in criticism of the measure, the Cummins administration bill designed to bring about equitable distribution of coal and to prevent exorbitant prices was the subject of free debate last week in the Senate which ranged broadly over the subject of coal, the railroad strike and strikes generally.

The general impression is that the Cummins bill, which has been substituted in the Senate for the Winslow bill on the same subject, which was passed by the House, will pass the Senate after extended debate and possibly with clarifying amendments to meet the objections of some senators that it is too broad in some clauses and too weak in others.

Senator Cummins himself declared that in his opinion the measure passed by the House is unconstitutional in that certain of its phrases may be interpreted as an effort to regulate intrastate commerce, and he therefore effected substitution of his bill for the House bill in the upper chamber.

Meanwhile the Borah bill to create a fact-finding commission to probe into conditions in the coal industry was laid aside at the request of its author when called up Friday by Senator Cummins. Senator Borah explaining that the anthracite strike appeared on the eve of settlement in such manner that amendments to his bill might be necessary.

In explaining his bill Senator Cummins said that the greatest question is one of distribution, that the Interstate Commerce Commission needs additional authority to meet the situation, and secondarily that the bill would operate to check runaway prices. He admitted that retailers could not be controlled entirely by the measure, but asserted that future deliveries could be denied retail coal dealers who might sell at exorbitant prices. He urged speedy action.

Senator Sutherland, of West Virginia, declared that while possibly some legislation should be enacted, in his opinion there was more danger in too hasty action than in too deliberate action.

Senator Frankfurter, of New Jersey, called attention to the bills he introduced two years ago and declared that Congress paid little heed, while coal operators and dealers vigorously opposed the measures. Although opposed to nationalization of the mines and government ownership, the New Jersey Senator said he would support the administration coal bills because of the emergency.

Senator Dial, of South Carolina, declared himself in opposition to the distribution bill. He declared that under the voluntary Hoover agreement prices had been increased to those who had contracts for coal. The bill would do harm, rather than good, he asserted.

Senator Underwood of Alabama, the democratic leader, declared the Cummins bill does not give any authority regarding priority of shipments in an emergency to the Interstate Commerce Commission that that body does not already possess under the Transportation Act, to which statement Senator Cummins agreed. The bill merely attempts to regulate prices and will fail in that purpose, declared the Alabama Senator.

Senator Reed, of Missouri, attacked the bill as unconstitutional and inquired at length as it was expected to get more cars to transport coal through mere legislation, greater transportation being the essential need.

Under the stimulus of a letter of approval from President Harding urging action in administration, the bill to regulate distribution of coal and, indirectly, control prices at mines in interstate shipments was passed by the House, Thursday, Aug. 31, 214 to 61.

Only one important amendment was made, that offered by Representative Sanders, of Indiana, providing that the measure shall expire Jan. 1, 1924, which was adopted, 122 to 77. As favorably reported by the Committee on Interstate Commerce, the bill would have had a permanent statute, its operation being suspended by President proclamation at the end of the present emergency but subject to revival by similar proclamation in the event of a future emergency.

Other wise, only perfecting amendments sponsored by committee members were written into the bill, many individual amendments being voted down during the three days of debate.

Attacks against the measure were made by both republicans and democrats of the House, on the grounds that it is unconstitutional, bad policy, will have the effect of retarding coal production, and that while it may regulate the price at the mines it cannot affect the price of coal. Opponents of the bill predicted that the precedent thus established will lead to demands to control the price and distribution of wheat, cotton and other commodities when shortages in these arise in the future.

Advocates of the bill defended its constitutionality and declared the necessity exists because of the shortage of coal and impaired transportation facilities.

Chairman Winslow of the Interstate Commerce Committee, read to the House, Wednesday Aug. 20, a letter from President Harding, under date of Aug. 23, transmitting copies of two bills drafted to meet the coal emergency. One of these was a measure to create a federal agency to buy, sell and distribute coal. The other was the so-called Winslow bill.

The President said that the problem is "a confessedly difficult issue. The limitation of constitutional authority on the one hand and the very great demand for government activity on the other combine to make it a problem well worthy of the earnest and early attention of the Congress. It has been a long and tedious route to the resumption of coal production, and the shortage of stocks and the general anxiety has opened a field for profiteering activities which ought to be discouraged in every way possible within the limits of constitutional law.

With the President's letter was one directed to him by Secretary of Commerce Hoover, inclosing the drafts of the two bills, which the Secretary said had been drawn under the direction of the presidential fuel committee, comprising representatives of the departments of Commerce, Interior and Justice and the Interstate Commerce Commission. The committee favored, the Secretary's letter said, the priority order measure as "being less cumbersome, requiring less expending in the federal organization and being more expedient in application than the alternate plan through actual government possession of coal."

"The committee is in agreement," continued Secretary Hoover's letter, "that the exertion of such powers in times of peace is highly distasteful, and can only be justified as a measure necessary to provide against the effect of a famine in so necessary a commodity."

"We are deeply impressed with the fact that, due to the almost total exhaustion of coal stocks and the inevitable and growing shortage in transportation, the difficulties of the country will be very great even with the resumption of coal production, and unless there is legislation enacted that will curb profiteering and will give control to distribution, there will be great suffering and difficulties during the period of readjustment."

Readings of these letters quieted the criticisms that the President's desires were not known to Congress and it was considered probable that the bill would be driven through the House within an hour, but the fact developed that a quorum was not present and a recess until Thursday was taken.

As passed by the House, the bill extends the authority of the Interstate Commerce Commission to issue orders of priority or embargo in the distribution of coal in interstate commerce, and creates a Federal Fuel Distribution with a Distributor to be named by the President, who may appoint assistants and whose duty is shall be to investigate supplies.
and demands, normal prices and current prices of coal and other fuel, and to make recommendations to the Interstate Commerce Commission. It is proposed to deny a car supply to those who charge prices above a "just and reasonable price." Penalties are provided for diverting coal from or by the consignee. An appropriation of $250,000 is carried, or $50,000 of this-to be available to pay the expenses of the presidential fuel committee in handling the situation through voluntary agreements.

The principal fight against the bill was directed at its price-control features and against the proposal to make it a permanent law. Repeated efforts to amend the former sections were defeated. In the latter attack, the entire section was stricken out in committee of the whole, 95 to 65, on motion of Representative Rayburn, of Texas, supported by Chairman Madden, of the appropriations committee; Representative Graham, of Pennsylvania, and other leaders on both sides, but Chairman Winslow, of the Interstate Commerce Committee, demanded a roll call on this section when the bill was in the House proper and it was restored by a vote of 148 to 134. The amendment of Representative Sanders limiting life of the bill to Jan. 1, 1924, subsequently was adopted over the protests of Chairman Winslow.

Efforts of Representatives Sanders, of Indiana, and Denison, of Illinois, to amend the bill to restrict the appointment and authority of the proposed fuel distributor failed.

### Grand Jury in Herrin Case Proves It Means Business; Union Calls It Labor War; State Strike Threat

A miners' union official has been jailed. That is the first and most important development in the grand jury investigation now going on at Marion, Ill., of the Herrin massacre of June 22. The second most important development is a concentrated propaganda campaign launched by President Frank Farrington, of the Illinois miners, intended to show that union labor as such is being warred upon in the prosecution of the case and that that labor is still open to self-exile under its own law against persecution by capital. Developing out of this above-board propaganda, a threat of a general mine strike in Illinois was surreptitiously made throughout southern Illinois.

The one man whom the law seized Wednesday, Aug. 30, the third day of the grand jury sitting, was Otis Clark, head of a union local and employed as a check weighman in a shaft mine. His arrest was sudden and the effect of it was instant upon the forces of organized labor assembled at Marion frankly to defend whatever union men might be involved. The refusal of Attorney General Edward J. Brundage and State's Attorney Delos Duty to permit the release of Clark under bond and the declaration of Brundage that every man in southern Illinois under suspicion was watched so closely that it was too late for flight brought down an angry storm of protest which vented itself in a flood of letters and warnings of other sorts to the officers of the law pushing the investigation.

At the end of the first week of the grand jury's sessions public sentiment in the solid-union region around Marion had grown so heated that almost any sort of outbreak could be expected. The campaign to make the case appear in the light of the individual laborer's struggle for existence was expected to have such effect that even the "Greater Marion Association" of business men in Williamson County's capital broke loose and notified the Illinois Chamber of Commerce not to stop in Marion this month when the association makes its automobile "good will" tour. The chamber has been active in raising funds to defray part of the expense of the investigation in lieu of state funds for the purpose.

The miners gave vent to their feelings in a second way, including interference, on Friday and Saturday, with the movement of coal trains out of the southern Illinois fields.

The federal government has agents carefully watching the progress of the case. They may even have taken a much more active part in the collection of evidence than has generally been supposed. The general feeling that "nothing will come of it" has about passed away among the people of the southern end of the state. Even the cloak of careful secrecy with which the jury has surrounded its proceedings thus far has failed to cover up the fact that a mass of incriminating evidence has been accumulated in spite of reluctance of witnesses afraid for their lives.

Grand jury action began on Monday morning Aug. 28 with the impaneling of a jury of 23. The miners except one lumber and furniture dealer, one part-time farmer and miner and a foreman who is a farmer now but formerly was a school principal. In his address to the jurors, every one of whom he knows personally, the district judge, DeWitt Talmadge Hartwell, got down from the bench, put his foot on the rail of the jury box and leaned across for a friendly but intense talk on the case that was to follow. The judge told the 23 that they had before them a job for real men, but that he was confident every one of them belonged in that category and that they would reach their findings absolutely without fear or favor. He said it was regrettable that Williamson County stood condemned already in the mind of the nation for lawlessness and a lack of will to enforce the law against criminals. He said he differed from many good friends of his in official position who seemed to hold that idea and that "no considerable percentage of the people of this county can be found who will endorse crime."

Late in the afternoon of Aug. 30, after a long procession of witnesses had gone in and come out of the jury room, the first definite action took place. The quick and quiet indictment and arrest of Otis Clark took place after 4 p.m., when it was noised abroad that Clark had sold a plow for $1.50 and it was feared he was unloading his possessions with a view to disappearing. "They have their first prisoner" was the only comment Frank Farrington would make.

### Northern West Virginia Mines Ratify Union Pact; Raise on Merit System in Logan

Many operators in northern West Virginia have entered into an agreement with the United Mine Workers and others are falling into line in both northern West Virginia and the Kanawha field. There still remains the half of West Virginia, which has about 26 approximately 150 company-operating subdistrict 4 of District 17 and some in subdistrict 3 had signed the union agreement. This was not true as to the Bethlehem Mining Corporation or any of the companies on the Charleston Division of the Baltimore & Ohio. In the Kanawha field there has been no change in the alignment, coal companies south of the Kanawha as a rule adhering to the policy of not signing a union contract. In all it is estimated that approximately 300 companies in northern and southern West Virginia have acquiesced in the Cleveland agreement and signed union contracts.

The increase in wages granted by coal companies in West Virginia, whether operating on the open- or closed-shop plan, has disturbed conditions to a marked extent inasmuch as it is causing wholesale desertions from other industries. Road building is being affected to a marked extent, as many contractors were unable to get men at $6.60 to $7.26 a day paid in the mines. A return to war wages in all industries is foreshadowed owing to the increase granted the miners.

Decision was reached by the Logan Coal Operators' Association late in August to increase wages. The operators made no announcement as to the rate of increase but did make a statement saying that the increase would be granted on the "merit" system. It was pointed out that the increase was granted voluntarily by the operators and that it had become possible to make the increase owing to the higher price prevailing on coal. It is stated by Logan operators that the increase applying in Logan territory is equal to if not greater than that granted in other fields where the 1920 wage scale is now in force.
Lewis Compromises on Contract to Sept. 1, 1923

Anthractite Production Expected Next Week

Long deferred, the solution of this year's strike in the hard-coal regions has been found in a compromise, in which the union gets about everything it demanded and the operators are called on to sign up to the miners' terms until Sept. 1, next—that is for about one year—instead of until April 1, 1924. The miners hail this as a victory, and the operators say nothing, save that they will be glad to get the mines going again.

Negotiations between the miners and operators were broken off in Philadelphia on Tuesday, Aug. 22, to be resumed in Washington on the 29th, following efforts of Secretary Davis and Senators Pepper and Reed, of Pennsylvania, to find some ground for a new conference. On the last day of the month the operators announced that they were ready and willing to start the mines on the miners' terms if the public would give them a "mandate" to that effect, for it is the public that would have to pay the high prices that such a course would entail.

They got the mandate from the public, both in the form of telegram from over the country and a message from President Harding. Accordingly on Saturday night, Sept. 2, they announced that a tentative agreement had been reached, tentative only in that it must be ratified by the miners' convention, called for this week in the region. The agreement provides for continuation of the contract that expired last March until Sept. 1, 1923. It is planned to have the mines in operation by Monday, Sept. 11.

The statement of the operators, given to the press on Aug. 31, asking the public to pass on the question of whether the operators should grant the demands of the miners, follows:

"We are faced with a demand for continuation of war wages beyond April 1, 1923. In order to bring about an immediate resumption of mining we have reluctantly agreed to continue the old wages until next April, but we have not felt that we were justified in going further than that.

"The bituminous miners have gone back to work under the old scale until next April. The anthracite producers know of no reason why their men should not do the same thing, and want to be entirely satisfied that conditions warrant a longer period of the old wages for anthracite miners.

"To continue the war wages beyond next April inevitably carries with it a continuation of present prices. The public has protested against buying at these prices longer than is absolutely necessary. The adjournment taken today was to enable the operators to canvass the situation and to obtain, if possible, the views of others as to conditions which would be fair to all parties concerned, not forgetting those who buy the products.

"If the public necessities for coal and the urgent request of public authorities are such as to induce us to continue the old wages beyond April 1, 1923, this demand must come to us in the form of a public mandate. We will conform our action to such a mandate, but no other reason would impel us to enter into an agreement which will continue for longer than the present emergency prices, to which emphatic objection has already been made."

Illinois Operators Tell Congressmen What Industry's Ills Are and Their Cure

Taking a position opposed to the Cummins bill or anything like it, the Illinois Coal Operators' Association has sent a letter to all Illinois United States Senators and Representatives and some other national legislators stating the operators' stand on the general points now at issue in the industry. The operators contend for arbitration and not for making labor unions legally responsible for their acts. They believe some fact-finding body of able, disinterested men should be appointed by the President to study coal. Admitting many ill in the industry, they declare that most of them would be automatically righted if law and order were maintained, adequate transportation of coal guaranteed and wages reduced. The letter follows:

"With respect to pending legislation before the Congress, you will doubtless desire to know the sentiment of Illinois operators.

"(1) They continue to feel and are positive that there can be no correction of the actual or alleged evils of the industry that does not contemplate equal and adequate control of the organized labor in the industry. Legal responsibility for their acts and a clearly defined form of arbitration for every disputed point on which employer and employee may not agree, either in bargaining a new wage scale and working agreement or in settling disputes afterward arising thereunder, is imperative; otherwise, as the past few months have clearly indicated, the most threatening kind of monopoly will become permanently established and to an extent that will be beyond the control of the government itself, there having been very manifest evidence of the possibility of such ultimate outcome during the past ten weeks.

"(2) Nor is it believed, based upon the experience of the Fuel Administration in 1917 and 1918, as well as the arbitrary action of the Railroad Administration in 1919, that any arbitrary action of the government through bureaucratic organization can handle any situation of emergency for a major industry, as well it can be handled under private ownership. For this reason the Cummins bill is believed to be decidedly inimical to the entire public and to every branch of industry.

"(3) Operators quite universally have publicly and repeatedly stated their belief that through some fact-finding agency appointed by the President, composed of first-class, high-grade, public spirited citizens, on whom both the operators and miners might depend and in whom the public would have entire confidence, gave promise of the most satisfactory results, through the establishment of the exact facts regarding the production and distribution of coal. The public has never known the facts and never through any effort of the parties at interest—i.e. the miners and operators—or through any commission or committee the motives of which may be subject to suspicion, because of fear that political expediency might enter into the final determinations.

"(4) Nor do the operators believe any more at this time than they have throughout the past five years that either the disease with respect to sporadic, unfortunate fuel conditions, or the remedy for correction, should be assailed through the coal industry, but should rather be approached through,

"(a) The guarantee of adequate transportation, and,

"(b) The maintenance of law and order.

"Prior to the abandonment of these two basic conditions ample and adequate volumes of coal were always available to the American public for any use and at the lowest prices know anywhere in the world, nor throughout all this period were wage earners in the coal-mining industry paid as little as was paid in other lines."

"An average of $1.074 an hour paid today to Illinois miners for a class of work, as to severity and skill required, for which the steel companies are paying 30c. an hour, is a reflection of approximately the same conditions that have for the past score of years prevailed in the coal industry with respect to wages."

"With the removal of the unwarrantedly indulgent wage rate made available to coal miners during the last five years, through the compelling power of their union, the question of too many mines and too many miners will very promptly correct itself after the same fashion that it has always done so heretofore."
Rapidly mounting production from the bituminous coal mines, as district after district has returned to work, has eased the market and put a soft pedal on high prices. Coal Age Index of spot prices of soft coal at the mines dropped 17 points this week, to 420 from 437 a week ago. The high point so far this year was reached last week of July and since then the decline has been consistent, though unsteady. The average price on Tuesday of this week was $5.08, compared with $6.73 on July 31, the peak. In the West, prices now average under $5 and in the East from that figure up.

The market is still in the process of finding itself. A week ago buyers who could wait were holding off. The market was dropping and the tone of the news was that production soon would be sufficient to take care of everyone. The past week, however, has found many small as well as large users in the market, both because they have reached the bottom of their stockpile and because they feel that prices have little more to slump before touching the base for the immediate future. Prices are irregular and doubtless will continue so until the extent of the expected car shortage is fully developed. The big questions are: To what extent will the soft-coal mines be called on to replace normal anthracite requirements, and at what figure will bituminous coal output be halted by car shortage and transportation disability?

**Expect Price Upturn When Weather Gets Cold**

It is the present expectation that prices will decline even more for several weeks and then with cold weather and the full pressure of winter demand plus the necessity for winter storage, to start up, slowly at first and then rapidly. What will happen then, it is predicted, will depend on the legislation passed by Congress. If that proves to be effective, provided it is passed, prices may be held in check; otherwise another ascension.

Production last week is estimated at a little short of 10,000,000 net tons, all soft coal. The gains each week are now from the union fields that were on strike, and of course nearest to markets that were shortest of coal. Alabama, for instance, that has been exporting coal north, is cast back on its home markets. West Kentucky finds its bonanza in Chicago smothered by local output and its fancy prices a thing of the past. Only the Northwest seems in any serious danger and that is because it is so far from the mines and the weeks are few in which to move coal over the Lakes.

Hovering over the eastern part of the United States and likewise the area around the head of the Great Lakes, and also eastern Canada, is the fear of a serious shortage of anthracite for households. Production has been lost for five and a half months, an amount that everyone conceives cannot be made up. The most optimistic predict nothing worse than generous substitution of coke, gas and bituminous coal coupled with parceling out of the available new supply of hard coal. The other side of the picture is carried by those who say that the hard coal that will be available will not suffice to cover the actual needs of those whose habits and necessities require that fuel and that there will be suffering from its lack. The big problem for the fast-forming state fuel-control organizations is going to be domestic distribution during the winter months rather than price control.

Production of beehive coke is too light for

furnace men to attempt to build up a supply. This, rather than the high prices asked, is the main deterrent to buyers.

**BITUMINOUS**

"Soft coal production shot upward almost as suddenly as five months ago it had plunged downward, when district after district, accepted the Cleveland wage agreement and resumed work," says the Geological Survey. "Late returns for the week ended Aug. 26, indicate an output of 6,700,000 tons of bituminous coal and last week (Aug. 28-Sept. 2) will show 9,700,000 tons."

"The rapid gain in output is indicated by the statement below of cars loaded daily. Following a sharp increase on Friday and Saturday, as coal began to flow in volume from the mines of Illinois and Indiana, last week opened with loadings of 30,054 cars on Monday. A decline to approximately 28,000 cars on Tuesday and Wednesday marked the first tightening of car supply. On Thursday additional shipments began from western Pennsylvania, and loadings reached 29,027 cars."

"This increase has come almost exclusively from mines opening under the Cleveland agreement. The non-union districts of the middle and southern Appalachians are still limited by low viability and in spite of a slight increase in car supply are producing only 65 per cent of the rate attained before the strike began."

"In fact complaints of lack of cars have already been received from the union districts of eastern Ohio and northern West Virginia. The limiting factor in production of bituminous coal has thus changed over night. A week ago it was the supply of men; now it is transportation. The first response of the railroads to the demand for more service has been favorable, partly because they had a surplus of 112,000 empty coal cars when the union mines resumed work. Whether the roads can maintain the present rate of coal movement when the surplus of cars is exhausted remains to be seen."

"Even in the bituminous mines the strike is not yet entirely over. Some thousands of men are still out in the non-union fields of Pennsylvania, particularly the Connellsville coke region, in the Georges Creek field, and in the union districts of West Virginia."

"Shipments during the first half of the week were at a rate 2 per cent in excess of the daily average for the preceding week and 81 per cent over that for the week of June 19-24."

"The districts showing notably increased shipments were central Pennsylvania, where the daily rate is now about double that of the week before; western Pennsylvania, where the increase is about 40 per cent; Ohio, about 33 per cent; Indiana-Illinois about 300 per cent; and the Iowa-Missouri-Kansas-Oklahoma-Arkansas-Texas region, about 120 per cent. Increases at these rates cannot be expected to continue."

"Shipments in the middle and southern Appalachian region averaged during the first half of the week about 10 per cent higher. This was due to the large increases on Monday, after which on Tuesday and Wednesday shipments dropped off to less than the average for the preceding week and in some districts to less than shipments on corresponding days of that week. Shipments have declined most in the southernmost districts of West Virginia, in eastern Kentucky and Alabama. Mining in this region is suffering severely from transportation difficulties, and shipments are now at best 700,000 tons less per week than during June."

"The all-rail movement to New England over the Hudson River increased to 917 cars of bituminous coal and 226 cars of anthracite during the fourth week of August. The total all-rail hearings this year to Aug. 26 amounted to 116,622 cars divided as follows: 50,560 cars of anthracite and 55,552 of bituminous coal through the principal gateways;"

a Figures furnished through courtesy of American Railway Association.

Following the recent order of the Federal Fuel Distributor of the flow of coal to the Lakes has greatly increased. During the week ended Sept. 4 total dumpings were 359,961 net tons—305,654 tons cargo and 34,907 tons vessel fuel—as compared with 258,598 tons in the preceding week. The season's total to date is 5,554,014 tons; in the corresponding period of last year 16,739,653 had been dumped. Some Indiana and Illinois all-rail coal is beginning to trickle through to the Northwest, but this tonnage is insignificant as yet.

Hampton Roads dumpings for all accounts were 329,895 net tons during the last week in August, as compared with 350,537 tons in the preceding week. More and more this coal is now flowing in its accustomed trade channels as the maktens tension has been lessened by the union re-union.

ANTHRACITE

Production during the week ended Aug. 26 was about 35,000 net tons, principally steam sizes dredged from the rivers. A rush of orders has followed the announcement that mining will soon be resumed and it is hoped that coal will be moving by Sept. 11.

Coal No. 1 bituminous coal had been sold as a substitute for anthracite as the consumer has felt that soft coal would be available at the last moment, if wanted. Some British coal has been sold for this purpose along the Atlantic seaboard, however, and it is certain that substitute fuel must eke out the current supplies of hard coal for some time, as the output will have to be spread very thinly over a large territory to begin with.

Experiencing Difficulty With Welsh Coal

Several plants that are meeting the present fuel emergency through the use of Welsh coal are finding that certain modifications will have to be made in their stokers if they are to carry the same loads as with American coal.

At the plants of the Interborough Rapid Transit Co., New York, approximately a third of the boilers are being supplied with coal from Wales. It is a high-grade coal, running about 14,500 B.t.u., 15 per cent being volatile and 6 per cent, ash. Up to 200 or 225 per cent rating of the boilers the coal gives excellent results but above this it cakes and does not permit the proper quantity of air to pass through the fuel bed. The cake is readily broken, however, and does not seem to be of the nature of a cinder. At these plants the boilers are forced as high as 320 per cent rating and it is, therefore, impossible to run the boiler at more than 70 to 75 per cent of the capacity hitherto attained. It was found that the older type of over feeds which break up the fuel bed handle this coal better than the underfed stokers.

Therefore the engineering force of the Interborough have endeavored to meet the difficulty by increasing the air passages through the stokers, cutting down the velocity and the pressure from 5 to 3 in. and increasing the volume of air. Tests under these conditions are now being made for the Transit Commission.
Foreign Market
And Export News

British Market Feels Effects of American Resumption; French Coals Stronger

The British market has eased off considerably in the past week. Heavier production of bituminous coal in the United States has affected the demand from that section and from Canada. Shippers have heavy orders in hand, however, which will tax export facilities for the next few weeks. European buyers, quick to sense softened demand, are reported to be holding back and prices are showing a downward tendency. Production during the week ended Aug. 19 was 5,158,000 gross tons, according to a cable to Coal Age, indicating a sharp recovery from the holiday slump of the preceding week and comparing with an output of 5,125,000 tons for the week of Aug. 5.

It is reported in Glasgow that the Scotch railway rates for coal have been reduced. The new rate will be the present rate plus 75 per cent, plus a flat rate of 3d., with a maximum increase of 3s. 6d. Formerly rates were the present rate plus 100 per cent, plus a flat rate of 6d.

Tonnage waiting 35,295 19,300

U. S. Strike Aids French Coal Market

The situation of the French coal market is now comparatively satisfactory, and some coal is being taken from stocks. This improvement is, of course, partly due to the United States strike. Not much, if any, French coal has moved across the Atlantic so far.

Of the 1,725,000 tons of German reparations fuel to be monthly supplied from Aug. 1 to Oct. 31 to France, Luxembourg, Belgium and Italy (1,600,000 tons from the Ruhr and 125,000 tons from Upper Silesia) France (with Luxembourg) obtains 1,120,500 tons of the tonnage to be supplied from the Ruhr.

France also produced in June 78,929 metric tons of coke and 219,817 tons of briquets. Sarre collieries produced 864,096 metric tons of coal and 19,832 tons of coke. The pit head stocks were 619,285 tons on June 30.

Coal Paragraphs From Foreign Lands

GERMANY—Production in the Ruhr district for the week ended Aug. 19 was 1,813,000 metric tons, according to a cable to Coal Age.

ITALY—The price of Cardiff steam first is quoted at 42s. 5d., according to a cable to Coal Age, unchanged for the last two weeks.

CZECHO-SLOVAKIA—The tax on the export of coke has been abolished by a decree of the Minister of Commerce, with retroactive effect as from March 15, 1922.

Rail Situation Improves at Roads

Dumpings during the week ended Aug. 31 showed a slight decline, while for the month the decrease was approximately 1,000,000 tons. During August the piers dumped 1,297,981 tons, against 1,350,364 tons in July.

The tendency of prices was downward, having shown a steady reduction for three weeks. Dealers were expecting still lower prices within ten days. Dealers were moving about 50 per cent of normal, with a slight increase in prospect. The N. & W. was steadily increasing the movement from the mines, while the other coal carriers were holding their own.

Market Weakens With

Heavy Influx of Receipts

Absorption of Output Effected by Cut in Spot Prices—Growing Car Shortage Slows Production—British and Southern Water-Borne Coal Plentiful

Heaver receipts have weakened the market. Central Pennsylvania is very active and while the demand is absorbing current production, it has been done by reducing spot prices. That quotations may go very little lower, however, is indicated by a growing car shortage, which is beginning to slow up production at a time when there is need for every pound of coal that can be mined.

Southern coal, via water, continues to arrive in good volume, as does British fuel. The foreign coal is in much less demand since the resumption of union mining and prices are being cut to move the unobligated tonnage now arriving.

NEW YORK

Increased production and continued lack of demand has resulted in a further softening of quotations. More coal is coming forward but a serious car shortage is imminent. Complaint has already been made of conditions along the B. & O. road and it is said the trouble is spreading to other roads.

Southern coals are coming forward freely. The transit companies are well provided it is said and are practically out of the woods so far as soft coal is concerned." Quotations range $1.25@1.35 c.i.f. on coal in stock at this harbor.

Receipts of British coal during the first five days of last week were not as heavy as the previous week. Ten vessels brought over 5,000 tons but many others were believed to be near port. Inquiry has been quieter since the strike settlement, and as production gradually increases it will fall off. On another factor in the falling off in inquiries is the advancing freight rates. Quotations for British Admiralty were around $9 c.i.f. New York harbor and for Durham gas coals, No. 2 quality, $8.50@8.75.

There were 784 cars reported at the local docks on Sept. 1, little of it being free coal. High-volatile steam coals were quoted $4.75@$5.25, low sulphur gas coals, $6.50@6.50 and Broad Top around $6.25.

BALTIMORE

The fact that many production points have begun a steady flow of supplies and that there was every indication of still further increase lead to a brief cut in prices during the past week, but the market is now once more ascending. The demand is such that there is more than ready assimilation of production on a mine basis of $6@$6.50 for the better grade steam coals.

There are offerings of less desirable fuels down to $5.25. Lump gas is demanding. The car shortage and the steadily increasing demand for coal has turned the scale of prices upward once more. While the Maryland Distribution Committee is to be kept in expanded life as long as coal circles that their powers will be so circumscribed without federal support that their duties will be largely negligible. Of the various points of the news from Cumberland, Md., that six of the smaller coal companies operating in the Georges Creek territory have signed an agreement recognizing the union and paying the 1920 scale. The total output of these is small, however.

PHILADELPHIA

All mines are fast getting under way, as the rush to sign up to the union scale has gathered great momentum in the last few days. Almost without exception the operators are bitter in their denunciation of the reasons which have compelled them to bow to the miners, but accept the scale as the only way out for the time being.

The amount of coal offered has increased considerably, and the consumer has shown a greater disposition to buy. There is, however, that prices will not drop much lower, and some shippers express the opinion that another upward trend may soon set in. Already there is much complaint of car shortage, especially on the Pennsylvania. This road has claimed all along to be in the best of shape and doubtless the sudden resumption of mining has thrown a load on it for empties that will soon straighten itself out.

So far every one is distributing coal in the best manner possible, as the provisions of the new Fuel Control Act are being applied and at the expiration of the same is awaited with much interest.

Foreign coal is still being offered, with some shippers of tare contracts closed recently. However, the recent drop in domestic prices has been such as to discourage this in some measure. Cargoes on orders placed some time ago are arriving almost daily.

CENTRAL PENNSYLVANIA

Production has advanced to more than 60 per cent of normal. During the first week following the settlement of the strike, daily loadings averaged 2,555 cars, while the low mark reached during the strike was 2,050 cars.

Practically all the union mines are now producing coal. The non-union operators absolutely ignored the request of the U. M. W. for a conference in Somerset on Aug. 29. The non-union operators declare that there is absolutely no chance for them ever recognizing the union. They are paying the same wages as the union operators and they say that is as far as they will go. An increase of more than 100 per cent is shown in the non-union

field in Somerset County within the last month. Some of the mines are operating full time.

At the convention, the Somerset union miners passed a resolution to remain on strike until the operators agree to meet them and their district officers in conference or sign individual wage scale agreements according to the policies of the district and national agreements.

FAIRMONT

Although more mines are in operation as a result of the strike settlement, an acute car shortage is greatly curtailting the output. Many of the larger companies have signed a contract with the union but on the Charleston Division of the B. & O. and in the section reached by the Morgantown & King.

The most of the mines are running on the open-shop plan and no agreement is in prospect.

UPPER POTOMAC

Neither the Upper Potomac nor the Georges Creek operators have signed any agreement with the union, nor is there any prospect that they will take such action and that is responsible for continued idleness in Georges Creek territory. Car loadings in the Maryland field of the Western Maryland in the Upper Potomac field where most of the mines are running and where production is being increased.

KANSAS CITY

So far as the coal situation is concerned it is all that could reasonably be expected in the way of supply but there is some grumbling over the price of domestic grades, which is $6 for Kansas lump and nut coal. The price for steam grades started very ragged, but has settled to around $2.75 for soft and $3.25 for hard and some contracts are being closed at that figure.

The mines are now producing about 50 per cent of their normal capacity and should be able to meet the demand for it. A great many steam plants have gone to oil and they are not likely to change back to coal just to revert the change to oil again next April.

The retailer is taking very little coal as he made no money the past two years and is largely to buying too early and running into a much lower market later in the season.

SALT LAKE CITY

Dealers are finding it difficult to meet the demand of their customers, who now realize that delay in putting in their winter supply of coal may prove dangerous. Car troubles is being experienced here already, especially on the D. & R. G. W. R.R. It is thought the situation will be serious before long.

Local yards are carrying little coal with the exception of that of the Western Fuel Co., which has about 20,000 tons. Most of the others are empty, however, and nothing further has been said regarding an increase in prices. Production is not far short of capacity now.
News of Settlement Brings
Flood of Retail Inquiries

Prospect of Early Production Hailed with Relief—Some Time Must Elapse
Before Coal Reaches Householder—
Substitutes Will Be Needed for a While.

The news that an agreement has been reached and that production will soon be resumed has been hailed with relief by all concerned. The announcement has brought forth a flood of inquiries at retail, but is evident that it will be some time before the householder receives any coal on orders recently placed.

Not much bituminous coal has been distributed as a substitute for anthracite. Some British coal has been sold for this purpose and it is probable that a considerable tonnage of substitute fuel will be used before hard coal is available this fall.

NEW YORK

Dealers and consumers are carefully watching for word that the so-called suspension has been ended and that the miners are returning to the mines. At the same time consumers realize there will be no reduction in prices and that they will be fortunate if they will be able to get their winter coal at the March figures. Some retail dealers are delivering small tonnages of pea coal to those customers who want it but there is little if any of the larger sizes to be had in New York.

Considerable pressure through newspaper statements and advertisements is being exerted in an effort to induce the use of bituminous coal and dealers look for increased tonnage as a result. Coke is also being urged as a substitute.

Several of the smaller independent operators have been reported as visiting local wholesale offices during the week inquiring as to the future prospects.

No steam coal except a small quantity of buckwheat and river barley is coming forward. Some pea was quoted around $15, alongside, this harbor, Buckwheat No. 1 was quoted $12.50 @ $13, alongside, and river barley, $5.90 @ $6.25. Quotations for river barley for loading point was around $3.50.

BALTIMORE

The regular hard coal dealers are fast becoming scarce but, there are at least a few "semi-bituminous" dealers. Every few days another joins the list of suppliers contracting for the English coals which are now running to this port. Ten vessels are now on their way to this port with Welsh coal, some of it in foreign bottoms and some in Shipping Board vessels.

The dealers here as a whole are asking around $13.50 a ton for this British coal, delivered in the cellars of house-
Trade Begins to Liven
In Central West Region

Country Demand Rolls In as Customers See Real Shortage and High Prices Ahead—Steam Picks Up Too—Market Remains Fairly Firm.

The much-talked-of softening of the coal market in this territory has not materialized. Car shortage has made itself so distinctly felt in all fields and labor disturbances of one sort and another are popping up so constantly that almost everybody is ready to believe at last that the coal men were right when they prophesied a dry market and costly production this fall and winter. Country and retail demand is heavy and even the steam consumers, who have held out for several days, using up the last of their high-priced strike coal and hoping for a drop in local fuel, have started back into the market.

Railroads cannot extend much comfort to operators. For the time being they are distracted with demands for cars in which to move crops and freight traffic generally has become so heavy and motive power so debilitated that coal is getting a bad deal. Illinois has not yet reached 70 per cent production and Indiana is somewhat short of that, with very little likelihood of either doing any better in the near future. In Illinois a score of tie-ups are due to soreness on the part of miners against company men. Miners' bitterness over the Herrin prosecution apparently is going to lead to further shut-downs if not to the general state mine strike that is threatened.

WESTERN KENTUCKY

Resumption of production in Indiana, Illinois and north of the Ohio River has resulted in an almost complete elimination of western Kentucky coal in the Chicago and some other Northern markets, with the result that operators are endeavoring to locate business, and are reported to be handicapped in finding enough priority business on which they can secure cars for loading.

According to some reports received coal from western Kentucky is being offered as low as $2.25 for screenings, and up to $6 for lump, at Chicago. However, it is said that anything at under $4 represents either unclaimed bank screenings, or else demurrage coal that brokers have to unload.

Some of the railroads are trying to sidestep their priority contracts for coal, it is said, due to the fact that they are now able to secure coal on shorter haul in other fields, and at a slightly lower price, as it is reported that some coal north of the river has sold under $4. As a result Chicago is refusing to bid more for western Kentucky coal than prices at Northern mines, less the difference in freight from Western Kentucky.

SOUTHERN ILLINOIS

The mines of the southern countries are getting at the present time from three to four days per week on account of no cars and barding labor troubles and prices range $4.90@$5.15 for domestic sizes, $5.50 for mine run and $4.50 for screenings, although some screenings and mine run is sold for considerably less. Railroad tonnage is light, everything considered. Some what similar conditions prevail in Duquoin and East Jackson County, with the same prices and the same danger of dissatisfaction and trouble. Carphy bont reduced the price for mine run and screenings $0.50 for domestic sizes.

In the Standard district practically all mines are working from three to four days per week. Car shortage is unusually severe on the L. & N. Southern, Mobile & Ohio and B. & O. Railroad companies are not able to get enough cars out of this field in a pretty fair volume on old contracts. There is a wide variation in the price from $3.50@$4 for 2-in. lump and other steam sizes, including screenings and mine run. Six inch lump is quoted $4.25@$5, and the same for 3x6 egg and 3x2 nut, it all depending upon where the coal must go and who needs it.

INDIANAPOLIS

Indiana prepared sizes may cost Hoosier consumers $8@$9 a ton in bins this winter, according to calculations of operators and retailers. Consumers will pay even higher prices for coals from outside. At Carterville the mine quotations were $4.35 for 11-in. lump, $4.50 for 2-in. sizes and $5 for other prepared sizes. Following failure of the Indiana emergency coal committee and a committee representing the operators to reach an agreement to fix a price of not more than $3.50 a ton at the mines, which was proposed by the state committee, the responsibility for the establishment of prices has been turned over to the Indiana operators.

CHICAGO

At last the public lethargy appears to be cracking. The coal market is bricking up a bit. And this comes at a time when coal shortage is shutting down many mines in Illinois and Indiana and making it nearly run fractional days.

Very little fuel other than that mined in the two states is trading on this market. Illinois coals from the northern and central fields have softened a shade in price but most of the southern field output has held the market firm at $4.25@$5.15. Even screenings are now selling about as fast as they can be delivered for the double reason that strike coal is now about used up and that the steam trade is practically finished that prices are not going to slump.
Lake Situation Paramount, Local Markets Being Easier

Receipts Gaining at Lower Ports, Though Retarded by Transit Conditions—Removal of Restrictions and Absence of Price Control Aid Movement—Prices Decline Gradually.

The Lake situation holds the center of the stage. While receipts at the lower ports are growing rapidly they are still much retarded by transportation difficulties. A heavy tonnage must be moved up the Lakes in the remaining twelve weeks of navigable weather if a serious shortage in the Northwest is to be averted during the winter.

Eastern Inland markets are in an easier position. Production is increasing and local fuel shortages are being quickly overcome. Removal of many priority restrictions and the breakdown of Ohio’s price regulatory measures have caused a freer movement of coal. Prices are gradually being lowered by the heavier spot offerings and the bargain-hunting tactics of buyers.

Cleveland

Chief interest centers upon activities to rush coal to the Northwest in an effort to head off a fuel famine. The slow movement to the lower docks has retarded the operation of pooling arrangements, under which permits for moving coal to the Northwest will be issued by D. H. Robertson, representative of the I. C. C., who will have headquarters at the Ore & Coal Exchange. Pooling of coal for Northwest started last Friday. Except for special consignments Lake coal is placed first in priority. Receipts at Lake were about 400,000 tons last week. Expect 800,000 this week and 1,000,000 weekly thereafter.

An interesting development since the strike settlement has been the heavy inflow of orders for household coal. Retail dealers literally have been swamped. As yet these orders are being accepted with the understanding that deliveries will be made on them in the order they are received. Some dealers are urging their customers to buy Ohio coal, fearing that the government may find it necessary to shut off West Virginia coal coming into this district for all but Lake shipments. Coke is also being offered as this is in better supply. Orders for Pocahontas are being accepted on the basis of $10.75 a ton for shoveled lump and $12.25 for forked lump.

Industrial demand continues strong. With the breakdown of the present system of local committees on fuel distribution in many parts of Ohio and the abandonment of efforts to establish fair prices, the trend is toward free conditions in the open market with everything depending on the roads' ability to meet demands upon them.

Pittsburgh

At a meeting of the Pittsburgh Coal Producers’ Association on Aug. 29, the Pittsburgh Coal Co. having previously withdrawn, it was decided to hold a Cleveland agreement. The following day the Pittsburgh Coal Co. signed the scale. Operators in the Freeport vein and previously signed, as had most of the steel companies operating in the Pittsburgh district.

The Connellsville strikers did not return to work in numbers after the posting of notices restoring the scale of Sept. 1, 1920, although some straggled back to work. Many meetings were held at which resolutions were passed to hold out for union wages. Day by day the trade watched the situation to see when the strike, as a strike, would end. Sept. 1 brought the almost certain realization of a car shortage developing of such magnitude as to make it of no interest whether or not additional strikers were disposed to return. Of the new men that have been brought into the region.

There has thus far been no regular trading in Pittsburgh district coal, except that recently Youghiheny gas coal appeared, developing a price of $6.50. Connellsville steam coal, quoted a week ago at $5, weakened to a range of $4.50-$5, while on the appearance of Lake demand and the development of car shortage the market stiffened to a range of $4.75-$5.25. The trading has been light except in Lake coal.

Northern Panhandle

Resumption of operations at the few union mines has been extended to increased production but the bulk of the output is coming from open-shop mines since most of the mines in the Panhandle are operated on such a basis. A part of the increased output is going to the Lakes but the railroads also are securing a large tonnage. There is comparatively little free coal available.

Eastern Ohio

Car shortage and transportation disability were the only deterrent elements of significance prevented, the movements of eastern Ohio mines from attaining maximum production during the week ended Aug. 26. Production aggregated 220,000 tons against a potential capacity of 620,000 tons.

The bulk of mine output during the past two weeks has gone to railroads and public utilities. Arizona dealers have much anxiety existing over these larger consumers has been somewhat relieved. Buyers in general continue to show a procurating disposition toward entering the market at this time. Their anticipa- tion is that coal may be purchased a few weeks later at prices below those now prevailing in the open market.

Spot prices remain firm at the new low levels of a week ago and it is not expected by those well informed in the trade that they will recede any further for some little time, as a considerable portion of Ohio coal will be directed to the Northwest. Slacks for the Lake market, black and mine run are quoted $5@5.50, and lump sizes range $3.25@$3.75.

Receipts of bituminous coal at Cleveland during the past week show a substantial increase over the preceding week, total arrivals aggregating 814 cars, 742 cars to industries and 71 cars to retail yards.

Detroit

Though the railroads report a freer movement of bituminous coal and continue to fall short of daily requirements and the city is “not yet out of the woods.” Jolters and wholesalers find very little inquiry. The chief impediment to an increased present supply is the inability of the roads on which the coal originates to supply cars and their lack of success in making connections to connecting roads serving Detroit.

To facilitate distribution of domestic coal, Detroit dealers at a meeting held under the auspices of the Detroit Coal Exchange voted to appoint a committee of five representative retail dealers, which will have supervision over prices and distribution for household use.

Columbus

With all fields working and a large tonnage being produced the market is settling down. The most insist demand now coming from dealers who are anxious to secure stocks as early as possible.

Householders are asking for delivery on orders placed with retailers sometime ago. Since only a small amount of smokeless is coming into the market the trade is demanding largely upon Hocking and other southern Ohio grades. Hocking lump is in small supply and Ohio midwest mines. Dealers prices are $9.50@$10. Pomeroy Bend is retarding at about the same prices while Pocahontas lump is $10.50@$11.

The Lake tonnage shipped over the H. V. Docks at Toledo during the week ended Aug. 30 was only 50,276 tons as compared with 29,686 tons in the preceding week. So far this season the H. V. Docks have shipped 1,774,163 tons as compared with 2,968,000 up to Aug. 27 of last year.

Buffalo

The trade proceeds slowly toward normal. More is sold is met by an increased demand. How far this movement is to continue is hard to say. The demand for midwest coal to the Lake and the scant car supply will both have an effect. The mines have been accumulating cars as much as possible, so that deliveries as yet are good, but they are not likely to continue.

Miners in the Allegheny Valley in general went to work sooner than those farther south and the coal is already on the market. Prices are very unsettled and will remain so awhile yet, for the ideas of buyer and seller are much at variance. Allegheny Valley mine run is quoted $3.75@$4 and the run now is $5 or so higher, with a little Youghiheny gas at $7. The Lake allotments are likely to cut out most of the No. 8 from this market.
Upper Lakes Region Is
Still in Coal Ferment

Doubt in Many Quarters over Size Of Fuel Supply to Reach North—Prices Make General Advance Sept. 1, Amid Groans.

The Northwest is almost as badly worried today over coal as it was before the government promised plenty of fuel. Only one or two ports have received any considerable amount during the past week and every one of them has been hit by a general price increase of 75c. or $1, which moves the public to emit loud groans. However, it remains that there is no suffering yet for fuel and essential industries seem to have enough for the time being.

A strong effort has lately been made to get more Illinois and Indiana coal by rail to make up for the fuel that is not coming by vessel. Some coal has arrived by this device but not enough to count for much. Many wise coal men are cautioning the region to restrain its panic tendencies because the next two weeks will see a Lake Movement that will bring joy to the whole territory.

MINNEAPOLIS

From all present indications, the supply of hard coal reaching the Northwest will be very much reduced—possibly a third of the normal tonnage, if that.

This is causing unhatched chickens on the assumption that early incubation may be expected, and that hard coal production will be resumed soon. There were several hundred thousand tons of hard coal carried over—principally of unpopular sizes—but not enough to count heavily.

Increased demand for coke has resulted in the price going up another $1.50. Soft coal of various grades is also being ordered for use in domestic heating plants.

So far, the Northwest has been favored with promises of 400,000 tons of coal a week. But this has not been delivered. Just why cannot be quite determined. New plans follow old ones which prove unworkable. But none of them seems to produce coal. The harvest is over and past, the summer is ended and salvation is still a long way off. There is a great feeling of irritation over the situation.

A little all-rail Illinois coal was rushed up to the Twin Cities the past week, as an encouragement of future hopes in that direction. There is— with some exceptions—no crying need for fuel, though many supplies are close to the vanishing point.

New England

Withhold Orders as Stocks Are Good and Output Gains

Distress Unlikely Unless Buyers Hold Back Too Long—Early Resumption of Anthracite Mining Would Ease Steam Coal Situation.

A recent survey in this territory shows comfortable stocks for the next sixty days. Reports of much increased production also influence consumers in withholding purchases at present quotations. It may be that some will overstay, but in view of receipts this year so nearly matching those of 1921, it is hard to see how there can be any real distress in this market.

Should anthracite mining be resumed within a fortnight, as now seems probable, a very slight increase in current receipts would make the situation here relatively easy so far as steam coal is concerned.

With the volume of British coal continuing to arrive there is certain to be ample fuel during September and October. Certain foreign cargoes that have reached here unsold have been absorbed only with difficulty, and there are still small barges and lighter being offered on the current market for prices much lower than was quoted c.i.f. in large cargoes. Under these conditions there will be no broad market for bituminous unless car-supply or some other controlling factor intervenes.

The Hampton Roads agencies have made a distinct gain in tonnage. Less coal is being sent to railroads like the Pennsylvania and the Erie, such requirements being met from central Pennsylvania, but it is amazing that coal be as late as Sept. 2. N. & W. cars were being sent all-rail to help supply the New Haven Road. When Washington undertakes cross-haul movement of this kind it is not surprising that car shortage is predicted.

Consumers who made their contracts on smokeless coals are beginning to hear of the recent wage increase in Pennsylvania, but this has not been translated into increased shipments as coal is subject to many factors. The market has not recovered from the drop that followed the reduction in demand.
Normalcy Awaits End of Railway Shopmen's Strike

Report Return of Groups of Workers to Duty—Scarcity of Cars and Condensation of Locomotives Cripple Production—Prices Soften as Consumers Lay Low.

The shopmen's strike is the nub of the fuel situation. Other rough spots occasioned by the long strike are beginning to show signs of softening and it seems generally agreed that normalcy is not so far off if the railroad workers would get back in the traces. Considerable interest is shown in the report that little groups of workmen of the C. & O. are coming back to work and that the violence is growing more intense. On the L. & N. cars are getting scarce and the action of the I. C. C. in turning down a number of engines doing duty in the fields was a further crippling.

Production is now largely a matter of obtaining cars. Prices are softer, as consumers play a waiting game.

**HIGH-VOLATILE FIELDS**

**KANAWHA**

Much of the coal originating in the Kanawha region is still coming from open-shop mines although approximately 50 per cent of the mines in the district have signed an agreement with the union. Production is being slightly increased but cars are still short of requirements that the output of most mines is necessarily limited.

**LOGAN AND THACKER**

Production was hardly on as large a scale in the Logan region during the latter part of August, owing to an acute car shortage. This diversion of coal to the Lakes made for a shortage of supplies at automobile factories and among other industrial concerns and also cut the supply of free coal.

Mines in the Williamson field are just about managing to maintain production at 165,000 tons a week, owing to the fact that the car supply is not fully equal to the requirements of the mines. There is an unusually heavy movement westward through Williamson, particularly since the district has been called upon to furnish a large part of its quota to the Lakes. Although many strikers are drawing benefits in this county, yet as a matter of fact all the men needed are available.

**NORTHEASTERN KENTUCKY**

Transportation disabilities are still material handicapping mines so that the output is still under 50 per cent of potential capacity. With a heavy tonnage being shipped to the Lakes under government orders, there is little coal available for general market purposes. Most of the coal is moving at $4.50 or less.

**LOW-VOLATILE FIELDS**

**NEW RIVER AND THE GULF**

Production is being gradually increased in the New River field. Upon the signing of a union agreement in other fields miners at a few of the plants in this region declined to go to work. This work was not general and did not affect production. The only factor which is hampering the mines is the difficulty of securing cars and of moving coal after it is loaded. Production is resultless, however, in a somewhat larger movement of coal to Tidewater.

Winding Gulf mines are still being handicapped to some extent by a shortage of cars and by the difficulties attendant upon the movement of coal on the western end of the Virginian. Labor is plentiful.

**POCAHONTAS AND TUG RIVER**

By the end of August production in the Pocahontas region was back on about the same level as observed during the early part of the month. A shortage of cars is still handicapping mines to some extent. The Eastern movement is large, there being approximately twice as much coal going to Tidewater and Eastern markets as to Western points. There is also a good deal of fuel moving under priority orders so that there is comparatively little spot coal to be had.

Tug River production is once again above normal, being not far short of 100,000 tons per week. This improvement is due to more improved transportation facilities on the part of the N. & W. which supplies this territory.

All the free coal available, however, is moving under priority regulations.

**CINCINNATI**

Lake coal is still the uppermost question here. It has been found that the permit system has been merely one of the shipper who contracted low-priced coal and that priorities are easier to obtain than is healthy for the good of the trade. Word comes that there will be an agreement to put in the port facilities at the port of Cincinnati which will get coal to the Lakes. The movement in this direction, in spite of all of the impediments that the movement has to be handled with care on prices on a $8 range.

The Kentucky coal distributing committee has gone by the boards and the Ohio dictators have shown up their hands and decided to let fair prices take care of itself. Illinois and Illinois coal is beginning to show that the coal being sold is being filled, all of which has slowed down the local business that was taking care of this. The coal and there a robust wholesaler bidding 25c. on top of the spot market and can get all that he is looking for at that price.

The price of the usual coal of the Hoover prices than the others. Recent wage advances, however, are forcing the 8 per cent commission to be taken when sold.

The retail market has taken another spurt upward. The new prices follow: Smokeless lump, $10.50@$11; mine run, $9@$9.50; screenings, $8.75. Bituminous: Lump, $9@$9.50; mine run, $8.50 @$8.75; slack, $8.25.

**Coke**

**CONNELLSVILLE**

Coke production has continued increasing and, at a moderate rate, until Sept. 1 a car shortage of impression proportions developed, and operations will be controlled by that factor in future. There remains a fairly prevalent attitude that they are holding out for union recognition.

Increased production has been chiefly on the part of the large ovens and market offerings are but slightly increased. There is no opportunity now for any number of furnaces to resume by reason of increased supplies of merchant coke, whether on old contracts or by fresh buying. Furnace coke was quoted a week ago at $11.50, but the market has since stiffened to a range of $11.50@$12.

Furnacemen generally claim prices are altogether too high to justify their considering the market, and talk of $7, but the practical fact is that offerings are too light to encourage a furnace to attempt to build up a supply, irrespective of price.

Foundry coke has been in lighter demand and the market is off $1.50 for the week, being at a range of $13@$13.50.

The Courier reports production during the week ended Aug. 28 at 69,900 tons by the furnace ovens and 16,250 tons by the merchant ovens, a total of 86,150 tons, an increase of 3,590 tons.

**UNIONTOWN**

Just as Connellsville coal operators believed they had the strike situation well in hand the long expected car shortage made its appearance, due principally by demands for equipment from union regions resuming operations. The Connellsville region may now be considered as operating at 50 per cent of capacity despite the continued strike of the recently organized miners. The mines and ovens are being mined by men who have left the union and other men, all labor attracted by the present high wage and by imported labor.

Coal closed the week with a quotation of $9.50@$10. Percolating coke, which used to be sold on the B. & O. but the market appeared open on the Pennsylvania. The present effort to coal the Northwest before the Lakes is said to be furthered by the poor condition on the Connellsville trade, this vein of coal being considered too fine for the Lakes trade.

**BUFFALO**

Demand is fair, especially for domestic sizes, but the supply has not increased much yet. Reports are sent out that the prices are off, but that seems to mean merely that some very extravagant asking prices have been dropped.
News From the Coal Fields

CONNECTICUT

Thomas W. Russell, of Hartford, has been appointed state geologist by the State of Connecticut by Governor E. J. LaFave.

Mayor Fred Atwater of Bridgeport is planning to establish a municipal coal yard at Bridgeport to purchase their winter supply of coal. Coal will be $1 per ton, alongside, the purchasers to do their own haulage.

ILLINOIS

The Ellisville Coal Mining Co., of Galesburg, has been incorporated with a capital of $30,000 by A. B. McDonald and W. R. Hawkins.

The Mutual Fuel Corporation, Chicago, has been incorporated with a capital of $100,000 by John M. Munshower, in South Chicago. The company is to acquire and operate coal mines and real estate property.

KENTUCKY

The West Kentucky Coal Co. has opened a new mine between Fairmont and Wheatfield, on the Providence branch of the Illinois Central.

The Kentucky Retail Coal Dealers' Association has called a meeting to be held in Louisville, September 14, to see what can be done to make things better in the coal trade. The letter is signed by R. A. Watson, president, and J. C. Taylor, secretary.

The Gordon Hill Development Co., Central City, has filed $150,000, has been chartered by W. O. Field, Louisville; J. G. Hodges, of Asheville, N. C.; J. H. Frost, Coal Co., and the Louisville Coal Co.

MISSOURI

The Hawk Point Coal & Mining Co. is planning a new mine at Raven Spring, a strip mine has been opened east of Armstrong, and coal is being marketed there. The coal was mined years ago and hauled to Glasgow, where it was sold to owners of steamboats for firing engines.

The St. Joseph Coal Mining Co. has been incorporated with a capital of $50,000 by J. H. Licit, H. T. Lavrette, M. A. Simms, G. A. Koontz and H. B. Blake.

NEW YORK

David Taylor, vice-president, Coal & Iron National Bank, New York, recently returned from his vacation in the Pocahontas district.

Jack DeQuin, assistant cashier, Coal & Iron National Bank, New York, recently returned from his vacation at Raquette Lake, N. Y.

Effective Sept. 1, the Jefferson Coal & Coke Co., Pittsburgh, will sell the coal produced by the Jefferson Coal, Keyser & Hohendorf Coal Co., and the Wet Branch Mining Co.

Central Pennsylvania will be represented on the committee appointed by W. D. B. Armstrong, board of trade, who will look after the backing up of the coal and the issue of certificates for bituminous fields, by Charles O'Neill, Altoona; H. J. Mecham, Johnstown; G. W. Martin, Huntingdon; and J. L. Peale, Clearfield; William Lamont, Elizabethtown; John Kiniry, Clearfield; J. R. Caseley, DuBois, and J. C. Forshay, Clearfield.

The Erie Railroad Co.'s ten small mines in the vicinity of Bloomsburg and DuBois, will be opened by the Boddy Coal Co., of Chicago, beginning Sept. 1. The railroad takes practically the entire output of the mines, and raises the total number of mines operated by the railroad to 10. A tonnage said to total 20,000,000. The coal mined originally sold from the three-vein coal of Wyoming, eastward through Oklahoma to eastern Kentucky, is now being sold for the production of the new mines to be shipped to the Bethlehem Steel Co., at Bethlehem.

The Pennsylvania State Fuel Commission has recently announced the appointment of state fuel commission agents to carry out the orders of the Public Service Commission. The commission appoints the State Fuel Commission for bituminous coal loading and distribution in the six coal fields in Pennsylvania. The agents were made representative of the six coal fields and一点 true of which had consisted of operators. The two agents for the central Pennsylvania district are: J. Patterson, Greensburg; west Pennsylvania district: J. F. Gilbert, Westmoreland County; J. T. Davis, Uniontown, southwestern Pennsylvania district; W. K. Perry, Somerset; southeastern Pennsylvania district: Charles F. Milner, Greensburg; northeastern Pennsylvania district; J. B. Butler, northeastern Pennsylvania district; T. D. Davis, Uniontown; southwestern Pennsylvania district: A. J. Davis, Butler; southwestern Pennsylvania district; T. D. Davis, Uniontown; southwestern Pennsylvania district: A. J. Davis, Butler; northeastern Pennsylvania district: Charles F. Milner, Greensburg; the six regional committees are: Thomas A. Burmeister, competition district; S. John Morro, Uniontown, southwestern Pennsylvania district; J. T. Davis, Uniontown, southwestern Pennsylvania district; W. K. Perry, Somerset, southwestern Pennsylvania district; J. F. Gilbert, Westmoreland County, southwestern Pennsylvania district; J. B. Butler, northeastern Pennsylvania district; T. F. Milner, Greensburg.

The Ayrdale Coal Co., Philadelphia, has notified the state Department at Harrisburg that it has changed its corporate title to the Arch Coal Co.

IOWA

A group of business men of Independence are interested in the sinking of a new coal mine in the back of J. C. Word, Kirkville, Mo., is in charge of the work. The syndicate backing the new mine has taken option on about 400 acres of land. Only local men are interested in the project.

The enginemen and boiler house of the Smoky Hollow Coal Co.'s mine No. 11, south of Hiteman, have been destroyed by fire which swept the plant. The hoisting engine was wrecked, and the coal is ruined and the coal car in the bottom of the shaft. The blaze started in the boiler room.
In the Dauphin County Court the anthracite tax act was recently declared to lack a sufficient basis to sustain the value of coal when prepared for the market. J. Claude Bedford, Philadelphia, counsel for the Dauphin County Coal Corporation, Philadelphia, which operates more coal, lost his last appeal in the Commonwealth Court involving upward of $2,000,000 in taxes. The other cases are still pending and according to questions raised will be argued later.

The Graceton Coal & Coke Co. has notified the Pennsylvania Railroad Company of an increase in its indebtedness of $450,000 to the D. M. Shriver, New York City, president.

The Schuylkill County Commissioners have purchased a total of 242,544.87 acres of land properties, which total $72,397,456 under the old valuations. The new total includes only the coal, and not the surface valuations, which are approximately $72,397,456. Breaker property will also be bought by the corporation and the company, with one of similar suits filed and has no direct bearing on the appeals from the State Court, will now be at the United States Supreme Court.

TENNESSEE

A new coal mine has been opened at Cartwright by the Palmetto Coal Co. The mine is located near Chattanooga and St. Louis R.R. It is the first one to be opened in what is known as the Tracy City field. It will have a capacity of 400 tons a day.

TEXAS

The Dollins Coal & Lumber Co., of Gonzales, has been incorporated with a capital stock of $3,000, to do a retail coal business in connection with the operation of a lumber yard in Gonzales. The incorporators are M. Davis, Ruby Davis and J. B. Gober.

The Empire Fuel Co., recently organized with a capital stock of $500,000, is incorporated under the laws of Delaware, will begin operations within the limits of the county of Rockelle. The company owns 5,000 acres of lignite lands in Milam, Limestone and Polk counties. It has also developed, Adam H. Davidson, of Dallas, is president of the company. E. A. Neisanger, formerly efficiency expert of the Dallas Power & Light Co., of Dallas, is vice-president and general superintendent of the mine. R. M. Summers is local manager on the properties of A. D. Pierson, for the SEC. The company has purchased a briquetting plant at Rockelle which will represent a production of 1,000 tons a day, and has been sold the Rockelle mine for 500,000 acres of land on the Guadalupe-Colorado & Santa Fe Ry., eight miles from Rockelle. The company also owns 3,000 acres of undeveloped lignite lands in Limestone County.

UTAH

A. D. Pierson, for the past ten years general sales manager of the Utah Fuel Co., at Salt Lake City, has resigned. He has not decided his plans for the future, but may go into business for himself.

The Carbon County R.R. Company, an auxiliary of the U. S. Lumber Co., has received a permit from the Public Utilities Commision to build a line from a point on the D. & R. G. Co. to its company's coalfields which are under development in Carbon County, the company possesses.

Mr. Pierson is well known in Utah coal circles, having been in the coal brokerage business in San Francisco.

A new mine superintendent of the Utah Fuel Co. is Thomas Farmery, who enjoys the ecclesiastical title of "Bishop."

VIRGINIA

Men yukus Lankford has been appointed chairman of the Norfolk Fuel Distributing Company of that city. This appointment was made by this committee to get Norfolk's supply of coal, estimated to be 12,000 tons to meet the needs of September.

The Chesapeake & Ohio Ry. will erect at Newport News a new powerhouse. The cost estimated to be in the neighborhood of $2,000,000 for the erection of the new powerhouse will not be paid until the board of directors of the road meets later in September. The cost of the new powerhouse will be on a rate, according to the specifications preferred by Richmond officials. The C. & O., has announced the projected expenditure of $18,500,000 in improvements in the electrical equipment of which will be the new powerhouse. This will give Newport News facilities likely to place it abreast of the foremost coal handling ports in the world.

WEST VIRGINIA

The coal holdings, equipment and assets of the LeMar Coal Co., have been purchased by the Smith & Chiea Coal Co., which is capitalized at $600,000. The property of the LeMar company was purchased for $32,000. The holdings consisted of about 80 acres. In addition to a developed mine, a modern tipple and sidetracks. The new company is making a specialty of the production of Sewickley coal.

The Goodrich Coal Co., has been organized by Clarksburg capitalists for the purpose of engaging in the coal business in Harrison County. This company has a capital stock of $50,000. The general office will be at Charleston and the new enterprise are: H. G. Smith, P. W. Bailey, M. Gibson, D. K. Smith and T. M. Pennington.

The Argonne Coal Co. has been organized in the Clarksburg field, having a capital stock of $25,000. Dan is to be the point of development and with this new enterprise are: F. N. Evans, F. D. Evans, J. N. Evans, Victoria Evans and M. P. Pennington.

Operations on a large scale are pressed by the organization of the Houch, Reidel Brothers, Coal Mining Co., just organized for the purpose of developing coal property in Preston County. This company has capitalized at $400,000. Active in the organization are: O. G. Houch, W. O. Houch N. P. Reidel and C. E. Reidel, all of Austen; R. D. Houch, Daniel Houch, of Charleston, Md.; G. W. Reidler, of Tunstall, Va. W. A.

Fatalities incident to the production of coal at the Argonne mine during the last week were somewhat less than during earlier months of the season. Ten miners were killed in a mine car accident, two by electrical shock and one in a local gas explosion. Two other miners were killed outside the mines. Two miners were killed in West Virginia, and in another single county, there being six deaths in that county.

Coal property in Clarion County of the Northern Minnesota Railroad is capitalized at $150,000. The offices of this company will be at Wheeling for the time being. Ohio County company is looking particularly interested in the new venture.

The Consolidation Coal Co. has just completed the training of five miners in the New River-Pocahontas division at Coalwood in two weeks, who were hired on the line under the direction of George M. Grer, of the Coalwood Mining and Safety company. The Consolidation devotes a good deal of time to training its mine force, and has many well-trained crews.

The Herald and Railroad Coal Co. has been organized by well-known citizens of Charleston, the short-line road to be constructed being the line of crossing several mining fields. This company was organized by J. B. Hart, Edward Hart, Fred B. H. and H. S. Horn.

Organization of the Barton-Weaver Fuel Co., presages further development of coal mining in the Carpenter Mountain Co, which has a capital stock of $15,000. The company will be capitalized at that amount. Having an active part in effecting a preliminary agreement were J. H. Barton, E. B. Weaver, Mary E. Barton, J. M. Downes and L. Hyre.

The newly formed company of Fairmont, is giving consideration to the question of purchasing 15,000 acres of coal lands in West Virginia, and is thinking of being in the Kanawha series.

ONTARIO

The Reliance Coal & coke Co., Ltd., has been incorporated under the laws of Ontario and is a general purpose company. It has been granted an Ontario charter authorizing the company to engage in a general coal handling business. The authorized capital is $35,000, and among the incorporators are E. B. Kendere, E. C. B. Connors and G. O. O'Brien.

A group of Toronto business men have formed a company known as the Toronto Coal Briquetting Co., and have taken over the assets of the Naukeasau Coal Co. The purpose is to manufacture anthracite coal briquets. Manufacturing will be commenced and deliveries are being made.

The Toronto Coal Briquetting Co., Ltd., will deal in the trade of coal briquets and carbonaceous materials. The authorized capital is $250,000 and the provision for dividends is $1.00 per share. The directors are C. B. Hender, E. E. Hender, R. E. Clark, R. A. James and H. Rowe, of Toronto, where the head office will be located.

WASHINGTON, D. C.

The United States Civil Service Commission announces an open competitive examination to determine the eligibility of candidates for positions in the Technical Staff of the Income Tax Unit of the Board of Internal Revenue, Department of the Treasury, Washington, D.C., at $3,600 to $4,800 a year, and in positions paying $2,400 or higher or lower salaries, will be filled by this examination, unless it is found in the interest of the service to fill any vacancy by reinstatement, transfer, or promotion. No person shall be considered for this examination, unless he has served for (1) General Mining; (2) Oil, Gas and Coal; or (3) Forest Industry.

Approval No. 1600 was issued on May 25, 1922, sanctioning the employment of the equipment approved under Schedule No. 18,208, for the purpose of providing machinery and equipment for hand lamp and trip line service, when equipped with a white glass dome, for trip line service, when equipped with a red or yellow glass dome and when used on either special holder which was tested with the lamp, plate and is furnished by the manufacturer.
Oblituary

L. B. Weisenburger, president of the Val- ley Coal Co., Gulfport, Miss., Oct. 27. An ex- ample of coal yards in that city and Middletown, died Oct. 16. The coal is delivered by Mr. Weisenburger at 11 a.m. on Oct. 1. The coal is delivered by the U.S. Steel Co. of Middletown.

Traffic News

A meeting of the executive committee and advisory council of the Indiana State Chamber of Commerce was held in Indianapolis on Oct. 16. The meeting was attended by representatives of the Chamber of Commerce and the State Chamber of Commerce of the city, and a group of local coal representatives.

Association Activities

The Statistical Committee of the National Coal Association is composed of the follow- ing members: J. F. Clemens, secretary and treasurer; F. C. F. chairman, chairman, coal (chairman), chairmen, and chairman of the next meeting. The committee is composed of Mr. Clemens, Mr. F. C., and Mr. J. F. Clemens. The committee is composed of Mr. F. C. and Mr. J. F. Clemens.

Miner’s Carbide-Lamp. E. J. Billings, Pittsburgh, Pa., filed Oct. 7, 1919; issued Nov. 21, 1921; serial No. 141,896.

Coming Meetings

Coal Mining Institute of America will meet Dec. 13, 14 and 15 at Pittsburgh, Pa. The meeting will be held at the Chamber of Commerce Bldg., Pittsburgh, Pa.

American Institute of Mining and Metallurgical Engineers will hold its next meeting Oct. 3 at Birmingham, Ala. Secretary, J. J. Davidson, Birmingham, Ala.

National Coal Association in Philadelphia will hold its annual meeting Oct. 23 and 24 at the Hotel Roosevelt. Secretary, Charles F. Roth, Grand Central Palace, New York City.

American Mining Congress. Twenty-fifth annual convention and exhibition of mining and metallurgical engineers will be held in the same hall, Cleveland, Ohio, Oct. 9-14. Executive secretary, J. M. Harriman Hotel; C. E. Porter convention manager.

National Exhibition of Power and Machin- ery at the same hall, Cleveland, Ohio, Dec. 7-10. The exhibition will be held at the same hall, Grand Central Palace, New York City.

American Institute of Mining and Metallurgical Engineers will hold its fall meet- ing during the week of Sept. 25 at San Francisco, Calif., and will hold its annual meeting Sept. 4-7 at Pittsburgh, Pa. The meeting will be held at the Carnegie Institute of Technology and general meetings at Carnegie Music Hall.

The Rocky Mountain Coal Mining Insti- tute will hold its next meeting at Glenwood Springs, Colo., Sept. 7-8. Secretary, W. F. Whiteside, Denver, Col.

American Gas Association will hold its annual meeting Oct. 15-17 at the W. N. J. Secretary-Manager, 126 East 15th Street, New York City.
Who is Assaulting Unionism at Marion?

The law's investigation into the Herrin horror is on. A grand jury of twenty-three Williamson County men—all farmers except a lumber dealer and a part-time miner—has been listening to testimony wrung from scores of witnesses fearful that their revelations will bring about their death by some stroke from the dark. It is a serious and conscientious effort to get at the facts in the case of the slaughter of non-union men who surrendered to a mob which had attacked the strip mine they were trying to work. It is an investigation by officers of constituted authority. It is an action by a court of the American people. Yet already this due process of law is being obstructed by devious tactics. Already the action has been labelled "persecution of labor" in a well-developed campaign of propaganda. Dominated by the moneyed interests, the courts, we are told, are trying in this case to crush organized labor. Such was the labor defense in the Mooney case. It has become well worn by usage.

But if an assault is now being made on unionism at Marion, who is making it? Who is it that stirs up public sentiment against the prosecution of the case to such a point that the prosecutors are threatened horribly—not once but hundreds of times and by many devices? Who is it that frightens witnesses to the point of silence? Who is it that openly condemns the jury action as tainted by money? Who is it that agitates for a general strike of Illinois miners as a protest against further action in the case? Who is it that suddenly begins a vicious campaign of stopping shipment of coal from the mines of Williamson County as a form of protest against the investigation? Whoever performs these acts is taking a definite stand against law and government. If it is proved that the United Mine Workers of America sanctioned and condoned such acts then the "assault upon unionism" is an assault by the United Mine Workers of America and by nobody else.

Huntington Greets Electrical Engineers

Coal mining, as we now view it, is the art of extracting coal from the ground by electrical apparatus. The engineers of West Virginia and Kentucky some few years ago felt the need of an association that would deal in the main with the mechanical and electrical problems that new methods of operation were making of vital importance to the coal industry. They felt that the old institutions—the coal-mining institutes—laid most of their stress on management, social questions, legislation, geology, air circulation, drainage, roof support and like subjects with which mechanical engineers had little or nothing to do. They wanted an institute that would limit its study to the mechanical problems of mining and would give those attending its meetings that mental pabulum which would be of value to them in their daily careers.

Electrical and mechanical engineering at the mines has a distinct industrial flavor. In some ways the mine electrician has problems in common with those of the electric-railway engineer. He has the same interest in wheels and axles, brakes and brake shoes, trolley-wire suspensions, draw-bar pull, starting problems and portable resistances. Still his problems are different. His shop facilities, to begin with, are less. His locomotives are subjected to greater violence, his tracks are lighter, his wheel gages are narrower, he must suspend his wires from the roof of the mine, from timbers or from supports drilled in the coal. He could not feel at home for this and many other reasons in societies like the American Electric Railway Association, and indeed that organization might not be pleased if he intruded his peculiar needs into the discussion of problems so widely different, though analogous.

The electrical engineer at the mines has his central stations, but his troubles are with plants far smaller than those which are maintained by most public utilities. His loads are different; his coal is obtained at a different price and is or should be in many cases inferior, for he is often striving to consume the unsalable; he is not selling power; he may be buying it. An endless line of items would be needed to show the differentiation between the public-utility electrician and his brother at the mine.

For these and similar reasons he would not be welcomed at meetings of the National Electric Light Association, for again he would introduce conditions alien to those under which public-utility engineers are operating, and the papers he would present and the discussion he would offer would be likely to lead the meeting from its special subject, which is how to generate electrical energy for the public and how to sell it when generated.

There is no industry perhaps with the meetings of which mine electrical engineers could associate themselves with advantage. They want every paper to be helpful to themselves, and the other industries have similar desires. Some use storage-battery trucks but not trolley locomotives and some use the latter and not the former. Most have a more even load and few problems in common.

The superintendent of the power and mechanical department of a mine has a machine shop to manage. He has the duties, therefore, of a machinist: but here also his problems are special. He has few repetitive jobs. His work is mainly that of repair. He cannot attempt to arrange his work after the model of a Ford, a Lincoln or a Willys. But though his jobs are smaller they can be as much bettered by judgment as can those of an automobile factory. The right tools to buy, the way to do the best with what is on hand, what extensions should be made, can best be learned from those who have the same problems to confront.

Furthermore, the American Institute of Electrical Engineers, which would seem an appropriate place for electrical mining men, gives more time to questions of
Price Control—by Indirection

AFTER some hesitation and considerable debate the Senate passed the Cummins coal-control bill last week. In principle this is the same as the Winslow bill passed in the House. When these bills are harmonized in conference the country will have legislation giving price control of coal—by indirection. It does not appear that there was more than a modicum of hesitation on the part of Congress to give the administration price control; hesitation was entirely on the point of how to do it without overreaching the Constitution. Many there are who hold that Congress has not yet, in either the Winslow or the Cummins bill, found a way to fix maximum prices on coal that is not in violation of the Constitution, but the bills have been passed notwithstanding.

The attitude of the administration on the subject of price regulation and control of distribution was voiced by Secretary Hoover on Aug. 28 in a statement to the House Committee on Interstate and Foreign Commerce. He said: "It does seem to me that there is a public necessity for action; that there should be some restraint on the exorbitant prices. It is obvious that regardless of the resumption of mining there will be an alteration of the situation from that of a short production to that of a short transportation—that we have a continuous condition of effective famine in coal. In the face of shortage in supply the coal will go to the highest bidder, and price alone is not from a social point of view a proper basis of distribution. That means the poorer classes must bear the burden of deprivation. If distribution is to be based solely upon the highest bidder, it means suffering for a large portion of our population, and it does not in this situation mean an addition to production. The usual defense of unlimited price during shortage is that it stimulates production. Our limit of coal at fair prices is a limitation on transportation, not of mining."

Mr. Hoover said that two ways of accomplishing price control had been considered. One was "to use various federal authorities as a foundation for the government taking possession of coal at a fair price." This, he explained, would put the government in the coal business, and therein lay its chief difficulty. The organization to handle it would take too long to bring together. The trouble would be over before the machine would be working.

The plan adopted by Mr. Hoover and his conference on the Presidential Coal Committee contemplates an extension of the powers of the Interstate Commerce Commission to enable that body, on the advice of the Federal Fuel Distributor (whose duties, we are told, "practically amount to the determination of facts and the establishment of co-operation"), to permit the use of coal cars only by those shippers in interstate commerce complying with established orders as to distribution and price.

It is far from clear on what constitutional grounds this power is to be granted. Washington, official and unofficial, has been debating the question for weeks. The chief counsel for the Interstate Commerce Commission, Mr. Farrell, appears to base his belief as to its legality on the theory that "if by reason of that exorbitant charge, interstate commerce is made impossible, then they go to the root of the evil and apply it to the thing over which Congress has control." That is to say, he looks to the commerce clause of the Constitution to sustain this legislation. Further on he says: "It depends upon whether it is a burden upon interstate commerce. Congress, in the first instance, has the right to exercise its judgment in determining the facts."

Whether it can be done legally or not, beyond doubt it is to be done, or tried at least. There are abundant reasons why it should be tried, reasons that lie mainly in the domain of distribution, however.

The supply of anthracite will be woefully inadequate and can be made to serve only by careful distribution all the way down the line. The government at Washington can direct the flow of this coal only between states; beyond that, at the actual point of retail distribution the good sense of the retail dealer, supported by local opinion and in some instances by state legislation, is our only hope. We feel that the trade will respond manfully.

As for bituminous coal, the immediate prospect is for a current output this winter averaging little above actual requirements, leaving such large budgets as normal storage for the Northwest and for railroads and industrial plants over the country in precarious state. Just now prices on soft coal are declining. They will continue on the downgrade only so long as buyers are willing to hold off. The recession is temporary, and prices, unless arbitrarily checked, will soon start another ascent. The pending legislation is designed to perform this checking.

Thus the coal industry faces in times of peace the kind of regulation it has been fearing and opposing since 1919. External causes have brought it about and it appears that external agencies must be depended upon to remove, at some later date, its incubus on the trade.

There is little comfort in the Herrin case for those violent anti-aliens who froth lavishly at the mouth when any crime is committed by a man named Pellini, or Malakoff, or Papafangs or Pahmkinzcheick or anything like that. The names of a large number of coal miners in Williamson County indicate that they sprang from the racial stocks of the four corners of the world, but there also are a large number in that county whose forbears trailed long rifles through the Blue Ridge Mountains and other purely American "God's countries." It would appear, from a casual glance at the long list of Hancocks, Coopers, Baxters, Kirbys and Craigs indicted by the grand jury that aliens are socially ineligible for some of "bloody" Williamson County's gristy enterprises.

Railroad Labor Is Finding Out that its goal is not within striking distance.—Washington Post.
Economical Ways of Transmitting Power Underground*

Importance of Keeping Trolley System Separate from Power Circuit—Alternating-Current Power Cheaper Than Direct—Protection Against Electric Fires—Outside Stationary Motors Should All Be Built for Alternating Current

Seeing that the problem of distributing electric power in mines is so closely connected with the source of power and the outside feeders of that power, a brief description of these will be given before dealing with the subject of underground transmission and distribution.

The main points to be considered are the voltage of the circuit used, the kind of current used, and the method of bonding the mine tracks.

The U. S. Bureau of Mines divides the voltage of circuits and equipment into three classes, as follows: Class 1—"Low." Not over 300 volts direct current or 240 volts alternating current. Class 2—"Medium." Between 300 volts and 600 volts direct current, or 240, and not over 480 volts, alternating current. Class 3—"High." Six-hundred volts direct current or 480 volts alternating current and higher.

It might well be to summarize a few of the rules that two of the states have adopted regarding electrically operated mines. The State of Alabama has the following rules: No apparatus or conductors carrying a voltage within Class 3 shall be allowed in or about working places. Portable apparatus using voltage of Class 3 is prohibited. Electrical equipment installed after this date (date not available) shall not use any voltage higher than that in Class 1 in or about working places. This does not prohibit the use of voltage defined in Classes 2 and 3 (except in or about working places) provided such apparatus is installed and maintained according to these regulations.

Three-wire double voltage systems having a maximum voltage within Class 2 may be used if the neutral is effectively grounded and if the maximum voltage between any conductor and the earth complies with these requirements.

We might also mention the following rules adopted by the State of Pennsylvania: All electrical apparatus or conductors shall be of sufficient size and power for the work they may be called upon to do, shall be efficiently covered or safeguarded as the law thereafter prescribes, shall be so installed, worked, and maintained as to reduce to a minimum all danger from accidental shock or fire and shall be of such construction, and so worked, that the rise in temperature caused by ordinary working will not injure the insulating material.

The Pennsylvania (bituminous) law also has the following provision: At every mine where electricity is used below ground for power, a competent mine electrician shall be employed who shall have full charge of the electrical apparatus in the mine, but shall be subject to the authority of the mine foreman.

We will now consider what the electrical installation of an electrically operated mine should be. A success-
ful mine haulage requires direct current for the motors of locomotives. Hence, as there must be a trolley wire and possibly some feeder wire, it is only natural that the cutting machines and pumps also should be driven by direct-current motors fed from the trolley system. Recently, however, mine owners have come to realize the importance of keeping the trolley system separate from other power circuits, so that accident on the haulage roads which may tear down the trolley wire will not interfere with the supply of power to the cutting machines, pumps, booster fans and other apparatus.

The potential supplied to trolley and feeder wires should not exceed 250 volts direct current. If the mine is of any size and the direct current is generated outside, excessively large feeder wires must be installed if a sufficient voltage is to be maintained at the working places.

With a 250-volt system electric current can be transmitted without excessive loss in voltage only for limited distances. As the current is inversely proportional to the voltage of a given connected load and the losses are proportional to the square of the current it is easy to show marked savings by the use of higher transmission voltage. These savings show up in the amount of copper required in the circuit, the output of the machines and the cost for the maintenance of the motors. Reduced voltage causes motors to operate at low efficiency and at underload and underspeed, the current used also is increased, and as the heating is proportional to the square of the current, motors soon overheat and burn out, causing delays and high repair charges. With reduced voltage at a cutting machine the lineal feet of coal cut per shift falls off. With reduced voltage the haulage locomotive hauls fewer cars per trip and makes fewer trips per shift, and eventually its motors burn out.

No set rule can be given for determining the economical limit of distance for a 250-volt system, because it will vary with the nature of the connected load. Some mines cut and haul coal on the same shift, and in this case the transmission problem is quite different from that in a mine that cuts on one shift and hauls on another. Then again the nature and development of a mine also has to be considered, so that the economic value of any given electrical system must be figured out for each separate mine.

For a large mine the use of high-tension alternating current probably will be most economical, in that a substation equipped with a rotary converter can be installed near the load center, the alternating current being dropped through a borehole into the mine at 2,100 to 6,600 volts. For this purpose a three-conductor lead-covered and armored cable is used, insulated for twice its working voltage. It is for such an installation that a rotary converter has been recommended because with most mine loads the peak determines the capacity of the machine. A synchronous converter will carry about twice as much momentary overload as a synchronous motor generator. Consequently with such a converter it is possible to use a smaller unit, which even with the necessary transformers will not cost more than the equivalent motor-generator set. Where no regular attendant is at hand to adjust the rotary converter for load variation it can be set so as to give a higher average power factor than a motor-generator set.

The room in which an underground substation is housed should be of fireproof construction, well ventilated with fresh air and wired in accordance with the requirements of the National Board of Underwriters. Transformers should be so arranged that if one should explode the oil would not flow outside the room.

The high-tension supply lines should be equipped with lightning arresters of approved type, with proper ground connections. Arresters should be located on the surface at a point near where the cable enters the borehole. A fused horn-gap disconnecting switch should be provided for each phase.

As the substation usually is located at a point near the load center, the 250-volt direct current is sent from
this station to the different parts of the mine through feeder and trolley wires, either in one or several different circuits, according to the layout of the mine. In planning the installation of these wires care should be taken to install wires of the proper size to carry the maximum amount of current which may be needed. In doing this consideration should be given to the future load to be transmitted. In any event no smaller trolley wire than 1/0 B. & S. gage should be used, but, regardless of the size, it should be securely supported on approved hangers placed at such intervals that the sag between the points of support will not exceed 5 in., unless, indeed, the height of the trolley wires is 5 ft. or more above the rail and the wire is so supported that it will not touch the roof when the trolley runs on it.

The height of the wire above the top of the rail should be made as uniform as practicable and the wire should be placed at least 6 in. outside the rail and on the opposite side from the traveling way and shelter holes. On straight runs langers should be spaced between 20 and 30 ft. apart, according to the height of the roof. On curved runs enough hangers should be placed to keep wire from swinging unduly in either direction should any one of them fall out. At about every 2,000 ft. a quick-break single-pole switch or a section-insulator cutout of the correct carrying capacity should be installed, so that, when desired, the wire can be entirely disconnected from the power supply.

All joints in trolley wire should be made electrically and mechanically efficient. This usually is done with the aid of what is called trolley-wire splicers. Means should be provided for cutting off the current in circuits branching off the main trolley wire. At some of the mines of the Consolidation Coal Co. a scheme to prevent mine fires has been put in successful use. Throughout the mines where this scheme has been adopted many pumps are located which it is necessary sometimes to keep going day and night.

In this case besides the Ohio Brass type M section insulator switch, which is installed on all branch circuits, a bypass is provided through a quick-break single-pole switch and also a fuse of the proper capacity to take care of the night load on this circuit. When the motormen make their last trip at the end of the shift they throw the regular branch cutout. This takes the power off the circuit. When the night pumper comes in, in order to get power for his pumps he throws in the bypass switch, making all the power delivered to the pumps go through the fuse. If a fall occurs during the night and the trolley wire comes in contact with the rail or any other material that will cause a ground, the fuse is blown out and before a fire can start the power is cut off.

In most mines both the feeder and the trolley wires must be placed along the roadways. These passages are necessarily low and in many places poorly lighted, if at all. Consequently these circuits must be protected at all points where men must pass under them while at their work or when traveling to or from it. It seems that the best method of safeguarding these places is to have boards on each side of the trolley wire, these boards being supported by iron hooks wedged in the roof. For feeder wires only one board may be needed.

The method of hanging feeder wires along haulageways demands careful consideration. Feeders should be so located that they will be as free as possible from mechanical injury, such as a fall of rock or coal or a derailed mine car might occasion. All trolley or feeder wires coming in or leaving the mine should be provided with lightning arresters, located near the mine opening.

The trolley and feeder wires installed in a mine should be large enough to carry the maximum current not only without danger of overheating but also without a drop in voltage exceeding 15 per cent at any point under load on the system. For this reason not only should plenty of copper be hung overhead but a good return should be provided. The rails usually are employed as a return.

This part of the circuit is just as important and has just as much bearing on the proper operation of the equipment as has the positive wire. For this reason the track rails should be fishplated and be provided with bolts drawn up tight enough to reduce the vibration of the rail as much as possible. Every joint should be bonded and the two rails cross-bonded every 200 ft. Provision also must be made for bonding around all
switches, frogs or openings in the track, so as to insure a continuous return, no bond of less than a 2.0 wire being used, and where necessary 4.0 should be provided.

On main-haulage roads it is good practice to bond both rails. After the bonding is installed it should be carefully maintained and given care equal to that afforded positive wires. If not properly maintained the voltage drop may become excessive. There is danger also that shocks may be received from a poor return.

In the last few years the electrically welded bond has been used extensively in mine work, and no doubt it will be adopted eventually at every mine where greater efficiency at low cost is sought. At one mine two men did all the bonding, using compressed terminal bonds. The placing of ten bonds was considered a good day's work, the men being required to drill the necessary holes in the rails.

After a little teaching these men learned to install electric-welded bonds, and after a short time they did not feel satisfied unless they had installed on old track:

![Image of a switchboard]

**BACK OF THE SWITCHBOARD AT MAIN SUBSTATION**

Showing also part of one of the alternating-current motors on the left and the resistance grid above the switchboard.

At least forty such bonds in a shift and as many as sixty where the track was new. Two years ago about 400 such bonds were installed in a certain mine, and up to the present day not over six of these bonds have been reported as loose. Every one of the defective bonds happened to be among the first installed. At the time they were made the men had not had the required experience to do good electric welding. The men in charge of this work are convinced that the electric welded bond is far superior to any mechanical bond so far used: first, because a better electrical and mechanical joint is obtained, and, second, because the cost of installation is lower.

In recent years many engineers have advocated running all machinery, except the haulage locomotives, with alternating current. As a result fans, pumps, coal loaders and mining machines are now available driven by alternating-current motors, but before adopting this current for mining machines particular attention should be paid to the type of machine selected and the conditions under which it is to operate.

The squirrel-cage induction motor generally used for mining machines has practically constant-speed characteristics, and the speed cannot be satisfactorily varied by the use of resistance, but the three-phase squirrel-cage induction motor is more rugged and freer from trouble than the direct-current motor. As it has no commutator or brushes, repairs to windings are made much more easily. This type of motor when over-loaded or subjected to a reduced voltage will practically quit, so it is not likely to burn out like a direct-current motor.

The starting torque or ability to accelerate a load from a standstill is more definitely fixed or limited in the squirrel-cage induction motor than in the compound-wound direct-current motor, and as a result the mine wire must be well installed and normal voltage maintained under full load if an alternating-current installation is to be operated satisfactorily. This feature of the induction motor of not operating when the voltage has dropped is really more of an advantage than a fault as it demands better voltage regulation, which in turn means efficiency and increased production at lower cost.

Should direct-current motors refuse to work when proper voltage is not maintained many mines in the long run would make a much better showing. They would produce coal more cheaply and keep the cost per ton more uniform year in and year out.

**SHOULD ALTERNATING-CURRENT CUTTERS BE USED?**

Everything considered it is a question whether in the larger mines the alternating-current motor-driven mining machine should be used where the mine has not been developed to a point making electric haulage necessary. Provided alternating-current power can be purchased, it might be good policy to use it, installing transformers above ground and supplying power to three-phase induction motors on the mining machines through a three-phase cable properly installed in the airway or lowered through a borehole. Such an arrangement might give good results at a minimum cost of equipment.

Whether alternating-current motors should be used to drive pumps inside a mine depends on many conditions, but where they are favorable and alternating-current power is obtainable there should be no hesitation about the matter. It is sometimes an easy matter to lower a 2,200-volt three-phase cable through a borehole located centrally over a number of the larger pumps.

In this case the transformers could be located at the bottom of the borehole, in a room of fireproof construction, the 2,200-volt current before entering the transformers being passed through fuses of the proper capacity, and from the fuses into a three-phase oil-break switch equipped with an automatic overload trip having a trip coil in at least two phases. From this oil switch the wires could then be brought to the three transformers.

The circuit leaving the transformers need not be provided with either switch or fuses if these are installed at the places where power is used. It is hardly necessary to mention that the transformer room, besides being of fireproof construction, should also be well ventilated and well lighted and that all wiring should be done according to the requirements of the National Board of Underwriters. The secondary of the transformers should be either of 220 or 440 volts. The motors driving pumps should be of the squirrel-cage type and motors above 5-hp. should be equipped with either a manual or an automatic starting compen-
sator, either type to have no-voltage and overload release coils.

The cost of power also is an item to be considered when figuring on such an installation. The following figures give the costs of alternating-current and direct-current power per kilowatt-hour. They are taken from four large mining properties operating their own central power plant and are for the year 1921, when coal prices and wages were at their highest. We will call the different plants Nos. 1, 2, 3 and 4.

No. 1 plant generated alternating current at a cost per kilowatt-hour of 0.66c., the direct current at the mine cost 1.13c. for the same unit. At No. 2 plant alternating current cost 0.75c. and direct current 1.57c. per kilowatt-hour. At No. 3 plant alternating current cost 1.10c. and direct current 2.54c. per kilowatt-hour. At No. 4 plant alternating current cost 1.44c. and direct current 2.86c. per kilowatt-hour.

From these figures it will be seen that the difference in cost of power alone is an item on the side of economy large enough to favor the installation of alternating-current motors on pumps wherever possible, but, as mentioned before, the final saving in the power bill depends on many other conditions besides the cost of the current used. The lower maintenance cost will justify the extra investment involved in providing an alternating-current installation. In gaseous mines, of course, preference should be given to alternating-current equipment regardless of first cost, for an alternating-current motor has no commutator and brushes to form arcs and so explode any gas that may be present. For these reasons whether to use alternating- or direct-current motors to drive pumps is a problem to be solved individually at each mine.

DETAILS OF TOMS CREEK ELECTRIC INSTALLATION

The following is a description of the underground transmission system installed in the Toms Creek, Va., Mines of the Virginia Iron, Coal & Coke Co. H. E. Carlton is electrical engineer for this corporation and credit must be given him for this information. Should the potential be 250 volts direct current in place of 600 volts, and other conditions remain the same, the installation would be a model in every way, but this committee could not recommend the installation of any direct current having a potential exceeding 250 volts.

The Virginia company has ten openings at the plant mentioned. These are scattered over a distance of approximately four miles and are disposed almost in the shape of the letter “S” with the curves flattened out. A substation is located at each end of the long line of openings and a third has been built three miles from one end and one mile from the other. The machines are 200-kw. 600-volt direct-current generators driven by 2,300-volt 60-cycle synchronous motors. They are all hand-started with full-automatic feeder panels. Two machines connected for parallel operation are installed in each station and each station is connected with the other two for parallel operation. The center station, although the last installed, is the key or main station and operates 24 hours per day.

The other two are operated for 8 hours only, one machine being normally used in each station. This leaves two machines in reserve at all times, so that any one station may be out at any time and not interfere with the operation of the mines.

The outside feeder capacity is so distributed that at full loads no more than 10-per cent line drop is allowed. The result is that the voltage is practically constant at every point of delivery.

No. 1 mine is on the retreat so that the problem of filling future requirements is past. The mine is fed by 2/0 figure-eight trolley wire suspended on pipe driven into boreholes in the side of the coal so as to give the wire a uniform height of 6½ ft. above the rail and 18 in. to the right of the track. All crossings where the standard height cannot be maintained are guarded with 3x6-in. boards fastened to the roof.

BOND JUST LONG ENOUGH TO CLEAR SPICE BARS

The return is secured by bonding one side of the 40-lb. steel with 2/0 pin-driven all-wire bonds 26 in. long, which is just long enough to clear the splice bars. When installed in this manner a wrecked car rarely will cut out a bond. These bonds are installed on the inside of the rail.

The load consists of one 20-ton bar-frame locomotive, one 20-hp. pump motor, and one 25-hp. fan motor. The coal in this mine is gathered by mules, and the loaded cars have to be drawn up heavy gradients.

Number 2 mine is fed by approximately 6,000 ft. of 4/0 figure-eight trolley wire with 2,000 ft. of 300,000-circ.mil cable feeder in addition. The current returns by 40-lb. steel with 4/0 pin-driven all-wire bonds up to 4,000 ft. where the return feeder from No. 2 station comes in, the rest of the road being bonded with 2/0 bonds of the same type. The trolley wire is supported by pipe hangers in the side of the coal rib and by roof hangers fastened in the roof with the aid of expansion bolts.

When the roof is of sandstone a timber hanger is used. This is installed by drilling two 1-in. holes 4 in. deep, a poplar wood plug being driven into the holes thus formed. Two 20-lb. track spikes driven into the wood complete the job. This method gives a secure support of low cost, and it stays in place longer than any other type of roof construction I have ever used.

The load in this mine consists of two 15-ton trams, four 4-ton gathering motors and mine-pump motors aggregating approximately 100 hp. Two storage-battery locomotives also are used in this mine.

No. 3 is the largest of the mines and has the most coal for future development. It is being worked on the three-way system with the left and center main both tracked to the heading. The east and west headings are driven on the face with cross entries to the right and left. The main feeders are two 4/0 figure-eight trolley wires for approximately 11,000 ft. with a 300,000-circ.mil cable extending about 8,000 ft. into the mine. The current returns by a single track bonded on both sides with pin-driven 4/0 all-wire bonds installed on the inside of the rails.

This track is of 56-lb. steel. The other main is laid with 68-lb. steel and is bonded with the same size of bond. Both tracks are cross-bonded every third rail and the two tracks are connected every 300 ft. with a 300,000-circ.mil cable.

The trolley wire is supported by mine-timber hangers installed with expansion screws part of the way and spikes and plugs the rest of the way. To date the spikes have given the best service, but as the Merkel of them have been in place only six years, the lasting qualities of this method of construction have not yet been completely tested. As the hangers put up with spikes and plugs have been up six years and so far have not given any trouble the chairman of this committee
toward charges for slate yardage which are not matters of opinion than for dead work (which is not so clearly specified in the understanding between employer and employed and which is not as easily assessed) the mine boss will turn in dead work as yardage. Nothing will be said here of actions not having even this degree of justification except that they have been known to occur. I may say also that a method closely resembling this has been used by the Pennsylvania Coal & Coke Co. with offices at Cresson, Pa., using a cross surrounded by a circle as a station and an acute-angled L to designate a corner.

More Details as to Jerry Dunn's Output

Desire having been expressed to obtain more information regarding the output of Jerry Dunn described in Coal Age, Aug. 10, p. 216, the following further details will doubtless be of interest: The rate paid was 60c. per car, making a straight earning of $255.47. In addition he received a bonus of 8c. per car, or $37.52, a prize as leading coal loader at No. 3 mine of $10, and a further prize as crack leader in the contest between Loma No. 3 and Corna No. 2 of $20—a grand total of $362.99 for thirteen days' work, or $25.61 per day for straight earning and bonus, and $27.92 per day figuring in the prize awards.

The coal, which was of the Island Creek seam, was free from impurities; a No. 3 shovel and a breast auger were used by Jerry Dunn for loading and drilling shotholes respectively except that about 25 per cent of the drilling was done by electric coal augers; the working place was dry; the coal was shot by Monobel; two tracks were laid in the 36-ft. room and a gathering locomotive supplied the cars.
Cost and Track Data and Other Facts Relating to Upkeep of Mine-Locomotive Wheels and Tires

Worn Wheels Make Locomotive Parts Drag Roadway, Causing Wrecks —Tables Showing Commercial Sizes of Wheels—Replacing, Resurfacing, Rebuilding and Grinding Tires—Frog and Switch Formulas

GREAT is the need for a detailed investigation of mine-locomotive wheels and tires, their care and maintenance. Mechanical engineers should thoroughly analyze the conditions to which such equipment is subjected and determine those which are favorable and find methods of remedying shortcomings.

Too much of the so-called "experience" related and "advice" given is not based upon investigation but is handed down time after time and used as a remedy for all conditions, little thought being given to the original circumstances to which it had reference. Personal favoritism and prejudices enter into such experiences or advice, and as such are without much weight. If you can back your practices by facts developed from research, time will be saved and waste prevented.

The time required for a thorough research or investigation into this subject is not a matter of a few weeks or months. It can come only as the result of records which have been well and industriously kept for years, in which is shown the service received, maintenance required and the conditions encountered for each of the various classes of wheels and tires. Until you keep a record of these things you will be at a loss to know what service to expect under conditions obtaining and will be unable to compare the relative merits of the different types of wheels and tires.

The standardization of these parts is of mutual interest to manufacturers and coal companies. The chairman of the committee on "Mine Locomotive Wheels and Tires" of the Electric Power Club, which is investigating the subject, informs us that they will soon recommend such standards.

It is to be hoped that these specifications will be such as can readily be adopted by manufacturers and local companies, and that the committee will be found to have based its investigations as to these standards upon actual conditions met in the mines rather than on a too liberal use of theory or on tests made on factory tracks.

Some of these proposed standards could be announced but until the Power Club Committee has completed its recommendations these details will not help you to resurface the worn tires and wheels that lie waiting at the mine for your return.

To appreciate more fully how important it is to take proper care of wheels and tires let us consider for a moment the interrelation between tracks and locomotives. Badly worn wheels and tires invariably cause poor track, and poor track generally causes excessive wear on wheels and tires. Some coal companies permit their locomotives to operate through pools of water, over muck-covered rails and through sands that literally grind out the bearings. Where the responsible parties are ignorant of such conditions or believe it is an economy to ignore them they continue to add heavily to the cost of mine operation.

When we look back to the day of mules, from our present electrified mines, it recalls to us the manner in which we figured their values. It was obvious to anyone that a mule's value continually became smaller with passing years. Given two mules with a difference in age of five years but equal in all other respects, the younger one was worth more money, for, barring extraordinary circumstances, it was practically certain that he would outlive the older. The mule had a limited life and consequently as year by year elapsed he possessed less potentiality for usefulness and his value accordingly decreased.

The mine locomotive has a period of life just as defi-
FIG. 1—DESMOUNTABLE TIRE FOR LOCOMOTIVE WHEELS

A, the demountable tire; B, the axle; C, the solid gear; D, the wheel center; E, the inclined retaining ring; F, the tackle retaining ring and G, the key for the ring.

mine as a mule and consequently is just as sure to depreciate in value. With a mine locomotive running day after day for months, doing its assigned work without any apparent loss of efficiency, it seldom strikes some people that it is in any other than the best of condition. Every machinist knows well that a silent lessening of its value is going on and that eventually it must be abandoned.

Harming obsolescence, the life and depreciation of any mine locomotive will vary according to the conditions under which it operates and more particularly upon whether timely or untimely repairs are made. Its parts subjected to the hardest wear should naturally receive first consideration in maintenance; if they do not, the life of the locomotive will be greatly shortened by this neglect.

You will notice instances where wheels and tires are worn so badly or resurfaced so often that parts of the locomotive will drag on the bottom or catch on switches or cross-rails. Many wrecks can be attributed wholly to this cause, and the loss due to the delays they occasion and in the damage done will far exceed the expense which would have been incurred had the wheels been duly re-tired.

The damaging effect of badly grooved wheels on mine track is seemingly slow, but track subjected to such conditions will depreciate 10 per cent faster than other track carrying an equal volume of traffic but traversed by locomotives having well-surfaced wheels. Without good haulage roads the mine cannot be operated successfully, and care always must be taken to keep transportation facilities favorable to good track and by prompt attention to the needs of the haulage equipment.

If you are at all interested in the condition of your locomotive, you cannot afford not to be just as interested in the mine tracks. If you boost for good locomotives, boost first for good track on which to run them. You may not be responsible for the maintenance of the tracks, but report their inequalities to those who are. Keep on reporting them until to keep you quiet they are put in proper order.

Keep the maintenance of the locomotive wheels and tires one step ahead of that of the track and there can be no retaliation. About 20 per cent of all accidents in the mining industry are due to haulage. In all probability 50 per cent of these are due to poor track, wheels and tires. Investigate as many wrecks as possible and remedy the conditions that cause them wherever you can. Some general track formulas are listed in this article for this specific purpose.

In many cases it is impossible without first removing the trucks from the locomotive to determine the exact diameter of the wheel centers for which tires are to be purchased. Some tires have a shoulder which extends over the outer rim of the wheel center, and owing to the design of the locomotive it is impossible to measure on the inner side of the wheel. Locomotives are left to

* Under Morgan-Gardner are expressed thus: 14G (16G). 14G is the inside diameter of tire and 14 the diameter of wheel center, both in inches.
run on worn wheels because the management believes it cannot afford to stop them long enough to remove the trucks for the taking of these measurements.

If the record of the sizes and performance of tires to which we have previously referred were kept this trouble would be eliminated. Rarely is information to be found on hand around the mine giving general data on the sizes of tires and wheel centers, and for this reason information of this kind has been sought from several manufacturers, and it is listed herewith. All mine-locomotive wheel and tire manufacturers should indicate on all wheels and tires in some permanent manner their exact diameters, widths and thicknesses.

ON CURVES, FLANGES AND TIRES WEARUNEQUALLY

Where curves in the mine tracks are in one general direction, the flanges and tires on the outside-rail side usually will wear faster than those on the opposite side. Under general haulage conditions in the mines it is also often found that the wheels or tires on the gear end of the locomotive wear much faster than those on the opposite end, but that the flanges on the gear side do not wear thin as fast as those on the opposite side.

The wear on wheels, tires and brake shoes is materially reduced by the use of a dynamic-braking controller on the locomotive, for a heavy downgrade can be negotiated under heavy load without putting on the brakes and sliding the wheels, and because in stopping a trip the brake shoes have to be applied only after the controller has reduced the speed of the locomotive to practically zero. With this controller the motors are connected in series. This reduces the possibility of spinning the wheels when starting a trip.

The dynamic method of braking is accomplished by connecting the motors as generators. By proper manipulation of the controller when the motors are so acting the controller will regulate the resistance sufficiently to produce the desired braking effect.

In removing tires from wheel centers it is customary to heat them with a gasoline or kerosene torch, upending the axle so that the wheels can be imbedded in a fire, air under pressure being supplied through a circular pipe fitting around the wheel. They also are frequently

FIG. 5
Preparating
to Turn Badly
Grooved Tread

Too often a tire that has become badly grooved is allowed to run on long after prejudice would favor its re-surfacing or removal. It is probable that if the turning when turning is all that is needed, could be done without the locomotive being hauled off during operating hours it would be far more frequently done with less risk of derailment and less hazard to life and property. A mine is fortunate indeed if it has motive power enough so that one of its locomotives can always be in storage or can be readily spared so that at any time it can be put in the best of condition for safe and efficient operation. This illustration shows a fatigue in the workshops of the Arrow Coal Co., Rockingham, Pa.
removed by the use of a special type of forge over which the tires can be revolved.

The new type of demountable tire developed by the General Electric Co. for mine locomotives is worthy of consideration, for such tires can be removed in much less time than those which are not so designed. Furthermore, with this type of tire the axle or wheel center is not subjected to excessive heat such as is sometimes developed when tires are removed by other methods.

When tires are worn to a point where they must be discarded, it is better to break them by the methods shown in Figs. 1 and 2 than to remove them by heating.

Only in a few cases are the machine shops at the coal mines equipped with a tire lathe—that is, one that will turn two tires at one time and do it without the prior annealing of the metal. A lathe of this type will turn two tires in two hours. The small lathe usually found at the mines cannot turn tires unless they have been annealed, for the lathe cannot cut the hard crystallized surface which has developed on them. Before placing the tires on such a lathe they must be annealed to a dull red and allowed to cool naturally in air.

They are generally shrunk on the wheel center while cooling and they are then resurfaced. If the tire is turned by the use of chucks it must be reheated after turning and shrunk on the wheel center. Three tires a day is a fair average for this method of turning. In either case when the tire is being turned a drip composed of two parts petroleum and one part turpentine should be used for lubrication.

The use of abrasive brake shoes has done much to retain the proper contour of the wheel or tires. The grades on the haulage roads have much bearing upon the manner in which they should be used. To eliminate undue wear upon the wheels and tires they must be interchanged in many cases with common brake shoes.

A grinding machine has been placed on the market for the resurfacing of tires. It is so designed and operated that the tires can be ground without removing the trucks from the locomotive. The grinding wheels are on the same elevation as the track, and the motor
is run into position as if it were being spotted over a pit in the machine shop. A limited inquiry into the merits of this machine discloses quite a difference of opinion as to its performance and results. It cannot be condemned or recommended until a thorough investigation has been made and until several questions have been answered by practical experience:

(1) When grinding the locomotive wheels are turned by the friction of the grinding wheels. This may prove satisfactory on a special type of locomotive but will it work well on all types?

(2) If there is 1 in. or more play in the journal boxes caused by worn bearings or wheel hubs, how can the flanges be prevented from playing on the grinding wheel?

(3) If two tires are worn unequally or to different diameters how will the two be brought to the same diameter in one operation?

(4) How many tires per day can be resurfaced?

As far as the lathe or the electric welder can be placed in constant service for general repair work as well as to resurface the tires the investment in the electric welder and maintenance costs for a grinding machine, which has only one definite use, be justified by considering its use affords. If not its installation will be unwarranted.

Building up worn tires and wheels successfully and economically with the use of the electric welder requires an operator who has by experience acquired the technique of manipulating the electrodes and their application to the various classes of welding.

For building up tires a 1/2-in. metallic electrode does the best work but more speed can be made with one of 3/4-in. diameter. The 1/2-in. electrode requires 200 to 250 amperes whereas the 3/4-in. requires from 250 to 300.

The worn space to be filled up, using a 26-in. tire as a fair example, will require on an average about 10 lb. of metal. A competent operator should fill this in at the rate of 2 lb. per hour. At this rate two tires could be rebuilt in ten hours.

In general practice around the coal mines the tires are placed flat upon a turntable at a convenient working height. The welding is then done in 2- to 3-in. sections at a time, starting at the flange and welding across the tread and in four equidistant points around the tire. If instead of removing the tire and placing it on a turntable the locomotive truck is set up on a pedestal the operator will make two welds, one on each tire, while in the one position, then roll the axle 180 deg. and repeat the welding, and so on until the original weld is reached.

Such a procedure holds the localized heat to an absolute minimum, and this becomes more essential as the carbon content of the metallic electrode is increased. An electrode having 0.10 per cent carbon or less will give complete satisfaction. However, if it is desired to use a rod having approximately the same carbon content as the tire itself, there are no difficulties, except that the price is slightly higher per pound.

For tire work no metallic electrodes in which the carbon is in excess of 0.75 per cent should be used, for with the harder metal it seems difficult to prevent local strains. Tires will break by using this high-carbon metal because the local strains cannot be compensated.

How to handle the resulting tire after it is built up doubtless will puzzle operators who are not equipped with lathes large enough to swing an axle complete, much less the larger size tire. A portable grinding wheel satisfactorily overcomes this condition. It is possible to use these tires without turning if the operator has put on the finishing layer expertly.

It is claimed for the electric welder that a tire can be built up three times after each surfacing. Upon this assertion, using prices as indicated above, the life and maintenance cost per tire would be as in Table VII.

As it is not considered profitable in general practice to rebuild flanges on tires, the flanges in all probability will be worn beyond repair before the tires could remain in service for a life such as indicated above. Many mine locomotives are designed so that the wheels cannot be resurfaced, and must be maintained as near their original diameter as possible, because of the under-hangings of the locomotive, which if lowered by worn wheels will catch on switches, etc.

The electric welder has its advantages in cases like this, and it means a considerable saving. When one wheel is worn deeper than the other, it is necessary to resurface both wheels to the diameter of the one worn the deepest, thereby unnecessarily shortening the life of the other tire, but by rebuilding the tires electrically this waste is eliminated.

A locomotive having the minimum height above the rail has many advantages, but it is always well to investigate the conditions, prepared if possible to sacrifice a few inches of height in order to allow space for the complete utilization of tires and if possible to use tires as much as one inch oversize.

### TABLE VIII. FROG AND SWITCH FORMULAS

Relative Merits of Storage-Battery, Combination and Conductor-Cable-Reel Gathering Locomotives

Believed That Larger Capacity Straight Battery Type Might Show Rate Two Cents per Ton Lower Than Combination—Reel Type Fits Heavy Grades; Combination, Medium Grades and Straight Battery, Low Grades

The authors of this paper hope that the relative merits of the various types of locomotives now in use have been laid down in this article without bias, the sole purpose of preparing it being to bring to light the advantages of one class of gathering locomotive over another under certain specified conditions. This is done for the benefit of those who have invested or who may be contemplating investing their money in motor equipment.

Miners and electrical men of recent years have much discussed the merits of the different kinds of gathering locomotives practically all of which will come under the three classifications named in the title. Widely differing experiences have been reported. There is reason to believe that much prejudice has crept into the argument because of the misapplication of the equipment and the slowness of all human beings to admit their mistakes and accept new developments. Therefore this article will be confined to facts so far as the members of this committee have been able to obtain them, associated, we hope, with logical reasoning.

All Three Machines Have Their Proper Place

In this way, with no selfish end in view, we hope to show the relative merits of straight-storage battery, combination and conductor-cable-reel gathering locomotives from an operating point of view. This will be done primarily under what we consider average mining conditions, but we will state before going further that we expect to find an economical place or condition for each of the above classifications.

Before presenting any data it is in order to discuss briefly how and under what conditions these data have been obtained and compiled, and the kind and size of the equipment considered.

Records of Nineteen Locomotives Collected

Records of nineteen gathering locomotives have entered into this comparison. They are owned and operated by the Logan Mining Co. in the Logan field.

These engines are classified as follows: Nine combination storage-battery machines, all equipped with 88-cell lead batteries, all 13-plate except one, which is a 15-plate cell; seven straight storage-battery machines all 48-cell; and, two 17-plate, three 19-plate, two 21-plate, making the average 19 plates; three locomotives of the conductor-cable-reel type.

These locomotives are not all at one mine but are divided as follows among four operations: One mine has one straight battery and one cable-reel machine; another has four combination machines that gather and rip their coal to the slope bottom; another has four straight battery, two combination and two cable-reel machines; the remaining mine has two straight battery and two combination locomotives.

The coal beds at the four mines range from 5 to 6.5 ft. in thickness and are generally considered level, but have numerous local dips ranging up to 4 per cent. These of course will average about "fifty-fifty" in favor of and against the loads. In general these mines have what would be considered good average mining conditions. Forty-pound steel is laid on all main haulways and 20-lb. in all butt entries and rooms.

Locomotive Maintenance Costs Closely KEPT

This company has kept an extremely accurate maintenance-cost system on the practical operation of its locomotives from March 1, 1920, to date. It is through the courtesy of this firm, the chairman of this committee being an employee in the capacity of chief electrician, that we have been given access to a large part of the facts that will be presented in this paper with the assurance of their reliability.

A monthly cost record is kept of each locomotive on standard forms printed for this purpose. The electrician at each mine makes an itemized record of each repair part used, the date of its installation, and the number of hours consumed in making the repairs. Also on this same sheet the daily tonnage of each locomotive is accurately kept. When a new battery is installed and after a deduction is made for credit on the old battery returned to the manufacturer the rest is charged monthly with depreciation calculated on a two-year life, stopping the charge at the end of two years where the battery exceeds the estimated life or doubling up during the last months should the battery perishance fall short of that period of usefulness.

Maintenance of the batteries, including the replacement of water, is recorded on these sheets, and at the end of the month the results are totaled up, showing the tonnage, total cost and cost per ton for the month. One or two good months will not be picked from these records and a comparison made from these, but the records back to March 1, 1920, covering a continuous operating period of twenty-seven months, terminating June 1, 1922 will be taken. A point that we wish to emphasize here is the length of the time interval that these records cover. The experience over a number of months is essential if figures of this nature are to furnish reliable indications.

The many conflicting stories and reports on the subject under consideration doubtless arise from the fact that the most of us do not dig deep enough when making comparisons or drawing conclusions. Offhand it might seem that compiling and comparing the records mentioned above would be all that would be necessary to settle this question, but it is not, because this compilation does not represent more than 30 per cent of the cost that should be entered against these locomotives.
and introduced when making such comparisons. We must not be satisfied till we have reduced every possible alleged advantage or disadvantage to facts or figures. It matters not what claims may be put forth; if they fail to show a reduced cost per ton they are not worth considering, for this is the vital point of interest and is the only characteristic that can really be counted of advantage. In other words this is not a question of individual likes or dislikes, it is a question of dollars and cents. After our data are exhausted, however, we will consider some of the points of advantage for which we have no substantiating figures.

The largest item of cost entered is for the wages of motormen and brakemen. The average wage these operatives received during the period under consideration was $5.59 per 8-hour day, the mines working 404.5 eight-hour shifts during this time. The next important item is the power-demand charge, which in this locality is based on the highest integrated 5-minute peak that occurs during a month. This charge is $1.80 per kilowatt per month, and to it the regular charge for energy must be added. By the use of straight storage-battery locomotives this demand charge is at a minimum, as the day load is reduced and the power consumption spread out more evenly throughout the 24 hours of the day. The straight battery machine being the most economical from this point of view we make it as a base.

Accordingly we must charge the cable-reel locomotives with a demand equal to the capacity of their motors, which is 30 kw., as they all draw their power from the trolley and do it during the day shift, when the maximum load is on. The motor capacity of the combination locomotives is 20 kw. Apparently they should be charged with 20 kw. of demand, but as they operate from the trolley only 20 per cent of the time they rarely ever all draw their maximum capacity from the system at the same time. Consequently they are charged with 75 per cent of their capacity, which is 15 kw. per locomotive per month.

CHARGES AGAINST MACHINES THAT USE TROLLEY

Reel and combination locomotives are charged with increased copper, trolley hangers, bonds and labor for bonding butt entries, but these charges are spread out over the total tonnage of a 1,000 x 300-ft. panel in a 5-ft. seam with 80 per cent recovery. The maintenance cost of the wire and bonding is not considered, as it will just about offset the value of this material when the entry or panel is worked out. But there is another charge of like nature. It is well known that if cable-reel or combination gathering locomotives are being used more substation capacity and more copper in the whole transmission system are required because a greater percentage of the total power consumption is being used in a shorter period than would be the case where straight storage-battery machines were being employed. Hence these two charges must be made against these two types of locomotives. They are divided between them in about the same proportion as the demand charge, but they are based on the total tonnage of an average-size lease or mine.

We have investigated and reduced to conservative figures another claim or charge that must be made against the cable-reel gathering locomotive. This is power failure or interruption. It is certain that if this type of locomotive is being used when there is such failure or interruption the whole mine comes to a dead stop almost instantly, so far as the moving or transport of coal to the tipple is concerned.

When failures of 10, 20 or 40 minutes duration occur does the cost stop? Most assuredly not. Can we prevent these interruptions? No; they are not within our reach. Are they the fault of the locomotive? They certainly are. They should continue working, power or no power, for that is just what a battery locomotive does. Consequently we must admit that when it comes to the question of considering merits and demerits the reel type of locomotive should be charged with at least a portion of the additional cost arising from this weakness and inflexibility.

The power company's record in this locality from a time standpoint shows 98 per cent supply. This means that during 2 per cent of the time no power is available at the mines, and we accept this as a pretty fair degree of service. But it also means that on an average during 28.8 minutes out of every 24 hours no power is available. It is reasonable furthermore to believe that 75 per cent of this failure will come during the 8-hour working shift, because this is the period of heaviest load. This being the case, the period when power is lacking averages 21.6 minutes during each working shift, or is equivalent to 4.5 per cent of the working time.

Assuming the average cost of production throughout the period of time under consideration as being about $1.75 per ton, 4.5 per cent of this is 7.78c. of cost per ton arising from power failure. The coal company's records show that the mines operated only about half time and as power failure would not be particularly injurious on the days when coal was not actually being produced we cut the above figure in half, which still leaves 3.94c. per ton. Because this figure still looks too high and because we might have overlooked something this charge is further cut and entered against the reel-type gatherer at 1.75c. per ton.

We realize that a battery locomotive could not continue its work over any protracted period of time should
The power not be restored, because the mine cars would all be filled and because the mine could not continue to operate without ventilation, but the records show that the average duration of these failures is 15 to 20 minutes. It is obvious that with storage-battery locomotives these short interruptions are scarcely felt, as the main-haulage locomotives and tippers almost always have a surplus of capacity sufficient to overcome these short delays, provided the leaders at the working face are kept going.

So far we have considered only the total power failures. There are not all, however, as in all probability the local or partial failures from the substation to the mine are as frequent and as long in duration as the total failures. We have no definite data on this detail, however, so we merely drop it here as a demerit against the cable-reel gatherer.

Another consideration in connection with power failures that we have not been able to convert to figures but one which is nevertheless pronounced in its effect on cost is the fact that miners are difficult to hold in a mine when they fail to get cars promptly, especially when the delay comes in the afternoon; consequently a power failure of 30 minutes in the afternoon often leaves a mine badly crippled for the remainder of the shift. To those who closely watch the daily cost statements of a mine the effects of such happenings are often noticeable to the extent of 25 or 30¢ per ton.

We conclude here the description of how the data to be presented have been assembled. We have been highly conservative in the few estimated figures entering into this comparison, and without question the locomotives against which charges have been made have been given the benefit of all doubt. Therefore, Table I is presented to show the relative merits of combination, straight battery and conductor-cable-reel locomotives.

**TABLE I—RELATIVE MERITS OF COMBINATION, STRAIGHT BATTERY AND CONDUCTOR-CABLE-REEL LOCOMOTIVES**

<table>
<thead>
<tr>
<th>Combination</th>
<th>Straight Battery</th>

<tr>
<td>Cost per ton, kw.</td>
<td>25.21</td>
<td>21.90</td>
</tr>
</tbody>
</table>

The foregoing tabulated data show that the straight storage-battery locomotives have an advantage of 0.07¢ per ton over the combination machines. Although this is correct, if we stop here we will not do justice to the straight battery locomotive; therefore we present Table II, showing the comparative capacity of the two.

</table>

From this it may be seen that the combination machine drawing 20 per cent of its power from the trolley has a battery equivalent of 4.23 kw.-hr., which gives it an advantage of 35 per cent in capacity over the straight battery locomotive. The table of percentage shows that the combination has led the straight battery machine by only 23 per cent in tonnage notwithstanding its 35 per cent advantage in capacity.

**INCREASING SIZE OF STORAGE-BATTERY MACHINE**

This difference in tonnage cannot be traced to anything but a difference in capacity resulting from the fact that the mileage rating of both types of locomotives under consideration is the same when operating from the batteries, but the combination has 42 per cent advantage in speed over the straight battery machine while operating from the trolley, providing 250-volt pressure is maintained on the section from which cars are being gathered. This latter condition is possible but not practical, consequently we drop this apparent advantage and assume that the straight battery machine equipped with the same capacity as the combination locomotive will gather the same tonnage under the conditions being considered. This would require about a 27- instead of a 19-plate battery, which is approximately a 50-per cent increase.

If we go back to the data in Table I referring to the seven straight battery locomotives and increase the battery depreciation 50 per cent and the repair cost and tonnage 25 per cent based on the combination tonnage, while the operating cost remains the same, it will give the results set forth in Table III, showing what the cost and tonnage figures would have been on these locomotives had they been equipped with this additional capacity.

**TABLE III—TOTAL TONS INCREASED BY 38.9 PER CENT, OR FROM 355,852 TO 494,278**

Had the data already given in this paper been procurable at the time the above equipment was purchased Table IV could have been prepared.

**TABLE IV—RELATIVE MERITS OF STORAGE-BATTERY, COMBINATION AND CONDUCTOR-CABLE-REEL GATHERING LOCOMOTIVES, LOGAN MINING CO.**

<table>

</table>

By comparing the repair cost alone of the three types of locomotives the combination will seem a little high, as it has no cable cost or reel maintenance. This is due to a rather delicate equipment originally installed in eight of these locomotives. This equipment was taken out about eight months ago and replaced with a later
and more rugged type, which has already lowered the maintenance from 2.51c. per ton to 2.11c. over the whole time period of 27 months.

Figured on the last eight months alone it is down to 1.42c. per ton. This is one pronounced advantage that the cable-reel locomotive has had over the combination machine in this comparison. Had the combination had this latter equipment in the beginning the difference would have been 0.69c. per ton more in its favor. Having been in service for many years, the design of cable-reel locomotives has reached a comparatively high state of perfection. This has been greatly in their favor wherever they have been called on to compete with storage-battery locomotives.

The cost of motor cable is used as a common argument by battery-locomotive "boosters" as an item sufficient to just about offset battery depreciation. This we do not believe can be verified except possibly in a few extreme cases. The average life of a cable on the locomotives for which results have just been given is eight months. Worked out in cost per ton it stands at about 0.3c. compared to battery depreciation of 2.92c. and 3.11c. per ton.

**Battery Locomotive Has Low Repair Cost**

The straight storage-battery locomotive has a clear advantage over both the other types in maintenance cost, and it is not likely that either of them will ever be able to compete with it in this particular. Its entire electrical circuit is insulated from the ground. There is thus no difference in potential between the motor windings and frame, and for this reason the tendency to ground is eliminated, for the insulation must break down on both sides of the circuit before a short-circuit can exist.

Moreover, as the straight storage-battery locomotive has its whole source of power on its back and is not subject to transmission troubles or losses, the electrical equipment is designed for a much lower voltage than the combination or reel type. This, in addition to the double insulating feature, almost entirely eliminates electrical trouble. Records show that the number of such troubles with this kind of locomotive compared with that of the other types is about in the ratio of 1 to 12.

This brings in another important point of merit for which, for want of more definite data this locomotive receives no credit in the tabulation. Had we had a record of the actual working time that these other locomotives lost by reason of their various electrical troubles we could have worked out fairly closely the additional cost incurred by them. The magnitude of these seemingly little disadvantages surprises us when we dig into them.

What does it mean to have a locomotive in the middle of the shift come hauling in another that is incapacitated from a burnout? It means that one locomotive is taken from its work for at least 15 or 20 minutes while the cost on that section goes right on. The other machine is out probably for the rest of the day; the miners on its section go home; the day is finished with 50 or 100 tons of coal short, yet with no curtailment of the day's expense. Do we notice these things? They certainly take place around all coal mines utilizing electrical haulage. These are the things that really count when it comes to considering the relative merits of various types of equipment.

The lower voltage of the straight storage-battery machine gives it another advantage over the combination type from the battery point of view. The first cost of the battery is less per kilowatt-hour of capacity, because of the smaller number and the larger size of the cells. This reduced number of cells and lower voltage reduce the battery maintenance cost, there being fewer cells to keep up and less tendency for grounds and leakage due to lower voltage and a completely insulated battery circuit. From this company's records this consideration seems to have netted 12 per cent longer life on this battery. Of course this is all worked into the data given and it also is noticeable to the extent of 0.19c. per ton on the battery depreciation, notwithstanding the fact that the combination locomotives did 20 per cent of their work from the trolley.

Another misfortune that to some extent has held down the tonnage of the straight battery machine is that it did not have sufficient battery capacity to even get a chance in competing with the combination locomotive for the larger producing territories. Consequently it has been forced to take the odds and ends of territories, in some of which enough miners could not be placed for the battery locomotive to make use of what capacity it had.

**Delays Kill Chances of Reel Locomotive**

It seems that the greatest disadvantage of the reel type of locomotive lies in its inability to compete with the battery machine in tonnage under average gathering conditions. This is due to a number of considerations, the majority of which probably have already been pointed out in this report and entered as dollars and cents in the comparison. They may be summed up, however, in three primary causes, some of which are made up of many details. They comprise power interruptions or failures from various causes, cable and reel troubles, inconveniences of changing from trolley to cable, and vice versa. These all represent delays, and the more concentrated the work and ideal the conditions for battery operation the more these delays are multiplied and the greater is the difference in favor of the storage battery.

In considering efficiency from a power standpoint it is generally thought that the cable-reel locomotive is more efficient than the battery. We do not believe there is much difference in the controllers of the two types of machine as the loss in a battery usually just about equals the line drop sustained in the other type. But from the controller to the rails sufficient reason exists to believe that the battery considerably leads the other type. In the first place the reel type almost always has a higher mileage rating, which tends to give quicker acceleration but which also results in considerably more slippage, thereby consuming energy uselessly.

From an investigation covering several days spent
It is true that the real type with a higher mileage rating must necessarily under the same conditions operate with more resistance in the circuit than the battery machine. Another argument in the same direction is that in almost every case where the operator is changed from a real type to a battery locomotive, he "kills" the battery on much less tonnage than the old operator who has learned to save through a realization that his supply of energy is limited. There is no question but what a battery teaches economy in this respect. We believe that if an accurate test were made regarding this saving it would show that the storage-battery locomotive is about 40 per cent more efficient from a power standpoint than the cable-reel type.

So far in this discussion we have found no economical place for the cable-reel or combination locomotive; the straight battery machine has had the best of them on every hand. We have considered, however, only one condition, or what we have called normal or average, with a grade range of not over 4 per cent and that only locally. This leaves, however, quite a field to be covered by the other two types, with which the straight battery machine is almost sure never to interfere, for its usefulness is certainly limited to moderate grades and concentrated work. Even if the question of weight did not enter and it was practical to get a battery with sufficient capacity on a locomotive for such work the heavy battery depreciation would prohibit its use.

**Cable-Reel Locomotive for Steep Grades**

The combination locomotive is a cross, or compromise, between the straight battery and the cable-reel machine, embodying some of the advantages of both. The place for the cable-reel type is down over the hill, the combination just over the brink a little and the straight battery on top of the hill. If they will stay in their respective places there should be no trouble or argument, but if the battery goes down over the mountain it can be expected to run out by the cable-reel locomotive, or if the cable-reel persists in coming up or staying on the level it will be put out of business by the battery machine. In like manner the combination must not go too far over the hill or try to cover too much of the top. This designates an economical place for each of the above types of gathering locomotives, and it is doubtful whether there is a single large mine in the country that should not have just such a mixture of equipment if economy is its slogan.

The Logan Mining Co. was among the first in the country to install storage-battery locomotives. It started to use their use in coal mines was an experiment and made the mistake that nearly everyone else made in its first installation. It accepted batteries too small for the work. This led to troubles and held back the use of storage-battery locomotives more than any other one consideration. The locomotive manufacturers, it seemed, were slow to design their machines so as to accommodate batteries of sufficient capacity.

The Logan Mining Co. is still confronted with some of this trouble, as it is now trying to install 25-plate batteries on locomotives originally designed for accumulators of 17 and 19 plates. The last five locomotives purchased are 48-cell 25-plate machines, and it is desired to replace all of the 48-cell batteries with 25-plate accumulators, and those with 88 cells with 15-plate batteries as fast as renewals are made. This is about what experience has taught is necessary under existing conditions.

From the above paragraph as well as in view of considerations mentioned elsewhere in this report it will be noted that practically all the batteries that have entered into this comparison have been at a disadvantage because of undercapacity. There probably is nothing so detrimental to the life of a lead battery as excessive overdischarge, yet this has been unavoidable with the above batteries. The only reliable safeguard against this contingency is plenty of capacity. Because of this difficulty and improper charging facilities this company realizes that it has not been able to exercise the proper care in the handling and operation of its batteries, but despite the short life that this lack of capacity has caused it knows that it has saved money. It is now making arrangements to install the modified constant-potential charging system, and as it is also installing larger batteries it expects much better results in the future than have been shown here.

In conclusion it should be reiterated that there is an economical place or condition in almost every coal mine for each type of locomotive, the relative merits of which have been here considered. The field is large and the conditions many; therefore, only a question of the right application remains.

An urgent request is made that electrical and mechanical men connected with coal mining adopt some system of cost accounting and record keeping as to the performance of the locomotives under their charge, to the end that their companies may be profited, they themselves may become better posted and the inquirer be able to obtain more reliable information whereon to base conclusions.

An example of the effect on the cost of production of such record keeping over a period of 27 months divided into three periods of 12, 8 and 7 months is presented in Table V. The figures include total maintenance and battery depreciation on all the locomotives that the Logan Mining Co. possesses. Some of these results were not considered in making the comparisons here set forth because of the comparatively short time during which they had been in service.

Note the uniform reduction after the first twelve months. It may be correctly assumed that had it not been for the record keeping the cost would have continued somewhere near that of the first year, and if so the total outlay on the above tonnage would have been $81,624.26 instead of $55,791.27. This shows a net saving of $25,832.99, or approximately $1,000 per month. If the cost is held down to 2.09c. per ton the
Until recently the standard four-speed windings of alternating-current motors afforded speeds of 600, 900, 1,200 and 1,800 r.p.m., the latter two speeds being twice the two former. Introduction of the new speed of 720 r.p.m. constitutes an important improvement in design and gives this motor a marked advantage over its predecessors. The speed increments of 20, 25 and 33% per cent as contrasted with those of 50, 33% and 50 per cent, the former range in such machines, makes it possible to obtain almost as accurate an adjustment of motor speed to required machine speed as has in the past been obtainable only with direct-current motors.

These new units are known as Watson multi-speed motors and are manufactured by the Mechanical Appliance Co., of Milwaukee, Wis. They are all rated on the 40-deg. basis, that is, they will carry full rated load indefinitely without exceeding a 40-deg. rise in temperature. A 25-per cent overload may be carried for two hours with a temperature rise not exceeding 55 deg. C.

Motors can be supplied to furnish either constant horsepower or constant torque or any combination of horsepower and torque in two, three or four speeds on 60-cycle current. The same ratings can be furnished for other frequencies and in either two- or three-phase.

Suitable control apparatus for these motors has been developed and tried out so that these machines may be operated on either automatic or remote control. Adequate protective apparatus has also been developed for use with this equipment.

It will be evident that effective individual alternating-current drive is now available for many types of machines that heretofore have been actuated by direct-current motors only. Machine tools, conveyors, fans and the like can be operated at a variety of speeds without loss of efficiency, while such machines as air and ammonia compressors may be run at only a slight deviation from the exact speed required.

"In addition to the technical information to be given in connection with each course each individual is given some instruction in first-aid treatment, and all persons who work underground are given a certain amount of instruction in methods of preventing explosions, in general principles of mine ventilation, in mine rescue, and such other information as will make mining a safer and thus a happier occupation. More than this, each individual is given certain elementary instruction about the formation of coal and the classification and characteristics of coal, in order that they may more fully appreciate the industry with which they are closely associated. Workers in industry must have something more than skill if they are to live more completely and give to the world their best efforts. They must be contented, they must be happy, and they must have a pride in their work if industry is to get the best results from the energy that goes into it."

"The Department of Public Instruction and with industry and with local school districts in the establishment of industrial courses as well increase the intelligence, broaden the horizons and add to the happiness of the men and women who work. Public education is doubly interested in the education and welfare of the skilled workman and his family, of the skilled workers and their family and of the professionally trained person and his family. And this interest is not peculiar to the public school."

One of the most wholesome rays of progress today is the intensive study of the education and welfare of its workers. It has not been many years since employers of industry paid little or no attention to the education and training of the workers in unskilled occupations, and little enough attention to the training of skilled workers. The attitude today is wholly different."

Chairmen of Committees Who Will Report at the Huntington Session of the Association: Sept. 14-17

R. R. Webster is chairman of committee on insulating oil; F. M. Reigher, of committee on cable insulation; C. J. Fuetter, of committee on underground transmission and distribution; C. E. Rogers, of committee on relative merits of gathering locomotives; J. J. Fluck, of committee on mine hoisting wheels and track; Roscoe Wolfe, of committee on resistance grids; M. A. Maxwell, of committee on power costs.
Relative Value of Cast Grids and Grids of Steel Plate
For Use as Resistors in Mine Locomotives

Cast Grids Do Not Warp as Much as Plate Grids—They
Rust Less and Are More Rigid and Require Fewer Tie
Rods—Punched Sheet-Metal Grids Resist Shocks Well

Resistor grids are used on mine locomotives
mainly for the purpose of protecting motors and
controlling their speed when they are connected
to the source of supply, whether that source be a
battery or a trolley system. Much effort has been made
to eliminate resistor grids, but alternative devices are
either excessive in first cost or too bulky and too much
attention may be needed to keep them in order. In fact
practically all the devices designed for this purpose have
all three of these objectives, particularly for equipment
like the mine locomotive. Needless to say, resistor
grids have been the subject of much study, the object
being to provide units having the following character-
istics:

1. Small change in resistance for any given change
in temperature.
2. Greater thermal capacity.
5. Non-rusting qualities.
6. Fewer tie rods.
7. Fewer contacts between grids when assembled.
8. Lower first cost and
9. Lower expenditures for maintenance.

Cast Grids Fill Specifications Closest

As a whole, cast grids fill the above requirements
much more satisfactorily than any other type of grid
as far developed, particularly in mine service. Grids
of smaller cross-section which have lower capacity and
a higher resistance per unit do not, as a rule, give the
satisfaction that is obtained with grids of larger cross-
section and lower resistance per unit. The electrical
characteristics are the same regardless of the difference
in cross-section, but grids of small cross-section usually
are mechanically weaker than those with large cross-
section.

This, of course, might be expected. It is, however,
possible to overcome this difficulty to a great extent
by the proper design of the grid convolutions and by
the location and number of grid supports.

The resistor grids used on stationary apparatus are
less likely to be subjected to severe shocks and vibrations
than those in haulage or gathering locomotives or in
portable equipment such as is used for battery charging
or for welding.

In both stationary and portable apparatus, particular-
ly in mines, resistor grids are often subjected to the
effects of moisture and often come in direct contact with
sprayed or flowing water. The latter, being more or
less contaminated with impurities of an acid nature,
readily attack metal and also destroy the insulating
qualities of various dielectric materials.

Theoretically cast resistor grids have a hard surface,
which, as is well known, has much higher rust-resisting
qualities than the surface of steel plates or punched
grids. As a result cast grids corrode less than those of
punched sheet steel. Much research, however, has been
made into the possibility of combining this rust-resisting
with the qualities that are required of a resistor
grid.

Resistor units traversed by high currents are sub-
jected to widely varying temperatures. The electrical
resistance of any of the metals will be altered with a
change in temperature, each material having its own
temperature coefficient of resistance. Metal of the
nature used in grids of the cast-iron or cast-alloy type,
as well as sheet metal used for punched metal grids,
has an increasing resistance with increasing tempera-
tures—that is, a positive temperature coefficient of
resistance. Different metals, whether cast or in sheets,
have different values for this coefficient.

The resistor grids for mine locomotives should be
made of metal having a low temperature coefficient of
resistance. Much effort has been expended to develop
such a metal, consideration being given, of course, to
the possibility of manufacturing the material so that
the results always will be consistent. Cast-iron grids
and cast-alloy grids when manufactured in large quanti-
ties and by men experienced in the casting and running
of the heat can be produced with consistent results as
to weight per unit, resistance per unit, thermal capacity
and temperature coefficient of resistance. Reliable manu-
facturers make it a practice to have each grid unit
tested, and they require that it shall come within fixed
limits as to the above characteristics.

Owing to their lower cost cast-grid products have
been more generally used than grids of any other type
so far developed. To give a product with electrical
characteristics equal to those of the cast grids it is
necessary to use a special alloy steel. Grids punched
from sheet metal have mechanical characteristics of
some merit, the principal one being their ability to

*Report made to the committee on "The Use of Mine Locomotives,
Resistor Grids Made of Rolled Steel Plates as Compared with Cast Grates." This report was presented by the Huntington
Mechanical and Electrical Engineers, May 18, 1903. The committee consisted of Howard Wilcox, (chairman), Martin J. Warlis, A. Paul
withstand more severe shocks than cast grids, particularly those of the smaller cross-section, but cast-iron grids of the larger section are seldom affected by the most severe shock found in locomotive service. Cast-alloy grids are tougher than cast-iron grids and, therefore, small grids of cast alloy can be used in more severe service than similar cast-iron grids.

When overloaded both cast- and punched-steel grids are susceptible to overheating. When, however, the overloading is of but short duration the grids are in no way injured, but if the overload lasts for a long time it will burn out the resistor. In locomotive service the frequency and duration of overloads depend on the care of the motormen; especially is the overload unduly prolonged when the locomotive is allowed to run for a long time with the controller in the resistor notches.

Grids Warp When Severely Overheated

The units of punched-metal grids are less rigid than those of cast grids and more supports for the grids are, therefore, necessary. It has been found that when these grids are heated to high temperatures such as are common in resistors used in locomotive service, the grids warp excessively. Cast grids also will warp, but not as much as those that are made of punched metal. When the grids warp, adjacent elements come in contact and are short-circuited. This imposes on the other grids a heavier load, and once the warping starts and causes contact with other grids, it is likely that this will continue to a further destruction of the grid units if attention be not given to remove the faulty grids first found to be warping.

In the assembly of grids, particularly of the type from punched metal, care must be taken to have sufficient spacing between the grid units. The reason for this is two-fold:

First, on account of the rapid corrosion, for rust particles soon make a contact between the grids if the spacing is small. This usually causes pitting and ultimately has the same effect as a warping of the grids. It causes short-circuiting of a part of the resistance until finally all the resistors become short-circuited. These difficulties are largely the outcome of faulty design and to a great extent may be prevented by a wider spacing of the grids and by the proper arrangement of the insulation between them.

Second, adequate spacing is necessary because of the heat from the assembled units, which must be effectively dissipated or it will become too intense. If sufficient spacing is not used between the grids hot spots are likely to be found in the grid assembly; these usually will be at the center of the grids and at the center of the grid assembly.

In connection with my attempt to get some tangible comparison between the two types of grids I have had a number of reports that the steel-plate grid gave better service than the cast grid which it replaced, but these reports do not mean much unless we know the characteristics of the cast grid that was removed and also know that the cast grid, of whatever type it may have been, was in good condition, the points properly proportioned, etc.

For instance, in my experience, trouble with the resistance on several occasions has been reported, especially on gathering locomotives where it is necessary to run on points a considerable length of time. In a number of instances I found the resistors were not properly assembled and the terminals not properly spaced, and in other cases I have found that an inefficient type of grid had been installed.

I have had occasion recently to inspect two main-line haulage locomotives at one operation and a gathering locomotive at another. These have been equipped with steel-grid resistors for a number of years, and I found them to be in unusually good condition, and yet the maintenance cost had been negligible. The gathering locomotive, however, accelerated somewhat too quickly. This probably was due to a lack of space for mounting a sufficient number of the steel grids.

Experience with Two Types of Grids

Below is a report from an engineer of one of the larger coal companies, giving the experience of that corporation with the steel-grid resistor:

"To date we have used the steel grids only on 10-ton haulage locomotives. A trial of the steel grids was prompted by excessive trouble due to breaking of the standard cast grid which was supplied with this locomotive. On long, heavy hauls it sometimes happened that the locomotive would get a severe jolt when the grids were red hot and almost a whole set would go to pieces at once.

"In 1919 we allowed the Post-Glover Electric Co. to send us a set for one locomotive, this set consisting of three stacks of a specification which they recommended for the purpose. The cost of the set was approximately $290. After using it for one year without trouble we decided to replace cast-iron with steel-grid resistors on nine of these 10-ton locomotives at our various properties. As the first set was still giving apparent satisfaction we again allowed the Post-Glover Co. to furnish the type which they recommended for the service. At this time the steel sets cost $300 against $150 for the cast-iron sets.

"Soon after the installation of this second order we had many complaints to the effect that the locomotives did not accelerate uniformly on the controller indices. We then made tests to find the actual resistance between controller points. Attached is a copy of a few of these tests. You will note that the steel resistance was not properly proportioned; for instance, R1 in R2 contained 57 per cent and R5 to R6 only about 1 per cent of the

Low-Roof Trolley Ear Carries Any Kind of Wire That at Any Time May Be Desired

A NEW highly compact trolley ear for mine service is so constructed that not only grooved or figure 8 trolley wire, but also round feeder wire in sizes up to 0000 can be strung from it. When desired, this latter may be replaced with trolley wire, using the same ears.

Chief among its advantages are its simplicity, holding power and the high headroom that it affords. It consists of two parts: the stud and the wings, or jaws, that grip the wire. The stud is threaded both inside and out: inside for screwing into the suspension, and outside for the clamping nut that forces the jaws together. The lower end of the stud terminates in a button around which the jaws are clamped. In installing all that is necessary is to screw the stud on the suspension, insert the trolley or feeder wire between the jaws, and screw down the holding nut.

Tests have been made on the holding power of this ear. These show that in all cases where grooved or figure 8 wire was under test for pull-down strength a section of the wire sheared off before the ear was damaged or let go. The average downward pull for four such tests, using different sizes of wire, was about 2,600 lb. With round wire (00) the pull needed to remove it from the ear was 2,100 lb. When tests were made for side-pull strength an average pull of about 1,950 lb. had to be exerted with grooved or figure 8 wire before the ear let go. In side pull with round wire the ear relinquished its hold only when a tension of 2,350 lb. was reached.

In addition to those just mentioned this ear possesses other advantages, both mechanical and electrical. Being only 2½ in. in height over all, it allows plenty of headroom, which is an important consideration in low roadways. The jaws are so shaped that they offer no obstruction to the passage of the trolley wheel, thus eliminating arcing, which always is dangerous. As this support can be used equally well with both grooved and figure 8 wire, a double stock of ears need not be carried in mines where both sections of wire are used.

This ear, known as the form W, has been developed by the General Electric Co. As it will hold round or cable wire up to 0000 it can be used to support the temporary feeder wire by which current is supplied, in developing entries, and for the operation of pumps, drills and cutting machines. Later, if it is decided to operate locomotives in these headings, the temporary feeder may be replaced with trolley wire, and the same ears will be found equally suitable.

TROLLEY EAR HOLDS ANY KIND OF CONDUCTOR

The trolley ear that at the beginning of development carried a light feeder cable later may be found supporting a trolley wire of grooved or figure 8 section.
Safety Council Debates Hazards to Health and Limb—I

Sanitation in Mines—Septic Tanks—Water Supply—Carbon Dioxide
Added to Oxygen in Resuscitation—Better Accident Records—Pressure of Water and Diameter of Hose in Fire Fighting—Standard Couplings

BY R. DAWSON HALL*

Despite the present uncertainty in industry the National Safety Council held a most successful convention in the Cass Technical High School, Detroit, Mich., Aug. 28 to Sept. 1. Even in the mining section little if any falling off was to be noted in the attendance and certainly none in the number and quality of the papers presented. About 2,500 persons registered. As usual the registration represented inadequately the number of persons present, for Detroit being a big manufacturing center many people attended who were not members or delegates of the organization.

In the opening session on Monday in the auditorium of the magnificent but only partly completed wing of the technical school, a large number were present to hear the extremely hopeful and satisfactory reports of the president, A. H. Young, and the secretary-treasurer, W. E. Worth. No one can overlook the fact that the treasury was in grievous condition at the close of last year and during the early part of this. Stringent economy, clever financing and the recovery of business have, however, changed a heavy deficit to a small surplus. The decline in membership has been stopped, and since the date of the report—July 1—the memberships have been slowly but steadily increasing in number.

COUNCIL HAS QUARTER-MILLION DOLLAR INCOME

The loss in membership in the fiscal year ending July 1 was 566, making the membership 3,066. The gross revenue was $205,996.32. At the beginning of the fiscal year the notes payable were $21,968.80 and at the closing of the books these were entirely wiped out. The accounts payable had also been reduced from $6,222.48 to nothing, and $4,662.78 was added to the surplus, making that reserve $34,819.78.

The National Safety News brought in $20,386.24 and cost $24,220.40. It should be said that the former figure did not include any of the allocated dues from members of the Council, though it did cover a number of extra copies which are sold to members on their order. The 120,000 calendars distributed cost $16,190.10 and brought in $23,358.81, a profit of nearly $7,000.

On Monday evening a dance was held at the Statler Hotel, on Tuesday evening a smile party, on Wednesday evening a boat ride and on Thursday a banquet. At the function last mentioned the speakers were A. H. Young, the president of the Council; Marcus A. Dow, general safety agent of the New York Central Lines, and Edgar A. Guest, of the Detroit Free Press. The new officials of the National Safety Council were announced. These were M. A. Dow, president; Charles B. Anel, Westinghouse Electric & Manufacturing Co., East Pittsburgh, Pa., vice-president in charge of industrial safety matters; David Van Schauk, Accident Life Insurance Co., New York City, vice-president in charge of public safety matters; George T. Fonda, Fonda & Todd, Washington, D. C., vice-president in charge of sectional activities; L. A. DeBlois, Delaware Safety Council, Wilmington, Del., in charge of local councils; Homer Niez, Commonwealth Edison Co., treasurer and chairman of finance committee, and William H. Cameron, managing director and secretary.

During Thursday morning's session of the mining section the nominating committee, consisting of Dr. R. R. Sayers, J. W. Reed and J. T. Ryan, brought in a report advocating the retention of the present official roster: B. F. Tillson (chairman), G. M. Gillette, J. L. Boardman, William Conibear, vice presidents, and R. H. Seip, secretary. The report was unanimously adopted. These then will be the officials for the coming year. The chairman will appoint his own committee men.

The mining section had its first session on Tuesday, Aug. 29, the first paper being that of Dr. R. R. Sayers on "Mine Sanitation." In the discussion B. F. Tillson inquired whether any mine had established underground a regular toilet installation with a flushing system and septic tank. Apparently no one was able to report that any company had to date such an installation.

M. S. Murray, of Curtisville, Pa., reported that his concern, the Ford Collieries Co., had installed a septic tank with three stools on the top of it. The tank was fed with some form of deodorizer and disinfectant which converted the fecal matter into a clear fluid which in turn passed to the sump and was of such a character that it did not foul the pumps as does the discharge of ordinary fecal matter not so treated. B. F. Tillson stated that at the New Jersey Zinc Co.'s mines cans were used and to prevent splashing sawdust was provided in place of water. These cans when brought to the surface were cleaned and disinfected by steam. Difficulty was experienced in incinerating the sawdust as it was so thoroughly saturated with water as to be dripping wet.

CAUSTIC SODA TURNS ALL TO A FLUID MASS

Dr. Sayers declared that a 3-per cent solution of commercial caustic soda would thoroughly disinfect and deodorize sewage and liquify paper of a suitable character. Unfortunately galvanizing will not resist the action of the solvent, but when the tank is properly covered with an asphalt paint and handled with a proper degree of care the caustic soda will not destroy or seriously injure it.

Dr. Black, of Connecticut, requested Dr. Sayers to state what showing of bacillus coli was considered evidence of contamination of drinking water and took exception to the moderation of advice that the watershed should be inspected before water from it was used. He said that the inspection should be repeated at frequent intervals to make sure that the watershed did not become polluted. Dr. Sayers said that he did not regard the presence of a single bacillus in any one sample out of ten, each of I c.c. capacity, as evidence of a

---

*Engineering editor, Coal Age.
A dangerous contamination became known and was found in all animal foods, and dogs, rabbits and like animals might well be the source of such impurity, which was not in any way objectionable in itself. The objection by its presence was that where the liquid salt was used the water must contain animal fats and at any time such from might become harmful by the introduction of the germ of some communicable disease.

J. S. Boardman stated that the Anaconda Copper Mining Co. piped cold water to every level, the pressure being regulated by the use of tanks. The water was passed through pipes in each tank, ice being placed around the pipes. Miners obtained their water through a faucet. Most of the men brought the liquid containers of their dinner plates to the tank, but the use of the common drinking cup had not been entirely eliminated.

Leaving the main subject, someone asked Dr. Sayers whether the Bureau of Mines favored the use of 5 per cent of carbon dioxide in the oxygen used for resuscitation, and he replied that the Bureau had so far not given its approval. He added that oxygen, if taken pure, is a long time removing carbon monoxide from the system. With 5 per cent carbon dioxide present the work is performed in a fourth and with 8 to 10 per cent one-fifth or one-sixth of the time.

HURTS CLEAN THE BLOOD BUT MAY HARM THE HEART.

Dr. Yandell Henderson strongly favors the use of 5 per cent of the dioxide. Most of Dr. Sayers' experiments with animals had been made with 8 per cent and in some cases death resulted. The use of dioxide was injurious to the action of the heart, and if the heart was weak the effects might be undesirable—even fatal.

Dr. Henderson, however, believed that 5 per cent of dioxide would in no case kill the patient. Dr. Sayers was not yet sure and would feel better satisfied had he made experiments on animals with that percentage.

With such an authority as Dr. Henderson in favor of the use of such a proportion of dioxide Dr. Sayers felt that it was in all probability safe, but only a medical man should use such an admixture, for the administrator should be able to judge of the effect which the dioxide was having on the heart.

Discussing his statement that in several Southern states hookworm had been found in the mines, he declared that the Public Health Service stood sponsor for that declaration and felt confident that the mines were the source of the particular infection that they discovered and not the surface. He also believed that stigmatmae to be a disease resulting from the effect of working in bad light or light falling at an improper angle, or both, for men had been afflicted by stigmatmamus who had never worked in the mines. He hardly credited the notion that it was a germ disease, though the theory had advocates. It may be said in passing that some believe that changes in the blood pressure due to death may be the cause of the disease, which is of quite frequent occurrence abroad. This is about to be investigated by the U. S. Bureau of Mines.

W. W. Adams, statistician of the Bureau, introduced several forms of accident reports and occupational censuses for each member of the National Safety Council as desired to use them in making returns to the Bureau. These were prepared with the aid of C. L. Calburn. Their purpose is to discover not only the number and kind of accidents, fatal and non-fatal, and their minute causes but also the occupational hazard for each type of work in the mine. The definition of an accident is a casualty that causes a disability extending beyond the shift in which the accident occurred.

This goes far beyond the general practice today, which is to pay attention in most cases only to fatal accidents or to such as are of compensable severity. Several members of the National Safety Council want for their own use figures which will give this information relative to their own mines. They want similar aggregate figures from the mines which already are preparing such data and they want to formulate a practice in reporting accidents in all such mines as will make the figures from them comparable. No one, of course, need give such information, and when the bureau gets it it will use it solely for tabulations which will not reveal the figures of any one company or the name of that company. The data of any one corporation or any one mine will, however, be furnished to the company headquarters of the mine reporting.

Many changes were made in the original draft, the whole matter being discussed at length at the first session and at a special meeting in the afternoon of Wednesday. That meeting lasted three or four hours, and the blanks will be corrected by Mr. Adams to accord with the outline then agreed upon. Simplification, uniformity between coal-mine and metal-mine reports, elimination of questions which it was thought could not be answered from facts already being collected and the deletion of questions that could only bring forth matters of opinion were the directions in which most of the changes were made.

The second meeting, that of Wednesday, Aug. 30, was addressed by R. H. Seip, safety engineer of the New Jersey Zinc Co., of Franklin, N. J., the subject being "Fire-Prevention and Fighting."

In discussing this subject B. F. Tillson desired to know what size of stream should be used in fighting fires underground. He himself believed in high pressures and small nozzles. The pressure available usually was high—too high if anything. Consequently no great harm would result from the loss of pressure consequent upon the friction encountered when passing water through a small hose. It was important to use a high pressure, for the nozzle could rarely be advanced near the fire and the water would have to be allowed to travel in a nearly horizontal stream. In outdoor fires the nozzle could be directed several degrees above the horizontal and could often be held at no great distance from the fire which was being fought.

UNCERTAINTY AS TO "STANDARD COUPLINGS."

William Conibear said that the Bureau of Mines had investigated this matter and favored 50-lb. pressure and a 21-in. hose. To Mr. Tillson that seemed too low a pressure and too large a diameter. The smaller hose would give greater portability. J. L. Boardman said that he had been told that he should use "standard pipe couplings," so that he could connect up with the Butte fire department's equipment. He took the advice, ordered "standard couplings," only to find that the standards varied and that the Butte fire department couplings have one half thread, more or less, to the inch than the "standard" couplings of the hose furnished to the Anaconda Copper Mining Co. However, as one member pointed out, the use of one coupling of the standard of the local fire department would make it possible to connect the company's line of hose with that of the city.

CAUSES OF BURNED-OUT MINE-MOTOR ARMATURES

Poor Bonding of Rails — Bad Joints in Feedwire
Conductors Cause Large Loss of Voltage — Insufficient Copper or Too Small Area of Feedwire

In my experience, there are just two main causes that lead to the burning out of armatures on mine locomotives and other motors. As mentioned in the excellent article of F. C. Sinback, Coal Age, Mar. 23, p. 492, these causes are the poor bonding of rails and bad joints in the feedwire conductors; also, the use of undersized feedwires.

In this connection, I recall reading a well written article by B. F. Grimm, which appeared in Coal Age some time ago (Vol. 20, p. 291). If I remember rightly, Mr. Grimm emphasized the same points in speaking of the burning out of armatures.

It is surprising to know that 75 per cent of our mines are operating, today, under these conditions. Owing to the desire to economize, or, in other words, to save copper, in making an electrical installation, it is a common occurrence to use a feedwire that is too small.

WHERE TO SAVE MONEY IN MAKING ELECTRICAL INSTALLATIONS

Comparatively few operators realize that by using more copper in making the installation, they will save money in the rewinding of armatures and cutting down of power bills, to say nothing of avoiding the consequent delay and loss in production that results from insufficient power.

Of somewhat less importance, because it can be easily remedied by going over the line, is the bad jointing of feedwire conductors. Many do not appreciate the loss of voltage due to bad joints in the feedwires. This trouble is at once shown by the joint becoming hot when the feeder is carrying a load and the insulation is burned and fire may result.

When making a joint, the wires should first be wrapped tightly around each other and soldered. If this is done properly, a joint will have twice the current capacity of the wire, as it has twice the sectional area of the conductor.

GOOD RAIL BONDS NEEDED

The bonding of the rails is not so easy and requires constant watch on the part of the electrician to keep the bonds in good condition. It is not generally known that a loose or broken bond will cause a loss of from one ten to ten volts; and a few such defective bonds will greatly increase the line drop and impair the service.

A little circulation will show that most mines have not sufficient copper in the feedwire installed. For example, in order to operate a 10-ton locomotive, at a distance of a mile from the powerhouse, assuming the perfect bonding of the rails and allowing a 10 per cent line drop, with a pressure at the generator of 250 volts, there will be required a 0000-trolley wire and a feedwire of, say, 500 mil. wire.

The average mine locomotive is rated at 10 hp. per ton, which will require 100 hp., for a 10-ton locomotive, and a current of $100 
\times 746 = 250 = 300$ amperes. The line drop is 0.10 \times 250 = 25 volts.

The amount of copper for this transmission is, therefore, $(100 \times 5,280 \times 300) / 25 = 684,300$ circ. mil. Then, using a 0000-trolley wire (211,600 circ. mil.), there will be required a feedwire of 684,300 — 211,600 = 472,700 circ. mil. This assumes that the trolley wire and the feedwire are in parallel and the locomotive operating full load.

Now, if less copper is used, more current must travel through the armature and fields than what they are designed to carry to develop the required horsepower. This will cause heating of the coils, commutator and field coils. In time, the armature coils will burn out and the solder run from the commutator, making it necessary to rewind the armature in a short time.

TROUBLE OFTEN WRONGLY ASCRIBED TO "TOO MUCH CURRENT"

It is commonly thought that the cause of a field or armature lead burning off is "too much current." This is ascribed to two causes: first, insufficient copper; second, overload on the motor. Half the time, however, it can be traced to the cause first named.

Bear in mind these three facts in mind, what can one expect when several locomotives and a number of mining machines are operated on a 0000-trolley wire? Is it at all strange that burned out armatures are the frequent result? It is usually the case that what is saved in installing these feedwires is later in maintenance and repairs.

Johnstown, Pa.

[Attention should be drawn to the fact that this correspondent has omitted to allow for the loss of voltage in the rail return. For example, using 40-lb. 30-ft. rails, cross-bonded, and 24-in. 6000-rail bonds, the rail resistance for 1 mile will be 0.0748 ohm, making the loss in voltage for a current of 300 amp. $300 \times 0.0748 = 22.4$ volts.]

SLOWING DOWN FAN AT FIRING TIME

Explosion is heading, fan running at normal speed—Better results follow slowing down of fans.

An account is given by a Kentucky engineer, in Coal Age, July 20, p. 95, of a mine explosion that he ascribes due wholly to the lack of sufficient ventilation. It is not my purpose to controvert that conclusion, but I always draw the instance in my own experience that was the direct reverse of the one he has given.

The circumstances were about as follows: Some four years ago I had a pair of entries driven in the solid coal and shot with black powder. Rooms were turned off both entries by the entrymen, who always drove the roomers. There was an air current of 10,000 cuf. of air sweeping the faces of these headings.

When three rooms had been turned on each entry, I would put six leaders at work in the rooms, who with the leaders made eight leaders in all those headings. An old line shofitier was employed to fire the shots and this was done at night, after the men had left the mine.

A SERIES OF EXPLOSIONS

One night the shofitier had an explosion that blew out all the brattice and trapdoors for a distance of 2,000 ft. back on these entries. The following week another explosion occurred with the same result and, again, still another a few nights after that.

Naturally, the shofitier became alarmed and quit.

At this point, another shofitier was secured and he decided to slow down the fan when firing shots in the mine. The result was that we had no more explosions, until the rooms had been driven to a depth of 70 or 80 ft. The fan was then turned on running at normal speed when, one night, an explosion occurred and the shofitier was burned; although he was able to come out of the mine and report it to me before I had left for home.

When performing his work, the shofitier stated he was making his report that he had found a small amount of gas in a corner of the mine, at the time of the entry.
When to Seal

Ventilation insufficient—Sealing off to extinguish fire—Draining gas through boreholes.

PERMIT me to offer a word giving my view in regard to sealing off abandoned areas in mines, which has been under discussion in Coal Age and which I am greatly interested. What I have to say will bear more particularly on mines that are generating gas.

There are, no doubt, instances where the only thing to do, in order to make the mine safe is to seal off abandoned places. This is particularly true where the ventilation is normally insufficient to dilute and render harmless the gases generated in the old workings. Under such conditions, we realize that any drop in atmospheric pressure (fall of barometer) will be compensated by a considerable outflow of gas, from the sealed places, into the live workings. Then, if the volume of air in circulation is not adequate to counteract this condition, there is danger arising from the unsealed areas where the gas has accumulated.

Sealing to Extinguish Fire or to Close Worked-Out Panel.

Mention has been made, in this discussion, of the need of sealing off places for the purpose of extinguishing a fire that has started from one cause or another and defies other means of treatment. It is unnecessary to dwell on this point of the subject, which we all agree is the thing that must be done.

Again, when it is necessary to adopt the method of panel working, sections will often require the complete sealing off of a panel. That will generally present the only plan to follow when such panels have been worked out and abandoned. The sealing off of a panel will regulate, or control the flow of styre or other gases from such areas.

We have, doubtless, many mines in such a condition, in respect to ventilation, that it is impracticable to deal with certain abandoned areas by any other method than sealing. In this Dugger coal field, there is No. 10 mine—a large mine in one case. In that mine, it would not be safe to handle the large abandoned areas in any other manner.

Gas Drained Through Boreholes. Avoids Danger in Mine.

The management of No. 10 mine has adopted the plan of drilling boreholes from the surface, into each abandoned and sealed area. This plan gives a vent for the gas generated in the sealed portions and avoids the danger of those gases being forced out through the seals into the live workings.

In my opinion, this is a safe and practical practice to allow these pent-up gases to be released and flow into the mine through a pipe built into the seal. According to all accounts, this is the procedure in some districts. It may seem a radical statement to make; but, to my mind, such a practice is prohibited by state laws that would close down the mine where it is done.

I firmly believe that the continuance of such practice will eventually pay a high price in life and property. Certainly, men employed in mines where the gas is led through boreholes extending to the surface will feel safer than where this gas is released into the mine. W. H. LUXTON.

Linton, Ind.

Timbering Hard Roof and Bottom

Experience of a timberman—Setting posts on pieces of slate and mounds of slack unsatisfactory—Tapered posts give best results.

MY EXPERIENCE in timbering mines where both the roof and floor are hard may be of interest to "Timberman," who writes from Iowa, Coal Age, July 27, p. 136, saying that he has had trouble by reason of the roof pressure, breaking the timbers where the roof and bottom are hard.

In reply to that inquiry, the editor has described the main principles of post timbering, and mentions several methods that have been employed to avoid the destruction of posts, under the condition named.

In a practice of several years, I have used all of these methods and still another not mentioned; namely, setting a post on a piece of slate, after the custom of some miners. However, my conclusion is that there is but one reliable method on which dependence can be placed with certainty. That is to employ tapered posts and use good cap-pieces at the roof. When set in this manner will take the weight slowly and seldom be broken.

When a post is set on a piece of slate, the latter is almost sure to be broken when the weight comes on the timber, or the post will fall out. The same result follows when a post is set on a mound of dirt or slack, unless the work is done properly and just the right amount of soft material used to take up the settlement of the strata.

Experience Must Determine

Experience in a given district may enable this method to be used successfully. But, my observation is that when too much slack is used, the timber will either be shot out, or will fall out of itself. Again, if too little slack is used, the oncoming weight will break the post, the same as if it was set on the hard floor.

The one method that I have found seldom, if ever, fails is to taper the foot of the post, as described and illustrated in the reply given to the inquiry, on page 136. A good cap-piece must also be used above the post, which will help to distribute the pressure on the roof and bind the top of the post together.

Footboards and Cap-Pieces Used

Some prefer to use footboards on the floor and cap-pieces at the roof, in preference to tapering the posts. With any amount of roof pressure, however, the timber will generally be forced through both the footboard and the cap-piece and, in some cases, the pressure will break the timber.

At times, I have known tapered props to yield as much as four or five inches, under the pressure of the overburden. Indeed, I have observed tapered posts still standing, after two or three years. Seldom have I known a post that is carefully tapered to be broken or fall out.

Herrick, Ill. A

ANOTHER LETTER

AFTER reading, with deep interest, the reply to an inquiry in reference to avoiding the trouble often experienced in setting posts between hard roof and floor; and after giving the matter careful consideration, I am inclined to believe that the chief cause of trouble, in this case, is the lack of a suitable system of timbering.

Notwithstanding the hard roof and floor, it should be possible to timber this shaft, a seam of coal, under 250 or 300 ft. of cover, without serious difficulty if the system adopted is suited to the conditions in the mine.

ONE GOOD RULE TO REMEMBER

While it is possible to make numerous suggestions regarding troubles experienced in timbering, there is one general rule to remember. It is always practical to keep the working places well timbered, as the coal is mined, and to maintain a good supply of posts in every place.

My advice to this correspondent is to keep his timber within 4 ft. of the face, setting the posts in rows and at a distance of 3 ft. 6 in. apart. Use only oak timbers, 8 in. in diameter at the small end, using a soft cap-piece over
Self-Acting Gravity Plane

**Difficulty with rope on a single-track plane—Three-rail system above passing track avoids trouble—Clearance at upper end of siding marks center of tram.**

**Referring** to the inquiry on the question of installing a self-acting gravity plane, *Coal Age*, Aug. 10, p. 211, kindly permit me to offer a suggestion that, if adopted, will greatly simplify the operation of such a plane.

With a single-track tram, there is always considerable trouble experienced in keeping the rope clear, above the siding. It is evident that when the empty trip reaches the switch at the upper end of the siding, that branch of the rope attached to the loaded trip must be carried on the outside of the track, or it will interfere with the ascending empties.

In order to avoid this difficulty much skill will be required in placing the sheaves and rollers; and, even then, there is bound to result considerable annoyance and expense in the operation of the plane. It is far better to adopt some method that will keep the rope clear and avoid a possible accident by reason of the rope jumping the sheave at the side of the track.

Experience has shown that the proper procedure is to carry a single track from the tipple up to the siding or passing track. Then adopt a three-rail system above the siding and reaching to the top of the plane.

This arrangement will cost a little more to install, but it will give far better satisfaction than to use a single-track system throughout. Moreover, there will be required but one switch at the lower end of the siding, which means less labor to keep it clear and in working order.

The accompanying figure makes clear the arrangement of the system. Care must be taken, however, to have the point of clearance a little above the center of the tram, so that the ends of both ropes will sit a little below the point where the trip is clear of each other. It hardly seems necessary to state that the clear length of siding should be sufficient to hold the number of cars that are to be hauled in a trip.

<td>General Mine Potential for Split Circulations</td>
<td>Every Mine Has a Certain Potential Value—The Potential Evaluates the Mine in Respect to the Circulation of Air—Summation of Split Potentials Explained</td>
</tr>
</tbody>
</table>

**Somewhere** I have seen it stated that a mine ventilating fan, running at the same speed, will not give the same volume of air, at different mines. While this has always seemed strange to me, I have never had the opportunity of testing the truth of the statement until recently.

The matter was forcibly impressed on my mind, however, when I undertook to transfer a 14-ft. Jeffrey fan, from No. 1 to No. 2 mine. In the old location, this fan had been giving 280,000 cu.ft. of air per minute, under a 2-in. water gage, when running at a speed of 100 r.p.m.

Much to my surprise, at the new location, while the same speed of fan developed about the same gage, it produced a very much smaller air volume; and it was necessary to increase the power of the engine and drive the fan faster, in order to obtain the volume of air at which it was rated, at a 2-in. gage. I would very much appreciate information that will throw more light on this matter.

**Manager**, Colo.

Only a few years ago, when a mine operator ordered a fan, he thought it was sufficient to specify the volume of air be desired, and the mine. It is now generally understood that the order for a fan must also specify the water gage against which the fan is to operate when delivering the required volume of air. In other words, the present circulation (air volume and gage) must be given as a basis of calculation for determining the size of fan needed.

Every mine has a certain resisting power in respect to the passage of air through the shaft and the underground entries. This resisting power has been called the mine potential. It is the ratio of the sectional area of the airway (or area of passage in the mine, depending on the number of splits) to the cube root of the product of the coefficient of friction and the rubbing surface (a/f ft.), as expressed in terms of the airway.

This is the power potential. It evaluates the mine in respect to the volume of air that can be circulated therein by a given power. Expressed in terms of the circulation, its value is the ratio of the quantity of air in circulation (cu.ft. per minute) to the cube root of the pressure on the air (ft. lb. per min.) (Q/Af ft.).

On the other hand, the pressure potential is the ratio of the quantity of air in circulation (cu.ft. per min.) to the square root of the unit pressure (lb. per sq.ft.). But, since the quantity of air circulated in a given airway or mine, varies as the square of the pressure, or the cube of the power, producing the circulation, it is easy to see that the cube of the power potential is equal to the square of the pressure potential. Therefore, calling these potentials \( X_p \) and \( X_p \), respectively, we have the following equal values:

\[ X_p = X_p = \frac{Q}{\sqrt{P}} = \frac{Q}{\sqrt{P}} \]

Now, applying these values to the solution of the question in hand, the mine-pressure potential, at No. 1 mine where the fan passed 280,000 cu.ft. per minute, under a 2-in. water gage, required a unit pressure \( P = 2 \times 5.2 = 10.4 \) lb. per sq.ft., is

\[ X_p = \frac{Q}{\sqrt{P}} = \frac{280,000}{\sqrt{10.4}} \]

The correspondents has not given the circulation in No. 2 mine previous to the change; but we will assume the mine was passing 125,000 cu.ft. of air per minute, under a 2-in. water gage. In that case, the pressure potential of No. 2 mine is

\[ X_p = \frac{Q}{\sqrt{P}} = \frac{125,000}{\sqrt{10.4}} \]

In fan design, the best results are obtained when the pressure potential of the fan is from two to two and one-half times that of the mine. A fan so de-
exceeds will give its highest efficiency. Now, it is clear that if a fan designed for No. 1 mine is operated at No. 2 mine, where the potential is practically 4l of No. 1; the potential will not produce the same results. While the efficiency of the fan will be increased, the quantity of air supplied will be utterly incapable of producing the same results. The practical value of the mine potential is shown in estimating the circulation produced by a given pressure or power, in a mine where the air is conducted through a main airway and then divided into a number of smaller ones, before passing into the main return airway and out of the mine. In that case, the general mine potential is obtained by the summation of the several split potentials. In other words, the potential for the entire mine is found by adding together the reciprocals of the cubes of the several power potentials and extracting the cube root of the sum. The reciprocal of this root is the mine potential for power. In like manner, the reciprocal of the square root of the sum of the reciprocals of the squares of the several pressure potentials will give the pressure potential for the entire mine. This will be found a useful application of the potential, in problems that admit of no other method of solution.

**Examination Questions Answered**

**Alabama Mine Foremen's Examination, Birmingham, July 24-27, 1922**

(Selected First-Class Questions)

**Question:** In what conditions and in what sorts of mines is coal dust most dangerous and why?

**Answer:** Where the air is most dangerous, when it is in a finely divided state and carried in suspension in the air. In this condition, it lodges on the timber, the roof and sides of all roads and air-ways. In mines where blasting is performed, the accumulations of fine dust at the working faces is a source of grave danger, because of the dust being blown into the air by the forms of the shots and the fans produced in blasting.

**Question:** How to dust, without being removed from a mine, confined to a mine in any particular place?

**Answer:** The usual method of dealing with dust is to mine it in mines, to its effect is regular and complete removal, as far as that is practicable. Permit no accumulations of fine dust in the workings. In mines where the dust danger is less, the road highly instrumented, or efficient in dusting, the ventilation system should be installed for the roads and air-ways and every means adapted to prevent the accumulations of dust. Strict regulations should be enforced in respect to blasting. The coal and only permissible powder should be used in such a manner that a mixture of air with the powder from the blasting, is an essential means of distributing the rain to the working places and in the faces. The trial of this means of overcoming the dust danger has proved effective in numerous instances and is now employed in many dry and dusty mines. The salt acts to reduce the amount of the fine dust and slack to fire in the waste.

**Question:** What measures, if adopted and properly executed, would reduce the production of dust or the accumulation of dust?

**Answer:** No means is more effective for reducing the production of dust, in mines, where blasting is performed, than the enforcement of strict regulations limiting the amount of powder to be charged in the holes; and determining the location, direction and depth of drilling the holes, the exclusive use of permissible powder and the careful inspection of all holes by safety inspectors before shots are fired. In machine mines, the cuttings should be removed in dustproof cars. Greater safety is insured and a less production of dust occurs in mines where all holes are drilled, charged and fired by competent shot-fiers.

**Question:** Give, in detail, the plans you would recommend for keeping a dusty mine in a constantly safe condition.

**Answer:** First, employ the method of mining the coal that is best adapted to the particular conditions existing in the mine. This will require a careful and close study of the character of the coal and the method by which it can be extracted with least danger. Second, employ safety inspectors charged with the duty of inspecting the mine during working hours and preventing all unsafe practices. Third, provide an ample circulation of air and an efficient method of ventilating all working places in the mine. When this is performed, use only permissible powder and employ shot-fiers to examine, charge and fire all shots, and having authority to forbid the firing of any holes that, in their judgment, are unsafe. Lastly, install an efficient spraying system in the airways and working places.

**Question:** What precautions would you take in the management of a dry and dusty mine generating explosive gas, with reference to the protection of life and property?

**Answer:** Equip the mine with duplicate ventilating fans of ample capacity. Adopt a method of working that will insure the production of a minimum amount of dust in the mining of the coal. Use only permissible powder in blasting and employ dust-proof cars for hauling the coal in the mine. Employ shot-fiers to examine, charge and fire all holes drilled by the miners. Install an efficient spraying system throughout the mine. Make and enforce strict regulations in regard to the examination of the mine by fire-bosses and safety inspectors. Permit no open lights, but furnish the miners with the cup lamp. Keep the accumulations of dust in the working places and have all roads and traveling-ways cleaned at regular short intervals.

**Question:** What precautions should be taken in blasting to safeguard the employees in mines that are dry and dusty and generating explosive gas?

**Answer:** Use permissible powders only. Employ competent shot-fiers to examine, charge and fire all holes drilled by the miners. This work must be done after the men have left the mine. The firing should commence on the end of the air and proceed in order against the air current. Each place of charge to be carefully examined for gas before a shot is fired therein.

**Question:** What, in your opinion, are the principal causes of the greatest number of fatalities in our mines? Give a list of six causes in the order in which you have seen them occur.

**Answer:** The principal cause of fatal accidents in mines is falls of roof and coal at the working faces. The following six causes of accidents in mines may be given: 1. Falls of roof and coal. 2. Premature blasts or unsafe practices in blasting. 3. Movement of cars and motors in mines. 4. Overcome by gas. 5. Contact with live wires. 6. Hoisting accidents or falling down of shafts or slopes.

**Question:** If a water gage placed in a door 4 ft. 6 in high and 5 ft. wide showed a reading of 2.7 in, what is the total pressure on the door?

**Answer:** A water gage reading of 2.7 in. corresponds to a pressure of $2.7 \times 5.2 = 14.04$ lb. per sq. ft. The sectional area of the door is $5 \times 4.5 = 22.5$ sq. ft. The total pressure on the door is then $14.04 \times 22.5 = 315.9$ lb.
Texas Unaffected by Strike Developments; Large Mines Operate Open-Shop

RECENT DEVELOPMENTS in the national coal strike have not affected Texas mines. Most of the larger mines in Texas are operated on an open-shop basis, while those involved in the strike at this time are involved because of local labor disturbances and not because of the national strike, according to W. N. Willis, secretary of the Southwestern Electrical, Coal & Gas Association, with headquarters in Dallas, Texas.

The larger coal sections of Texas are in the vicinity of Eagle Pass, Thurber and Laredo. The mines at Eagle Pass and Laredo are not affected by the strike, being worked by non-union labor. In the vicinity of Thurber, the Texas Pacific Coal & Oil Co. is the largest operator. One mine of this company has been in operation since a few weeks after the strike was called, an agreement having been reached. Another, being operated on the open-shop basis. The two mines in operation are working about 200 men against a normal working force of about 800 men. Output of the mines, which in normal times ranges from 1,000 to 1,400 tons of coal daily, is now about 300 tons.

While the coal shortage has not been felt in Texas during the summer, it is likely to become acute, especially if cold weather comes early, according to wholesale and retail coal dealers, many of whom maintain distributing plants at Dallas. If the railroad strike continues and the railroads are unable to handle the coal cars promptly when the mines are reopened, the shortage will become much worse.

"The shortage of coal is being felt now in Texas," R. H. Young, vice-president of the Southern Fuel Co., of Dallas, declared. "The Southwestern mines are to be reopened under the recent agreement reached between operators and miners. Although the mines may be reopened at once and operated on full time, the supply of coal will not be adequate to the demand for months, and not then if a coal shortage results on the railroads as is now indicated."

"If the Southwestern mines were reopened immediately, the coal shortage could not be relieved until late in the winter," Charles C. Taylor, manager of the Southern Coal Co., declared.

Harry Penniman, Jr., of the Penniman Coal Co., declared that although the situation is bad, coal consumers of Dallas will be able to obtain sufficient supply for all emergencies unless provided the railroad strike does not interfere with the movement of coal to a great extent.

"Coal is wanted everywhere at present," according to W. H. Pulliam, vice-president of the Pulliam-Trewitt Coal Co. "We are receiving orders for coal from many of the smaller towns in Texas, and it is almost a certainty that the smaller towns will suffer most from a fuel shortage when cold weather comes. It will require several months, at least, for production to meet needs. Virtually all coal yards are empty, but our company has been fortunate in obtaining a supply from Colorado and New Mexico mines."

The supply of anthracite coal has been exhausted at Galveston, which draws its supply of domestic coal mainly from non-union soft coal fields, and this source has been ample for all needs. Bunker coal for Galveston ships is also drawn from such non-union fields as have been little affected by the strike.

Utilities Consume More Coal During June And July Than in Earlier Strike Months

Coal consumed by electric public utility power plants during June was 2,489,321 net tons, according to the recent report of the Geological Survey. June consumption by these plants was the heaviest of any month since the beginning of the strike—April, 2,456,592 tons and May, 2,471,123 tons. During March, the latest pre-strike month, 2,722,146 tons were consumed.

The average daily output for June was 127,700.000 kw.-hr., that is, the unit rate of production of electric energy was not as great as in 1922 and exceeded the daily production in May by 1-3 per cent. The proportion of the total output of electricity produced by water-power declined from 43 per cent in May to 41.4 per cent in June.

During July 2,566,658 net tons of coal was consumed by these plants. Although this is slightly greater than the tonnage consumed during June, the increase is due largely to not being a 31-day month. Average daily consumption in July was 82,580 tons, compared with $5,000 in June.

The average daily production of power during July was 124,000,000 kw.-hr., a decrease of 3 per cent from the record rate for June. The decline in the production of power was in plants operated by water power, due to the decrease in water available during the summer for power purposes.

Railways Consume Less Coal in June Than In May; Six-Month Total Below Last Year

Class 1 railroads consumed 6,787,000 net tons of coal in June, 1922, as charged to account 394, compared with 6,774,000 tons during the corresponding month last year and 6,533,000 tons during May, according to a report made by the Bureau of Statistics of the Interstate Commerce Commission, covering 182 steam roads. For the six months ended June 30, 1922, these roads consumed 45,074,000 net tons; during the same period last year they used 45,619,000 tons.

The delivered cost per ton of the coal used during June was $3.83; last year it was $4.09. For the first five months of 1922 the per-ton cost was $3.58 as compared with $4.12 in 1921.

Consumption of fuel oil by these roads is steadily growing. During June 119,359,000 gallons was used, as compared with 108,860,000 gallons in June, 1921, and 118,263,000 gallons in May. For the first six months of the year 714,296,000 gallons was consumed, as compared with 696,598,000 gallons in 1921.

Lake Coal Loaded During Season to End of July*

Plaintiffs Urge Rehearing of Coronado Case

Petition for rehearing of the so-called Coronado coal case, now before the U. S. Supreme Court on June 8 handheld down a noteworthy decision holding that labor unions, although not incorporated, are liable and liable for damages resulting from acts of their members on an authorized strike in matters affecting interstate commerce, was filed with the court Thursday by John W. Davis in behalf of the Coronado Coal Co. and others, plaintiffs in the original suit against the United Mine Workers of America.

The Supreme Court, while rendering a broad opinion in the case and establishing a new principle of legal procedure between labor unions, held that it would not sustain the claim of damages to the original plaintiffs because it had not been established to the satisfaction of the court that the acts complained of were in restraint of interstate commerce during an authorized strike, and expressed regret that Davis was on.

In the petition for rehearing the petitioners set forth that "Encouraged by the statement with which the court closes its opinion, and believing that the court will recognize the real possibility of error in drawing inferences of fact from a record so voluminous and complicated, petitioners center to assert that the decision of the court declared recovery in the present action is founded upon essential mistakes and misconceptions of the facts presented by the record."

The petitioners declare that when the principles of law associated by the court are applied to the facts the judgment against District No. 21, U. M. W. of A., must be affirmed, if not also against the International union. The judges in the lower court declared that the destruction of the mine property be with intent to restrain commerce, the trial judge on declared and the three judges of the Circuit Court of Appeals reached the same conclusion, the petition declares.

The mines were not flooded and burned until they were ready to ship coal, the petition emphasizing, calling attention to the insistence of the United Mine Workers for interstate agreements and the point that while the Arkansas strike was local in application it was national in policy, because of the national principle of the open shop involved. The motive of destroying the mine property was to protect union operators in Arkansas and other states against the competition of the cheaper mined open-shop coal, the petition recites, which was the motive declared by the jury, the trial judge on Circuit Court of Appeals were driven off July 17 and the Hartford and Coronado mines were not burned until July 18 and 20, the petition states.

An award of judgment against the union is again urged because "the mere lapse of time since the injury was incurred will inevitably embarrass the further prosecution of the case."

The Supreme Court will act upon the petition for rehearing after it reconvenes Oct. 2.

L. & N. July Car Supply in Kentucky Was 57 Per Cent of June's, Tabulation Shows

As a result of the continued argument relative to car shortage on the L. & N. lines in Kentucky, figures are here set forth from a report of the general coal and coke agent of the L. & N. to D. M. Goodwin, freight traffic manager. They show that car supply was better than many coal men claimed since July loadings were 57 per cent of June's. The report in part reads:

In June, 1922, the road established a great record in coal handled, and comparing the 64,558 cars handled in June, 1922, with 37,535 cars handled in July, 1922, it is shown that movement dropped to 57 per cent of the June movement, this being due to the shopmen's strike on July 1, which has held back movement of empty cars to the mines and loaded cars from mines. June movement was almost at capacity, but was held back somewhat by the fact that many large consumers did not believe the coal strike would run into July, and as a result waited for reduced freight rates to become effective as of July 1, not figuring that prices would jump.

The L. & N. R. R. was perhaps crippled worse than other coal handling roads in the state. The Illinois Central in western Kentucky has been able to handle from 75 to 100 per cent of cars needed at practically all times, the road reporting 700 to 800 cars handled daily.

Eastern Kentucky Coal Plants Improving

Activity in mining operations throughout the Elk horn-Hazard coal field of eastern Kentucky has caused a building boom to be in evidence on every hand. At Glemlan, below Whitesburg, Ky., the Reliance Coal & Coke Co. has completed a modern new tipple with conveyors, towers, bustles, and new homes for miners. The Imperial Elk horn Coal Co. at Sargent, has a modern new tipple almost completed. The company also will do much other building. The Lotts Creek Coal Co. and the Ajax Coal Co. are each building modern new storerooms at Lotts Creek. The latter company also is erecting a large number of new houses for miners. The Petry Coal Co. and the New Duane Coal Co., at Duane, are each doing considerable building as is also the Blue Diamond Coal Co., at Blue Diamond, in the First Creek section.

Other companies making various improvements are the Liberty Coal Co. and the Mitchell-Willis Coal Co., in the same section. Several hundred men have been added to the plants of the Consolidation Coal Co. at McRoberts and the Elk horn Coal Corporation at Flem ing and Raymond.

Central Pennsylvania Fuel Committee Names Officers and Prepares to Function

Members of the central Pennsylvania regional committee of the Pennsylvania Fuel Commission met in the office of the Central Pennsylvania Coal Producers' Association on Aug. 29, and effected an organization and formulated plans for functioning. The responsibilities of the committee have been reduced by reason of the strike's ending but the members will prepare for any emergency that may arise during the coming months.

That attended were W. Brooke Moore, of Harrisburg, service agent of the Interstate Commerce Commission, and Attorney Thomas C. Hare of Altoona, recently appointed by Chairman W. D. B. Ainey to head the state fuel commission as the representative of the public in the central Pennsylvania district. Others present were Charles O'Neil, representing the operators on the state commission; Rembrandt Peale, H. J. Mitchell, G. M. Clark, William Lamont, operators; W. A. Jones, statistician of the Coal Producers' Association; J. T. Carbine, of the Pennsylvania Fuel Commission; W. K. Nichol, of the Buffalo, Rochester & Pittsburgh Ry.; J. D. Beaver, of the Pittsburgh, Shawmut & Northern R.R., and W. H. Macquown, divisional freight agent of the Pennsylvania Railroad Co. at Altoona.

Charles O'Neil was elected district chairman, and W. A. Jones, secretary. It was decided to allow the business of the district to operate through natural channels as far as possible and the use of priorities will not be made at present.
Price Boosting Ford Rails Against Was Practiced by Him Two Years Ago

Cincinnati, Ohio, Sept. 12.—(Special Correspondence).—In the strong box of the U. S. Attorney in Covington, Ky., there are some interesting data relating to the Banner Fork Coal Mining Co. It would seem to put a different effect upon the complaint that Henry Ford, automobile manufacturer, of Detroit, Mich., is making against the coal trade and the jobbers and brokers in particular. It would appear that Mr. Ford in bawling the high price of coal is coming before the great court of the general public with a smudge on his fingers, for not long ago Mr. Ford, the owner of a coal mine in southeastern Kentucky, was himself the cause of the high cost of coal.

It will be remembered that the Ford interests purchased the coal properties of the Banner Fork company in 1920. That was the year that coal prices soared. In some places they rose as high as $10-$12 a ton. It was said at the time that Mr. Ford desired the property so that he could get coal at its original cost.

In taking over the Kentucky property with its equipment Mr. Ford did not turn in to the making of steam coal entirely. There was plenty of lump left over that could be sold on the open market. Most of this went to the Blue Diamond Coal Sales Co., which has its general offices in Cincinnati. Some of it also went to the Riddle Coal Co. of Chattanooga and some to the Bewley-Darst Co., of Knoxville. This was given to them to handle as jobbers, or on a brokerage basis. The ruling, however, was strict that this coal should be handled on a 26c-a-ton basis, and this at a time when the operating corporations were allowing brokerage greatly in excess of this.

The stipulation also was strict that the price at which this coal was to be sold would be as high as possible, and this is the returns that were made to the Ford company.

Then the complaints started to come in. Some of them went whooping to Washington at a time when complaints were no rarity—but the volume of them against the Banner Fork company was sufficient to attract the attention of the Department of Justice and in due time the selling agents for the Banner Fork mines were asked to account for the extreme high prices that were being charged for the lump coal that was being shipped from its tipples.

These reports were forwarded to Thomas D. Slattery, then the District Attorney for that section of Kentucky and Louisiana.

While most of this coal was disposed of in the South, Mr. Ford's mining interests were not asking at trying to sell it north of the Ohio river. A former president of the Cincinnati Coal Exchange who directed the sales department of a large wholesale coal firm at the time remembered this coal very well and the conditions under which it was offered.

"I should say I do," he said when asked about it, "but to the best of my knowledge our firm never was able to sell a ton of—it was too high in price."

Other firms here recollect the period and the offer of the Banner Fork coal and say that they refrained from handling it because of the small brokerage allowed in view of the high prices that were asked.

Nor does the Ford trail of high prices end there. Others who were selling coal to the Detroit plant at the time say that there was not hesitancy on the part of the Ford company to pay "the highest in the market" for steam coal and that when it landed in Detroit it was put to the test and that which would not come up to the requirements was sold through Detroit brokers of coal to users in the surrounding territory. It would appear at this particular time that the brokers against whom Mr. Ford now rails were a medium that he found worthy of use.

Salesmen who handled the Banner Fork coal to the south looked up their sales sheets and found that the sales ran from $0.25 to $10 a ton.

Standing upon the published statements of Mr. Ford to the effect that he thought the government price for coal was fair, Michael T. Roach, president of the Logan-Pocahontas Fuel Co., in a telegram to Mr. Ford on Sept. 5, renewed his offer to supply the Ford company with coal at the government prices and urged immediate action in the matter. In his telegram Mr. Roach said that it was particularly arranged that the entire output of one of his mines to the company although having expressed a desire to retain 25 per cent of the output for other uses.

Following the published announcement last week that the Ford factories were to close for lack of fuel, mainly through Mr. Ford's allegation that profiteers and coal bootleggers were boosting the price, Mr. Roach on Aug. 31 offered to turn over the output of the Walls Creek Cottiers in Harlan County, Kentucky, of about 85 carloads a day and the output of some West Virginia mines. Approximately 15,000 tons a month is produced on the Norfolk & Western line and the other coal is produced on the Chesapeake & Ohio.

In response to the first telegram Mr. Ford made arrangements to have his mine representatives, Amherst Thompson, confe with G. H. Martin, representing the Logan-Pocahantos Fuel Co., to determine upon the quality of the coal and arrangements also were made to have the Detroit representative of the Logan-Pocahontas Fuel Co. confer with Mr. Ford. Coal was offered to the Ford company on the basis of a two-year contract at the government prices, it being understood that when the government price changed, the price to the Ford company also would automatically change.

In an effort to get direct action on the matter of supplying Mr. Ford with fuel sufficient to run his factories, Mr. Roach on Sept. 5 sent a telegram to Mr. Ford in part as follows:

"Refer to your telegram of yesterday afternoon regarding the prices. As such we are in existence, we are not buying coal on two-year contracts at government prices and you cannot force us to guarantee regular routing. How many cars are you loading daily? We are not of the opinion that you have increased your bid from $5.45 to $8 a ton when you can load coal at our own mine in your district for $12 a ton."

"The second line of your telegram we can get as many cars to load at cost as you desire, allowing us to supply you with regular switching and car supply that you or any other shipper on the L. & N. could make. Our railroad allowance has been obtained from the government and cannot be cut from ninety carons on allotment which will be effective the tenth of the month. Answering the fifth line of your telegram, upon which you base your opinion that we cannot make delivery.

"Answering the sixth and last line, none of our contracts to you have been broken as this impression has been created, a proposition for two years based upon government prices and which would warrant $8 a ton for us to operate. You are wrong in the statement that we lowered our price would accordingly change."

"You are mining coal from your mine described, which is costing only $1 and you are charging the same method of charging mining costs as in effect by other operators, including yourself. Of the small brokerage allowed and charges, the net price of the coal we can supply at is $3.50 a ton, as such with a scale of wages as we are paying and put coal on the cars at $2. Now, Mr. Ford, my proposition was made you in good faith and based entirely upon prices at which you are contemplating closing down your plant or at least day of this month and giving as the clear reason in profiteering in the coal business.

"If the prices reports have correctly quoted you as stating that the coal prices are set at $8 a ton which system was put into effect by the government, then indeed you are very fortunate and the balance of us are unfortunate. In addition to the coal to be handled by us we are ready to negotiate on the basis of my proposal of $3.50.

Fix Maximum Prices for Alabama Coal

Governor Kirby and Fuel Administrator Roy T. Cox announce the following maximum prices for coal from Alabama mines: Steam, Seam coal—$2.85; Granulated, Brunsvig, $6.00; domestic lump $4.45; Cullman and Black Creek gromes, $3.60; domestic lump $2.50. Montgomery and Bessemer, the high price of coal. The retail prices are lower than at this time last year and the current prices are regarded as reasonable, where they range from 20 per cent in miners' wages affecting dept. I consider
Miners' Union Has 25,000 Fewer Members
In West Virginia Than Before Strike

As far as it is possible to estimate, it is believed that there are now 25,000 less miners in West Virginia in the United Mine Workers entirely, so that as a matter of fact District 29 no longer exists except on paper. That means a loss in membership of from 8,000 to 10,000 miners. New River operators have declined to enter into negotiations with the miners' union and have insisted themselves with simply posting the 1920 wage scales and of continuing to operate on an open-shop basis.

Operators in the Georges Creek region have advanced wages to the 1920 level. Just how many miners will return to work in view of the increase in wages remain to be seen. In the Upper Potomac region most of the miners are at work and have been for some time. Officials of the union assert that miners will not return to work until the Cleveland agreement is signed.

Operators of the Georges Creek field assign as their reason for declining to enter into a further contract with the United Mine Workers "the absolute violation of Article 11, Section 1, of the Maryland basic agreement, dated Dec. 11, 1920, which provides for no suspension of work for a period of at least 60 days subsequent to March 31, 1922."

Even under the "Maryland basic agreement," in force until March 31 and which the operators assert that the miners violated, there was no recognition of the union, nor do operators propose to amend the union such recognition now although always having been willing to engage in collective bargaining with the miners.

The operators in the Georges Creek calls for a wage of $1.304 a ton for pick mining and of $7.25 per day for general inside labor.

The possibility of taking testimony by groups in some of the anthracite tax cases listed for hearing in the Dauphin County Court, Harrisburg, Sept. 12, may cause changes in the plans to hear all of the appeals at that time. It is probable that the eighty or more cases pending will be so grouped and heard. Appeals are now being perfected by some of the large producers, and these will be added to the list.

Mine Fatalities in July Exceed Those of June in Ratio to Output

Coal-mine fatalities during July, 1922, numbered 74 as compared with 162 in July last year, according to reports received by the U. S. Bureau of Mines from state mine inspectors. The reduction was due primarily to the fact that most of the mines throughout the country were closed on account of the miners' strike, which caused the output of coal to decline from 37,693,000 tons in July last year to 17,151,000 tons in July, 1922, a reduction of about 54 per cent. The fatality rate was 4.31 per million tons of coal produced, almost identical with the rate for July last year, 4.30. For bituminous mines alone the July rate this year was 4.05 as against 3.78 for July a year ago. Fatalities in June last numbered 92, or 4.11 per million tons.

During the past nine years (1913-1921) the month of July has averaged 203 fatalities, with an average production of 48,446,000 tons, representing a fatality rate of 4.19.

During the first seven months of the present year 917 men have been killed by accidents at coal mines, as compared with 1,163 during the corresponding period last year, a decrease of 246 fatalities, or 21 per cent. The production of coal has declined about 19 per cent (from 279,859,000 tons to 220,202,000 tons). The fatality rates for the two seven-month periods were 4.16 last year and 4.05 for 1922 per million tons.

With two exceptions, all of the main causes of accidents during 1922 compare favorably with the seven-month record last year and with the entire year 1921. The largest reduction is in accidents from explosives. The rate from haulage accidents is about the same as for the first seven months of 1921 but it is about 14 per cent higher than the average for the whole year 1921. Gas and dust explosions have resulted in a fatality rate more than double that for the year 1921 or for the first seven months last year.
Administration Coal Bills Now in Conference; Passage Expected Next Week

Washington, D. C., Sept. 12, 1922.—Conferences on the bills to create a federal fuel distribution and to control distribution and the price of coal through priority orders of the Interstate Commerce Commission continued their efforts to harmonize the House and Senate measures today with prospects of an early agreement.

The Cummins bill was taken up Sept. 11 by the conference, who remained in session until late in the evening without reaching any conclusion. Most of the time was devoted to testimony by officials of the Interstate Commerce Commission, who explained how the proposed measure would operate.

The principal difference between the conferences developed over the inclusion in the House bill of references to intrastate coal, which the Senate conference believed rendered the measure unconstitutional, in view of the Supreme Court's recent decision in the Child Labor case. House conferees insisted the cases were not parallel and that the broader clause was legal because of the commerce clause of the Constitution.

Senate conferees on this bill are Senators Cummins, Kellogg and Smith, and House conferees are Representatives Winslow, Newton (of Minnesota) and Rayburn.

As soon as agreement is reached on this bill, conferences on the fact-finding commission bills will begin. The House has the same conferees on this bill as while the Senate conferees are Senators Borah, Sterling and Walsh (of Massachusetts).

As H. B. Spencer is understood to be unwilling to take over the duties of distributing coal under the Cummins bill, a new federal distributor must be found. No less than fifty names already have been suggested to Secretary Hoover. While it is believed that the position can be filled best by a traffic man, it is possible that some man known to be a good administrator will be chosen if a transportation man of the required caliber cannot be induced to accept the appointment. Among the names being put forward is that of Henry Ford. The suggestion is made seriously on the ground that he has distinguished himself as an organizer and recognizes keenly the desirability of an equitable distribution of coal and the need to suppress profiteering.

Donald D. Conn, of Minneapolis, who is in Washington representing the governors of the states of the Northwest that receive their coal supply largely from the upper lake docks, probably will be named an assistant to the federal fuel distributor to advise on the lake situation.

Varying dates for the expiration of the measure form the greatest difference between the House and Senate bills to control the distribution and the price of coal, the House bill providing a life until Jan. 1, 1921, and the Senate bill providing that it shall expire six months after enactment.

The Senate bill to create a fact-finding commission provides for a commission of five members and includes instructions to report recommendations on the standardization of mines on the basis of production and efficiency, standardization of wages and working conditions and the advisability and wisdom of nationalization of mines and government control of the industry, while the House bill lacks the latter features and provides for a commission not to exceed nine members. The provision written into the Senate bill directing a separate investigation of the anthracite field with a report to be submitted not later than July 1, next, which was included after the settlement in the hard-coal field, probably will be accepted by the House conferees.

Both the distribution and price-control bill and the fact-finding commission bill were passed by the Senate without difficulty once the time for final vote arrived, although both encountered vigorous opposition from individual Senators. The Cummins bill, to create the office of Federal Fuel Distributor and to broaden the powers of the Interstate Commerce Commission so as to control distribution and prices of coal, was passed Thursday, 40 to 7. It was amended in only two important respects, an amendment by Senator Sutherland reducing its life from one year to six months being adopted and one by Senator Dial, providing that its terms should not apply to contracts for coal at not more than $2 per ton that were made prior to July 25, 1922, being included.

The Borah fact-finding bill was passed Friday, Sept. 8, without any amendments other than those offered or advocated by its author. The vote on this measure was without a roll call, but sentiment had been tested a few minutes before the bill was put on final passage by the rejection, 19 to 30, of an amendment offered by Senator Dial which would have stricken from the measure the instruction to the proposed commission to report on the question of nationalization of coal mines.

Senator King, of Utah, offered an amendment to the distribution and price-control bill designed to prevent speculation in coal by providing that for six years it should be unlawful to purchase coal with intent to influence the market price. After objection, he withdrew this as an amendment and offered it as a separate bill, which was referred to the judiciary committee.

Repeated efforts, through amendments in various forms, were made by Senator Dial, of South Carolina, to amend the fact-finding bill by Senator Sutherland. Senator Sutherland also offered an amendment along the same line. Conferees were made that some contracts at an unreasonable price might be included and thus defeat the purposes of the bill. Finally, Senator Dial brought his amendment in so as to include coal at not more than $2 a ton on contracts closed prior to July 25, and this was accepted. The South Carolina Senator is interested in a mill which had a contract for $3.50 a ton, he stated, and which could not get delivery because the mine operator could not get coal. He is willing to wait, he said, if the Senate makes the contract unlawful.

Mine prices of bituminous coal should range from $2.50 to $3.50 in his opinion, Senator Kellogg declared, figures which Senator Sutherland characterized as "absurd."

The whole purpose of the bill, Senator Cummins asserted, was to supply the Interstate Commerce Commission with authority "to classify preferences on account of unreasonable prices that may be charged," and while he disclaimed any intent to cause coal operators as a class to be declared some power necessary to "check the greed" of those who would take advantage of the situation.

The most strenuous objections voiced against the Borah fact-finding bill were directed against its instructions that the proposed commission report on the advisability and wisdom of nationalization of the mines.

Senator Borah by Senator Shields of Tennessee, to amend the Borah bill so as to exclude from membership on the proposed commission any coal operator or miner not objection from Senator Borah and was defeated. The Idaho Senator declared the President should be free in his selection. The bill as passed excludes members of Congress and executive officers of the government from the commission.

Senator Dial attempted to have the Federal Trade Commission make the investigation instead of a special commission but this amendment was rejected. The South Carolina Senator then tried to have the nationalization and government-control sections of the instructions to the commission stricken out, declaring them to be merely "an invitation to all the disgruntled people of the country to appear before the proposed commission to complain and take up questions having to do with the coal industry.

The State Illinois state coal commission committee has passed into history. The passing was entirely informal. It received official word from the U. S. coal distribution administration that the federal body regards the strike as ended, that it can no longer look after allocation of coal to applicants and that normal trade channels may be relied on to take care of the country's requirements. Governor McCray had designated the Indiana Public Service Commission to cooperate with the federal administration.
May Apply Class 1 Priority to Gas Coal
For Utilities Having Contracts

Washington, D. C., Sept. 9.—The Federal Fuel Distributor in replying to urgent requests from numerous artificial gas and manufacturing companies for supplies of gas coal, which they are unable to obtain from West Virginia, Virginia, Kentucky and Pennsylvania steam mines, has granted requests from New York City, Chicago and various smaller cities in Michigan, Illinois, Indiana, Iowa, Missouri and other midwestern states. The difficulty in supplying this coal is due to the inadequate car supply in the districts nearest and to the fact that the gas-coal producing companies are promoting their coal among parties who have contracts. This means an even greater pinch in the supply of what coal is available, as the whole is being taken for steaming.

Fuel Distributor Spencer is considering the policy of applying Class 1 priority to gas coal moving to public utilities with whom the mines have contracts.

Dangerous of coal at the lower Lake ports for this week will amount to approximately 450,000 tons, with 3,500 cars reported at Lake ports this morning. As coal is not moving to the Lakes under the usual November specification, the differential is not available and it is impossible to make up the Fuel Distributor's program. Priority No. 1 letters are being issued today directing lake-side sufficient supply of coal to insure the attainment of the full Lake program for next week. These priority authorizations are being placed with a view to causing the least possible disturbance to the normal movement of coal. Difficulties experienced in the unloading of iron ore from boats at lower Lake ports have been solved, and there is now no shortage of vessels for the transportation of coal to Lake Superior docks.

The Fuel Distributor has found it necessary to issue Priority No. 2 orders for the movement of a limited tonnage of coal necessary to keep some non-essential industries in the Southeast from closing. Authorization for the movement of 10,000 tons of coal from Norton, Va., to the State Fuel Commission of South Carolina has been given. Representations are being made from time to time that industries will be compelled to close unless given certificates of priority which will aid them in obtaining fuel supplies. These cases are being considered on their individual merits, under a general policy of issuing priority authorizations only where real emergency needs cannot be provided for by other means.

New York Coal Dealers Pledge Support to State Fuel Administrator

Recalling from its policy of opposing federal or state administration of fuel supplies, the New York State Coal Merchants' Association adopted a resolution Sept. 8 at the convention at Richfield Springs supporting Governor Miller and State Fuel Administrator W. H. Woodin in their effort to provide an equitable basis for the distribution of coal and pledging full co-operation to prevent a crisis.

Use of bituminous coal as a substitute for anthracite in homes until the emergency is passed, restriction of the quantity given each consumer that all may have coal, and licensing of all dealers, both wholesale and retail, in order to curb irresponsible dealers, were among the measures advocated for dealing with the crisis. The "fair price" differential of 5 per cent fixed for jobbers' profit was denounced as four times too high.

Illinois Protests Priority Order That Favors Domestic Coal

Illinois coal trade is somewhat exercised over the recent amendment to I.C.C. Service Order 24, giving car priority to anthracite of all. A protest meeting held in the office of State Fuel Distributor R. M. Medill in Chicago brought up the argument that the amendment should be lifted because if steam sizes are not readily shipped from the mines they will accumulate to a point where many mines will have to shut down. Two plans of action may result. Mr. Medill on Saturday last urged that a committee go to Washington forthwith and plead with the Interstate Commerce Commission for a temporary repeal on the ground that there is no coal shortage in Illinois now and therefore the ruling should not apply to that state. The other plan which wise heads counsel is that the ruling be observed with all possible rigor so that its effect on coal consumers would cause such loud public complaint that the repeal would be granted.

Cape Breton Miners Return to Work:
Recall of District Officers Asked

All troops have left the Cape Breton mining district and the miners have returned to work. All of the mines with the exception of those flooded when the pumpmen left their places are in action again. The flooded mines are being pumped out gradually. The flooding has created much danger to the miners.

Springhill local of the United Mine Workers Union has petitioned John L. Lewis, International president, for the recall of the recently elected officers of D. strict 26, including District President Dan Livingstone. The local asserts that the new officers of the district were instructed to agree to nothing short of the 1921 rates. Instead a compromise was agreed upon with the coal operators.

Connellville Output Mounts, Though
Strikers Flock to Union Mines

Output in the Connellville coke region continues to increase slowly and steadily, most of the companies who are operating continuing to import labor. At the same time there is a large exodus of the strikers taking place to union mines in all directions since the union mines have been getting in operation. During the past week the H. C. Frick Coke Co. has fired additional ovens as follows: At Crossland plant, 50; at Leisenring No. 1, 40; at Leisenring No. 2, 40; at Leisenring No. 3, 70; at Davidson, 40, and at Trotter, 70, a total of 266. W. J. Rainey, Inc. has started up the Allison plant with imported labor.
Herrin Grand Jury Has Indicted 59 Thus Far; Jail Is Filling; Union Has Big Defence Fund

The grand jury in the Herrin massacre case is making good its declared intention of doing its duty in spite of "pressure" and threats. Thus far, after two gruelling weeks of investigation through the hottest kind of southern Illinois weather, it has indicted fifty-nine men on the three charges of murder, conspiracy to murder and riot. Up to Saturday night thirteen of the fifty-nine men—most of them union members—have been tried in Herrin jail and demurred to the securing of the country for the trial. Many of them gave themselves up through lawyers for or officials of the United Mine Workers of America who have been in Marion, county seat of Williamson County, watching proceedings from the beginning of the investigation.

This group of officials has told Attorney General Brundage it will bring in and surrender every union man who is indicted, providing Brundage will agree in advance to accept bail for their release. Brundage refuses that every man who goes to jail goes there to stay until the case comes to trial later in the month. The union's first attempt to obtain release of the prisoners on bail failed, but it is daily expected that some new effort will be made.

The main interest in the case just now is to see what further action the union forces will take. On Sept. 8 the Illinois miners' executive board, in session at Peoria, voted to assess every union member. Evidence came easier from the long line of reluctant witnesses after that and on Sept. 7 a list of thirty-seven more indictments was signed. Next day the judge indited twenty-one more and then adjourned until Sept. 18, when it will resume.

It has announced in a statement to the public that the jury intends to delve thoroughly into the part which the Southern Illinois Coal Co. and its president, William J. Lester, played in the circumstances leading up to the massacre on the company's non-union strip mine, June 22, the surrender of the men therein and the slaughter of nineteen and wounding of thirty which ensued. Thus far practically all the indictments have been against union men. If findings are to be made against the coal company or its employees for the killing of two union miners the day before the massacre they will have to be made after the jury resumes Sept. 18.

The investigation thus far has been greatly hampered by the incompleteness of Coroner William McCown's records of the individuals killed in the riot of June 22 and of the records of undertakers who buried them. The coroner's list identified only ten of those buried. There was a description filed of one more. The others were merely put in graves marked "Unknown" and little or no record made of them. Even the belongings of the slaughtered men were jumbled up or thrown away. Thus the case is much befogged. There is clarity enough, however, in the case of the following dead: C. K. McDowell, mine superintendent, the first man to be killed and for whose death Otis Clark, the first union man to be indicted and arrested, is now held; Robert J. Anderson, Sparta, Ill., who was hanged to a tree and riddled with bullets; J. H. Shoemaker, civil engineer, son of the Mayor of Charleston, Ill., shot at John Kuehl; Fred Landers, Saline, Mo.; John D., John N., and John H., Chicago; Ed Miller, of Chicago, who died wearing a Chicago police badge; Antonio Muklevich, American legionnaire; Robert March, of Chicago, an overseer veteran, and Howard Hoffman, of Huntington, Ind., and was one of those who escaped the slaughter at a barbed wire fence where so many died, but who was caught later, taken to the Herrin cemetery and killed there.

The jury has heard and recorded volumes of testimony about the revolting events of the attack on the mine and the massacre. Several of the victims were savagely mutilated before they were killed. A taxicab driver, who is among the indicted and for whose arrest the jury was especially anxious, is to be charged with driving through the region of the slaughter feeling every victim he found on the ground and cutting the throats of any who gave signs of life. This man, known as "Hillie" by the miners, is charging men in jail, is the man said to have stood over a bound group of terribly wounded men in the hot sun and who refused at the point of a gun to allow anybody to give even a drink of water to the dying.

The general sentiment among men who are watching the case and who stand for law and order is that it is going to be difficult indeed to mete out full justice to the guilty. The grand jury appears to be doing its level best. It is accumulating a mass of damning evidence against many prisoners and a good many of the indicted men are behind the bars with no sign yet in the troublesome county of a jail delivery to free them. It is freely prophesied, however, that, when the case comes to trial before a jury impanelled in the regular way, and not hand picked, as the grand jury was, in order to exclude possible partisans, the progress of the case will be difficult. The Rutherford Miners of America is armed with a large fund and an array of legal talent purposes making a powerful and intricate legal defense. There is little chance of removing the case from Williamson County because of the constitutional right of every man to be tried within the jurisdiction where the alleged crime was committed and because of his constitutional protection against being tried twice for the same offence. Thus: Indicted mining millionaires, the two church men, the former mayor, police commissioner, county commissioner, the marshal, a lawyer, the editor of the local newspaper, eight guards, the mining company's president, three members of the executive board, the manager of the strip mine and the Rutherford union's secretary, with whom the above are associated.

The fifty-nine men indicted, including Fred and William Travelstead, sons of one of Marion's respectable families; James Brown, a negro deputy sheriff of the town of Colp, and Otis Clark, president of a miners' union local, are these: Peter Miller, Charles Reaugh, Marion; Joseph Carnegie, Nava Cannaday, Herbert Rushing, John Rushing, Clyde Lee, James Galligan, Joseph Rhodes, William Stanley, John Kelley, Hubert Walker, James Norris, Roy Pennington, Harvey Perdue, Dallas McCree, Otis Maynard, Alvin Stewart, Joe Murray, Campbell Lively, Wesley McPharon, Frank Adams, Alvin Lollis, Floyd Stokes, George Anderson, Fred McGough, Phillip Fontanetta, Tom Weeks, Lee Howard, Louis Corbett, Bert Grace, Gerald Bernard, Peter Black, Noble Bell, Lew Corian, Charles Hancock, Ernie Craig, V. R. Wilson, Henry Skeltcher, Bill Gullidge, Darby Babington, Sam Catone, Jesse Childers, Orrie Kirby, Earl Baxter, Bill Clander, Fred Cooper, Lee Herron, William Sellers, Fred Travelstead, William Travelstead, Otis Clark, James Brown, Percy Hall, Blockhouse, Hastings, Giles Holley and Tony —

Strike Slowly Petering Out in Utah

It is difficult to say whether the coal strike in Utah is at an end. All but twenty-five or thirty members of the National Guard have been sent home, but no one, including the state officials, is willing to be quoted saying the strike is over. Following overtures from the strikers the opera-

This content is extracted from the COAL AGE publication on September 14, 1922. The text contains information about the Herrin Grand Jury indictment of 59 miners in connection with the Herrin Massacre, the trial proceedings, and the general sentiment among those watching the case. The text also mentions the strike in Utah. The natural text representation is provided as is, without additional processing.
Buying of British Coal Has Passed the Peak

Late in June British coal began to seep through to the Atlantic ports. It came slowly at first, largely as an experiment on the part of a few Eastern railroads and utilities. As the shortage of home coals became more pronounced, however, heavier orders were placed, taxing British export facilities and calling into service a number of U. S. Shipping Board vessels. This flood of foreign coal reached its peak late in August, when in New York harbor above 1,25,000 tons was received in seven days.

As September opened seaports not accustomed to handling a heavy volume of coalsea coals were congested with British cargoes, and even Boston harbor, the best equipped to receive coal by water, was plugged with the arrival of six thousand cargoes. Eight more ships, arriving forty-eight hours later, were forced to anchor and await their turn at the unloading machines. The congestion at New York, with its lower daily discharge rate, necessitated diversion of tonnage to other New England ports. All this meant heavy demurrage charges for someone.

Prices mounted with the volume of business placed. When the Shipping Board first chartered a few of its vessels for this business it set a freight rate of 7%, having chartered eighty-nine vessels in all at this writing. The British rate was slightly higher at the outset and rose to 13½@13½, because of the scarcity of bottoms and the urgency of orders. The Shipping Board rate advanced to 15s., but remained lower than the British figure at all times. British 1, 5, 6, prices also advanced, good Admiralty coal going from 20s. late in June to a high of 32s. 6d. in August.

When late in August production in the United States started upward the effect on the British market was instantaneous. Ocean rates and coal prices began slipping, but the reductions brought little business. Shipments to this country are expected to continue throughout the year and may reach 1,500,000 tons by the end of September. But now, as in the beginning, shipments are largely on firm orders placed by railroads and utilities. A few traders bought cargoes and shipped them "free" to this side when prices were nearing the peak. When American coal quotations declined with better production harbors were congested, heavy vessel demurrage accumulated and this trading speedily became unprofitable.

British coal can still undersell ours in our own seaport markets but with domestic reductions paralleling those abroad the time consumed in filling orders introduces an element of risk that deters coal men from ordering tonnage to throw on the present sensitive spot markets of this country. It requires nearly six weeks' time to obtain British coal, about one-half of which is consumed in ocean transportation. The coal received and still on order is needed to fill the strike gap, but this is rapidly closing.

United States production is better and British coal "on spec" faces an uncertain reception on this side of the Atlantic.

The illustration shows three British cargoes of coal being unloaded at New York Central R. R. piers at Weehawken, N. J., across the river from New York.

Depreciating Cause for Alarm, Woodin Urges Economy in Use of Electricity and Gas

William H. Woodin, New York State Fuel Administrator, appointed on Sept. 6 by Governor Miller, has already issued a warning against profiteering, stating that he sees no reason why coal should be any higher in price than it was last winter.

Mr. Woodin, who is the president of the American Car Manufacturing Co., entered upon his duties the day following his appointment and after conferring with the members of the Governor's Coal Commission appointed Colonel William J. Donovan, of Buffalo, legal adviser, and continued in office the existing Coal Commission members.

The Fuel Administrator has been promised the cooperation of the city administration of New York City in his work. He attended the conference of anthracite producers and representatives of the federal and state governments held in Philadelphia on Sept. 7 but before going to the conference Mr. Woodin announced that the state would be divided into nine districts with a district fuel administrator in charge of each.

Names of the nine district administrators will be announced this week and they will meet in conference with Governor Miller and State Fuel Administrator Woodin at Albany.

Permanent offices for Mr. Woodin and his staff have been opened at 165 Broadway, New York City.

It is the intention of Mr. Woodin, in order to avert any emergency that might result from a continued shortage of anthracite, to educate the public in the use of substitutes. He will ask all consumers to exercise economy in the use of electricity and gas, but made it plain that at present there was no cause for alarm.

J. W. Paul, coal-mining engineer of the U. S. Bureau of Mines, recently examined a fire on Neville Island, Pittsburgh, Pa., in a fill composed of coke breeze, cinders and slag. This fill is 500 ft. wide, 2,000 ft. long and 20 ft. deep. At the time of Mr. Paul's examination the fire was not yet under control and had already caused a loss of more than $300,000.
MINING of anthracite was resumed on Monday, Sept. 11. At Scranton, before noon of that day the United Mine Workers and the representatives of the operators signed the contract that is to insure uninterrupted operations for the next year. The signing of the contract was but a formality following the ratification by the miners’ union of the compromise agreement between John L. Lewis and the operators arrived at on Saturday, Sept. 2, at Philadelphia.

According to the decision of the Shamokin convention last January, it was necessary to submit the terms of this agreement to the vote of the men. A gathering of delegates from the locals in the hard-coal region assembled in Wilkes-Barre on Wednesday, Sept. 6, to listen to the speeches of the officials and vote on the proposed contract. The meeting was stormy; it lasted until late Saturday, giving everyone a chance to get his views into the record. But after every supporter and every opponent of John L. Lewis had had his say, the vote was overwhelmingly in favor of acceptance, as Mr. Lewis had said it would be.

The men go back to work at the same wages and with the same working conditions they had before the strike. They are under contract to stay at work until Sept. 1, 1923. They were obliged to forego the advance in wages they had demanded and they did not get the check-off, which they asked among their nineteen demands of last January. On the other hand, the operators did not get the wages of the men reduced, as they had desired, nor did they succeed in providing for arbitration of future wage contracts, a point on which they were urgent.

Delegates to the Wilkes-Barre convention from around Pittston, Olyphant and Kingston were instructed to oppose any ratification of the agreement. Many of the delegates from Shamokin and around Pottsville wore badges on which was emblazoned “Stick and Fight to the Finish.” There was a general feeling that Lewis would meet strong opposition. On the opening day he was made chairman of the meeting. Thursday morning Thomas Kennedy, president of District No. 7, read the 55-page report of the scale committee.

Friday morning he offered the agreement to the convention. Philip Murray spoke at length in favor of acceptance. “We need not deduce ourselves at the nineteen demands,” said he. “Industrial conditions of the country did not warrant the granting of these demands. All other basic industries in the country have taken decreases. Eighty-five thousand maintenance of way men work at 23c. per hour. Ours is the only organization that kept its wages of 1920. The union that has succeeded in retaining what it has won a great victory. In principle the victory of the anthracite miners is a greater one than that of the bituminous miners. Arbitration means that some outside party that knows nothing arbitrarily says to you what hour you shall rise in the morning, what wages you shall receive, and compels you to accept.”

After speech-making through Friday and until six o’clock in the evening on Saturday the miners overwhelmingly voted for acceptance of the agreement. The opposition remained silent and registered no vote of protest.

Meanwhile steps were being taken by the national and state governments looking toward control and regulation of the price and distribution of hard coal, when it should again be made available. Secretary Hoover called the representatives of the operators together at Philadelphia on Thursday, Sept. 7, to get their views as to the best way to handle the situation. As a result of this meeting a Committee on the Distribution of Anthracite was appointed. Hending the committee is S. D. Warriner. The others are W. J. Richards, W. H. Williams, W. L. Connell, Alan C. Dodson and John F. Bermingham, all executives of producing companies. E. W. Parker, director of the Steel Bureau of Information; R. C. Morse, representing the State Fuel Commission, and W. H. D. Alvey, chairman of the Pennsylvania Public Utilities Commission and acting state fuel administrator, also are on the committee. A member is to be named by Secretary Hoover.

This committee has made no official announcement of any action but it is understood that the sentiment of the trade is that each producer and shipper shall allocate his tonnage equitably on the basis of the last coal year, 1921-22, although it is recognized that until the tonnages that are to be sent up the Lakes and to such distant markets as Canada and northern New England are sent on their way, such ideal distribution will be difficult to realize. The trade has made it plain that in its belief the best results will be obtained with the least interference on the part of the authorities, and it is understood that both Washington and Harrisburg will give the shippers every opportunity to make good. The operators will keep current and definite records of distribution and thereby check up on those who may endeavor to divert coal to take advantage of high prices in certain localities.

If there is to be any check on anthracite prices it will have to come from Washington after the Fuel Distributor bill has been signed by the President. As most of the hard coal goes into interstate commerce the Pennsylvania Fuel Commission has advised the trade that it will countenance no prices or margins higher than those obtained last March, prior to the strike. This advice was tendered to the independent producers and the retailers. Retailers are to be restrained from giving any consumer more than sixty days’ supply and shippers are not to furnish coal to any but established dealers.

Cumulative production of anthracite for the calendar year to Sept. 1, stands at 22,199,000 tons. This is 30,700,000 tons behind last year and 33,800,000 tons behind 1919. In addition to the current production a considerable tonnage of anthracite has been forwarded from storage. Total shipments of ex-storage coal from April 1 to Sept. 1, according to reports furnished by the railroads, amounted to 28,000 cars, or about 4,250,000 net tons.

The West Virginia Public Service Commission has issued a priority order similar in form to that outstanding with the Interstate Commerce Commission. The order applies to the lines of any coal-loading carrier within the state. Classes of priorities are specified. Class 1 is for special purposes specifically designated by the State Fuel Commission or his agent; class 2 is for fuel for railroads and other common carriers, public institutions, hospitals, United States, state, county or municipal governments, and for their public institutions.
Scientific Study, Not Emotional Denunciation, Says Hoover, Will Solve Nation's Coal Problem

The favorable progress of legislation for the creation of a national coal commission fully empowered to get to the heart of the troubles is the first step in one of the most vital problems we have, according to Herbert Hoover, Secretary of Commerce, before the National Association of American Chemical Industry, Tuesday, Sept. 12, 1922, in New York. That he has been earnestly recommending such a commission for the last three years, he declared, was because he does not believe great solutions are to be found out of emotional denunciation, but out of sober, scientific examination. Portions of his address follow:

We have made the victim of infinite loss and suffering by such disagreements as we have witnessed; when the whole nation can, once every two years or less, be pushed to the edge of the precipice of want and commercial collapse, when our public utilities, hospitals, schools, and kilnites are dependent upon short rations of non-union coal; when the federal government is forced to interfere with business and transportation by the movement in essential points; when we are brought to considerations of price fixing against extortion in peace time; when hundreds of thousands of workers not only in the industry but outside of it are thrown into skipping and starving; when the nation is made to suffer the shame of Herrin and rampant crime that has followed in train of strikes; then some examination of our industrial sanity is called for.

Two Problems Requiring Constructive Solutions

There are two distinct lines of problems for which constructive solutions are needed: employer-employee relationship and economic reorganization of the industry. I believe such a commission would find that collective bargaining, conciliation and arbitration upon their present basis of organization have been broken down in this industry. In this connection if we look inside workings of this recent strike we will find situations new in industrial relations. Under freedom from the restraint of trade laws the workers' organizations have grown in strength, solidarity and devotion; they have shown able leadership, whereas the organization of employers for the purpose of collective bargaining has been to a large degree destroyed by the raids, wars upon entering into the history of rights or wrongs of this phase, the bare fact exists: that the recent agreement in the bituminous industry was determined by only 15 per cent of the employers, and this minority's decision controlled the whole.

The federal laws on conciliation have failed to obtain any results for years. The conception of arbitration is a settlement based upon compromise to abide by the decision of a third party, but this is now refused "on principle," for in this industry the workers consider that arbitration always results in compromise and that this is compromise with their bread and butter.

Workers have a right to protest to prevent and improve wages and conditions of labor. They have a right to collective bargaining. They have a right to strike. They have a right to refuse to join some organization. They have a right to work without intimidation and assault. Employers have a right to refuse to recognize such organizations. They have a right to lockout. They have a right to keep open shops. No one seriously denies any of these rights, but a lot of people are overlooking a superior right. That is the right of the public to a continuous supply of the vital necessities and conveniences furnished by employer and employee. When these various rights infringe upon the public right, then the dominant right is public right.

Aside from employee relationships, most of the economic demoralization lies in the bituminous, as distinguished from the anthracite, industry, and my discussion hereafter refers to bituminous alone. This industry, indeed, functions very badly. Some state officials say it will work itself out if left alone. But it must be borne in mind that it has not been left alone in the past, and the present situation is in large degree due to legislative interference. The control of decisions among operators, without such restraint among employees, the rules of artificial car distribution, the state legislation of various sorts, and other acts, have a great responsibility for the present condition. I am not here questioning the necessity of these measures, but their influence in the situation must not be overlooked, and they must be either supplemented or amended by wise provisions, if we are to have coal peace.

The perpetual labor disputes are but one of the inevitable byproducts of this poor organization. Labor is struggling on one side to set up remuneration based on such days' pay, and such piece-work rates, as will give a standard of living from 60 per cent of time employed. Labor is thus honeycombed with the worst of stimulants to unrest—instability of employment. At the same time, men who have the opportunity to work full time in regularly operating mines earn returns far above the average income of our most prosperous farmers and other workers. There can be no solution either to the operators or to the workers as long as this condition continues.

The largest contributor to overexpansion of the industry is now the almost regular biennial quarrel, with its undue prior demand for coal and its subsequent shortage with temporary high prices. Beyond this the non-union mines in the South are gradually causing the industry to migrate from the North to the South, with consequent overequipment in the North.

Intermittent operation also arises in the chronic annual shortage of railway cars because a sufficient car supply for the short-peak period is economically impossible to the railways. A bad system of distribution of cars to mines by the railways contributes also.

Should Earnestly Consider Co-operative Schemes

A contributing remedy that will need the most earnest consideration is the possibility of permitting the co-operative system of marketing developed by the farmers to be applied by such mines as wish to adopt it, under circumstances that would assure competitive conditions. Such an arrangement would decrease distribution costs, would give more regular flow to orders, would get better car distribution, would increase transportation, would enable the laying down of coal in storage at points of consumption, and would consequently give more regular operation with reduced working costs.

It has also been proposed, although I have doubt as to practicability, that there should be a penalty in higher wages for short-time employment. Others propose a basic wage with a participation in the realized profit of the industry.

I recognize that stabilization of the industry, or anything that lends stability to the industry, is opposed by a small minority of speculative operators who use the periodically disturbed production to reap a recurrent harvest. It would be opposed on the other side by some of the more narrow-minded labor leaders who contend that their object in all industry is to reduce the number of hours of actual labor to some minor fraction of the time. Then there is the nation's desire to socialize in desperation for coal, or who deny the public right to any voice. However, I believe that the constructive men on both sides are in full agreement that we must have a broader and better solution than results from the truces of the past few years.

These periodic wars in the industry are, therefore, in part symptoms of a disease. But, before we treat this disease, we must have a more accurate diagnosis. We must have adequate, accurate information from which to weigh the different causes. We must be able to apply to all the test of fact. From such an understanding we should be able to return this industry to sanity. The proposed commission has the greatest opportunity for constructive work.

The public demands results; it is sick and weary of periodic warfare and futile attempts at solution.
UNION mined coal is on the market in quantity. Heavier receipts and offerings have softened spot prices in the East. Markets supplied by non-union fields have registered but little decrease in prices and in some cases have shown a slight uptum. So heavily have the facilities of the roads originating non-union coal been taxed in the last five months that the movement of cars and consequent production has been considerably affected.

Coal Age Index of spot prices of bituminous coal rallied slightly, standing at 427 on Monday, Sept. 11, 7 points above last week. The average price was $5.17, as compared with $5.08 in the preceding week.

Consumers are floundering around in the market, some trying to cover on contract but many being tempted to delay buying a little longer in the hope that prices may slip down another notch or two. It is the old story of curtailed demand on a falling market with only the inevitable end in view. Delayed demand following the prolonged strike will shortly push prices up as fast as they have in recent weeks declined.

**SUPPLY OF SURPLUS CARS DWINDLING**

The present rate of coal loadings is fast exhausting the supply of surplus cars. Surplus coal cars numbered 111,521 on Aug. 15, prior to general resumption of mining. On Aug. 23, a week later, they were down to 96,405 cars. Resumption of hard-coal mining is causing an additional drain on car supply.

Domestic sizes are already in strong demand and Ohio, West Virginia and some other Middle Western domestic coals advanced sharply last week. Lake buyers, on the other hand, while clamoring for tonnage, disappear at the slightest price advance. Steam coal is heavy at New England, where receipts via water from Hampton Roads and Great Britain have made active canvassing again necessary to dispose of tonnage. North Atlantic centers are in better supply and prices are easier, as is the case in that section of the country east of Pittsburgh and Cleveland. Illinois and Indiana fields are hard hit by car shortage but comparatively light production is so far meeting with light demand.

Welcoming the news of the resumption of anthracite mining the consumer is hopeful that he may not have to resort to the use of much substitute fuel. Dealers, however, are advising the purchase of such fuel to last through October, when it is hoped that small lots of hard coal will again be available.

The Connellsville labor situation is not clearing as fast as was expected. Beehive coke prices are lower but the supply is not heavy.

**BITUMINOUS**

"Instead of the 2,400,000 tons suggested by the first report, final returns on soft-coal production show only 9,142,000 tons in the week ended Sept. 2," says the Geological Survey. "The record of the week was awaited with interest as an indication of the supply to be expected after general resumption of mining under the Cleveland agreement. Because of the Labor Day holiday, the output for last week can hardly exceed 8,700,000 tons.

"The trend of output day by day is shown by the following statement of cars of bituminous coal loaded. On Labor Day 10,021 cars were loaded by the non-union mines, confirming the experience of other years that the day counts for a

The all-rail movement to New England was 1,292 cars during the week ended Sept. 2, as compared with 308 cars in the preceding week. Central Pennsylvania grades are offering freely in that market but are slow sellers because of the heavy receipts of water-borne coal from Great Britain and Hampton Roads.

Dumps at the Roads for all accounts were 315,658 net tons, a slight decline when compared with previous week’s figure of 329,652 tons. Receipts at the piers are slowly rising, despite the heavy Western movement of coal from West Virginia fields. Prices at the Roads are softer, as crosswise markets are now obtaining ample supplies.

The Federal Fuel Distributor’s orders directing coal to the Lakes is reflected in the largest tonnage of the year during the week ended Sept. 11. According to the Ore & Coal Exchange, 623,508 net tons were dumped—594,772 tons varex 28,735 tons vessel fuel—as compared with 463,242 tons in the preceding week. The total movement for the season is now 6,300,803 tons; in the corresponding period last year 17,183,200 tons was dumped.

### Anthracite

It is estimated that full production of anthracite cannot be approached this week or even next, at the very earliest. During the week ended Sept. 2 the output was confined to 38,000 net tons of steam coals dredged from the rivers. This river coal has fallen from grace with the prospect of an early supply of fresh-mined steam sizes. The heavier bituminous coal production also has reduced its sale.

### Coke

Production of beehive coke was 142,000 net tons during the week ended Sept. 2, as compared with 117,000 tons in the preceding week.

Shortage of coal cut deeply into the production of byproduct coke during August. The total output was 1,794,000 net tons, a decrease when compared with July of 692,000 tons, or 48.8%.

To produce the coke manufactured in August required 3,427,000 tons of coal, of which 2,577,000 tons was used in byproduct ovens and 850,000 tons in beehive ovens. The cut in consumption in byproduct plants was nearly 1,000,000 tons as compared with July.

Railroads Now Most Important Factor In National Coal Situation

With all the advantages of a large surplus of cars, the railroads did not transport coal during the period that the surplus was available at a rate sufficient to transfigure the market. It only slightly in excess of 9,000,000 tons was transported during the week ended Sept. 2, for instance, it is regarded as a good indication that the railroads will not be able to come anywhere near that figure again while the shopmen's strike continues. On the other hand, it is apparent that enough coal can be transported to meet the necessities for immediate consumption, which will mean that careful attention must be given to distribution until the railroads can handle twelve to thirteen million tons a week.

The Attorney General's injunction has been the source of constant coalmen discussion on Capitol Hill since the day of its issuance. As Congress is composed so largely of lawyers, the subject is one in which all members are taking a keen personal interest. Little has been said about it on the floor of either house, largely on the ground that discussion of the subject in Congress prior to action on the request for the injunction might be interpreted as an untoward attempt to influence the judiciary. While it is apparent that the majority of the members in each house, regardless of party, believe the Attorney General's action is entirely justifiable, there are some prominent figures in Congress not particularly friendly to unionism who regard the injunction as snatching at the fiftteenth century. To attempt to restrain American citizens from expressing sympathy for the strikers or from holding peaceable meetings goes too far, they think. Such drastic restraints as are proposed in the injunction would be in a better setting in Russia, they contend. They call attention to the fact that the situation is quite different from that of 1894, when President Cleveland made use of the injunction weapon. At that time there had been a general resort to violence and lawlessness. In the present strike there is genuine reason to believe they say, that 90 per cent of the strikers are entirely innocent of sabotage.

On the other hand it is pointed out that the government has been more than patient since July 1. It has been patient when every day's prolongation of the strike, with its attendant lawlessness, interruption of the mails and interstate commerce, was costing the majority of the people of the United States a stupendous sum, to say nothing of the enormous losses and the menace to the public health. To compare the situation with the situation 1894 was in that of 1894, it is being told, is impossible.
Ships were getting bunkers fairly regularly. Movement of coal to port was about 50 per cent of normal, with railroad equipment improving. The spot market was being subjected to the natural frenzied activity, because of the scarcity of coal in spite of the downward market. All piers showed an activity similar to that of the previous week. Receipts are slowly gaining.

**British Prices Slip with Waning American Demand; Germany Seeks Coal**

British coal is facing the lowering of the tension in the United States. Orders from North America are dwindling, being chiefly from Canadian producers. Prices are slipping downward again. It is estimated that by the end of September, 1,500,000 tons will have been shipped to fill the strike gap and that the movement, in smaller volume, will continue throughout 1922. Germany is also importing coal, but her financial situation is determining closing. Production during the week ended Aug. 28 was 5,428,000 gross tons, according to a cable to Coal Age. This 10,000 tons less than the preceding week's report.

Owing to lowered demand for tonnage, freight from the Tyne to the United States have been reduced and ship-owners are accepting 3s. a ton.

Coal Paragraphs from Foreign Lands

**Greece** - Production in the Ruhr district has increased by 1,500,000 metric tons, according to a cable to Coal Age, as compared with 1,500,000 in the preceding week. The price of Cardiff steam coal is unchanged at 42s. 3d. according to a cable to Coal Age.

**France** - Reduction Heavy Mine Stocks

The situation of the coal mines of the Nord and Pas-de-Calais remains compactable, as favorable stocks are being reduced, although still running very high. Almost nothing came out of the offers which were made by French coal mines to American producers.

In July, France and Luxembourg received from Germany on repARATION account the following: France, 365,473 tons of coal, of which 132,957 tons carried by sea, Luxembourg, 4,969 tons. France received 403,550 tons of coke; Luxemburg, 131,471 tons.

The adjusted price of German reparation coke delivered to French blast furnaces by the Sociétés des Cokes de Hautes-Fourneaux has been maintained at 97 fr. at the Franco-German frontier. On the other hand, from Aug. 1 to Oct. 31, French mines of the Nord and Pas-de-Calais have agreed to sell to the Sociétés des Cokes de Hautes-Fourneaux, for pooling and distributing purposes, metallurgical coke at 55 fr. and coking coal at 67 fr., at mines.

**Prices Drop at Hampton Roads**

No change was apparent in the situation last week except a slight reduction in prices. The outlook has not improved much from any angle, dealers expecting another price increase soon.
North Atlantic

Will Consumer Seek Cover Or Gamble on Lower Prices?

Buying is spasmodic, due to Waver- ing in policy—Complaints Heard of Car Shortage, Especially on B. & O.

—Few Orders for British Coal.

Many complaints of car shortage are heard. It is reported that conditions are especially bad on the B. & O. The effect of this lost time is not yet reflected in the larger markets, where heavier receipts have softened spot prices. Buying is spasmodic. Consumers appear to be floundering between a desire to get under cover and the temptation to delay purchases in the hope that prices will drop further.

Very few orders for British coals are being placed. Cargoes are arriving daily but the receipts are now mainly on old orders for railroads and public utilities. It is likely that deliveries against these orders will continue throughout the balance of the year.

PHILADELPHIA

Production grows, and better shipments are coming in, although not anywhere near normal yet. The real difficulty is car supply.

Service on the Pennsylvania is good, with a car supply up to 75 per cent. and movement of loaded cars quite prompt. Much the same condition applies to shipments coming off the N. Y. C. and the Western Maryland. There does not seem to be any likelihood, however, of an improved car supply when it is considered that a great number of cars in the bituminous coal trade are fast being withdrawn for anthracite loadings. It is on the B. & O. where the real trouble is.

There is very little active solicitation by houses for orders, as every shipper already has far more orders on the books than he will be able to ship for several weeks.

Prices continue to fluctuate unevenly, with just a slight downward tendency, and while some houses report firmness or even a slight upturn in quotations, it is not believed that another forward movement has as yet developed.

Each day now sees the survival of one or more cargoes of British coal, but it is not likely that any new business of consequence is being closed.

CENTRAL PENNSYLVANIA

Production is steadily increasing. The forces in most of the mines are being recruited to something near normal. Production is now running around 3,000 cars daily, something like 500 cars short of what is considered normal.

There are still some local strikes resulting from on cause or another, while the operation of operators do not, as a rule, have a full complement of men. Production for August was 35,129 cars, as compared with 14,079 in July.

Some operators, whose miners drifted away during the period of the strike, have not been able to get them back again, so that it will be some time before the normal output is reached.

BALTIMORE

An increasing volume of shipments have brought a decline in prices for steam and gas coals at this point. Demand, however, has prevented anything like a rush drop and there is now every indication that the present level is likely to be retained, at least for some weeks.

While there is practically no coal of Pools 1 or 71 now offering, and Pool 9 is also scarce in supply, good coal such as Pool 10 still runs $5.50@5.60. There is now considerable Pool 11 on the market, offering at $4.75@5.50. As the market supply increases there will be a let-up in the rush for gas and industrial coal as the market for gas coals are not changing hands as freely as steam varieties.

The above situation applies, despite the fact that the State survey conducted under the auspices of the Maryland Fuel Distribution Committee showed that a serious shortage of coal exists in nearly every section. It is probable, therefore, that the Maryland committee will be in service by Governor Ritchie for some time and that a representative will be named in each of the twenty-three counties to keep the committee informed so that it can act to secure coal in emergencies.

NEW YORK

There is no lack of coal at the local ports, 1,280 cars being reported on Sept. 8, although most of it is Pool 11 or coal of that quality. In addition there were small free tonnages of both British and Southern coals which were offered at higher quotations than coals regularly offered here.

Buying was spasmodic. There were many inquiries, some of them for contracts for the "balance of the coal year." As a rule the small operators practically ignored the latter, preferring to take chances in the open market. The operators with larger tonnages, however, were reported to have negotiated several contracts, some of which it was said were at figures ranging $4.65@$5.25.

The matter of car supply is already entering into the situation. Most complaints so far heard refer to shipments along the B. & O., while Pennsylvania conditions of the New York Central and the Western Maryland are said to be much better.

British coal is still being purchased by American stove companies in small lots. During the six days ended Sept. 8, twenty vessels carrying 125,909 tons arrived in New York harbor. With production of domestic coals increasing it was reported there were some cancellations of British shipments. Shipping Board officials do not believe any of their charters will be canceled unless by agreement. Toward the end of the week a couple of cargoes of British anthracite were offered to local buyers at $111.

Buyers are of the opinion that quotations will gradually become lower and for that reason are holding off.

UPPER POTOMAC

Upper Potomac mines continue to increase production and is now not far short of 40,000 tons a week, with some of the larger companies contributing heavily to the aggregate output and more men return to work. There are still a good many miners on strike however, insisting upon a recognition of the union. Transportation facilities are ample. In the Georges Creek region idleness still prevails, although there is a report in circulation that ten companies have signed an agreement with the union.

FAIRMONT

Trouble has been experienced by mines in securing enough cars to keep running. Most of the mine owners in northern West Virginia have signed the union agreement, and some of them are already putting out record tonnage. From now on it looks like a question of transportation.

Some steam contracts have been closed at $3 for 3-in. slack and purchasing agents are offering sales agents contracts at $2.50, but the opinion of the best-posted sales managers is that the price for steam coal will be higher and they are inclined to play the market.

One of the operating companies which has yards in Fairmont and other points is out with a new retail price list that is causing some concern as this list cuts the price of some grades, $2 and $3. Prices are well maintained at the mines and are as follows: Kanawha lump and run, 80c.; mine run, $2.50; slack, $3.

SALT LAKE CITY

The announcement of an increase of $1 a ton in freight rates is a break throughout Utah. Individuals and business organizations are lifting up their veils and are trying to find ways to get around the situation. During the days when the increase was merely prophesied, a Salt Lake City newspaper and an operator got into a dispute over a headline, resulting in a cancelled contract, to which the coal was withdrawn. The newspaper column read, "Keep out of the contracting business, whereas the operator said, 'Don't buy coal where you haven't bought.'

Car advantage is almost non-existent in this region, although the I.C.C. has promised to put in for all ports of coal increasing.
Anthracite

Resumption of Mines Hailed.

But Sales Are Not brisk

Consumers Seem Confident Substitute Will Be Available, When Necessary

—British Coal Pressed Into Breach

—Price Announcement by Companies Awaited.

The resumption of mining is welcome news to the household. Dealers are advising their customers to procure enough substitute fuel to last through October at least, as they realize the distribution problem that confronts them. The consumer, however, feels that there will be little difficulty in obtaining a substitute at the last moment, if necessary, and sales are not brisk. Some British fuel is being taken in for this purpose.

Price is still an open question, no announcement having been made by the companies. A few independent quotations are heard.

NEW YORK

Well notified orders sufficient to keep them busy for several months retail dealers are anxious to have the mines resume. Since the announcement that an agreement had been reached and that only approval by the miners' convention was needed to send workers back into the mines, there has been no indication about substituting bituminous coal for anthracite. In many instances the consumers have been advised to "hold off" as sufficient anthracite would be available to keep them at least warm.

Prices have received considerable attention in the past week but so far no announcement has been made from the producing fields. It is not expected, however, that the companies will make any considerable changes in the price list of last spring, but it is possible that with the heavy demand for hard coals the independent operators will be able to get premiums.

Some small lots of washery coking and peat were offered here during the week but retail dealers were not buying at the prices quoted, claiming they could not sell the coal to their regular customers.

A few retail dealers in the outskirts of Greater New York have small tonnages of peat and cokemort on hand which they continue to deliver.

BALTIMORE

Some consuming interests are urging upon the governor the necessity of having his fuel commission name a representative to go to the fields and check up on the Maryland allotments. Governor Ritchie has not indicated whether he considers such a service necessary and it seems doubtful that

a step will be taken, especially as the committee would have no powers to enforce shipments.

Consumers should be advised that they should lay in supplies of bituminous coal, at least for the months of October and November. A number of dealers are now selling English coal which continues to arrive. Some of the dealers continue giving their customers demonstrations of the good burning qualities of this Welsh coal. The price runs $13.50-$14.50, delivered in carloads.

PHILADELPHIA

With close to two weeks taken out of the month there is going to be very much of a scramble for the limited tonnage that will be available, during the balance of September. The consumer demand grows more insistent each day.

There is still a meager quantity of peat available at $11 a ton, delivered, but the yards have no stocks now of this size.

As the early opening of the mines is assured, the matter of price is one of much interest. Of course the consumer has lost sight of this factor in a measure, being overshadowed by his desire to get coal, but the retail man is anxious to know what is going to cost him and what he will have to charge. One of the independent companies is reported as having already announced its prices, effective Sept. 1, as follows: English nut $9.25; peat, $7.50; buckwheat, $5; and rice $4.

There is some indication that the larger companies are intending to ship considerable coal to distant points, particularly the West. As it will take the mines some time to get up capacity production, they are apprehensive that they will have a long wait before receiving fuel in any great quantity here.

River barley is fast losing its market, as the better receipts of soft coal are displacing it. Prices are $1.75-$2.50, the latter figure demanded for fuel almost entirely free of pebbles, and with light sales made.

BOSTON

Dealers realize there is but a few short weeks to the time when fuel will be in urgent demand, and, except in the direction of bituminous coal, they are helpless to give any real relief. Most anxiously are they looking forward to the first shipments of proper sizes. Meanwhile, there are but extremely few stray cargoes of peat that come forward.

Pet is selling for $15 per net ton delivered in Boston at retail. One of the newspapers here inquires why the retail dealer does not give the consumer the benefit of the July 1 reduction of 10 per cent on carload lots. And the volunteer fuel committees on the same day insist that no more than one ton shall be delivered to a consumer.

BUFFALO

The public looks for coal in some quantity soon, though the agreement to resume mining is not fully ratified.

The amount of coal held over is quite large here. The prospect of gas is good, both on account of the increased amount of byproduct, and the natural supply which is expected to be good.

Shippers and distributors are trying to keep consumers reassured by calling attention to the fact that we have had a long period of shortage and there was coal enough. As to what the price will be nobody is able to speak with authority, although one shipping agent ventured the opinion that the reduction in freight, amounting to about 36c. a ton, will be absorbed by the companies. He does not look to any material change in prices.

ANTHRACITE FIELDS

In spite of considerable opposition, John L. Lewis last week secured the ratification of the contract negotiated by the scale committee. It is expected that production will reach a high figure by the end of this week. The men will all be in as soon as the mines, which are being washed out of repair, have been placed in shape for operation.

The companies are estimated to have rush orders for at least 20,000,000 tons. Little coal will be made during the early part of this week, and no more than 1,500,000 tons the week following.

The resumption had an immediate effect on the market for river barley, which had already been showed by the heavier use of bituminous coal.

South

BIRMINGHAM

Although inquiries are somewhat more restricted in scope than it has been, spot demand is still good and in excess of the supply. Priority consumers are getting the first call and the requirements of non-essential industries are not so well taken care of.

Market conditions are becoming more stable with the recent pressure from outside territory and prices seem to be settling around the schedule fixed by the State Fuel Administrator, effective Sept. 1. The allowed mine prices are as follows:

<table>
<thead>
<tr>
<th>Mine</th>

</tbody>
</table>

Domestic coal under contract f.o.b. mines for September ranges $2.75 for Big Seam to $4 for the rest. Railroad service is very inadequate and much time being lost account of car shortage. Slow movement is keeping the operators in a difficult situation and an excessive period. Production for the week of Aug. 26 was approximately 380,000 net tons.

VIRGINIA

Production is gaining slightly, the increase being most marked in that section of the field which during the period ended Aug. 26 was the most affected. Transportation conditions have been somewhat improved. Producers lost share to be attributed entirely to a car shortage.
Car Shortage Handicaps
All Midwestern Fields

Illinois and Indiana fields started off the past week with a fair car supply, following Sunday and Labor Day, but by the end of the week the lack of power had put the production of those states down below 30 per cent and Kentucky was in the same fix. Demand generally continued light, however, so that the only coal to feel any buoyant price tendency was southern Illinois lump, which climbed about 50c.

There was nothing going on to cause any upset beyond a little flurry in Chicago against the I.C.C. supplemental order giving domestic shipments priority over steam. In the Kentucky fields more attention is being given to Lake trade, since much Western business has been lost to other fields.

ST. LOUIS

An unusual quietness for this period prevails in that domestic trade is slow and steam is not as active as it should be normally. Domestic buyers seem to think that something will happen that will reduce the price though there is a shortage of Carterville that cannot be made up.

Generally speaking, things are easy and quiet. The extremely warm weather has prevented heavy deliveries of domestic and the domestic business in the country is reported to be in a somewhat similar condition. Country steam is quiet, with practically no storage going on. The same condition holds in St. Louis. The past week the dealers raised the price of Carterville from $8.50 to $9.90 per ton with delivery. No anthracite, smokeless or Arkansas coals are coming in and the supply of coke is limited.

CHICAGO

The decided handicap or car shortage in all Illinois and Indiana coal fields has so reduced production that the light demand on this market has been met with a comparatively light supply. The expected pick-up in both domestic and steam has not materialized with any speed although domestic call may have been responsible in part for the hike in quotations on southern Illinois prepared sizes from $5 to $8.90@$8.50 along toward the end of the week. This was about the only change in the circular on any coal coming into this market. The general tendency is slightly upward, however, and coal men are predicting the tendency will be more marked next week when the hot spell has passed.

For several days there has been a dragging influence making itself felt here. A good many odd lots of steam coal have not materialized and unloaded at prices that verged close to the red. Occasionally these deals were made at $3.50@$3.75 for screenings when the market waved around $4.25. The fact that domestic sizes are to have priority in shipments hereafter may end this sort of thing though big buyers are still hoping for a marked drop in all steam sizes.

Practically no coal from states east or south of Indiana is reaching here nowadays. Kentucky is as hard hit as Illinois and Indiana by the transportation difficulty and all Eastern coals are absorbed elsewhere or cannot penetrate the various railroad congestions.

INDIANAPOLIS

The Indiana Coal Committee left the price of coal to the operators’ concealments and quotations range at $4.75 at the mines with the accent on the latter price. The termination of the strike has relieved the fuel situation in the state. Few rail dealers are doing business. Quotations from the dealers show prices to be about $2 a ton higher than last year. A number of dealers have been unable to get coal delivered.

No substantial orders are being placed and operators say when winter comes there will be a mad scramble. At the present time the delivery end of the coal market is the big problem.

The mines in Indiana can produce the coal, but the railroads are falling down miserably in making deliveries. During the past week there has been no change in prices of coal from outside the state.

LOUISVILLE

It is the general belief of the local coal trade that other than some big tonnage movement to the Lakes, there will not be much priority regulation of any kind after a few more days. Some operators are having a little trouble, it is reported, in finding buyers at the market price. Demand for prepared sizes is steadily increasing, but operators would rather load mine run.

With the present price range all the way from $4.75 for screenings to $6.50 for best eastern Kentucky lump, there does not appear to be much prospect that Washington will have very much to say for the time being. Coal is much cheaper than the way to $4 to $5.75 at the mines, not including brokerage. Some reports have been received of $5.50 coal in West Virginia and Kentucky, but $5 is also as high as is being bid for anything here with $6.50 asked, some lump selling at that.

Until eastern Kentucky moves considerably higher the mine run—there is not much prospect of any large production of prepared sizes in the districts that are handling this business. As a whole the general situation is much better. No real shortage of coal is being heard of, no plants are closing down, and movement is generally better, with the market steadier all along the line.

WESTERN KENTUCKY

The present small car supply in western Kentucky—said to be 33 to 40 per cent on L. & N. lines, and about 65 per cent on the Louisville and Illinois Central—is preventing any over-production which would tend to weaken prices. Priority orders are still in effect. This is holding down the amount of coal moving on open shipments. Operators are finding some trouble in moving their output unless they have priority orders.

There is better demand for prepared sizes, but operators are not willing to make much lump coal because they feel that cars are too scarce, and they would much prefer shipping mine run or the higher priced material which is on the night switch or partly loaded.

It is rumored that about 100,000 tons of coal from western Kentucky is in prospect for movement to the Great Lakes. The supply moving from other fields to the Lakes is small.

While western Kentucky mine run has not been plentiful at any price under $4.25, there have been some advance offers. Jobbers have been trying to find lump at $4.75, but supplies are scarce. Quotations are reported as low as $3.50 a ton, and prospects are for lower steam prices.

Some of the operators now need business, and are calling jobbers every evening in order to sell the day’s produce. Jobbers have been not nearly as plentiful in the field as they were, since Chicago dropped out as the dominating influence in the market.

SOUTHERN ILLINOIS

The situation is disappointing to operators and more than likely accounts for the shortage. The average working time is only a little better than three days a week in the Carterville field on account of no cars. The weather is bright and the domestic demand seems heavier than usual. Steam mines are not active. There is nothing unusual going on in the southern end of the state except that the miners are watching closely the investigation of the Herrin massacre at Marion.

Somewhat similar conditions prevail in the Duquoin field, though the miners are getting ready to do so. Prices in the districts range $4.90, $5.00 on domestic sizes and $6.50 to $2.25 on screenings. Mr. Old fool conditions are quiet with good tonnage moving to the Chicago and Northwestern markets.

In the St. Louis field a peculiar situation prevails, but coal is moving as low as $3.25 for domestic 200-lb. bags while others are asking as high as $4.25 for the same size and about $3 for the 90-lb. bag. Last week, 100 cars were open on the cars, but it is understood that lower prices will be made on contract. It is a peculiar market but what the value of coal is,
Eastern Inland

Demand Slackens as Prices Fall and Receipts Mount

Scrambling Buyers of Recent Weeks

New Baby on Stocks—Car Shortage Increasing—Empties Return Slowly—Movement to Lower Lake Ports Gaining.

Larger receipts have softened spot prices. Consumers who recently scrambled for tonnage at any price are now using this supply and are not buying. It is the old story of curtailed demand on a falling market. Car shortage leaves are growing rapidly and there is no doubt that production has about absorbed all the serviceable cars that were idle when the union mines resumed work. A slower return of empties is now noticeable.

Lake buyers are anxious to obtain coal but fail to place orders when the faintest sign of price advance appears. The movement to the lower ports has been aided through priorities and the 1,000,000-ton per week goal is nearing.

COLUMBUS

The Ohio coal trade is in a peculiar condition. While domestic demand is keen there is not as much strength to the steam market as might be expected under the circumstances. Public utilities and all industries are pretty well supplied and general steam users are holding off for lower quotations.

Retailers are selling a fair amount to householders, but as in the case with stockholders, many of the domestic consumers are waiting for lower prices. Retailers are selling Hocking and Pomeroy lump around $3.50-$4.10, while West Virginia grades are somewhat higher. Only a limited amount of cokes and other grades from West Virginia is coming into the market.

Lake shippers are anxious for tonnage but prices are too high and they are holding to class contracts. Offerings at $6-$6.50 have not attracted shippers to any great extent and the Lake is held off to see what happens. Operators are not facing serious contractions are shipping coal and the various Lake docks are handling a fair tonnage.

DETOIT

While extremely hot weather is prevailing from the midwest and south, there is no thought of winter fuel requirements, the condition of unsatisfactory supply is developing a situation that could become a trade trouble for many later in the year.

There is very little steam inquiry. While the amount of free coal is not great, it is possible to find a few cars when demanded. Most of the coal now reaching Detroit, is the product of union mines in Ohio and prices range $6-$8.25 for slack or near run.

With practically no anthracite in retail yards, the outlook for household consumers in Detroit is far from encouraging. Many of the homes are equipped with heating plants unsuited to using bituminous coal. The supply of coke is scarce and retail prices have advanced from $12-$13.50 to $14-$15.50 over approximately three times the pre-war cost.

CLEVELAND

Sharply increased production is being reflected in larger supplies of fuel in this section and consequently lower prices and a much larger active market. Coal is now available in ample quantities at $5.25@$5.75, the average for the past few days being about $5.50.

Buyers who were scrambling to get fuel a few weeks ago at any price are now following a policy of using up their stocks before going into the market again.

While the present price looks good compared with that prevailing recently, it is the old story of curtailed demand upon a falling market. Consumers have not forgotten the $3 level prevailing before the strike. Operators, however, point out that railroad equipment is bad on some lines and distribution may become more and more hampered as the season advances and the strain upon the roads grows heavier.

The Lake movement is being successfully expedited through priorities. Shipments now approach the 1,000,000-ton weekly goal of the Ore & Coal Exchange, however, do not believe that it will be possible to move more than 10,000,000 tons between Sept. 1 and the close of the season. This will give the Northwest about 15,000,000 tons in all.

EASTERN OHIO

Notwithstanding a car supply of only 35 to 40 per cent on the B. & O. and W. & L. E. production during the week ended Sept. 2 was increased 21,000 tons over the preceding week. Total output was 288,000 tons as against a potential capacity of 620,000 tons, or 46 per cent of normal. Only 660,000 tons have been produced out of a potential capacity of 21,120,000 tons for the week.

While there is a ready market for all coal offered for sale at this time, inquiries are not numerous and no anxiety appears on the part of steam users to take cars of coal more than is immediately required. Spot prices have softened somewhat during the week, quotations ranging 25c. @ 40c. lower than those obtainable a week ago.

Receipts at Cleveland during the week ended Sept. 2 registered a decrease of 30 cars under the quantity received during the preceding week. Total arrivals amounted to 784 cars, 451 for industries and 113 for retail yards. The decrease at industrial centers is accounted for by the failure of non-union coals from West Virginia and eastern Kentucky to get through the blockade at Ohio River gateways and also the price structure on the part of buyers, who anticipate that as production is speeded up, prices will be lower.

PITTSBURGH

Although the Pittsburgh Coal Company's wage scale a day after its resignation from the Pittsburgh Coal Producers' Association, the remaining members of the association having then signed, it is understood that the resignation has not heretofore been withdrawn.

Resumption of mining has been fairly rapid. There has been no scarcity of cars, but the loadings thus far are no certain criterion as to the future. It seems certain that each of the cars that have long been idle. The real test of transportation capacity will be furnished in the attempt to bring cars back to their former and subsequent loadings. Already reports are accumulating of large numbers of loaded cars lying near mines.

The first regular business in Pittsburgh district coal was in Yougicoheeny gas, nearly a fortnight ago, the price being $6.50. Now there is an open market in steam and byproduct also, with the trend in both fields downward. Pittsburgh steam mine run is quotable at $4.50@$4.75, and fair grades of gas mine run, $4.75@$5.

Connsville steam is held at $4.50 but for the 300,000-ton annual run a Connsville byproduct is at about $5@$5.25 but there is not much movement as offerings are light.

BUFFALO

The market is not brisk, for the consumer now looks on the supply as sure to be adequate with a possibility of lower prices. Cars are already running down, however, and a shortage always means stiff prices.

At the same time consumers are pretty well supplied and they will not need the needed cars away. They are enjoying a reduction of $2 or more from the strike prices, though the suggested bottom price of $2.50 did not appear.

The prospective return to anthracite mining tends to further ease off the stress, but if it cuts into the car supply, as it likely will, the soft coal supply will be sure to run down. Prices are standing down some, with a fair quotation, mine price, of $6 for Yougicoheeny gas slack, $5.50 for Pittsburgh $6.50 for mine run and $5 for slack, with Allegheny Valley mine run at $5@$6.25.

Vessels are paying $8.50 for 30-inch coal on the board. There is a very small spurt of soft coal from Ohio ports this way, but it will be light till cars are more plentiful. August receipts were only 35,000 tons. For the season the amount is 690,310.

NORTHERN PANHANDLE

With union mines again producing and open-shop mines also running at the usual rate, production is again increased, but in normal proportions as the railroads are not supplying all the empties needed. Much of the output is being secured by the railroads and a large proportion is going to the Lakes.
Lake Vessels Once More
Begin to Deliver Coal

But Demand Keeps Docks Empty—
Prices Are Stiffening—Doubtful Quality
In Blunden or Pooling Plan at Lower Lake Ports.

While the flow of coal by Lake has shown signs of strengthening considerably the demand for coal is so keen that the docks are emptied as fast as vessels dump. The country trade is hungry for fuel and is grudgingly buying it at the prevailing high price rather than take a chance of getting caught short later on. There is little chance of anybody loading up too heavily this year. Altogether the Northwest feels that its loud wail of recent weeks has not won much compassion from the rest of the country but that, now that coal is slowly coming in, there surely will be enough unless the car shortage down in the mining fields shuts off the supply. A good deal of dirt in cargo coal draws condemnation for the Lake pool.

MINNEAPOLIS

While fuel commissioners are working tooth and nail to get an adequate supply of coal on the docks for the coming winter, here they are finding the reception accorded them and their wants rather indifferent. Producers are not much inclined to go out of their way at all to help out the Northwest. Since prices at the mines are higher than the Northwest wants to pay, purchases for this region are not as heavy as they might be. Even the effort to get all-rail coal from Illinois and Indiana is not lively and car shortage interferes with that source of supply also. As the situation stands now coal is on its way up with quotations especially high for immediate delivery.

There is serious consideration of rationing fuel and of reducing consumption by cutting off unnecessary street and window lighting and other places where economy might be practiced to avert a fuel shortage.

MILWAUKEE

The coal strike has been eased to some extent by the arrival of a number of cargoes of soft coal. All sizes of Pocahontas and the popular grades of steam coal are now obtainable in reasonable quantities, while they last, at the prices fixed on the first of the month.

However, this temporary relief does not allay the anxiety regarding future supply, and it is freely admitted that the fuel problem will be the worst that Milwaukee has ever confronted, unless the railroad situation improves soon.

Save for Heavier Receipts
By Water. Market Is Quite

Quotations Erratic on Fuel Bound Inland—Buying Scattered. Consumers Reluctant on Accumulations—Outlook for Shippers Not Rosy,

With the improving condition of the All-rail market, the shippers are using the water in a manner that is not attractive to the market. However, the market is rather quiet as a whole, and this is due to the fact that the receipts are not heavy enough to affect the market.

DULUTH

Receipts for August at Duluth—
Prices and freight were far below the average, according to announcement made by official weighing bureaus here, aggregating but 9,502 tons, of which 9,002 tons were 11.75 and 8,802 soft. August receipts last year aggregated 492,012 tons—25,512 soft and 466,500 hard.

Despite the fact that the Northwest has been in desperate condition for coal, reports show that 5,000 tons were shipped from this port to Lake Michigan ports in the past months. This brings the total of down-shipments for the year to 224,500 tons.

Since the first of the month nine ships have arrived in port and eight more are scheduled to arrive soon. Shipments from the docks for August were 20,373 cars. This seems to indicate that the dealers throughout the territory served are willing to get their own in immediately and that there will be no tie-up on the docks to hinder arrivals.

An increase in price has taken place. Heaver lump is now quoted at $12.25 a ton, while the coal is quoted at $11.50, and screenings at $9.50.

Elkhorn, which is scheduled to arrive this week will be $1 higher than the dock men say. One five-car lot of Illinois coal has been received, at $8.50 at the mine.

New England
Cincinnati Gateway

Strike of Coal Buyers Makes Its Appearance

lake and Hamilton Pashers Missing From Market When Hoover Press Fail to Hold—Heaver Output Handled Without undue Congestion.

A coal buyers strike, sporadic but of definite proportions has made its appearance in the Cincinnati market. Some weeks ago, Lake buyers, in the hope that the government price would hold, attempted to get values down to the Hoover level, less the transportation. Now that the Hoover prices have gone by the boards they are playing another game. As soon as prices take an upturn, the Lake buyers are strangely missing from the market. Coal that was offered at $5.50 was bought while $5.75 asked in other quarters was turned down. Hoosier production has so far been handled by the carriers without any additional congestion. Cars are becoming scarcer, however, and during the past week these losses have been mounting. Prices are stronger, high-volatiles leading the smokeless coals.

HIGH-VOLATILE FIELDS—KANAWHA

Strike troubles prevent the railroads from furnishing enough cars to keep the mines going near to their peak. An entire week is going by at present without a delivery of cars. In the Kanawha district, that is where there has been no union agreement—there are more mines at work. Much of the product has been moving at the Hoover prices since May. Some coal has been sold within the last few days at $5.50.

LOGAN AND THACKER

Logan mines during the week ending Sept. 2 appeared to be harder hit by a shortage of cars than the plants in any other high-volatile field, the supply at times dropping as low as 180 cars a day. Limited operation made it almost impossible to take care of contract customers and to comply with priority instructions for Lake movement.

Kisson-Thacker mines are beginning to recover after a fashion from the effects of a car shortage which materially curtailed production. Of the tonnage, however, only 500 tons daily large volume for Lake points.

NORTHERN KENTUCKY

Owing to large production elsewhere there is not so strong a pressure for fuel in northeastern Kentucky as there was a short time ago. Consequently prices are on a somewhat lower level, the range being $4.50 to $5.00. There is a better demand for gas coal than for other kinds of fuel.

LOW-VOLATILE FIELDS—NEW RIVER AND THE GULF

Although transportation conditions underlying improvement in the New River field, mines are on a limited basis. Car shortage is chiefly responsible for limited production, most of the miners being at work notwithstanding the fact that the mines are operated on an open-shop basis.

Gulf mines have been able to speed up production to some extent owing to an important turn round in the furnishing furnished by the Virginian and the C & O. But car service is still far short of normal. It is now possible to move more coal to Tidewater.

POCAHONTAS AND TUG RIVER

Pocahontas mines are once again finding it possible not only to speed up production but to hang up some new records, at least at intervals, Monday, Aug. 26 being a red-letter day, when 10,000 tons were loaded. The most prominent of them is the move to Western points, to which little Pocahontas fuel has been moving recently, owing to embargos. Although spot prices have reached $8.00 a ton, based on the average is about $4.50, the figure at which the bulk of the coal has been moving in recent months.

In contrast with the Pocahontas field, Tug River has found it possible to increase production in view of improved transportation facilities. The Western gateway was not so congested so that it was possible to move more coal to Western markets and particularly to steel and byproduct plants. With production much increased a labor shortage is beginning to develop again. Even with the larger output there is comparatively little coal available for the open market.

CINCINNATI

Lump coal has gone soaring, $8 being asked in some quarters without the hat of an eye. This because most of the output is now on a straight mine run basis. The result is that the takers of domestic coal are buying only as their absolute needs require, hoping for the turn of the market to lower levels. Still other concerns are taking another course. Instead of going after coal of high grade and efficiency they are taking off-grades that can always be picked up 800. @ 75c, a ton below the market, hoping that in this way they will be able to get action toward a lower level.

One fact is outstanding and that is that the smokeless operators and sales agents, while they moved prices upward with the removal of the Hoover restrictions, they are holding these way below that of the high-volatiles, comparatively.

The movement of two days a week from the Pocahontas fields has been going forward. Car shortage could be avoided if there were a set time for this instead of the coal being taken under the tipples on the days that the railroad personnel decide.

The retail price adjustment made last week still holds. Even though there has been a general advance $11 is still top for Pocahontas lump, with $8.75 for mine run; $8 is top for bituminous lump, with $8.75 @$7.50 for the slack.

COKE

UNIONTOWN

The Connellsville coke region will remain the greatest non-union field in the country but only a portion of the miners who went on strike April 1 will return to work under the present conditions. A great labor turn-over is taking place in this district. Miners who became thoroughly imbued with union principles are leaving the field for those working under the Cleveland agreement and their places are being taken by miners from other fields. Increased production by imported الو万人次 to be found near New Kensington, up by operators by a general increase in the number of evictions. Since the strike became effective a total of 3,500 miners have been broken up and it is declared to be the policy of operators to claim possession of every company house before cold weather arrives.

The coal market for the time being seems to have been stabilized at $4.50 @5. There are an abundance of orders but consumers are disposed to balk at higher prices.

Connellville

Statements that a car shortage has definitely developed are premature but the condition is much the same as if a shortage were actually visible, since the limit of possible production for cars has evidently been reached. It is plain that no material increase in shipments can occur with transportation conditions as they are practically certain to be in the near future. In other words, the strike is not really the dominant factor in the situation.

The strike continues with remarkable perseverance. So far from the posting of the high wage scale, some men have drifted back to work, but the drift has been no greater than formerly. The operators have various reasons for feeling that, but apart from these reasons the ending of the strike on account of transportation conditions, would not materially increase the shipments.

Furnace coke has softened a trifle in the week, being now quotable at $11 @11.50, but the total offerings would probably be insufficient to run a single blast furnace, so prices have been as regards transactions between operators and blast furnaces. The coke offered goes to miscellaneous consumers, in small lots. Foundry coke is off about 50c. @ $12.50@13.

The Courier reports production during the week ended Sept. 2 at 73,810 tons by the furnace owners, and 16,490 tons by the merchant owners, a total of 90,300 tons, an increase of 4,200 tons.

BUFFALO

The situation in the Connellsville district does not appear to be clearing up as fast as was expected. Car shortage would be avoided if there were a set time for this instead of the coal being taken under the tipples on the days that the railroad personnel decide.
News Items
From Field and Trade

ILLINOIS

Coal mines in seven states closed for one day on Aug. 25, out of respect for the memory of Francis S. Peabody who was buried on that day. A five o'clock service that evening.

The Peabody Coal Co., of which Mr. Peabody was chairman of the board, Mr. Peabody died on the Sunday preceding. Pallbearers at the funeral were George F. Geis, Frederick W. Upham, C. D. Caldwell, C. J. Gray, Henry H. Hooper, M. F. Piter, G. W. Gainer, W. D. Reedy.

A contract by which the Southern Grov Coal Corporation, of Chicago, has arranged for twenty-five years from the Willis Coal and Mining Co., of St. Louis, 7,000 surface acres of two- vein coal property in Perry and Randolph Counties, for which negotiations began six months ago, was signed with the end of the coal strike in Illinois. The Chicago company agreed to a mine minimum of 1,500,000 tons in the period of the lease. The property includes two mines, and the lessee contracted to open a new 5,000-ton shaft.

Charging Illinois operators with unnecessarily increasing the prices of coal sold to the public, Freeman Thompson, a union official at the hearings of the recent petion court injunction to prevent operators from charging more for coal than they did last winter, Mr. Thompson argues, therefore, the coast of coal has been raised.

The following September itinerary of the Illinois Miners' Examining Board has been announced: H. M. Battaglini, of Medill, of the Department of Mines and Mining, Champaign, Sept. 5; Harrisburg, Sept. 5; Herrin, Sept. 7; Waukegan, Sept. 13; Frankfort, Sept. 8; Du Quoin, Sept. 9; Stauton, Sept. 11; Dickson City, Sept. 13; Decatur, Sept. 14; Danville, Sept. 15; Springfield, Sept. 18; Peoria, Sept. 17, and La Salle, Sept. 19.

A. J. Hall, of Minneapolis, Minn., has been named district manager of the Peabody Coal Co., for central Illinois, with headquarters in Springfield. He succeeds W. S. White.

E. F. Stiehl, New Baden, Clarence and E. H. Reinhart, Belleville, have purchased the interest of Frank Patterson in the Patterson & Harding Coal Co., operating a mine near St. Louis, and have opened a new field out of Belleville. Eno G. Harding retains his interest in the mine.

The Ellisville Coal Mining Co. has been incorporated with capital of $30,000 by William H. Peck, A. H. Donaldson and W. R. Hawkins.

Harry Weeks, sales manager for the new Mining Service Coal Co., which has operations in Indiana and offices in Chicago, is returning to business after a summer's vacation.

The Springdale Coal Co. of Pana has been incorporated with capital of $25,000 by John H. Jones, L. W. Sherlock, Silas A. Shafter and L. B. Shafter.

INDIANA

An organization meeting of the Seventh Ward Coal Co., was held in Terre Haute recently, at which plans for the operation of a mine owned by the Shirkles and Shafter families were announced. The mine is the only one that the newly-formed company is contemplating taking now. The mine has been opened for about a year and a half. If the new company continues the business and the operators are Clement J. Richards, Frank H. Bickford, S. O. Hoyse and R. W. Ham.

One case set for trial in the September term of the St. Joseph County court in the State against Dave Jones, one of the officials of the Eleventh District, of M. W. W. A., and others, with 50 miners whom the police are defendants are charged with riot. The charges are that the miners struck when they sought to close the strip mines and wagon mines. Sixty of the defendants were arrested and gave bond and the others escaped from the scene of activity.

Two of the oldest coal companies dealing in coal, both wholesale and retail, and building materials in Indianapolis, the Indianapolis Mortar & Fuel Co., and D. B. Meyer & Co., have been consolidated into one company called the Indian- apolis Consolidated Mortar & Fuel Co. Articles of incorporation have been filed with the State. Consolidation creates probably the largest company of its kind in Indiana.

MASSACHUSETTS

The New England Coal Co., of Waltham, has completed a new coal plant and in the future will be able to handle the seven million dollars worth of business which has been opened in the lower section and the Tioga fields.

The Carnegie Steel Co. has awarded the Kewanee Company a contract for a large expansion to the present by-products plant at Clarksburg, already the largest of its kind in the country. It will consist of 364 by-products coke ovens, a benzol motor fuel recovery plant and by-products plant. This will bring the number of ovens the company has in operation to a total of 1,134, with a carbonizing capacity of 2,715 tons of coal per day.

Bituminous coal companies recently incorporated at Harrisburg were: H. K. Coleman, of Philadelphia, capital $25,000; treasurer, James P. O'Leary, Allentown, Pa.; W. L. Arlinghaus, mining, quarrying and selling coal. Incorporators are Mr. Arlinghaus; James Holm, of Jacksonville, Ill.; George H. Meyer, of Pennsylvania; W. S. Fish, mining and quarrying. At Mingo, capital $25,000; Edward T. Kelley, Comfort, and Della Ford have incorporated in this town. This will increase the number of ovens on which they will operate to a total of 24 to 120,000 tons of coal per day.

Again reports come from Pittsburgh of the coal merger, this time with more details than before. The following companies are involved according to one report. John H. Barbee, president of the Carnegie Coal Co., said that the Carnegie Coal Co., 1,500,000 tons Versailles Coal Co., 250,000; Carnegie Coal Co., 250,000; Henderson Coal Co., 250,000; Kies Creek Coal, 250,000; Morceller Creek Coal, 250,000; Mayfield Mining Co., 250,000; Pittsburgh & Eastern Coal, 250,000, including the western Pennsylvania Counties to remain under the management of Mr. Barbee. The new corporation will be called the Pittsburgh & Eastern Coal Co. The new coal companies are held by the new project and will be controlled by Barbee.

Mahaffey Coal Mining Co. of Harrisburg, has 100,000 capital, has been incorporated by J. H. Mahaffey, Paterson, New Jersey. The company is in the mine and all properties and the incorporators are P. W. Mahaffey, P. W. Mahaffey, and Alex. Key Mahaffey.

UTAH

Professor Schaefer of the University of Utah and thees students are at present on a trip up to the mining districts in the State. The students are accompanied by a number of men who are mining engineers and are on the same trip.

The four mines which are being held ready for occupancy near the mines at an approximate cost of about $1,000 to $2,000 each.

David G. Gray, Big Basin Coal Co., of Winchester, Ky., was in Cincinnati recently for a few days, claiming the prize hardluck operator of the eastern Kentucky. When business was at its best and business on the company off for two months.

The Peabody Coal Co., Chicago, has taken over the new western Mining Co., which includes operations of the Tri-State Coal Co., in the Dubois section and the Tioga fields.

The Carnegie Steel Co. has awarded the Kewanee Company a contract for a large expansion to the present by-products plant at Clarksburg, already the largest of its kind in the country. It will consist of 364 by-products coke ovens, a benzol motor fuel recovery plant and by-products plant. This will bring the number of ovens the company has in operation to a total of 1,134, with a carbonizing capacity of 2,715 tons of coal per day.

Bituminous coal companies recently incorporated at Harrisburg were: H. K. Coleman, of Philadelphia, capital $25,000; treasurer, James P. O'Leary, Allentown, Pa.; W. L. Arlinghaus, mining, quarrying and selling coal. Incorporators are Mr. Arlinghaus; James Holm, of Jacksonville, Ill.; George H. Meyer, of Pennsylvania; Edward T. Kelley, Comfort, and Della Ford have incorporated in this town. This will increase the number of ovens on which they will operate to a total of 24 to 120,000 tons of coal per day.

Again reports come from Pittsburgh of the coal merger, this time with more details than before. The following companies are involved according to one report. John H. Barbee, president of the Carnegie Coal Co., said that the Carnegie Coal Co., 1,500,000 tons Versailles Coal Co., 250,000; Carnegie Coal Co., 250,000; Henderson Coal Co., 250,000; Kies Creek Coal, 250,000; Morceller Creek Coal, 250,000; Mayfield Mining Co., 250,000; Pittsburgh & Eastern Coal, 250,000, including the western Pennsylvania Counties to remain under the management of Mr. Barbee. The new corporation will be called the Pittsburgh & Eastern Coal Co. The new coal companies are held by the new project and will be controlled by Barbee.

Mahaffey Coal Mining Co. of Harrisburg, has 100,000 capital, has been incorporated by J. H. Mahaffey, Paterson, New Jersey. The company is in the mine and all properties and the incorporators are P. W. Mahaffey, P. W. Mahaffey, and Alex. Key Mahaffey.

Association Activities

Northern West Virginia Coal Operators' Association

The car shortage in northern West Virginia has been recognized as a problem early in September and was interfering so materially with the loading of coal at that time that a meeting of the transportation committee of the Association was held at Charleston to devise ways and means to meet the shortage and find a remedy. It was suggested that the Pittsburgh & Lake Erie and the Western Maryland lines be connected by a line from the Fairmont region over the B. & O. and the coal after being loaded be transferred to the Pittsburgh & Lake Erie for the emptying, a sub-committee was appointed to investigate the possibilities of the project with Vice-President C. W. Galloway of the H. & O.

Obituary

O. A. Blackburn, aged sixty, president of the Pittsburgh Coal Operators Association and one of the best known bituminous coal promoters in the country, died recently at his Pittsburgh home after a short illness.

National Exposition of Chemical Industries is holding its eighth national exposition at the Grand Central Palace, New York City, and will be followed by the American Mining Congress, twenty-fifth annual meeting and exhibition of coal mining equipment in the Auditorium of Public Hall, Cleveland, Ohio, Oct. 9-14. Executive officers are: President, Henry F. Sharpless, Hollenden Hotel; H. F. Sharpless, convention manager.

National Exposition of Pottery and Ceramic Engineering is held at the Grand Central Palace, New York City, Dec. 15-18. At the meeting they will be followed by the American Mining Congress, twenty-fifth annual meeting and exhibition of coal mining equipment in the Auditorium of Public Hall, Cleveland, Ohio, Oct. 9-14. Executive officers are: President, H. F. Sharpless, Hollenden Hotel; H. F. Sharpless, convention manager.

American Institute of Mining and Metallurgical Engineers held its fall meeting during the week of Sept. 26 at San Francisco Cal. It is proposed to form a party for a tour to New York on Sept. 28, stopping at various cities on route. Executive officers: F. F. Sharpless, Engineering Societies Building, New York City.

American Gas Association will hold its annual meeting Oct. 23-25 at Atlantic City, N. J., Secretary-Manager Oscar H. Foote, 158 East 15th Street, New York City.
Congress and Price Control

An Act of Congress extending the powers of the Interstate Commerce Commission to permit the granting of priorities in transportation to prevent the purchase or sale of coal "at prices unjustly or unreasonably high" is now or soon will be the law of the land. In so far as it pertains directly to price control this is the extent of the coal-control bill urged by the administration and as framed "on the hill." The Federal Fuel Distributor, an officer created by the act, is empowered to ascertain, among other things, the prices normally charged for coal and the prices correctly charged and whether current prices, "considering the costs of production and distribution, are just and reasonable."

Nothing is said in the act about fixing maximum prices. The inference is that arbitrary limits for prices will not be set by the government. Every time the government has set maximum prices it has been obliged to defend them and the defense has been costly and difficult. It would be more than ordinarily difficult now, for the final disposition of the cases instituted by the government against "profiteers" under the Lever Act have heartened those who would take the top of the market. To define when a seller of coal takes more than a reasonable price and becomes a profiteer is more of a task than to define "socialism." Those, for instance, who took issue with the navy over the price at which its coal was commandeered were able to regain substantial amounts through the courts.

No price can be set for the product of a particular field that is within reason as respects the majority that is not below the cost of a small portion of the production. Should the Federal Fuel Distributor and the Interstate Commerce Commission attempt to say what price should be charged for all the coal from any field, these high-cost producers would, it appears, have a clear case in court to prevent the application of the price. A consideration of the official statements of those who appeared before the House committee when the bill was pending leads one to expect rather that Washington will endeavor to avoid some of the pitfalls previous attempts at price fixing have disclosed and will steer a course designed to put the offending "profiteer" entirely on the defensive. It is obvious that individual instances of "unjustly high and unreasonable" prices may be uncovered if the expected spirit in the market develops, instances with respect to which it may be possible to establish that the price level is opposed to the public interest. The penalty, denial of cars in which to ship further coal, is sufficiently severe to dampen the superlative price ambitions of others when once the offense is defined and the penalty successfully applied.

Seemingly it would be difficult to maintain the position that charging a price, however high, that was mutually satisfactory to both buyer and seller is in violation of the general welfare clause of the Constitution or interferes with interstate commerce, the legal back logs of the legislation. Such disruption to distribution as undoubtedly would follow unfettered selling at "mutually satisfactory" prices could be corrected by the exercise of priorities in cars. If field prices are not fixed under this legislation, we may then expect a multitude of car priorities. From the standpoint of the producer, the transporter and the consumer, priorities are infernal nuisances. They are possible of terror abuse. They interfere with the movement and therefore with the production of coal. The Fuel Administration hung itself high and dry through the initiation of this practice in the early months of its régime and abandoned the method at the first opportunity.

There is a string in this coal-control bill that is new. He who buys coal at "unjustly high and unreasonable prices" is as subject to the penalty of embargo as is the seller to the denial of cars. We may yet be treated to the spectacle of an industrial plant or railroad closed down by order of the government as penalty for tempting the coal operator with too much money for his coal.

In between the producer and consumer there may be the wholesaler or jobber who does not physically handle the coal or the car in which is is loaded and is transported. He cannot be denied cars, for he does not ask for them and he cannot be embargoed if his name is not on the consignment. Heretofore in a strong buyers' market with fixed limits on price the tendency has been to short-circuit the middleman. He may be found useful this time in facilitating the "bootlegging" of coal.

The legislative remedy is unique. It doubtless goes as far in controlling price and distribution as the government considered it has the power to proceed. Its effectiveness will not really be tried until the market is much more active than at present, when the Federal Fuel Distributor and the Interstate Commerce Commission will require for their arduous task all the sympathy and support they can muster.

The "Conspiracy" of March, 1922

"Operators and miners conspired to cause this strike in order to boost prices." How often is this base charge heard in the byways—and even in high places! There is no use denying that today it is given general credence. Many a good man and true is convinced in his own mind that there was a conspiracy against him in March, 1922, and that the battles of Cleveland and Pittsburgh and the skirmishes of Chicago, Terre Haute, Kansas City and other points were fought purely for moral effect upon the American people. It is difficult for even average efficiency in楼市 today to coal quotations from their dealers without becoming more definitely convinced than ever. They cannot see, for instance, the logic of the operators'
argument that the heavy cost of mine accidents should be
borne by coal and being mined, apparently forgetting
that mine maintenance, property depreciation and in-
interest on indebtedness take no entire of strikes and
that, since coal is the operator has to sell, it must
bear the entire cost of its production.

Did operators "conspire" to strike prices upward?
Turn back to March, 1932, the last month of pre-strike
operation. Industry and the demand for coal were at
low ebb. Summer was coming on with its accompanying
stock market for coal. Non-union operations throughout the
country had a producing capacity of 5,000,000 tons a week. Stocks in the hands of con-
sumers were at unprecedentedly high levels. The wild-
erness industrial optimist could not honestly prophesy that
the country would need more than a minimum weekly
volume of coal until fall. There was no sound reason
expect a transportation would be hamstring and the flow of non-union coal choked. Railroad strikes had loomed before—and collapsed. If ever a time was un-
necessary for union labor to quit work, if ever the ex-
erction were ill for a long or successful strike of miners,
that time was the end of March, 1932. How could a
strike at such a time be counted on to boost the price of
coal enough to compensate for the inevitably heavy
expense of labor strife and non-operation?

This is not to deny that operators generally welcomed
the strike of March 31. The non-union producers were
well satisfied to be in undisturbed possession of the
market. The union operators welcomed it mainly be-
cause they hoped that out of the conflict would emerge
a new set of wages and working conditions that would
deflate the cost of coal not only to themselves but to
every coal consumer as well. They were seeking oppor-
tunity to meet the non-union field competition with
lower cost coal. It is true also that operators in certain
sections welcomed it as an opportunity to regain once
more from the union the control of their own business.
It is equally true that many an operator who had been
selling coal below cost said frankly that he didn't care
if his men did strike, for he couldn't go on doing busi-
ness "in the red" forever. But the circumstances and
events of the day were not those of conspiracy to boost
prices.

Then came the summer. Railroad strikes with their
accompanying car and power shortages, the exhaustion
of industrial and railroad fuel supplies and other de-
velopments over which the operators had no control
combined to increase the price of coal. After the re-
sumption of mining the market subsided somewhat but
whereas the average spot price of all coal near the end
of March was $2.02 today it is just above $3. This is
proof enough for the man who charges conspiracy, he
needs no further. The circumstantial evidence appears
heaping. But a fair consideration of the facts of March,
1932, should clear the operators in spite of flagrant atti-
tion by some among them. Coal is high but a "conspiracy" of operators to put it there by strike
is yet to be proved. In view of their inability to stick
together on any program or project, the charge is one
of those of the "interesting if true" variety.

A THIRTEEN STRIKE would put us out—Wall Street Journal.

As NEARLY AS WE CAN figure it, a living wage is pay
sufficient to enable you to strike a couple of months each
year for a living wage.—New York Tribune.

Haulage Accidents

FROM dangers resulting from the weakness of the
mine roof we can never hope to be entirely free.
There always will be a degree of risk in excavations of
this kind. It is true something nearly approaching
absolute safety might be found in measures such as
forepoling, cribbing and square setting, but the cost of
mining then would be prohibitive. Such plans even in
building subways are not found to be universally suc-
cessful in the entire prevention of accidental death.

In mechanical details such as hauling, however, it
would appear possible to make accidents less frequent.
Why do we have so many derailments? Surely a little
testing would reveal a loose wheel in some less signific-
antly more important way than is afforded by the wrecking of a trip. On
well-conducted railroads how rarely do trains leave the track and how seldom do cars pile up in the ditches?
Something surely might be done to reduce such acci-
dents in mines and also to make coupling accidents less
frequent.

These protective measures are engineering problems, but unfortunately our mechanical and electrical en-
engineers are not often consulted in their solution. Our
mine managers, who try to answer them, are mostly
better skilled in coal mining proper than in transporta-
tion problems, and our mine inspectors usually are
men who have not studied engineering and whose up-
bringing has been in manually operated mines with
mule haulage.

The mechanization of the mines involves problems in
safety that only mechanical engineers can solve. We
must look, at least partly, to such men to perform our
inspection work. We may have to employ two kinds of
inspectors if we are going to follow out in our methods
of inspection the lines of development of our mines and
the present practice of the coal companies. At well-
ordered plants there is either a power and mechanical
engineer or one engineer for mechanical and another
for electrical problems. No attempt is made to leave
these difficult subjects to men without such professional
training.

In all inspection little attention is paid to the rolling
stock or any other kind of machinery. The mine ins-
pectors are supposed to supervise such matters, but
they are not trained for that purpose, so they find their
way rapidly to the working faces, of which their pre-
vious experience makes them the more competent
judges.

The great advances in safety have mostly been made
by engineers, and it has been found that being safe
pays, not alone in freedom from accident and compensation
charges but usually in economy also. Two in-
stances may be given: When careless handling of lead
caused many deaths in the lead industry, the engineers
devised ways of keeping the lead out of the air and the
devices used made the cost of handling so much cheaper
that the change could be measured not only in lives but
in profits also. When band saws were bursting and kill-
ing men in sawmills, frequent sharpening was recom-
ended by engineers as a means of reducing the "strain
on the saw.

The result was a reduction in lives lost, fewer men
injured, fewer broken saws and a greater output per
man and per unit of power. A dull saw is an unecono-
nomical unit at best. In a similar way due attention to
the safety of mechanical haulage probably would save
both lives and dollars.
Manner of Operating Electrical Apparatus in the Automatic Substation at Van Lear, Ky.*

Station Is Set in Operation and Shut Down by Action of Time Clock—Detailed Description of Its Self-Acting Regulatory Devices—After a Month of Tuning It Needs No Further Regular Attention

IT IS safe to say that in the mining industry central power, either bought, pooled or made by the coal company itself, has come to stay. The automatic underground substation for 250-volt direct-current operation will year by year supersede the old heavy feeder system, and the 600-volt system with its heavy maintenance cost will go with the feeders. This evolution will be hastened by the greater risk to life of such high voltages and by the legislation which such risks are likely to put on the statute books.

A station of the type suggested is that furnished by the Westinghouse Electric & Manufacturing Co. and installed by the Consolidation Coal Co. in its Millers Creek Division, Van Lear, Ky.

This station was put in operation Jan. 12, 1922. It has now been in operation a little over seven months, and with the exception of the first month of operation, during which time the station was given daily attention by a man who was acquainted with the workings of the switchboard, this attention being required to adjust the different relays for load conditions, only weekly and sometimes semi-weekly inspection of this equipment has been made. The mine foreman, who was a mine electrician for many years, has a key to this station, looks it over once or twice a day and at any time when he happens to pass the door.

The Consolidation Coal Co. has five mines in this division, numbered 151, 152, 153, 154 and 155. The automatic substation is located inside of Mine No. 154, a distance of about 4,400 ft. from the pit mouth. The drift mouth of Mine No. 153 is located on the opposite side of the valley about 1,000 ft. from that of Mine No. 154. A substation, equipped with two 150-kw. motor-generator sets, is located about midway between the two openings. For a number of years both of these mines were supplied with 250-volt direct-current power from this one substation, but the working places in Mine No. 154 advanced so far away from this substation that it soon became necessary to consider some means of bettering the power at this mine.

The problem was solved by installing a 150-kw. motor-generator set inside the mine about 4,400 ft. from the drift mouth and about 5,000 ft. from the outside station. Both stations were then operated in parallel. In order to take care of any emergency that might arise the inside substation was given the entire time of an attendant. Conditions made it impossible to give him any other duties such, for instance, as looking after a pump, so his whole salary had to be charged against this substation. This was a heavy item and made the direct-current power at this station rather costly.

After the station had been in operation for about three years an outside substation located at the entrance to Mine No. 155 became overloaded, so it was necessary to get more power. This substation had only one 150-kw. motor-generator set, which was a duplicate of the one installed in the underground station in Mine No. 154; so it was decided to move the 150-kw. motor-generator set from the underground station in Mine No. 154 into the substation at Mine No. 155, making the capacity of this substation 300 kw.

This move having been decided on, it was necessary to plan for a unit for the underground station in Mine No. 154, and having in mind the high operating cost of the manual substation at this point, it was decided

---

---

![Complete Switchboard for Automatic Control of Synchronous Converted Station](image)
to install one that was automatic, so a 150-kw. synchronously converter with three 55-kva. transformers and a full automatic switchboard were purchased. The equipment complete was received in about seven weeks after placing the order and, as already stated, was put under load Jan. 12, 1922.

This automatic sub-station is run in parallel with the outside manually operated sub-station, the distance between the two sub-stations being about 5,000 ft. The room in which the automatic sub-station is located is about 20 ft. square with a cement floor. The walls and ceilings are of natural rock, which received a heavy coating of cement applied with a cement gun. The current is brought down to the station through a 122-ft. borehole by a three-conductor No. 2 stranded cable. Each conductor is covered with A-in. varnished cambric insulation, and the three conductors are then covered with the same insulating material. This is coated again with a lead-sheet covering % in. thick, a wire armor jute and asphalt finish being laid over all. This makes the outside diameter a little over 2 in. This cable furnishes the transformers with 4,000-volt three-phase current.

The operation of the automatic sub-station is regulated by an eight-day time clock so set that the station will start at 6:15 a.m. and shut down every day at 4 p.m. At any time after the station closes down its operation on the following day can be prevented by pulling the main operating switch 19. As it is not necessary to operate the station on Sunday, a certain pumper has been detailed to pull this switch. In order to arrange for the starting of the station on Monday morning, the pumper puts back the switch at any time after 4 p.m. on Sunday. He also winds up the clock on Sunday evening.

The following is a description of the scheme of operation of this station:

This station is designed to start either by the pressing of a push button or by the operation of a time clock. When either of these devices makes contact, the station starts, comes up to speed, straightens its polarity if necessary, applies full voltage from the transformers, and connects itself to the direct-current load. Although this converter is a commutating-pole unit, the brushes are not raised during the starting period.

The various relays and contactors are so connected and interlocked that they will perform the same opera-

tions as the attendant does in a hand-operated sub-station. Of course, everything must be right electrically before the next step is started. After the unit is on the line delivering energy to the load, protective relays will anticipate every electrical condition and secure it against external or internal damage.

In a manually operated sub-station the operator goes through the following routine in putting the converting unit on the line: (1) He closes the line oil circuit breaker, thus energizing the power transformers; (2) he closes the starting switch, putting low voltage on to the converter rings, the unit coming up to synchronous speed; (3) he watches the direct-current voltmeter as the slip approaches zero and makes the armature slip a pole by reversing the shunt field circuit in case the voltage is "upside down"; (4) he transfers from the starting to the running switch when the direct-current voltmeter reads in the right direction and (5) he closes the carbon circuit breaker and knife switch in the direct-current outgoing line.

By referring to the schematic diagram, Fig. 4, or to the wiring diagram, Fig. 5, it will be seen that the automatic control equipment goes through the same routine as fast as the electrical conditions permit.

As the push button of the time switch makes contact the circuit of the master relay 3-A is completed, and the relay closes. This circuit is from one side of the operating transformer A, through contact 7-A on the polarized motor relay, through resistance R1, through the operating coil of 3-A, through the overspeed device, and through the push button of the time-switch contact to the other side of the operating transformer B.

**MACHINE FOLLOWS MANUAL-CONTROL METHODS**

The master relay 3-A has but a single contact which is in series with relay 3. Hence the latter relay closes as soon as the master relay 3-A makes its contact. This action locks in the master relay 3-A by paralleling the contact 7-A by a contact on relay 3. That relay, through another contact, energizes the A1 bus. Thus circuits are set up so that the starting operation may begin. As stated before, this sequence follows the same lines as with the manual control already described:

(1) The line oil circuit breaker closes. This operating unit consists of the three operating coils 20, 21 and 22. This mechanism is shown in Fig. 3. It consists of the main closing magnet, 20; the latching magnet, 21, and an auxiliary contactor, 22. This contactor closes as soon as the A1 bus is energized. As contactor 22 makes contact, the main-coil circuit of 20 is completed, and the breaker is closed. The latching magnet 21 is energized as the breaker goes in. The breaker is mechanically held in this position as long as 21 is energized. An interlock on the latching contactor opens the coil circuit of contactor 22, which, as that contactor opens, de-energizes the main closing coil, 20. Thus the breaker closes, latches in mechanically and cuts off its own main closing circuit.

(2) The starting switch, 6, closes. This is accomplished through the closing of relay 4. The circuit of this relay is interlocked with both relay 19 and the running switch, 11. Thus starting voltage is applied to the converter rings, and the converter starts and comes up to speed. During this starting period the commutator end of the converter has an alternating voltage of the frequency of the slip across its terminals.

(3) As the slip approaches zero, or the unit pulls into synchronism, a direct-current voltage is established.
on the commutator. The polarized motor-driven relay 7 is connected across the direct-current end as long as the starting switch is closed. This relay has a permanent magnet field, so that its direction of rotation depends on the direction of current through the armature circuit. In case the unit "pulls in upside down," the current through the armature will be in such a direction as to rotate toward and make contact 7-D. The closing of this contact affects that of a multi-contact relay, 9. This action energizes the four-pole double-throw contactor, 10, which reverses the shunt-field connection on the converter.

The shunt field is divided into halves, the two parts being in parallel when the field reversing switch 10 is energized. The converter armature is then forced backward until the midpole position is reached. At this point the direct-current voltage is zero and the multi-contact 10 drops out. The field-reversing contactor is de-energized, and the normal field connection is restored. The converter armature continues through the midpole position and again synchronizes with the correct field-pole rotation.

The right direct-current voltage is now on the commutator and relay 7 runs in the opposite direction to make contact 7-B. This action completes the circuit of transfer relay 12, which, upon closing, opens relay circuit 4 and completes its own holding connection. Thus it is seen that the polarized relay 7 operates to effect the transfer from the starting to the running switches only when the direct-current voltage of the converter as it pulls in step is found to be in the right direction.

(4) Through the opening of the contact of relay 19 in the operating coil circuit of relay 4 that relay is opened, which in turn opens the starting switch 6. An interlock on the starting switch makes contact as that switch opens and completes the circuit of field-control relay 5. This relay closes the running switch 11 and short-circuits a resistance in series with the shunt field of the converter. Full direct-current voltage is then available on the converter terminals.

(5) The converter unit is now ready to be connected to the direct-current line. Field relay 38 is a series relay which picks up as full voltage is applied to the alternating-current rings when running switch 11 closes. The circuit of the service-restoring contactor 12 is now complete. This circuit may be traced from the positive terminal of the machine through a 5-ohm grid resistance, through the operating coil of circuit breaker 12, and then through the contacts of the overload relay 12T, a single-pole single-throw knife switch, master relay 3, field current relay 38 and an interlock on the running switch 11 to the negative side of the machine. An interlock on the direct-current breaker 12 bridges the contact of relay 3, which connects the A and A1 buses.

The converter will now deliver energy to the load until it is shut down by the push button or time switch, or some protective device. The total time re-
required for the foregoing operation of starting the unit and connecting it to the line is approximately 12 seconds.

In case the load on the motor-generator set rises to such a value that it would be advisable to open the direct-current breaker, the overload relay 12T will pick up and open the operating coil circuit of breaker 12. This disconnects the load from the machine. The resistance of the circuit being fed must rise to a point where the breaker may reclose and stay closed. The breaker 12, in opening, completes the circuit of a timing relay, 12B, which makes a contact in the circuit of the restoring relay 12A after a predetermined time.

The restoring relay 12A is calibrated to close its contact only when the resistance of the feeder section has risen to a value that will limit the output of the machine to a safe capacity. When this value is reached relay 12A energizes the reset coil of breaker 12. The breaker, therefore, opens on overload, stays open a definite time before the resistance-measuring circuit is set up and then recloses only when the reason for the overload has disappeared.

The usual procedure in shutting down a manually controlled substation is as follows: (1) Trip the direct-current circuit breaker and open the knife switch. (2) Open alternating-current oil circuit breaker of the incoming line. (3) Open the running switch.

As in starting up, the shutting-down action is practically duplicated by the switching equipment. When, as is most usual at this station, the motor-generator set is shut down by the time switch, the contact in series with relay 3A is opened at a predetermined time. This relay in dropping out opens relay 3.

Although relay 3 opens its contacts between the A and A1 buses, the connection is retained by an interlock on direct-current contactor 12. However, as relay 3 opens, one of its contacts opens the circuit of contactor 12, causing it to drop open. Thus the direct-current coil of the converting unit is disconnected.

(2) The action of disconnecting the direct-current load, just described, opens the bridging contactor 12 between the A and A1 buses and de-energizes the A1 bus. The holding contactor 21 on the oil circuit breaker mechanism is therefore opened, and this, in turn, opens the coil circuit breaker.

(3) The running contactor 11, with its control relays 5 and 19, also drops open as the A1 bus is disconnected from the transformer. It will be observed that relay 5 in opening inserts a resistance in series with the shunt field of the converter, thus causing the voltage to fall rapidly. This makes it possible to get back on the line in three or four seconds in case of a momentary outage.

The protective features also should be described: (1) Lockout relay 30 is used to permanently lock the station out of service until a maintenance man has visited the station, located and remedied the trouble and reset the lockout relay by hand. This relay is operated when something has happened inside the station which makes further operation of the equipment hazardous.

(2) Overload relays of standard induction-motor type are set to operate on short-circuit in the converter, on transformers or in case of flash-over on the direct-current end. When a flash-over occurs the unit is not put in service again until an insulation test has been made to make sure that the armature has not been permanently damaged. The service restoring breaker, as previously described, takes care of legitimate direct current overload. However, one other condition remains to be provided for; this is continued small overloads which would never open the direct-current circuit breaker but would overheat the machine windings if allowed to continue long enough. Thermal relays 29 furnish this protection and simply shut down the unit until it has cooled sufficiently that it may be allowed to start again without injury.

(3) In case a phase opens while the unit is running and the load is of sufficient magnitude to overheat the
converter, the unit is locked out of service by phase balance relay 46. This action may be made selective so that the relay will lock the station out in case of phase failure on the low side of the power transformers and will simply shut the station down in case of phase failure anywhere on the incoming high-tension line. A polyphase low-voltage relay, 18, will then hold the substation out of service until three-phase voltage is again available. Thus this relay prevents the station from starting with single-phase high-tension line current.

(4) A contact-making thermostat is located on each of the main converter bearings. These thermostats are mounted on the pedestals, and the operating tubes are inserted in holes where they touch the outer surface of the babbitt. The heat drop through the babbitt is small, and the unit is locked out of service before any damage is done to the bearing surface. As a rule after a little scraping the overheated bearing may be returned immediately to service.

(5) If the overspeed reaches 15 per cent the standard contact-opening overspeed device permanently opens the coil circuit of the master relay 3A. This device must be reset by hand, and for this reason its operation locks out the apparatus.

(6) Eighty per cent of normal high-tension voltage must be available for starting the station or it will not start. This applies to the converter as well as the various alternating-current relays and contactors. The polyphase low-voltage relay 18 is calibrated so that it closes its contacts at all voltages below 80 per cent of normal and by short-circuiting the coil of master relay 3A prevents the unit from starting.

(7) In the same way the polyphase low-voltage relay 18 shuts the station down in case the high-tension voltage drops below 80 per cent of normal. In case of momentary "high-line" outage, the station would shut down and come back immediately upon restoration of normal voltage. To make sure that there can be no false electrical indications during a rapid restart, a short-circuit is put on the coil of 3A by contacts on the oil circuit breaker 20 and the shunt field series relay 38. This prevents restarting until the voltage of the converter falls to a point where relay 38 will open. All this requires but two seconds, for resistance is inserted in the shunt field circuit when shutting down. This same connection shuts the station down in case the circuit breaker opens for some unusual reason while the unit is operating. While this condition is unlikely with this type of circuit breaker, it is important that such a protection be provided.

(8) A standard reverse-current relay is used to shut down the unit should the current reverse.

(9) If the circuit in the shunt field of the converter be opened the unit will fall "out of step" on small direct-current load. It is important that the direct-current load be disconnected at this time. A contact of shuntfield circuit 38 is, therefore, placed in series with main direct-current breaker 12, which removes all load from the converter as relay 38 opens.

The switchboard of this unit is equipped with the
Graphic Time Study of the Efficiency of
A Shovel Removing Overburden

GRAPHIC records possess an advantage over those of tabular form chiefly in that they show their results almost at a glance. When prepared to show the performance of a coal-stripping shovel they exhibit plainly whether the machine is doing what may be logically expected of it and whether it is attaining its maximum efficiency. A record of this kind is shown in the accompanying illustration.

To make such a record the observer, watch in hand, notes the number of shovel dips made during any given time interval. He is in a position to decide whether any decrease in the speed of operation arises from unusually difficult digging or is the fault of the machine crew; whether delays encountered at any given time are warranted and how and by what means better efficiency can be attained.

This system is especially useful when a stripping operation is first started. At such time the shovel operator is not accustomed to the operation or, as it is said, “has not got his bearings yet.” A little coaching will then help appreciably in effecting better operation and bigger output. It may also be employed advantageously whenever the superintendent notes any falling off in the yardage moved.

It will be noted that the total amount of overburden moved during the day on which the record here shown was made was 1,537 cu.yd. This is far below a normal day’s output. If observations are carried over a number of successive days and the records made are placed side by side a comparison of the results will be easy.

This method of recording shovel operations graphically has been adopted by the Stine Coal Mining Co. in its Shoveltown operations, near Osceola Mills, Pa. The record shown in the accompanying illustration was made at the firm’s strip pit. As previously stated, the results obtained are far below normal and the record is here presented to illustrate the principle involved and not to show a phenomenal movement of overburden.
How Mechanical and Electrical Engineers Can Increase Their Usefulness in the Operation of Mines

Rapid Evolution of Electrical Engineer—Economies Possible Where Unit Cost of Every Operation Is Known—Cost Sheets Help Management to Determine Relative Upkeep of Machines and Efficiency of Repairmen

BY W. C. SHUNK
Big Stone Gap, Va.

O NLY a little more than two decades have elapsed since electricity was first introduced in a crude way for power purposes at collieries. A short time prior thereto the electrical engineer was completely foreign to the personnel of any coal-mining organization. Since then, however, and more especially during the past ten years, he has become an important and essential figure at the mines.

During the early days of the electric mine locomotive and the coal-cutting machine, electricians in charge of the comparatively few electrified collieries were looked upon as being finished and qualified engineers as soon as they had become familiar with the mechanical routine of dismantling and reassembling direct-current motors of the simple series and shunt-wound types. No one expected that they would understand the principles of field and armature winding. All that was required of them was that they always use the utmost care in marking corresponding leads of the connections they opened so as to assure their proper reconnection. The average mine electrician was satisfied to follow such methods not merely for the sake of convenience but because he lacked knowledge of the paths by which current flowed through the windings and was unfamiliar with the characteristics of the mysterious electric motor and so could follow no other plan without injury to the equipment.

ELECTRICAL ENGINEER DOES HIS OWN DEVISING

Meantime a great evolution has taken place. No longer merely an electrician he is now an electrical engineer. Not only has the design of equipment been improved but the average electrical engineer has himself developed so that he now can more successfully cope with the characteristics and peculiarities of the complicated types of motors and other apparatus used today than he could formerly with the simpler equipment of earlier years.

The electrical engineers now employed in the field are better equipped from the standpoint of general knowledge because they keep in closer touch with manufacturers' designing engineers than they have ever done before. Indeed, these men in the field can not only operate the machinery entrusted to their care but are to be credited also with originating many new and highly practical suggestions as to the way in which the design of equipment could be improved.

Many able engineers are now engaged in the power departments of the coal industry, and not a few of the collieries already have in their employment or are developing men of contriving genius who have the ability to devise methods of making their electrical equipment operate more and more efficiently.

The wonderful progress made during the past ten years in coal production has been rendered possible to no small extent by the more or less complete electrification of the old as well as of the more recently developed collieries. This has created a demand for the electrical wizard and his protégé, the practical repairman.

MEN IN CHARGE COME FROM THREE SOURCES

The vast expansion in the use of electrical energy along with the proportionate growth of the coal industry has demanded the attention and services of some of the most eminent engineers and technical men of our country. Many of the men emerging from our colleges and universities also have been absorbed directly by the operating end of the electrical and mechanical professions. In addition to these, a surprisingly large number of electrically inclined young men, particularly those of the so-called "self-made" type, have passed through the school of practical experience, having begun in an elementary way and having risen to positions where they can perform services of real worth to their respective companies.

Notwithstanding the dependable and efficient equipment and apparatus introduced during the recent past, which requires only a little attention and repair, there is still a marked demand for competent electrical and mechanical engineers in the coal-mining industry. This arises from an increase in mine electrification, the displacement of other means of transmitting power, the installation of new plants and the substitution of equipment of modern design for that now old and obsolete.

DIFFICULTIES BOTH MECHANICAL AND ELECTRICAL

Men now connected with mining operations are confronted with many perplexing problems of which their predecessors of a half decade ago never dreamed. They range in importance from the simple application of the incandescent lamp to the complex undertaking of erecting and maintaining a modern central-power station. Between these extremes at the average colliery lie problems of many degrees of complexity, for all types of equipment have their peculiar difficulties.

As most electrical problems to be met are in a degree mechanical, and vice versa, it is becoming the prevalent custom of mine managements to select one man to supervise the whole power department, seeking to find some one person adept in both mechanical and electrical engineering. Exceptions to this rule can be found only in the plants of the largest mining companies and then only when the nature of operations lends itself to the major use of mechanical equipment. Generally speaking, therefore, men who would be successful should...
be skilled in both the professions and should study and
gain experience in both branches of the industry.

It might be well here to call to the especial attention of
electricians who shoulder the responsibility of super-
vising the installation and maintenance of mining
machinery that a lack of knowledge and interest in
machinery of the reciprocating type is becoming rather
prevalent. Since the advent of the central power sta-
tion and the consequent abandonment of the small iso-
lated power plant and its reciprocating steam engine
the electrical engineer at mines has concentrated his
efforts upon equipment of the rotary type, the me-
chanical characteristics of which lend themselves to
extremely simple alignment. A machine of the rotary
or some other equally simple type that may be sub-
stituted for the reciprocating air compressor, upon
which the majority of collieries must still depend for
rock and other hard drilling, as well as for many other
uses, must yet be developed.

On account of their flexible application portable
machines of this kind are more or less adapted to all
kinds of hard drilling below ground. Recently the
general tendency of compressor design has been toward
smaller units moving at higher speeds. In order to
secure efficient and certain operation these machines
require somewhat more intelligent attention than the
mechanical parts of the electric motor. Consequently
they, along with pneumatic drills and tools, should not
be overlooked as part of the mine equipment to be
carefully studied.

MUST FURNISH POWER BUT DO IT WITH ECONOMY

There are many ways in which the personnel of
the power department can and should religiously co-operate
with the mine-operating department. Of course, this
co-operation should be reciprocal, but here only the
duty of the electrical engineer in this matter will be
referred to. Favorable earning capacity depends, of
course, on costs; and, naturally, the economic aim of all
reputable industry is to yield the greatest production.
in a safe and sane manner, at the least possible expense
per unit of production, whatever that unit may be. In
coal mining that unit is the ton of coal, and accordingly
the significant object is the cost per ton.

As machinery is now one of the most important
factors in connection with the industry, naturally it should
become one of the foremost items in cost consideration.
There are many avenues in the power department
through which a share of the cost per ton may leak
incompletely. These avenues treated individually
may seem unimportant and in some cases almost
negligible. When viewed in the aggregate, however,
because of the many machine applications involved, the
loss is often found to express itself in surprisingly large
figures. These so-called "leaks" really are too numerous
for mention here, so their character will be only outlined
and reference made merely to some of their more im-
portant phases.

One of the important ways in which the power de-
partment can co-operate with the operating officials is
by preparing authentic data regarding the costs of
power consumed in the various mining operations and
transmitting this information to all branches of the
organization concerned. Those responsible for produc-
tion cost from the management down generally are
eager to know all the items in detail entering into the
total expense.

Unfortunately, however, at most collieries the power
department has prepared itself only to submit the total
cost per ton for electrical energy consumed and the
number of kilowatt-hours used per ton of coal produced.
This information the mine clerk can readily prepare
by a simple calculation when the three quantities in-
volved are known. In most cases the mine-operating
personnel is wholly dependent on those in the power
department for the more intimate power-cost information.
Lacking this co-operation from the power engineer the
management in many instances trails along in the dark,
inunformed as to the power cost per ton for each item
of the highly diversified consumption at mines.

FINDING COST OF EACH INDIVIDUAL OPERATION

Much benefit would be derived from a knowledge of
the exact cost and the kilowatt-hours per ton consumed
in ventilation, haulage, machine cutting, tipple opera-
tion and other classified items peculiar to the general
average operating conditions. It would be constructive,
as well as interesting, also for those in the operating
department to know the power cost of operating each
machine in the mines over a given period of time—in
an hour or a shift, for instance.

If an employee is engaged to perform a certain class
of work, his wage is rated at so much per hour, day
or month, the exact rate being supposedly commensurate
with his occupation, training and ability. The fore-
man, superintendent and their superiors know how
much the services of that employee are costing per day.
Why not know, approximately at least, how much it
costs per day to operate any particular piece of equip-
ment?

It is needless to say that this would be interesting
indeed to everyone, even to the foreman and to the men
who are operating the equipment. Such information
would give the foreman an opportunity to compare
the power costs of one with any other operation and
enlighten the machine runner as to the real value of the
energy he is consuming. It would, of course, involve
much detail to follow out such a practice at close and
regular intervals, but it is certainly worth while to
obtain such information for distribution from time
to time as convenience permits.

Those in charge of the upkeep of equipment can be
of much assistance to the organization in general by
lending their efforts toward obtaining reliable facts and
figures regarding maintenance cost. Maintenance is a
phase of operation where large sums of money may
be expended without attaining the desired results. This
economy depends somewhat, however, upon the knowl-
edge and experience of the repairman and his capacity
for making good, workmanlike repairs, as well as on
the degree of care taken of the machine by the at-
tendant or runner during operation. Proper super-
vision along these lines is as important as efficient
operation, and the costs when obtained will give an
indication of the places where closer supervision is
needed.

Considering the variable conditions under which simi-
lar machines work, one may readily ascertain by check-
ing up maintenance cost whether equipment is being
properly operated or is working under normal or
abnormal conditions, also whether it is being properly
repaired. Furthermore, by it may be determined
whether one machine is or is not better adapted than
another for any particular service.

Some inference indeed may be drawn from close
observation, but a real and convincing conclusion can-
not be obtained without a careful analysis of the cost figures. The operating force is as dependent as the power department on the facts and information obtained regarding this matter. Consequently intelligent cooperation from those familiar with power technique is of much importance to the mine manager.

In yet another and an effective way can the mechanical and electrical engineers convince other branches of the organization at their mines of the real importance of the work they are able to do. In every industry the ability to train men to the highest point of efficiency is one of the most desirable of accomplishments. This desired end may be obtained by establishing conferences at which men who have to handle electrical equipment may receive training and instruction and gain inspiration and help from the experience and ideas of other men. All this can be accomplished by group meetings and conferences.

In nearly all organizations periodical executive conferences, superintendents' and foremen's meetings are now held for a similar purpose. Their value is beyond question. Why do not the power departments at our mines hold like meetings? Perhaps they already do so in some organizations, but in all probability not as frequently as is desirable.

Another invaluable trait in a power engineer is the development of foresight. He should carefully inspect his apparatus so as to forestall interruptions of service and injury to equipment. It is well known that continuous operation is reflected directly in cost. Expensive delays have occurred, and many more will be encountered, until at last foresight and inspection have been much more highly developed than they now are. Those who anticipate trouble and are prepared for it in advance—or who, better still, prevent its coming—never fail of recognition by others. They are recognized as exceptional men.

The suggestion is therefore advanced that occasional careful surveys and analyses be made of all equipment, and that decisions be made beforehand, as far as possible, as to the procedure to be followed when a breakdown occurs, assuming that such an event is inevitable and cannot be averted. Each machine should be considered separately. To keep the wheels turning with the least delay to operation oftentimes requires real genius, and this qualification cannot be overlooked.

Careful planning and forethought will correct many seemingly "impossible situations."

The importance of systematized, emphasized and relentlessly practiced inspection is nowhere more evident than in relation to the uninterrupted service of electrical and mechanical equipment. The intricate mechanism and complexity of such devices need only be considered to substantiate this statement to the full. Never was the old adage "a stitch in time" applied more appropriately than to the upkeep of machinery and its appurtenances.

The continuous operation of machines cannot be relied upon without proper anticipation, inspection and repair, for without these the process of deterioration will soon progress to the point of不可逆转的 stoppage. Substantial reduction in upkeep expense can be effected by adhering to the rule requiring frequent detailed inspections followed by necessary minor repairs, thereby forestalling subsequent costly replacements and probable delays.

Nothing is more desirable in the make-up of a real supervising engineer, electrician or mechanic than an ability to observe and to carry out rigid inspections. His capability along these lines should be carefully weighed and regarded as more important than many other desirable traits.

Along with the few suggestions here presented it should not be out of place to mention the importance of keeping in touch with other branches of the coal industry. Is there any fundamental reason why the progressive mechanical or electrical engineer should not share along with the mining engineer the honor of rising to executive positions in the organization? Surely there is not, providing he takes advantage of opportunities to inform himself as far as possible of the workings of the other branches of the organization and shows a keen interest therein while not losing sight of his own particular job. The successful executive is careful not to overlook men possessed of these qualities, and it would be unwise in any electrical engineer not to acquaint himself with all kinds of data and experience likely to fit him for such preferment.

Making Comminuted Smokeless Powder Available for Blasting Purposes

At the close of the late war the government had on hand vast quantities of various military explosives—far in excess of the current needs of both army and navy. As such explosives differ somewhat from those ordinarily used in industry and deteriorate to some slight extent with age, it was deemed advisable to seek means whereby they might be adapted to use in the arts and sciences of peace. Experiments have shown that detonating explosives such as TNT and picric acid may be used in various kinds of industrial blasting with entire success.

Among the explosives left over when the armistice was signed, however, was a large amount of smokeless powder. As ordinarily manufactured, this possessed qualities ill adapted to commercial blasting. It has been found, however, that granular introcellulosics which function as propellants by progressive burning, when ground to a fine powder may be detonated by a dynamite primer. This renders this explosive, known as comminuted smokeless powder, available for use in blasting.

The Bureau of Mines has performed extensive experiments upon this explosive, the results of which are set forth in a report (Serial No. 2.386) entitled "Comminuted Smokeless Powder as a Blasting Agent," by C. E. Monroe and Spencer F. Howell. Some of the conclusions drawn are as follows: This explosive can be used to advantage for certain kinds of blasting in the open, such as for stumps, boulders and ditches, but it should not be used where inflammable dust or gas is present or in close places such as tunnels or mines unless the ventilation is exceptionally good and ample time is allowed for the gases to be swept out by the air current circulating. It is fired most effectively by means of an electric detonator. In loading, an adequate quantity of stemming should be used.

A SANITARY SURVEY of the mining town of Torrington, Utah, has been completed by Dr. A. L. Mury, superintend of the Bureau of Mines. A compilation of mortality and morbidity statistics of Park City, Utah, has been made by Dr. Mury. Conferences have been held with the state health authorities regarding sanitary surveys of the Price River and Spring Canyon districts in Carbon County in that state.
Safety Congress Debates Hazards to Health and Limb—II

Radio Fails Underground—Metal Vs. Fabric Ventilating Tubes—Rounded and Gabled Locomotive Covers—Dangers of Broken Trip—Gongs, Lights and Tags—Cable Substitutions and Their Dangers—Hoisting Hazards

INTERESTING indeed was the discussion at the meeting of the mining section of the National Safety Council, Aug. 30, on the effect of air which is grievously lacking in oxygen as may result either from breathing fresh air unsupplied by or supplied with oxygen or fed from an oxygen supply in which nitrogen is present in some quantity. The subject opened with the reading of an article by D. J. Parker on "Mine Rescue Training and Operations," at the conclusion of which R. F. Tillson, the chairman, remarked that too great a restriction had been placed on traveling up ladders in mine-rescue work.

He could not altogether sponsor such a statement as that made by Mr. Parker: "Travel by crew up or down vertical ladders in irreparable atmospheres should be absolutely forbidden, unless it is definitely known that there is a probability of saving life by such action."

Mr. Tillson felt that mine-rescue apparatus showed such reliability as to make such precautions unnecessary. He thought that mine-rescue work still had coal-mining conditions mainly in view and that rules were made to suit conditions where vertical raises were the exception rather than the rule. His experience in apparatus had made him feel quite ready to undertake to climb ladders and crawl long distances. He realized, however, that laboring under the terrific strain of rescue work the nerves were likely to be unstrung and the action of the heart and breathing organs different from that under normal conditions. D. J. Parker said that men were only too prone to climb ladders and take risks. At the rescue work at the Argonaut mine fire in California, and still going on, he had been informed, a crew of men climbed up ladders for a distance of 200 to 300 ft. to open a door. They achieved their purpose and returned without injury, but had one fallen none of them would have come back alive.

FORGOT TO TURN HIS OXYGEN VALVE AND DIED

R. H. Seep asked D. J. Parker, the author of the paper, whether it was well to use more than one type of rescue apparatus. Commenting on Mr. Parker's reply that uniformity resulted in certainty that each man would understand the type of apparatus apportioned to him for use in any emergency and that uniformity also made a considerable saving in the number of spare parts required, J. S. Boardman related an incident of a man who went to the rescue station of the Anaconda Copper Mining Co. for an apparatus for the shift boss and one for himself.

Though shift bosses alone are allowed to requisition for these he was permitted to take them. It was arranged that he and the shift boss were to plaster up certain cracks in a brattice built to seal up a mine fire. The shift boss and man met in the mine and the boss, having other duties to perform, went away, saying he would be back in half an hour. The man could meantime mix the batch of plastering material. He did so, but as at the end of that time the shift boss had not arrived, he put on the apparatus himself and went in and nearly completed plastering up the brattice.

For some reason—probably because trembling of his limbs convinced him that all was not right—he came out, got within about 6 ft. of the fresh air and fell dead. The nose clip was still on his nose. He was in fact practically in fresh air. Had he taken off the nose clip he would have had a fighting chance for life. It was found that he had failed to turn on the oxygen and had been working in the same air which was in the bag when he started in. The action of his breathing had, however, converted the oxygen into carbon dioxide, which the regenerators had in turn absorbed. Consequently the air had been largely depleted of oxygen. The air near the brattice contained 13 per cent of that gas and had he divested himself of the nose clip or the whole apparatus he could have continued to breathe and even to work in the atmosphere surrounding him.

Dr. R. R. Sayers said that with carbon dioxide absent there is no irritation of the respiratory centers in the brain, for the absence of oxygen causes no such stimulation. For this reason the lack of oxygen is not noticed until after a while, when the victim begins to tremble. He added that no pain is experienced from a deficiency of oxygen if it comes slowly. D. J. Parker remarked that such a deficiency will cause the victim to fall suddenly.

LOW OXYGEN PRODUCES NO REACTION BUT DEATH

Dr. Sayers said that during the war the British found that whereas only 2 per cent of their flyers were shot down, as many as 8 per cent fell with their planes. This was ascribed to men attempting to fly when not in normal condition. The men would not reveal their unfitness to the commanding officer because such a declaration of momentary unfitness might have been construed as cowardice. It was finally ordered that every man submit to inspection before every flight. In rescue work no man should be allowed to participate unless he has been examined and found to be in normal health.

J. S. Boardman said that the automatic valve of certain apparatus did not begin to feed until the oxygen percentage fell to 16 and the automatic valve of other apparatus delayed action until the percentage fell to 13.

D. J. Parker remarked that with automatic apparatus the relief valve should be opened every 20 minutes so as to clean the machine of excess nitrogen. Dr. Boorier asked whether that was necessary only with the automatic feed and Mr. Parker replied that working hard with a fixed feed it was well also to open the relief valve by hand. With ordinary work the fixed feed is so excessive that the relief valve opens itself. With pure oxygen the relief valve would be needed only in case of excessive pressure, but with oxygen made by the liquid-air process and not electrolytically quite

*This trembling is not usually regarded as significant by the raw rescue-apparatus man and he may delay action till too late.
a percentage of nitrogen might be present—perhaps as much as 4 per cent—and then with the removal of oxygen by the combined action of the human organism and the regenerator the quantity of nitrogen in the air being breathed might be dangerously or at least injuriously excessive.

J. S. Boardman sided with Mr. Parker in regard to the climbing of ladders. In rescue work men rarely have to scale ladders, for before being overcome the men in the workings have usually been able to get down to the roadways and are all to be found there. In the North Butte disaster not a single one of the victims was found in his working place. It is rarely that anything is gained by leaving the levels. Nevertheless the Anaconda Copper Mining Co. is leaving room so that the apparatus men fully equipped can travel up ladderways without danger of colliding with the timbers, and moreover in fighting mines the crews have at times ventured to climb 100 ft. in their apparatus.

D. E. A. Charlton's paper on "The Use of Telephones in Mines" was then presented by R. H. Seip. Joseph W. Reed said that his company, the Consolidation Coal Co., had been experimenting with qualified success on the so-called "wireless telephone," which, though it does not operate with a wire specially strung for that purpose, depends on a single metallic feeder which is either a pipe line or a rail, the ground serving for the return of the circuit. This system is practically identical with the Reineke system, described in Coal Age, Jan. 31, 1914.

D. J. Parker took exception to Mr. Charlton's statement that the telephone should be kept under lock and key. He knew a case where the men in a rescue party found a telephone that they had managed to reach of much assistance in their work, and he felt that men shut in the mine by a disaster would hardly regard a locked telephone as a safety provision. C. L. Colburn said that the U. S. Bureau of Mines and the Westinghouse Electric & Manufacturing Co. were collaborating in an attempt to use radio-telegraphy underground.

**Radio Waves Intercepted by 50 Ft. of Cover**

They had endeavored from a point in a coal mine to listen in on the KDKA sending station. Where the cover was less than 50 ft. they could hear satisfactorily, but beyond that the volume decreased rapidly. The ground appears to absorb the waves, and this made the sending to points at great depth quite problematical. Perhaps it might be different where the radio communication was made with the underground workings of a metal mine. The metallic minerals might assist in conducting the waves. Experiments were still being made and it was found that the equipment which gave best results on the surface proved less effective underground. A 20-watt sending current was used.

Mr. Colburn then described his safety visits in the past year, those of the present year and those which he planned during the rest of the year, illustrating his itineraries with a chart. He stated that some criticism had been leveled at his short stops at any one station, but this activity was unavoidable in view of the large area to be traversed and it could hardly be corrected until two or three were engaged in making the rounds instead of one. Mr. Colburn described his duties as those of a consulting safety engineer. He furnishes information on safety practices only at the request of the managers at the mines visited. Not only does Mr. Colburn visit the mines, however; he also contributes two pages monthly to the proceedings of the National Safety News.

After the election of officers for the ensuing year, with which the third session opened on Aug. 31, E. G. Ludlam, of E. I. duPont de Nemours & Co., delivered an address on "Portable Ventilating Equipment for Mines." He said that a flexible tube is being made that will give as little resistance to air as metal tubing. It was, of course, unsuited to suction ventilation, but it had the advantage over metal tubing that it did not leak, which metal tubing invariably does after extensive use under the conditions to which it is subjected in mines. It furthermore was resistant to acid, which metal tubes, such as were used, were not. Mr. Rowe, of the American Blower Co., who had made many experiments, said that a coefficient of 0.302 could be obtained for the use in the equation \( p = \frac{ke^2}{a} \) where \( v \) = velocity in feet per second.

Lucien Eaton, superintendent of the Ishpeming District Mines of the Cleveland-Cliffs Iron Co., was not present. His paper on "Underground Transport" was read by William Conibear.

**Locomotives Should Ring Gong Before Start**

In a discussion on the use of gongs on locomotives Mr. Tillson said that such bells had been connected with the axle of the locomotive so that any movement would actuate the clapper of the gong. Some believed that locomotives in motion made noise enough to warn anyone and that the men soon became accustomed to the sound of the gong and failed to be warned by it. Some gongs were actuated electrically, but such bells did not operate when the locomotive was coating. All such gongs sounded only when the locomotive was moving, whereas they were most needed perhaps when locomotive engineers were preparing to start, as at switches.

Mr. Eaton's paper was followed by those of H. L. Reese, electrical engineer of the Susquehanna Collieries Co., and J. S. Boardman, safety engineer of the Anaconda Copper Mining Co. These were discussed concurrently. Mr. Boardman said that in view of the use of chutes, which made the trolley wire especially dangerous, his company had begun to install storage-battery locomotives. They had now fifty such units. The first thirty had curved covers, which were furnished so as to make it impossible to use the top of the locomotive as a tray for tool steel. The new units are gable-covered for the same reason. He believed that, owing to the damage from trolley wires, storage-battery locomotives should be used wherever they can be installed with economy.

B. F. Tillson said that a man had recently been killed at his plant when riding on the electric locomotive. It had been the custom to allow two men besides the motorman to use this means of transportation. The men who dumped the cars into the skip had also to fill the cars at the chutes. To this they had to travel with the locomotive, and he wondered why the designers of locomotives never made them long enough to accommodate more than the motorman. Since then he had provided on each trip a sort of caboose for these two men.

J. W. Reed wondered what could be done with such a caboose under normal operating conditions with the locomotive pulling the trip, as the caboose could not fail to be in the way. The manufacturers were always ready to make any needed changes if they could be embodied without detriment to the equipment. Any ins-

Denny, of the U. S. Bureau of Mines, read a paper written by himself in collaboration with G. M. Gillette, general manager of the Maryland Division of the Consolidation Coal Co., Frostburg, Md., on "Methods for Maintaining Safety Interest at Mines." Mr. Tillson declared that bonus systems for safety work were good if they were so arranged that an unfortunate occurrence early in the year would not destroy a foreman's chances of earning a bonus throughout the rest of the year, for if it did it would remove his interest in safety. Bonuses should be given for monthly, semi-annual and annual merit so as to give the man who had a bad record one month a chance in the following month to receive some reward for his safety activity.

FOR ATTENTION. PUT BUT ONE BULLETIN ON A BOARD

R. T. Somers, supervisor of bulletins of the National Safety Council, spoke on "Bulletin Boards," urging that bulletins be posted on a proper board and not posted on the sides of cars or barrels or even the walls of a shed. The psychological effect of giving the bulletin an honored place was not to be neglected. Bulletins should be posted one at a time and not more than one should be exhibited at any one time. They might be varied with photographs, especially such as are of local interest. Such bulletins might or might not convey a safety message. Some might have merely a gossipy interest to those for whom the board is intended.

J. S. Boardman condemmed bulletins which instilled fear and someone remarked that if posted they would tend to make men fear to work at the plant even though its dangers were far less than those at plants which displayed no such bulletins. Another questioned bulletins which condemned tomsawd as they were likely to promote imitation rather than abdication from the practices portrayed. One advocated that bulletins be posted when the men were gathered around, as the action advertised the bulletins. It was recommended also that the night watchman be designated to post bulletins under the instructions of the safety engineer. When left to the foreman the work was likely to be neglected. Mr. Colburn stated that one company employed a schoolboy to post bulletins in the evening.

Rudolf Kundlich, assistant to the chief mechanical engineer of the U. S. Bureau of Mines, then read an article on "Hoisting Equipment at Mines"; Graham Bright, general engineer, Westinghouse Electric & Manufacturing Co., one on "European Hoisting Practice," and E. O. Kentor, civil engineer, of Dayton, Ohio, an article on "Wire-Rope Connections."

DANGER WHERE LOW-STRENGTH IS SUPPLIED

Mr. Kentor's remarks emphasized the importance of standardizing wire rope. His attitude to the subject was that of a civil engineer who had seen the ill effects of lack of uniformity in the cables used on contractors' equipment. Possibly it is true that contractors buy cable from jobbers without much inquiry as to the type of cable supplied or needed and that jobbers are likely not to know plow-steel cables from crucible-steel or the latter from iron cable.

Consequently accidents occur, but around the mines cable is bought mostly from the manufacturer, who has a likable failing for demanding specifications or details as to the kind of service required. No mistake is likely to be made by the purchaser after receipt of the cable, for he probably does not have more than one cable of the required length and diameter; so he can make no unsuitable substitution. Errors, of course, might be made with ropes purchased for crane hoists and general purposes but not with main-hoist equipment.

There is, however, some call for a little better understanding as to rope clips. The foreman may use too few clips and may fail to make them tight enough to hold the rope. However, as Mr. Tillson remarked, for hoisting purposes the clip is so far inferior to the speltered cap that clamps should be discarded. Care should be taken to use spelter and not babbitt or lead, and the wire should not be bunched but spread. The spelter takes such a hold on the rope that there is some justification for the statement that the spelter alloys with the steel. Mr. Tillson said, however, that some foremen preferred clamps because their condition could be noted and because the strain is not likely to be localized as it is when the speltered cap is used.

Someone advocated that not only should overwind devices be provided against raising men above the landing at which they left the cage but also for the decelerating of the hoist so that it could not arrive at the landing for the men at a speed that might tend to carry the cage beyond the landing.

Mr. Reese said that indications of the landing at which keps were out were furnished to the engineer because he was likely to forget to which level he was required to lower the cage. Mr. Tillson said that it would not be impossible to so interlock keps with the mechanism of the hoist as to prevent letting the cage fall on the keps with undesirable violence. He did not know of any instance in which this interlocking had been provided.

F. C. Carstephen, of the American Steel & Wire Co., read a paper on "Aerial Tramways." At the close of his paper the meeting adjourned.
Coal Reserves in Washington County Are Second Largest in Pennsylvania

By John F. Reese

WASHINGTON COUNTY has the second largest reserve of coal within the State of Pennsylvania. Five beds are considered of economic value, and the quantity of coal in the ground has been calculated for each of these beds. In order of present importance as shipping coals, these are the Pittsburgh, Redstone, Waynesburg, Washington and Freeport.

Extensive mining and prospecting in the Pittsburgh bed and its outcrop throughout the county have furnished many measurements of its thickness, thus making possible a reliable computation of quantity. For some localities, particularly the old abandoned workings along the Monongahela River and large areas in the northwestern part of the county, no maps or other data are available from which to determine the size of the areas already mined out.

The Redstone bed is developed locally in three townships within the county—namely, Union, Carroll and Fallowfield. Measurements on the outcrop and in mine workings furnish the only data available for computing the quantity. It has been assumed that the bed is continuous within these townships and an average thickness of 3 ft. has been used in the calculations. This coal is mined on a small scale for shipment and for local use.

The extensive outcrop of the Waynesburg bed throughout the county has furnished many measurements of its thickness, thus making possible a fairly reliable computation of quantity. This bed is broken by many partings, is extremely variable in its section, and in many localities is under shallow cover. For these reasons it cannot be considered as a good reserve for future commercial use, and in computing the quantity of coal only a small percentage of the bed has been figured as workable. The coal is mined for local use only.

Measurements on the outcrop of the Washington coal bed have been obtained in sufficient number to make a fairly reliable computation of tonnage. Like the Waynesburg coal, this bed is broken by many partings, is variable in section, and in places lies under shallow cover. It is extremely dirty and in many places is represented by carbonaceous shale. For these reasons in computing the quantity of coal only a small percentage has been considered recoverable. The Washington coal is mined for local use only and cannot be considered as a good source of future supply.

Records of drillholes along the Monongahela River furnish the only reliable data on the thickness of the Freeport bed. Churn-drill records show coal at its horizon throughout the southeastern and central parts of the county. It is assumed that this coal underlies the entire county. A thickness of 42 in. has been assumed in the townships along the Monongahela River.

The county has been divided into several northeast-southwest belts and an arbitrary thickness for the Freeport coal assigned in each zone. The assigned thickness was regularly decreased westward to a minimum of 24 in. in the northwestern part of the county. The quantity recoverable has been estimated as 50 per cent of the whole, from which has been deducted 15 per cent for loss in mining.

Because of the irregularity and many partings of the Redstone, Waynesburg and Washington coals, it is believed that the Freeport bed will yield a larger output than any of the others when the Pittsburgh bed had been exhausted and necessity demands the development of deep-lying deposits.

Other coals are mined for local use, but as they come from small beds and little is known of their extent and thickness, they are not included in the computation of reserves.

The result of computing the coal reserves in Washington County based on the latest maps, engineering data, and methods is shown in the following table:

* The total area of Washington County is 884.6 square miles.

Detailed tables of the coal reserves in each township have been prepared and will appear in printed form in a report now being written on the bituminous-coal fields of the state. They can be consulted in the office of the Topographic and Geological Survey, or figures for a single township will be sent on request.

Shows Possibilities of Distillation of Pennsylvania Bituminous Coal

In Bulletin No. 9 of the Bureau of Topographic and Geological Survey of Pennsylvania, George H. Ashley, state geologist, treats the subject of the "Future Use of Raw Coal." In this paper, mimeograph copy of which may be obtained upon request, Mr. Ashley shows some of the possibilities of distilling the bituminous-coal output of Pennsylvania.

After reviewing briefly the shell and ordinary byproduct process of distillation the author takes up the various low-temperature coking processes that have been developed into commercial propositions. These include chiefly the Coalite process in England and the Charcoal process in this country. While these two yield a residual fuel differing widely in appearance and physical characteristics, the byproducts, both in quality and volume, are closely similar. The solid fuels produced also are far more efficient as heat producers than are the coals from which they are made.

In the latter part of the paper Mr. Ashley goes into the possibilities of coking by the low-temperature process the bituminous output of Pennsylvania. It would appear that it would be well within the range of possibility to produce 400,000,000 gallons of water fuel, 1,260,000,000 gallons of diesel and lubricating oil; also 1,050,000 tons of sulphates of ammonia and about 105,000,000 tons of residual solid fuel, which because of its smokelessness and efficiency in burning is more valuable than an equal weight of raw coal.
Testing a Safety Lamp Before Entering The Mine

Every Lamp Should Be Tested Before It Is Taken Into the Mine

Blowing Hard Against the Lamp: A Good Test—Tighten the Lamp Only After It Has Become Heated—Custom in France

WITH much pleasure I read the several letters that appeared in Coal Age, Aug. 17, p. 247, regarding the practical testing of a safety lamp to ascertain that it is in safe condition to be carried into the mine. This is no important matter that I feel has not been given the attention it should receive in this country.

In addition to carefully inspecting every part of the lamp when it is assembled every lamp should be put to a practical test. In the old country, we have apparatus for that purpose. There, the lamp is subjected to horizontal and vertical air currents by the use of compressed air. Besides this, each miner tests his own lamp by blowing against it. He also examines the lens by skewering the bonnet that protects the lamp.

Many of the modern lamps are not made with a bonnet that can be removed without unblocking the lamp. For that reason, it is important that the gauze should be carefully examined before the lamp is locked. This, of course, must be done in the lamphouse when the lamp is assembled.

Blowing Against the Lamp Is a Good Practical Test

One writer seeks to regard it as not being a good test to blow against the lamp. It is his belief that there is no danger of cracking the glass in a lamp having good expansion rings. When properly made and adjusted in the right position in the lamp, these rings should take up any expansion due to the heating of the glass.

Back in 1896, when working in a mine in France, it was my duty to serve several entries with fresh safety lamps. The lamps had no relievers, in those days, and were easily extinguished when tilted only a little. It was nothing uncommon to have sixty lamps brought to the lamphouse in a single day to be relighted.

There have been many changes since that time, but there is far less care taken in the right use of lamps, today. Then every miner was made responsible for his lamp if it was found defective on being returned to the lamphouse. For that reason, if a miner thought his lamp was unsafe he had the right to refuse to take the lamp and ask for another.

Precautions Taken in French Mines to Insure Safety

In this connection, a brief summary of the practice at the Carvin No. 2 mine (Pas-de-Calais) will be of interest. In that mine 500 miners were employed. On going to the lamphouse in the morning each miner would find his lamp completely taken apart, glass, bonnet, small and big gauzes, standard bowl, etc. The miner would assemble his lamp, and, after satisfying himself that it was safe, He would then take it to the testing man, who must pass on the lamp before it is taken into the mine. This practice would, of course, not do, at the present time, in large operations; but it shows the care that was then taken to see that the lamps were safe.

A flame safety lamp is a dangerous thing at the best; and when carried into the mine by an inexperienced person, or is carelessly handled by a miner at his work, it is doubly dangerous. Sufficient attention has not been given, in this country, to instruct miners and foremen in how to use the safety lamp.

Miners Gassy in Southern Illinois

In a mine in southern Illinois, some time since, I noted a firefellow, at a lively gait, with a lighted carbide lamp in his cap and a lighted safety lamp swinging at his side. I mention this only to draw attention to the fact that a man who falls into the habit of swinging his safety lamp will be apt to do this sometime when he is traveling in a gas charged atmosphere. The swinging of a lamp exposes it to a velocity greater than what is safe and should be avoided at all times.

Peru, Ill. GASTON F. LIBEZ.

Other Letters

PERMIT me to add a few words to what has already been said in the interesting letters on the practical testing of safety lamps before taking the same into the mine. I fully agree with my friend, Joseph Cain, whose letter in Coal Age, July 13, p. 60, started this discussion.

With Mr. Cain, I believe there is no more practical test that can be readily applied by every miner, to test his safety lamp before going into the mine, than to blow hard against the lamp, both at the base of the gauze and below the globe. In my opinion it is a most effective way of telling whether the lamp is really safe.

To my knowledge, this method has been practiced for many years in the British Isles and I believe the same test is used by a large number of miners, in the majority of our coal fields, today. My observation is that it has always given satisfaction.

A CAUTIOUS MINING INSPECTOR

Not so very long ago, a mine inspector, in the bituminous fields of Pennsylvania, was making an inspection of a mine, with the foreman in attendance. After descending to the shaft bottom, the inspector examined the foreman's lamp and found it to be improperly assembled. By blowing at the bottom of the globe, the lamp was readily extinguished.

Leaving the lamp at the bottom of the shaft, the inspector proceeded to make his inspection of the mine, accompanied by the foreman, who had procured another lamp. In their rounds, they found one entry that contained several hundred cubic feet of gas accumulated at its face.

It is easy to imagine what might have happened at that time had not the inspector taken the precaution of inspecting the foreman's lamp and blowing against it. It is probable that not only the two men would have been killed or badly burned, but other fatalities might have resulted.

In one of the letters, in this discussion, the belief is expressed that a lamp can be readily extinguished by blowing hard against the lamp. My experience is that if the lamp is properly assembled it cannot be put out by blowing anywhere around the globe or the gauze of the lamp.
Let me say, also, that the carbon dioxide exhaled from the lungs, in blowing, would have no effect to extinguish the lamp flame. Although the proportion of carbon dioxide exhaled in the breath is 2.6 per cent, at rest; and, I believe the Wolf lamp is extinguished in an atmosphere containing 3 per cent of carbon dioxide, it must be remembered that the exhaled air blown against the lamp will be rapidly diluted before reaching the flame. Neither of these statements appeal to me as correct.

Dante, Va. J. A. Holmes, Jr.

REFERRING to the instance narrated by Joseph Cain, in his letter Coal Age, July 13, p. 60, there is only one conclusion at which a person of any experience in the use of safety lamps can arrive. Either these three firebosses were very careless in putting their lamps together, or they did not know how to assemble them.

Whenever view is taken of the situation, a fair judgment must pronounce these men as clearly incompetent to hold the responsible positions for which they were chosen. It is not stated specifically, in any way, with respect to the lamps failed; but I assume that they were all alike defective by reason of not being tightened up sufficiently.

Practice of an Old Fireboss

My last experience of this nature was with a Wolf lamp. The lamp was equipped with an expansion ring and I also used a rubber or asbestos washer on each end of the glass, where the cylinder came in contact with the metal frame of the lamp.

On arriving at the mine in the morning, it was my custom to light my lamp and tighten it up only partially. This lamp was done, so as to proceed to change my clothes and by that time my lamp would be hot and ready to be tightened up securely. I would continue to screw up the lamp, while blowing against the glass cylinder, until the flame seemed to flicker.

One mine at which I was employed was worked exclusively with safety lamps, and the practice there was to treat all lamps in the same manner that I have just described. I never heard of a glass cylinder being broken by expansion.

In regard to testing safety lamps to ascertain that they are safe, before taking them into the mine, in British Columbia the law calls for all oil safety lamps to be submitted periodically to a test in a gaseous mixture. The results of this test determine whether or not the lamp is in a safe condition to be taken underground.

In a proceeding to follow: Each miner receives his lamp at the lamp cabin where it has been assembled by men appointed for that work. At the mine entrance, each lamp is again examined by the fireboss, as the man enters the mine for work.

Just here is where I claim the blowing test has its value. I regret to see that some contributors, in this discussion, speak lightly of the test by blowing against the lamp. Besides blowing on the lamp, the fireboss examines to see that it is properly assembled and no parts missing.

Blowing Test Must Be Properly Made To Be Effective

When the blowing test is properly applied it shows, by the flickering of the flame, that the parts are loosely fitted together or that some part is missing, or a washer is broken or damaged. If any one of these defects is revealed the test shows that the main principle on which all safety lamps are constructed is violated. In other words, no air must reach the flame, except through the proper channels and gauze-protected openings.

As far as the extinction of an oil-burning lamp by reason of the carbon dioxide in the exhaled breath blown against the lamp is concerned, Dr. Haldane has shown that the extinction of an oil-burning lamp by reason of the presence of carbon dioxide requires about 14 per cent of that gas; whereas the presence of carbon dioxide in the exhaled breath varies from 2.6 to 6.6 per cent, according to whether the person is at rest or is undergoing violent exercise.

From these facts it is easy to see that the slight amount of carbon dioxide in the breath would have no effect to extinguish the flame and would in no way affect the result of the test. It may be of interest to state here that, within the past year or two, the advent of the electric cap lamp has almost entirely eliminated oil-burning safety lamps, in this province, except for the purpose of testing for gas.

George Murray.

Nanaimo, B. C., Canada.

Improved Longwall Panel System

Method of side approach to longwall face—Plan reduces cost of development if properly applied—Criticism of proposed plan.

REFFERING to the interesting article of M. L. O'Neale, Coal Age, May 25, p. 877, in which he has proposed a new modified longwall panel system of mining, permit me to offer a few comments on the method he has outlined only too briefly.

If I understand correctly, the plan has many features that commend it to careful consideration. As Mr. O'Neale has stated, it can be modified in various ways to suit different conditions. The description he has given applies particularly to a fairly level seam of coal underlying a slight cover.

In my opinion, the method has certain features that cannot be excelled. It is certainly an improvement on the ordinary longwall advancing method, which requires the building of extensive backwalls to maintain the roadways leading to the working faces.

Agam, the whole plan promises an increased production of coal from a given territory, together with a much desired concentration of the working faces, a practically complete extraction of the coal and the utilization of improved mechanical equipment.

In all of these respects, the proposed method possesses distinct advantages over the room-and-pillar system of mining and either the longwall advancing or the retreating systems. As I regard it, the chief feature that distinguishes this method from other longwall panel systems is the driving of face headings that enable a side approach to the working face, without entailing the expense of driving separate pairs of headings.

Save Cost of Development by Driving Face Headings Single

I may be wrong, but it seems to me that the sketch presented in Mr. O'Neale's article, page 877, does not properly illustrate the method he describes. In attempting to show both the longwall-advancing face and the drawing back of the face-heading pillars in one sketch, it appears as though the development required the driving of the face headings three abreast.

In this respect, let me say that, to my mind, the cost of development can be much decreased by driving only single headings, one on each side of the longwall face, keeping them in advance of that face, say 80 ft., or the distance between crosstabs. I believe this is the plan intended by the description given, as it would afford good ventilation of the working face, at a minimum cost for yardage in entry driving.

In the accompanying figure I have attempted to show this feature of the

REVISED PLAN OF LONGWALL PANEL plan, as I understand it. Of course, it is understood that the face-heading pillars can be withdrawn before the panels on either side have been abandoned. Allow me to offer one other criticism of the plan, having reference to the distance apart of driving the butt headings; or, in other words, the length to which the face headings are driven before driving back the pillars.

In the previous sketch, the distance between the butt headings was given as 1,200 ft. Assuming face cost considerations, I cannot understand why the face headings should not be extended to a distance of 800 yards, or more, before turning another pair of butt headings.

The face headings are supported by good pillars on either side of the roof.
Inquiries
Of General Interest

**Coal Age**

Vol. 22, No. 12

and there is no particular weight thrown on these figures, rough as
they may seem, since the estimated
rise of the coal in the past runs
perfectly consistent.

If I am not mis-

the proposed method can be
improved in respect to producing coal at a minimum cost for
development.

Finally, may I say, that this method has now before it, the present, progress.
progressive strike, there would not be, nor
will there be, a desire to lay aside the expenses of mining required to put the mines in
good shape again for work. I only wish that Mr. O'Shaunessy was present and given us an ap-
proximate estimate of what it would cost to open a mine as an affair capable of producing say 5,000 tons of
coal a day. I believe such an estimate would show some interesting figures in favor of the plan.

Linton, Ind. W. H. LEXINGTON.

Reply to Criticism of a Recent Canadian Report

Chemical analysis of air samples given by Freer's report—Vesfion of gas generated, per ton of coal mined, estimated.

**My** attention has been called to a criticism of a previous report, contained in the Annual Report of the British Columbia Mines Department.

The criticism appeared in Coal Age, July 18, p. 60, and calls for some comment.

The criticism is signed "Mining Engineer;" its references are rather scarce terms, an alleged variance on the part of Freer in arriving at the report. It is claimed that he neglects an explosive gas found in a mine that is rated as generating 4000 cu.ft. of gas, per ton of coal mined.

Our critic does not state the page of the report from which he gleaned his conclusions, however, it is probably he has not read Freer's report, appearing in pages 227-231 of the Annual Report of the Inspector of Mines for British Columbia, for the year 1921.

On this page is given the chemical analysis of air samples taken in the various coal mines, located in the east coast district. He has not read all the data contained in the table mentioned, he would have found the answer to his question as to what is a fair percentage of gas that may be expected to be found in the return airway of such a mine.

Now, considering the percentage of gas contained in the return air of a mine, it is absolutely necessary to have the quantity of atmospheric air passing into the mine also the quantity of gas generated. These data are fully given in the table to which I have referred.

The chemical analysis of sample 247, taken in the main return of No. 3 East Mine, North, Aug. 23, 1921, is given as follows: Carbon dioxide, 14.1 per cent; oxygen, 20.5 per cent; methane, 1.08 per cent; nitric, 7.37 per cent.

The quantity of air circulated in this mine is given as 100,800 cu.ft. per min.; intensity 100 per cent; methane generated, 1,085 cu.ft. per min., or 1,569,600 cu.ft. in twenty-four hours. The output of this mine is given as 350 tons of coal, per day, from which it is estimated that the volume of methane generated is 3,500,000 = 4,480 cu.ft. per ton of coal mined.

These quantities, let me say, were obtained by the compilation of all the samples taken during the year. In the course of inspection, explosive gas was found ten times, generally located in cavities in the roof (see p. G335 of the report). The mine employed 98 men and 8 hores were working in the twenty-four hours.

Tests were made daily, in the return of every split, with the Burrell gas detector, and the results were entered in the fireboss's book kept for that purpose. The percentage of methane shown in the return air (1.09 per cent) would only give a small cap on the Wolf lamp. This percentage is far below what is considered, by the Coal Mines Regulation Act of British Columbia, as necess-

in view of these facts, there appears to be little need of the "rigid investigation by some higher official in the district," as thought by this correspondent.

**Horserpower of Engine: Specific Gravity of Gas**

**Estimating the Horserpower of an Engine—Data Required: Diameter of Cylinder, Mean Effective Cylinder Pressure, Piston Speed—Specific Gravity of a Gas Its Relative Weight Referred to Air as a Standard**

KINDLY explain, through the columns of Coal Age, two questions that are not clear to me and which, in my present situation, I have not the means to study, at hand. They are: 1. How is the power of a steam engine estimated? 2. What is meant by the specific gravity of gas, and how is it measured?

--- W. Va.

The horsepower of an engine is an expression of the work it is capable of performing in a given time. The unit of work is the foot-pound, or the work performed when a pound is raised through a vertical distance of one foot; or a pound pressure exerted through a distance of a foot. The accepted horsepower is the power capable of performing 33,000 units of work in one minute: or 550 ft.-lb. per hour.

In the steam engine, the total steam pressure acting to drive the engine is the mean effective steam pressure in the cylinder multiplied by the sectional area of the cylinder. The distance traveled by this pressure is exerted in a single minute, is the piston speed (ft. per min.) of the engine.

Therefore, to find the horsepower of the engine, multiply the total steam pressure (lb.), in the cylinder, by the piston speed (ft. per min.), and the product will be the foot-pounds per minute, or the work performed in that time by the engine. Finally, dividing this item by 33,000, gives the horse-

power of the engine.

Calling the mean effective steam pressure in the cylinder (lb. per sq.in.); p; the sectional area of the cylinder (sq.in.), a; length of stroke (ft.), l; number of strokes per minute, n; the indicated horsepower of the engine (H) is expressed by the formula

$$H = \frac{\text{plan}}{33,000}$$

In this formula, pa is the total average pressure of the steam in the cylinder, in pounds, and ln is the piston speed of the engine, expressed in feet per minute.

**Specific Gravity of Gases**

Specific gravity is another expression for the relative weight of a substance, referred to an accepted standard, taken as unity. The standard for gas is air, at the same temperature and pressure as the gas. The specific gravity of a gas, therefore, expresses the relative weight of the gas as compared to the same volume of air, at the same temperature and pressure.

For example, the specific gravity of carbon dioxide is 1.529. This is another way of saying that carbon dioxide is 1.529 times as heavy as the same volume of air, at the same temperature and pressure. Again, the specific gravity of methane or marsh gas is 0.559, which shows that this gas is 0.559 times as heavy as the same volume of air, at the same temperature and pressure.

It is clear that when the specific gravity of a gas is greater than one, the gas is heavier than air; and when it is less than one, the gas is lighter than air. In practice, the specific gravity of gases is determined in the laboratory by careful measurements of equal volumes of the gases, at equal temperatures and pressures.
**Examination Questions Answered**

**Miscellaneous Examination Questions**

(Answered by Request)

**Question**: How much work expressed in horsepower is done in raising 400 tons of coal up an incline 3,000 ft. long, having an inclination of 1 in 3, when the friction of the cars adds 40 per cent to the load?

**Answer**: For a rise of 1 ft. for every 3 ft. measured on the incline, the total rise or vertical height through which the load is lifted in ascending this incline is 3,000 ÷ 3 = 1,000 ft.

Adding 40 per cent for friction, the gross load hauled is 400 × 1.40 = 560 tons.

The work performed in a single hoist is, therefore, 560 × 1,000 = 1,120,000,000 ft.-lb.

It is not possible to express this work as horsepower, without knowing the time in which it was performed. For example, 100 hp. would perform this work in 1,120,000,000 ÷ (100 × 33,000) = 340 min.

which would represent an 8-hr. day, less 40 min.

**Question**: A shaft, 900 ft. deep, is passing 200,000 ft. of air per minute, under a water gage of 2 in. What is the horsepower producing the circulation; and what is the width of the furnace if the bars are 5 ft. in length?

**Answer**: The horsepower on the air, in this case, is $H = \frac{(200,000 \times 2 \times 5.2)}{33,000} = 63$ hp.

The area of grate (A), in square feet, for a depth of shaft (D), in feet, and horsepower (H) on the air, is estimated by the formula:

$$A = \frac{34H}{34 \times 63} = \frac{V}{900} = 71.4, \text{ say } 70 \text{ sq. ft.}$$

Therefore, if the grate bars are 5 ft. long, the width of the furnace is $70 ÷ 5 = 14$ ft.

**Question**: An airway is 5 ft. wide at the top, 8 ft. wide at the bottom and 6 ft. high; if the average speed of air is 250 what is the quantity of air passing?

**Answer**: The sectional area of this airway is $\frac{1}{2} (5 + 8) \times 6 = 39$ sq. ft. Then, assuming the given reading represents an average velocity for the entire section of the airway, the quantity of air passing is 250 × 39 = 9,750 c.u.f. per minute.

**Question**: If you suddenly found yourself in an explosive mixture of gas, state briefly what you would do.

**Answer**: Keep cool; make no quick movement, but promptly and slowly lower the lamp, at the same time muttering it as well as you can beneath your coat, while withdrawing as carefully and quietly as possible from the place. Any quick movement would only disturb the gas at the roof and cause it to descend, thereby increasing the danger of the lad passing flammable and igniting the gas surrounded by coal gas. A fire boss, under these conditions, requires great presence of mind to enable him to act intelligently and safely.

**Question**: Do you believe in systematic timbering? Who is the better judge of the need of timbering, the boss or the miner? How often should the roof be examined?

**Answer**: Under uniform roof conditions, requiring the setting of posts to support the top, the safest plan is to adopt such a systematic form of timbering as is best suited to the conditions. Where the conditions are not uniform, the style of timbering employed must be determined by the best judgment and experience of the miner and the officials in charge.

Many experienced miners are good judges as to what timbering is needed in their places. However, such is the miner's desire to make a good day's run that he often does not think the roof above him is not unsafe for a time. On the other hand, the foreman or safety inspector, feeling his responsibility for the safety of the men will generally make the best judge as to the need of timbering in a place. The roof in a working place should be examined frequently during working hours and every precaution taken to avoid even the possibility of accident.

**Question**: How much air will be required to dilute 500 c.u.f. of marsh gas to a 4 per cent mixture?

**Answer**: In this case, 500 being 4 per cent of the mixture, the total volume of gas and air is $500 ÷ 0.04 = 12,500$ c.u.f. The volume of air required is therefore $12,500 - 500 = 12,000$ c.u.f.

**Question**: What precautions should you take to avoid accidents on a gangway along which men are obliged to travel and on which cars and mules or cars and motors are passing frequently?

**Answer**: Where men are obliged to travel on haulage roads there should be provided a good clear space on one side of the road to enable men to pass the cars in safety. There should also be provided refuge holes, at regular short intervals, on one side of the road, and these should be kept free from all obstruction and whitewashed so that they can be easily found in the dark. In addition, all locomotives should be tripped, if possible, with headlights and guards, or other means of warning to herald their approach. The speed of hauling cars and trips should be limited to a reason-

able amount, say not to exceed six miles per hour.

**Question**: What are the dangers pertaining to a broken power wire or a poorly insulated wire, in a coal mine?

**Answer**: A broken power wire may, by contact with pipes or rails or other wires in that vicinity, cause a short circuiting of the current and the dangerous charging of such pipes, rails or wires. Anyone coming in contact with a pipe or wire so charged would receive a shock that might prove fatal. A poorly insulated wire presents the danger of accidental contact with the wire, together with loss of voltage, by reason of the short-circuiting of the current at that point.

**Question**: How would you determine whether a hoisting rope is unsafe and what portion of the rope would you consider the weakest part, or the part most liable to give out first?

**Answer**: Every hoisting rope should be carefully examined at the beginning of each shift to detect any possible broken wires or other points of weakness. This is done by allowing the rope to pass through a bunch of waste held in the hand, while the engineer hoists the cage slowly. A close examination must be made of all ropes, sockets and fastenings on the drum. That portion of the rope within a few feet of the cage coupling is weakest and most liable to give out first, owing to its being subjected to the most severe usage and bending.

**Question**: State how you would commence to remove a large body of flooded water in the mine and what precautions you would take. State what danger there would be in doing the work.

**Answer**: Without knowing the particular conditions, it can only be stated, in a general way, that no attempt must be made to disturb or remove the gas from its lodgment, until all the men have been withdrawn from that section and the mine area cleared. There is no danger to the men if the mine is cleared of the gas. This being done, the work of removing the gas must start from the back end of the section. The circulation must be increased as much as practicable and praticable and be permitted to reach the air in such a manner that it will sweep the gas from its lodgments. Lights other than safety lamps and approved type must be permitted, and each lamp must first be carefully examined and tested before being taken into the mine. The breathing must be extended gradually, keeping a careful watch on the progress, and the men must be instructed in the use of a lamp or making ready to use the lamp with a lamp or other substitute. In the meantime the work must be continued, until all the gas has been removed from the section. Each working face must then be examined and reported safe before the men are permitted to return to work.

To substitute a coal of the same general character so that the engine crews will have no trouble in burning it. An effort is being made to induce the Bureau of Mines to undertake the preparation of such a classification.

One of the staff working on distribution remarked recently that they are not much better equipped to undertake distribution than were the Soviet authorities who attempted to distribute fuel on a B.t.u. basis. As a result, gas plants got peat, and plants equipped to burn peat were allotted gas coal. They got their requisite number of B.t.u.'s but in a form deficient to utilize.
Smokeless Output in June 90,000 Tons in Excess of That of May

West Virginia smokeless fields produced and shipped 3,777,558 net tons of coal during June, approximately 90,000 tons in excess of the May figure and 907,584 tons more than in June, 1921. Total smokeless output for the first six months of 1922 was 19,388,409 tons, 5,382,239 tons in excess of the corresponding period last year.

"Standardize" Still Is Watchword of American Mining Congress

Some notable advances in standardizing mining methods and machinery are expected to be made known at the twenty-fifth convention of the American Mining Congress, October 9 to 14. Much will be said on the general subject at several sessions of the convention but the entire day of Oct. 12—the heart of the convention—is to be devoted to standardization, for this is to be the third national standardization conference. Many committees on various phases of the question will report.

It is expected that striking progress will be made known in the following discussions and recommendations: "Drilling Machines and Drill Steel," by W. R. Braly, general manager of the North Butte Mining Co.; "Mining and Loading Equipment," by E. N. Zern, of the Keystone Consolidated Publishing Co.; "Mine Timbers," by Gerald Sherman, consulting engineer of the Phelps-Dodge Corporation, and by R. L. Adams, chief engineer for the Old Ben Coal Corporation; "Outside Coal Handling Equipment," by Dr. H. M. Payne, consulting engineer, of New York City: "Fire-Fighting Equipment," by William Conibear, of the department of safety, Cleveland-Cliffs Iron Co., and "Mechanical Loading Underground," by Lucien Eaton, superintendent of the Cleveland-Cliffs Iron Co. Many other reports will be read, in addresses made, opening with an address on "What Standardization Has Done for the Coal-Mining Industry," by Colonel Warren R. Roberts, former chairman of the general committee on coal mining of the congress' standardization division.

Coal Production Costs and Profits in Great Britain

Costs of production, output and proceeds of the mining industry in Great Britain during the first quarter of 1922, as published by the Iron & Coal Trade Review, are as follows:

* Compiled by Ore & Coal Exchange, Cleveland, Ohio, H. M. Garrett, Manager.
Legislation Passed in Ohio Would Control Coal Price at Mine and Bin

Final action on Ohio's coal-price-control legislation came shortly before noon Sept. 12, when Governor Davis signed the measure without the appointment of a fuel administrator and setting up price-fixing machinery and that approximating $9,077,000 for the use of the administrator in operating mines taken over under the bill and far payment of orders. Officers of both houses of the Legislature had stipulated the measures that morning and officially adjourned the special session.

By the action of the General Assembly, Governor Harry L. Davis, when making his address at his address, effective whenever he does its use necessary, to create the necessary machinery to fix prices at the mines and at the coal bins and, if necessary, to seize the mines of the state to assure production and distribution. The Senate enacted the bill by a vote of 25 to 3 while the vote in the House of Representatives was 61 to 2. The concurrence carries an emergency clause, both branches effecting this step by a margin of a single vote.

By virtue of the power conferred upon him Governor Davis is vested with authority, at his discretion, to appoint a state fuel administrator, who shall make such an investigation as may be necessary to ascertain basic costs of production and distribution, in order to fix prices which may be charged by the producer and the distributors.

Governor Davis, chairman of the State Utilities Commission and present State Fuel Administrator, has been most frequently mentioned as the Governor's probable choice for the position.

What use the Governor will make of the new law depends on the course to be pursued by Ohio coal operators. If they refuse to regulate from their present position that $3.50 at the mines is the lowest price at which they can sell their product, the Governor will appoint a fuel administrator and set the machinery of regulation in motion.

It is not expected that the Governor will make use of his power to seize and operate the mines until a complete survey of the situation in Ohio by the administrator shows that coal cannot be obtained at prices fixed by him.

No official suggestion has been made as to the prices which may be fixed for the operators. Inasmuch as the Governor, in his advice to reach a voluntary agreement with the operators prior to the calling of a special session, urged prices ranging from $3.75 to $4.30 a ton at the mines, it is believed that mine prices will be approximately those figures.

There have been no indications as to retailers' prices.

Coal operators and dealers and mine-union officials opposed passage of the bill and now predict its failure as a final measure. Furthermore, existing high prices is the drawback of cars. Were there a full supply of cars and adequate motive power, prices would soon come down to normal, they aver.

While the ink on the bill to provide for price fixing was still damp, Hocking Valley operators came to the Governor with a proposition, presented by John S. Jones, head of the Sunday Creek Coal Co., and E. M. Putnam, president of the New York Coal Co. It provided for a price of $3.50 at the mines when the car supply is 100 per cent, the price to increase 5c. on the ten each time there is a reduction of 10 per cent in the car supply, the maximum price to be $5.

In the meantime Governor Davis indicated that the state would proceed with the organization of the Fuel Commission as provided in the new law.

Skilful Utilization of Reserves Was Achievement of H. B. Spencer

The most striking accomplishment of Henry B. Spencer in his handling of fuel distribution was the skilful way in which consumers were induced to utilize their reserves of coal. There has been no small amount of criticism of Mr. Spencer's acts, but to those who see the entire picture it is plain that it is entirely unfair to make Mr. Spencer the scapegoat for an impossible situation. It was apparent from the first that he would have to make bricks without straw. His job necessarily was a thankless one, since the character of his decisions obviously would offend many where one was pleased.

Despite these difficulties, many disinterested observers believe that the distribution plan as carried into effect by Mr. Spencer saved the consumers of the country many millions of dollars. It is true that the tangible effects of his handling of the hard times situation of existing coal production again approached normal volume, but the psychological effect of the distribution plan unquestionably was to hold prices within bounds. Large consumers were prevented from bidding against each other and means were found to relieve all cases of acute distress before serious disruption occurred.

It must be kept in mind that Mr. Spencer was not responsible for the general policy of distribution, which was framed prior to his appointment. In Mr. Spencer's case, however, control began at the point of production—distant from the point of consumption. In the best of times coal originating in the middle Appalachian region cannot be delivered in New England, in the Middle West or at the Lakes much under two weeks. Under the conditions such as existed during August, the delay in the movement from the mines to the point of consumption necessarily gave rise to complaints from impatient consumers.

Sight must not be lost of the fact that the acute emergency lasted only 23 days after Mr. Spencer took hold. As a result the accomplishments of the distribution plan were not fully apparent during the time that it was functioning.

There are those who characterize the work done under Mr. Spencer as an absolute farce. They characterize the whole scheme as a gesture, and a menacing gesture at that, in which a club was held in a menacing position in the effort to carry out the so-called voluntary agreement. The public utilities feel that the operators dominated Mr. Spencer's administration and as a result things were so manipulated as to sever effectually the consumers having low-priced contracts from their source of supply, thereby making it necessary for them to buy coal at the higher prices. It was the equitable distribution of cars. Had the wishes of the operators been observed it would have meant a preferential car supply to mines with contracts. This, it is argued, would have disrupted the whole co-operative plan.

New Tariff Increases Duties on Explosives

The new tariff bill transfers dynamite, blast powder and other high explosives suitable for blasting, when put up in sticks, cartridges or other forms, from the free list to the dutiable list with a rate of 11c. per pound.

Coal-tar explosives are carried in the new bill at a heavy increase over the duties in the 1913 tariff law and the supplemental rates adopted in 1916. These rates are 60 per cent ad valorem, based on the American selling price of a 50-lb. box of product. Plus 7c. per pound for two years, after which the duty shall be 45 per cent, American valuation, plus 7c. per pound.

Coal and coke remain on the free list, with a provision for a retaliatory duty equal to the duty any other country may impose on these products from the United States.

Lumber, including mine timbers, remains on the free list. Structural steel was increased to 0.20c. per pound if not assembled and to 20 per cent ad valorem if drilled, punched or assembled. Wire, nails, spikes, nuts and screws were increased over the 1913 rates. Steam engines were given a duty of 15 per cent ad valorem.
Coal Distribution Control Bill Goes to President; Probably Will Become Law This Week

With the approval by the Senate on Saturday, Sept. 16, of the conference report on the bill intended to prevent profiteering in coal and providing for the control of distribution, the measure was sent to the House. The signature of the President probably will be affixed and the bill become a law during this week. Only twelve votes were cast in the Senate against the conference report on this bill, despite the fact that it was vigorously opposed by such influential members as Senator Underwood, minority leader, and Senator Sutherland, of West Virginia.

Senator Underwood contended that the emergency has passed and that under the changed conditions, the bill should not assume the great responsibility of the precedent established by this measure. He declared that the government could not undertake to regulate the prices of commodities every time the price level exceeded that which commonly is regarded as fair. He expressed doubt as to the success of the Fuel Administration during the war. While there may have been some reason for attempting this control under war conditions, he contended that there is no justification for it in peace times, especially when it is doubtful whether such control does not more harm than good.

He emphasized the fact that he intended no criticism of Dr. Garfield and admit that certain phases of the Fuel Administration may have accomplished good, but, he declared, “it annoyed nearly every man, woman and child in the United States and seriously hampered the business of the United States.”

Misses Profiteer, but Lands on Consumer

One of Senator Underwood’s objections to the legislation is that it does not reach the profiteer but concentrates its penalties on the consumer. “No provision is made,” he said, “for a jail sentence for the coal profiteer. The only way he will be punished is by the refusal of the Interstate Commerce Commission to back up cars to his door. On the other hand, the consumer—the man who is being frozen because he cannot get coal—is to be sent to jail, if perchance, he should lie a little about the coal he needs. I do not think it would be a very great crime for a man whose family is cold to exaggerate a little bit about the coal he will need to run his house during the winter. He will not exaggerate a great deal, because he will not want to pay present prices. If he exaggerates, then the coal dealer can send him to jail. The only question now involved is whether consumers will have to pay a dollar or two more a ton than they should pay. That is not a great emergency.”

Senator Sutherland, in the course of his remarks, said: “It is a great mistake to pass this bill. It is establishing a precedent that will be very dangerous. It is in contravention of the Constitution. It will come before us many times to plague us when similar measures are attempted in the future for the purpose of fixing prices by governmental action.”

Too Much Left to Opinion of Bureau Official

“The bill is intended to be retroactive in its effect. It is not even intended that contracts in actual existence shall be protected. When those contracts are tested in the courts there is no question but that they can be sustained, but so far as it can be done by the arbitrary act of a bureau official, those contracts will be abrogated and the coal diverted. The entire matter will rest upon the personal opinion of an underemployee of a bureau here in Washington as to whether or not the coal has been sold at a fair and reasonable price.

This situation will cure itself in a short time in so far as soft coal is concerned. The entire difficulty would be solved more readily if the transportation companies and the shippers were authorized to proceed to get this coal to the market in the usual manner, according to methods that have been adopted after many years of trial and experiment.”

Senator Reed, of Pennsylvania, among other things said: “Because for the moment what we call profiteering is unpopular, we have an effort to tear up the Bill of Rights of the Constitution; an effort to pass an ex post facto law; an effort to take from the owner of coal a part of the market value of his property without pretending to make compensation to him for what is taken. It is all attempted to be justified by the assertion of an emergency which now has ceased to exist. Every time anything goes up in price and some people wish to get it cheap, they will come rushing again to Congress to fix the price.”

Senator Kellogg, of Minnesota, asked if it is not reasonable that some priority in the distribution of coal be given to mines willing to charge a fair price. “The so-called Fuel Administration,” he said, “was nothing more than a board of inquiry to furnish the Interstate Commerce Commission with facts and to make recommendations. The commission has not the force, the time nor the facilities for doing that. The government has been carrying on similar activities for some time. This bill merely is designed to enlarge the powers of the Interstate Commerce Commission temporarily to meet a great emergency. I submit that this bill is not retroactive at all. There is no power in the commission to deny cars on account of anything that has occurred in the past.

Does Not Think Emergency Has Passed

“I do not think the emergency has passed. It is true that coal is being produced in considerable quantities, but it is not possible before Lake transportation closes to produce and transport a sufficient quantity of coal to supply the needs of the Northwest.”

The Senate bill was not greatly changed in conference. The length of the period during which the act may remain in force was increased from six to twelve months. The word “extortion” was eliminated from the bill and the words “unjustly or unreasonably high” were substituted where reference was made to prices. As much as may be necessary but not to exceed $50,000 of the appropriation may be used to meet the expenses incurred since May 15 by the President’s Fuel Distribution Committee. The full text of the bill follows:

EMERGENCY ENDANGERS PUBLIC HEALTH

“That by reason of the prolonged interruption in the operation of a substantial part of the coal-mining industry in the United States and of the impairment in the service of certain carriers engaged in commerce between the states and by reason of the disturbance in economic and industrial conditions caused by the World War, a national emergency exists which endangers the public health and general welfare of the people of the United States, injures industry and business generally throughout the United States, furnishes an opportunity for the disposition of coal and other fuel at unreasonably high prices, limits the supply of heat, light and power, threatens to obstruct and hamper the operation of the Government of the United States and of several departments, the commerce and defense of the United States, the operation and efficiency of the army and the navy, and the operation of carriers engaged in commerce among the several states and with foreign countries.

“Sec. 2. That the powers of the Interstate Commerce Commission under the act entitled ‘An act to regulate commerce,’ approved Feb. 4, 1887, as amended, including the Transportation Act, 1920, and especially under Section 1 of the Transportation Act, 1920, are, during the aforesaid emergency, enlarged to include the authority to issue in transportation of coal or other fuel orders for priorities in car service, embargoes, and other suitable measures in favor of or against any carrier, including vessels suitable for transportation of coal on the inland waters of the
COAL AGE
Vol. 22, No. 12

Purposely states which, for such period and shall be subject to the Interstate Commerce Commission, and as may be determined, con-
mencing on the 1st day of January next, and to take into account necessary and appropriate steps for the provid-
end in transportation and for the available distribution of coal or other fuel as best to meet the emergency and to pre-
mote the general welfare, and to prevent undue or ex-

a sign of public convenience or necessity, or for the pur-

purpose, association or company, for its own purposes, or in steady or un-

jectably high. This rule shall not be construed as

binding any of the provisions hereinbefore granted by law to

the Interstate Commerce Commission, but shall be construed as

conforming supplementary and additional powers to said

Commission, and as an amendment to Section 1 of the Inter-

state Commerce Act, and subject to the limitations and

defense of that act, and all laws hereby said Interstate Commerce Commission shall be

applicable in the execution of this act.

CREATES OFFICE OF FEDERAL FUEL DISTRIBUTOR

"Sec. 3. Because of such emergency and to assure an ade-
quate supply and an equitable distribution of coal and other fuel
and to facilitate the movement thereof between the several states and with foreign countries, to supply the
army and navy, the Government of the United States and its several departments, and carriers engaged in interstate
commerce with the same during such emergency, and for other
purposes, and for the further purpose of assisting in

carrying into effect the orders of the Interstate Commerce Commission, enacted or under Section 2 above
there is hereby created and established an agency of

the United States to be known as federal fuel distributor,

whose appointment shall be made and compensation fixed by

the President of the United States. Said distributor shall

perform his duties under the direction of the President.

Sec. 4. It shall be the duty of the federal fuel distributor

to ascertain:

"(a) Whether there exists within the United States or

any part thereof a shortage of coal or other fuel and the

extent of such shortage;

"(b) The fields of production of coal and other fuel and

the principal markets to which such production is or may

be transported and distributed and the means and methods of

distribution.

Thus far normally and usually charged for such

coal and other fuel and whether current prices, considering

the costs of production and distribution, are just and reason-

able and

MOST IMPORTANT WHO SHALL BE GRANTED PRIORITY

"(d) The nature and location of the consumers, and what

present, anticipated, corporate and personal, municipali-
tes or communities shall under the acts to regulate com-

merce administered by the Interstate Commerce Com-

mission, including the Transportation Act, 1920, in time of

shortage of coal and other fuel, or the transportation

thereor, receive priority in transportation and distribution,

and the degree thereof, and any other facts relating to the

protection, provision Ay, and control of the general

welfare; and when so ascertained the federal fuel dis-

tributor shall make appropriate recommendations pertain-

ing thereto to the Interstate Commerce Commission from

time to time, either on his own motion or upon request of the

commission, in the end that an available distribution of coal

and other fuel may be secured, as best to meet the

needs of the general public welfare. All facts and data

within the possession of the federal fuel distributor shall be

at all times accessible and furnished to the

State Commerce Commission upon its request. The

Interstate Commerce Commission is hereby authorized and

to receive, consider and act on the recommendation of the

federal fuel distributor, based upon his reports upon the

foregoing matters or any other information which it may

secure in any manner authorized by law.

"Sec. 5. The federal fuel distributor may make such rules,

regulations and orders as he may deem necessary to carry

out the duties imposed upon him by this act, and may

cooperate with any department or agency of the govern-

ment, any state, territory, district, or possession, or depart-

ment, agency, or political subdivision thereof, or any per-

son or persons, and may avail himself of the advice and

assistance of any department, commission or board of the
government, and may appoint or create any agent or agency

to facilitate the power and authority herein conferred upon

him. He shall be subject to removal, and for the

compensation of such assistants and employees, not in

conflict with existing laws, and to make such expenditures

for rent, printing, telegrams, telephones, furniture, station-

ary, office equipment, travel, and other operating ex-

penses as shall be necessary for the due and effective ad-

ministration of this act. All facts, data, and records rela-

ted to the production, sale, purchase, transportation, or dis-

tribution of coal and other fuel in the possession of any

commission, board, agency, or department of the govern-

ment shall at all times be available to the federal fuel distributor

and the Interstate Commerce Commission, and the person

having custody of such facts, data, and records shall furnish

the same promptly to the federal fuel distributor or his

authorized agent or to the commission on request

therefor.

"Sec. 6. That whenever the President shall be of the

opinion that the national emergency hereby declared has

passed he shall by proclamation declare the same, and

thereupon, except as to prosecution for offenses, this act

shall no longer be in force or effect, and in no event shall

it continue in force and effect for longer than twelve

months from the passage thereof.

FALSE REPRESENTATION SUBJECT TO HEAVY FINE

"Sec. 7. Every person or corporation who shall knowingly

make any false representation to the Interstate Commerce

Commission or the Interstate Commerce Commission, or any

person acting in their behalf or the behalf of either of

them respecting the price at which coal or other fuel has

been, is being, or is to be, sold or bought, the inquiry being

made for the purposes of this act, or whoever having ob-

tained coal or other fuel through a priority order or direc-

tion shall dispose of the same for purposes other than those

for which said priority order or direction was issued without

the consent of the Interstate Commerce Commission, shall

be deemed guilty of a misdemeanor and upon conviction

thereof shall be punished by a fine or not less than $1,000

nor more than $20,000: Provided, That any person or any

officer or director of any corporation subject to the pro-

visions of this act, or the interstate commerce act and the

acts amendatory thereof, or any receiver, trustee, lessee,

agent, or person employed by any such corporation, who shall be

convicted as aforesaid, shall, in addition to the fine herein provided for, be liable to im-

prisonment in the penitentiary for a term not exceeding two

years, in the discretion of the court. Every violation of

this section may be prosecuted in any court of the United States

having jurisdiction of crimes within the district in which

such violation is committed or through which the trans-

portation is conducted, or in which the car service is per-

formed, or in which such concession or discrimination is

granted or given or solicited or accepted or received; and

whenever the offense is begun in one jurisdiction and com-

pleted in another it may be dealt with, inquired of, tried,
determined, and punished in either jurisdiction in the same

manner as if the offense had been actually and wholly com-

mitted therein.

SCHEDULE. There is hereby authorized to be appropriated

the sum of $250,000, available until expended, for the pur-

poses of this act, including payment of personal services in

the District of Columbia and elsewhere, and all expenses

incident to organizing the work of the President's fuel

distribution committee, and not exceeding $50,000 thereof

shall be available for reimbursement or payment upon

specific approval of the President of expenses incurred

in May 15, 1922, in connection with the work of the

President's fuel distribution committee organized for the

purpose of helping to meet the emergency existing in

the matter of fuel.

THE HERCULES POWDER Co., of Wilmington, Del., announces a reduction in its selling prices of high explosives and blasting powder effective Monday, Sept. 18.
Nash Counsels Better Co-operation Among Rocky Mountain Mining Men to Hold Trade

Oil and electricity have cut so deeply into the natural market for coal that today it is more than ever necessary for the operating men of a coal-mining company to work in thorough harmony with the selling end of the business, Harry F. Nash, vice-president of the Oakdale Coal Co., of Denver, Col., told the Rocky Mountain Coal Mining Institute at its fall meeting in Glenwood Springs, Colo., Sept. 7 to 9.

The program of the meeting included a good deal of sport as well as some solid and interesting technical contributions, including these papers: "Electricity in Coal Mining," by Graham Bright, of Pittsburgh, Pa.; "Wire Rope in Mining," by J. P. Howe, of Worcester, Mass.; "Practical First-Aid Work," by W. F. Murray, of Dawson, N. M., and Mr. Nash's paper on co-operation. Mr. Bright was the particular star in swimming contests in the Glenwood pool, winning three events. In the water sports for mine inspectors Robert Sneden, of Wyoming, won the all-round swimming championship from John Crawford, of Utah, though Mr. Crawford was the victor in diving. Thursday night some absorbing coal-mining and industrial moving pictures were shown and Friday evening C. W. Darrow, the principal speaker at the annual banquet, over which Harry Nash presided as toastmaster. A dance followed the dinner. All sixty of the men at the meeting enjoyed the automobile rides through beautiful canyons near Glenwood Springs as the guests of the Lion's Club.

**Potential Bituminous Output Greater Since War**

"Within the last ten years," said Mr. Nash, "electricity and oil have largely displaced coal in industry, so that the use of bituminous coal is decreasing, relatively, though the potential production of bituminous coal has largely increased since the war. High wage scales and high freight rates make the delivered price of coal to the consumer 50 out of proportion to the cost of electricity and oil—and strikes make the supply of coal so uncertain—that industry is rapidly turning to electricity and oil. The energy in 1 ton of coal can be transported by electric current a distance of 250 miles for 78 per cent of what it costs to ship the coal in bulk by rail in the East, and for about 60 per cent of what it costs in our section of the country."

"The use of fuel oil, distillate and gasoline in industry has increased by leaps and bounds. Especially was this noticeable during the strike this year, as the large New York plants in Kansas City, Omaha and Chicago, and the chemical plants in Kansas City,Omaha and Chicago, that formerly used nothing but coal, are now practically all using oil. This also applies to other industrial plants throughout our territory in Texas, Oklahoma, Kansas and Nebraska. Many railroads are using oil, as are also the smelters, cement plants, etc. Then years ago 100 per cent of the threshing in the State of Kansas was done with coal; today not over 25 per cent of it is done through that means, and so it goes all along the line. The use of our coal is being yearly more restricted in industry."

"In the case of domestic consumption the circle is also ever decreasing. In small towns and on farms kerosene, gasoline and wood are largely utilized for cooking. For the past four years along any country road it has been a common occurrence to hear a buzz-saw cutting old fence posts or tintering old fence rails. Many thousands of tons of coal are displaced each year through the use of corn and cobs. In larger towns gas plants have been installed, and many housewives use gas—in communities contiguous to natural gas, that is used for industrial and domestic purposes.

"Time has gone when industrial and domestic consumers or dealers satisfied with anything that is black. Competition among the coal-producing states is keen, and will become more so. Eastern and Southern fields are turning out splendidly prepared coals of high quality, and with their lower freight rates to competitive territory, will entirely nullify the use of our Western coals unless harmony and co-operation exist between the sales department, the mine superintendent and his assistants."

"To be successful, the salesman must, first of all, believe in his product—must feel that he has a good article in point of quality and preparation to offer his customers—and must feel that the initial shipment a new customer receives will measure up to the salesman's representations—and all subsequent consignments to be done. The salesman knows full well that if the coal shipped any customer is not up to standard, the next time he calls, the customer's reception to him will be fair from pleasant; in short, the salesman will be unable to sell that customer again because through no fault of his, the salesman's representations have been false. A salesman further knows that a disgruntled customer will tell other dealers of the poor preparation of his coal, so that, even if he wants him in the face wherever he goes, as he sees dealer ordering other coals of better and more uniform preparation.

"Probably the mine staff do not realize what trouble, expense and loss a company is put to in forwarding a car that has been refused by the original consignee. Let us take for example a poorly prepared car of coal arrives at Brush, Col. The original consignee refuses it and the shippers invoice it to the new customer at Holdrege, Neb., but without paying a $6.75 reconsigning charge, plus any demurrage which might have accrued at Brush. Let us suppose the car is also refused by the consignee at Holdrege. In order to get rid of the shipment, the company is compelled to pay another reconsigning charge of $6.75, plus demurrage and the through freight charges to Holdrege, plus the local freight rate from Holdrege to wherever the car is finally placed. Offtimes this local rate is greater than the sales price of the coal at the mine, so that the transaction is a total loss. To cap all of this, it is very often necessary to make a reduction in the mine price of the coal, to say nothing of telegrams and telephone calls incident to reselling the originally refused car of coal.

**Cities Advantages of All-Round Co-operation**

"How much better it would be to have every car sold out of the mine absolutely free from risk, how and at an excess amount of slack. How many companies have had their attention called by someone at the mine to the fact that the coal in certain cars was not up in standards, but have taken the attitude that they were too busy to inspect these cars, have the coal cleaned, or even to notify the sales department of the poor preparation of coal in that particular car? How often have they known that the coal coming from certain mines in the mines was being loaded dirty, that permitted the cars with this poor coal to those to be billed out, with the idea of "passing the buck" to the sales department? How many of them, when they receive a letter from the sales department, to the effect that customers are complaining of preparation, give the sales department a "hawling out" before their assistants, and do nothing to obviate further complaints? How often is the co-operation between the various departments of the company weak to stop this friction and insure larger revenue for each company.

"I am quite sure that the sales department will always gladly co-operate with the mine force. Most of the salesmen know the many troubles that confront them at the mine, as many of them have worked at the mines formerly in various capacities or have at least often visited the properties.

"As soon as the mines throughout the country have recovered from the recent short and the coal shortage is a thing of the past, the coal operators of the West will have to "fine-cash" the territory for orders, and unless the operating departments see to it that nothing but clean and well-prepared coal is sent out, a decrease in annual production is sure to follow, rather than the increase we should expect."
Questions Propriety of Car Distribution
Based on Price of Commodity Carried

The attitude of the Interstate Commerce Commission toward the emergency fuel distribution and price control act was pointed out in the testimony of Commissioner Cyrus K. Atchison to the effect that the commission never seeks jurisdiction, yet in every emergency finds the duty of coal distributor for the country thrust upon it, and if this is to be the case without the additional authority granted it under the Wilson-Cummins act.

In giving his testimony before the House Interstate Commerce Committee, Commissioner Atchison appeared more in the role of a member of the President’s coal committee than as a member of the Interstate Commerce Commission yet because of his office it was generally considered by committee members that he speaks for the commission.

Commissioner Atchison agreed with Representative Graham that the Federal Fuel Distribution, created by this emergency legislation, functions as a referee and that the Commission, as executive, has the active duties of creating priorities or authorizations for the equitable distribution of coal and control of the price rates in the Interstate Commerce Commission.

“I do not think it is sound public policy as a business proposition that the Interstate Commerce Commission should have to do this,” said Commissioner Atchison. It is federal upon us and we are confronted with a situation of this sort, to be the coal distributor of the country.”

Later, Mr. Atchison said: “I trust the position of the commission in the past that it never seeks jurisdiction is clearly the mind of all the members of the committee.”

Commissioner Atchison asserted his opinion that the Transportation Act, in its emergency clause gives the commission the authority to deal with emergencies of car service and not for medical emergencies to distribute any commodity equally among various sections of the country, and certainly not to order a distribution of cars based upon the price of the commodity these cars are to carry. He declared that Chairman McChord and, he believed, Commissioners Lewis and Cox, held a contrary position that the emergency clause “is broad enough to cover anything that may occur to us as being detrimental to the conditions of the country,” excepting the question of price, but that no other member of the commission, or its chief counsel, had voiced such views and that it was not the policy administered by the commission in its last efforts to handle the car situation two years ago.

The questions of whether the Transportation Act is broad enough to include all emergencies, excepting price control was the basis of considerable debate in Congress during passage of the Wilson-Cummins Act and it generally was answered in the affirmative. Senator Cummins, chairman of the Senate Interstate Commerce Committee, declared repeatedly that the only additional power conferred upon the Interstate Commerce Commission by the emergency legislation was the power to regulate car supply according to the price charged for coal at the mines.

——

Woodin Names District Fuel Administrators

William H. Woodin, State Fuel Administrator of New York, appointed his district fuel administrators last week, all of whom have accepted. They are Arthur S. Leary, of Thoro, Nealo & Co.; Albert E. Cluss, Troy; Clarence B. Kline, Saratoga Springs; Samuel J. Knebel, Binghamton; George D. Bondbright, Rochester; Arthur W. Lawrence, Bronxville; A. Conner Goodyear, Buffalo, and Carlton H. Chase, of Syracuse.

Mr. Woodin held several conferences during the week. In Albany he met his newly appointed district administrators and at a conference in New York City he met the representatives of the public-utility advisory group at which J. W. Lieb, vice-president of the New York Edison Co., presided.

Roderick Stephens, formerly president of the National Retail Coal Merchants’ Association will represent the coal dealers on the staff of the State Fuel Administrator. Harry T. Peters, of Williams & Peters, was appointed Assistant State Fuel Administrator and Girvan M. Snyder will be the director of the bituminous coal division.

The first general order issued by the State Fuel Administrator prohibits dealers from delivering more than a two weeks’ supply of domestic sizes or peat anthracite and then only if a customer has less than that quantity in his bin.

Defends Kentucky-Tennessee Operators

Editor Coal Age:

We refer to statement in your valued paper, page 256, Aug. 17, to say that we deny in toto the malicious implications contained in statement referred to.

Members of the Kentucky-Tennessee Coal Operators’ Association have not profited to the extent that some others have, now active in spreading propaganda detrimental to the Kentucky-Tennessee membership. Our membership is in full sympathy with the Hoover plan to control prices and are co-operating fully to that end with federal and state committees.

The Kentucky-Tennessee Coal Operators’ Association was the first to restore the 1920 wage scale in the mining industry and has no apology to make to anyone. Our operators know, or they think they know (time has proven), the trend of the industrial conditions, that living costs were advancing and that there was a shortage of labor in the steel mills and that they were going to increase wages immediately following settlement of the coal strike, if not sooner. This information coupled with other well-known financial and economic facts indicated clearly we were entering another period of inflation and that the sooner operators realized the situation and made just wage adjustments, the better for all concerned.

The Kentucky-Tennessee Association is operating under a local wage agreement, open-shop basis with no “check-off,” being a modification of the Knoxville 1920 wage agreement, extended to run to March 31, 1924. The principal feature of the modification is the clause providing for wage adjustments from time to time to meet competitive conditions. Under this plan our mines have operated (barring car shortage) almost continuously until the railroad strike, July 1.

J. E. McCoy, Secretary.

Kentucky-Tennessee Coal Operators’ Association.

Knoxville, Tenn., Aug. 26, 1922.

Government Department Reorganization to Be Carried Out; Plan Being Modified

There has not been the slightest surrender on the part of the administration of its intention to bring about practical reorganization of the executive departments of the federal government. A tentative report was laid before the President several months ago. It has not been made public due to the fact that the report as submitted is not acceptable to all of the department heads. It is believed, however, that certain changes in the plan can be made so as to obtain for it the unanimous support of the department heads or at least any dissenting opinions that may be offered will be of minor importance.

Were the report to be sent to Congress without the endorsement of certain of the department heads, it is recognized that the possibility of obtaining the legislation would be lessened. Moreover the legislative situation, since the report was submitted to the President, has been such as to preclude action on reorganization. In addition if the report were made public in its tentative form and before unanimousendorsement by department heads had been obtained, there is a feeling that it would invoke non-constructive criticism and arouse agitation which would serve no good purpose.

It can be stated authoritatively that the reorganization proposal has not been laid aside indefinitely, but will be taken up at an early date.
C. E. Spens to Be Appointed Federal Fuel Distributor, Is Report

Washington, D. C., Sept. 19.—It was stated unofficially today that Conrad E. Spens, vice-president in charge of traffic of the Chicago, Burlington & Quincy R.R., would be appointed Federal Fuel Distributor under the distribution and price-control act.

Mr. Spens was director of transportation of the U. S. Food Administration in 1918 and early in 1919 was appointed assistant in the director of traffic of the U. S. Railroad Administration and later that year also assumed the duties of manager of inland traffic of the U. S. Wheat Corporation. He resumed his official position with the Burlington R.R. March 1, 1920. His home is in Chicago.

Though Anthracite Shortage Is Inevitable, Public Lags in Ordering Substitutes

Indifference marks the attitude of the general run of householders who depend on anthracite for their homes. The same is true of most of the small retail dealers. Ask the man on the street what he has done about his hard-coal supply for this winter and more than likely he will tell you that he has put in his order and that his dealer has told him that he will get the coal all right. "It may be a little later this year than usual, you know, because there has been a strike, but you will get it," is what they are being told. On the part of the householder there is little or no planning to use substitutes. The feeling seems to be that whereas some may have to do with soft coal, this particular fellow stands all right with his dealer and therefore will get his hard coal as usual. Many dealers feel the same way.

The general manager of a moderate-sized house in the East recently sent out a letter to his retail dealer trade, telling them that the supply of hard coal would be short this winter, and belated as well, and suggesting that dealers order some well-prepared soft coal. Just one out of twenty was the way they replied with orders. The order nineteen intended to wait, they said, until they had some orders on their books for soft coal. Then they would order. But, they were told, that would be too late.

The vice-president of another company, producing several million tons of bituminous coal, has found considerable interest in bituminous coal on the part of a certain class of consumers, notably large apartment houses, hotels, schools and churches and this interest is manifesting itself in orders through the dealers. The order starts with the ultimate consumer, however, and the dealer orders soft coal only when he has to.

Opinion is divided among the larger producers as to how serious the situation will be this winter because of the lack of production of anthracite this summer. There are some in high places who feel that they will be able to worry along without causing anyone hardship, that all they have to do is to distribute their larger sizes with care, that there is no cause for alarm. They are said to be advising the several state fuel administrations and officials at Washington to that effect. The result is that there has been little effort on the part of the public servants to whom the people look for advice to get the ordinary man interested in putting in substitutes for part of his winter’s requirements. The figures of production and consumption of hard coal show, it is pointed out, that the country will have but little over 80 per cent supply and that even that will be late in reaching the consumer.

A week ago Mr. Woodin, state fuel administrator for New York, ordered that dealers should in no case deliver a customer more than two weeks' supply. This is considered by the trade as an impossible and impracticable dictum. Two weeks' supply may be, and in most instances is, less than half a ton, they say, and add that they hope for modification setting a minimum of at least a ton. The trade feels that this order, however, has done much to awaken interest in the hard-coal situation.

Next to distribution, price of anthracite is bothering the trade. About half the "company" tonnage has announced circular prices. These prices are little different from those of last March. The Hudson Company has adopted the new range size and quotes that instead of nut and pea. The other companies are said to be disposed to want advances over last year, but as time goes on and the older prices come out, their chance of adding anything is lessened. Independents are feeling their way about with price ranges on the large sizes from $9.25 to $11 per gross ton, having one eye on the Pennsylvania state administrator and the other eye on Washington and the price-control legislation.

Deadlock of Conferences on Coal-Commission Bill May Endanger Its Passage

Washington, Sept. 19.—Failure of the conferences of the two houses of Congress to agree today on the terms of the bill to create a fact-finding commission to investigate the coal industry led administration leaders to express some fear that the deadlock might be prolonged, so as to endanger passage of the measure before the adjournment of Congress.

While this was considered an extreme view, it is true that members of both houses are extremely anxious to end the session this week and adjourn until the regular session, which will begin Dec. 4. Although not considered strictly as emergency legislation, administration leaders are anxious to have the fact-finding bill enacted immediately in order that the commission may be named and begin its labors within a few weeks, so that there may be opportunity for full investigation before the time for the next wage contracts in the coal fields to be negotiated.

Conferences on the bill stated that the deadlock was over the scope of the instructions to the proposed commission, principally because of inclusion by Senator Borah, author of the Senate bill, of instructions to report on the wisdom or advisability of nationalization of the coal mines. The House conferences are vigorously opposed to this clause and also oppose inclusion in the Senate bill of instructions to report on various forms of standardization.
Consolidation Coal Co. Gets Restraining Order in Georges Creek Region

In an effort to prevent crude and coal shipments in the Georges Creek region, the Consolidation Coal Co. obtained a temporary restraining order as Sept. 25, against the officers of District No. 16, which controls the Georges Creek and Upper Districts.

The order denies crews, local organizers and members of the United Mine Workers as defendants, President Francis J. Driscoll being included in the suit. A hearing in the suit is held on Sept. 28, at which time arguments will be made upon the question of making the injunction permanent. Many charges of lawlessness and violence are incorporated in the bill of complaint. The Consolidation and other companies operating in the Georges Creek region have refused to recognize the union in this field. Here as in the Upper Pocahontas district the coal strike is still officially in effect.

The miners are being operated on a non-union basis with a short labor supply.

Fines and jail sentences were imposed on several individuals by Judge George W. McClintic of the United States District Court for the southern district of West Virginia during the course of a special term of district court held during the week ending September 9. These fines and sentences were imposed for violation of federal injunctions issued by Judge McClintic in recent months in connection with the coal strikes. The defendants being adjudged in contempt of court in a dozen cases.

According to reports received in Cincinnati the Kanawha operators who have refused to deal with the United Mine Workers because of the strike-off and other features that are erected are still firm in their stand and each week shows more and more men returning to work in their mines. Some at length of the agreement are taking stock of the situation and are voicing their sentiments. The director of the union corporation wrote his instructors the other day that he had had out $1,600 to the union as check-off money. "This means $60,000 a year that we are giving them as the expenses of war to fight us again when the time comes," was his concluding remark.

Storrow Quits as Massachusetts Fuel Chief

Phelan Appointed to Succeed Him

James J. Storrow has retired from the chairmanship of the state advisory fuel committee of Massachusetts. Governor C. has accepted the resignation and has appointed as chairman James J. Phelan, who has been head of the Boston fuel committee.

The reason given for Mr. Storrow's resignation is that as he is chairman of the Governor's committee to work out a plan for grouping the New England railroads, it has become urgent that he devote his greatest efforts to preparing for the hearings to be held before long in New England by the Interstate Commerce Commission.

It was announced that the fuel committee will continue to seek a fair abatement of coal, an equitable distribution and to restrain prices.

Middle West Does Not Enthusiate Over Ogle Plan for Legislative Conference

Leaders of the coal industry in the Middle West are deeply interested in but not seriously worried by the pending coal legislation in Congress. The idea of national price fixing and control is generally regarded as fraught with great possibilities for confusion and the bills, now in the hands of various committees, that are aimed to create a coal-investigation commission are not regarded with interest because they may very well produce governmental action that will completely subvert the Lewis plan for a fact-finding body of miners and operators. In spite of the fact that some operators profess a desire for Congress to create a federal commission quickly—even before the Oct. 2 Cleveland meeting which President Lewis of the miners' union has arranged—there is general hesitancy in the West about pushing to Washington to express an opinion to the congressional committee which is working over the bill.

The suggestion of A. M. Ogle, president of the National Coal Association, for a meeting of operators either in Cleveland, Buffalo, or elsewhere, this week, to formulate a legislative plan did not receive a favorable reply in Illinois. The position of many operators is that if Congress is going to do something that will cast even greater confusion into the coal business, the quicker it does so and the greater the confusion thus caused, the sooner a normal condition will thereafter be attained.

Logan Mine Marcher Convicted of Treason; Ten-Year Sentence Recommended

Walter Allen, accused of being one of the union marchers on the unorganized mine fields of Logan and Mingo Counties in August and September of 1921, was adjudged guilty of treason against the State of West Virginia by a jury at Charles Town, W. Va., Saturday, Sept. 16. The jury, which was out forty-six minutes, recommended that a sentence of ten years in the penitentiary be imposed.

Allen's bond was increased from $10,000 to $15,000, and he was sent to jail until the higher bond is furnished. Attorneys for District 17, United Mine Workers of America, who conducted the case for the defendant, will appeal to the State Supreme Court for a writ of error.

C. Frank Keeney, president of District 17, United Mine Workers, is the next defendant scheduled for trial. His trial, which is expected to begin Oct. 23. He is also indicted for treason. There have been two previous convictions and one acquittal so far, the Rev. James E. Wilburn and his son John having been convicted of second degree murder and William Blizzard, the first to be tried, acquitted.

Herrin Grand Jury Resumes Its Work

On Monday, Sept. 18, the Williamson County grand jury, which has already indicted 59 men in connection with the massacre of a score of non-union miners and the wounding of 30 others at Herrin, June 22, resumed its investigation at Marion, Ill. It is expected the jury will not open its work soon. Of the 59 men indicted, many are still at large though the Williamson County jail with its remodeled tier of cells is about full. Men indicted for murder have been refused bail but those indicted for conspiracy to kill are out under bond given through lawyers for the miners' union. Prisoners are fed the best that the Marion restaurants can supply and at the expense of the union. This relieves Williamson County of part of the heavy cost of the case.

ARTHUR W. AMBROSE has been selected to succeed E. A. Holbrook as assistant director of the U. S. Bureau of Mines. Mr. Ambrose has been in the service of the Bureau since 1917, during which time he has risen through the various grades from petroleum technologist to chief of the petroleum division of the Bureau. His appointment as assistant director is an indication of the increasing importance of the Bureau's petroleum work. F. B. Tough, who has been serving the Bureau as chief supervisor of oil and gas leases, will succeed Mr. Ambrose as chief petroleum technologist.

F. J. Bailey, the assistant to the director, under a re-arrangement of the work, will take over a portion of the duties formerly assigned to the assistant director so as to allow Mr. Ambrose to give a portion of his time to the petroleum work. Salary provision has been made to compensate for Mr. Bailey's enlarged responsibilities.

STUYVESANT PEABODY, president of the Peabody Coal Co., automatically assumes the office of chairman of the board lately vacated by the death of his father, Francis S. Peabody. Thus is ended a great deal of speculation throughout the coal industry as to who the successor of the late Mr. Peabody would be. There remains a vacancy in the directorate of the company that has not been filled. No other changes in the personnel of the company are to be made, it is informally stated at the company's headquarters in Chicago.
Pledge Aid to Expedite Movement of Bituminous Coal; Distribution on Highest-Bidder Basis Decreed

A pledge by leading commercial interests to aid in expediting the natural processes of increased supply, in order that the price of bituminous coal may be kept down and complete supplies be assured the householders and industry, was given at the conference on the bituminous coal problem held last week at the Department of Commerce in Washington. At the same time determination was evidenced on the part of the government that advantage shall not be taken of the recent strike to exact high prices for coal. Officials of the U. S. Chamber of Commerce, the American Railway Association, the National Association of Manufacturers, the National Association of Purchasing Agents and the Public Utilities Associations met with the Secretary of Commerce, H. Foster Bain, Director of the U. S. Bureau of Mines, and C. B. Aitchison, of the Interstate Commerce Commission.

Secretary Hoover, in opening the conference, stated that the government welcomed the co-operation of the commercial and industrial community in solving the situation. It was most desirable, he said, that readjustments in prices and distribution take place by the natural means of increased supply and the holding down of consumption pending such increase. Protection for the public must come, he warned, by one means or another.

"In every situation such as this," the Secretary said, "there are social considerations which absolutely override the economic. The government cannot permit the distribution of coal this winter on a highest-bidder basis. That condition during the present emergency is an impossible social condition."

The Secretary stated that while the bill pending in Congress would give powers to embargo shipments of extortionate priced coal moving in interstate commerce, the federal government could exert no constitutional control over coal produced and sold within state boundaries or over speculation in interstate coal once it had reached its destination. Many states were taking drastic legislative powers in these domestic matters and unless the situation quickly improved no doubt many more of them would do so in order to protect their citizens.

It was agreed that the mines had ample capacity, even to the point of surplus, to meet the situation, that the problem was wholly one of transportation, and that the price would ameliorate if transportation could be increased and if in the meantime consumers would purchase only for their immediate needs.

The conference voted to organize voluntary campaigns for three major purposes:

1. To induce manufacturers, utility corporations and buyers generally not to purchase coal beyond their day-to-day needs until the flow of coal becomes more normal.

2. To persuade holders of contracts not to call for delivery on those contracts past their day-to-day needs. It was considered that about one-half of the coal in the country is under contract at normal prices and that a relaxation in the demand for this coal to the minimum daily requirements would increase the supply to the general public.

3. To expedite movement of coal in every possible way.

The co-operation of the responsible coal operators in these matters will be sought.

The question of priorities in coal movement was discussed at great length, it being the consensus of opinion that the problem that more mobility would be given to those areas with less of the supply for special purposes and the priorities to special uses, which have been necessary prior to the reopening of the union mines, should be relaxed and priority parallel with agricultural produce should be given to the movement of all coal without discrimination as to consignees. It was also pretty generally the opinion of the meeting that all reconsignment rights upon coal should be abolished in order to prevent speculation in coal.

It was decided to organize special committees under the leadership of the U. S. Chamber of Commerce to advance these purposes. Those present were:

Harry Conly, Pickands, McQuiddy & Co., Cleveland.
R. F. LaMond, American Steel Foundries, Chicago, Ill.
A. A. Lamborn, American Radiator Co., Buffalo, N. Y.
A. S. Clarke, Connecticuta & New York.
J. P. Jackson, representative, Baldwin Locomotive Works.
S. M. Vannin, president, Baldwin Locomotive Works.
W. Atterbury, president, Interlake Steamship Co., Chicago.
R. C. Wright, general traffic manager, Pennsylvania System.
C. W. Sneed, chief of transportation, Pennsylvania System.
S. Barr Perch, general traffic manager, Pennsylvania R. R.
J. N. Spiker, coal traffic manager, New York Central Lines.
A. N. Needles, vice-president, Norfolk & Western Railway Co.
D. E. Spangler, superintendent of transportation, Norfolk & Western Railway Co., Roanoke, Va.
J. E. Purser, general superintendent transportation, Illinois Central Railroad Co., Chicago.
H. W. Miller, vice-president, Southern Railway System.
C. B. Kellogg, vice-president, Monson Steamship Lines.
H. H. Carpenter, president, National Association of Manufacturers, Nashville, Tenn.
Nathan H. Williams, associate counsel, National Association of Manufacturers, Nashville, Tenn.
Frederick Nash, associate counsel, National Association of Manufacturers, Nashville, Tenn.
Conrad E. Spens, vice-president, Chicago, Burlington & Quincy R. R.
Charles K. Foster, vice-president, American Radiator Co., New York.
J. A. Campbell, president, Youngstown Sheet & Tube Co.
D. Willard, president, Standard Oil Co.
R. H. Vors, president, Chicago, Rock Island & Pacific R. R.
M. J. Gormley, chairman, Central Traffic Co., Kansas City, Mo.
Charles D. Aitken, associate general counsel, Self-Service Commission.
C. G. Hoxie, director, Bureau of Service, Interstate Commerce Commission, Chicago.

Alexander Logan, president, International Harvester Co.
Julius H. Barnes, president, U. S. Chamber of Commerce.

F. E. Waddish, Department of Commerce.

Acting on the recommendations of Friday's meeting the Chamber of Commerce called on national business associations, local chambers of commerce and individual corporations and firms in an attempt to equalize and expedite the distribution of coal and to prevent prices from soaring to undue levels.

Full co-operation by all concerned, the Chamber declares, will enable the federal and state governments of increasing regulatory legislation and will be welcomed by the administration as offering a promise that business itself will solve its problems without injection of government into its affairs.

Industries throughout the United States are asked in a letter which is being sent out over the signature of Julius H. Barnes, president of the Chamber, to lend their assistance to the effort by performance of the following acts:

1. Confine purchases of coal under present conditions of supply to current needs only as safety permits.

2. Suspending accumulation of advance stocks of coal until the present emergency passes and production is relaxed. This particularly applies to persons having low-priced contracts and who are, therefore, under no price pressure to withhold necessary delivery.

3. Distributing coal among immediate and retaining them to service.

4. Promptly furnishing names and addresses of coal handlers and equipment or repairs.

5. Cooperating with the government in the purchase of local railroad, electric and steam equipment and in the establishment of local lending banks to accommodate them in the purchase of local railroad, electric and steam equipment and in the establishment of local lending banks to accommodate them in the purchase of local railroad, electric and steam equipment.

In his letter to industries, Julius Barnes, president of the Chamber of Commerce of the United States, says: "It is obvious that the bituminous coal problem is one solely of transportation, as the productive capacity of the mines is able to care for the current needs and at the same time to supply the normal amount of coal under the law of supply and demand."
Production is being held in check by the diminishing supply of cars and the congestion of loads. The surplus of empties on hand when the strike ended has dwindled to almost nothing and a shortage is now general. Car shortage usually enlivens the market, but so far this one has had little stimulating effect on prices. With the exception of the growing Midwest demand for domestic coal, caused by the approach of cold weather, bituminous coals weakened all along the line and Coal Age Index of spot bituminous prices declined to 412 on Sept. 18 from 427 last week. This represents an average mine price of $4.99 as compared with $5.17 the previous week.

The lowering prices continue to hold back orders. Consumers, anticipating that the rail strike is about over, argue that with the roads functioning properly they should be able to pick and choose their replenishments at prices that are more attractive than at present. So, while the quality fuels still make easily much of the tonnage now produced is sold under strongly competitive conditions. Nevertheless there is a wide range in quotations and a strong undercurrent of belief that the market is due before long for a long sharp upturn.

JAM OF LAKE COAL AT LOWER PORTS

Priorities are taking most of the production. Shipments under Priorities 1 and 2 have eliminated free tonnage for general demand, particularly from those fields shipping to the Lakes. The pressure on Lake shippers has forced a jam of 12,000 loads at Erie ports awaiting dumping. Slow vessel movement, disability of machines and multitude of pool classifications is responsible for the congestion, to offset which barges have been placed in several fields. These are only temporary, although they cause the priority shipper to coast around in a hurry for another outlet, often at a cut price.

The situation in the Northwest is improving. More coal is afloat and while Canadian, Lake Michigan and river points are obtaining more than their share, the upper docks are sure to benefit. The Northwestern buyers' strike shows signs of weakening. The Great Northern R.R. has just purchased 600,000 tons of Lake and rail coal, setting an example which it is hoped others will follow, so that the docks can cover on seasonal commitments while there is yet time. It is not anticipated that to exceed 50 per cent of the requirements on Lake Superior will be moved up the Lakes.

Heavy arrivals of British coals have congested the Atlantic seaports. Demurrage costs are large and it is evident that few new orders will now be placed. Southern coals via water are plentiful, especially since a N. & W. embargo on west-bound movement makes mandatory larger shipments to Hampton Roads.

Anthracite has commenced to move in good volume. Production is not expected to reach normal before Oct. 1 at the earliest, but mines are seeking to reach maximum work time as soon as possible. The resumption has drawn many cars from the soft-coal fields, where they had been used during the strike. But few prices have been announced although all sorts of independent quotations are rumored, ranging from 50c. above old company schedules up to $14 for the family sizes. Half of the companies have announced circular prices approximating their old schedules and absorbing the Pennsylvania State Tax. No settled policy of distribution has as yet been made. The entire movement so far has been eastward and no coal has been sent to the Lakes.

BITUMINOUS

Production of bituminous coal during the week ended Sept. 16 may reach 9,500,000 net tons, according to the Geological Survey, based on statistics at hand when the report was issued.

(a) Subject to revision. (b) Revised from last report.
Seventh 9 show 8,758,000 tons, which, although less in the aggregate than for the week before, was at a higher daily rate, the holiday (Labor Day) considered," says the Survey. "For last week (Sept. 11-16) the output of bituminous coal is not expected to exceed 9,500,000 tons. Over the three-weeks period following general resumption of mining under the Cleveland agreement production has been at a rate less than 9,500,000 tons a week."

LAKE LOADINGS PASS 1,000,000-TON MARK

Priority movement to the Lakes has increased rapidly in the last few weeks. Dumpings were 1,058,600 net tons during the week ended Sept. 10-10,650 tons and 30,926 tons vessel fuel. The season's movement is now 7,453,307 tons, as compared with 17,669,670 tons last year.

Tidewater dumpings at Hampton Roads increased to 341,558 net tons during the week ended Sept. 14 from 315,628 tons in the preceding week. The C. & O. piers showed a decline, the others a substantial increase. Accumulations at the piers are growing as the railroads are able to make quicker deliveries. New England is taking the bulk of the tonnage dumped, although the surfeited condition of that market is making it increasingly difficult to place spot coal.

Tidewater business has been greatly affected by the strike, chiefly through the curtailment of exports. The total of 18,988,000 net tons dumped during the first eight months of 1922 was a third less than the average during the three years preceding. The principal factor in the decline was a drop in exports to 1,592,000 tons. During the corresponding period in 1920 and 1921, 3,049,000 and 8,782,000 tons, respectively, were exported overseas. Dumpings for bunkers also decreased sharply to 3,171,000 tons, which was little more than half the 1921 figure. Waterborne shipments to New England were greater than in any of the three years.

## Anthracite

Production of hard coal started promptly after the ratification of the wage agreement on Saturday, Sept. 9. Work was resumed the following Monday and the loadings—1,783 cars—while not large, are encouraging evidence of the operators' determination to lose no time in filling the gap caused by the strike. In the last week of the strike 63,000 net tons was loaded, principally steam sizes dredged from the rivers.

Consumers are not yet clamoring for coal but with the first cool weather the distribution problem will be a difficult one. Small lots only, of course, will be doled out for many weeks to come. Not much substitute fuel has been purchased, as the feeling prevails that bituminous coal can be had quickly if needed.

## Coke

Production of beehive coke was 139,000 net tons during the week ended Sept. 9, practically unchanged from the preceding week. Connellsville prices are unchanged, offerings are very light and the takers of merchant coke are largely miscellaneous users. Furnaces are only occasionally in the market because of the prevailing high prices and variety of grades offered.

Foreign Market
And Export News

British Prices Sof ten as
American Buyers Withdraw

French Market Improves as Result of
Diversion of British Coal to America,
but Wages Are Still Vexing Issue—
Labor Unrest Upsets German Trade.

British shippers feel the slump caused by the withdrawal of Ameri-
can buyers. Prices have dropped to
a point where they are attracting
new business from the Continent and
South America. An attempt is to be
made to effect a further reduction in
British rail freight rates.

The French market has improved
materially. Emergency business in
America, secured by Great Britain,
diverted much tonnage that had been
entering France to the detriment of
home fuels and mines have been able
to clear their heavy pit-head stocks.
The wage controversy still continues
and has resulted in an ultimatum by
the owners, announcing a cut in pay
as the last resort.

Germany is in the throes of labor
shortage and unrest. Production is
not ample for her own needs and
imported coal is flooding in, further
depreciating the value of the mark.

Declining British Prices Attract More
Continental Buyers

British shippers are very active in
filling all orders for the United States.
This movement continues around 200,-
000 tons weekly. New business from
this source is falling off rapidly, but
prices have receded, attracting more
buyers from the Continent and South
America. Germany is seeking a heavy
tonnage but shippers are cautious in
accepting these orders because of Ger-
many's unstable financial condition.
Production during the week ended
Sept. 2 was 5,204,000 gross tons, ac-
cording to a cable to Coal Age, close
to the record for the year.

The recent increases in the retail
prices of household coal have led to
much speculation as to the causes that
prompted them. What has happened
is this: Recent developments have led
to an increase in demand for certain
varieties of house coal produced at cer-
tain mines. The inevitable effect of
an increased demand is the same in the
coal trade as in every other industry
for producing or manufacturing com-
modities—there is a tendency for prices
to rise.

It is no longer a case of disposing
of stocks and cutting losses, but of
producing something approximating
an economic figure. It is not reason-
able to expect colliery owners more
than anybody else to sell at an actual
loss. This explains the slight increase
in prices, which, however, is sent only
a fraction of the amount which has
been taken off the price of domestic
varieties since last autumn.

The failure of representatives of
the collieries and ship-owners and the
men to come to an agreement on the ques-
tion of the three-shift system in re-
spect of the northeastern ports has
cause profound disappointment.

Overtime may do something to help
matters, but it is by no means a satis-
factory substitute for the third shift.
It is all the more regrettable at a time
when unemployment is so prevalent,
for the additional "turn" would have
absorbed an amount of extra labor.

As far as the collieries are con-
cerned, the continuance of the two-
shift system must tend to congest traf-
cic, check output, and from time to
time hold up operations.

The Mining Association has issued
a statement pointing out that the Scot-
tish coal trade is entirely unaffected
by the reductions recently conceded by
the Scottish railways to the representa-
tives of the P.B.I. Except in respect
to coal for shipment and for ironworks,
the rates remain at the maximum at-
tained in September 1922, 100 per
cent of the pre-war rate, plus 6d. per
ton flat rate. The representatives of
the Scottish coal owners met the Scot-
tish railway managers recently to
press for a substantial reduction.

The English and Welsh railway com-
panies are again to be approached by
the Mining Association of Great Brit-
ain with a view to obtaining a further
reduction on the rates for the carry-
ing of coal. These, under the agree-
ment which took effect at the beginning
of the month, are 60 per cent above
pre-war level with the addition of a 2d.
flat rate. It is the prevailing opin-
ion in all branches of the coal trade
that these rates should be reduced to
50 per cent and the flat rate abolished
altogether.

It is understood that the subject will
be reopened at the Railway Clearing
House late this month.

Outlook Improves at Hampton Roads

The situation was without much
change last week, some slight improve-
ment in coal movement being noted. A
better supply of coal was on hand at
the piers, while a slight increase in dump-
ings took place during the week.

The market was somewhat easier,
with prospect of increased movement
on the three roads serving the port. The
downward tendency in prices on the
spot market continued, reaching a low
of $85 during the week.

Some prospect of a revival of export
business was seen. One cargo of 9,000
tons moved to the Canal Zone. All
ships were being hunkered with fair
regard to lines of the present embar-
rassing difficulty in serving the trade. Delay
in service was being steadily diminished.

French Market Improves; Miners' Wage
Cut Is Imminent

The present selling activity of the
Northern and Producers' coal 
mainly satisfactory. House and indus-
trial coals are good demand, and
picket lines are being further reduced.

Some idea of the amount of British
coal received at Hampton Roads dur-
ing August did not amount to daily aver-

Sept. 21, 1922  COAL AGE  471
Germany Must Check Flood of Import Coal by Working Longer Shifts

The coal situation in Germany has again become one of the chief topics of the day. Complaints are raised in all public and engineering meetings and the situation is affecting the industry in 1921. It is being pointed out that the imports coming from the coal districts show a steady decline in the past, with a slight rise last week. Imports are rising at an alarming rate. Import coal is mostly used in the shipping trade, which is growing steadily, and it is feared that domestic coal will be penetrated further inland, and the coal situation in the Ruhr area is being felt. The situation is not as serious as it was in the past, but the situation shows some signs of improvement.

The coal situation in Germany has been such that the manufacturers have been forced to import coal to meet the demand. The coal situation has been affected by the decline in the Ruhr production, which has dropped to a new low. The import coal has been used to meet the demand, and the coal situation is not as serious as it was in the past. The coal situation in the Ruhr area is being felt, and the situation shows some signs of improvement.

Coal Paragraphs from Foreign Lands

ITALY—The price of Cardiff steam first is now 40s. per ton according to a cable to Coal Age. Last week's figure was 42s. 3d.

A note from Milan says that Italy is feeling the indirect effect of the American demand for coal. The coal business is not as active as it was in the past, but the demand is still strong.

GERMANY—Production of coal in the Ruhr region during the week ended Sept. 3 was 1,792,000 metric tons, according to a cable to Coal Age, as compared with 1,819,000 tons in the preceding week.

SWEDEN—According to a message from the Stockholm ship owners, the export trade to Spitsbergen this year, beginning with July, will be directed to Gothenburg instead of Narvik. The trade is expected to be carried by both Swedish and German ships, which still charge considerably lower freight rates than Swedish vessels.

BELGIUM—The coal market shows signs of greater activity, even in the Belgian coal districts. The export trade of coal in Belgium has been considerably reduced, owing to the low strike in the United States. Competition on the part of British coal is no longer so much felt as it was on the Belgian market. The coke market has also improved as a result of consignments to France and Luxembourg.

NEW SOUTH WALES—Coal shipped from Newcastle outside the state during June amounted to 347,273 tons, as compared with 362,012 tons in June, 1921.
North Atlantic

Spot Prices Sag as Demand Drops and Receipts Mount

Consumer Nurses Belief That Heavy Offerings Will Produce Bargain Replenishment Prices—Car Shortage Handicaps Output—Market for British Coal Hard Hit.

Consumers are not taking more coal than they actually need for current use. Heavier receipts, coupled with the weaker demand, have lowered spot prices still further. The weakness is attributed to the consumer’s belief that, with the rail trouble over, the volume of offerings will depress prices to a point where he may replenish his supply. The car shortage is proving more troublesome, however, reducing production at the recently reopened mines and it is hard to see how prices can go much lower. The anthracite resumption has also taken away many cars that had been used in the soft coal industry during the strike.

The market for British coal is hard hit and new business is scarce. Cargo receipts have been heavy and discharging is slow, resulting in heavy demurrage costs.

NEW YORK

The receipt of anthracite had its effect upon the situation. Buying was quiet throughout the week. Car supply is playing a prominent part in the situation. On the B. & O. and Pennsylvania it was estimated that there were about a 50 per cent car supply while along the Oswego and B. & P. complaints had to do with locomotive equipment.

Southern coals came forward in good volume, with the exchange averaging $14.50 per ton New York harbor. Considerable British coal arrived here during the week. Railroads and public utilities continue to receive it, but it was reported toward the end of the week that the enthusiasm was dying down and that orders were not being placed so freely. During the period, Sept. 7-14, 19 vessels arrived in this port with 114,591 tons. While most of it was on order there were some free cargoes which were offered to local houses around $8.25. Consumers were also offered Welsh anthracite at $14.50 per ton.

There were 1,446 cars at the local piers on Sept. 15, considerable of which was on order.

UPPER POTOMAC

Still further gains are being made in the output of the Upper Potomac as men gradually drift back to work. All the cars needed are being furnished, despite the shortage on other roads. Although there are a few mines in operation in the Georges Creek region, most of the miners are still on strike. Strange. There is even a mad rush to sign agreements, however, are attempting to operate with varying degrees of success and a few companies have signed an agreement with the union.

FAIRMONT

Between a holiday at organized mines on Sept. 4 and a most acute shortage of equipment less coal was produced during the week ended Sept. 14. The car supply was on the day following the holiday but as soon as the accumulation had been absorbed, the supply dropped again and many mines were forced to close for several days at a time. Mines having orders in preferential classes were given cars for the most part. Lake shipments were on a fairly large scale. As far as spot coal was concerned the price ranged $4.50 to $6.25.

CENTRAL PENNSYLVANIA

Operators and miners alike are reaping a big harvest and production is steadily increasing throughout the entire union territory. In Somerset County, where the operators refused to sign the agreement, production is somewhat curtailed owing to the inability to secure a sufficient number of men. The shortage of cars is already being felt and it is feared the pinch will seriously affect production before long. The reopening of the anthracite mines has already felt the effect of taking cars from this field.

During the strike, many new operations in Clearfield and Cambria Counties were prepared for production and are now in operation and the capacity of the railroads entering these fields is taxed almost to the limit.

PHILADELPHIA

Car supply more than anything else is dominating the situation. The consumer having found the shippers anxious to accept orders, is now becoming somewhat anxious that deliveries have slowed down.

There have been moderate receipts. The Pennsylvania continues to give the best service, but this road is also beginning to feel the transfer of many thousands of cars to the anthracite trade.

Buyers in many instances areやはり making heavy commitments at present, fully believing that much lower figures are due. There has been a particular tendency for high-grade coal to become scarce, as the smaller consumer seems intent on buying the best now, after having put up with some very inferior fuel during the past few months.

Some of the central city buildings which had shifted to bituminous coal on account of anthracite shortage have been both satisfied and pleased, and are now inclined to try out oil. For the present, winter this will not worry shippers and many still express the opinion that the increasing cost of freight will eventually offset all of its advantages.

The end of the month will probably see the last of the British receipts, as no new business has been placed. It is difficult now to interest the larger consumers in this coal.

Baltimore

While nobody is laying in any material amount of soft coal for storage, due to both the urging of producers and the fact of a wide distribution as possible and to the thought on the part of a number of consumers that they may get better prices later, demand for anthracite is keeping well up with the receipts. This has a tendency to hold prices firm, except that there is a little wider distinction between classifications.

Demand has been for the sweeping embargo placed by Eastern railroads on freight competing with coal which is being speeded up the movement that has been delayed by coal freight applied for the way for the rush of anthracite shipments that must take place if the public is to be protected.

Except for the taking the English coal and some other substitutes, the usual burners of anthracite here have ignored the suggestion that they lay in stocks of soft coal. In many cases consumers who have taken British fuel report excellent results, and a number of smaller houses, some who bought with the expectation of getting practically all lump, and who received instead a broken-up coal through frequent handlings, have complained to their dealers.

West

SALT LAKE CITY

The agitation here against the recent increase in price has grown so severe that an official investigation may be made. Talk of placing mining under the control of the public utilities commission by special legislation. The Salt Lake Telegram has led the attack from the first, criticizing the railroads on the retailers because they have no organization whereas the operators of the state have none.

One company with mines in Wyoming has announced a reduction of $1, which brings its retail price back to 90. It is claimed that this coal is of a inferior grade, but its producers deny this. The agitation has big enough to be found and customers are very hostile. The newspaper responsible for the trouble is trying to show that costs of operating are no higher than they were before the strike, if at all.

Production continues satisfactory, except as far as the car supply hinders.

KANSAS CITY

An ample supply is being produced in the Southwestern states in care for all demands. Much is turning up, too, from handling the coal in an expeditious manner. Very little steam coal is coming in from outside fields.

Prices for domestic coal are higher than last year, due to the low prices on steam grades that must compete with fuel oil. The higher grade of domestic coming from Oklahoma, commonly known as second anthracite, is being quoted at $8.50 for car loads and slack is going begging at $7.

September 21, 1922
Anthracite

East Gets Fresh-Mined Coal Soon After Resumption

No Lake Tonnage Shipped—Western Markets Not Likely to Receive Any for a While—Some Prices Named but Companies Not Releasing Coal Pending Their Own Announcement.

Fresh-mined coal put in a prompt appearance in Eastern markets following the resumption of mining. The entire movement so far has been eastward. No Lake tonnage has been shipped and little is anticipated before Oct. 1, while Western markets will receive little hard coal for some time.

Prices have been published by only half the companies as yet, and no settled policy of distribution has been made. The announced prices adhere approximately to the old circulars, absorbing the State Tax. Companies are not releasing their coal to dealers at destination pending their announcement of prices. Independent coal is moving on sales ranging $9.25—$14 on egg, stove and nut.

BUFFALO

Some coal is said to be on the way, so that it remains to be seen what will be done with it. The administrator for the district has not given out what he intends to do. The local distributors were not allowed to place the coal as they thought best, will give it out in small quantities until every consumer has had a share. No real coal yet it is expected that most of the coal will be sent up the Lakes for awhile at least.

One point also to be considered is the price to the companies will make. It appears that even the independents do not know what to expect, for as yet they have declined to give out any price.

NEW YORK

The delay of the larger producing companies in announcing their prices at the mines for the various sizes caused some uneasiness among the retail dealers. Coal has been coming forward in increasing volume since early morning of Sept. 1, when the first shipment, consisting of 40 cars, arrived at Port Amboy.

Retail dealers took in whatever coal they could get without waiting for the prices, as the general average being around $10. Some few operators were reported as quoting $11.50. Per quotings ranged $8.25—$8.50; buckwheat, $5.00—$5.50; range, $5.25—$6; barley, $2.50—$3.25. Many consumers of anthracite have apparently put in a supply of bituminous coal to tide them over until plentiful. Because of this retail dealers do not look for much rushes before it is time to start furnaces.

BOSTON

Retailers are much relieved to find that large are winning to be assigned at the Philadelphia and New York piers. The process will be slow for awhile, but it is something to have a light gain in output from the mines each day. Originsiting companies are slow in announcing prices. Eight dollars and fifteen cents has been named by one producer for grate, egg, stove and range and chestnut or peat, while still another that was classified in 1918 as "indispensable" has named $8.25 as the figure for egg and stove.

ANTHRACITE FIELDS

There seems to be quite a shortage of labor at the mines, many of them reporting that they are short from 30 to 40 men each. At the same time, the general average being around $10. Some few operators were reported as quoting $11.50. Per quotings ranged $8.25—$8.50; buckwheat, $5.00—$5.50; range, $5.25—$6; barley, $2.50—$3.25. Many consumers of anthracite have apparently put in a supply of bituminous coal to tide them over until plentiful. Because of this retail dealers do not look for much rushes before it is time to start furnaces.

PHILADELPHIA

Some coal is now arriving in the city, being evidence of the railroads' intention to give the best of service.

The one drawback to better shipments is that the mines have not been able to reach about 60 per cent of their production, due to lack of men. It is believed that normal production will not be approached before Oct. 1.

The companies have not yet announced prices, although some independents have set schedules. At least one of the latter have announced $8.25 for egg, stove and nut, and $6.75 for peat, but most of the independents who have given out prices are 25c. higher than this all sizes. There was quite a definite rumor that one of the small concerns was asking $14.

It would seem that the companies are intent on increasing their prices of last March by 25c—30c., but are having difficulty to convince the various fuel authorities. Those who speak for the Government have repeatedly stated that there would be no increase over prices prevailing last March. It appears that the companies are determined to cover themselves for the State tax and something in addition for the losses suffered during the past five months.

Baltimore

Anthracite men here are figuring that they will probably get some fair receipts around the first of October. As a rule Baltimore gets some cold snaps in November and dealers realize that they have only about one month in which to make deliveries. They are now figuring for the most part to hold down their deliveries to small lots. An open early winter will certainly prove a blessing not only to the public but to the coal men.

Coke

CONNELSVILLE

Car shortages are now frequent and it is plain that the strike, which continues in a way, must take a remote place as constituting any factor in limiting the total output of the region. A very important proportion of the present working force are men far out of the region, some imported by definite arrangement, some drifting in from union districts. Evictions have become common, as the houses are needed for workers.

Coke prices are quotable at precisely the same level as a week ago. There is a free movement in the foundry coke market but of limited proportions. Offerings and demand are relatively light, many foundries being unable to pay prices now asked for pig iron.

In furnace coke the market is very narrow, sales being usually to water-gas producers, lime burners, bakeshops, etc. Furnaces are only occasionally in the market, which presents a far from inviting aspect. Only one lots can be picked up, usually of indifferent grade, and any furnace attempting to operate on open-market purchases might have to use it.

The Courier reports production during the week ended Sept. 9 at 77,920 tons by the furnace ovens and 20,010 by the merchant furnaces, a total of 97,930 tons, an increase of 7,030 tons.

BUFFALO

The situation does not clear up as fast as the bituminous coal trade does, for the standard ovens do not appear to be open and accounted for. About three dozen coke furnaces.

Recovery from the coal strike is now dependent upon the ability of the railroads to provide transportation. While the number of strikers who have returned to work is yet negligible there has been sufficient labor secured to load all the cars placed. The policy of evictions continues without abatement but instead of locating in tents near the above evidence the strikers are gathering up their belongings and going to other fields.

Furnace operators are again looking toward the Connellsville region for coke requirements and there are numerous active inquiries for tonnage, with at least one contract closed for 15,000 tons, delivery in September.
Shortage of Cars Cuts
Middle West Production

But Fields Working at 30 Per Cent Can Meet Fair Domestic and Light Steam Demand—Prices Generally Firm but Screenings Are Softening.

This region is having its troubles. Car shortage is the greatest of them. Railroads have been totally unable to supply enough cars to handle even a fair-sized output. Generally speaking, car supply has been about 30 per cent although it has averaged a little better than that in the central and northern Illinois regions where hauls average shorter and where several railroads are able to make most of their coal deliveries on their own lines without letting loose of their cars. The sharp restrictions upon production have reduced the available coal on the market to a point which makes it possible for a few jobbers to hike prices on domestic sizes although company circulars show few increases over those of last week.

Steam demand is still light. Buyers appear to expect a drop in the price of screenings. They were rewarded with a 25c. reduction on central Illinois and on the Chicago market every day or two big consumers were able to gather in large lots of mine run and screenings that had been shipped on consignment and were getting into distress. The price went as low as $2.90 in one case. St. Louis, with less coal available, steadily maintained as high a scale of quotations on most coals as prevailed in Chicago.

SOUTHERN ILLINOIS

Box car supply has almost put the Carterville field out of operation. This week will show about a two-day car supply. Some mines are getting less than that but few get better than three days. An average would show about 25 to 30 per cent.

Some of the mines are loading almost entirely railroad coal on account of the increased traffic which means the railroads cannot assign cars to mines and give the mines more working time than competitive mines working on commercial business. This has practically tied up some of the big fields in Illinois and is the subject of much controversy at the present time.

Prices vary from day to day, but always going higher. There are no unusual labor troubles. Everything is quiet, excepting that the miners are uneasy over working time. Somewhat similar conditions prevail in the Duquoin field. Mt. Olive district gets about 300 cars daily, and the priority ruling that everything must be billed out in class 2 of Order 23 of the I. C. C.

CHICAGO

Coal trade on the Chicago market maintained its comparatively even way during the past week. The demand for domestic sizes of Illinois and Indiana coals continued sufficiently strong to hold last week's increased price firm and the call for steam sizes continued so weak that some operators stored fire coal on the ground in order to use the scarcity of carfith for more profitable shipments. Practically no coal other than the output of those two states was traded in here. A little volume of coal from the West was moved at prices ranging from the Hoover level of $4.50 plus 8 per cent, up to $7.50 for a little that got into the hands of jobbers. It is expected that smokeless coal will continue here in fair demand as soon as it can be had. Certain heavy priority orders are filled by the producers.

Steam buyers still are holding aloof and have been losing every day or two by the chance to pick up large lots of mine run and small sizes, that have been moving into this city on consignment more or less regularly. Although screenings and screenings have not dropped below $3.50 in any case except the central Illinois field, these consignment shipments often have sold for as low as $3.25.

Output has been so restricted by car shortage on practically every railroad serving the Illinois and Indiana fields that the market glut predicted at the end of the strike by several big buyers, and still confidently counted on by them, has not yet appeared.

INDIANAPOLIS

A scarcity of cars is reported from virtually every coal county in the state, and despite the approach of cold weather, has not been very active. Both industrialists and domestic consumers are waiting until the last minute to buy in the hope that the price will drop. Some quotations for Indiana coal at the mines have reached as high as $5.75 and foreign mined coal is very scarce. Only from this week the Indiana office of the Indianapolis reported quotations of $4.75 for screenings at the Indiana mines. At present quotations Indiana coal will cost the consumer about what Pennsylvania did last year.

WESTERN KENTUCKY

It is claimed that unless Northern lines return cars more promptly, profits made in the summer may be turned into losses, as car supply is reported at around 17 per cent on the L. & N., and about 63 per cent on the I. C. The latter was furnishing 100 per cent prior to the reopening of Northern mines. The I. & N. supply is as bad as it was at the worst. Operators report good demand for all sizes, but are producing very little other than mine run.

Retailers are demanding lump more freely, while general demand for steam is picking up. With priority orders practically off the market, there is more and more coal moving for general use.

LOUISVILLE

With a full car supply it is felt that there would probably be some trouble in selling production. But with a car supply estimated at 50 to 75 per cent in Kentucky, and between 15 and 30 per cent in Indiana, the coal trade is excepted on the I. C. C., which is reported to have about 65 per cent, operators are not making much headway in meeting demand, and so far there has not been much domestic stocking, as retailers are not supplied, and producers are not making prepared sizes in any amount. Eastern Kentucky production is so small that by the time contracts are filled and some Lake coal shipped, there is very little left for general utilities, gas and byproduct plants, steel and general industrials, to say nothing of the retailers.

With the whole country demanding coal, movement on shorter hauls will eventually slow down demand, but in the meantime prices are holding and are a little stiffer. Jobbers report that eastern Kentucky lump is quoted as high as $7.50 this week.

ST. LOUIS

The present week shows an improvement in the demand for domestic coal. Several of the big companies have suspended prices on Cartersville, being unable to get it, even though they offer $6 at the mine. The dealers are here in it. Olive points which retail at $7.50, though some dealers are charging slightly in excess of this. Standard is moving slowly on account of price, excepting on contract for apartments, of the like.

No smokeless and no Arkansas has arrived thus far, but some anthracite is promised for late in the season. Steam trade is quiet. As a general rule the steam trade is fairly good. Several steam plants are unable to get any coal on account of the heavy ruling, even though the mines are reported as not.

The situation is an uncertain one and carries with it an air of anxiety for the future.

Canada

TORONTO

There is now no immediate sight and it is not expected that any considerable quantity will be received and in the market. All supplies available are on the Lakes. Demands come from the machines, as a rule, only in small quantities for present needs.

Quotations for bituminous coal are 10c. for 75 pounds and 75c for 500 pounds. Some fluctuations from day to day. British coal is beginning to show. The Welsh coal entered in the last week will be released for local.
COAL AGE

Vol. 22, No. 12

Eastern Inland

Output Rests on Car Supply: Congestion Slows Deliveries

Production is now measured by the car supply. Line congestion is slowing deliveries, but despite these warnings the consumer remains out of the market, except for his day-to-day needs. Prices have declined further.

The slow movement of Lake vessels has caused a jam of 12,000 cars at the lower ports and has resulted in temporary embargoes along the lines. Priorities are taking most of the current output and these embargoes are forcing priority shippers to cast around hurriedly for an outlet, often at a cut price.

The passage of the Ohio fuel-control bill is an important development of the week and this, together with the end of the labor trouble on the B. & O., is mainly responsible for the spastic buying attitude of consumers in that state.

COLUMBUS

With possible state control of prices in the future, buying has not been quite as brisk. Dealers are rather anxious, however, to replenish stocks, which are still at a low point, and since some householders have been delivered, retailers are asking for quick shipments. Retail prices are still at high levels, with Focliment selling around $11 and Hocking grades, $9.50@10. Only a small amount of West Virginia coal is coming in.

Steam demand has fallen off. Purchasers are loath to pay the high prices and have been waiting for some sort of price control.

The Lake trade is considerably up in the air. Shippers are objecting to the prices asked and in many cases are holding off. But since priorities force the producer to ship a large tonnage to the Lake much of it is going begging. Except for the Pennsylvania the car supply is far below 100 per cent. There is little hope for improvement in this situation and consequently firm prices are expected to prevail for sometime.

PITTSBURGH

Production is now at the limit of car supply. Mines are not shipping their product with little if any interference by the distribution authorities, or congestion by the railroads. Substantially all the merchant production is absorbed by priorities, and any further shipping without a priority is almost certain to find himself with cars the next day.

There are about 12,000 loaded cars at Lake docks, due to slower vessel movement than was expected. Embargoes are being put on or taken off almost daily, sometimes on roads, sometimes on small divisions. The bulk of the merchant coal produced in the district for the Lake trade. Placing of an embargo requires a shipper to find a new customer in a priority class and as coal must be moved promptly the regular price frequently has to be cut. Sales have been made at $4.25 and even $4. In such cases, the regular market, otherwise applying, being $4.50@5, for Pittsburgh district steam coal.

There are reports of byproduct coal being sold at $5, but it is impossible to see how such sales could be effected in the case of the byproduct plants of the MiddleWest which as a whole are similar. Only steel works can use the by-product and the utilities, and thus have no priority.

CLEVELAND

The settlement of the railroad strike on a number of important roads, and the passage of the coal control bill by the Ohio legislature have been developments of outstanding interest to the coal trade. The immediate result of these events has been to further slow down the demand for industrial fuel. Consumers feel certain that the end of the strike will help to expedite coal shipments, and that the state machinery will cause quotations to work lower. The prevailing level in the last days has ranged $4.50@$4.75 for spot coal. This represents a decline of $1 in a week, and about $3 since the termination of the coal strike.

The natural operation of the market is expected to do more in regulating the price than the state. The railroad operators have offered to settle on a price of $3.50 at the mine, based upon a 100 per cent car supply. This proposal is being studied by state officials.

Lake shipments are being speeded up. For the season up to Sept. 11, 6,019,000 tons of cargo coal had been shipped, against 3,650,000 tons in the same period of 1921 and 12,201,000 in 1920.

EASTERN OHIO

Daily output during the week ended Sept. 11 was increased some 8,000 tons, notwithstanding no operations on Labor Day. Total production was 280,000 tons against a potential capacity for the 5 days of 227,000 tons. Cumulative figures for the year indicate that 6,280,000 tons have been produced, with potential capacity placed at 21,937,000 tons, 29 per cent for the year. Now that the railroad strike seems to be in a fair way of settlement, a more optimistic tone is prevalent that not only a greater quantity of coal will be available in the open market, but that it may be had at lower prices than those now quoted.

No general or widespread demand for coal exists and steam users throughout this section continue to procrastinate so far as commitments for immediate delivery are concerned. Despite a sliding off of 50c@$.10 a ton on spot quotations during the week, no increase in inquiries is discernible.

Retail dealers have not yet been able to replenish their yards to meet the fall demand as little domestic fuel can be had. West Virginia and eastern Kentucky because of the railroad congestion at Ohio River crossings, and on railroads originating coal in those fields. However, relief from this situation is expected within the next few weeks.

Bituminous coal receipts at Cleveland during the week ended Sept. 9 were only 697 cars, 577 cars for industries and 120 cars for retail yards. Industrial receipts have declined during the past two or three weeks.

BUFFALO

Consumers refuse to be disturbed by the warnings of a car famine. The idea seems to be that the crisis is over and there is coal enough. Jobbers believe that the 250 cars delivered to the West Virginia coal market soon will convince consumers that it is the thing to buy freely now, before prices go up on account of a short supply.

Hence the natural attitude is to permit some members of the trade, as well as consumers, find that the higher the price the better the coal is as a rule and the faster it moves. So shipment has been moving with increased rapidity and the consumers are often able to get $6 in preference to a lower price and some coal is selling for even more than that. A fair quotation would be $6.25 for gas lump, $5.75@6 for Pittsburgh 4-inch, and $.25@$.50 for all mine run, with slack scarce enough to command a few cents more than mine run.

DETOIT

Consumers display no eagerness to add to their stocks although the supply of coal available continues far short of normal requirements. According to daily reports, the coal receipts have averaged about 250 cars through the last month, while local representatives of the coal trade place the daily requirements at about 550 cars.

William W. Potter, Michigan Fuel Administrator; Charles F. Dunn, Wayne County Administrator, and the Detroit Coal Exchange have joined in a protest against the I.C.C., issuing a modification of Service Order 23. It is their contention that the continuance of this order in effect serves to prevent obtaining for domestic consumers the coal required by law, provided that the coal be sold to public utilities. No improvement has taken place in the situation as regards anthracite.

NORTHERN PANHANDLE

Some mines were unable to work for a time during the week ended Sept. 9, owing to a wreck on the main line. The effect of this curtailed production to some extent. Little more than half the potential capacity of the district is being produced, due to lack of cars. There is a ready demand, much of which is for railroad fuel. Lake shipments are larger in volume.
Lake States Feel Good

Over Arrival of Coal

Vessels Deliver Heaviest Volume Seen
Since Normal Times—Prices Remain
High—Many Buyers Hold Out—Wise
Men Say There Will Be No Drop.

There is better cheer in the
states around the Lakes nowadays.
During the past week more coal
reached the docks than had arrived
in any one week in a long time. The
tendency of prices does not seem to
be definitely upward any further for
the time being and all in all con-
tions are much brighter.

Many buyers are still holding off,
counting on a heavier flow of fuel
within the next two or three weeks
and a resulting drop in price. Others
expect all-rail coal from the Midwest
to reach here in great volume. Coal-
men, however, feel that prices will
not drop and that the Northwest will
get just barely enough fuel for the
winter. The first hard coal is yet
to be loaded.

DULUTH

Twenty-six cargoes arrived during
the last week, and twenty-four more
are scheduled to arrive here before the
week end. This will be by far the
highest number of coal laden ships to
come here for several years within one
week. This resumption of shipments is
perhaps the best indication of the way
the Northwest is recovering from the
coal strike. Coal moves off the docks
as fast as it arrives which insures
against dock congestion. No contracts
are being made by the dock men.

The first anthracite is expected
Thursday, Sept. 21. It may sell at the
old price. Fairly steady levels have
been reached in soft coal. Youglio-
gherb, Hocking and Splint lump are
selling at $14 per ton, run of pile at $11.50
and screenings at $7.50. Strangely, one
dock is selling the last Pocahontas at
the same price as high-volatile coal.

Since the Northwest got plenty of
c Coal after the 1902 strike which ran
a month later than this one, it seems
certain enough will arrive this year.

MINNEAPOLIS

A few cargoes of coal have finally
reached the upper docks. But instead
of the 400,000 tons a week which were
supposed to be the minimum there was
barely 200,000 per week. This still
appears that priorities do not
assure coal. Buyers here apparently
must bid high if they are to get coal.
Car shortage has its inevitable effect on
coal buying generally. Dock men are predicting a shortage
that cannot be prevented. State of-
icials are alarmed over this, and have
issued proclamations urging economy
of fuel and cutting down unnecessary
consumption. They are looking to the
Illinois all- rail fields for a supply at
lower prices. All- rail coal from south-
ern Illinois has been offered at $4.75 @
$5 at the mine, and has been refused in
some cases as too high. Buyers are
counting upon a break in the market
and ample supplies of coal within a
short time. They recall the situation
two or three years ago, when after a
panic fall, the first of December saw
all the coal that could be used, and
prices slumping constantly.

Coal men fear that a bad situation is
being made worse by the frantic efforts
of politicians, doubtless earnestly seek-
ing to find coal, but not forgetting the
main chance of personal aggrandizement.
They have pyramided the proba-
table needs of the district to an impos-
ible figure.

MILWAUKEE

Milwaukee is experiencing consider-
able relief from the soft coal shortage
for eleven cargoes, aggregating 124,815
tons, have been received since last
week's report. There is still an
unknown quantity in this market, and
the outlook for consumers is not good.
Railroads have been refusing cars for
carrying coal to interior points because
of a federal order directing the prompt
return of empty cars from the mines, but
they have now agreed to provide cars
to dock companies when shipments are
authorized by the state committee.

A local coal company, which has a
contract to deliver 54,000 tons of coal of
a specified analysis has requested the
city council to relieve it from com-
pliance with the quality clause of the
contract until it is able to secure coal
which does not have to be shipped to the
pooling ports established by the government. The company stands to
lose approximately $200,000 if it is held
to the contract.

The following figures show the re-
cipts from all sources at Milwaukee
from April 1 to Sept. 1, 1922, compared
with the receipts during the same
period last year:

New England

Big Buyers Well Supplied,
Market Lacks Life

Rehandling Piers So Congested That
Few Shippers Send Coal Forward—
Hoover Level is Price Basis—Recess-
ion Expected Before Long.

There is no life to the current mar-
ket. The larger consumers are sur-
feited with supply for a long time to
come, and there is so much congestion
at rehandling piers here that few
shippers will take the chance of send-
ing coal forward on the market. It
is only with the utmost difficulty that
contract deliveries are being received,
for practically every unloading facil-
ity is being worked to the limit.

The west-bound embargo on the
N. & W. is throwing an extra volume
to Hampton Roads. The Hoover fair
price now is the basis of trade and
lower figures can be looked for
within a reasonably short time.
Several of the agencies are working
hard to plug what holes are remain-
ing and there is every reason to
think that September quotas will be
amply filled by the end of the month.

At this writing there are seventeen
steamers in the harbor with British
coal awaiting berth, and since but two
of these are for utilities or retail
dealers at their own wharves, the
rest are for railroad docks where there
is now detention for at least three
weeks. The changes on these cargoes
will therefore mount to high figures
and there are more than a few large
consumers railroads included, who regret
following the broad advice given them a
few weeks ago. We understand there has been but one cargo of
Southern coal shipped here on the order
of Mr. Hoover's organization for dis-
tribution under direction of the
Distributor, and on this one shipment not only have there been diffi-
culties over landing the coal but the
original applicants have in several in-
stances cancelled their orders.

Steam grades from central Pennsyl-
ania are offering freely at prices up
from $4.50 per net ton at the mines.
Efforts to interest retail dealers in
carloads of one ton or more have met
with meager results. Now that the
press informs consumers that anthra-
cite is being produced in volume it will take
a touch of colder weather to
holders take notice. Pennsylvania opera-
tors are also apt to overlook the high
rates that apply to New England points; in many cases the prices
are only 10 cents lower than for
main line coal on the bargain and makes the cost well in advance of what the
companies are assuming their intention
to charge for prepared anthracite.

At Boston, Providence, and Portland
there is the same coal awaiting dis-
charge that consumers are naturally
induced either to charter steamers or
agree to receive further deliveries
even on a contract basis. Steamers that have
been operating regularly for several
months are now being laid up.
Softness in Market Brings
To Light More $5 Coal

Recession of $1 from Early in Previous Week—Railroads Now Turn Back
Cars Shipped on Open Contract—Cincinnati Jobbers Underbids by Some Competing Fields.

A perceptible softness has developed in the market and as a result there is more $5 coal to be had, in small lots to be sure and for the lower grades, but this is in direct contrast to the price that was $1 higher early last week. The ear-
marks of the buyers' strike that could be seen last week became more and better defined. Perhaps the hardest blow of all is the fact that the railroad-
roads, which have been the heavy takers of coal, are now turning back cars that were being shipped on open contract. Lake buyers are proceeding cautionously and there is no longer a rush to complete cargoes.

More and more the Cincinnati job-
bers are coming in contact with Ohio and Indiana as well as Illinois coal, and in many plates these fields are underbidding. Operators not shipping under Permit 1 will bewail an ever-
increasing car shortage.

LOW-VOLATILE FIELDS
Pocahtanzas and Tug River
Progress is being made by Poca-
htanzas producers in speeding up pro-
duction to some extent in view of more favorable transportation conditions pre-
vailing on the N. & W. During the early part of September mines were giving out in a large part of the state. Relief from the congestion which prevailed for a time is enabling the N. & W. to handle more coal upward. TheBetter is securing the bulk of the coal, with some moving north-
ward by rail but with a prospect that rock movement will cease with better grades. Production Spot prices $4.50 to $4.80, but with comparati-
vely little tonnage moving.

Under more favorable transportation conditions the Tug River field is now main-
taining production at about 90-
000 tons a week, which is considered normal. Western territory, to which much of the product of this field is usually shipped, is now shipping slightly. Prices are getting more stabilized, not ranging much above the Harvet maximum.

NEW RIVER AND THE GULF
Mines in the New River field are not getting a car supply of more than 30 per cent of the total to which they were entitled under their allotment. Trans-
portation conditions are being slightly improved but the process is very slow.

Conditions in the Winding Gulf are much the same as in the New River region. Following an improvement in transportation conditions on the west-
ern Virginia, however, a little more coal is being handled. There is an active market with the demand still in excess of the supply. What short coal there is to be had is quoted $4.50@$5.50.

CINCINNATI
Small operators in the splint and gas districts have not awakened to the change in market conditions. They do not care to ship coal even though there is a tremendous shortage of coal. The competition from other fields is in-
creasing and there is only one thing that talks when the two meet on a com-
mon ground. Cincinnati jobbers, how-
ever, are fully aware of the situation and some of them already are reverting to tactics that mean sale.

Permit 1, by which certain mines are favored with either cars or billing, is the big problem. Some mines saw the light this week and as a result have reverted to the flow of empties. Others that could not square with the permits have been bawling a shortage.

The smokeless situation seems to have hit the most even stride of all. Prices are balanced better with mine costs and orders are booked ahead with the hope that they will be caught up with some day. Orders for total ship-
ment here are too low, on other words of operators who were about to catch up with the orders ahead.

The retail situation has not varied since the last report. Most dealers are putting in only what will just run their customers instead of making an attempt to fill orders that have been on the books for months. Pocahontas lump sells for $3.75@$4; bituminous lump, $8.75@$9; slack, $6.50

HIGH-VOLATILE FIELDS
Kanawha
Labor Day had a tendency to curtail production, although an accumulation of coal over the double holiday made it possible to make up for the loss later in the week. Open-shop mines con-
tinue to produce to a great extent on the holidays. The biggest handicap under which all operators are laboring is the car shortage. Not more than 20 or 25 per cent of the normal supply is being furnished. The car supply is a little better in Kanawha & Michi-
gan than on the C. & O. There is a strong demand for coal in all grades, but the difficulty is in getting orders in preference to others which it is hard to secure cars.

LOGAN AND THACKER
Not more than a third of the number of cars allotted to the Logan region are being actually furnished so that mines are limited to between 35 and 40 per cent of potential capacity. With so few cars available, mines having orders coming within certain classifications are of course being given preference and that is tending to disarrange marketing plans of producers. There is little or no spot coal available and much of the fuel shipped from that field is greatly delayed in reaching its dest-
ination.

More coal is being mined in the Kenova-Thacker field owing to a bet-
ter run of cars. Labor Day made a little difference in the region, the only fac-
tor standing in the way of capacity production being a shortage of operators and equipment. Railroad fuel loadings are large but there is also a heavy commercial movement to West-
ern points when embarkages do not in-
clude or prefer coal moving under contract or preferential orders so that there is comparatively little free coal to be had.

NORTHEASTERN KENTUCKY
A heavier domestic demand is being re-
flected in a call for prepared sizes at some mines even with recent price prev-
ailing, such as $6.50. At the same time there is a firm demand for mine run, but screenings are not quite so active. Conditions have shifted and there is a growing shortness of coal in the mill. Mines are reverting to the use of mine run, not of merely waiting for orders to turn up.

South

BIRMINGHAM
The market is fairly good. Demand from industrial users is general in char-
acter, but not persistent as heretofore. Dealers have sufficient business in hand and being booked to take care of the output, but with any great relief in car supply and accelerated movement the activity will be further lessened. Bunker coal is in fair demand.

Priority in the use of cars has been an-
nulled by the Public Service Com-
nission, as Class 1 and 2 consumers were getting more than they necessarily needed. Others were unable to get fuel account of cars not being available. Domestic sizes are somewhat scarce in the spot market and dealers are slowly stocking account poor transportation conditions.

Prices are practically stable on basis of the fair-price schedule, comparatively little coal being sold above average figures, which is permissible on interstate business.

Car supply was somewhat better in the field the first of the week, but fell back later, particularly on the Southern, where mines lost con-
siderable time. On an average all lines probably furnished 60 per cent. A further decrease in production is not brought about by a more serious shortage of equipment.

VIRGINIA
Car shortage continues to curtail production. There is a demand for further only 3 cent ever-
owing to the inadequate transportation facilities, reducing the output to about 125,000 tons a week or little less than 51 per cent of of capacity. There is an active market for coal but cars are difficult to obtain except where companies have shipments to make under certain preferential orders. Quotations $4.50@$5.50 on mine run on a spot basis.
ILLYNOIS

Eugene McAuliffe, for five years president and general manager of the Odd Fellow Coal Co., has been associated with the company for some three years as its sales manager. The announcement of his resignation, with headquarters at St. Louis, was made to E. Young, who has been associated with the company for some three years in the office of the Pittston Coal Co., in Pennsylvania. Mr. McAuliffe, who has been associated with the company for some three years in the office of the Pittston Coal Co., in Pennsylvania.

INDIANA

Articles of incorporation have been filed by the Celina Coal Co. of Indianapolis, which recently bought the Indiana Fuel Co., owning two mines in Pike County, near Petersburg. The capital stock of the new company is $100,000. Geo. C. Neal is president and Herman E. Neal is secretary and treasurer.

The boiler room at the Glenn coal, No. 1, formerly the Bennett mine, east of Terre Haute, was burned recently. The loss includes part of the machinery, besides the building. The origin of the fire has not been determined.

The Columbus Coal Co., organized in Cincinnati, Va., by Mr. B. E. Clark, of Chicago, and Thomas Grant, of Brazil, as the promoters, has bought the mine of the McCullough Coal Co., near Rockville. The mine, the near Riley. Several of the leading stockholders are interested in the Brazil Collieries Co., and the Bright Gem Coal Co., both of Indianapolis, and the company with which the combined offices of Terre Haute, Thomas Grant, of Brazil, will be manager of the three mines.

KENTUCKY

The Coal, Coke & Iron Ore Committees, of Central Pennsylvania and Southeastern Territory, Pittsburgh, will hold a public hearing on the rates for byproduct coke cars, to New Richmond, Ripley, and Manchester, on Sept. 22. The rates, which are prevailing rates, will be heard at New Richmond, Ripley, and Trinity, Ky. This hearing will be held on Sept. 25, 1922, at 10 a.m.

NEW YORK

Alfred D. Thompson has been appointed vice-president of the Titan Fuel Co. 32 Howland. Mr. Thompson will be in charge of sales for central and western New York and eastern New York, with offices in Utica. Until the end of August he was manager of bituminous coal sales for Patullo & Bowes, Inc., and has been identified with the trade since 1905.

OHIO

The Trojans Coal Co., Cincinnati, has been incorporated with a capital of $10,000 to job coal. The incorporators are Everett C. Kline, Resty W. Dye, George W. Holts, J. F. Roberts and Charles B. Clark.

The States Coal Co., Columbus, has been organized with a capital of $25,000 to do general mining and wholesaling business. Directors: Henry C. Moore, R. W. Kitten, C. F. Weaver and Charles Stokley.

The Dudley Coal Co., W. S. Dudley, president, and the Marion Coal Co., G. F. Yamashita, vice-president, have announced that these concerns have purchased an interest in the Kears Coal Co. of Cincinnati. The monies from the Ohio market will be made to the Ohio field.

Jake Brady has been appointed general sales agent for Jewett, Rigby & Brooks, according to an announcement issued by E. H. Jordon, the president of the company. Mr. Brady takes the place of Louis Stone who has been in charge with headquarters in Cincinnati for several years. Mr. Stone is now connected with the Wall's Creek Coal Co. in Kentucky.

Pennsylvania

The Jefferson Coal & Coke Co. was formed Sept. 1, and is a partnership composed of Messrs. Crawford, Cameron and Ashcom. It will sell the coal produced by the Jefferson Gas Coal Co., the Lindley Coal Co., and the Wet Branch Mining Co. The new company is located at Penova, and is in partnership with the companies operating the coal field.

N. C. ASHCOM, General Manager

Jefferson Coal & Coke Co.

A new company co. is located at Penova, and is in partnership with the companies operating the coal field. The general manager of the new company, N. C. Ashcom, was born in Pensacola, Fla., and has been identified with the bituminous coal trade.

The Dauphin County Court, on Sept. 13, heard appeals from the State substantial key coal tax, which is estimated to range from thousands of dollars and based on the claim that the law is not only unconstitutional, but that its provisions are impossible to carry out. The Washington group of coal companies purchased their coal under the law, under the law, estimated at $20,000. The Philadelphia and Reading group of companies purchased their coal under the law, estimated at $147,000, and those cases were called for hearing.

Elecon Superheaters. The Superheater Co., bulletin T-1, pp. 8 x 10 in, illustrated. Among the advantages of the Elecon Superheaters are their suitability for application to all types of boilers, freedom from leaks, ease of installation and for inspection and repairs—Advertiser.

Considered Coal Application to Four 2,610-hp. Units. In the May 28, 1922, issue of Power Plant Engineering, was presented by H. D. Savage before the Meet. of the Club of the Electric Society of Western Pennsylvania, at Pittsburgh, Pa. It is a bulletin published by the Combustion Engineering Corp., New York, together with plans and specifications for this installation for a year or more—Advertiser.

Reclaiming Roller Feed Water. Northern Equipment Co., Erie, Pa. Pp. 20; 8 x 10 in. A bulletin of a new method is devoted to an article reprinted from Power Plant Engineering, next is an analysis of a regulator that meets the most exacting requirements, and finally are charts showing how the various service requirements are met.

The following bulletins on lighting have been written out by the Edison Lamp Works of the General Electric Co. Bulletin L. D. 125, a directory of lamps and cabinets on resultant illumination: Bulletin L. D. 138 contains information on fundamentals of projection lighting, and Bulletin L. D. 140 is on the lighting of small stores. These are all 8 x 8 1/2 in. and illustrated.

Obituary

David J. Han, a coal operator near Carbondale, died recently, following a hospital at Danville, Ill., as a result of burns received when rescuing his four children from a house that was wrecked by the explosion of some coal gas powder some of which his nine-year-old son strapped on a hot stove.

George P. Pitchard, head of the Virginia Fuel Co. and connected with several mining interests in West Virginia, died on March 31, 1922. He was known for the talent he displayed in the fields of coal mining and manufacturing in West Virginia. A report from Knoxville, Tenn., stated that David James Wine sold, of Middleboro, is an honest, industrious, strong politician and prominent business man, was stricken with heart trouble in his room at his hotel terminal.

The Birmingham district has lost two prominent mining engineers, Harry L. Fleetwood, superintendent of the British Columbia Co., Hurnwell, Ala., and George R. Williams, superintendent of the Fleetwood Coal Co., Fort Worth, Texas. Both had been undergoing a trip to Chicago, and their deaths were confirmed. Mr. Fleetwood was one of the pioneer mining men of the district.
The Cleveland Meeting

MUCH thinking and some talking is being done these last days of September on the question of whether to go to Cleveland for the gathering of the clans on Oct. 2, and if to go, what to do. Until the gavel falls for the first meeting no one can say how representative the operators' side may be, but as the days pass it seems as if the tide is turning toward participation.

The meeting has two announced purposes—to set up a committee of inquiry to make report at a later date on the best, or a better, method of negotiating wage scales in the bituminous-coal industry and to arrange for negotiations next January looking toward a contract between the United Mine Workers and the operators of union mines to become effective on April 1 next. Necessity for the committee or commission of inquiry seemingly has passed with the provision for a commission of broader power and jurisdiction by Congress. Collection of the same data and hearings on the same general topics by two bodies would be a needless duplication of expense. But a study and report by a group from the main body that may assemble at Cleveland, a study and report on the very important question of future relationships between the operators and miners is something that might be accepted with better grace and be more effective than if the congressional commission should attempt the same thing.

Left to their own devices the operators and miners may not succeed in bringing back that time-honored method of wage settlements in time to forestall a strike in April, 1923. In view of the history of the past year, it is quite possible that the Cleveland meeting and such successors as it may have will be sterile of results. So thoroughly ingrained is the theory and practice of collective bargaining in the soft-coal industry, however, that if peaceful effective relations are not restored this winter, they will be one, two or three years hence. Barring outside interference, the bituminous-coal industry will in the course of time work around to sounder methods of handling its relations with labor. The schisms of recent months will heal.

The industry is not to be left to its own devices, however. The country is in no mood to put up with turmoil year after year, its coal supply threatened and curtailed, prices fluctuating wildly the meanwhile. The war and post-war relations of labor and capital have been such as to produce a definite urge on the part of the public for the initiation of steps to forestall and prevent these periodic upheavals in the coal industry. The congressional coal commission is primarily for that purpose. It is only to be expected that if the coal operators and the miners' union are not able at once to demonstrate their willingness and ability to get together on a sound, sensible basis, then the government will be compelled to step in. Which, being interpreted, means that if the industry cannot satisfy as to its ability to restore collective bargaining in its true full sense, then we will see imposed something in the form of a national coal labor board.

Cleveland therefore presents an opportunity. The miners' union, which does not want the government to settle its wages under such a scheme, must recede from its position of extreme arrogance and power; the several groups of operators must merge their interests and overcome their many differences and the two sides must convince the public and the congressional commission that they are capable of intelligent self-government if they hope to be left to govern themselves.

There are many who think that the day has passed when the country may be left at the mercy of a nationally organized union of miners and another of operators, who feel that some governmental check must be placed on the industry. The federal commission may make such a recommendation. Whether or not that follows, the need is as great for the organization on a national basis of the operators who deal with union labor. The avowed purposes of the Cleveland meeting cannot be attained unless the operators are unionized. Not having accomplished that in advance, such may be a result of the meetings next week.

On the Use of Weapons

CONGRESS has put in the hands of the administrative branch of our national government a weapon to hold over the coal industry. This weapon is the Coal Control Act that provides a method for punishing those who charge for their coal more than some price which an officer of the federal government may decide is just or reasonable. This legislation is predicated on the theory that the country is short of coal and that a high market is impending. A great many consumers are facing short rations of fuel. Generally speaking those who burn coal are in no wise responsible for the present condition of shortage, yet under the circumstances they will be called upon to pay the cost, and then some, of the strife that produced the shortage. The control of prices, whether by state or nation, is held to be justified on the ground that high prices will not, under the circumstances obtaining in either the anthracite or bituminous coal fields, operate to produce an added supply. Lack of men and mines in the hard-coal region and lack of transportation from the soft-coal areas act as a brake on the law of supply and demand. Beyond a certain figure, which is not so very high in either instance, doubling or trebling of price brings forth no more coal. General appreciation of these simple and established facts will tend to popularize price control to governments.

It was an axiom in the older days of two-gun men out West that he who reached for his six-shooter and did not shoot as he drew was not a dangerous man. Our government has not only pulled its gun but has cocked and aimed it at the coal man, but instead of
This has asked him to come along peacefully. There are those who draw the inference that the shells are blanks and that this is but a gesture. A great many are ready and determined "to stand on their constitutional rights" and defy the Fuel Control Act. It will be unfortunate indeed if matters be allowed to come in such a way that the Federal Fuel Distributors and the Interstate Commerce Commission are jockeyed into a position where they attempt to set a price and discriminate in car supply to force its acceptance, and the operators retaliate with legal proceedings to prevent such discrimination—unfortunate on the one hand because the law is unfortunate and on the other hand because of the extremely bad will that will adhere to the coal trade for fighting it. Bear in mind that if there is a prospect coal prices this fall it will first appear in the last half of October, and that the country is full of congressmen campaigning for re-election in November. If the present law isn't effective, more drastic action can be promised if a constituency appears to make the demand.

There is a way, of course, to prevent all this prospective trouble. Just make the railroads haul all the coal the mines can produce and tell the anthracite-learning public to buy one ton of soft coal or coke and two tons of hard coal where three tons of hard coal are nominally required.

**Real Men, These**

DOWN at Marion, Ill., the seat of "bloody" Williamson County, a grand jury of 23 men has finished its investigation of the Herrin massacre of nineteen non-union miners on June 22. It did a masterly job of it. No less than 214 men stand indicted for "conspiracy and rioting," "conspiracy to commit murder," "assault to murder," and 44 of them for "murder." It was a mighty mob of bloodthirsty men who, unhindered by law or any enforcer thereof, encircled the strip pit of the Southern Illinois Coal Co., accepted the surrender of the non-union workers and guards therein and then shot and cut nearly half the captives to death, wound many others. Nobody could hope that a grand jury three months later could learn who all of the men in the mob were. But indictment 214 of them was a masterly job.

When the grand jury was impaneled in August it began one of the most undesirable tasks imaginable. There were, those twenty-three farmers, selected from among the non-mining residents of a county whose main industry is mining. It is a county where popular sentiment was such that a man either said he was against the prosecution or else he kept his mouth shut. Dark threats against prosecutors down there were not uttered idly. It was in "bloody" Williamson County. But at the jury took the case Judge Hartwell, of the Circuit Court, leaped across the rail of the jury box that measurements took and told them "to know them all and he knew they were real men ready to submit themselves as such in the face of 'influence,' bribes, and direct threats. They have done so. Their action and the language of their report to the court is sound evidence that there lives in "bloody" Williamson County an element worthy of the title "American."

The grand jury is to be commended not only for the fearless investigation it made but for the evident honesty of its effort to get at the truth and the whole truth. It minced no language in blaming a mining company for foolhardy action. It flatly said the ill-advised message of John L. Lewis, president of the United Mine Workers, telling the union miners of southern Illinois that the men in the strip mine were strikebreakers "and should be treated as such" was the spark that touched off the magazine of hate. It charged the miner sheriff of the county, a candidate for office, with a cowardice that was indulged for political gain and stripped state officers of the flimsy defence of their own failure to do their duty before the massacre took place. It gave the miners' union a much-soiled bill of health and otherwise displayed its impartiality and stalwartness.

The grand jury's work may be finished. It has named 214 men who may be guilty. The case now goes to the courts for trial. It remains to be seen whether a jury impaneled in the ordinary way in the solidity unionized county of Williamson can be as fearless and honest and impartial in the upholding of the arm of the law. It is by no means proved that government and justice and decency have regained command in "bloody" Williamson.

**Keep Your Hand Close to the Work**

AN ARTICLE this week by Joseph A. Maguire gives an interesting description of the ways in which power is wasted. In fact it was the misuse of compressed air that made it disappear so suddenly from its former rôle as the main medium for power transmission at mines. It was too freely used to remove smoke, gas and even water. Lines were laid too carelessly; valves were left "with just a crack open" for air to escape, and the result was inevitable.

Of course there were other causes, line friction being among them. The lines were designed to provide certain machines with air and to do it at a certain location. As the pipes were extended and more machines were needed and used and more places had to be ventilated by valve cracking (for it seemed inevitable to use the air when it was so handy) and when, also, leaks became more frequent and troublesome, the main lines became inadequate, and it seemed too great an undertaking to dismantle the line, move the pipe forward and put new and larger pipe near the main compressor.

But losses due to leaks and cracked valves turned the tide definitely against compressed air. One way to avoid leaks as also line losses is to put the compressor near the work to be performed, driving it by electricity.

Such a compressor needs no attention, automatic regulation providing for its operation without raising excessive pressure or using power wastefully. When only a few men are served by a compressor they will be more likely to see to it that the air is not wasted, though they may be somewhat careless as to what happens when none of the men is using his drill. Where a big compressor is used the men are too far apart to watch wasteful users of air, and so the responsibility, being largely spread, is almost entirely unfelt.

Small units also provide for the shutting down at off-hours of all the compressors save the one near the pump or other machine that must work during the otherwise idle period. With the compressor portable the hand is kept near the work and the air power is always under control. When generated at the mouth of the mine the chances are that it will be largely wasted in inefficient ventilation and leakage.
More Power Often Wasted by Leaky Pipes and Cracked Valves Than Would Run a Compressed-Air System

In Off-Shift Operation Leakage Consumes Unusually Large Proportion of Power—Partial Change from Air to Electricity May Merely Add Cost of Latter to Former Air Cost

By Joseph A. Maguire

Compressed air plays an important part in the production of coal, particularly anthracite, being largely used to operate inside hoists, pumps and drills. Electrification of hoists and pumps has tended to reduce the use of this medium of power transmission, but this reduction is being offset to a certain extent by the increasing use of air drills. The efficiency of an air system is of the utmost importance, not only on account of the operating expense of such a system but also because the production of coal and its total cost per ton is greatly affected by the efficiency of the air system.

It may be beneficial, therefore, to point out some of the common ways in which this efficiency is lowered. The average mine using compressed air contains a network of distributing pipes, the result of various extensions, generally made in a hurry, with little or no regard for proper sizes, drainage and the like. This network is an ever-growing one, as lines are not generally taken out when the work in a section is stopped. These pipes soon cause losses, for leaks develop either at the joints, where the valve packing gives out, or at points where the roof falls and breaks the pipe. It is not uncommon to find that this method of making extensions to the piping system causes an excessive pressure drop in the pipe lines. In time this results in such low pressure being maintained that neither hoists nor drills can operate effectively. This pressure drop sometimes occurs at the shaft but more often in sections of the mine where lines, put in originally to supply one or two hoists, have been converted, in part at least, into mains. It is not uncommon to find hoists that are barely able to pull a trip at more than a snail’s pace, or to find these machines waiting until the demand eases up and the pressure increases, before being able to operate at all. Frequently this can be remedied by putting in a few hundred feet of larger pipe or sometimes by merely installing traps.

Loss in energy and pressure due to leaks is likely to be heavy unless pains are taken to keep leakage at a minimum. It is not always easy to put good threads upon present-day pipe. The dies employed do not get as careful usage as could be wished, making it a still more difficult matter to get tight joints. For these reasons it would pay handsomely to furnish the mechanics doing this work with white or red lead or some other pipe compound. The practice of running air pipes along the bottom or on the mine floor is another prolific source of leakage, particularly when the pipe is rela-
Proper maintenance and in operating power will be obtained by keeping the pumps on the top.

When it is necessary to maintain pressure on the piping system continually, as for the operation of pumps, leaks become of serious importance. As a rule, 24-hour operation is required for the only one or two pumps or for the installation of a section, but service is nevertheless maintained on the entire system. The average that the losses from leaks on the entire system are going on continually.

Just what this amounts to may be appreciated from the data made to determine these losses. One mine plant tested consisted of two 1,700-cu. ft. crossed compound non-condensing steam-driven compressors supplying hoists, pumps, and drills. One pump was operated by air continually and for this purpose pressure was maintained on the entire system at all times. The results obtained from this test follow:

Average flow of air from compressors during working periods, 1,950 cu. ft. per minute; average horsepower input, 340; flow of compressed air to supply leaks, 350 cu. ft. per minute; horsepower to supply leaks, 157; total power cost per year to supply compressed air, $18,200; power cost per year to supply leaks, $12,400; power cost to supply mechanical apparatus, $5,300.

Thus because pressure was maintained on the lines continually, the losses in energy from leaks were twice as great as the energy actually furnished to the hoists and other mechanical apparatus.

Loss by Reason of Leaks is Great

Another installation which was subject to test maintained pressure 24 hours a day to supply a small dip pump of 200-gallons capacity operating against a 30-ft. head. With nothing operating off the air system but this pump, the input to the air compressor was 105 hp. The magnitude of the loss incurred by reason of leaks can readily be appreciated when it is realized that 3 hp. would be ample to pump the water handled.

These two instances are cited from a number of similar tests. It is believed that they cover average installations, neither better nor worse than hundreds of others.

Another large source of loss is the use of compressed air to ventilate chambers. It is much easier to crack an air valve in a chamber before going home than to stop and put up brattice cloth. Many foremen seem to think that in this practice even when the ventilation in the section is beyond criticism and in spite of strict orders prohibiting it. This probably is because they do not realize the cost of ventilating in this manner. This practice, however, results in more than the loss of power to supply the air. It springs primarily from using compressed air to blow out powder smoke, but gradually grows to ventilating chambers day and night, until together with the leaks it overrides the compressor plant until the pressure gets so low that nothing will operate effectively. When this occurs the miners who are saving themselves trouble with brattice cloth by the use of air are the first to go home because the pressure is low.

To cite one instance of this, I once investigated a mine where trouble was being experienced in maintaining pressure. A 400-cu. ft. compressor had operated a few small air hoists and managed to maintain a reasonable pressure. These hoists were electrified and some air drills installed. It was soon necessary to procure a larger compressor and a 600-cu. ft. machine was put in place. In spite of this the pressure continued low. An investigation showed that leaks and the use of compressed air for ventilation was responsible for this condition. In extending the piping into the chambers many leaks had resulted and the practice of ventilating with compressed air had started. The 600-cu. ft. compressor could maintain only 75-lb. pressure even though no machines were operating. Air-flow measurements showed that the compressor worked properly but was overloaded.

Electrification is Often Disappointing

Leakage and valve cracking have been the cause of much disappointment when air hoists and similar apparatus have been electrified. Estimates have been made showing that large economies should be realizable from the electrification of air-actuated equipment. After electrifying the hoists and other machines it frequently has been found that the compressors consumed as much power as before.

As a case in point, one mine operated two 1,000-cu. ft. steam-driven compressors. These machines were rather old, not in the best of repair and consumed about 60 lb. of steam per horsepower-hour. From these two compressors a number of hoists and pumps were operated. It was estimated that by the expenditure of $50,000 an economy of $18,000 per year could be obtained. After electrification one compressor was shut down and the other operated slowly to supply a few air drills. After a few months the operation of the compressors increased and in a relatively short time both were pounding away at full speed during the day and one at night and on Sundays. Apparently not only was the $18,000 economy not obtained but the power costs were actually increased $12,000 per year.

Careless Pipe Laying Causes Many Leaks

Called to investigate this condition, I found the original estimates conservative and the installations properly executed. What had actually happened was that a number of air drills had been added and in running the connections to the chambers extremely careless piping had been done and old cast-off valves had been used. In addition compressed-air ventilation had gotten a foothold to such an extent that the only reason for operating the compressors other than during working hours was for the purpose of ventilation.

The pipes accordingly were put in proper shape, one compressor was dismantled and the engineer was required to operate the other only during working periods. Later, however, this ruling had to be modified in order to provide for development work. To prevent waste valves were installed on each main distribution pipe, so that all sections other than the one in the territory in which work was going forward were shut off when the "all-over" whistle blew.

In electrification of air-actuated apparatus on the basis of economy it should be realized that for the reasons stated the power actually used to operate the mechanical apparatus may be, and frequently is, a minor portion of the energy consumed in compressing air. If compressed air is to be entirely eliminated this can be disregarded, but if it is to be supplied for any purpose after the electrification of pumps and hoists it should be considered a part of the electrical program.
to overhaul and put in good condition the air pipes that are to remain in service and to dismantle all piping not absolutely necessary.

Another common practice in the utilization of steam-driven compressors which is highly wasteful is to regulate their operation by hand. The regulators that automatically maintain the desired pressure either are overlooked when installing the compressors or are allowed to get out of repair to such a point that the compressors are operated by hand. Theoretically, when no governor is used the engineer adjusts the speed of the compressor to meet changing load conditions. Actually he sets the hand throttle to meet the maximum requirements and allows the safety valve to regulate the pressure. I know no easier method of wasting money.

Efficient compressors of course are essential to economical operation. Many machines are in use which, though sturdy and rugged, are of inefficient design. They were purchased when the low price of fuel at the mines did not appear to justify the expenditure necessary for more efficient types. They have, in the majority of cases, served long and well and under prevailing fuel prices can be profitably retired from active service.

**POWER COSTS PER YEAR**

<table>

</table>

In choosing between steam and electricity as a motive power for compressors consideration should be given to a number of factors other than the price of steam or electric energy. No hard and fast rules govern, for what may be the more economical drive in one case may easily be the more expensive one in another. Some idea of the operating power costs of simple steam, compound non-condensing steam and electrically-driven compressors can be obtained from the accompanying figures, taken from actual installations and corrected to a common basis of operating conditions. This base is as follows: The machine is assumed to furnish 900 cu.ft. of air per minute for 275 working days of 8 hours each per year and 400 cu.ft. per minute during the rest of the year; the cost of steam is taken as being 30c. per 1,000 lb., whereas electricity is assumed to cost 1c. per kilowatt-hour in one case and 1c. per kilowatt-hour in the other.

**Coal Flotation and Briquetting of Float Make Rapid Strides in Many Countries**

At the annual meeting of the Minerals Separation, Ltd., of London, England, the chairman, Francis L. Gibbs, reported that the company was compressing coal with 50 per cent of water and about a third the usual quantity of binding material and producing a briquet containing only 4 or 5 per cent of water, the water expressed coming out in clear jets without a particle of coal in it. The coal being thus briquetted is that of the Powell Duffryn Steam Coal Co., of Wales.

The statements that follow are taken from a recent annual report of the chairman. The briquets made by the process, which will be known as "Minesep," come out in a compact shape with a more or less hard surface and become in a few hours so strong that they can be thrown about without breaking. The briquets as marketed "can be made to contain only about 3 per cent of ash and 3 per cent of moisture." Thus by this process the cost of drying and driers is said to be saved as well as the cost of pugmills, and the product, having an unusually small quantity of binder, causes less smoke than other briquets. Furthermore, the fuel does not open up in the fire. It is purposed to manufacture 2,000 tons of this fuel daily at the Powell Duffryn plant. Some of the fuel already has been tried on a railroad in Wales having steep gradients, and it has given great satisfaction.

Another briquetting plant is to be installed at Ashington, to be run in connection with the flotation plant in operation at the mines of the Ashington Coal Co. Here tests will be made on the flotation of coal and the briquetting of coals and "brasses."

The work at the Skinningrove Iron Co.'s plant has been delayed by the depression in the iron and steel industry; nevertheless progress has been made in the construction of a plant which will treat 600 tons every 24 hours.

A plant of like size has been erected and operated at the Oughterside Collieries in Cumberland and is said to give a coke far superior to that produced before. At Low Laithe Colliery, in Yorkshire, a plant with a daily capacity of 250 tons is in course of erection and another will be built by the Team Byproduets Coke Co.

Much work has been done in an attempt to coke coals which are rated as semi-coking, and several large-scale tests have been made. This problem is not yet solved completely, for, although part of the charge of coal after treatment produces excellent coke, part does not. The solution of the problem of coking the more resistant material appears likely to be found either in the adjustment of the temperature or in the substitution of a different form of coke oven from that which is generally used, one that will suit the particular product which has to be coked.

At Noeux-les-Mines, in France, a plant is being installed with a capacity of 1,000 tons. This plant should be in operation early next year. A briquetting plant will also be erected, owned partly by the coal company and partly by the Minéraux et Métaux, the representatives in France of the Minerals Separation, Ltd.

In Spain the Aprovechamiento Residuos Minerales Sociedad Anónima, a subsidiary of the Minerals Separation Co., purchased the coal plants Mariana, La Modesta, Maria Luisa and Baltasara, the Mariana plant being put into commercial operation early in April. The high ash content of the coal gave some difficulty, but this has been overcome and the product now meets requirements. This plant, in common with all other coal plants in Asturias, except the Ujo plant, has been shut down since May 16 on account of a general strike. However, construction work has continued.

The Pena Rubia plant continued its production until shut down by the strike, producing a product of good coking quality. At Ujo, after considerable delay a 600-ton plant was put into commercial operation at the mines of Hullera Española and the latest advice indicates that the production is now maximum and minimum production of 200 tons a day of clean coal may be expected. The product has an ash content below the expected figure. Within a short time this plant will be running at its full capacity.

In China a plant is to be erected for the Chinese Engineering & Mining Co., Ltd. It will have a capacity to treat 250 tons every 24 hours. The plants in Belgium, Germany, Australia, South Africa, India and Chili have not arrived at stages of development which would justify reference to them in those columns.
The extensive development of the outcrop of the Pittsburgh bed furnish much information as to its extent and thickness. Pittsburgh coal has been mined so many years in Summit and Elk Lick townships that it is practically exhausted. In Southampton, Brothers Valley and Jenner townships this coal has been developed in recent years. Brothers Valley township contains the largest reserve.

The No. 2 Price coal of the Berlin area in Brothers Valley township has been correlated as the Pittsburgh coal and is here computed as such. From drill-hole records and outcrop it has been possible to define fairly accurately the extent of this bed. The area as defined will subject to correction when more information is available from future prospecting and development.

A fair amount of information is available as to the extent and thickness of the Lower Freeport coal. It is thickest in Somerset and Quemahoning townships, and because of its exceptionally fine quality in the vicinity of Friedens it is in great demand as a smelting coal. As this bed is extremely variable in thickness and persistency, it has been considered as a reserve only in areas contiguous to mines or to drillholes that prove it to be of workable thickness. A low percentage of recovery has been assumed also because the bed is so irregular.

The Clarion coal has been computed as of economic interest in six townships, namely, Addison, Black, Milford, Paint, Somerset, and Upper Turkey Foot. Little is known of its thickness and extent, and only areas surrounding developed or proven ground have been computed. Future prospecting may enlarge these areas, but information is meager at the present time. The Clarion coal is thickest in Black township, ranging from 40 to 58 in. This coal is extremely variable and is broken by partings. Therefore a low recoverable percentage was used in these computations.

The No. 1 Berlin coal in Brothers Valley township has been correlated as the Sewickley coal, and no quantity has been computed as such here. From drill-hole records and outcrop it has been possible to define with fair accuracy the extent of this bed. The area as defined is subject to correction when future prospecting and developments furnish more information. The Sewickley coal is mined only in Brothers Valley township in the vicinity of Pine Hill, where it averages 44 in. thick.

Brookville coal is considered of economic interest in six townships, namely, Black, Brothers Valley, Elk Lick, Milford, Somerset and Summit. Data are meager as to its thickness and extent, and it has been considered as existing only in areas contiguous to localities where mined. This bed is 50 to 36 in. thick in Black and Somerset townships.

The result of computing the coal reserves within this area, based on the latest maps, engineering data and methods, is shown in the accompanying table.
Shaking Chutes, Swung from Roof or Resting on Rollers Meet Loading and Gathering Problems in Low Coal

Chutes Made of Heavy Galvanized Iron in Ten-Foot Sections and Often Over Three Hundred Feet Long Receive Impulse from a Machine Sixty to Ninety Times per Minute—Troughs Deliver Timber

By A. Gerke
Waldenburg, Silesia, Germany

Many considerations influence the choice of a method of mining coal—economy, protection of the workman, preservation of the surface and neighboring seams and, among the others, the provision for conveying the coal when mined. No difficulty is experienced in the conveyance of the coal when the seams to be excavated are of such thickness and of such a moderate gradient that cars can be taken readily to the working faces. Nor is the problem difficult where the coal will readily slide to the gangway, as, for instance, when the gradient is 30 deg. or more. The problem is found where the inclination is oversteep for cars and not steep enough to move the coal by gravity. In such cases to avoid unnecessary shoveling of the coal the length of the “bords” should not exceed 33 to 40 ft.*

It follows, therefore, that in the development of the mine an unusual number of gangways will have to be driven, and in all of these rock will have to be shot down or lifted if the seam is not thick enough to provide headway for the mine equipment. Moreover, the driving of such a multitude of gangways would not only be expensive but the maintenance also, and, furthermore, their many roof falls would interfere with operating efficiency. Such gangways would have to be kept standing for a long time.

It is also true that their ventilation would be both difficult and expensive. In mines generating firedamp another objection would be that it would be no easy matter to keep these many roadways free of gas. Supervision would require several men because of the lack of concentration of the operating faces. Above all, the work would be excessively prodigal of labor, because the work would be done under many disadvantages.

As these many drawbacks are even more troublesome where the coal is thin, and as low seams of coal are becoming ever increasingly operated, no efforts have been spared to devise some method of replacing such a system by another more effective.

That this difficulty has been recognized in America is evident from an article published in Coal Age in 1916, Vol. IX p. 1,044, entitled “Scraper Mining for Low Veins,” which describes an installation in the mines of the Lehigh Valley Coal Co. This, it is true, is used with the room-and-pillar system of mining. It provides for the use of a scraper pulled to and fro by a hoist located in the gangway. The width of the working places usually is 24 ft. and their length about 50 yd. Successful use of this method has been made at the Seneca and Maltby mines, not to mention others.

In Europe troughs of galvanized iron are used to bring coal from the working faces to the gangway, these being either hung from the timbers in the bord or supported on rollers. The trough, which has an ultimate length of from 200 to 230 ft., is pushed to and fro 60 to 90 times per minute by an electric motor or one driven by compressed air. The impulses cause the coal to slide down the trough.

When the trough, suspended by hangers or sustained by rollers, is pushed forward the particles and lumps of coal go with it. When the motion of the trough is arrested at the end of its stroke the coal, not being attached to it, continues to go forward, retarded slightly by the friction of the trough, which trough is now traveling backward. When this movement ends the trough again begins to go forward, aiding in the advance of the coal. The trough, having gone to full range of its motion, again starts forward, causing the coal to continue on its way. In this manner the coal is moved toward the loading point, to which it may be harnessed with speed, receiving as it does 60 to 90 impulses per minute.

Fig. 1 shows a part of the trough on rollers and Fig. 2 a single unmounted trough. It will be seen that it

---

*Herr Gerke overlooks the many schemes of driving on a level between pitch and strike, of using a room hoist or two tracks with a retarding “gravity hoist,” of loading the coal into a small “buggie” which is run on a grade nearly level and dumping the coal from the buggie into a full-sized mine car, and of using a trough and “bucketing” the coal in the trough. His reader, however, to another method, that of the scraper above. The English word “bord” is used here to express a roadway driven like a room for the disposal of coal but unlike the room in that it is narrow and without a neck and so resembles a gangway or slighter—backward. See Fig. 6 and 7 in this article.—Editor.
The trough usually is 6 in. thick, and the depth of the trough is 5 ft. At the top the trough is, as a rule, 5 ft. wide and at the bottom 11 ft. Its weight is about 132 lb. per ft. Unit lengths of the trough are from 10 to 15 ft. long, but, as stated, when joined up these units may constitute a trough 200 ft. long, and sometimes the length is made even greater.

For transmitting the motion throughout the length of the trough a so-called "driving trough" is used which rests against brackets bolted to ends of adjacent trough sections, which brackets are curved into a sort of ramp where at their ends. These curving edges are fitted for the reception of bolts. The brackets therefore keep the troughs together in position.

Each 10 or 15 ft. length must be firmly joined to its neighbors on either end, as the reliability of the trough as a whole depends on this characteristic. Only a good joint can successfully contain such severes and continuous compressions as those to which these joints are subjected. Yet it must be a joint that can be disconnected readily, and simply also, for it must not have too many parts that are likely to get loose.

Underneath the bearing trough two rollers are fitted, moved by an axle as in Fig. 1. To prevent them from cutting into the bottom a frame has been devised for them to run on. This frame is so built that the runway for the rollers is at a steep inclination, as shown in the same illustration.

The motion of the trough, as stated, is obtained from a motor, driven by compressed air or electricity or even by steam. The former source of power is preferred and for this reason is here described. The motor can either be placed under the trough and be attached to it directly through an iron rod or it can be located at the side and be propelled by a transmission as illustrated in Fig. 4. In Fig. 3 the cylinder has a piston rod which bears a crosshead with rods which pass outside the cylinder on either side and are connected on the opposite side by another crosshead. An iron rod or rope is connected to the front crosshead at one end and through a three-piece motion is connected with the trough (see Fig. 4). When compressed air from the pipe lines enters the cylinder of the motor, the piston and through it the three-piece motion is moved back, thus setting the trough in forward motion. When, however, the piston has advanced a prescribed distance the compressed air is shut off by a valve, but the piston continues to move forward by the expansion of the compressed air and by the inertia of the parts. Thus the trough is brought slowly to a standstill. The trough then falls back by gravity to its original position, but the coal still glides along and it is still moving when the trough makes its next forward movement.

The motor is screwed solidly to a block of timber or a piece of channel iron and this is held immovably in place by pieces of wood or iron which are braced holes excavated in the bottom of the seam.

So much for the mechanism: now for the methods by which advantage may be taken of it. If the roof in the bord is strong and the seam not too thick, the troughway can be driven a length of perhaps 165 or 200 ft. It is carried, of course, in a straight line, the coal being removed either by working on the pillar or by driving cross bords.

Fig. 5 illustrates the former method of working, one which can be kept open only if the coal is removed with sufficient rapidity. If this precaution is observed the roof will then come down evenly as the work progresses. But if the face remains stationary for some time too much will be demanded of the roof. It will bear down on the face of the coal, thus breaking it off. To avoid this a large force of miners must be employed on the coal face. In fact there should be a hewer in every 11 ft. of face length. As the trough will carry 40 tons an hour it can remove the coal from more men than are thus indicated. This method concentrates the working
force much more effectively than is possible with room-and-pillar methods. Among the advantages are fewer haulageways to be maintained, fewer workmen to be employed, more efficiency from those employed, and fewer haulage plants and appliances needed.

Besides this method of working, which can, it is true, be employed only where the roof permits, others have been devised which may be used with advantage where the seams are thin. Fig. 6 shows pillar workings completely furnished with shaking chutes. In these cases the main bord is driven as far as the gallery above, whereupon cross bords are driven at 33- to 65-ft. distances on either side of the central bord. From these the pillars are removed by slabling them on the ends, slabbing commencing in the upper cross bords before it is started in those lower down.

Fig. 7 shows another method of working. Here a single bord is driven between the bottom level and the top gangway so as to establish an air connection. In this bord a main trough is placed. The pillars on either side may be arranged 65 to 265 ft. wide, depending on the slope. In front of each of the pillars a trough is placed discharging into the trough in the main bord. In this method the coal is worked from the top downward following down the slope of the coal. This method is more simple than that in Fig. 6, and there are only two gangs of miners to be accommodated on the main trough. Supervision is also better than in the type of working shown in Fig. 6.

Timber may readily be transported where the troughs are installed provided the bord is driven through to the highest gallery, for it can be introduced in the trough at that point and the trough will move it down to the point desired. A man stationed at that point can take it off. Where, for any reason, this may be impossible a small windlass operated by compressed air or electricity may be placed in the highest point in the bord, and the timber then can be “snaked up” by this means. Another advantage of troughs is that they can be used where the coal is so thin that it would be necessary otherwise to shoot top or bottom to drive the bords. This saves much expenditure of money but also reduces the time otherwise needed for development.

The advantages of reciprocating chutes in the working of a coal mine are first of all that the work can be expedited to a greater extent than by any other method. Few bords are needed and what there are need be driven only in coal, thereby saving much rock work. As the coal is carefully transported in the chutes its conveyance is marked by an absence of dust. As the troughs are strong and offer much resistance to wear and breakage, the plant deteriorates more slowly than almost any other form of equipment.

Other advantages are that the plants are quickly installed at little cost both for installation and operation. Such troughs can be used for the conveyance of rock, coal, ore and salt—in brief for all materials not disposed to adhere to the chutes. The troughs may be used where the ground is irregular and in surface workings as well as underground. The conveyance of coal by these means has today passed the experimental stage. The troughs have proved their value as a cheap medium of conveyance in a multitude of instances both below and above ground.

Small Steam Turbine for High-Temperature And High-Pressure Steam

SMALL steam turbines, normally used for driving power-plant auxiliaries, such as exciters, circulating, hot-well and boiler-feed pumps, coal crushers, fans, stokers, etc., ordinarily receive, and should require, but little attention. They also should be able to use steam at high pressure and superheat, and for their size, should develop from the steam consumed the greatest possible quantity of work even though arrangements are made so that some of this steam subsequently may be utilized in feed-water heaters or for industrial purposes.

The velocity-stage turbine shown in the accompanying illustrations has been designed to meet these requirements. It is built in sizes up to 1,200 hp., and can be directly connected to high-head centrifugal pumps, blowers and compressors, to alternators and to small direct-current generators, or by means of speed-reducing gears, to alternators and direct-current generators of medium size, to large centrifugal pumps and blowers, to belt pulleys and rope sheaves, and in general to machinery operated at slow or moderate speed.

To adapt it for operation with steam of high pressure and superheat, the steam chest and nozzles are located
TURBINE CONNECTED DIRECTLY TO A PUMP

The simple high-speed rotary motion of both turbine and centrifugal pump naturally adapts them to direct connection to each other. The boiler-feeding unit of this type because of its reliability and freedom from water hammer and other ill effects steadily gains in favor.

The safety and health campaign conducted in the mining camps of Utah by Dr. A. L. Murray and C. A. Allen of the U. S. Bureau of Mines yielded such satisfactory results that they are being extended to other sections. Dr. Murray and Mr. Allen are at present conducting a similar campaign in the Oeur d'Alene district. This work is done in conjunction with the training in first aid.
Proper Handling, Care and Testing of Insulating Oils

Special Mineral Oils of High Insulating Value, Free From Acid, Alkali and Moisture, Used—Danger from Absorption of Moisture and Formation of Sludge—Test Transformer-Oil Samples Twice a Year

EARLY all transformers, compensators and oil switches that are used for lighting, power, etc., employ an insulating oil of some grade or other. In transformers the oil is used for insulating the windings and for the purpose of radiating the heat generated in the coils to the outside, where it may be radiated to the air.

In compensators and switches the oil is not only used for insulating purposes but to extinguish the arc formed on the opening or closing of contacts. It is important, therefore, that a proper grade of oil be used for each purpose. It is considered the best practice to purchase this oil from some standard electrical company that makes a specialty of handling and preparing such liquids.

Oils for this purpose must be of mineral origin, of high insulating value, free from acid, alkali and moisture. They also must be of relatively high flash and fire points, low congealing or freezing temperatures and must make a minimum quantity of sludge at the temperatures experienced when operating at full load for long periods. To obtain these properties great care must be taken during the manufacture of the oil to filter and dry it. The employment of an unprepared oil may cause serious damage to the apparatus in which it is used.

In storing and putting into service insulating oils, much care should be exercised. Oil of this kind generally is shipped to the purchaser in sealed tins or steel drums. Sometimes it is transported in the apparatus in which it is to be used. On receipt, if it is not to be put into immediate use, it should be stored in a dry wareroom. When steel drums are set on end moisture is likely to collect on their heads and this may be drawn into the drum by the breathing action induced by changes of temperature if even minute holes are present in the head. Consequently steel drums should always be laid on their sides with the bung down.

OIL FOR REPLENISHMENT MAY BE BOUGHT IN TINS

Oil for spare transformers or to make up for leakage therefrom should be purchased in tin cans, as these are more nearly airtight than barrels. The cost of holding a steel drum for a long period would more than offset the expense of the tin cans.

In transferring oil from container to apparatus care should be taken to prevent the entrance of moisture or foreign matter. Before opening a steel drum or tin all dirt should be wiped away from the mouth of the container, then the oil should be strained through several layers of clean dry cloth (to remove any foreign matter) into clean previously dried receptacles.

Oil cans or drums should not be opened in a temperature that is materially warmer than the oil. The temperature of room and oil should be nearly equal in order to prevent the inside of the drum from sweating.

Oil should never be transferred in damp or rainy weather without taking every precaution to exclude moisture. If the oil is received in good condition and is immediately placed in the apparatus it is reasonably certain that it is safe, but if it has been stored for some time the only sure way to ascertain its quality is by a dielectric test. This will be explained later.

In transferring oil the drums should not be opened until everything has been made ready for its transfer, and no rubber hose should be used as the oil will decompose the rubber and the sulphur thus set free will attack the copper of the apparatus. When the equipment container has been filled to the proper height it should be sealed up as tightly as possible, making sure that all felt and other seals are properly in place.

MOISTURE AND SLUDGE SPOIL INSULATING OIL

Apparatus containing oil seldom gives trouble, and for this reason it is likely to be neglected. It is a well-known fact that after oil has been in service for a long period it begins to change quality. Moisture will find its way in, sludge will begin to form, impairing the insulating qualities and stopping up the oil ducts. This in turn will either cause the insulation to break down or stop the oil passages, so that the transformer winding will run warmer than it should. It is therefore necessary to give such apparatus systematic inspection and to sample and test the oil regularly.

Apparatus of large capacity where the load is fluctuating through wide ranges should be inspected at least twice a year and samples of the oil taken and tested. A record of each inspection and the results of the test should be carefully kept. In this way it can be determined whether tests should be made more frequently.

In equipment other than transformers where the quantity of oil is small it is not necessary to test so often unless it is known that the apparatus is running overloaded. This may cause the oil to become too warm and result in deterioration. In switches and circuit breakers the oil deteriorates from a carbonizing effect rather than from the introduction of moisture. Lightning arresters usually will contain more moisture than other pieces of equipment because they are in contact with the electrolyte. This does not materially injure the oil for this purpose but when cleaning or restacking the arrester the oil should be passed through a filter or else new oil should be substituted.

It is desirable when taking a sample of oil for testing to obtain the poorest part of the contents of the container. This usually is located at the bottom as water, sludge also being heavier than oil, will settle to this point. If this sample proves acceptable it is reasonable to assume that the rest of the oil is safe. If a bottom sample cannot be obtained the next best expedient is to obtain a test quantity from the top after the apparatus has been working and the oil has been thoroughly stirred. When drawing a sample from a test valve at the bottom of a container, caution should be observed not to include any of the oil that has been standing in

*Report of committee on "Proper Handling and Care of Insulating Oils" presented at meeting of West Virginia-Kentucky Association of Mine, Mechanical and Electrical Engineers, Sept. 28, held at Huntington, W. Va. The committee consists of W. H. Webster (chairman), T. C. Harmon, T. W. Blake and M. A. Maxwell.
When oil is tested by a company making a business of such work the matter of preparing samples and shipping them must be given careful attention. Bottles for receiving samples must be thoroughly cleaned and dried. They should have a wide mouth and be sealed with cork rather than rubber, the cork first being coated with paraffin. The final closure is made with a sealing compound. This will avoid any possible chance of moisture getting in. After the oil has been placed in the bottle it should be immediately sealed and not allowed to stand even for a few minutes, as this might possibly make the test unreliable.

When the dielectric strength only is to be determined, 16 oz. will be sufficient, but if other tests are to be made not less than one quart should be sent. Each sample should be tagged, stating what part of the apparatus or drum it was taken from, the name of the apparatus and the serial number. The samples should be packed carefully to avoid any chance of breakage in shipment.

Companies desiring to make oil tests of their own might be interested in a few words concerning the apparatus used and its cost. The tester usually employed ascertains only dielectric strength and consists of a transformer, step-up switch and a cup that holds the oil and a standard spark gap. The cost of this outfit is about $125. The standard spark gap used for all oil testing consists of two terminals 1 in. in diameter and 6 in. in apart.

Raising Voltage Until It Breaks Down Oil Gap

This apparatus may be connected to an ordinary 110-volt alternating current. The voltage is raised by degrees until final breakdown occurs. In testing oil with this equipment the cup containing the gap should be carefully cleaned and dried and then filled with the sample of oil. It should then be allowed to stand for a few minutes to permit the air bubbles to escape. This is especially necessary if the oil is cold. The voltage can then be applied in steps as fast as the voltmeter can be read. Five breakdowns should be given to each filling and then the receptacle should be emptied and refilled from the original oil and again tested. This procedure should continue until at least three fillings are consistent within 10 per cent.

Oil in service, except in electrolyte lightning arresters, is graded as follows: If the oil fails between 25,000 and 30,000 volts it is considered excellent; if between 20,000 and 25,000 it is regarded as good; if between 22,000 and 16,000 it is said to be fair and below 16,000 it is considered bad and should be renewed or filtered immediately.

If only a small quantity of oil is involved it would be preferable to renew it outright. For firms having large quantities of oil to keep in condition the filtering process is much more satisfactory and economical. Filtering can be done while the apparatus is in service, the process being continued until the oil proves by test to be entirely safe. When oil is simply renewed it is a difficult matter to remove all of the old inferior liquid. That which remains may lower the dielectric strength of the new oil.

The filtering process consists of forcing the liquid under pressure through several thicknesses of dried filter paper. This removes all moisture and foreign matter. The filtering machine is connected to the top and bottom of the container, and the oil is circulated through the filter press until tests prove it to be safe. Several machines are on the market using this principle. The cost of the smaller sizes ranges between $275 and $300.

The cost of filtering 870 gallons of oil with one of these machines by an outside company that already had its apparatus on the job was approximately 12c per gallon. Another company filtering oil with its own machine filters 1,000 gallons during a period of three days, allowing one day to move the machine from one place to another. This would make the cost of actual labor about 2c per gallon. Where the machine has
to be shipped from one location to another the expense, of course, is much higher. It is a rather difficult matter to determine the exact cost of filtering on account of differences in the oil treated. Some oils would require much more time to filter and dehydrate than others.

In one instance, in 1921, 363 gallons of oil were renewed for 38.6c. per gallon, the cost including the freight and being reduced by the credit for empty steel drums. This shows that it is much cheaper to filter the oil than to renew it.

Another type of filtering and dehydrating machine utilizes the principle of centrifugal force and employs no filter paper. It appears to be highly satisfactory but actual data as to how thoroughly it dewater's the oil or what it costs per gallon to operate are lacking.

A copy of the record sheet of a test conducted on the oil from several transformers owned by a certain mining company is presented in the table herewith. It might be well to note on this sheet that in some tests the breakdown voltage was zero, but on a second trial proved good. This probably was due to moisture getting into the sample at some point. In other samples the dielectric strength of which proved to be low, the oil was dark in color and the low breakdown voltage probably was the result of sludge rather than of water. It will be well also to note the difference in the breakdown voltage of the top and bottom samples from the same transformer, showing in all cases that the bottom is the place where the poorest quality of oil is to be found.

Storing Bituminous Coal in a 40-Ft. Pile

STORAGE of coal is one of the big problems of the day. The following hint by F. W. Randall, assistant to the general manager of the Rockingham County Light & Power Co., of Portsmouth, N. H., published in the Electrical World, is intended for central-station storage but may appeal to any kind of consumer. If operators could recommend to consumers a method of storage that would be reasonably safe and economical it would be possible to approach strikes of mines and railroads with coal on hand convenient to the point where it has to be used. Some features of this plan with trifling modifications should be available also for use in storage of coal around the mines.

It will be noted that pipes are put in place before the coal is deposited. These pipes are used as runways for thermometers lowered and raised by strong cords marked at regular intervals by knots which enable the depth at which readings are made to be noted. Then, by reference to an appropriate drawing the behavior of the coal in any section of the pile can be studied.

When a new cargo of coal is placed in the pocket, tests of the temperature are made daily in each pile until the exact conditions in all parts of the pile are determined. The pipes are 2 in. in diameter and are placed at frequent intervals and permanently clamped into position. The tunnels from which the coal is drawn for station use are numbered, and chutes 5 ft. apart are installed. If any spot shows signs of overheating, coal is drawn from the nearest chute until the hot spot is removed. The thermometers are enclosed in wooden frames to prevent breakage.

The arrangement was inexpensive to install and has permitted the storage of large stocks of coal to a maximum depth of 40 ft. with a substantial degree of security from fire. The pocket installation was designed by W. H. Allen, of the company's engineering department, and has given excellent service.

Chain Curtain Saves Coal on Long Chutes

BY JOHN S. WATTS
New Glasgow, N. S.

COAL or other material traveling down a long chute will attain a destructive velocity, and as it is not always possible to avoid using such a long incline and the excessive velocity thus engendered the retarding curtain shown in the accompanying sketch was devised.

The curtain is made of several lengths of chain salvaged from the scrap pile and connected to a bar which is bolted to the chute sides as shown in the sketch. When the material to be handled is in large lumps a heavy chain spaced 6 to 9 in. apart gives the best results. For smaller pieces a large number of small chains is most effective. The best size and length of chains can be quickly determined by trial.

When the chute is delivering onto a picking table it is most desirable to have the stream of coal delivered in a thin, steady sheet, and to effect this the chain should be fairly long.

This curtain has proved an effective retarder and at trifling cost will keep the speed of the coal within reasonable limits on the steepest and longest chutes. For long chutes two or more curtains may be needed.

Chain curtain saves coal on long chutes.
By Measurement of Current Used and Extended Records

Large Savings Can Be Made in Power Cost*

Importance of Cost Records Grows as Power Use Increases — Need for More Recording Devices — Contracts Should Be Based on Peaks Longer Than Five Minutes — Keep Power Factor Near Unity

In a business as highly competitive as that of bituminous-coal mining, it is essential that accurate production costs be kept covering, by separate classification of items, every step in the operations performed from coal face to railroad car. In the earlier years of the industry the investment was so moderate and the operating expense so low that the item of power cost was almost negligible as a factor in production. As a result recording, measuring or weighing apparatus was omitted from the original equipment and consequently it was impossible to calculate how much was expended in power. Rough approximations were used in the cost sheets of the mine.

Of late years the general introduction of purchased power, with the necessity of comparing costs between energy purchased and that generated, has brought about entirely different conditions. Another reason for proper cost keeping is the fact that the expense of both classes of power has risen so much that the original policy of power expense now represents a substantial percentage of total costs. Records show a variation of from 2 or 3c. up to as much as 23c. per ton over a fairly large output. It is now therefore necessary to give this item close attention.

The checking of power costs falls naturally into two divisions: (1) Where a power plant is installed and operated by the mining company and (2) where power is purchased from a central station.

Totalizing Watt-Hour Meters Needed

In the first case, in order to proceed intelligently, totalizing plant watt-hour meters must be installed. Accurate account should be kept of all items of expense such as oil, wages, repairs, upkeep and the like, and provisions must be made for either weighing or closely estimating the fuel consumption. The man responsible for power-house operation should be furnished with monthly detailed cost sheets for his department, just as the superintendent of mines is furnished with a mine cost sheet, because it is only by scrutiny of these various items and by comparisons of the results that improvements can be effected.

Determination of the proper charge for fuel consumed presents a problem of real difficulty, the solution of which depends both on the point of view of the accountants and the varying mine costs. Obviously under conditions of high market and ample car supply fuel should be charged at the market price, whereas when the market is weak and the car supply is limited a different value is represented. This holds true also when the coal supply is insufficient. This item, therefore, must be left to individual judgment, and on account of its variable nature it is the source of much dispute between mine owner and central-station power salesman.

Assuming that proper measuring devices are installed and accurate cost accounts are kept, power production may be tabulated under the following headings:

<table>
<thead>
<tr>
<th>Total Kw.-Hr. Generated</th>
<th>Total Cost per Kt.</th>
<th>Kt.-Hr. per Tons Mined</th>
<th>Tons Mined Total</th>
<th>Tons Burned per Ton</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Other tabulations may of course be used if the completeness of the records make such cost keeping possible. A column headed "Pounds of coal per kilowatt-hour" indicates the generating efficiency from boiler furnace to switchboard. Naturally a wide variation will be obtained in these entries on account of the market, car supply, and similar items that influence the mine output, but after such records have been compiled for months or years, comparisons are obtainable which will cover a wide range in operating conditions. Monthly or even daily study of these records will enable the power superintendent to discover either a falling off or improvement in results and to locate the cause.

In the case of purchased current, which has been largely adopted where available, power superintendents find themselves called upon merely to check the accuracy of the monthly power bills. Some territories are served by several power companies, all with different rate schedules. All, however, first impose a "demand charge" or "capacity charge" at a fixed rate per kilowatt of the "highest integrated demand" over a stated time interval. This period may be one, three, five, ten or fifteen minutes. In fact it may be any period, but the list given covers those that are commonly used. The energy charge is made up by computing the cost of the kilowatt-hours through application of a sliding rate scale.

Demand or Readiness-to-Serve Charge

A word as to the origin and meaning of the "demand charge" may be in order. Many years ago, when the power companies, on account of the great growth of this part of their business, began to pay scientific attention to their rate schedules, it was observed that one consumer might require heavy installation investment on the part of the power company amounting to many horsepower, but through intermittent use might yield only a small monthly return in the shape of a power bill. Another consumer with an installation requiring a similar investment but calling for steady service might afford a highly satisfactory return.

Little-used storage warehouses, for example, equipped with freight elevators might require 25 kw. in line and transformer service though they would return to the power company such insignificant sums monthly as would be in many cases insufficient to pay even the interest on the installation equipment.

Accordingly a charge was established known in the earlier days as a "readiness-to-serve" charge. It was

held that inasmuch as a consumer of large demand but small consumption expected to take from the lines his maximum requirements at any hour of the day, the power company must hold this amount of energy subject to his call—that is, would be prohibited from contracting for it to another. The public service company therefore expected him to pay at least $1 per connected horsepower per month as a "readiness-to-serve" charge.

For some years this was considered in the light of a minimum payment, but later a distinct separation of charges was made based on the following process of reasoning. At that time the cost of one horsepower installed in a steam generating station was considered to be about $100. Figuring 6 per cent interest and 6 per cent annual depreciation, a yearly "demand charge" of $12 per horsepower was indicated. Soon the power companies were basing their rates on, first, a "demand" or "capacity" charge of $1 per horsepower per month, and, second, an "energy" charge of so much per kilowatt-hour consumed. This was done in order to guarantee a return from each horsepower of installed station capacity sufficient to carry interest and depreciation, regardless of the energy the consumer actually used.

**One Dollar Per Month Found Insufficient**

With the development of large steam turbo-generators, which, because of their large capacity, cannot reach out over a sufficiently large territory to absorb their enormous output without both extensive and expensive transmission systems, this charge of $1 per horsepower per month was found insufficient to meet the charges on the heavy unit investments. A change accordingly was made to the "kilowatt-per-month" basis with a substantial increase in the rate.

It must be borne in mind that this charge is in no sense intended to cover the energy delivered but is made solely in order that the consumer may bear the "stand-by" charges of interest and depreciation on the capacity reserved for his use. It takes effect regardless of whether he consumes any energy or not. Obviously, this being the case, this "demand charge" should yield no profit whatever to the power company, which must look to the sale of energy for dividends. The suspicion on the part of consumers that the power companies are really making profits out of these demand charges through overlapping has been the cause of much litigation before the public service commissions and has resulted in most cases in the commissions prescribing the charges for this part of the total billing.

**Demand Charges in Huntington District**

In the territory adjacent to Huntington, W. Va., three large power systems have been installed. One of these charges $1.80 per kilowatt of highest integrated 5-minute demand per month, another $1.92 per kilowatt of highest integrated 3-minute demand, and the third charges $1.65 per kilowatt on a 15-minute demand, the two last named using an alternative method known as "agreed standard capacity" or demand calculated from connected load. All have energy rate schedules with little in common.

Through the courtesy of J. H. Edwards, who has compared the demand made by the same load over several months, based on these different time periods, the following table is presented. This gives an idea of the effect of these different peak-period specifications on the total demand charges.

Consideration of this table shows the importance to the mine owner of having a peak period of at least 5 minutes and longer if obtainable.

Other companies in the northern part of West Virginia include in their contracts a clause providing penalties for bad power factor. Inductive load, such as that resulting from the application of induction motors to fans, pumps tipples, etc., causes the current to lag behind the impressed voltage, with which it is therefore out of step to a certain extent. The cosine of the angle of such lag is expressed as a decimal, or percentage, and is used to indicate the power factor or P.F. That portion of the current flowing through the receiving apparatus which is out of step with or is lagging behind the impressed voltage represents no energy, and is therefore known as "wattless current," while that in step is called "energy current."

Without discussing the technical features of this phenomenon it may be stated that the use of induction motors tends to increase this lag and results in low power factor, while synchronous motors possess the inherent capacity of not only correcting the inductive effect of their own windings but of compensating for a certain quantity of other inductive load. This is accomplished by overexciting the field circuit of the synchronous machines, and if the proportion of these units to the total load is large enough, the current may even be made to precede or lead the impressed voltage. Under these circumstances a leading power factor is secured which is fully as undesirable as a lagging power factor.

**Combine Synchronous and Inductive Load**

As unity power factor is most advantageous a judicious combination of synchronous and inductive load is desirable. The rotary converter may be designed with sufficient field capacity to bring about unity power factor and even to compensate for a limited amount of induction-motor load. The synchronous motor, however, has a wider latitude in this respect and may compensate for an appreciable quantity of inductive load.

Central-station companies object to low power factor because the presence of any considerable quantity of lagging or wattless current in their circuits results in poor transformer and line regulation, making necessary an inordinately high generating voltage if a given receiver voltage is to be attained. This also necessitates greater carrying capacity in the generator windings. The line losses arising from this cause may be appreciable.

The consumer, with his short distribution lines and generally ample motor capacity, is not greatly concerned over low power factor so long as it does not affect his pocketbook. In view of the tendency of the power companies toward penalty clauses and with due regard to the betterment of over-all efficiency, modern design should provide for reasonably good power factor on all receiving circuits. It is unfortunate that the
In keeping records of mine power bills the following tabulation has been found convenient.

</table>

The figures above tabulated have been taken from records of a mine located in the Winding Gulf field. By keeping a sheet for each operation and placing the results for the whole twelve months of the year on each sheet, any bill that is "out of line" may be spotted at a glance. By keeping these sheets in a loose-leaf binder, records covering years of operation are made easily available. As new entries are made comparisons with similar outputs in previous months show whether the bill is normal or needs investigation.

Such companies use meters rather freely about the works, differentiating the power consumed into "used for machines cutting, tipples, fans, town lighting, haulage," and the like. This is of value, however, only where the company is sufficiently large and prosperous to maintain a superintendent of power distribution, as the average mine electrician usually is too busy with pressing repair work to inspect and analyze such records.

### DAILY AND MONTHLY LOAD-FACTOR CALCULATIONS

Careful consideration of the method outlined above of making a total charge based on a combination of the highest peak multiplied by a fixed rate plus a scale rate for the energy (kilowatt-hours) consumed shows that the lowest net rate per kilowatt-hour on the total billing will accrue if the peak is kept down to as small a fraction of the total power used as possible. The daily load factor of a given receiving installation is the ratio of the number of kilowatt-hours actually used to the maximum number of kilowatt-hours that would have been used had the maximum demand been maintained throughout the entire 24 hours. Thus expressed mathematically the daily load factor becomes:

\[
\text{Daily Load Factor} = \frac{\text{Kilowatt-Hours Used}}{\text{Maximum Demand}} \times 24
\]

and the monthly load factor then is:

\[
\text{Monthly Load Factor} = \frac{\text{Kilowatt-Hours Used}}{\text{Maximum Demand}} \times 24 \times \text{days in month}
\]

As showing actual load factors at various plants the following may be of interest. These are taken on a monthly basis assuming an average of 750 hours per month:

<table>
<thead>
<tr>

</tbody>
</table>

Another term frequently heard among power solicitors is "diversity factor." This is the ratio of the actual peak obtainable by combination of several separate loads to the sum total of the individual peaks. For example, assume a certain coal acreage, with a number of developments, each supplied by its own power plant. The instantaaneous peaks at plants Nos. 1, 2, 3 and 4 may be 200, 250, 300 and 150 kw, respectively. The sum of these peaks is 900 kw.

Now if lines are run to a central point, and the total power requirements are either generated at one central plant or purchased from a power company, the peak will not amount to 900 kw, because of the improbability of all four plants taking their maximum peaks at the same instant. On the contrary, the actual peak obtained may amount to only 700 kw, in which case the diversity factor is 900 or 77.7 per cent.

### WHY FIVE-MINUTE INTERVAL SEEMS FAIR

In mine work, however, because average hauls up tramway grades last but one or two minutes, if 5 minutes or more is the time period over which the load is integrated, it will be found that the combined peak approaches the total of the individual peaks quite closely, so that consideration of the diversity factor assumes less importance except where few units are thus combined.

In reference to town lighting, inspection of available records made by companies that have installed house meters warrants the conclusion that a charge of 1c. per watt per lamp per month will amply protect the power company from loss on this business. All large power users should install curve-drawing meters. Aside from their absolute check on the power company's demand meters, these instruments afford opportunity for study of the load.

Of all the suggestions here made none is more valuable than that advocating monthly tabulation sheets of power costs. It would be a busy electrician indeed who could not find the time necessary to jot down these data and compare results with previous entries. When this is done any power bill that is "out of line" will be spotted instantly.

A LIGNITE FUEL has been produced by the Bureau of Mines in the course of the its North Dakota experiments at a cost comparable with that of the domestic sizes of anthracite in Pennsylvania. No small portion of the credit for this successful outcome of these experiments is given by the Bureau of Mines to Dean E. E. Babcock, of the University of North Dakota. The beneficiation of the lignite was accomplished by a new type of shaft furnace which was built after careful preliminary study. The results show a greater efficiency than had been expected. Two carloads of lignite were recently carbonized at the rate of ten tons per day. A satisfactory residue was obtained at an approximate cost of $5.50 per ton, as against a cost of approximately $6.25 a ton for the residue produced in the oven used in the experiments conducted during the summer of 1921.

The costs are low enough to demonstrate conclusively the practicability of establishing commercial plants. It is understood that North Dakota officials have plans under way which insure manufacture on a commercial scale.
Problems of Operating Men

Edited by James T. Beard

Humidifying Air Currents by Means of Steam

Sprinkling by Water Cars and Pipe Spraying Systems
Not Reliable—Humidifying by Means of Steam Gives Better Results—Plan Adopted in a Western Mine

WHAT appears to be an effective method of laying dust in coal mines is described, in an interesting manner, by F. C. Cornet, Coal Age, Aug. 3, p. 169. The article draws particular attention to the need often presented of treating each air split separately, because of the practical impossibility of suitably humidifying large air volumes with steam.

In reference to other methods of dampening the dust to prevent its suspension in the air current, it is commonly known by those acquainted with the dust problem, in coal mining, that too much reliance cannot be placed on the use of water cars and pipe spraying systems for that purpose. These methods only reach such places as are easily accessible and a wider distribution of the water is required in order to be effective.

In his "Mining Engineer's Handbook," page 1439, Robert Peele gives four ways of wetting dust in coal mines, namely: 1. Liberal hosing. 2. Thorough wetting by force-pump sprinkling cars. 3. High-pressure, fixed sprinklers, at close intervals, on continuous pipe lines, so that when turned on all surfaces will be wetted. 4. Humidifying the intake air current with exhaust steam from the fan or other engine, both by carrying it away from the mine and, by supersaturating, to carry in moisture that will be deposited on the dust on ribs and roof.

PLAN OF HUMIDIFICATION ADOPTED BY COLORADO FUEL & IRON CO.

As previously stated, the first three methods here given are ineffectual. The method last named has been successfully employed by the Colorado Fuel & Iron Co., at several of their operations in the West. The plan adopted there has been described by B. J. Mattox, of that company, and is the following:

Steam radiators are placed on both sides of the intake heading where the entire volume of air is passing into the mine. Live steam is supplied to these radiators, by which means the temperature of the entering air is raised and its capacity to absorb moisture correspondingly increased.

The waste steam from the radiators, passing through a one-inch gate valve, is conducted by a perforated pipe to a point a short distance in the air-way, where is arranged a curtain of burlap or brattice cloth, the purpose of which is to bring the moisture or condensed steam more intimately in contact with the passing air.

By these means, the saturation of the air current is rendered well nigh complete at its increased temperature, which is practically 70 deg. F. It is clear that in its passage through the mines, the temperature of the air will be lowered and much of its moisture will be deposited in the workings.

Suffice it to say that this arrangement has proved eminently successful in every mine where it has been installed. The result has been that all parts of the workings have been kept in a moist condition. In Colorado, the relative humidity of the atmosphere, in the winter time, does not average above 15 per cent. At such times much water must be furnished to the air current, or it will dry out the mine in a short time.

CHARLES M. SCHLOSS.

Denver, Colo.

ANOTHER LETTER

Information asked regarding data that will assist study of the problem—The Mt. Mulligan explosion—What it demonstrated—The Monongah explosion.

As an old student of watering problems and designs intended to increase the safety of mines through the application of water, I have been much interested in reading the article by F. C. Cornet regarding the humidifying of mine workings by steam, Coal Age, Aug. 3, p. 169.

For the purpose of studying the matter more closely, I would like to ask through Coal Age, if Mr. Cornet will kindly furnish interested readers with the following data, calculated to throw much light on the actual results obtained in the application of the method of humidifying a mine in the manner described. The points on which information is asked are the following:

INFORMATION DESIRED

1. Are all the main haulage roads in the mine return airways? 2. Is any reversal of the air current contemplated in the mine? 3. What is the temperature of the exhaust steam, at the point where it issues from the pipe? 4. What is the water gage in the air-way, at this point? 5. What are the readings of the wet- and dry-bulb thermometers, at the same point; also, at various distances from the fan, say at the first working face; at least, at the farthest point in the mine; and at the last working place, say 100 ft. or so from the shaft or slope bottom or the discharge point of the mine? 6. Is the mine naturally wet or dry?

THE MT. MULLIGAN MINE EXPLOSION—QUEENSLAND

Mr. Cornet may have noticed the report of a disastrous explosion that occurred at the Mt. Mulligan collieries, in Queensland. The report of the explosion gave the outside temperature as between 80 and 90 deg. F., and the temperature in the mine about 85 deg., compelling the miners to work in light attire and minus their shirts.

The Mt. Mulligan mine was a dry one. The roof and floor of the seam were of a fireclay nature that disintegrated on the application of water. The packwulls in the mine being built of this material, it was necessary to keep the ventilating current as dry as possible; and, owing to the high temperature of the mine, the mine air must be as dry as possible, in order to enable the men to work with more comfort.

Under these conditions, humidity readings, in the mine, varied from 84 to 88 for the dry-bulb, and from 73 to 79 deg. for the wet-bulb thermometer. These readings showed that the air contained from 6.7 to 9.0 grains of water, per cubic foot of air. While it would have been possible to have saturated the 88 deg. temperature with 14 grains of water, per cubic foot, the miners would not then have been able to work in such an atmosphere.

WHAT THE EXPLOSION PRODUCED

The Mt. Mulligan explosion demonstrated that, in a mine totally devoid of drydamp and where the road dust consisted of about 25 per cent. of non-inflammable dust, and the moisture content was probably in excess of that in Mr. Cornet's proposition, the conditions did not prevent the flame of the explosion from spreading throughout the mine and killing every person therein to the number of 363.

There was, however, evidence of some retarding influence present, as the explosion did not extend throughout the mine at what we might call the usual speed. For example, the force of the explosion was not demonstrated at the...
It is a common practice for a miner to
quarrel with the shotlighter on this
point. Where the coal has been mined
by a machine the miner will often have
arranged a round of shots that he
would fire at one time, claiming that
they are not dependent on the other.
Contrary to this kind will continue
as long as the law is not more specific.

With the ordinary type of coal-cutting
machine that undermines the coal at
the face, particularly in the working
of a hard coal, a complete round of
shots is fired at or near the roof, necessarily
providing a condition of dependent shots
when fired by fuse.

In this connection, allow me to offer a
sketch showing the plan I would suggest
as to how the coal should be cut and
the shots located and which I believe
will prove safe practice. On the
left of the figure is shown the face
of the coal in a wide, double-track room,
in a seam of coal varying from 8 to 10
ft. in thickness. On the right of the figure, is shown a
similar cutting of the coal and locating
of shots when driving a narrow head-
ing, in a thick seam. In each case the
shots at the face are fired first to mine
the lower bench of coal, the shots at the
roof being fired later. Likewise the rib
shots, in the wide opening at the left,
follow the firing of the center shots.

**DANGER IN FIRING SEVERAL SHOTS
IN QUICK SUCCESSION**

The shooting of several holes at one
time, in a working place, is always
dangerous when the holes are fired by
fuse or squib. In the use of that
method one shot follows another in
quick succession and, often, not in the
order desired. In any case, succeeding
shots discharge their flame into a dis-
turbed atmosphere laden with dust and
inflammable gases.

It is not anything strange that this
often results in a local explosion of the
gas and dust produced by the first shots,
or at least a very windy shot. The
miner is particularly fortunate if the
explosion is not propagated throughout
the mine, which will depend alone
on the conditions.

In order to avoid this danger, not
only is it advisable to eliminate the use
of black powder and examine the place
for gas before shooting; but all shots
should be fired with an electric battery,
which will insure their simultaneous ex-
piration, as a single shot.

Incidently, firing shots by battery
will no doubt tend to slow down the
high-speed habit of many shotlighters,
some of whom make a marathon run-
er look like an ice wagon, in their

**MINING AND SHOOTING THE COAL**

burry to seek a place of safety after
lighting a round of shots.

In a few words, let me say that the
firing of shots in rapid succession,
whether they are dependent or other-
wise, has undoubtedly been the cause of
a number of explosions in our mines.

More time given to the firing of shots
will not only increase the cost of pro-
duction, but this will fall far short of the
cost of putting a mine again in
shape following an explosion.

Allow me to remark, in closing, that
where solid shooting is permitted in a
mine the issue can only be met by the
employment of highly skilled, conscien-
tious and practical miners as shotlight-
ners, and clothing them with authority
to condemn and refuse to fire any shots
that, in their opinion, are unsafe.

**THOMAS ALLEN.**

**Why Change the Colorado Law?**

Colorado law requires the certification
of mine foremen and other mine offi-
cials—The law makes any interfer-
ce with the mine foreman a misde-
meanor punishable by fine or impris-
onment or both.

KINDLY permit me to offer a few
comments, in reply to the letter of
"Colorado Miner," Coal Age, July 6,
p. 19, who thinks that the Colorado law
should be changed so as to require all
men in charge of operations underground
to be certified.

In that letter, the writer repeats the
argument so often made that the mine
foreman is frequently overruled by the
superintendent, who is his superior in
office. He claims that for a mine fore-
man to dispute the authority of a super-
intendent will cost him his job. While
that may be true in some few instances,
I cannot think that it applies, in general,
to foremen in Colorado where the law
is very specific in this regard and makes
the mine foreman supreme in this
matter. It further strengthen the belief
that the writer believes the mine superinten-
dent, also, should be required to hold a cer-
tificate, the same as the mine foreman.

In that case, we would have to include
any mine owner, lessee, manager, oper-
ator or agent, all of which are placed
in the same category, by Section 1 of
the Colorado law.

**PURPOSE OF CERTIFICATION**

Now, without prolonging the argu-
ment, I want to ask: What is the pur-
pose of the certification of mine officials
and who is responsible for this require-
ment of the law? Evidently, the pur-
pose is to secure the safety of all mine
workers; and public opinion is respon-
sible for this feature being incorporated
in our laws.

As I read the Colorado statute, any
person in charge of underground opera-
tions is obliged to hold a certificate,
showing his competency to fill that posi-
tion, as determined by examination
and in the best judgment of the state
board of examiners.

Allow me to quote briefly from two
sections of the Colorado law, bearing on

**Shooting Machine Mined Coal**

Dependent shots unsafe—Law restrict-
ing shots in Colorado mines—Firing
a round of shots in machine mining.—
Shooting holes in thick coal.

**REFERRING to the interesting let-
ter of Oscar H. Jones, Coal Age,
June 13, p. 606, permit me to say that,
in writing on the subject of "Following
or Dependent Shots," he has drawn atten-
tion to one of the most dangerous
practices in the mining of coal.

I agree with him that all such shots are
shots on the head.

That dependent shots are unsafe in
underground mining, and no argument is
needed to convince a practical miner
of this point. In my opinion, our mining
laws should be more explicit in defining
allowable practices in the shooting of
coal and severe penalties should be
imposed on violators of the acts.

In Colorado, prohibited, in relation
to blasting, dependent shots and shots
that are synchronized are prohibited
(see 185). Even with these restric-
tions, the question is often discussed as
if a shot being dependent is prepared
by a miner.
the authority of the mine foreman in matters pertaining to the mine as regards its safe operation. Section 44 of the law reads, in part, as follows:

"The mine foreman shall have full charge of all inside workings and of all persons employed therein, in order that all the provisions of this act, so far as they relate to his duties, shall be complied with and the regulations described for each class of workman under his charge carried out in the strictest manner possible. Any superintendent or other person who interferes with the mine foreman in the discharge of his duties as described by this act shall be deemed a misdemeanor."

Again, in reference to penalties prescribed by the law, Section 172 reads as follows:

**COLORADO PROVIDES PENALTIES FOR VIOLATIONS OF THE ACT**

"Any violation of any provision of this act shall be deemed a misdemeanor and shall be punished by a fine of not more than one thousand dollars or by imprisonment of not more than one year in the county jail, or by both such fine and imprisonment." How any law could be more specific in prescribing the authority of mine officials in charge of underground operations is hard to understand. Neither is it clear, to my mind how the certification of the mine superintendent would improve the situation in any respect whatsoever.

Take, for example, any of the large coal companies in this state, say the Colorado Fuel & Iron Co. Let us assume they have twenty-five mines in charge of twenty-five mine foremen. In addition, let us say, there will be fifty assistant foremen, fifty foreboses, and fifty shofitters.

Here are 175 certified men in charge of underground operations in these twenty-five mines. Allow me to ask, if the certification of the twenty-five superintendents of these mines would make the operation of those mines any safer? In discussing these questions, let us use some common sense and view the matter from a practical standpoint.

In closing, I want to say that if a mine foreman is overruled by his superintendent, in matters pertaining to the safe operation of the mine, there is something wrong. If, in the judgment of the superintendent, the foreman is incompetent, a more capable man should be secured at once and the sooner the better.

**ROBERT A. MARSHALL**

Walsenburg, Colo.

**Peace and Harmony**

Timely suggestions applying to the present situation in coal mining—The get-together spirit—Meetings of mine officials and men promote good will and harmony.

J ust now, nothing is of more interest and importance than suggestions looking to the promotion of peace and harmony, in the general rank and file of the coal-mining industry. Ever since reading the suggestion made by one writer, sometime since in *Coal Age*, I have been deeply impressed with the thought then expressed that great good would result if employees and employees would meet together at regular short intervals.

**Weekly Meetings a Benefit**

In my opinion, such weekly or bi-weekly meetings, at some convenient place, would be the means of avoiding much of the trouble that now arises between miners and mine officials. Questions relating to the health and safety of mine workers, the most improved methods of mining the coal, timbering of airways, ventilating the working places, and other matters of interest could be profitably discussed at these gatherings.

To my mind, it would be an excellent plan to hold one of these meetings the night before the regular meeting night of the miners local organization. By so doing, it would give an opportunity to anticipate and discuss any grievances that might be arranged to come before the miners’ meetings the following night.

My idea is that all mine officials, from the superintendent down, should be present at the meeting and, by showing a real concern for all that pertains to the welfare of the employees, establish an ever-growing confidence of the men in their good faith of their employers.

With much pleasure, I read the excellent letter of G. W. Breeden, *Coal Age*, Aug. 24, p. 290, entitled “Gainin g the Confidence of Men,” and I want to endorse what he has said in regard to the effect of kind treatment and a reasonable familiarity of mine officials with their men.

It is not too much to say that many suggestions would often be forthcoming from the men that would enable a reduction in the cost of producing coal and these would relate to every branch of mining, hauling, pumping, drainage, tracklaying and other work with which the men are most familiar.

There are mines where such meetings have been conducted with great success and profit to all concerned. At times, reading rooms and classes of instruction have been organized and it would be a pleasure to know that such a system is, or shortly will be established in every locality. Not the least result is a general reduction of accidents in all classes of work in the mine.

**NANTY GLO, Pa. M. J. FACEMEYER.**

---

**Inquiries Of General Interest**

**Estimating Equipment for Engine-Plane Haulage**

**Allowance Made for Unavoidable Delays and Changing Trips—Number of Hoists per Day—Speed of Hoisting—Size of Rope and Drum—Horsepower of Engine and Boiler**

A subscriber of *Coal Age*, I take the liberty of asking its assistance in working out the solution of a proposition with which we are concerned. It relates to the necessary equipment for changing trips, say one minute at the top and one minute at the bottom of the plane. The proper solution of this problem will be greatly appreciated.

**JOFET, Pa.**

EDGAR I. ARZT.

The first step, in the solution of this problem, is to estimate the time occupied in actual hoisting of the loaded trips up the plane. In an 8-hr. day, there are 8 × 60 = 480 min., from which we will deduct, say 40 min. for unavoidable delays during the day. Hauling 200 tons, in 2-ton cars, will require 100 hoists per day. Then, allowing one minute lost in changing ropes at the top of the plane and the same minute at the bottom of the incline, makes a total of 200 minutes lost between trips. The time remaining and consumed in actual hoisting the loads and lowering the empty cars is, therefore, 480 - (40 + 200) = 240 min.

Now, hoisting at a rate of, say 5 ft. per sec. gives 400 ÷ 5 = 80 sec. for hoisting a single loaded car. For convenience in calculation, we will assume the time for hoisting a loaded car is 84 sec. and the time for lowering an empty car 60 sec., making a total of 84 sec. for a single round trip. The total time consumed in hoisting 100 round trips is, therefore (100 × 144) ÷ 60 = 240 min., which agrees with our previous allowance.

The next step is to estimate the load on the rope when hoisting a loaded 2-ton car, adding 40 per cent of the load for the weight of the car, which makes the actual load hoisted 2 × 1.40 = 2.8 tons, exclusive of the weight of the rope itself, lying on the plane where the rope is at the foot of the incline.

- **Hauling on a steep 30°-deg. slope, the slope in the case of the gravity pull and the friction pull.**

- **The weight of the loaded car is 2.8 × 2,000 = 5,600 lb.**

- **The gravity pull is 5,600 × sin 30° = 5,600 × 0.5 = 2,800 lb.**

It would be interesting, if space permitted, to go on and estimate the size
and kind of boiler required. Suffice it to say that, in boiler practice, it
is customary to estimate on an evaporation of 55 lb. of water, from and at
121 deg. F., per hp, per hour. Knowing the feed-water temperature and
the gage pressure in the boiler, it is possible to calculate the corresponding
heat value of this evaporation and, allowing 2,545 B.t.u. per hp, estimate
the boiler horsepower required.

Approximately, it is customary to allow 8 sq. ft. of heating surface, for plain
cylindrical boilers; 10 sq. ft. of heating surface, for horizontal flue boilers; and
15 sq. ft. of heating surface, for horizontal tubular boilers, per horsepower.

Examination Questions
Answered

Illinois Mine Managers' Examination
Springfield, July 17, 18, 1922

(Selected Questions)

QUESTION—(a) What is the law in reference to persons seeking certificates of competency as mine managers? (b) Fly whom and how often should a passageway to the entrance shaft be examined?

Answer—(a) Section 2 of the Illinois Coal Mining Laws specifies that each applicant for a certificate of competency as mine manager shall produce evidence that he is a citizen of the United States, at least 24 years of age, and has at least 4 years practical mining experience, a man of good repute and temperate habits. He must also pass the examination required by the board covering his experience in mines, and handling of men and knowledge of mine machinery and appliances, surveying and other instruments used in mining, properties of mines gases, principles of ventilation, first-aid treatment of injured, mine rescue and the duties and responsibilities of mine managers.

(b) Section 30 (a, 10), requires the mine manager or his assistant to examine, at least once a week, the roadways leading to the entrance shaft, or other openings for the safe entry of men to the surface, and make a record of any obstructions or unsafe conditions existing therein and cause the same to be promptly removed.

QUESTION—(a) What are the provisions of the mining law in reference to air currents and splits. (b) Trolley or other exposed electrical wires. (c) Runaround at shaft bottom?

Answer—(a) Section 14 (b) requires the main air current to be so split or divided as to give a separate current of reasonably pure air to every 100 men at work, and authorizes the inspector to give a written order for separate air splits for a smaller number of men.

(b) Section 17 (b) requires all trolley and positive feed wires, crossing or passing over where persons or animals are required to travel, to be safely guarded or protected, in a manner to prevent contact of persons or animals.

(c) Section 10 (i) requires the construction of a safe passageway, free from all obstruction and dry as possible, around the bottom of a shaft where men enter or leave the cage, or must pass from one side of the cage to the other. This passageway must be 3 ft. wide; and the law forbids animals or cars to be taken through it when men are using the passage.

QUESTION—A return airway is 10 ft. wide and 5 ft. high, the velocity being 600 ft. per min. The pressure is controlled by volum as follows: Nitrogen 79 per cent; oxygen 20.96 per cent; carbon dioxide 0.04 per cent. What number of cubic feet of such gas is passing per minute?

Answer—The sectional area of the airway is 5 x 10 = 50 sq. ft., and the volume of air passing, 600 x 50 = 30,000 cu. ft. per min. The volume of each cubic foot of gas is found to be 12,450 cubic ft. and its specific gravity is 1.15; what was the thickness of the seam?

Answer—The area covered by this pillar is 450 x 132 = 59,400 sq. ft. The specific gravity of the coal being 1.25, its weight can be estimated as 1.25 x 59,400 x 78.125 = 24,560,000 lb. per cu. ft. The gross weight of coal mine being 12,430,000 + 24,560,000 lb., the cubic contents of the pillar worked out is 24,560,000 + 78.125 = 318,208 cu. ft. Finally, the height of the seam is therefore 318,208 + 59,400 = 5.35 ft.

QUESTION—Find the length of a dumb drift, which is driven from a total of 240 ft. from the shaft and enters the shaft at a point 100 ft. above the level.

Answer—The dumb drift is the hypotenuse of a right triangle whose sides are 240 and 100 ft. respectively. Therefore, the length of the dumb-drift is \(\sqrt{240^2 + 100^2} = 260\) ft.

QUESTION—What is meant by the term (a) ventilating pressure, (b) water gage; (c) mine resistance?

Answer—(a) The term "ventilating pressure" describes the pressure required to circulate the air in an airway or mine. The unit of ventilating pressure is this pressure expressed in pounds per square foot. The total pressure producing circulation is the total pressure exerted on the sectional area of the fan drift.

(b) The term "water gage" describes an instrument used to measure the unit of ventilating pressure, by showing the difference in height between the absolute pressure on the intake and that on the return airway by the height of water supported at the point where the gage reading is taken.

(c) The term "mine resistance" describes the work, in foot-pounds, absorbed in the circulation of air in a mine or airway. It is the total ventilating pressure multiplied by the velocity of the air current.

### 80,761,604 Tons of Coal Mined in 1921 in West Virginia; Value, $375,541,458

Official figures covering the production of coal in West Virginia for the fiscal year ending June 30, 1921, given in the seventy-seventh annual report of the West Virginia Department of Mines, just issued, show that there was produced in the period mentioned 80,761,604 gross tons of coal as against 79,991,316 tons for the preceding fiscal year, the gain amounting to 770,288 tons or less than 1 per cent. In the same period coke production amounted to only 836,782 tons, as against 1,172,271 tons for 1920, a decrease of 335,489 tons or 28.2 per cent.

The Department of Mines estimates that the total value of all coal produced in the 1921 fiscal year was $375,541,458; that the value of coal used in operating was $56,074,400; that the value of coal used for power and light was $54,075,000; and that the value of coal shipped from the mines was $35,442,091.30 and that the value of coal mined by small country mines was $3,295,000. It is estimated that the value of coal sold was $364,811,705.50 and that the value of coke sold was $8,015,564.24. The increase in value as compared with the previous year is as follows: for coal, $113,788,553.50; for coke, $560,005.12.

The department estimates that the average price received by pick miners throughout the state for mining run-of-mine coal was 95c. per ton, as against 91c. in 1920. The average tonnage produced by pick miner was 1,287, a decrease of 368 tons from the fiscal year 1920. The average annual wage of pick miners was $1,165.65, that being a decrease of $285.80 from that of 1920. The average daily earnings of pick miner, or the value of the mines was $4.65 per gross ton, run-of-mine coal, which was an increase of 3.25 per cent over the price received in the preceding year. Coke was sold f.o.b. at the oven during the year at an average price of 90c. per net ton, which is an increase over the previous year of 3.22 per cent.

In the fiscal year ended June 30, 1921, there were 116,726 people employed in connection with the production of coal and coke. Of that number 17,140 were employed in preparing and making coke, 39,582 as machine miners, 6,025 as machine helpers, and 32,778 as inside laborers, 29,183 as outside laborers, and 1,050 as coke workers.
Local Explosion in England Takes Toll of Thirty-Nine Lives

A local explosion at the Main Pit of the Whitehaven Colliery Company, Whitehaven, Cumberland, England, near the town of Inverness, on Sept. 8, caused the death of a man. The pit was sunk about nine years ago, the shaft reaching the mineral coal, a B.C. bed, at about 1,200 ft. Working in this bed is carried on under the men, and the point where the explosion occurred was about 1,000 ft. from the adit where the men work. The men are situated in a separate ventilation district, and the explosion is said to have come from the Mine to the surface at the time of the explosion had not been working on the affected mine system nearby.

This phase of mining worthy of notice was the assumption which rescue operations were started. The general manager was within the mine directing the work of rescue operations when the explosion occurred. A number of men were killed by the explosion, and several others were injured. The general manager was killed in the explosion, and one of the rescuers was also killed. The other rescuers are said to be injured, but their condition is not known.

The rescue operations were carried on for several hours, and the rescue party was finally successful in saving the lives of several miners. The miners were rescued from a shaft located near the explosion, and were taken to the surface for medical attention.

British Empire Steel Corporation and Coal Miners to Sign Agreement Soon

The new wage agreement between the British Empire Steel Corporation and the miners of District 26, U. M. W. of A., will not be signed for a week or ten days, according to a statement issued Sept. 18 by J. B. McLachlan, secretary-treasurer, when, after a week's negotiation, he signed the Inverness miners to the new contract, the same as that entered into with the British Empire Steel Corporation.

The new contract is practically the McKinNON award, which is considerably less than that paid under the Montreal agreement, under which contract the miners of Inverness have been working for the past month, but is somewhat higher than the rate of wages awarded the Inverness miners by the Osborne conciliation board. Under the conciliation board award the minimum day rate was $3.10, while under the new contract it is $3.25.

There is considerable work to be done in the matter of straightening out local contracts as well as getting the new rates that the men employed in the machine shops will work under. When this is done, Mr. McLachlan stated, the agreement will be signed.

Underground employees of the Western Fuel Corporation, Ltd., Nanaimo, B.C., are preparing the basis for a new agreement with their employers when it is intended that the agreement shall exist for three years on and from Oct. 1. Their desires have been placed in the form of a report which will be submitted to representatives of the management. The report is interesting not alone because of the several demands made but as illustrating the amicable relations that exist between the men and the company.

Provision is made for the permanent establishment of an agreement committee which, it is proposed, shall hold monthly meetings with a similar body delegated by the management. Before this joint agreement committee will come for settlement everything of a contentious nature.

At a mass meeting of the employees of the corporation held Sept. 16 it was agreed to accept the increase in bonus to the underground workers from the old rate of 84c. to $1. It was decided to reorganize a miners' union, the district having been without a union during the last two years. A committee was appointed with that object in view. A resolution was passed and a copy of it has been forwarded to the Minister of Mines, requesting that the Coal Mining Act be amended and made to exclude Oriental labor in and around the coal mines of the province. A large proportion of the employees of some of the companies working mines on Vancouver Island and Orientals. Another resolution was passed and a copy of it forwarded to John Oliver, Premier of the province, requesting that a system of state insurance be inaugurated.

Plan $50,000,000 Merger of Coal Retailers

Consolidation of retail coal companies in various cities into a national organization with a capital of about $50,000,000 is under way, according to a report current in financial circles. The nucleus of the organization will be the Burns Brothers Coal Co. which recently took over the William Farrell Coal Co. in New York City.

Negotiations already are under way, it is said, to take over the business of the Consumers' companies of Chicago, retail distributors of coal in that city. Other properties which are to be included in the consolidated company, according to the reports, include the Polar Wave Company, of St. Louis; the Metropolitan Coal Co., of Boston, and the Newton Coal Co., of Philadelphia.

The Burns Brothers company, according to an officer of the company, has approximately 3,000,000 tons of unfilled orders on hand.
Bill Creating U. S. Coal Commission Becomes a Law; Compromise Measure Provides for Seven Members

Appearing as a compromise from the conference committee of the two houses of Congress, after pressure had been exerted from high administrative quarters to break an apparent deadlock among the conference, the bill to create the United States Coal Commission, which is to investigate the industry broadly, was enacted into law speedily on Friday, Sept. 22. The conference report was adopted by both houses on the same day and with very little debate.

In its final form the legislation provides for a commission of seven members, instead of the five proposed by the Senate bill and not more than nine provided by the House bill. Restrictions as to the personnel of the commission were removed in conference excepting that no member of the House or Senate may serve if appropriation of $200,000 is provided, this sum being half way between the $300,000 of the House bill and $100,000 of the Senate bill.

The point which nearly wrecked the conference, that of inclusion in the Senate bill of instructions to the commission to report on “the advisability or wisdom of nationalizing the coal industry” and “the feasibility or necessity of governmental regulation and control of the coal industry,” was compromised by rewriting these two subsections into one, reading “the advisability of any legislation having to do with government or private ownership, regulation or control in the coal industry.”

This rewriting of the two subsections into milder form represents a considerable concession on the part of Senator Borah, author of the Senate bill, which was compensated to a large degree, however, by acceptance by the House conferees of the terms of the Senate bill instructing an inquiry and report on various forms of standardization, of wages, production, etc.

The act provides that the first report of the commission shall be presented to the President and to Congress not later than Jan. 15. It provides for a separate investigation of the anthracite industry, with a separate report on this field to be submitted on or before July 1. The life of the act is limited to one year. The salary of the commissioners is fixed at $7,500 annually and no employee of the commission is to be paid a salary in excess of this sum.

The act also provides that any vacancy in either house on the adoption of the conference report. A motion to recommit to the House managers, with instructions to provide specifically for inclusion on the commission of representatives of the miners and of operators, which was made by Representative London, socialist, was defeated, 106 to 156.

Text of Fact-Finding Commission Bill

To establish a commission to be known as the United States Coal Commission, for the purpose of securing information in connection with questions relative to interstate commerce in coal, and for other purposes.

That for the purpose of securing information in connection with questions relative to interstate commerce in coal and all questions and problems arising out of and connected with the coal industry, there is hereby established a governmental agency to be known and designated as the United States Coal Commission, to be composed of not more than seven members appointed by the President of the United States, by and with the advice and consent of the Senate; provided, That the House of Representatives shall be eligible to serve on said commission. Said commission shall elect a chairman by majority vote of its members, shall maintain central offices in the District of Columbia, but may, whenever it deems it necessary, meet at such other places as it may determine. A member of the commission may be removed by the President for neglect of duty or malfeasance in office but for no other cause. Each member of said commission shall receive a salary of $7,500 a year. Any vacancy on the commission shall be filled in the same manner as the original appointment. Said commission shall cease to exist one year after the taking effect of this act.

The term “person” as used in this act means any individual, partnership, corporation, or association; the term “coal” means anthracite, bituminous, and other coal, lignite, coke, and culm, whether in place extracted or not banked.

It shall be the duty of said commission to investigate and ascertain fully the facts and conditions and study the problems and questions relative to the coal industry, with a view to and for the purpose of aiding, assisting, and advising Congress in matters of legislation which will insure a supply of this commodity to the industries and the people generally throughout the country and maintain the uninterrupted flow of commerce among the states, or any legislation which Congress may after said investigation deem wise and which under the Constitution Congress has the power to enact.

To this end said commission shall ascertain and report to the President and Congress: As to the ownership and titles of the mines; prices of coal; the organizations and persons connected with the coal industry; cost of production; profits realized by the operators or owners of said mines during the last 10 years; profits of other persons or corporations having to do with production, distribution, or sale of coal; labor costs; wages paid; wage contracts; irregularities, regulation; waste of coal; and suggestions as to the remedy for the same; the conditions generally under which coal is produced; distribution; the causes which from time to time induce strikes, thereby depriving interstate carriers of their fuel supply and otherwise interrupting the flow of interstate commerce; and all facts, circumstances, or conditions which would be deemed helpful in determining and establishing a wise and efficient policy by the government relative to said industry.

Said commission shall, under the provisions of this act, make a separate investigation and report for the anthracite industry, which investigation and report shall cover all of the matters specified in the last preceding paragraph, and shall cover also every other phase of the anthracite industry, including the production, transportation and distribution of anthracite, and the organized or other relationships, if any, among the mine operators or the mine workers, or among any persons engaged in the production, transportation, or distribution of coal.

Said commission shall also submit recommendations relative to:

(a) Standardizing the mines upon the basis of their economic productive capacity and regarding the closing down of mines which, by reason of their natural limitations, or other conditions, fall below the standard.

(b) Ascertainment and standardizing the cost of living for mine workers and the living conditions which must be supplied or afforded in order to surround the workman with reasonable comforts, and standardizing as far as practicable the amount of work a man shall perform for a reasonable wage, recognizing the value and effect of such surroundings in respect to their efficiency.

(c) Standardizing a basis of arriving at the over-all cost of producing and distributing the coal, including delivery at the door of the consumer, recognizing in this computation that the standardized cost of living to the miners should be the first and irreducible item of expense.

(d) The advisability of any legislation having to do with government or private ownership, regulation, or control in the coal industry.

Said commission shall render its first report and recommendations to the Congress and to the President not later than Jan. 15, 1923. Said commission shall render its separate report on the anthracite industry on or before July 1, 1923, and shall endeavor, in said separate report and in the recommendations contained therein regarding wages in the anthracite industry, to work out the plan which will enable the miners to live in accordance with the standards set up.

Further details for each state are provided in the full report, which includes data on production, value, and distribution of coal production across different counties.
Harding Signs Coal Distribution Bill and Names C. E. Spens as Federal Fuel Distributor

President Harding signed the Coal Distribution Act and appointed Conrad E. Spens Fuel Distributor, Sept. 22. The selection of Mr. Spens meets with general approval among representatives of operators, wholesalers and railroad executives. Mr. Spens is regarded as one of the outstanding traffic men of the country. He has been given leave of absence by the Chicago, Burlington & Quincy Railroad Co., of which he is vice-president. The appointment was made by the President on the recommendation of Herbert Hoover, Secretary of Commerce. Mr. Hoover had ample opportunity while serving as food administrator, to become familiar with Mr. Spens' ability. Mr. Spens was chief of the traffic division of the Food Administration throughout its existence.

The new Fuel Distributor will have as his chief assistants Donald Conn, who is a specialist in the Lake trade and the requirements of the Northwest, and F. R. Wadleigh, chief of the coal commodity division of the Department of Commerce. Mr. Spens expects to expand the organization which was maintained during the period of voluntary distribution. For the present the Fuel Distributor will occupy the same quarters as were occupied by the voluntary distributor, but Secretary Hoover states that the organization soon will outgrow the floor space available at 718 Eighteenth Street.

Says States Have Principal Control Over Price

One of the first acts of the new distributor was to telegraph the governors to emphasize the fact that the principal control over price must be exercised by the state authorities and that federal control can be applied only to coal which moves in interstate commerce. The text of Mr. Spens' telegram is as follows:

"The federal act signed by the President the 22nd instant provides that it shall be the duty of the Federal Fuel Distributor, among other things, to ascertain in which parts of the United States there shall be a shortage of coal and the extent of such shortage; the fields of production and principal markets to which such production is to be transported and distributed; the prices normally and usually charged for such coal and whether current prices, considering the costs of production and distribution, are just and reasonable; the nature and location of consumers, and what persons, regions or community should receive priority in transportation and distribution, and the degree thereof.

"The federal government can exert its influence on distribution and restrain extortion only so far as concerns coal that may be transported from one state to another.

"It has no jurisdiction as to: (1) Coal produced and sold within the state of its production. (2) Retail or wholesale margins or handling coal within these states.

"Responsibility as to these features must rest with the state authorities and if profiteering in coal is to be prevented, except as to coal that may be moved across state lines at extortionate prices, the proper remedy must be applied by state authorities.

"Coal production capacity exceeds transportation capacity. The problem of adequate supplies and diminished prices is therefore primarily a problem of transportation. The federal authorities, in cooperation with the carriers, are making every possible effort to expedite movements. Coal today enjoys the same priority in transportation as food and feed. Transportation of coal is ample to meet current necessities, but is not sufficient to permit stocking either by household or commercial consumers and possibly will not be ample for that purpose for another thirty to ninety days.

"It is necessary that state organizations or agencies be created in states where they do not now exist that will invite cooperation, that will prevent stocking of coal beyond current necessities and that will establish reasonable margin for retailers and wholesalers.

"As above stated, the constitutional authority of the federal government is limited, but it will gladly cooperate with these state governments as far as it can properly do so. The major responsibility, however, for the price at which the coal is sold to the consumers by the wholesalers or retailers within the state must rest with the state authorities.

"The federal act is, of course, nationwide in its scope and I am, therefore, addressing this communication to the governors of all states and to the State Fuel Administrations, where such agencies now exist, although I understand there is considerable territory in the United States where there is no imminent coal shortage nor complaint as to the cost of this commodity. We shall depend upon the judgment of the state authorities in each state as to whether or not the aid of the federal government is desired or necessary as to interstate coal.

"I would appreciate early advice from you as to the situation in your state and the measures taken or contemplated to meet the emergency."

Donald D. Conn, of Minneapolis, who has been named as Assistant Federal Fuel Distributor, has been stationed in Washington for some time as chairman of a special committee appointed by the governors of seven Northwestern States to represent them in connection with the coal-supply situation.

C. P. White, of St. Paul, Minn., has been designated as assistant to the Fuel Distributor in handling the fuel situation in the Northwest. Mr. White acted in a similar capacity in the later days of the President's Fuel Committee.

C. J. Hepburn, of Philadelphia, has been retained as general counsel to the Federal Fuel Distributor.

F. R. Wadleigh, chief of the coal division of the Department of Commerce, will act as an assistant to Mr. Spens.

E. M. Durham, of the American Railway Association, was directed to Philadelphia Monday to represent Fuel Distributor Spens at the sessions of the Committee of Anthracite operators and Pennsylvania state officials who are considering the problem of the distribution of anthracite.

H. M. Griggs, of the Cleveland Ore & Coal Exchange, who has been handling the movement of lake coal, will continue in this capacity.

It is planned by Fuel Distributor Spens to name special
.advocated inaction, representing the general business and
advocacy of business and the national interests of the country.

The administration, continuing its tentative policies
of the Federal Fuel Policy.

The view of the fact that I have only today assumed the
powers of the Federal Fuel Distributor, I am not prepared to
publicize the provisions of the railroad carriers and
producers of coal, and at this time devote my efforts to the
promotion of the interests of the coal operators.

The coal production capacity of the country is ample to
meet all demands. The immediate problem is transportation.
This demand and the requirements for abnormal transportation
has no known reason for the physical capacity of the
transportation facilities, and at a time when the offerings
of foreign coal are at a peak, we must find a way to ameliorate
the present attitude of the administration as well as of the
public.

Consumers AS WELL AS CARRIER MUST CO-OPERATE

The cooperation of the consumer is practically as
necessary as that of the carrier. At the request of the admin-
istration, Julian H. Barnes, president of the Chamber of
Commerce of the United States, has addressed American
industries, commercial and trade organizations urging that
purchases of coal under present conditions be confined
exclusively to current needs and that there be no accumulation
of stocks of coal moving under contract or otherwise.
I fully appreciate and add my appeal to that of Mr. Barnes,
but will direct my aid only to the 'industrial' consumer
but limned to the 'domestic' consumer.

Sufficient coal can be moved for current consumption, but
sufficient coal cannot be moved within the immediate future
to meet the demand that obtains and provide a surplus
which is necessary. The increased cost of frequent pur-
chases in small quantities creates a situation that might be
repeated by a rapid distribution due to exaggerated anxiety
or lack of preparedness in the coal-going public.

If all consumers of coal, whether domestic or industrial,
will calmly consider this appeal and will co-operate as sug-
gested, not only will their current needs be taken care of
but the result will be reflected quickly in the price of coal,
which today in many sections of the country manifestly
exceeds the market price of coal.

The administration is not suggesting that the operator in
should sell his coal at cost. Nor is it suggesting that he
shall sell his coal at less than cost. The administration
is, however, indicating, and the present act of Congress con-
vention, that he shall sell his coal on a basis that will not
yield an abnormal profit; in other words that he shall not
take undue advantage of the present unfortunate eco-
nomic situation.

Many coal operators are co-operating in a splendid man-
ner. Regrettably I must add that there are some who are
not. It is asking too much that, during these critical times,
our coal operators shoulder the important necessity to comfort
— to live their present case, and that there be only legiti-
mate concern—swing, based on American standards of fair
value.

In announcing Mr. Speer's appointment the President
made public a letter which he had written to the new dis-

The Frisco Railroad Buys Contract Mine-Run
At $2.225 Per Ton

The Frisco R.R., it is understood, has contracted with the St. Louis & O'Fallon Coal Co. for 700 tons per day of standard mine-run coal at $2.225 per ton, and also for a small tonnage of 14 x 23 nut coal at $2.55 per ton. This is the cheapest contract made in that section and operators generally cannot understand how such a low price could be made on a contract that will expire next March.
Service Order 25, Issued Sept. 19, Allows Broader Priority in Coal Movement

Shifting its policy from priorities on coal cars to a broader priority on coal transportation, the Interstate Commerce Commission on Sept. 19 amended Service Orders 23 and 24 and supplanted them with Service Order 25, which removes classifications 1 to 5 for coal-car loading and directs the carriers to observe a priority in movement of open-top cars in which coal ranks with road and building materials, ore, mine supplies and fluxing stone when the movement is in the direction of coal mines. The way is left open, however, for the commission to direct special classifications if occasion arise.

The Interstate Commerce Commission explains the need of the order and outlines the purposes which it intends to accomplish as follows: "By reason of certain embargoes issued by carriers, complaints have been made that various commodities, which in the public interest should be handled currently and promptly, have not been so handled. In addition to the commodities specified under Service Order No. 23 this order adds mine supplies, medicines, fertilizers, seeds, newsprint paper and petroleum and its products in tank cars to the list of commodities to be given preference and priority in movement, when carriers are currently unable promptly to transport all freight traffic offered to them for movement. The words 'fuel' as used in Service Order No. 23 are changed to read 'other fuels.' "

"Service Order No. 23 directed all carriers to discontinue the use of open-top cars suitable for the transportation of coal for the transportation of commodities other than coal so long as any coal mine remained to be served with such cars. There are extensive road-building projects with uncompleted gaps, which, in the public interest, should be completed before cold weather sets in. Furthermore, it appears that the priorities have been made by the states to the federal government. There are large building programs under way which must be completed without undue delay to avoid serious loss. "

"Service Order No. 25 permits the use of open-top cars suitable for the loading and transportation of coal, after the discharge of the coal lading thereof, for the transportation of commodities other than coal with such commodities for any shipper who shall fail or refuse to load the open-top cars within 24 hours after place for such loading thereof and are directed to place an embargo against any consignee who shall fail or refuse to unload such cars within 24 hours after place. The order further cancels the priority afforded consumers now embraced in class 2 in paragraph 7 of Service Order No. 23. The consumption of combustible coal has increased to approximately nine and one-half million tons per week, and should, with reasonable use, take care of current needs, if panic, undue storage and waste of fuel and equipment are carefully avoided. The commission therefore feels that it can now relax its previous order by omitting general priorities by classes of consumers, reserving, however, through special case of great emergency for the direct carriers to furnish rail coal mine with such open-top cars as may, in the public interest, from time to time be designated by it or its agent therefor. By virtue of the general priority which is given both to movement and use of open-top cars for coal, the effect of the change now made is to advance all coal into the priority class, instead of only those classes of consumers formerly embraced in the former designations. While it was necessary during the period of extremely limited production to give priority in use to certain highly essential classes, this necessarily involved deferring others. Under existing circumstances, it is believed that the course now taken will tend to a considerable improvement in the production of coal by facilitating its movement and general distribution. It will be necessary, however, to avoid a return to priority classifications, for continued efforts looking to the avoidance of overstocking, of delay to equipment, and to the curtailment of demand to meet bare daily necessities until the reserve of coal in circulation can once more be built up. "

"Service Order No. 24, which now requires carriers west of the Mississippi River to afford priority in movement to certain commodities, and for the removal of empty cars for such loading, has been amended to correspond with Service Order No. 25, applicable in eastern United States. Service Order No. 22, as to routing of freight to avoid congestion, remains in effect." Service Order No. 24, which provides for the priority in movement of certain commodities in the territory west of the Mississippi River, has been amended so as to enlarge the list of commodities. Paragraph 1 of that order, as amended, reads as follows: "That each such common carrier by railroad, to the extent that it is currently unable promptly to transport all freight traffic offered to it for movement, or to be moved over its line or lines of railway shall give preference and priority to the movement of each of the following commodities: Food for human consumption, feed for live stock, live stock, perishable products, mine supplies, medicines, fertilizers, seeds, newsprint paper, coal, coke and other fuel and petroleum and its products in tank cars." 

C. J. Neal Named Ohio Fuel Administrator: Fair Coal Prices to Be Established

Governor Harry L. Davis has named Clarence J. Neal of Cleveland as state fuel administrator following the passage of the price control law by a special session of the Ohio General Assembly. At the same time the Governor announced that "fair coal prices" will be established under the new law as soon as the necessary machinery can be set up. Mr. Neal is a business man and during Governor Davis' administration as Mayor of Cleveland served as city director of finance. During the war and the attending coal shortage he had been in charge of direction of distribution direct to the public in the City of Cleveland.

The first act of the new administrator was the naming of Clifford Gilversleeve, of Cleveland, as assistant and Frank H. Bear, also of Cleveland, as transportation director.

Illinois May Send Delegation to Lewis’ Cleveland Conference

Though they did not agree to do so in their Aug. 22 contract with the miners, operators of Illinois coal are figuring on sending men to the Cleveland conference, Oct. 2, called by John L. Lewis, president of the United Mine Workers of America. At that conference Lewis hopes to start the machinery of wage-making for the period after April 1, 1923. The operators of the 5th and 9th Districts of Illinois have already decided they will be represented. The other two Illinois operators' associations will meet in Chicago Friday, Sept. 28, to decide their course. It is generally expected, among operators, that a delegation will go. The delegation may point to the creation of a fast-finding commission by President Harding, contending that no parallel commission such as Lewis wants should be set up.

Colonel E. T. Tierney Dies Suddenly

Colonel L. E. Tierney died last week at his home in Powhatan, Va., after an illness of two days. Colonel Tierney was prominent in politics in West Virginia and at one time was on the Governor's staff in Richmond, where he was a director of the Crater Pocahontas Coal Co., vice-president and general manager of the Powhatan Coal & Coke Co., the Climbing Coal & Coke Co., the Eureka Coal & Coke Co. and general manager of the Elk Ridge Coal & Coke Co. The product of the four latter companies was sold by the Crater Pocahontas Coal Co.
Anglers May Tell Their Fish Stories, but Can Anybody in the Coal Industry Beat These Illinois Whales?

Vancouver Island Mine Safety Association Has Mine-Rescue and First-Aid Contests

The Vancouver Island Mine Safety Association held its seventh annual fall day of mine-rescue and first-aid competitions on the Central Sports Grounds, Nanaimo, B.C., Sept. 1. Twenty teams competed—five in mine-rescue work, eight in mine-first-aid work, four in ladies' competitions, and five in boys' and girls' competitions.

In the mine-rescue work the problems were drawn from mined entries, and the teams were allowed twenty minutes to study them before commencing work. The mine had been laid out so that a full view could be had from the ground level.

The results of the mine-rescue competitions for the V. I. M. S. A. shield were: Newbery's team (Western Fuel Corporation), Nanaimo, first; No. 2 team, Canadian Collieries (Hunter, captain); Ladysmith, second; No. 2 team, Western Fuel Corporation (Barton, captain), Nanaimo, third. The other prizes, donated by the Kehler Manufacturing Co., of Vancouver, consisted of six hand-bend aluminum safety lamps.

Winning a heavy downpour of rain it was necessary to hold the first-aid competitions in Odd Fellows' Hall, the first event being for the British Columbia Department of Mines Cup (first and second prizes). Barton's team (Western Fuel Corporation) won first prize and R. D. Keating's team (Ladysmith) won second.

After lunch the W. L. Collieries Cup was competed for. Barton's team won the first prize, and No. 1 team of the Canadian Collieries (Ladysmith, with J. Delaney as captain) was second.

There was keen competition for second place between the South Wellington team and Delaney's team and it took the judges considerable time to arrive at a decision in favor of Delaney's team.

The ladies' first-aid event for the V. I. M. S. A. shield (first and second prizes) was next, and after a hard struggle was won by Mrs. Scott's team, of Nanaimo. Mrs. Covert's team, of Cumberland, was second.

The one-man event was won by Calvert Beck and Evan James (patient), of Nanaimo, Brown and Ferguson (patient) being second.

In the junior competition for the V. I. M. S. A. Cup, the Ladysmith team of the Canadian Collieries came first, and Nanaimo team (Gard, captain) second.

The two-man event was won by Barton, Stobhart and Brown (patient), of the Western Fuel Corporation. McDonald, Aman and Delaney (patient), of the Canadian Collieries, Ladysmith, came in second.

The judges for mine-rescue work were Robert Strachan, of British Columbia, the inspection staff of the British Columbia Mines Department, and Inspector J. J. Moir, B.C. The judges of first-aid work were Drs. D. McCullough, Sutherland, Carson, Lees, Kennedy, Perry, Wilkes, Mrs. Wilson, president of St. Johns Ambulance Brigade, and Miss Pridaux, a graduate nurse, all of Vancouver, B.C.; also Drs. Ingham, Hall, Moore, and McPhee, of Nanaimo; Mrs. Schofield, first-aid expert and lecturer, of Vancouver, and Dr. Cairns, of Nanaimo.

In the absence of William Sloan, who was ill, John Hunt, general manager of the Western Fuel Corporation, distributed the prizes. He congratulated the teams on the splendid work done. After the presentations a large crowd adjourned to the dance hall, where a big crowd enjoyed themselves into the wee small hours.

The recent accident at Cumberland prevented participation in the contests by any teams from there, some of the members being in the hospital.

"Is this wire live? I'll touch and see." They wrote on his gravestone: R.I.P.

Just think, this time last summer our chief anxiety was, would the pressure of the coal burst out the side wall of the bin!—New York Evening Post.
Grand Jury Indicts 214 for Herrin Horror and Reports To the Court Without Fear or Partiality

The activity of the law in the Herrin case is a "private persecution by a political boss and a laboring organization," according to a public statement issued by Marion, Ill., by A. W. Kerr, chief counsel for the United Mine Workers of America. He charges Adjutant General Brundage with trying the case in the press and influencing the grand jury by that means and suggests that the grand jury's report was written by the Illinois Chamber of Commerce, which is raising money to finance the investigation. Kerr injects a play for the sympathy of Governor Len Small and his political machine by stating that Brundage conducted a "political trial" in the courts against Small last spring that "resulted in the death of the first lady of the state."

The special grand jury which for a month has been investigating massacre of nineteen non-union miners and the wounding of thirty others near Herrin, Ill., on June 22, last Saturday reported back to the judge. It brought in enough indictments that day to swell the number charged with murder and considered ringleaders were refused bail. Six were bonded for $20,000 each, twenty for $10,000 each and eighteen for $5,000 each. Several charged with rioting are already out under $1,000 bonds. The eight men refused bail are Otis Clark, Bert Grace, James Brown, Leva Mann, Philip Fontanetta, Pete Miller, Oscar Howard and Jess Childers. Howard and Childers have not been apprehended. Eighty-six men, from bankers to small storekeepers, provided the bail. These included most of the prominent men of Herrin, encouraged by Mayor Pace of that town, who marshaled them by saying this would be a good way of showing who was for and who against the miners' union.

The jury blames the Southern Illinois Coal Co. for its "foolhardy" efforts to operate a non-union mine under armed guard in the midst of such intense union sympathies as prevail in Williamson County. It blames President Lewis and the managers of the miners' union for the broadcasts and inflaming Lewis message saying the strip miners were "strike breakers and should be treated as such." It blames the county sheriff, Melville Thaxton, a union member and candidate for county treasurer, for being derelict in his duty for his own political benefit. It charges Adjutant-General Carlos Black, of the Illinois National Guard, with equal dereliction of duty for failure to rush state troops into the country when it was plain that violence was about to be done. It commends the local police for laxity and makes several other findings indicating the desire of the jury to lay a solid foundation for the enforcement of justice in the prosecutions that may now begin.

The text of the grand jury report follows:

We the special grand jury of Williamson Co. appointed to investigate the riot and the massacre of the miners in the town of Herrin, on June 22, 1922, in consequence of the refusal of the strikers to work at the coal mine of the Southern Illinois Coal Co., do find that the company in the prosecution of the coal business was guilty of a conspiracy to murder and to injure persons and their property, and in causing the death of the miners, by using steam shovels, and then lying about it, and that the miners and their families were terrorized, and that the conspiracy to murder and to injure persons and their property to prevent or hinder the operation of the coal mine lasted from May 21 to June 21, 1922.

The miners' union apparently raised no objection to the un-
SPECIAL GRAND JURY THAT INDICTED 211 FOR HERRIN MASSACRE

universal criticism upon the people of Williamson County, Illinois. Without discrimination, we feel keenly the horror of the tragedy. We protest, however, against the intimidation that all the people of Williamson County are lawless and un-American. The development of the mining industry in Williamson County and the surrounding counties has tremendously increased the population within the last decades. All of the adjoining counties contributed their quota of marauders, and the entire shame of the inhuman murders should not rest upon Williamson County alone.

It is true the electorate of the county is responsible for those of its citizens, weak and cowardly officials who permitted the disorders to grow from desultory rioting into a hideous massacre. These acts can be corrected by the great majority of the population who believe in law and order asserting themselves and refusing to be intimidated by a disorderly minority.

The adjutant general's office and the sheriff's office alternated in passing responsibility, with neither taking decisive action to prevent disorders and protect property.

The case with which firearms were obtained causes the grand jury to believe that legislation should be enacted to regulate or prohibit the manufacture or indiscriminate sale of firearms.

We condemn the laxity of the local police in the various cities wherein stores were loaded for firearms without interference by them.

I recommend the state's attorney of Williamson County, Delos Duty, for his courage and fidelity to his oath of office, and we express our gratitude to the Attorney General of Illinois and his efficient assistants whose aid has greatly facilitated the tremendous tasks confronting the grand jury.

In concluding this report the grand jury begs leave to state that it has indicted some forty persons for murder, fifty-eight for rioting, and five for assault to murder, and your jury asks leave for a recess of three months for the purpose of having those persons tried.

The grand jury is deeply grateful to the many representative, law-abiding citizens of Williamson County, for their assistance and encouragement in its efforts to enforce the law (various), and impartially.

Electrical Engineers at Huntington, W. Va., Present Reports on Mine Practice

Huntington held a well-attended and interesting exhibition in the Chamber of Commerce Building from Sept. 18 to 20. A large number of electrical supply companies made exhibits. Several of these were quite elaborate.

Consequently from Sept. 19 to Sept. 22 the West Virginia Academy of Mines, Mechanical and Electrical Engineers met in the City Hall of Huntington. Only morning sessions were held by the association, the afternoons being devoted to the exhibition, which were not less educational than the meetings themselves.

On Monday a report was made on power costs and on mine locomotives and coke, the first report being presented by C. E. Rogers in place of M. A. Maxwell, who was absent. On Wednesday reports were made on underground distribution of energy and on the relative merits of straight storage-battery, accumulator, and coiler receiving locomotives. These reports were presented by an address by C. B. H. Van Richten on automatic turning and substitution apparatus, this being the paper prepared by W. A. Whiting, also of the General Electric Co. In the afternoon a visit was made to the plant of the West Virginia Rail Co., where a number of interesting tests on the breaking of rails were conducted.

On Thursday reports were made on 'all-rubber insulator table' as compared to ordinary hard-covered cable for portable extensions, insulating cable, mine-machine cable, etc., and on the use on mine and mule lines of resistance grids made of rolled-steel plate as compared with cast grids." The article on "the manner in which mechanical and electrical men can increase their usefulness" was read by R. D. Hall; W. G. Shunk, the author, being absent.

On Friday M. W. Crenshaw read a paper on the wireless telephone with illustrations and display of apparatus. The committee on the proper handling and care of insulating oils reported, and the following were elected to office for the ensuing year:

Roscoe Woltz, electrical engineer, Stoneon Coal & Coke Co., Big Stone Gap, Va., president; R. R. Webster, Elkhorn Mine, Mining Coal Co., Weeksbury, Ky., vice president; Herbert Smith, Elkhorn Pipe Coal Mining Co., secretary and treasurer. The executive committee consists of J. H. Edwards, the retiring president; F. M. Reigher, George Suter, J. J. Flick and H. Maxwell.

John G. Smyth Killed by Fall of Slate

John G. Smyth, general manager of the Consolidation Coal Co., Jenkins, Ky., was instantly killed Sept. 21 by a fall of slate. The accident did not happen in a Consolidation mine but in a small operation on Shelby Creek, in which Mr. Smyth was part owner.

Mr. Smyth was 43 years of age, a son of the late William P. Smyth, Wilkes-Barre, Pa., who at one time was general superintendent of the Lehigh & Wilkes-Barre Coal Co. and the Parrish Coal Co. After leaving school he became connected with the Lehigh & Wilkes-Barre Coal Co., as well as the Parrish Coal Co., but later he left for the Virginia coal fields. Later he became affiliated with the Consolidation Coal Co. and was made general manager of the Kentucky fields, his residence being in Jenkins, Ky.
Production of Anthracite Rapidly Nears Normal Basis;
New Price Circulars Include Pennsylvania Tax

Production of anthracite has been brought up to normal more quickly than had been expected. From 1,064,000 net tons in the first week after the strike, the output rose to between 1,800,000 and 1,900,000 tons in the week of Sept. 23. This remarkable and unexpected acceleration in production brings the output to a figure comparable with that following the “miners’ vacation” in the autumn of 1920.

Fully two weeks elapsed after anthracite mining was resumed before all the old-line producing companies announced their new price circulars. Tonnage held at terminals pending price determination has now been released by the publishing of temporary prices which range up to $8.35 on the large sizes. The increases of from 15c. to 30c. as compared with the last pre-strike quotations presumably are made to cover the Pennsylvania state production tax. Quotations on steam sizes have been increased in line with soft-coal prices. Following are the ruling quotations per gross ton f.o.b. mine as quoted on the New York market:

Lehigh Valley—Broken, $7.75; egg, $8.15; stove, $8.15; chestnut, $8.15; pea, $6.15; buckwheat, $4; rice, $3; barley, $2.

Williams & Peters (Erie)—Broken, $7.75; egg, $7.75; stove, $8; chestnut, $8; pea, $6.15; buckwheat, $4; rice, $3; barley, $2.

Lackawanna—Broken, $7.75; egg $8; stove, $8; chestnut, $8; pea, $6.15.

The opening of Wilkes-Barre Coal Co.—Broken, $7.75; egg, $8; stove, $8; chestnut, $8; pea, $6.15; buckwheat, $4; rice, $3; barley, $2; boiler, $2.50.

Lehigh Coal & Navigation Co.—Broken, $8.10; egg, $8.35; stove, $8.35; chestnut, $8.35; pea, $6.20; buckwheat, $4; rice, $2.75.

Philadelphia & Reading—Broken, $8.15; egg, $8.15; stove, $8.15; range (new size), $8.15; buckwheat, $4; birdseye, $2.75.

Despite the statement by the Pennsylvania Fair Practice Committee that $8.50 was considered the maximum price that independent operators could charge for their coal, quotations are now within a range of $9@$9.50. Immediately after the resumption of operations, prices were fixed at $8.50, which is $14 above-the-ground, and high quotations are still rumored. Some independent producers say that they must receive a price in excess of that given by the committee and as an alternative may ship their product outside the state and beyond the jurisdiction of that body. The Pennsylvania state authorities, realizing that it is necessary to have the maximum production of anthracite to meet the needs of the country, have announced that any mines which cannot be operated at the $8.50 maximum shall be given a hearing and that after an analysis of their production figures by the Fair Practice Committee, a higher price may be granted to cover higher costs. These prices will be announced from time to time as examinations are made and the price determined by the Fair Practice Committee in the State of Pennsylvania.

William H. Woodin, State Fuel Administrator for New York, announced on Sept. 22 that the immediate supply of anthracite has been increased for the several states would be between 50 and 60 per cent of normal. This necessitates, Mr. Woodin said, the strictest form of economy in the use of domestic sizes of anthracite and the full use of substitutes.

Some hard coal is beginning to trickle into the Northwest. Shipments are very small, however, and no Lake charters have been signed as yet. Consumers in this territory are being urged to use lignite and coke as well as bituminous coal substitutes as far as possible.

Burns Brothers, in New York City, are advertising British coal as a substitute for anthracite for certain limited uses, at prices about the same as for anthracite. In New Jersey the Governor has issued a proclamation setting the price of coal for householders at 15c. above last year’s quotations. He did this through the New Jersey State Fuel Commission, after having refused to call a special session of the Legislature to pass on coal questions.

The Pennsylvania Fuel Commission, on Sept. 7, 1922, adopted the following regulations fixing the maximum gross margin for retailers and setting rules for distribution and standard of preparation for anthracite:

(1) The maximum gross margin per ton on sales of anthracite by retailers shall not exceed the gross margin per ton realized during the month of March, 1922, without the authorization of the commission.

(2) Retailers shall limit delivery of anthracite to domestic consumers to 60 days’ supply.

(3) To avoid hoarding and to insure equitable and supervised distribution, anthracite operators are prohibited from furnishing domestic uses for household use to any consignee other than an established retail coal merchant, unless authorized by the Pennsylvania Fuel Commission.

(4) All anthracite offered for sale or shipment shall be maintained at the standard of preparation existing in March, 1922.

Ford Plants Reopen; Idle Four Days

Plants of the Ford Motor Co. which were closed Sept. 16, throwing 70,000 to 80,000 people out of employment in Detroit, when the company was unable to obtain adequate coal supply, began reopening at midnight Sept. 21. Orders for the resumption of operations came within twenty-four hours after announcement of the action of the Interstate Commerce Commission in modifying Service Order No. 23 and substituting order No. 25, permitting distribution of coal to industrial concerns even though not included in the essential classification of priority group No. 1.

Under the operation of the order as it stood before the change the Ford company, though owning and operating eight thousand acres in the Banner Fork district of Kentucky and owning and operating a railroad on which the coal was brought to Detroit, was denied the use of the coal and would be required to turn it over to railroads or public utilities. Modification of order No. 23 will enable the company to use coal produced by its own mines and moved on its own railroad.

Henry Ford made the prophecy last week that coal will soon be much cheaper. He advised the people of the whole country not to buy much now but to wait for the slump. He said in an interview that there is enough coal above ground now to last the country for some time and that even anthracite is going to reach the Middle West, though the motor king is in some doubt about any drop in the price of that coal. The exalted price levels on soft coal were attained, he said, because producers tried to hold coal back from the market, but the prices are tending now. He said his company had recently bought 500 cars in Toledo at $5 a ton including freight and arranged for a 60-day supply through Cincinnati from agencies at $5 at the mine. "Before spring coal will sell a good deal below $3 at the mine," he prophesied.

An attack upon coal prices is being made in the Chicago City Council, where an alderman who is a candidate for office has charged that an operators’ ring and a retailers’ ring are holding up the market with heavy tariffs for those who undersell fixed price levels. The council’s committee on the high cost of living is expected to make an investigation. The Chicago Retail Coal Merchants’ Association denies all the charges and has filed suit against the alderman for $200,000.
Production and the Market

Weekly Review

Declining prices have been checked, temporarily at least, by the strong demand for domestic fuel. While the household consumer is not buying heavily, retailers in some areas, especially the Middle West, are filling their yards with bituminous coal for winter distribution. Dealers are beginning to realize that anthracite will not be obtainable in sufficient quantity before Jan. 1. Steam grades are in no better position than at the beginning of September and in some markets distress lots can be obtained at bargain prices.

The aggregate result of the stronger domestic demand and poor industrial call is reflected in Coal Age Index of spot bituminous prices, which registers a rise of 5 points to 413 as of Sept. 25, from 412 the week before. This week's figure represents an average mine price of $5.00, as compared with $4.99 for the preceding week.

Transportation Conditions Badly Upset

Transportation conditions are deplorable, especially in the West. Coal is moving very slowly, gateways are congested and mines are everywhere short of cars. In some parts of Kentucky production has been limited to one day per week by the carriers' inability to furnish supplies and haul loads. Lines furnishing the Hampton Roads piers are giving poor service. Resumption of anthracite mining has greatly reduced the car supply in the adjacent soft-coal fields. Surplus cars have been exhausted in the past two weeks for the first time since early in 1921, and until the railroads can increase the turn-around there will be no better car supply.

Despite these factors limiting the supply the buyer of industrial coal maintains his attitude of aloofness, in which the passage of the federal coal bills has added point. He believes that prices will not be allowed to ascend. State authorities are modeling similar measures—Ohio has already passed such a bill—and the buyer sees in these an argument for awaiting lower prices. Coal men are divided in their opinion on the future of the steam-coal market this winter. Some are of the very definite opinion that there is so little inherent strength in the industrial demand that prices cannot rise—in other words, the railroads will be able to haul as much coal as is urgently required. Others equally well informed and as thoroughly experienced in the trade look forward to a very definite shortage, a strong demand and high prices.

The Lake trade is very active. Dumpings passed the 1,000,000-ton mark last week and are still increasing. Record-breaking receipts and excellent rates of discharge are reported from the Head-of-the-Lakes, where an easier feeling now prevails. This heavy flow of coal has blunted the edge of climbing dock prices and the lowered quotations have brought in many delayed orders. Coal is flowing off the docks as fast as it is unloaded, and boats are making one-day turn-arounds in a feverish attempt to transport as heavy a tonnage as possible during the remainder of the season.

With the announcement of new circular prices by the old-line producing companies much anthracite that had

(a) Subject to revision. (b) Revised from last report.
been held at destination has been released for retail distribution. The new domestic coal prices are 15c. @ 30c. higher than the latest pre-strike quotations, presumably to cover the Pennsylvania state tax. Distribution is being carefully watched by state authorities, that the meager supplies may have adequate needs only. The movement so far has been eastward, very little tonnage going west of the mines. No Lake charters have been made, although some coal is dribbling into the Northwest.

Independent coal is moving generally at a high of $9.50 compared with the maximum of $8.50 announced by the Pennsylvania Fair Practice Committee. Unless a modification of the committee ruling is made it is likely that most of the independent tonnage will be shipped out of Pennsylvania to enable producers to obtain what they insist is an adequate return for their commodity.

BITUMINOUS

"Production of bituminous coal in the last week (Sept. 18-23) is estimated at 6,900,000 to 9,900,000 tons," says the Geological Survey, "a slight increase over the preceding week. Loadings on Monday, Sept. 18, were 37,330 cars, the highest since the close of the strike. On Tuesday, however, they dropped sharply to 29,496 cars.

"The present output is above that of the corresponding period of the year of depression, 1921, but is below that of the preceding four years. The present condition of the coal market resembles the three years 1918 to 1920 more than that of 1921. In those three years, as now, demand for soft coal was active enough to absorb all the coal that could be transported."

Movement of all-rail coal to New England increased to 3,009 cars during the week ended Sept. 16 from 2,722 cars in the preceding week. That market, however, is well stocked and prices are easy, movement being largely on contract. Chicago coal by water tends to restrict all-rail spot shipments. These Western coals are being kept from lower price levels by the more active Western demand for low-volatiles.

a Data furnished by the Massachusetts Fuel Administrator.

Hampton Roads dumpings for all accounts were 297,600 net tons during the week ended Sept. 21, as compared with 341,558 tons in the previous week. Some exporting has been
The Lakes are getting little anthracite as yet. Independent quotations are within a range of $10-$13 per ton, although some wild quotations have been rumored since the resumption of mining.

**Anthracite**

Production of hard coal during the first week after the strike was 1,384,000 net tons. Preliminary estimates for last week place the output at between 1,800,000 and 1,900,000 tons, or close to normal.

Large users are in active competition with soft coal. Cleveland buyers invaded Buffalo last week, only to find that no coal would be available to them for some time. Family

**Coke**

Bituminous coke production has remained at a rate of about 140,000 net tons—125,000 tons during the week ended Sept. 16—less than three weeks. Lack of cars is now limiting the output and the strike has been a waning factor since early in September. It is doubtful if additional furnaces can be started, and the only offerings are very limited and at a strong retail demand for coke has sprung up.

| How the Coal Fields Are Working |

Percentages of full-time operation of bituminous coal mines, by fields, as reported by the U. S. Geological Survey in Table X of the Weekly Report.

**Coal Age Index 418, Week of Sept. 25, 1922.** Average spot price for same period $5.06. This diagram shows the relative, not the actual prices on fourteen fields, representative of nearly 90 per cent of the bituminous output of the U. S., weighted in accord-

ance first with respect to the proportions each of slack, prepared and run-of-mine normally shipped and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ending June, 1914, an 100, after the manner adopted in the report on "Prices of Coal and Coke, 1912-1917," published by the Geological Survey and the War Industries Board. (Pittsburgh District prices not included in figures for last week.)

Foreign Market
And Export News

British Market Further Depressed; Better Trade Conditions Aid French

Compared with the activities of the last few weeks the north of England coal market is in a weak state. There is plenty of coal to be had, especially in the gas and coking varieties. Port congestion is still acute and operators are pressing their claims for three shifts for coal transport workers. Steam coals are lower in price and 20,000 tons have been sold for shipment during Jan.-March at 25s. Coasting business is more active but foreign buying is disappointing especially in the American, Italian, French and Scandinavian markets. Few contracts are worth reporting other than 50,000 tons of good Durham coking coal at 20s. 6d. for delivery f.o.b., during Sept.-Dec., and 5,000 tons of Durham gas coals for Bordeaux at 20s. 5d. c.i.f. for shipment in October. Inquiries from Germany continue to be strong.

The South Wales market is in a similar position. Since the rapid fall of off American demands prices have declined and operators have an abundance of coal to sell. On the other hand home demands for Welsh coal are slightly stronger. The Scottish trade is very quiet except for certain shipments to the Continent, especially Germany. Output during the week ended Sept. 9, declined slightly, according to a cable to Coal Age, falling from the previous week's record of 5,204,000 gross tons to 5,161,000 tons.

French Output Steadily Increases

Under the beneficial influence of the diversion created by sales of British coals to North America and influenced also by the present revival in the metallurgical and textile trades and by the approach of winter, the market may be considered quite satisfactory. Northern mines are taking from their stocks, and contracts are easily renewed. Production is being gradually increased by the heavier output from devastated mineworking and from extension and, as the principal cause of the present improvement—the American coal strike—is essentially a transient one, it is easy to understand why French coal owners were so insistent at the recent Douai conference upon an extension of the miners' working time. A bill which, if enacted, would give satisfaction on that point to the coal owners, is now pending before the French Parliament.

Deliveries of German coke to France amounted to 312,000 tons in August, as against 418,000 tons fixed by the Commission of Reparations.

Coal Paragraphs from Foreign Lands

GERMANY—Production of coal in the Ruhr region during the week ended Sept. 10 was 1,761,000 metric tons, according to a cable to Coal Age. The preceding week's output was 1,729,000 tons.

ITALY—The price of Cardiff steam first is now quoted at 39s. 3d., according to a cable to Coal Age, as compared with last week's figure of 40s.

BELGIUM—A rising tendency is displayed by anthracite and some coals on the Belgian market in contrast to the weakness shown by industrial descriptions. Coke remains firm and active, while sales of briquets are good, even for export.

INDIA—The tone of the market is dull. Stock is heavy. Mills and railways are not purchasing. Prices are: Bengal 1st, Rs. 30; Bengal good 2d, Rs. 27; English coal, Rs. 38; African coal, Rs. 27.

PANAMA CANAL COAL PASSAGES were 404,389 gross tons during the fiscal year ended June 30, 1922. Of this tonnage the largest amount—29,549 tons—originated in the British Isles. The United States moved 156,322 tons. The West coast of South America took 153,638 tons of the total movement.

CANADIAN IMPORTS DECLINE SHARPLY

Imports of anthracite by Canada for the first eight months of 1922 were 1,100,223 tons of domestic and 189,784 tons of steam sizes, as compared with average imports during the corresponding period for the last three years of 3,958,980 tons and 164,649 tons respectively. Imports of bituminous coal were 4,678,921 tons during 1922, while the three-year average imports for the same period were 8,368,524 tons.

Coke

UNIONTOWN

Only the tent colonies scattered about the Connellsville region show the existence of the miners’ strike. At plants where cargo is placed for loading there is sufficient labor to operate them.

The car situation is becoming acute but despite that development the coal market remains unchanged with the range of $4 to $4.50 which has prevailed for the past two weeks. There are plenty of orders for available tonnage but consumers are not disposed to bid against each other.

As a general condition striking miners are holding fast and the miners remain with the “lost cause.” Their confidence of ultimate victory despite the many broken promises of the organizers is one of the most remarkable things about the strike. Although union miners have now been working a month no effort has been made on the part of the union to supply that financial relief which was promised to striking Connellsville miners.

Connellsville

The coke market has advanced, furnace coke being at $12 and foundry, $8. Increased output is limited by transportation conditions at most plants. There are thousands of men in the region still who consider themselves on strike but a complete breaking out of the situation is hardly a likely effect except to start some plants and curtail operations at others, there being a re-distribution of cars rather than an increase in the total supply available.

All told only three or four blast furnaces have been able to resume in the past 30 days on purchases of Connellville coke, although running strong coke interests have bought some tonnage, to mix with their byproduct coke. It seems very doubtful if in present circumstances Johna, a quite 72 hr. Connellsville foundry at $13, 48-hr. furnace at $11.50.
Company Price Notices

Start Sales of Tonnage

Quotations Higher Than Latest Pre-Strike Figures — Heavy Independent Movement Beyond Pennsylvania Likely, as Producers Say Fair Practice Maximum Is Too Low — Steam Sizes Again Competing with Soft Coal.

New prices have been announced by the companies, who are now releasing the tonnage that had been held at destination pending this announcement. Quotations show an advance over the latest pre-strike figures, presumably to cover the Pennsylvania state tax. Independent domestic sizes are moving within a range of $9@9.50. The $8.50 maximum set by the Pennsylvania Fair Practice Committee may result in a heavier independent movement to points outside of that state, as many producers say their price must exceed that figure to enable them to operate.

No Lake charters have been reported as yet, although a small amount is dribbling into the Northwest. The movement so far has been almost entirely eastward.

Baltimore

Some light supplies have been received. These receipts are all independent coal apparently, which leaves the trade here in a rather peculiar position. The papers have drawn comparisons between the selling price of the retail ton in New York and the retail price in Baltimore as set by some individual dealers.

The freight differential in favor of Philadelphia and New York, however, together with the fact that the New York price is based on the net ton while the Baltimore price is gross by law, proved the big factor in showing that the Baltimore dealer is not getting too much for his coal. Should the day return when the Baltimore dealer can get one-half, or even one-third of company coal, or when the independent price comes down to or near the company price, then the dealer would be warranted in readjusting.

New York

Coal is coming forward in good volume. One of the features of the situation is the difficulty some dealers in independent buckwheat have in disposing of their supplies, although it is said they offered it at company schedule.

Most companies have made their new price lists and some retail dealers have done likewise. While

nothing has been said by the producers regarding their disposition of the Pennsylvania State Tax it is understood that it has been included in the new prices.

Retailers are advertising in the daily papers the fact that coal is coming forward and that those consumers who have not placed orders should place their orders and that they would be filled in their order. However the State Fuel Administration proposes to see that no consumer secures more than a two weeks' supply at any one time.

Independents are quoting $9@9.50 for the large coals, although there are reports that some of the smaller operators are exceeding those figures.

Buffalo

There is now a little hard coal coming in. So far no price has been made and the coal goes out without a bid. Practically all of the Canadian dealers have already been over here, asking for coal.

All sorts of reports come in from the independent districts. One jobber has obtained a mine price of $12. Another has sold considerable at $13.50.

There is to be Lake coal to load in a week or so, but no charters have been made. There is ample tonnage yet, in spite of the increased loading at Ohio ports.

Boston

Dealers are much cheered by early shipments that have already been made. The first cargo of prepared sizes reached Boston on Sept. 22, from Philadelphia, and this will be followed shortly by a large cargo from Baltimore. All rail, also, considerable shipments have already been made.

There is satisfaction also in the prices announced by the old-line companies. The new basis is regarded as fair to the public.

Philadelphia

When company producers announced their schedule of mine prices, the Coal Age forecast last week that an increase of $5@6.50 a ton was likely was largely borne out, as the average increase on the three large sizes figures out 25c. None of the companies has issued a circular and prices are quoted for current shipments only; neither has anything been said about State tax and this item has not been covered in the increases noted.

The independents as a whole have been somewhat slower to announce prices. As yet it is not known what action the independents will take upon the Governor's statement that maximum prices shall not be higher than $8.50.

Retail prices are far from settled, although it is thought those handling company coal will have a price of about $14.50 for prepared sizes with $11 for pea. However, those dealers who have been receiving prepared sizes at $9.25@9.50 have been charging $15 for it, and $12 for prepared sizes.

Steam coal prices have been considerably increased by the companies. There is considerable variation in independent prices, with the compelling buckwheat under $4 and some as high as $5. The demand for all steam sizes is strong and there is very little free coal on the market.

Anthracite Fields

Some of the mines have not as yet resumed operation but in these cases the absence of resumption has been due to heavy falls of roof that have to be cleared up first. The condition of the mines really depended on the action of the union locals. Many of the locals were willing for the companies to use sufficient men to keep the mines up while others would not permit any of their men doing this class of work.

Pond like this is probably kept down by the union themselves as they do not desire to see any coal in storage when the expiration of the contract comes.

South

Birmingham

Transportation service is still the greatest matter of concern in this district. An approximate 50 per cent represents the general average of requirements as furnished by all carriers. This situation is responsible for as active a market as now exists for steam coal, the coal being slightly in excess of the tonnage being produced. Consumers in general are not getting as much coal or receiving it as promptly as they would like but this is due to the service alone, which has crippled production and movement from the mines.

Some of the carriers insist on observing the priority regulations, although it is understood that first and second priority classes have been getting more coal than actually required, except in the case of domestic dealers. There is a distinct shortage of this grade in the spot market and inquiry is strong.

Prices on spot steam and domestic grades within the state have practically stabilized on the schedule, a slight premium being offered on both grades of fuel for shipment into adjacent territory.

Virginia

Transportation facilities have been quite as conducive to an increase in the output as was the case earlier in the month so that less than 50 per cent of capacity or less is being produced. There is still a healthy demand, although Eastern markets are becoming more absent, noticeably among domestic, with the result that egg and lump have advanced in price to some extent.
Chicago and Midwest

Car Shortage and Weak Steam Demand Prevail

Kentucky Mines Average One Day

While Illinois and Indiana fields worked two days a week—domestic prices firm but others soften.

Weak transportation and slack demand for steam coal continues.

In eastern Kentucky car supply got so bad last week that many a mine worked but one day and some of them got only a part of a day. Western Kentucky service was almost as bad.

In southern Illinois the average of 30 per cent continued in prevail while in central and northern Illinois the record was brighter, rising up in some sections to a point close to 75 per cent. Indiana was fully as affected in most fields as southern Illinois.

While the call for domestic size continued fairly good and prices level, steam coal here and there got too flexible so that a general softening of steam prices was noticed. The difficulty of moving steam coal was so marked that a number of contracts for the coming six months were reported. Some of these from central Illinois ran below $2.25.

The trade in anthracite promises some sort of revival with the first cold snap.

CHICAGO

The "hook" of big coal buyers is working away fairly fast. Prices are on the move and some continue to soften under the last move of heavy shipments.

As in the market for consignment as that alone limited the week it was possible to pick up large lots of consignments and much was down at prices ranging from $2.75 down to as low as $2.25, on a few invoices, where the premium was felt more deeply by the shippers. Through it all, however, Illinois operators generally refuse to drop their prices below $2.50, and getting away unsold at figures like $1.40, better quotations.

Many producers merely continue to put their coal on steam, waiting for the market to get away unloading at figures like $1.25. Some companies are in the market, but when they have no contracts on hand they are out of business.

The trade is watching sharply for the signing of new steam contracts.

In large cities along that this is the worst time in many years for the filing of such agreements for the future but the fact remains that some producers are buying heavy, and making them for the future. Companies have the tendency to improve car supply in the producer though they do not guarantee it. Much of this service is for the coming winter, although there is a prospect for the coming winter, and some below $2.50, even as low as $2.25 in some cases.

Domestic demand continues fairly strong and prices hold quite firm, but dealers have been doing a lot of buying without unloading to consumers and they have anticipated. In other words the householder has not felt the urge yet. A thin flow of smokeless is getting into Chicago and going to the billiard halls.

The first trip of anthracite is going to appear within a few days it is quietly predicted by one shipping concern but only a small volume of hard coal is expected before the first of the year.

INDIANAPOLIS

In spite of the fact that there is a serious industrial or domestic demand that was expected when the strike was settled. Along with the general unrest in the anthracite trade there is a considerable demand from various sections of the state of proffiteering in coal.

The Indiana Public Service Commission thinks $4.50 at the mine is fair. It is expected that the market will rise from all parts of the state that prices are much higher. Brokers are believed responsible to a large degree. An investigation of all of the shipments made. Same coal is selling at more than $5 at the mines. Practically all grades of foreign-mined coal, largely used in Indiana for domestic purposes, are bringing at least $2, for which they sold at this time last year. Retail demand is light.

ST. LOUIS

Locally there has been a vast improvement in the past ten days in the matter of domestic coal. The public is waking up to the fact that anthracite, coke and smokeless fuels are not available and they are ordering the next best thing, which at the present time is chiefly Mt. Olive. Carterville is hard to get and the big demand has caused St. Louis has refused to take any Carterville orders.

Mt. Olive is selling in greater proportion than all the other coal together. For open market Standard is bringing $4.75, while Mt. Olive for St. Louis is bringing $4 and Mt. Olive at retail is $5.50 and Standard, $6.75. The Standard operators are taking advantage of an outside market to keep prices up and are shipping heavily to Chicago on consignment. Locally in the country steam is quite market come numerous changes in the market and it is settled. Country domestic business is good, consumers taking any coal that can get.

WESTERN KENTUCKY

Car supply, which has been especially poor since Northern coal fields resumed, is growing worse. The Illinois Central, during the general strike furnished almost no supply, while now it is down to about 50 per cent. On the L. & N. car supply is reported at about 15 per cent.

Coal is a little scarce due to the small movement, and prices are slightly stronger than they have been, as there is a fair demand in the Louisville, Memphis, Nashville, Evansville and other central markets, with some demand still from Chicago and St. Louis. Lump coal is scarce and shows indications of further advances. It is quoted $4.75@ $5.25, with very little selling at less than $5.

Right now there does not appear to be much prospect of any material improvement in car supply, unless the plan of shipping cars under other loads in the direction of the owning line, aids in getting them moved from Northern lines. Today it is not a question of getting business but only to secure cars.

SOUTHERN ILLINOIS

A marked decrease in the amount of equipment furnished has almost stopped production at some mines in the Carterville field. The Missouri Western and Illinois Central are in the worst condition. The Burlington seems to be in the best shape. Railroad coal throughout the field is moving out heavily and is making good shipments on ordered sets. It will take at least three months, operators figure, to get caught up on domestic orders on the books now. Steam is dull, though. There is much dissatisfaction among miners on account of poor working time.

Somewhat similar conditions prevail in Duquoin and Jackson. Work time is being given the Mt. Olive operators. It is reported that no cars were furnished for eleven days at one mine on the Chicago & Northwestern. On account of congestion in this field coal tie-up tonnage is moving to Chicago and the North-west.

In the Standard district some mines are getting from within the field for Coventry. There is not a question of quality or preparation any more, it is merely a matter of coal. The county fairs in Illinois have helped to keep tonnage down this week for when these cars the mines would not work, especially on the Mobile & Ohio.

Steam sizes are slow and hard to move on account of the big plants that draw from this territory in Missouri using oil. The cancellation of Order 23 will help conditions some, but the assigned car order may cause another tie-up. The railroads decide they want all the coal.

The future is not good. Colder weather will mean an increased demand that cannot be met, and many indicate that car supply or motive power will show any improvement in the next two or three weeks.

LOUISVILLE

Although production of the country is increasing in Kentucky it is materially off due to the very poor car supply at Kentucky mines, and prices are advancing. Eastern Kentucky is asking as high as $5.25 for lump and mine run are low at $5@$5.25. Retailers need coal, but won't buy it at prices quoted, holding that they can't pay the freight and handling costs, and they quote it at a price that is fair to the consumer. It is reported that the producers of gas coal are getting better demand and a premium of $1.50 a ton.

Hazard field operators reporting only 8 to 11 per cent of cars needed, and Harlan producers report that the situation is even worse. Coal is reported running 18 per cent on L. & N., and 50 per cent on the I. C. The Kentucky coal trade believes that some railroads are holding many serviceable cars on sidings over the country that ought to be in service.
Northwest

Prices Softening Some
As Cargo Coal Flows In
Stream of Vessels Unloading at Every Dock—Make One-Day Turn-Arounds—Threatened Dock Strikes Cause Much Worry—Anthracite Arrives.

The Northwest continues to have its fretted feelings soothed by a heavy volume of cargo coal that is arriving in record-breaking quantity. Docks are concentrating every effort to make speedy discharges so that boats often make one-day turn-arounds. This coal has already blunted the edge of climbing prices. With all this coal coming in and prices softening the Northwest now worries principally about the threatened dock strikes which might cut off Lake coal during part or all of the remaining weeks in the shipping season.

The other main worry is over anthracite. The first shipments since the strike are just beginning to arrive and various conjectures are made as to whether enough will get through to meet the most urgent wants. Yard remnants are selling around $16, but in Milwaukee it is estimated the retail price for the rest of the winter will be at least $17.

DULUTH

Prices of Yougihoghey, Hocking and Splint have dropped. Coal men say that this is not so much an actual decrease as it is an adjustment to true values. It is openly stated in the trade that those who were asking $12 for lump, $11.50 for run of pile and $9.50 for screenings last week, are profiteering and that the downward revision is only an adjustment to the correct scale. At the dock lump is sold at $9.50 now, run of pile at $9 and screenings at $7.50. This adjustment has proven most stimulating to trade and many orders are being booked. The docks, of course, are absolutely clean, as coal is being shipped out as fast as it is received.

Receipts are passing all precedent. Last week forty-one cargoes arrived and thirty-four more are scheduled to arrive within a day or two. The forty-one cargoes brought in more than 350,000 tons. Docks are handling the rush in a most commendable manner. Boats are given one-day dispatch, which is unusual even in normal times.

The possibility of a seamen's strike and the reported disturbance on Lake Erie docks are the only two dark clouds on the coal horizon at present. If the seamen strike Oct. 1 it will mean that the Northwest will be in trouble, and if a strike occurs on the docks it is certain that a large proportion of the coal being routed to the Northwest will be diverted. If shipments continue as at present it is an assured fact that the Northwest will be all right this winter.

There is a large call for Pocahontas, which is selling at $12 for lump and $10 for mine run. Briquets also are being sold for anthracite substitute, the price being around $10. Coke is going at $11 a ton for the Northwest. Carnegie and Northwestern—say that they will start unloading anthracite early this week. No one here knows what the anthracite situation will be. Some claim that the seriousness has been over-estimated, and that not nearly the total tonnage estimated will be required.

MILWAUKEE

Milwaukee's coal supply has been materially increased since last week's report, and an easier feeling prevails. There promises to be a continuous procession of coal vessels to this port from now on. Receipts during September thus far aggregate 233,313 tons of soft coal, making the season's receipts by Lake, including those of anthracite, at 1,686,625 tons.

Interest is now centered in the prospective price of anthracite. Word that $8.55@$8.70 has been set at the mine, leads to the prediction that anthracite will cost Milwaukee consumers $17@18 per ton when the new supply is available. Remnants in town now are selling at $15.75 for egg, $18.95 for nut, and $16 for stove. No anthracite has arrived as yet but a consignment is expected some time during the next week.

The State Fuel Committee intends to prevent dealers from profiteering. The committee is sending a questionnaire to fifty-eight docking companies asking about costs. From this the committee expects to arrive at dealers' real costs and profits.

MINNEAPOLIS

At last cargoes are reaching Lake Superior docks in good number. If this can be continued for a few weeks, stocks will afford a fair promise of meeting the most urgent needs of the market. Only about ten weeks of navigation remain. Transportation troubles limit the volume of Illinois coal that might come up here by rail.

The real difficulty is and has been a matter of getting cars to move the coal from the mines to the docks. There may be now and then a shortage of cars at the lower ports for loading. But the primary difficulty has been cars,—always cars. And the same thing is equally true of the rail-rail mines.

One effect of the tonnage moving to the docks has been a softening of top prices. There will be an easing off right along, if transportation does not fail entirely. Coal men now believe the Northwest will be supplied with enough soft coal to serve all urgent needs, and with a portion of the usual hard coal tonnage.

Much complaint is made over alleged profiteering. One association of flour millers has set up that Illinois screenings were quoted at $1 at the mine less than a year ago, and are now quoted at $4.50 at the mine.

New England

No Improvement Shown;
Market Remains Inactive

Consumer, Well Stocked, Shows Little Disposition to Buy for Future Needs—Current Inquiries Small and Scattered—Car Shortage Severe.

There is no improvement in what is regarded as a very inactive market. Consumers are well stocked and it would take much more attractive prices than are now ruling to induce buying. There is a firm impression that steam coal is bound to be plentiful for months to come and there is little disposition to buy against January or February consumption. The larger corporations have ample reserves and the only current inquiry is from small users scattered all over the territory.

While there is little spot business at Hampton Roads a car shortage has developed sufficiently to curtail mining in certain of the smokeless districts. The market on Pocahontas and New River meanwhile is supported by Western demand.

A f.o.b. vessel at the Roads continue to range $7.90@$8.25 per gross ton, but a large proportion of what coal is dumped is applicable on contracts. Railroad piers at this end are so congested that those who have quotas does them are inclined to postpone shipment for the present.

There is a full line of Pennsylvania prices available for spot shipment at prices all the way from $4 per net ton at the mines to $5.50 for quality coals. The market for Tidewater shipments is sufficiently depressed, however, to have very little opening for rail deliveries within easy range of re-handling points. It is hard to say how there can be any improvement for Pennsylvania coals the boats or 90 days.

Delays on British cargoes continue. At certain of the railroads there is a delay of more than three days before the arrivals, other docks are also tied up for at least a fortnight, and foreign cargoes are still arriving. Very little of this, however, is offered on the open market, because the great bulk of the shipments are for account of manufacturers and other large consumers who made purchases six weeks or so ago.
Eastern Inland

Domestic Coal Is Strong,
Lake Dumpings Gain Rapidly

Yard Stocks Being Replenished and Mine Prices Are Up—Steam Stacks Ample and Demand Weak—Prices Hope for Lower Prices with Close of Lake Season

Domestic coal is the only strong market feature. Retailers are actively replenishing yard stacks and mine prices are up, with not much room real offered. On the other hand, steam supplies are ample and demand is weak.

This steam market quietude has been heightened by the passage of both state and federal coal measures. Ohio is to fix prices for her coal and Ohio tends to restrict current purchases to the hardest needs. Then, too, the buyer feels that with the Lake season closed, enough tonnage will be thrown on the commercial market to settle prices. Lake dumpings are steadily increasing and shippers are still hopeful of moving 15,000,000 tons this season.

Cleveland

Dull and listless market conditions continue. Supplies are ample and the demand weak. The feeling of coal men is that prices would fall if not bolstered by the present. Mine run is selling around $4.50 a ton and nearly $4 a ton in a little market. The demand is being supplied by the trade of developments in the special session of the legislature, the passing of the fuel law and the high prices of foreign coal. The legislation of a state coal commission is in the works. A new backing up of fixing prices is about to begin. No attempt will be made to lower bids for the entire state. Pending these detailed arrangements, prices are remaining their present position with little movement.

Lake prices are making excellent headway. The Erie & Coal Exchange, which has the place for settling the disputes, is still holding at a total movement of at least 10,000 tons.

Tonolulu is beginning to arrive in increased quantities. About 4,000 tons are about four weeks behind in their delivery, and 1,000 tons are being handled as rapidly as it is possible to do so. Shipment in quantity for western and northern on rail is being received.

Pittsburgh

Production is at the limit of coal supply and there is no prospect of any material change in this situation in the near future. In some quarters there is complaint that the line is slow in getting cars, but cars have been allowed to go to the Lakes.

COLUMBUS

Domestic grades are the strongest point in the market while steam has shown a marked reaction in price. Production is going along as well as possible under the circumstances. Available coal is quickly bought up but steam users are loath to pay the extreme high prices and quotations have sagged considerably. Lumps from all fields find a ready sale around $6 and even higher. The larger part of the tonnage coming in is Hocking and Pomeroy. Retail prices are rather high. Hocking and Pomeroy selling $4.75@$5.50, and West Virginia splints, $6.50@$11.

Lake trade is slower due to the high prices asked. One contract was made recently with the Hocking mine run, where the Lake shippers will screen the coal and take the lump and resultant size. Shipments over the H. V. Docks at Toledo during the week ended Sept. 20 were 2,570 tons, as compared with 121,756 tons the previous week, making a total of 2,148,723 tons for the season.

EASTERN OHIO

During the week ended Sept. 16, mining operations were speeded up and the output exceeded that of any week since the settlement of the strike. Production was 324,000 tons as contrasted with a potential capacity of 630,000 tons, or 52.5 per cent. The 300,000 tons that is recordable in the main to coal shortage. Thirty per cent of capacity has been produced so far this year.

Unless improvement can be had in the transportation situation, it does not appear that the proposed 75,000 ton district will be able to operate over 50 per cent of full time. However, with the striking shippers returning to the roads, the trade is more optimistic.

DETROIT

The modification of Service Order 23 has created a more optimistic feeling among both the industrial and domestic consumers and the feeling is expressed that a more favorable market will result. The buying that is now being done seems to come almost entirely from steam consumers who are obligated to come into the market. The market is not being overborne by talk. Hocking lump and egg is quoted at $6.50 f.o.b. mines, while mine run is $5.25@$5.50 and slack, $4.75@$5.50. Fairmont and Pennsylvania No. 8 take about the same price. Lump and egg from Kentucky and West Virginia is $7, mine run is $5.50, and slack, $5.25@$5.50.

Inefficiency of anthracite supply is occasioning much uneasiness. In many Detroit homes the heating equipment is of a character unsuited to use of any fuel except anthracite or coke and the supply of the latter is nearly as short as anthracite.

BUFFALO

Consumers refuse to buy at all liberally, no matter how the matter of car shortage is set before them. They are willing to pay the high prices that the railroads are charging and as they have coal they hold off.

Railroads have cut down the mines to about 30 per cent of capacity and then refuse to furnish that amount. It is not yet stated what the price is there and there will be coal that the railroads held off and as they have coal they hold off.

Prices range $5.25@$5.75 for Pittsburg 3-in., and $4.75@$5.25 for Allegheny Valley mine run. Slack sells a little higher than mine run. Add to this the rebates that are offered in some cases.

NORTHERN PANHANDLE

There is an active demand at the Lakes for the output of the region although there is a disinclination on the part of the Lake buyers to pay the current market prices. Northern shipments are as large as railroad facilities will permit. A large percentage of the output is being utilized by the carriers. Some producers are shipping by water in view of curtailed rail transportation.
Combination of Events Makes Market Uncertain

Softness at Tidewater, Price Fall at Fairmont, Afoofness of Lake Buyers and Change in I. C. C. Order Influence Trade—Buyer Now Better Able to Obtain Fuel at His Own Figure.

Softness of the market at Tidewater, falling prices in the Fairmont field, a general disposition of Lake buyers to remain aloof and a modification of the I. C. C. Order 23 all militate against an easy or set swing to the market. There has been a lot of running around to find out which way things were heading, a general uncertainty as to what might be expected and a disposition to go warily lest there be some untoward change that might upset the best of calculations.

The market in the meantime has developed its own soft spots, with steam coal edging off in price and an ability of the buyer to get fuel at his figures more readily than he has been in the past three months.

HIGH-VOLATILE FIELDS

KANAWHA

Partial paralysis of transportation is still the most potent factor in retarding production. During the week ended Sept. 16 mines were not able to produce more than 40 per cent of potential capacity. There is a better demand in Western markets than in the East. The call for prepared sizes is becoming much more active. Little coal is being prepared, however.

LOGAN AND THACKER

Logan mines have been greatly handicapped by exceedingly poor transportation facilities, the car supply not being equal to much more than 35 per cent of rating. There is little free coal available. There is a growing demand for domestic grades with little to be had, so that prices have stiffened to some extent.

Inroads were made on production in the Kenova-Thacker region by a shortage of cars but notwithstanding this the field is producing more coal proportionately than some other high-volatile regions. The Western movement is far from being satisfactory, however. Railroad fuel consumption is heavy. In common with operators in other fields, Kenova-Thacker producers observe a stronger demand for coking and lump owing to the necessity of retailers restocking.

NORTHEASTERN KENTUCKY

Demand is still much in excess of the output, which is not more than 30 per cent of potential capacity or less than 100,000 tons a week. Most of the priority orders placed in this region have been filled, but the mines are now shipping on regular business. Railroads are securing a good deal of coal and some is also going to the Lakes.

The fact that demand is outstripping the supply of domestic is responsible for increased prices on lump coal, ranging up to $6.50.

LOW-VOLATILE FIELDS

NEW RIVER AND THE GULF

New River mines are still working on an open-shop basis, but the car situation is extremely bad and precludes more than a 40 per cent production. Market conditions are conducive to a larger output than the transportation situation permits, yet very few producers are securing more than the Hoover price of $4.50. There is a growing demand for prepared coals and for mine run in the West. There are a few priority orders still in evidence but they are not numerous, the various committees having virtually ceased to function.

Winding Gulf mines are handicapped to about the same extent as New River. Production losses are still averaging about 150,000 tons a week as against an output of little more than 100,000 tons a week. For such coal as is produced there is a fairly active demand with comparatively little fuel from this field shipped to Western markets, owing to the difficulty of getting such coal through. Priority orders have largely ceased.

POCAHONTAS AND TUG RIVER

Pocahontas mines are faring better than those in other smokeless territories, owing to more satisfactory transportation conditions. The greatest difficulty is in getting coal to Western markets where there is sufficient demand to justify a large movement. The N. & W., however, is able to transport more coal to Western points than other lines operating in southern West Virginia. The bulk of the output is going to Tidewater and to Eastern markets where the demand is not very urgent and where there is a probability that the markets will be glutted with coal before long.

Tug River mines are situated just about the same as Pocahontas. There is also in Western markets an active demand for high-grade coal and for fuel for steel companies having subsidiaries in the West. There are no longer many priority orders in effect. Prices as a rule are not ranging much above the Hoover price level, except as to prepared grades, which are scarce.

CINCINNATI

The buyers' strike—if it may be so called—still continues and the most notable effect has been the number of suspensions of orders and rejections by Lake buyers. There, where all the handlers of coal expected the market to be the strongest, it is the weakest. The consequence of this has been to throw a heavy tonnage on markets which are not absorbing the coal as they used to. The submission of domestic buyers to take coal in quantity has had its effect too. Whether this attitude or the fact that more mines are now turning out domestic sizes is the cause, in any event there has been a drop of $1 on some of the offerings.

The smokeless situation has developed some different curves. More and more New River is being offered through the jobbers. Old-line firms are still offering to book orders at lower prices but with the stipulation that the buyer must wait his turn. Spot shipments are taking a premium, New River and Pocahontas lump selling up to $7.50 and mine run up to $6.50.

The retail situation still continues tense. There was another boost in price this week, one firm advancing bituminous lump from $10.50 to $11.50, and mine run to $9.

Other firms have hesitated in following suit, the range of prices being: Smokeless lump, $10.50 to $12, bituminous lump $7.75 to $10.50, smokeless mine run $7.50 to $8, bituminous mine run $8 to $9, slack, $7 to $8.

WEST

SALT LAKE CITY

Three or four retail yards have been closed during past week, in some cases for want of coal. Many dealers refused to buy coal during the early part of the summer thinking the price would drop. Then came a shortage in other states and coal produced here went elsewhere. Today, local yards have trouble getting fuel.

Following the announcement that a grand jury investigation would be made into the recent raise of $1 a ton, retail demand fell off. Neither operators nor dealers seem to be worrying very much over the investigation, which is regarded as a political move.

Car supply totals only 75 per cent; on some lines. Operators in afflicted areas regard the outlook as rather gloomy in view of the bumper crops that must be moved.

KANSAS CITY

The coal business is getting back to normal, although the market situation is surprisingly low. It may be that householders expect prices to drop. Some of the dealers lay the drop off to the high prices. There are more than 100 in Kansas City, who are putting out oil burning equipment and they are all busy taking orders and installing heating equipment.

DENVER

The shortage in the car supply is causing serious concern. Colorado farmers practically the only districts in the state getting any material are the normal suppliers. The Victor American Fuel Co. mines in Logan are now operating only 32 hours this month. Price increases at the mines vary from $1.50 to $2.50 per ton. The conservative operators are only asking $1 above the Sept. 1 price.

From Field and Trade

COAL AGE
Vol. 22, No. 13

NEW YORK
The Letchworth Coal Co. has opened an
office at Buffalo, with John A. Bragg, formerly
with the Pittsburgh Coal Co., as manager.

OHIO
The Consumers' & Manufacturers' Fuel
Co. has acquired the name of a new company, char-
tered in Columbus, with a capital of $30,000
stock to sell directly to the consumer. In a letter
to Governor Harry L. Davis, H. H. Shawson,
president of the company, advised that it is
planned to operate in the central Ohio area.

Successfully handled anthracite and bituminous
coals, established in the year 1819, and now
serving as the company representative in a
military and industrial manner, the company
will reorganize its operations.

The Ideal Coal & Eastern Coal Co., Columbus,
has increased its capital stock from
$75,000 to $100,000.

The Mining Co., with headquarters in Chicago, has
leased the Patsy mining company, a coal
company, from the owners for $1,000 per year.

Teresa has been re-organized, the plant
is in good condition, and the output
of 400 tons daily is going forth regu-
larly. The capital of $10,000 the La Vera
Coal Co. has been organized at Jawnsville.

The Star City Coal Mining Co. of Indian-
apolis, has increased its capital stock from
$50,000 to $200,000.

The Saxton Coal Co. has been organized
by the owners, with a capital stock of $12,000
in Jawnsville, and the directors are Hinkle C. Hayes,
C. F. Crooks, W. D. Streit and John T. Taylor.

The Jawnsville Fourth Vein Coal Co., at
Jawnsville, has filed preliminary certificate
of dissolution with the secretary of sta-
te.

The M. Pleasant Coal Co. Terre Haute,
has papers of incorporation. The artifi-
cer is a capitalization of $50,000 and
the certificates of the firm are George W. Wills
president, J. J. Hafer, vice-president.

KENTUCKY
It is reported from Palmetto, that
J. V. Oldham, of that point, had filed
a petition for the purpose of leasing for a
$7,000,000 water power project at that
point and is now furnishing current to cities and towns in
central and eastern Kentucky, and mines in some sections of northern and eastern
Kentucky.

The O. R. Coal Co., Whitesburg, has
been formed by W. C. Darby, H. C. Blower
and others, to operate a string of wagon mines. Wagon
wines are quite at present active, but there are
at present no payments. The owners are able to load cars promptly and are
expected to be prompt in payment.

R. C. Simpson, general superintendent of the Kanawha Elkorn Collieries, Inc.
for the past year, has resigned his position and will be succeeded by J. L.
Morgan, mining inspector, and at present mayor of
Pikeville.

Governor Morrow has disbanded the
Kentucky Fish Commission, which while it
lived, was one of the most active of the
date emergency boards.

A number of new Kentucky coal compa-
nies have filed charter articles the past few
months, list including the following:
Noble Coal & Lumber Co. Which, capital
stock $25,000, of W. Martha and Pearl Noble,
Coalville, operator of all of Coalville,
Brendt Bottom; Pikeville, $10,000.

J. A. Howard, vice-chairman.

The State of Tennessee, is interested in
the State of Ohio, and has recently
leased the Richland Coal Co. in Richland

MOORE mines.

The Richmond Coal Co. has filed
articles of incorporation, with a capital
stock of $50,000, to purchase coal in
Richland.

The Tennessee Coal & Coke Co.
has filed articles of incorporation, with a capital
stock of $100,000, to purchase coal in
Richland.

The State of Tennessee has recently
leased the Richland Coal Co. in Richland.

MINNESOTA
J. H. Sanford, president of the Carnegie
Back & Fuel Co., and J. A. Howe,
vice-chairman and general manager, were
at lunch in an inspection tour recently.
They represented that they had large sup-
plies of coal in that market, and
that the dock might be
all in a week.

A city committee on fuel has been named
Minneapolis by Mayor Leach, to carry
out the plans of the city
in that direction. It is
led by W. A. Kellogg, real
estate and land agent repre-
sentative from the railroads, pub-
lishers, motion picture
operators.

Governor Pease has proclaimed a war-
time fuel holiday.

OHIO
The Burn's Coal & Supply Co., a retail
dealer, has opened a wholesale depart-
ment in Columbus, with Edward Sharafinemker, president.

Edsel Ford, son of the Detroit auto
manufacturer, accompanied by H. S. Southee,
in charge of coal purchase, William Hunt,
purchasing agent, and Homer Lusford, in
charge of the Ford mining properties in
southeastern Kentucky, were visitors to the
Cincinnati market on Sept. 29th. Mr. Ford
had a preliminary agreement in
which they said the purpose of the
visit was to learn in detail the possibil-
ities for the movement of coal.

With the strong demand for coal there
has been a flood of new corporations for
mining and distribution purposes. There
has been on the average of a half dozen a
week chartered under Ohio laws. Among
them are the Wilton Coal Co., Colum-
bus, capital $25,000; mine coal near
Athens; Incorporators, C. M. Rossier, Pearl
Glenn and Andrew C. Gibson, and
F. L. Gibson; Blue Ridge Coal & Dock Co.,
Cleveland, 200 shares, no par value design-
ated; Emile L. Andrews, David A. Gaskill,
Clay Dietrich, Jerome C. Fisher and
D. F. Olmstead; Eastern County Mining
& Coal Co., Columbus, capital $5,000; R. M.

OKLAHOMA
The Coal Movers' Extension Course, Okla-
ahoma School of Mines, started its course of
this year, and is now flourishing with
an enrollment of 200 students. It is now
possible for those desiring to take the state
examinations to prepare for the same, to the
obtained amount of education. Tu-
it is free to all state residents. Informa-
tion: Oklahoma School of Mines, Coal Mine
Extension Dept., Wilburton.

Pennsylvania
A charter has been issued for the Marsha-
ll Coal Co., Robinsonville, with a capital
stock of $20,000. Its purpose is mining and
mining. J. H. D. Neale, Robinsonville,
R. D. no. 1, is treasurer and he with
J. H. D. Neale, R. D. no. 1, incorporated the
company.

The Laurel Coal Co., Clearfield, $50,000
capital, has been formed. A. House, House-
dale, is treasurer. The coal is bituminous coal. Incorpor-
ators: Joseph Jurcak and John Jurcak.

H. B. Powell, president of the County
National Bank of Clearfield, recently pur-
blished a report on the advances of coal
wealth, Cambria County, at a public auction held in handler. The price paid was
$10,950. This land was sold under par-
tion proceedings, it being owned jointly
by the A. S. B. Bank, the Israel Test
estate and the Philip Dott estate.

The Western Defense Co. have taken over
the mine of the Shipman Coal Co., near
Shamokin.
TEXAS

The Dickinson Ice & Fuel Co., of Dickinson, Texas, is the new operator of that mine with the secretary of state. The company was principally interested in the new company is W. K. Hatfield and J. J. Hyndman. The company estimated that it will be able to increase production to the extent of 2,000 tons a day with the new coal tipple.

A tract of between 500 and 600 acres of Coal Land has been purchased by the New Heights Coal Co., of North Panhandle, has completed plans for the construction of a coal tipple at its No. 1 mine. The contract for its erection has already been let. The company estimates that it will be able to increase production to the extent of 2,000 tons a day with the new coal tipple.

UTAH

The Channel Fuel Co., of Houston, has filed an amendment to its charter, increasing the company's capital stock from $100,000 to $200,000.

OREGON

A. E. Green, an employee of the Utah Fuel Co., for more than forty years, has been transferred to the Oregon Coal Co., of Portland, Ore., where his headquarters were recently opened.

HARRY T. HARDY, manager of the Dexter & Carpenter branch of the Chicago, Rock Island & Pacific Railroad Co., of Portland, Ore., has been transferred to the Oregon Fuel Co., of Portland, Ore.

The United Mine Workers of America, with headquarters in Washington, D.C., has filed notice at the State Department, Harrisburg, of an increase in its indebtedness from $2,500,000 to $5,000,000. The increase is expected to be used for coal mining operations.

WEST VIRGINIA

The Lehigh Coal & Navigation Co. has been organized by Grafton people with a view to developing coal lands in Harrison County. This concern is capitalized at $50,000, headquarters at Wheeling. The company plans to develop the coal lands in the new enterprise.

The Robinson Coal Mining Co. has been organized for the purpose of developing coal lands near Morgantown, W. Va. The company plans to develop the coal lands in the new enterprise.

The Averitt Coal Company has been organized for the purpose of developing coal lands near Lone Star, W. Va. The company plans to develop the coal lands in the new enterprise.

The Bell & Company has been organized for the purpose of developing coal lands near North Fork, W. Va. The company plans to develop the coal lands in the new enterprise.

The Fairmont Coal Company has been organized for the purpose of developing coal lands near Fairmont, W. Va. The company plans to develop the coal lands in the new enterprise.

The Four Oaks Coal Company has been organized for the purpose of developing coal lands near Oak Hill, W. Va. The company plans to develop the coal lands in the new enterprise.

The West Virginia Coal Company has been organized for the purpose of developing coal lands near West Virginia. The company plans to develop the coal lands in the new enterprise.

The Allegheny Coal Company has been organized for the purpose of developing coal lands near Allegheny. The company plans to develop the coal lands in the new enterprise.

The Baltimore Coal Company has been organized for the purpose of developing coal lands near Baltimore. The company plans to develop the coal lands in the new enterprise.

The Richmond Coal Company has been organized for the purpose of developing coal lands near Richmond. The company plans to develop the coal lands in the new enterprise.

The Wheeling Coal Company has been organized for the purpose of developing coal lands near Wheeling. The company plans to develop the coal lands in the new enterprise.

The Chesapeake & Ohio Coal Company has been organized for the purpose of developing coal lands near Chesapeake & Ohio. The company plans to develop the coal lands in the new enterprise.

The Norfolk & Western Coal Company has been organized for the purpose of developing coal lands near Norfolk & Western. The company plans to develop the coal lands in the new enterprise.

The Baltimore & Ohio Coal Company has been organized for the purpose of developing coal lands near Baltimore & Ohio. The company plans to develop the coal lands in the new enterprise.

The Pennsylvania Coal Company has been organized for the purpose of developing coal lands near Pennsylvania. The company plans to develop the coal lands in the new enterprise.

The Atlantic Coast Line Coal Company has been organized for the purpose of developing coal lands near Atlantic Coast Line. The company plans to develop the coal lands in the new enterprise.

The Chesapeake & Delaware Canal Company has been organized for the purpose of developing coal lands near Chesapeake & Delaware Canal. The company plans to develop the coal lands in the new enterprise.

The Kanawha Coal Company has been organized for the purpose of developing coal lands near Kanawha. The company plans to develop the coal lands in the new enterprise.

The Ohio Coal Company has been organized for the purpose of developing coal lands near Ohio. The company plans to develop the coal lands in the new enterprise.

The Pennsylvania Coal Company has been organized for the purpose of developing coal lands near Pennsylvania. The company plans to develop the coal lands in the new enterprise.

The Chesapeake & Delaware Canal Company has been organized for the purpose of developing coal lands near Chesapeake & Delaware Canal. The company plans to develop the coal lands in the new enterprise.

The Kanawha Coal Company has been organized for the purpose of developing coal lands near Kanawha. The company plans to develop the coal lands in the new enterprise.

The Ohio Coal Company has been organized for the purpose of developing coal lands near Ohio. The company plans to develop the coal lands in the new enterprise.

The Pennsylvania Coal Company has been organized for the purpose of developing coal lands near Pennsylvania. The company plans to develop the coal lands in the new enterprise.

The Chesapeake & Delaware Canal Company has been organized for the purpose of developing coal lands near Chesapeake & Delaware Canal. The company plans to develop the coal lands in the new enterprise.

The Kanawha Coal Company has been organized for the purpose of developing coal lands near Kanawha. The company plans to develop the coal lands in the new enterprise.

The Ohio Coal Company has been organized for the purpose of developing coal lands near Ohio. The company plans to develop the coal lands in the new enterprise.

The Pennsylvania Coal Company has been organized for the purpose of developing coal lands near Pennsylvania. The company plans to develop the coal lands in the new enterprise.

The Chesapeake & Delaware Canal Company has been organized for the purpose of developing coal lands near Chesapeake & Delaware Canal. The company plans to develop the coal lands in the new enterprise.

The Kanawha Coal Company has been organized for the purpose of developing coal lands near Kanawha. The company plans to develop the coal lands in the new enterprise.

Obituary

Edward J. Coness, widely known as an authority on coal and coal supply and head of the E. J. Coness Co., died recently at his home in Lewiston, Idaho. He had been in the coal business for 16 years.

George J. Boudreaux was president of the Mon-South Fuel Co. and manager of the Shamrock Fuel Co. of St. Louis, Mo. He was a pioneer in the mining and coal business. He was 90 years of age. He had been in the coal business for 30 years. Mr. Boudreaux was not only an authority on mining but was thoroughly familiar with transportation problems. He had been connected with the Missouri Pacific Railway for many years. He was a director of the Missouri Pacific Railway and the Shamrock Fuel Co. He was a member of the St. Louis Coal and Coke Co.,热心于煤炭生产和销售。他于1921年3月14日去世。

The Market Outlook

CONDITIONS appear to point to a season of strong demand for coal, of car shortages and high prices. The usual landmarks by which the trade judges an oncoming orgy of coal buying are lacking, however, and many find themselves lost and uncertain. To quote a specific case, a shipper began shipments of eight cars per day to a regular contract customer immediately after the strike settlement in August. Arrivals have averaged one car per day, the remainder being lost in the transportation tie-up. Now, under ordinary conditions that customer would have doubled his order and begun to buy wildly on the open market in fear that he never would get the coal he required. Instead he halved his order. Mines are running on short time, getting cars for one and two days per week. Yet the price is gradually softening and buyers appear confident and cocky.

In 1921 there was produced 415,000,000 tons of soft coal and 90,000,000 net tons of anthracite, a total of 505,000,000 tons. Production of soft coal to Sept. 30 this year was in round numbers 271,000,000 tons and of anthracite, 27,000,000 tons, a total of 298,000,000 tons. By the end of September last year the figures were 295,000,000 tons of bituminous and 60,000,000 tons of anthracite, a combined total of 364,000,000 tons. Thus the output of bituminous coal to date is some 24,000,000 tons less than last year, and that of anthracite about 42,000,000 tons behind.

Stocks of bituminous coal in the hands of consumers on Jan. 1, 1922, were about 47,000,000 tons; they are now not over 12,000,000 tons—some would say even less. This represents a drop of 35,000,000 tons, all consumed in the calendar year in addition to current production. In the corresponding period of 1921 stocks were reduced from 47,000,000 to 42,000,000 tons, or by 5,000,000 tons. In other words, in the first nine months of 1921 consumption plus exports of bituminous coal were 300,000,000 tons as compared with 306,000,000 tons this year.

At the rate at which coal is being consumed the country should have on Jan. 1 next a stockpile of between 35,000,000 and 40,000,000 tons to weather safely the real winter months of January, February and March, when cold and storms delay the movement of freight. That is to say, taking the more conservative figures both as to present and required stocks, some 28,000,000 tons must be added to reserves in the following thirteen weeks of this year. The outside figures indicate 40,000,000 tons as necessary to put the country on the safe side. This will be in addition to coal required for current consumption.

If we assume that the normal consumption of anthracite is 12,000,000 tons per month in coal-burning weather, then for the last quarter of 1922 requirements will be 36,000,000 tons. The prospect is for a production not to exceed 25,000,000 tons, leaving a deficit of not less than 11,000,000 tons to be supplied almost entirely by raw bituminous coal and coke. This added to the minimum estimate of 23,000,000 tons to replenish stocks by Jan. 1 gives us, at the lowest estimate, 54,000,- 000 tons over and above current consumption. That is, in addition to around 9,000,000 tons of winter consumption per week of soft coal there will be required an added load of nearly 3,000,000 tons to build up stockpiles and to pinch hit for hard coal. To those familiar with the anthracite situation this figure of 11,000,000 tons will appear absurdly low, for it is predicated on absolutely uniform distribution each week. The actual demand for hard coal that cannot be supplied currently will be much greater.

The mines, of course, can produce the 12,000,000 tons per week of soft coal thus indicated as necessary, but can the railroads haul it? They have developed real car shortage at less than 10,000,000 tons per week and it is quite obvious that a weekly average of 12,000,000 tons for the rest of the year is out of the question.

The question that is puzzling the coal trade is how to reconcile the apparent requirement for 12,000,000 tons a week of soft coal with an apathetic demand for around 10,000,000 tons. Beyond doubt the country is consuming coal in greater quantity than at this time last year and consumption is on the increase. Stocks in the aggregate are extremely low. Anthracite is lacking. Yet the market does not respond. Testimony of coal salesmen is to the effect that the small industrials are rather well stocked and are not eager for coal. They are not consuming coal at anything like the rate they have in previous periods of good business. Industrials burning a car or less per week represent 75 per cent in number of this class. They consume but 10 per cent of the coal used by industry, yet they normally carry around 20 per cent of the stocks.

The larger consumers are purposely staying out of the market for all save current requirements. An organized effort, engineered by the government through the National Chamber of Commerce, the National Association of Purchasing Agents and others, is being made to hold back the purchase of coal by 25 per cent of industrials—the big fellows—who consume 90 per cent of the coal used by industry, and also to restrain the railroads using 27 per cent of the total production. A demand for some 2,000,000 tons of soft coal per week for winter storage is being artificially held in check. Herein lies two-thirds of the answer.

Buying of soft coal to substitute for hard coal has not begun, and therein lies the remainder of the answer.

If 10,000,000 tons a week is as much bituminous coal as the railroads are going to give the country, then the future market depends entirely on the efficiency of the machinery set up in Washington to regulate coal. If Mr. Spens can so direct the flow of coal this winter that no consumer will be worried no matter how low his reserves may become or how much the railroads may be tied up by storms, then demand will not outrun production and prices will not unduly mount. The alternative is clear.
The American Mining Congress

A technical institution such as the American Mining Congress, approaching the twenty-fifth year—a quarter century of effort to promote in a national way the mining industry. It has achieved much. Perhaps its greatest achievement has been to give to mining a national consciousness, to make the interests of copper and coal, of iron and oil, of lead and gold in those spheres of action and thought where there is a common problem, a mutual interest and a universal contact.

The activities of the American Mining Congress lie in two directions. One of these is toward the general public and hence we find its headquarters in Washington, where the representatives of our federal government are reorganized. The day-to-day work of the energetic secretary, Mr. Callicrath, and his staff is that of keeping in touch with the national legislators and the many departments at Washington, in nearly all of which there is always under consideration some matter of interest to the mining industry.

Frankly and openly the Mining Congress has represented the mining industry at Washington. It has opposed some and has favored other legislation but in all its dealings with official Washington it has been frankly pro-mining. It has come to be recognized as fairly representing a powerful business constituency. Committees of Congress unhesitatingly call on it for suggestions, advice and counsel when matters affecting mining are under consideration. Its function in this respect is a continuing piece of work covering a wide range of subjects and requiring a close contact and never-ending attention to details. In the last sense of the word the American Mining Congress is the official lobbyist for the mining industry, but in this it neither threatens, trades nor cabals. It limits itself strictly to advice and information and finds legislators who do not know enough of coal and mining to listen to its words, and in making use of its fund of facts. Such is its principal purpose, its greatest opportunity and its warrant for continued support and existence.

In any community there are comparatively few individuals who voluntarily take on the burdens and responsibilities of civic progress. The active support and promotion of better government comes from a small minority. The same is true as regards an industry. It is the few who have the vision, energy and will to work for the common good. To muster the support of the many there has been developed the association through which the majority are pleased and inspired into concert with the programs of the active thinking minority. Thus we find the other important activity of the American Mining Congress is holding conventions—bringing members and adherents together, arousing enthusiasm, building support, moral and financial, and rendering other assistance and aid.

The annual conventions of the Mining Congress are real forums for the development of opinion. Here the business and political interests of the mining industry are distinguished from the engineering and their common ground. Taxation, cost accounting, legislation and industrial relations are among the subjects regularly discussed. It does everyone good to go and express his views as well as to hear what others have to say. The exchange of ideas is the worth-while production of a convention, of which this is typical. These meetings are seldom productive of concrete results, but they do help crystallize opinion and develop policy. Occasionally some tangible result, like the creation of the Bureau of Mines, can be traced to the activities of such an organization, but in the main what the participants carry away from the annual conclaves are ideas and renewed friendships.

In recent years an engineering slant has been given to the activities of the Mining Congress. The enthusiasm and energy of two men, Colonel Warren R. Roberts and Charles A. Mitke—one in the coal industry, the other in metal mining—have built up under the wing of the Mining Congress a National Standardization Conference for the mining industry. This year will be the third of such meetings. Standardization, co-operation, co-ordination and stabilization have become abused words, but each has an important place in the lexicon of the mining man.

The work of the Standardization Conference has not progressed far enough to demonstrate how far it may go or in what direction it eventually will lead. Obviously enough the aim is better engineering and more of it as well as better machinery and more of it. If it were sought to accomplish this by reducing all machines and methods to common types, the idea would fail. Fortunately, this is not the purpose. Standardization is not the word to define the definite engineering conception that is behind this movement, which is something different than that at the foundation of such organizations as the Institute of Mining Engineers.

Every convention must have a slogan. That announced for the silver anniversary of the American Mining Congress is "Greater Prosperity Through Lower Production Costs." To assist through the eye the preaching of this theme there will be an exhibit of many kinds of machinery—an exposition of mines and mine equipment. Thus do the promoters of the Mining Congress provide incentive for attendance, for these exhibitions are worth while, gain added support from manufacturers and tie the engineering and operating contingents together with the business and political.

In these multifarious activities of this organization we find at once its weakness and its strength. Cosmopolitan, it embraces every aspect of mining from drainage to politics and draws support from many fields. But because it is so all-inclusive it can give to none the intensive advantages of a partisan association. Thus we find the separate organizations for gold and silver, for zinc, for copper, for coal, overlapping in membership with the larger group, but having distinct objects. The American Mining Congress gives to the coal industry a contact with the remainder of the mining industry and it is just as essential that the coal men bear their part in its support and deliberation in order that the country may have a true picture of mining as its greatest basic industry as that the coal men have their own association and organizations for promoting their peculiar and particular objectives.
Where the Mining Congress Will Meet,
And What It Is Doing for the Industry

It is easier to prevent bad legislation than it is to repeal it. It is less difficult to correct a false judgment before it is uttered than to recall it when once it has gone forth. The American Mining Congress, being stationed at Washington, can prevent wrong at the source, for legislators, like other mortals, sin more often from lack of knowledge than from Adamic perversity.

The American Mining Congress officials are frequently consulted because, it would appear, they are believed to represent the mind and heart of the industry rather than its will. The Mining Congress is a loosely organized body, not a symbol of the power of a dominating industry but an expression of the mind of individuals. At the yearly meetings the legislators and the members of governmental departments and bureaus mingle with the legislated; they learn to know its members as men like-minded with themselves. The program is not carefully staged beforehand; rather it brings together many contrary minds. The men who attend it from outside the industry regard its assembly as if it were one of "just home folks." It is not a trades council; it is rather an institute for gathering new ideas. It impresses the outside man not as a battering ram to enforce an unholy will but as a gathering of men having kindred inter-

Above—Public Hall, Cleveland, Ohio, where American Mining Congress will meet and Exposition will be held

ests seeking guidance. It is not a force to be met with force but an open hand to be grasped.

The legislators who consult it probably do not know why. They cannot tell perhaps wherein they find it different from better organized, more representative bodies. Those, however, who frequent it year by year know that its strength is in the open forum, where those without the industry and those within rub shoulders and learn fellow sympathy. No doorkeepers are at the gate, no tickets of admission are demanded, and for this reason it commands confidence and accomplishes results.

First among its good qualities is that it has never created antagonism. Blithe with optimism, the American Mining Congress has never seen even a black cloud in the Congress on Capitol Hill. It has always believed that with the word of reason and the warmth of a handshake every evil anticipated could be averted and that all that is needed is that the men in the halls of Congress should know that mining men were seeking treatment in no way different from that imposed on other men. From mine and farm come the essentials of life but that is no reason why they should be made victims of special and inimical legislation.

Note—The accompanying drawings and photographs herewith are from courtesy of J. M. MacLaughlin architect.

Left—Auditorium in Hall where will be celebrated the Twenty-Fifth Anniversary of the Mining Congress.
Program of American Mining Congress at Its Silver Anniversary, Oct. 9-14, Public Hall, Cleveland, Ohio

The Mine Taxation division will hold its third national conference on Oct. 9, 10, and 11, when the following papers will be presented:

Variations of Mining Property for Purposes of Federal Income Taxation, by H. C. Allen, Cleveland, Ohio, vice-president, Lake Superior Iron Ore Association; member of committee on state and federal taxation, American Mining Congress; formerly member Tax Advisory Board, Treasury Department.

Inverted Capital of Mining Corporations, by George E. Holmes, New York City, author "Holmes on Federal Taxes," chairman special committee on state taxation of mines and vice-chairman general committee on taxation, American Mining Congress.

Special Cases under Section 216 Revenue Act of 1917, and Sections 217 and 245, Revenue Acts of 1918 and 1922, by Robert N. Miller, Washington, D. C.; formerly Solicitor of Internal Revenue; member committee on state and federal taxation, American Mining Congress.

Depreciation Dividends, by Paul Armitage, New York City; chairman general committee on taxation; member special committee on state taxation, American Mining Congress.

Settlements and Compromises with the Commissioner of Internal Revenue, by M. K. W. Kreigh, Washington, D. C.; chief Tax Division, secretary committee on state and federal taxation, American Mining Congress.

Other speakers announced are: Dr. T. S. Adams, Yale University, formerly tax adviser, Treasury Department; C. P. Smith, Assistant Commissioner of Internal Revenue and member of the Tax Simplification Board; Albert H. Fay, Chief, Division of National Resources, Bureau of Internal Revenue; Walter R. Irwin, consulting engineer, New York City; L. O. Ewing, general counsel, Anaconda Copper Mining Co.; L. P. Barrett, mineral geologist, State of Michigan; H. H. Fernsli, certified accountant, New York City; R. V. Norris, consulting engineer, Wilkes-Barre, Pa., and Howard N. Evans, consulting engineer, Pittsburgh, Pa., member, special committee on state taxation, American Mining Congress.

The standardization committee of the American Mining Congress will hold its third annual national standardization conference throughout the week, the general addresses being:

What Standardization Has Done for the Coal Mining Industry, by Colonel Warren H. Roberts, president Roberts & Schaefer Manufacturing Co.

The Purpose of Standardization in Mining, by Charles A. Mitke, consulting engineer, Bisbee, Ariz.

Eliminating Waste in National Expenditure Through Standardization, by General Charles G. Dawes.

National and International Progress of Standardization, by Dr. P. G. Agnew, secretary, American Engineering Standards Committee.

The following recommendations for standards in mining practice will be presented for discussion:

Drilling Machines and Drill Steel, by Norman Braly, general manager, North Butte Mining Co.

Metal Mine Accounting, by T. O. McGrath, Shattuck-Arizona Mining Corporation.

Underground Transportation, by William B. Daly, general manager, Anaconda Copper Mining Co., and C. E. Watts, efficiency engineer, Berwind-White Coal Co.

Milling and Smelting Practices, by Forest Rutherford, consulting engineer, New York City.

Outside Coal-Handling Equipment, by Dr. Henry Mace Payne, consulting engineer, New York City.

Fire-Fighting Equipment, by William Conibear, department of safety, Cleveland-Cliffs Iron Co.

Mine Drainage, by E. D. Knight, formerly engineer, power and electrical department, Cabin Creek Consolidated Coal Co., and William H. Gallagher, engineer Pickands Mather & Co.

Methods of Mine Sampling, by Philip Wilson, chief geologist, Calumet & Arizona Mining Co.

Steam-Shovel Equipment, by H. C. Goodrich, chief engineer, Utah Copper Co.

Mechanical Loading Underground, by Lucien Eaton, superintendent Cleveland-Cliffs Iron Co.

Standardization Day will be celebrated on Oct. 11. Other features will be papers on the relation of government to industry, on industrial co-operation, on the widening of the market for metals, also on co-operative combinations and possible modifications of the Sherman law to make possible greater economy in operation, with protection to the interests of the public. There also will be a national coal conference. The annual banquet will be held at the Hollenden Hotel on Friday, Oct. 13. A National Exposition of Mines and Mine Equipment, at which it is expected two hundred exhibitors will display their wares, will be held throughout the week in the Public Hall, where the convention will meet. The slogan of this Congress is "Greater Prosperity Through Lower Production Costs."
Big-Scale Operation Effects Economies at Columbine, Northern Colorado’s Largest Lignite Mine

New Shaft Yields 1,800 Tons Daily and May Reach 3,000—Swift Work on Panels of Narrow Rooms and Wide Pillars Results in High Extraction Despite Quick Caves and Squeezes

BY CHARLES M. SCHLOSS and F. L. PEART

YESTERDAY a barren hillside plot inhabited only by prairie dogs and chipmunks, today a prosperous mining community teeming with life and action—that is the story of Columbine, the newest, largest and best equipped mine in northern Colorado. It is the achievement of a man with a hobby. The man is George T. Peart, assistant general manager of the Rocky Mountain Fuel Co., and the hobby is—Columbine. Peart's imagination pictured it beforehand and his initiative carried the project from the nebulous paper state to its completion. Though an old-timer at this game of mining coal, he has young ideas, all embodied in this operation.

To reach Columbine one drives twenty-four miles due north from Denver. The railroad serving the property is a two-and-a-half-mile spur from the Chicago, Burlington & Quincy branch between Lafayette and Longmont. Erie is the nearest town, two miles west. Columbine is in the middle of the northern fields, equidistant from the Frederick-Dacona group and the mines at Lafayette and Louisville.

An increasing demand for coal and the exhaustion in the near future of workable coal in some of the company’s other mines made imperative the opening of a new property. Concentration of effort to reduce overhead dictated a magnitude of operation never before attempted in this particular field. The ownership of 960 acres of coal land near Erie, its accessibility to the market and the quality of the coal under those acres made the site chosen for the Columbine mine unquestionably the ideal spot.

The isolation of the place did not deter the company when once a decision was reached. A gang of laborers removed the first shovelfuls of dirt from the

FIG. 1—ANOTHER VIEW OF TIPPLE AND HEADFRAME

The tipple works, like practically everything else at the mine, were designed and built by the mining company. The headframe is of the derrick type with the legs which spread at the bottom to act to relieve the shaft collar of all load.

FIG. 2

Location of Mine

Columbine, 14 24 miles due north of Denver and situated on a 960-acre mining district.
future shafts in the next summer of 1926. However, since after the coal was reached it became evident that rapid development must be the order of the day. Since that time the output has been increased step by step until the beginning of the great strike, when Columbine really began hitting the stride of 1,800 tons per day.

"Maximum capacity every day" has become the watchword to such an extent that two shifts are worked instead of one. It is confidently expected by the officials of the company that the opening of more territory and the operation of a larger number of loaders will soon bring the daily tonnage up to 3,000.

Though every effort is bent toward producing more coal, the building of the camp is being prosecuted with vigor and enthusiasm also. New houses are springing up, all supplied with cold water piped from an artesian well. An amusement hall is already functioning and a baseball club has been organized which on Independence Day crewned late with the club from a neighboring community. The same day the company built a dancing floor and brought a high-priced jazz orchestra from Denver to furnish the music. "A good time was had by all."

In opening the mine a 9x18-ft. shaft was sunk 300 ft. to reach the thickest coal bed in the district—a seam that varies from 11 to 16 ft. A stratum of sandy shale tops it. Shale and fireclay constitute the bed. An inch-thick parting of white rock characterizes the coal, ever present though varying in position from place to place. Little water is encountered. An approximate proximate analysis of the sub-bituminous coal reveals ash, 6 per cent; volatile matter, 34½ per cent; fixed carbon, 43½ per cent; moisture, 17 per cent; B.t.u. per pound, 10,000.

In the northern Colorado field pillar drawing in general has not been successful. It is the exception and not the rule, though in a few instances a large percentage of coal has been recovered. In some mines the practice of driving wide rooms with narrow pillars between is still prevalent. Rooms are completed as soon as possible, and all the piller coal that can be taken is recovered before the inevitable floor squeezes or roof falls occur or before the pillars are crushed by the overlying strata. About 60 per cent of the available pillar coal is extracted.

**Quick Work Alone Will Assure High Recovery**

Natural conditions are largely the cause of these losses. The overburden lies on the coal like a dead weight. The minute a place is cut, the coal settles. The narrow kerf cut by a chain machine is not spacious enough to prevent the pinching of the cutter bar, which, in consequence, has frequently to be dug out. In addition the bottom is soft and when the room coal is taken out the additional burden on the narrow pillars brings such pressure on the soft bottom that it can no longer resist and up it comes to the roof.

The operators of the Columbine mine are trying to overcome these obstacles. Assistant General Manager Peart says of his method:

"Frankly we are experimenting. A panel system is being used, six narrow rooms being turned on each side..."
of the panel entries and on 70-ft. centers. The rooms on each side are driven up concurrently as rapidly as possible, 8 to 10 ft. of coal being taken and the remainder left for a top. Pillar drawing is begun as soon as the maximum room length is reached, the top coal coming down at the same time chain machines undercut the coal. The pillars in each room are attacked simultaneously, keeping their faces in line. By rapidly prosecuting this work the pillars are pulled before squeezes become dangerous. No coal has been lost so far, and we are sanguine that the scheme will be successful.”

Illinois operators who are constantly harassed by the fear of surface subsidence would consider this “the promised land.” The company owns half of the surface but that and the other half are so nearly valueless that subsidence means nothing at Columbine.

AUXILIARY AIRWAYS PROVIDE AGAINST ACCIDENT

Reference to the mine plan will show that the arteries of the ventilation system are the triple entries which provide large air passages and consequently reduce the power required to keep the air moving, and also, and this is not less important, furnish auxiliary airways in case of accidental squeezes, falls of roof or fires. Naturally the same provisions augment the haulage facilities. A Sirocco fan 60 in. in diameter and with a 40-in. face blows 75,000 cu.ft. per minute down the airshaft. An 11-ft. Jeffrey disk fan is installed close by as an emergency unit. At the foot of the downcast the air is split three ways; thus as far as ventilation is concerned there are three separate and distinct mines, any one or any two of which can be operated in case of accident to the other one or two.

The availability of electric power from the Western Light & Power steam plant near Lafayette makes generation at the mine both unnecessary and uneconomical. Transformers just outside the hoist house step the high potential current from 2,300 volts to 440 for use by the two 250-volt motor-generator sets. The cutting machines and the locomotives, of course, use this direct current. Because of the short distance of the workings from the shaft bottom the voltage is good, even though the generators are above ground.

If variety is the spice of life, then as far as machines

FIG. 5—MINE PLANNED FOR RAPID PILLAR REMOVAL

...are concerned Columbine is spicy, for a variety of types are in daily use. The initial purchase was a Goodman shortwall of the standard type. Soon after its installation the Oldroyd made its début at a neighboring mine.

The idea of shearing the coal besides undercutting...
the company’s mines. After a year’s use the company found the repair bills of the Oldroyd large though it was freely admitted that they were eminently satisfactory in most other particulars. Four Goodman shortwalls of the new automatic-control type have lately been added to the equipment of the mine.

The shearing feature of the Oldroyd is of immense value in the lignite coal. The extra lease end on which is about unintentionally permits the use of less powder and the production of not only larger lumps but also a larger percentage of lump, but this has not been sufficient to overcome the high upkeep costs and expense delays for repairs. The shortwall will cut on the bottom but this larger machine can cut no lower than the top of the rail, with a resulting bunch of coal which must be picked up or shot up at an additional cost. This cost, however, does not assume large proportions when the coal separates easily from the bottom.

Besides these two types, a Jeffrey shearing, idle at another property, was brought here and has given a good account of itself. Each machine has a territory to itself and does all the cutting in that territory. Only the shortwalls are used for pillar drawing.

In the initial stages of the mine, when it was decided to rush development, two Myers-Whaley shovels were placed in service in entry driving. These have done and are still doing good work. With a crew of four men—one operator, one man at the face and two car droppers—as much as 100 tons has been loaded and two or three entries cleaned up per shift. The output of the machine is limited by nothing inherent in the machine itself but only by the delay incident to keeping empty cars ready for it to load.

All gathering is done by ten mules—the work is not concentrated enough to justify the installation of gathering locomotives just yet; however, they are a future probability. Main haulage from partings to shaft bottom is accomplished by one four-ton and two six-ton trolley locomotives. One or two of these will be superseded by a 13-ton machine just ordered. The heavy grades down which the locomotives must retard the trips make this heavy weight necessary. At the shaft bottom mechanical brawn in the shape of Nolan automatic cagers supplant human labor in feeding loads onto the cages. The crew on the load side of the bot-

---

**FIG 8—LOADERS WHICH ADD TO PRODUCTION SPEED**

One operator, one man at the face and two car droppers can clean up two or three entries and load up as much as 100 tons per shift. It has been found difficult to deliver cars nearly fast enough to develop the full capacity of the shovel. This handicap, it is hoped, will be overcome later.

---

**FIG 9—AUTOMATIC CAGERS EASE LABOR AT BOTTOM**

Two men with the aid of an automatic cager deliver all loads to the bottom. Empties, pushed off the cages, run by gravity to a car line which raises them high enough to "kick back" to the empty line, where a third man couples them.
A model village planted incongruously in the midst of a vast gopher- and rattlesnake-infested prairie, within sight of the Rockies. This mine, which has broken many precedents, East and West, is being closely watched, as it is believed that many methods worthy of adoption have been inaugurated.

The Columbine hoist is a Denver-made Dewco, using a cylindro-conical drum 5 ft. in diameter at the small ends and 7 ft. at the center; its maximum hoisting speed is 1,400 ft. per minute. A 300-hp. 440-volt variable-speed Ideal induction motor supplies power to the drum through the medium of a double-reduction of Link-Belt silent and roller chains, all running in dust-proof and oil-retaining casings. A short countershaft supported by two bearings is driven from the motor by the silent chain and in turn drives the drum by a quadruple-strength roller chain, four heavy single-strands built integral. The layout is shown in photographic and diagrammatic form accompanying this article. A Cutler-Hammer master controller and magnetic contactor panel provide automatic acceleration for the motor.

The Columbine tipple, as well as the bath house, club house and all other buildings, was designed and erected by the company. The tipple machinery itself was made by them according to their own details and specifications, much of the material coming from other properties of the company. The screen is unusual in that it is supported on flexible boards and in that its perforations are all square instead of round or slotted. Furthermore, its speed is higher than is commonly found—130 vibrations per minute. The company has found from experience, however, that Columbine sub-

**FIG. 12—AN UNUSUAL WAY OF LOADING COAL**
Frequently coal is loaded so that the larger coal is at the top, so as to put, as it were, the best foot foremost. But sub-bituminous lump slack so readily that it is well to place them up with the finer coal. For this reason the coal is dumped so that the lump seek always the bottom of the pile and the slack remains in full view.
Trolley Clamp Needs but Two-Inch Headway

The mines of the country always have been desirous of obtaining a trolley clamp that would take up the minimum headroom. To meet this demand the device shown in the accompanying illustration has been developed. This trolley car, which is extremely simple in design, possesses certain improvements over its predecessors. It is composed of only four parts, namely, a machined steel center, two malleable-iron jaws and a locking nut. All of these are permanently assembled and sherardized.

The total height of the assembly is only 2 in., yet a positive grip on the wire is provided and the ear offers the least possible obstruction to the trolley wheel. In installation the upper hexagon nut is screwed up tightly against the suspension, after which the jaws are aligned with the trolley wire and locked in position by means of the lower hexagon nut. This is fitted with a left-hand thread, and the entire assembly is readily brought up tight and snug.

This new clamp is designed in two styles, one for 2, 0.3, 0 or 4/0 grooved trolley wire, and the other for 2, 0, 3/0 or 4/0 figure-eight wire. Consequently in mines where either grooved or figure-eight wire is standard, one style or two styles at the very outside need be stocked. This device is being manufactured and placed on the market by the Electric Service Supplies Co., of Philadelphia, Pa. Its great simplicity and small headroom will recommend it to the consideration of operators.

Measures for Prevention of Ignition of Gas

By Electric Detonators

Several ignitions of gas and at least one mine fire having been attributed to heated leg wires of electric detonators at mines in which outside firing was practiced, certain tests were conducted by the U. S. Bureau of Mines to determine, if possible, the cause of these ignitions. The results are set forth in reports of the Bureau Serial No. 2222.

Three series of trials were made, as follows: Tests in air to show the behavior of iron and copper leg wires when various values of current were passed through them, tests in mixtures of natural gas and air to determine the length of time required for various currents when passed through iron and copper leg wires to cause an explosion, and tests to determine the possibility of gas ignition from the re-establishment of the circuit after firing of the detonator.

As a result of this investigation the following preventive measures are suggested: (1) Detonators should be connected in parallel-series: series-parallel or in straight series. (2) The time during which the firing connection is made should be limited to 0.15 to 0.2 second. (3) Electric detonators with copper leg wires should be used. (4) A firing supply current having the lowest standard voltage that will fire all the detonators connected should be used. (5) An ungrounded firing circuit should be employed.

Testing Contact of Knife-Switch Blades

By J. P. Ruttin

It is important, especially in the case of big switches, that the blades make good contact with the jaws, for if they do not the switch will fail. It is sometimes difficult to determine whether the blade does or does not make a good fit if one does not know just how to go about it. The following suggestions therefore may simplify the matter:

A "feeler" can be used for finding when knife-switch blades make good contacts in the jaws. Any thin, hard material may be used for this purpose. A piece of nickei, say 1 in. wide and 2 in. long, is satisfactory, or a very thin piece of sheet steel will answer the purpose. The feeler should be about 0.001 in. thick.

To use this tool, try to insert it between the jaws and the blades at different points. At locations where it can be passed in readily the contact is poor. This may be corrected by light hammer blows on the jaws. The blades should always be "grounded" to insure good contact between them and the brass jaws.

The Coal Operator’s Blind Spot

Fails to See Duty to General Public—Rights of Individual Must Yield to Public Necessity—Can Simplify Problems by Improving Reputation

BY GEORGE OTIS SMITH
Director U. S. Geological Survey

SIX years ago, at a meeting of the American Mining Congress, the present editor of Coal Age and I began a discussion of the cost of coal with the obvious premise that “the price of coal is a matter of vital concern to the average citizen.” Since that time more than 3½ billion tons of coal has gone up in smoke here in the United States, and the price of coal has repeatedly become a national issue. Yet in these same six years, I fear, we have not been willing learners from experience; the consumer still fails to assume any responsibility in bettering the conditions of coal distribution, the public official still fails to distinguish between the essential and unessential in governmental “interference” with the coal business, and both the coal operator and the mine worker still utterly fail to appreciate that society is larger than any business and that the common weal is superior to any private privilege.

Were I writing for other columns I might well discuss another phase of the subject and appeal to coal consumers for help in reducing the burdens of those who mine and sell coal. The readers of Coal Age, however, are at the opposite end of the business, and I shall therefore better achieve my purpose by describing what I may perhaps be allowed to term the blind spot of the coal producer. It would be unfair to charge the leaders in any American industry with utter lack of vision, for we Americans like to consider ourselves forward-looking, yet the recollection of recent events forces me to the conclusion that far too many bituminous coal operators, however wide their angle of vision, have been blind in one particular—they have failed to see their duty to the general public; and, moreover, those leaders who at times have urged the recognition of the public interest have not had the following they deserved.

The Blinding Effect of Coal Dust

Possibly the miner, the operator, and the dealer are all too near to coal to see it in its larger aspects—the coal dust blinds their eyes to the truly beneficent part that coal plays in this world of ours. It is not merely a figure of speech but an evident fact that our social and industrial structure is built on a coal foundation. The labor leaders and the big operators realize this fact to the extent that it is the major premise in all their strategy, but neither the union executive nor the operators’ spokesman appears to appreciate the full social value of coal or see that a strike or lockout at the coal mines can bring-unmeasured distress to millions of fellow-citizens, and that even the partial stoppage of the country’s fuel supply for five months threatened widespread disaster all out of proportion to the wrongs that the disputants were trying to right. It is because he sees clearly the dangers of industrial paralysis that Governor Miller recently characterized as tyranny “the effort of any group of men to control on a nation-wide scale the production of any essential article,” and he applied to employers as well as to employees this rule of conduct: “When public necessity intervenes, the right of the individual to do as he will must yield.” All this is simply a fresh expression of the democratic principle of the rule of the majority, and as applied to coal it simply means that consumers outrank producers 100 to 1.

The lack of functioning in the coal operator’s blind spot is evident from the unfortunate fact that in failing to see beyond the few score or few hundred stockholder-owners of the mine he skillfully manages, or even the 500 miners he employs, he fails to realize that nearly 100,000 of his fellow citizens are dependent upon the product of his mine. In these days “dependent” is not too strong a term, for coal enters into every industry and forms an essential part of every commodity; the importance of coal even on the farm was brought to mind last summer, when a priority was requested for coal to run the threshers whose uninterrupted operation was essential to the saving of the world’s bread. It is not simply the steel works and the automobile plant and the gas works that are dependent upon a supply of coal, but every industry, large or small, in which mechanical power strengthens the arm of the workman and increases his ability to produce what his fellow men eat, or wear, or use in any way. The world lives on coal.

Property for Use vs. Property for Power

So it is that the distinction emphasized by an English professor between property “for use” and property “for power” may well be applied to the coal mine. The owner of coal in the ground has no inherent property right based on anything else than the use of that coal, and any neglect of the consumer’s right to have that coal as he needs it only incites such suggestive references to a bygone feudal system as are contained in the obnoxious term “robber barron.” That idea of property as a source of benefit to the owner alone is out of date here in the United States. The contention of a coal-mine owner that the only point of contact between his private property and the Constitution is the constitutional guarantee of protection is based upon a mistaken idea that coal is the only private property to be considered. Such an advocate of the constitutional rights of the coal operator is himself blind to the obvious existence of other citizens whose property rights and indeed whose health and happiness are dependent upon a supply of coal. It is this social value of coal for use that gives the operator and the mine worker their opportunity for profit and earnings, but even that ever-present friend in time of exigency, the Constitution, can hardly be summoned to destroy or injure the property rights of the majority in order to protect a monopolistic property right of the minority.

It was a representative coal man speaking to coal men who named the problems they continually face—
in unworthy prose, a distressing public, and the threat of malicious legislation. This statement certainly suggests a demand from which the coal operator must seek relief—a situation that calls for action. Whether he attributes this unhappy condition to prejudice or suspects that it is founded on vicious practices, the coal company, as well as the coal merchant, as a matter of sound business, must seek to better his reputation.

Fortunately, those who are engaged in the coal trade realize this, but between the parties they forget it, and I fear that the fairer reputation will not be won for the coal business until these crimes come into the whole industry, from the mine-room to the consumer's bin, a year-in and year-out sense of the great public service to be rendered to those who mine, transport, and deliver coal. It is not enough for a few to realize this; the great majority of mine workers, operators and dealers must fully realize their relations to the public.

It may be that the case of the coal operators has sometimes been presented so pleasantly that they themselves have come to believe it to be stronger than it really is. As an example of too many lawyers on the job, I cite some long-continued hearings before Congressional committees, where among the array of able attorneys came the confidence of the committee members and presented the passing of the relief legislation as effectively by a certain oil operator who made little claim to his rights but candidly told all the facts—so candidly that he was at the time accused by his enemies of "spilling the beans." But his frank presentation of the facts, regardless of whether or not they favored his case, saved the day, and it is interesting to note that, so far as the presidency of a national organization signifies priority, he is today the leader of the oil industry. Might not the coal industry profit by similar tactics?

In the six years since Mr. Leisher and I first wrote on the cost of coal I have more and more regretted the lack of the facts that are needed to clarify the issues raised by widespread criticism, and more and more do I believe that those facts, when found, will help the coal industry as a whole—not hurt it. My own view of the coal business in its relation to the public is that what will help the consumer will help the producer—that the true interests of operator, miner, and general public are not antagonistic. The respective equities cannot be determined, however, under any policy of withholding facts or of conducting the industry's case before the public by claiming everything and admitting nothing. The "strong front" presented by the attorneys for the coal operators—their uncompromising denunciation of others, their vehement claim of rights above those of the public—has had the temporary effect of shaking somewhat my faith in the integrity and good-will of the industry. The spokesmen of the coal operators have overplayed their hand.

The opportunity is now here to reverse that policy and to join in whole-hearted co-operation with a public agency whose purpose is to find facts and present them for public consideration. The United States Coal Commission has been authorized by Congress to study the whole subject for the sole purpose of advising Congress. The end in view is an adequate supply of coal for industrial and domestic use and the maintenance of uninterrupted commerce between the states. No one can render greater assistance in that study than the coal operator, and no one will receive greater benefit from a wise solution of this urgent problem.

I offer the opinion that the coal operator has too long been blind to his own interests in not seeing clearly his large and peculiar function in the service of the public. The failure of the industry as a whole to obtain a fair deal has been due in part to this blindness and to the unfair practices of the few. The facts may injure this minority, but in the long run they will help the fair-minded and fair-acting operators, who, I like to believe, from personal observation, constitute the large majority.
Hoists That Accelerate, Slow Themselves Down or Work Unattended and Substations Needing No Attendant*

Nokomis Hoist with Different Speeds for Coal, Supplies and Men, Speeds Up, Reduces Speed and Stops Automatically—Two Inspiration Hoists Work Continuously with Man to Oil and Watch

BY C. E. H. VON SOTHEN†
Schenectady, N. Y.

WHEN weighing ways and means for decreasing the operating expenses of a coal mine, two classes of apparatus should be given careful consideration. These are the automatic mine hoist and the automatic substation.

In many large mine hoists today some features have been made automatic in operation, particularly those devices intended for protection against overwinding, and in some electric machines devices for preventing excessive acceleration or retardation have been added. Thus a 1,350-hp. hoist of the Valier Coal Co. at Valier, Ill., is arranged for automatic acceleration, automatic slow down and stop. It is necessary only for the operator to close the control switch in order to start the hoisting cycle. A pilot motor then turns the controller to the full-speed position, whereupon this motor is cut off and unclutched. Near the end of the travel of the hoist cams turn the controller to the off position, and when this is reached the brakes are automatically applied.

Another hoist of this type is the 1,050-hp. machine of the Peabody Coal Co. installed at Nokomis, Ill. This hoist is provided with cams so arranged that the operator may obtain three definite speeds for hoisting—for coal, for men and for material. Automatic retardation and stop are provided at each speed. These hoists, of course, require the presence of an operator on the platform at all times. The automatic features simply permit higher hoisting speeds and more rapid retardation than could be obtained normally with manual control.

There are some large hoists in operation, however, that are completely automatic—that is, capable of performing their functions without an operator being present at the control levers. Where the rope speed is low, no slow down is required before the skip or cage enters the dump. In such cases a direct-current shunt motor or an induction motor may be employed. For speeds above 400 ft. per minute it is necessary to retard before entering the dumping apparatus. A reasonably accurate stop also is required for reliable operation. It is nearly always imperative, furthermore, that the automatic-control system act in the same manner irrespective of the load—that is, that the rate of retardation and the position of stop be nearly the same whether the skip comes up loaded or empty.

The direct-current shunt-wound motor with voltage

---

*Article entitled "Automatic Electric Apparatus Applied to Coal Mining" read before the West Virginia-Kentucky Association of Mine, Mechanical and Electrical Engineers, at Huntington, W. Va., Sept. 22.
†Power and mining engineering department, General Electric Co.
counted is the only type inherently suitable for automatic hoisting at high speed. This system of control has such characteristics that if the controller is moved back at a certain rate the hoist will be retarded at a proportionate rate and to nearly the same speed irrespective of the load being hoisted.

When the officials of the Inspiration Consolidated Copper Co. planned the layout of their main shaft several concurrent conditions indicated the possibility of effecting considerable savings in hoisting by the use of automatic hoists. Two three-compartment vertical shafts were sunk for two independent balanced hoists, either of which can in an emergency keep the upper works running at full capacity. The third compartment of one shaft contains a double-deck main cage and the third compartment of the other carries a counterweight for this cage together with air lines, electric cables and the like.

The hoists proper were built by the Nordberg Manufacturing Co., and the electrical equipment was furnished by the General Electric Co. Fig. 1 gives a general view of the two machines and the electrical equipment. Each hoist is driven by a 550-hp., 575-volt 2,840-r.p.m. shunt-wound motor through a flexible coupling and Furr-geary. Power is supplied to the hoist motors by a brushless motor-generator set. This consists of one 900-hp. induction motor, two 560-kw. generators and one 25-kw. exciter, also a 19,700-lb. 112-in. steel-plate shaft. Each hoist motor is connected separately to one of the generators and is controlled by varying the generator field.

From the dumping point to the chairs at the loading pockets underground is 1,020 ft. in each shaft. The rope speed is approximately 600 ft. per minute. A manway connects the two shafts, which are about 162 ft. apart, so that the same attendant without difficulty can take the entire care of the automatic weighting and loading apparatus of both the hoists.

To introduce automatic control at the beginning of a shift the operator closes two small control switches and leaves to two levers. To start automatic operation a master controller in then thrown to the automatic running position. One hoist or the other will then start, depending upon the position in which the skips have been resting. Suppose that closing the master controller energizes one pilot motor on the controller of No. 1 hoist, which starts, lifting its south skip; then as No. 1 controller moves away from the off position it simultaneously energizes No. 1 generator field and operates a pilot device which releases the brakes on the No. 1 hoist. This machine is accelerated by the controller building up the generator voltage.

Toward the end of skip travel the movement of No. 1 hoist actuates a pilot motor which moves the No. 2 hoist control gradually to the full-speed position in one direction, thereby accelerating No. 2 hoist to lift its north skip. Shortly before this skip enters the dumping horns the travel of No. 1 hoist, by means of cams, one of which is geared to each drum, gradually moves the No. 1 controller toward the off position. This decreases No. 1 generator voltage, thereby retarding the No. 1 hoist. Just as the north skip is about to land on the chairs No. 1 controller comes into the off position. This completes retardation and automatically applies the brakes. No. 1 hoist remains at rest while No. 2 is raising its north skip. In like manner No. 1 then hoists its north skip and then No. 2 its south skip. This sequence continues until it is interrupted or stopped by the operator.

In order that the transition from hand to automatic control and vice versa may be effected easily and quickly the levers on the operating platform are not disconnected from their controllers or brake engines when running automatically. During automatic operation, therefore, these levers move back and forth as if manually operated and are always in the correct position and in proper engagement for hand control.

Under all conditions, except when making adjustments, the cabs for effecting automatic retardation and stop remain mechanically fastened to the hoist drum. Limit and emergency switches also are provided.

**EMPTY OR FULL, SKIP ARRIVED SAFELY AT TOP**

After installation these hoists were started without difficulty, and on the second morning hoisted forty-four skips. After a few weeks of operation observations were made on the accuracy of stop. In twenty consecutive trips (ten each way) the total variation between maximum and minimum was only 1 1/2 in. of rope travel. During this time the ore "hung back" in the loading pockets on one side, so that six of the trips included in the above figures were made with an empty skip.

To operate two hand-controlled hoists, either steam or electric, of the size of those here described would require at least two operators per shift. Following the practice found in some localities an oiler also would be employed. For the functioning of the automatic hoist only one operator is required and he is able to attend to all the oiling as well as whatever hand manipulation of either hoist may be necessary on his shift. The saving thus attained is readily apparent.

Taking up the second type of equipment mentioned in this article, in order to understand thoroughly what is meant by an automatic substation the following definition may be submitted: An automatic substation is one which at the indication of a master circuit goes into operation through automatic sequence, maintains by automatic means the required character of service, shuts down and clears itself automatically at the opposite indication of the master circuit and protects itself while starting, running and shutting down. The master element may be a contact-making ammeter, a contact-making meter, a remote-control switch, a time
switch, or the station may be started and stopped by switching the alternating-current supply.

For mining service it is usually recommended that the station be started by some means other than a contact-making ammeter or voltmeter and that it run continuously until shut down by the opening of the master element. The reason for this will be apparent when the character of the load supplied is considered in connection with the low cost of electrical energy per ton of coal mined. The peak of a mining load develops so suddenly that a machine usually is unable to get on to the line soon enough after being started on load demand to be of any assistance. This together with the fact that the cost of electrical energy usually is not more than a few per cent of the value of the coal loaded for shipment makes it desirable to operate the station continuously during the hours when power may be needed suddenly. In certain mining installations, however, such as the double-unit synchronous motor-generator equipment of the Star Coal & Coke Co., the starting by load demand of the second set is now being used to great advantage.

That the advantages of automatic operation are being investigated and appreciated by the mining industry is well demonstrated by the remarkable increase in the use of the automatic substation within the past year. Both motor generators and synchronous converters are being automatically controlled with complete success, and it is only fair to assume that the practice will rapidly gain in favor as those engaged in the coal industry become more familiar with the advantages to be gained.

In the past, when labor costs were much lower than they are at present, it was possible to place the substations at or near the working faces and have each cared for by an operator or at least by a man who had little else to do. The time has now been reached, however, when this is uneconomical, yet grouping the substations so that one man can attend to several does not solve the difficulty because of the excessive amount of feeder copper that is required.

**Mechanism Proves the Better Attendant**

Not only this, but it is evident that the quality of service afforded by several substations cared for by one man cannot possibly equal that of a station in charge of an attendant whose sole duty is that of caring for that particular station. Making substations automatic permits their location near the working faces, thus avoiding long runs of feeder copper and simultaneously saving the wages of one or more operators. The reduction in the quantity of feeder copper necessary often amounts to enough to cover the extra investment entailed in making the station automatic, leaving the operator's wages as a net saving.

The automatic synchronous converter substation of the Lehigh Valley Coal Co. at Drifton, Pa., is located on the surface about 3,000 ft. from the nearest point where an engineer could be found during each hour of the day. This location was chosen in order to place the station at the approximate load center. During last winter this station was snowed under to such an extent that it could not be reached for five days. Throughout this period, however, the service rendered was entirely satisfactory.

It has been found that the quality of service afforded by the automatic substation is superior to that rendered by the ordinary manually operated station and is at least equal to the best. The number and length of interruptions to service ordinarily dependent upon an operator for correction are reduced, as already has been stated, and the voltage regulation is improved without excessive installation of feeder lines and without the addition of any attendants. With better voltage regulation all operations in the mine are speeded up, which in itself is of economic value. Wear and tear on substation apparatus is reduced through the elimination of unskillful handling.

When several manually operated substations feed into the same direct-current trolley system the loads may, of course, shift about to such an extent as to overload one substation and trip its direct-current breaker. This throws the entire load on the remaining stations and may, in an extreme case, so heavily overload them that their direct-current breakers may open successively. If these breakers do not trip, the stations will continue to supply the load, but through such a length of feeder and trolley that the voltage drop will become excessive. A form of automatic control has been perfected which permits a substation to limit its own load to its mo-
In England, as Here, Coal Miner Lives Long

NOT only in the United States but in England and Wales the mine workers and their political friends represent mining as disastrous to health and life. The table is not truer there than here, as the Registrar-General's Table of Mortality among Various Occupations in England and Wales, 1910-1912, conclusively proves. Of course the death rate at the higher ages is not important though motor-car and motor-tram drivers, who were probably not numerous in the period indicated, show a consistently low death rate at all ages. Mine accidents are included in the case of miners.

ANNUAL DEATH RATE PER THOUSAND AGE REPORTED FOR VARIOUS OCCUPATIONS IN ENGLAND AND WALES, 1910-1912

CADAVEROMETRIC TESTS to determine the losses in calories of coal heated in the air for various lengths of time are being made at the Pittsburgh (Pa.) experiment station of the U.S. Bureau of Mines by J. F. Byrne. At 125 deg. C. the following heat losses were obtained:

<table>
<thead>
<tr>
<th>Time of Heating</th>
<th>Per Cent Loss of Heat</th>
</tr>
</thead>
<tbody>
<tr>
<td>30 min.</td>
<td>1.01</td>
</tr>
<tr>
<td>1 hour</td>

</tr>
<tr>
<td>2 hours</td>
<td>5.27</td>
</tr>
</tbody>
</table>

Samples were heated for various periods of time ranging from a half hour to 100 hours, and the B.t.u. run by the coal lasted. The results show a regularly increasing loss in heating value as the time of heating increases. The coal samples show a change of weight on heating—at first a decrease in weight due to the loss of moisture. The decrease is generally less up to 24 hours, when there is an increase in weight of 0.64 per cent. After heating 100 hours at 125 deg. C. there is an increase in weight of 1.35 per cent and a loss in heating value of 3.02 per cent.
Mounting Power Costs, Tire Wear, Circuit Losses and Bonding Problems Well Discussed at Huntington

DEMAND charges, like taxes long established, seem to have lost their first sting. When he first realized that he had to pay them the operator could see no justification for their existence and could not understand why they should be imposed so relentlessly when he was running short time. True, the power company had provided a power plant for the operator’s advantage, but so had the coal company opened a mine and equipped it for the benefit of the consumer. Noting this parity of conditions, the operator could but wonder why the power company could make him pay for power when he was not using it, whereas he could not make the consumer pay him a ready-to-serve charge whenever he had an idle mine and consumers who were little disposed to buy.

The first day’s session of the West Virginia-Kentucky Association of Mine, Mechanical and Electrical Engineers, which took place Sept. 19, seemed to show by its tone that the severity of the demand charge, the unfairness of its fairness, if it may be so stated, is less felt than of yore, but perhaps it should be remembered that most of those present came from non-union fields and had merely felt the burden of the demand charge during the irregular runs due to car shortage and not the greater onus that arises from a complete shutdown or from the infrequent runs that are occasioned by lack of orders.

However that may be, the electrical engineers showed more interest in the locomotive wheel and tire question as introduced by J. J. Fluck, chief engineer of the Elkpborn Piney Coal Mining Co., Huntington, W. Va., than in the methods of checking power costs as presented in M. A. Maxwell’s report, excellent as it proved to be. Mr. Maxwell’s report appeared in Coal Age Sept. 28.

INSTITUTE MEETS ELECTRICIAN’S SPECIFIC NEED

TIt was nearly 10 a.m. when the meeting opened in the City Hall, the visitors most fortunately being unwelcomed by any of Huntington’s many spellbinders. The president, J. H. Edwards, electrical engineer, Elkpborn Piney Coal Mining Co., Huntington, W. Va., opened by reading a Coal Age editorial on the association’s reason for being, showing that no other organization was doing, or would care to take on, the important work that the present institute was undertaking. The association has its own special needs and cannot expect other societies which have theirs to surrender enough time for the discussion and the recital of the needs of the mine electrical engineer.

The first report read was that of the committee on “Methods of Checking Power Costs.” In the absence of Mr. Maxwell, C. E. Rogers, electrical engineer, Logan Mining Co., Logan, W. Va., ranking member of the committee, read the report. In the discussion which followed, W. H. Bennett, of the Buffalo-Weather Coal Co., Ottawa, W. Va., wanted to know what relation the demand charge should bear to the energy charge in a mine producing 10,000 tons a month.

J. H. Edwards, the president, stated that at one mine having about that production the demand charge was $990 per month and the total power bill, demand plus energy charge, was $8,700, showing that the demand charge was only about 25 per cent. However, as everyone hastened to explain, the relation depends on many factors.

J. Louis Dawson, of the Ironon Engine Co., said it depended on whether trolley or storage batteries were being used. Mr. Edwards declared it depended somewhat on the time of peak on which the demand factor was based, remembering, however, that if rates were fair a short peak-time rate would be made somewhat lower than a longer peak-time rate, thus tending to give an equal result.

DEMAND CHARGE IS OFTEN INEVITABLY HIGH

Mr. Edwards said it depended largely also on the track grades and the hardness of the coal; the demand charge would be high in relation to the energy charge with locomotives traveling on heavy grades and coal cutters working in hard or dirty coal. Though the ratio might be made more favorable by the use of judgment and skill there were inexorable conditions which would afford always a high demand charge regardless of professional ability and faithful attempts to better the ratio.

F. L. Stone, of the General Electric Co., remarked that the ratio depended on the load factor. An electrical engineer with a powerful hoist could not hope to keep his demand charge down to a low figure compared to his energy charge, especially if the main use of power was for hoisting.

H. M. McFarland, of the Simplex Wire & Cable Co., wanted to know the probable electrical cost per ton for a mine producing 2,000 tons per day, and A. Fred Phelps, of the Post-Glover Electric Co., declared that one company was getting power for 3c. per ton produced before the strike and during the suspension for 65c., so great was the effect of inactivity on its electrical costs. A. F. Brosky, of Coal Age, remarked that 3c. was a remarkably low figure. Inquiries in Pennsylvania had led him to believe that the cost lies between 7c. and 8c. per ton produced.

Mr. Edwards remarked that the costs of power per ton were estimated in so many ways that they were not comparable. Some overlooked entirely the cost of upkeep and some took no consideration of the losses derived from current which was sold for lighting in residences, stores, motion-picture shows and other places. His company charged against the electrical department all the costs of electrification, deducting income from electricity sold to employees and others, and then, having thus found the net cost of electrification, divided...
How Long May a Tire Be Safely Used?

The report of the committee on "Mine-Locomotive Wheels and Tires" was then presented by J. J. Fluck, its chairman. This report appeared in the issue of Coal Age of Sept. 14. R. E. Webster, of the Elkhorn Piney Coal Mining Co., Wilkesboro, Ky., in the discussion that followed, asked: "How long may a tire be safely worn before it, is discarded?" J. L. Butcher, of the Amherst Coal Co., Ashlanddale, W. Va., said that he believed in allowing a tire to continue in use so long as it "stays in center" and does not become loose. Another declared that with the larger wheels, such as those which were 20 in. in diameter, the tire could be allowed to wear till the tire when turned smooth would not be less than 1/8 in. thick. The tires on 12- or 14-in. wheels can be allowed to wear down thinner than 11 in. Mr. Butcher said that tires rarely become loose, but he admitted that he had observed wheels on mine locomotives with loose tires.

Mr. Butcher in reply to Mr. Edwards qualified his previous statement as to the safety of tires when worn almost away by saying that when the tire on a 30-in. wheel wore down so as to be only 3 in. thick after limbining it could not be regarded as safe. He said that he had built up the tires of small wheels electrically and got good results. He would not fill cast-iron wheels. It would not pay to weld on such a wheel either electrically or with acetylene, for by this time a new tire would have been annealed and turned it would have been cheaper to have bought a new wheel.

He thought that the manner of welding by small increments around the wheel, starting from four points equally disposed about the circumference, as described in the report of the committee, was the right method, as thereby warping was prevented. Asked why he welded only small wheels he said that large wheels could be welded with equal ease and with just as satisfactory results but that if the wheel was so large that there were no facilities at the mine shop to turn it it would not pay to do the welding.

He said that every mine shop should have an electric and an acetylene welding outfit. Mr. Rogers remarked that whether wheels are built up or not at the mine shop a welding outfit should be provided, for it pays to have one.

Mr. Butcher, of the Elkhorn Piney Coal Mining Co., turned wheels up to 30 in. in diameter.

The discussion revolved around dynamic braking and some one mentioned that where this practice was followed it was almost sure to start when a locomotive went down a grade to get a car which was on the pitch. Mr. Butcher, in reply, remarked that he was not greatly in favor of dynamic braking and said that the theory was good, but, unfortunately, in gathering the men will "goose" or reverse their motors instead of braking them. He did not think dynamic braking suited to main-line haulage.

The motors were supposed to start in series but the men would not make use of that method of starting, switching immediately instead to the parallel position. J. L. Dawson said that most of the "goosing" was done when gathering. The men did not wait to set brakes.

A. Fred. Phelps, of the Post Glover Electric Co., said that though he was strongly in favor of dynamic braking he could not "bring himself to see it" in the larger locomotives. He added that most of the companies were not using dynamic braking on locomotives weighing more than 8 tons, but Mr. Fluck said that the Goodman Manufacturing Co. was using it on locomotives in excess of that weight. One company had tried to equip a 14-ton locomotive for dynamic braking and had found that the result was not satisfactory.

J. W. Tierney, of the Electric Storage Battery Co., said he did not see how braking down a hill would heat up a motor if it did not heat going up, but Mr. Phelps replied that on going downhill the speed may and probably will exceed that pulling uphill and the heating is from the speed with which the armature turns. Going up the speed is about 6 miles per hour and going down it may be 10 or even 15 miles. Reuben Lee, of the Elkhorn Piney Coal Mining Co., of Stanhope, W. Va., said that he found that soft cast-iron brakes were preferable to ferrous. No one volunteered any indorsement of this declaration.

Fifty Automatic Substations Already Running

The attendance on Wednesday, Sept. 20, was larger than at any of the other meetings and the interest was considerable, though regarding the first paper and the close of the second there was little discussion. The automatic substation excites much interest but is so little understood by the average mine electrical engineer that he is not ready to discuss it. The first paper, "Automatic Electrical Apparatus as Applied to Coal Mining," was delivered by C. E. H. von Sothen instead of by M. A. Whiting, who was unable to attend. The paper was well illustrated by slides, among which were several showing an installation at the Inspiration Consolidated Copper Co.'s mine.

The marked trend in the industry toward automatically controlled equipment was voiced by Mr. Edwards. Three years ago his company considered installing a 300-kw. automatic substation, but the electric companies discouraged the project. He asked how many automatic substations were in this country, and the answer developed that about fifty of them were in operation.

Mr. von Sothen, in answer to an inquiry, declared that he knew of only one truly automatic hoist in the world and that was the one he had described. It was installed six years ago and consisted of two 580-hp. units. Asked as to the type of motor best adapted to an entirely automatic high-speed hoist, von Sothen said that the torque of the direct-current shunt motor with voltage control varied but little with the load, and therefore was best suited for that purpose.

Mr. Edwards expressed his belief that the time was not far distant when every modern mine, whether equipped with converters or motor-generator sets, will
have one or more automatic substations. His company, as well as many others, is beginning to realize more and more the importance of automatic devices, and he even went so far as to say that he believed that automatic starters would be used even for the operation of small squirrel-cage motors. Mr. Suiter added that the Winding Gulf Coal Co. has an automatic slow-down and stop at one of its mines. For the five or six years that it has been running the installation has been giving satisfactory service.

The second paper of the morning, on "Underground Transmission and Distribution," was read by J. C. Fuetter, chairman of the committee appointed to report on that subject. His paper was reproduced in full in the issues of Coal Age of Sept. 14 and 21. Mr. Edwards opened the discussion by asking whether substations close to the shops should be automatic or manual. Mr. Fuetter recommended that the automatic substation be used under all conditions, as it is far superior to one that is manually operated, being more reliable, less expensive to operate and more desirable in every way.

Squirrel-Cage Motors Suited to Mine Work

A. M. Lupton, of the Lincoln Electric Co., said that squirrel-cage motors of modern design should find more extensive use about the coal mines, where the torque rapidly falls off after a maximum torque is reached. E. D. Knight said that this type of motor is used extensively for raising and lowering loading booms on the tipples. He then asked what provisions were made for brush raising and lowering at the Van Lear installation, to which Mr. Fuetter responded that the substation was equipped with a motor-generator set.

The subject of electric-weld bonding having been mentioned in the paper, J. L. Dawson asked if the association would go on record as recommending electric-weld bonding in preference to all others. A decision was made to delay such positive action until a later date. According to Roscoe Woltz, the electrically welded bond is difficult to make on old rails. Mr. Lupton declared that successful arc-welding can be accomplished only with a motor-generator arc-welding set. Though its initial cost is several times that of the resistance type of welder, it should be used nevertheless, as only by its use can good work be expected.

C. E. Rogers then presented the report of his committee on the "Relative Merits of Storage-Battery, Combination and Conductor-Cable-Reel Locomotives." This report appeared in Coal Age in the issue of Sept. 14. L. W. Scott desired to know something regarding the length of haul and the territory negotiated by the battery locomotives mentioned in the paper and whether they were shifted from place to place. Mr. Rogers replied that a locomotive in most circumstances should be allotted to a particular territory, from which it seldom should be removed. The locomotives under discussion worked in a mine laid out in a panel system. 15 rooms on an entry, placed on 60-ft. centers and 300 ft. deep.

It was learned through Mr. Edwards that R. L. Kingsland, of the Consolidation Coal Co., recommends the straight storage-battery locomotive in places with grades up to 5 per cent, the combination locomotive in places with grades up to 10 per cent, and the cable reef for steeper grades. H. E. Carlton asked whether machine-wire costs should be credited to reel-type locomotives and debited to the straight-battery locomotive. Mr. Rogers said no; that haulage costs must be kept apart from other operation costs.

R. W. Whetstone said he believed that battery depreciation has a direct bearing on the compilation of costs, and that the charging apparatus should be made entirely automatic if depreciation charges are to be lowered and the life of batteries is to be increased. Mr. Edwards said that the depreciation of batteries will be lowered, as the men learn more regarding their care and maintenance for locomotive duty. He called attention to Mr. Rogers' figures showing that the cost of depreciation was being lowered each year even though the age of the batteries steadily increased.

In the afternoon a group of the men were the guests of the West Virginia Rail Co., whose rolling mill lies on the outskirts of Huntington. The party was shown through the plant by the superintendent, H. H. Diehl, who explained the processes involved in the evolution of a steel mine rail, whether made from scrap railroad rails or from billets.

Mr. Diehl said the manufacturer of steel rail was frequently blamed for defects that arose from the careless use of the electric-weld bonding machine. The burning of the rail frequently weakened the steel, and for defects thus caused the manufacturer could not be held responsible. He laid successively several lengths of rail over two supports spaced at an interval of 2 ft. and struck them with a steam hammer after first making a slight impression with a cutter on the flange of the rail. He showed thereby that a single blow of the hammer would make a clean shear. A similar rail without that slight nick would bend without breaking, which proved his contention that a slight weakness at any section will concentrate the strain at that point. He recommended the placing of the bond on the web of the rail instead of at the base or flange.

None of the Fractures Touched the Weld

The following afternoon several bond contacts were made by means of an electric welding apparatus in the exhibition hall, and these were taken to the mill to be broken. The results showed that it really makes little difference where the bond is made on the rail, provided care is taken not to burn the steel. Those who witnessed the tests were of accord in pronouncing the base of flange the most logical position for a bond because this is the place where it can be most easily applied. The samples broken had been bonded in different positions, but the fractures showed that the rail did not break through the bonding contact but rather around it, provided the weld had been made with due care.

Oxygen and Air in Monoxide Poisoning

R. R. SAYERS, chief surgeon of the U. S. Bureau of Mines, calls attention to page 412 of Coal Age of Sept. 14 and says that he should have been quoted as saying that ordinary air is a long time removing carbon monoxide from the system, but pure oxygen, if breathed normally, will remove the monoxide in about one-fourth the time and that oxygen mixed with 10 per cent of carbon dioxide requires one-fifth to one-sixth as long. Dr. Sayers adds that 5 per cent of carbon dioxide apparently works very nearly as efficiently as 8 to 10 per cent. Pure oxygen is often available at the mines and should be used as early as possible in the treatment of carbon-monoxide poisoning.
Grading and Making Height in Mine Entries

In mines where heavy gradings are to be used, where the roadways have been given low in headings or rooms, where creep has blocked the roadways or where gridding has to be done to promote natural drainage the illustrations of the work of the Illustrations in the mines of the Oil Iron Coal Corporation, Illinois, will be of interest. The purpose in this

FIG. 1—LOADING COAL FROM A STOCKPILE AT BELLINGHAM, WASH.

This is from a photograph taken at the Olive Iron Mining Co.'s iron mines at Chisholm, Minn. The shovel is in the starting position and, as will be noted, it has buried its nose deep in the pile.

operation about 50 cars were removed. It is much used by contractors for tunneling and, of course, would be available for similar work in mines where it would do the "mucking" far more rapidly and cheaply than men.

Production of Coal from leased lands on the public domain of the United States approximated 240,000 tons during the first six months of 1922. The production would have been considerably greater than this had it not been for the general coal strike which began April 1. Technical supervision of the operation of coal mines on leased public lands rests with the U. S. Bureau of Mines.
French Colliery Association Taxes Buyers of Low-Price Coal to Reimburse Those Charged High Rates

Price Controlling Body Thus Maintains Standard Price Established—Reparation Deliveries of Coal Decreased, Coke Increased—Suspension of Eight-Hour Law Proposed—Movement on Foot for University of Labor

BY C. H. S. TUPHOLME
London, England

In investigating the French coal industry that which first strikes the foreign observer is the power of the French Colliery Association or Comité des Houillères. The function of this organization in France is to dispense with all competition between the various industries in the matter of coal supply and to act as a permanent price-controlling body.

At regular intervals the Colliery Association takes inventory of all the coal sold in France, whether it comes from Great Britain, America, Belgium, German reparation deliveries or from the French mines themselves. When this is done what is known as a standard price is established based on the various prices paid for the coal obtained from the different sources and the conditions then obtaining both at the place of delivery and in the French coal-consuming industries. Then those concerns which paid less than this standard figure are taxed to the extent of the difference, and the revenue collected in this way is paid over to those who paid more than the standard. In this fashion conditions are evened up and the man who buys British coal pays no more for it in the long run than the employer who is located near the German frontier and buys German reparation coal. For instance, reparation coal from Germany, which has to be delivered to France at German home prices, was costing the association around 50 fr. a ton. This coal was sold to French industrial concerns at 90-100 fr., leaving a profit of 40-50 fr. on every ton of German coal. This margin was then paid over to those who had bought in the more costly markets.

Eliminates Competition for Cheap Coal

Naturally this method involves some very complicated and delicate accounting, and I have not yet met anyone who could tell me just how it was done, but it works out all right, since French coal operators are paid more for their coal than it is sold for to industrial concerns and the method obviates competition for cheap coal. The manufacturer is happy in consequence.

The French Coal Association is not in the nature of a state bureaucracy but it is a powerful organization, exerting great influence with the government and the press. It has also played a large part in the restoration of the devastated areas.

In connection with the reconstruction of the French coal fields in the devastated areas, it is of interest to note the progress made in the important Lens and Courrières fields. The output of the Lens mines for the first six months of 1921 was 107,500 tons against 205,600 tons in the same period of 1912. In the Courrières area the output was only 597,800 tons during the whole of 1921 against 556,700 tons in the first half of 1912.

Of mines which were not damaged during the war, the output of the colliery at Bruay (Pas-de-Calais) is now the largest in France. In 1920-1921 it produced 2,465,000 tons, but I am told these figures could easily be improved upon if need arose. During the war the annual output exceeded 4,500,000 tons. The possibility of expansion is due to the extreme regularity of the Bruay field, which renders it easy to extract the coal. Bruay coal is especially suited for boilers, as it gives very little dust and burns clean. The net profits of this colliery for the year 1920-1921, after payment for all plant and allocation to reserve, amounted to nineteen million francs.

After the European trade boom France found herself with a gradually accumulating stock of coal for which no market could be found. To remedy this situation the Colliery Association got busy with foreign sales bureaus, so that now coal mined in the Saar area is actually being sold in Germany at several francs less per ton than in France. Thus the curious situation has arisen of Germany delivering coal to France to recompense her for the French collieries destroyed by Germany during the war, while France sells the same coal back to Germany at a discount.

Lately, however, this system has not worked so satisfactorily. In order to increase revenue as a result of the demands of the reparation commission Germany has raised the home price of her coal—and thus the price of delivery to France, for it will be remembered that coal must be delivered to France at German home prices—and increased her freight rates. As a direct result the French Colliery Association has had to increase its standard price. Again, Great Britain has been selling coal at 6s. less than British home prices in order to
THE FRENCH MINING INDUSTRY

The French mining industry is viewed as one of the major coal producers. A recent announcement of the government regarding the abolition of the coal tax has brought attention to the industry's challenges.

The French Coal Congress, which met recently in Paris, supported the demand for the enactment of legislation suspending temporarily the application of the eight-hour day law in France. A bill has now been introduced in the Chamber of Deputies providing for the suspension of the act until the restoration of normal industrial conditions. Another measure before the Chamber proposes that coal miners be permitted to work more hours while importations of coal exceed 5,000,000 tons per annum.

The seriousness with which the outlook in the French mining industry is viewed is seen also in the recent announcement of the abolition of the coal tax.

There is a movement on foot in France to create a National University of Labor. This movement has the support of the majority of the large industrialists, and committees are working in the principal industrial centers with a view to founding in each area a university where the working classes of every age and type will be enabled to improve the selling value of their labor. It is proposed that a directing board be formed composed of state officials, technicians and employers and employed in the more important trades and that tuition be given by professors and lecturers from the neighboring universities and technical colleges.

Issue Bulletins Describing Geology and Coal Resources of Pennsylvania

The Bureau of Topographic and Geological Survey of Pennsylvania has put out in the form of bulletins much valuable information concerning the geology and coal resources of the state. Thus in bulletins Nos. 26, 32, 34, 38, 41, 42, and 46, J. D. Sisler describes the coal beds in Washington, Fayette, Westmoreland, Armstrong, Elk, Jefferson and Butler counties, respectively.

These bulletins in each case briefly take up existing conditions so far as commercial coal mining is concerned, following this with a description of the geology structure of the area under consideration. This is succeeded by a description of the stratigraphy and lastly by an enumeration of the coal beds present. This section of the bulletins contains much valuable information concerning the thickness and quality of the various coal measures.

Bulletins of this kind are of much value to those contemplating the opening of a mine or mines in the region treated or to those seeking detailed information concerning any one or all of the coal beds of the state. Monument copies of these bulletins may be secured from the Bureau of Topographic and Geological Survey.
Price the Connellsville Coke Region Will Have to Pay for Present Strike

By John L. Gans

Unearned Wages, Profits and Overhead More Than Offset by Other Losses That Are Irrecoverable—Permanent Diversion of Business to Other Fields and to Byproduct Ovens Constitutes Greatest Injury

The Connellsville coke region will pay a heavier price as the cost of the present sympathetic strike of its workers than for any previous interruption in its history as a fuel-producing center. The total will not be found by multiplying the number of weeks the strike lasts by $850,000, the estimated weekly loss in wages of the 28,000 men who have been idle since early in April, nor yet by adding thereto the calculated loss to the operators of the profits on 200,000 to 300,000 tons of coke which could have been made and sold at a fair price to furnaces and foundries had not the coal and railroad strikes laid their withering blight on transportation and industry.

Neither will the aggregate be found by adding to the combined wage and profit loss the extraordinary expenses incurred by reason of the measures necessary to safeguard the mining and coking properties, keep them in a workable condition, protect the men who are willing to work and preserve order in the strike-affected districts. What these costs are, or what they will amount to before the emergency requiring defensive and protective precautions shall have passed, cannot be approximated. They will vary greatly with the conditions, size and number of operations and other circumstances.

In the case of the H. C. Frick Coke Co., owning fifty-five mining and coking plants, the burden is plainly very much heavier than on any other single interest. The problems this and all operators who are striving to restore or maintain plant activity, if no more than on a small scale, will have to meet until the walkout is over and done, involve heavy expenditures. These are not limited to overhead at mines representing investments of millions of dollars in equipment and development where handfuls of foremen, mechanics and a few diggers of boiler coal who keep the mines in ship shape are the only employees on the job. Special watchmen and guards are on duty throughout the region. Transportation, commissary and other incidental expenses which their employment entails, and a wide variety and large number of miscellaneous items which do not come up in the normal operation of mines and coke ovens call for a prodigious outlay.

There are other and indirect costs, such as the inefficiency of untrained men who have taken the places of the strikers; the destruction or damage of miners' houses, mine buildings, tipples and other structures by fire or explosives, and the complete or partial wrecking of machinery and equipment.

But numerous and diverse in character as are the direct and indirect monetary losses which are being sustained by employers and employees because of the strike, and staggering as would be the grand total if it were possible to reduce it to figures, it is the deliberate judgment of persons who have given serious thought to the ultimate effects of the strike in the Connellsville region that the current losses are in part recoverable and in a sense inconsequential as compared with the losses that are likely to be irrecoverable.

May Suffer Permanent Diversion of Business

Much of the greater part of the price the historic and famous producer of the standard metallurgical fuel of the world will have to pay for having had the temerity to resist the demands of an oligarchy of mine labor is the permanent diversion of business to other fields and to the byproduct coke oven—the only formidable competitor of the beehive oven as the latter has been developed in the Connellsville region.

This development has been of comparatively slow growth, the rate of which has been measured by the expansion of those industries dependent upon coke for their manufacturing processes. Beginning in the early 80's to assume importance as a fuel source, the region grew gradually in productive capacity until the maximum of 21,654,000 tons was reached in 1912. Since that date each recurring interruption in industrial peace and progress, such as railroad and steel strikes, has been instrumental in further restricting the markets for Connellsville coke and has sent buyers to other fields or set them to building byproduct plants.

Competitive regions like West Virginia have taken a share of the trade previously believed to have been vouched for the Connellsville region for its natural life.
CONNELSVILLE DERIVED COKE HAS NOT YET PASSED INTO HISTORY

The man on the left has just been drawn, the lad in the middle is being charged with coal from the barrel above and the oven on the right is fired and making coke.

But the contemporaneous expansion of the byproduct industry has been the more direct cause of the reduction in the volume of demand for Connellsville coke. This is definitely shown by the fact that production in 1920 was barely 50 per cent of that in 1913, and last year, a lean one in industry, it was only about 16 per cent of that in the busiest year. The significance of these declines became more striking in view of the coagulated fact that until 1921 coke consumption had grown by a rate of geometrical progression.

Notwithstanding the sympathetic strike, which still persists with great obstinacy, at no time during the shutdown has production been as close to a point as in July, 1921, when the industrial depression restricted output to 20,000 tons and less per week. In view of the grimmess of the struggle to reduce the region to inactivity it is noteworthy that the average rate of coke production since April 1 has been considerably in excess of the average for 1921. The independent producers and merchant customers have not benefited therefrom, however, because 80 per cent of the production has been at plants of the coke subsidiary of the United States Steel Corporation, hence not available to the general market.

In consequence, coke consumers who have heretofore been dependent upon the Connellsville region have been forced to make other connections in order to obtain a supply of fuel. Some have gone to the Southern making fields and others have become buyers of the excess production of byproduct plants operated in connection with furnaces. Others have bought from merchant byproduct operators, which, so long as they have been able to obtain a supply of raw coal, have been running at maximum capacity. True, the railroad strike has made reliance upon these sources even less secure than upon the Connellsville region, but with production in the old mine fields again resumed the chances favor a resumption of relations established outside rather than a return of some former customers to the Connellsville region.

Contemplation of these things is what causes thoughtful observers of the situation to arrive at the conclusions they have with respect to the ultimate cost of the strike in the Connellsville region. Even when the natural order is again restored, as it will be in due course, there will be, it is feared, disinclination on the part of some coke consumers who have made other trade connections, to return to their first love. Especially will this be true if the strike settlement is of such character that the coke region will not be insured against periodic interruptions similar to those which have prevailed in the strongly unionized districts.

It may appear to some persons that even if the Connellsville region loses coke trade it will still remain a large producer of coal as the raw material in byproduct coke manufacture, and thus be compensated. This is quite true, but the mine operators of the region are essentially coke makers and to that product they very properly attribute the success they have achieved. Many of them have already adapted themselves and their plants to the simpler process of mining and shipping raw coal, but there is a lure and some sentimental association attaching to coke making, not to speak of the business advantage which is derived from the larger measure of profit obtained from coke when the market price is several times greater than the price of the coal equivalent. The present market, with coke $15 and up, compared with the Hoover price of $4.50 a ton for coal, is a pertinent case in point.

Such market conditions do not prevail except at more or less infrequent intervals, but there is a natural desire on the part of the operators to be in position to enjoy the benefits when they are obtainable. That a lessening in the number of such opportunities will be one of the costs to the Connellsville region in consequence of the sympathetic strike counts quite as much as part of the cost as does the disruption to selling connections established after a number of years of patient effort.
Robbing Pillars in Undersea Operations

Submarine Mine of the Dominion Coal Company—Drawing Pillars in Lower Seam—Work in Upper Seam Stopped While So Doing—Working Out Upper Coal First Is Suggested as Safer Plan

REFERENCE was made some time ago in Coal Age to the undersea mining of the Dominion Coal Co. at Cape Breton, N. S. It occurs to me that the following paragraphs quoted from the Canadian Mining Journal, May 12, 1928, will be of interest to readers of Coal Age.

The Dominion Coal Co., Cape Breton, has begun drawing pillars for the first time, in their largest undersea colliery, No. 2. As another seam overlying this one is being worked by a separate shaft, it was found necessary to stop mining above, until the pillar work below is well advanced.

"It is reasoned out that if work is concentrated on pillar sections and these are rapidly extracted the subsidence will be gradual and the strata will settle without danger of fractures running to the surface, which would not only be dangerous under heavy mountains of water but would affect the workings of the upper seam.

"The mining of undersea coal requires great care. So far it has been costly, as thick pillars had to be left while entering the submarine field. Heavy barrier pillars must be left between sections to provide against accidents from inrush of water. Now that the collieries are reaching the stage where pillars can be drawn, the necessity for continuous development will not be so great.

"There is 1,600 ft. of cover over the pillars of this colliery, at the point of pillar attack. Between the upper and lower seams now being worked there is 450 ft.

VIEWPOINT OF AN OUTSIDER ON THE ORDER OF WORKING SEAMS

In commenting on the above method, it is not my desire to do so in a critical way. The officials of the company in charge of the mine are thoroughly conversant with the local conditions and behavior of the strata forming the overburden. It is probable that they have determined their course of action after mature deliberation and careful study of these conditions in the light of their experience.

However, judging by the information given in the article to which I refer, it appears that they are proceeding in exactly the reverse order from what is the general custom and practice. From the viewpoint of an outsider not having the same intimate contact with the work, it would seem that the upper bed should be worked out first.

IRREGULAR SUBLINEMENT CAUSED WHEN LOWER PILLARS ARE DRAWN

Unless the strata lying between the two seams of coal are unusually strong and well knit, the drawing of the pillars in the lower seam will undoubtedly cause an irregular subsidence that will produce annoying faults and rolls in the upper seam.

On the other hand, should the drawing of the pillars in the upper seam, on its completion, cause fissures to develop that would permit water to enter the mine, there would still remain the 450-ft. of strata that separates these two seams.

In the later working of the lower seam, with 1,150 ft. of solid strata remaining undisturbed, there would be little doubt that the strata would overarch and be self-supporting. In that case, the work of extraction could cause no settlement that would entail danger by reason of water breaking into the mine from the upper seam. It will be interesting to learn the opinions and experience of others in this regard.

CHARLES M. SCHLOSS,
Denver, Colo.

Conditions Determine When It Is Advisable to Seal

Practice in regard to sealing abandoned areas varies with conditions in the mine—Experience in southern Illinois—Method of working the chief factor.

In reading the several letters that have dealt with the subject of sealing off abandoned areas, one is impressed with the thought that conditions alone can determine the safest method of proceeding in this respect. While my own custom has favored sealing off places that are finished, I must admit that many good reasons both for and against the practice have been advanced.

With Otto Ballock, who writes under the caption "Success of Any Plan Depends on How Carried Out," Coal Age, June 8, p. 263, I believe the conditions existing in the mine must be the only sure guide. The records show that practice varies with the conditions. What is a safe plan to follow in one locality would be a dangerous proceeding in another.

My own experience, in the mines of southern Illinois, has convinced me that the sealing off of old workings is the safest thing to do in that district where the mines are generally gassy. At any rate, this is true as long as the present method of working in those mines is followed.

An instance comes to my mind where we sealed off a pair of cross-entries that were worked out and finished. The section was generating much gas and, though the seals were well built, I have often found gas oozing out through the stoppings onto the main haulage road. This was more noticeable at times when the barometer was falling.

Owing to the fact that there was a good current of air traveling the roadway, the condition was not dangerous, as the gas was quickly diluted and passed out of the mine. Had there been no seals closing the mouths of these entries, however, I believe the volume of gas coming from them would have produced a dangerous condition at that point on the road.

GREATER PROTECTION AFFORDED BY MULTIPLE-ENTRY SYSTEM

In my opinion, the main point, in respect to sealing off abandoned areas to make the mine safer, is the method of working adopted in the general plan of the mine. I refer particularly to the use of the triple-entry system of working, in preference to the double-entry system so commonly employed. These two systems have been explained and illustrated so frequently in Coal Age that it is unnecessary to dwell on their points of difference.

It is well known that the double-entry system provides but single main intake and return airways; and the haulage road, even when this is made the intake, is not protected from conditions that may arise in the workings, on that side of the mine, by reason of a serious or a heavy fall of roof recurring in worked-out portions that have been sealed.

On the other hand, the triple-entry system provides a separate haulage road, which is made the intake for the entire mine and is flanked on either side by a main return adit. This separation is from the very outset, on the respective sides of the mine. In this arrangement the haulage road is protected from any dangerous conditions that may arise in the old workings.
Reducing Ventilation in a Mine

When Firing Shots

Results of the remarkable McAllister experiment, in Kansas mines—Experimental requirement in present exploders—Can the theory of black smoke be considered practical?

The event of a recent mine explosion and the result of black smoke, or a mine whose 66 minutes fired through, as given by a Kentucky newspaper (July 5, 1887), 29, raises the very remarkable experiment of Alexander McAllister, a Kansas miner, who strongly advocated the theory of reducing the smoke in the conclusion of his work, and when fires are shotted.

McAllister stated the experiments were published in an early volume of Coal Age (Vol. 10, 1886, p. 235), and Vol. 24 gave rise to a lengthy discussion on the conclusion of the condition of ventilation, at the time of incident.

Experiments Advancing Favor in Ventilating Mines

It was agreed, on the opinion of the theory that the introduction of more air fans, or a large ventilation of smoke was needed, an increase in ventilation, decreasing the development of the condition of the mine, as to be shown by the conclusion of the incident of the mine.

For this reason, it was claimed that when such conditions, as explained by McAllister, could not occur. In support of the

The inventor described an experiment that he performed in a mine to prove the correctness of his theory. The wonder is that the man survived to tell the story.

**Remarkable Experiment to Prove Theory Correct**

McAllister states (Vol. 3, p. 25) that for the purpose of this experiment, he arranged a series of 27 shots, or a mine, and placed a 25-lb. keg of blasting powder, with fuse attached and covered over with fine coal dust, at the face of the workings.

Having ignited the keg at the top of the shaft, so as to completely shut off the ventilation in the mine, with the aid of two others as intrepid as himself, the experimenter and his assistants lighted all the shots and the fuse attached to the keg of powder and retired to a safety hole they had prepared beforehand.

The account states that no explosion occurred save for a slight one following the firing of the fourth shot. That, however, was only local, not being propagated, though conditions were unfavorable for its extension could the mine atmosphere have supported the combustion.

**Experiment Supports Claim of Reducing Circulation**

The argument and the evidence corroborating it appear plausible could not be assured of one essential feature; it is curious, that there will always prevail a deficiency of the explosive gases to render the mine atmosphere incapable of originating and supporting an explosion.

Just here it must be remembered that the point of high explosibility must be contained and passed, before the resultant explosion can be insured. The practicability of this theory is 1 fear, still entertained by many mining men. To such an extent, a few years ago, did the theory gain ground that the late H. M. Wilson, then chief of the Associated Companies, wrote an article disparaging the idea.

**The Weak Point Exposed**

As I have already intimated, the weak point of the theory is the assumption that the mine atmosphere will always be non-supporting of explosive conditions, whereas the shafts are being fired. Little consideration seems to have been given, also, to the relatively larger air volume of the mine, in comparison to the shotting area.

Nothing more seems to have been regarded that an explosive condition in the mine air is cumulative, and similarly passed after passing through an extremely explosive condition. If I am not mistaken there is far greater danger in a succession of shots than when the same shots are fired simultaneously.

For example, when shafts are fired simultaneously the condition presented is analogous to that of firing a single shot. The occurrence of an explosion assumes both an explosive atmosphere and sufficient heat for its ignition. In the firing of a single shot the gaseous products and the heat appear simultaneously; but, after the dilution of the gases with air can form an explosive mixture, the heat required for its explosion has disappeared.

On the other hand, when successive shots are fired, the flame and heat of a following shot are projected into an explosive mixture formed by the dilution of the gases of preceding shots and an explosion results.

In closing, let me say that, while modern ventilation does not make mines free from explosions, it must be admitted that such occurrences are less frequent and less devastating than in years past. Inadequate ventilation in the early history of coal mining did not prevent explosions, which were often more widespread and devastating than those of recent occurrence.

Washington, D.C.

I. C. Parfitt.

**Misapplication of Principles in Mine Timbering**

Systematic timbering an innovation—Often followed blindly—Its object—Purpose of setting posts in mines.

I was deeply interested in reading the excellent letter of our friend, John Rose, who writes on "Safety in Timbering at the Working Face" in Coal Age, July 6, p. 18. He has very ably enunciated and emphasized a practical principle in this most important phase of coal mining.

Mr. Rose has drawn attention to the fact that the method of timbering each working face must necessarily depend on the particular conditions of roof and floor, in that place, and that no fixed rule will apply to all the conditions that so frequently occur, even in different sections of the same mine.

**Roof and Floor Conditions Never Found Uniform**

Others may have had a different experience from mine; but I have never yet seen or worked in a mine, either drift, slope or shaft, where the conditions of roof and floor were uniform throughout. I am reminded of this, particularly by the amusing way in which Mr. Rose narrated one incident that showed clearly the need of adapting the method of timbering employed to the conditions in hand.

The anecdote illustrated in a forcible manner the point that has impressed itself on my mind and is the chief point that I wish to emphasize here. In coal mining, as in any other industry, any new method that may be proposed as the result of study and experiment, be an innovation that must be demonstrated, in order to prove its effectiveness in a particular case.

**Innovation in Coal Mining**

Now, systematic posting may be regarded as such an innovation in the mining of coal. As generally understood, it means the standing of posts at regular intervals, in prescribed loca-
tions, and has little regard to the ever changing conditions in the roof, which every practical miner knows must be considered.

**FOREMEN OFTEN FOLLOW BLINDLY A METHOD PROPOSED**

As in the case cited, an innovation of this kind is often blindly followed by mine officials who fail to give a thought as to its adaptation to the particular conditions with which they have to contend. In their minds, the systematic setting of posts at the working face is a plan of universal application that they are eager to adopt.

Not to be misunderstood, let me say here that systematic timbering, under uniform conditions of roof and floor, has many good points. It eliminates any bad judgment, or lack of experience, on the part of the miner and, more particularly, his proneness to postpone the setting of needed posts at the working face.

The main object of systematic timbering in rooms is to distribute and equalize the roof pressure and thereby strengthen the roof in a miner's working place. By way of illustration, I have prepared two sketches, each of which is an example of systematic timbering in a breast.

**The More Effective System**

In the figure, the section shown above represents three lines of posts set 4 ft. apart in the center of the breast, which is the weakest spot in the span across the opening, assuming a uniform roof condition. This is analogous to setting a center post under a collar that shows signs of taking the weight. In the lower half of the figure, the three posts are set at equal distances apart and a like distance from the rib, on the gob side of the breast.

Although in each case the timbering is systematic, the second arrangement is not as effective as the first, since there is a greater width of unsupported roof over the roadway when the timbering is set to one side of the center of the breast. This second arrangement has a tendency to divert pressure from the supporting pillars to the unsupported span of roof above the road.

**Flow of Water in Pipes Under Equal Heads**

With Like Velocity, Sixteen 3-in. Pipes Will Carry the Same Water as One 12-in. Pipe—Under Equal Head, Thirty-two of the Smaller Pipes Will Be Required

MAY I ask Coal Age to kindly settle a disputed question regarding the number of 3-in. pipes that will be required to carry away the same quantity of water as a single 12-in. pipe. Where the question originated I do not know; but it has been knocking around hereabouts some time and has caused difference of opinion among those who are studying to fit themselves for examination.

It is argued by some that a pipe will carry an amount of water in proportion to its sectional area, which varies as the square of its diameter. On this basis, or in other words, that since the diameter of a 12-in. pipe is four times that of a 3-in. pipe, the former will carry 16 times the amount of water carried by the latter. In other words, it will require sixteen 3-in. pipes to carry the same amount of water as one 12-in. pipe.

On the other hand, a few claim that such is not the case. Although they have not been able to give a satisfactory explanation, they say that this question was asked a long time ago in a mining examination and, to the best of their recollection, a different answer was given. It would seem that the only way to settle this dispute is to appeal to Coal Age to answer the question again and explain the reason why more than sixteen 3-in. pipes will be required to discharge the same amount of water as a single 12-in. pipe.

**Inquiries Of General Interest**

**Flow of Water in Pipes Under Equal Heads**

We recall that this question was asked in a Pennsylvania examination, a few years ago. Very probably it was answered in Coal Age, at that time. While it is true that a pipe will carry water in proportion to its sectional area, that condition assumes that the velocity of the flowing water is constant. In other words, for a constant velocity, the flow of water in a pipe varies as the square of its diameter and sixteen 3-in. pipes would then be equivalent to one 12-in. pipe.

A more practical view of the question, however, is to consider the flow of water in pipes of different diameter. When the pipe is constant the pressure is always the same. Therefore we write the formula for the pressure, which if the units are consistent, will equalize the section of a larger pipe. (12 in. = 144 sq. in., 6 in. = 36 sq. in.)

Steubenville, Ohio. **STUDENT.**
EXAMINATION QUESTIONS ANSWERED

Illiinois Mine Managers' Examination, Springfield, July 17, 18, 1922

Question—Taking the weight of a cubic foot of air as 1.25 lb., what will be the weight of air in a shaft 25 ft. in diameter and 1,000 ft. deep?

Answer—The cubic content of this shaft is 21,825 (0.7854 x 125) = 17,187 ft. cubed. The weight of air filling this shaft and having a density of 1.25 lb. per cu. ft. is therefore 21,825 x 1.25 = 27,281 lb. or 13.6 tons.

Question—If 3,000 cu. ft. of air is passing through a circular shaft 15 ft. in diameter, what is the velocity of the current in feet per second?

Answer—The sectional area of this shaft is 78.54 x 102 sq. ft.

\[
\text{Flowing speed} = \frac{3,000}{\pi \times 78.54} = 120 \text{ ft. per sec.}
\]

Question—There are 18,000 cu. ft. of air passing through a water gauge having a rubbing surface of 24 sq. ft. and a sectional area of 30 sq. ft. What is the water gauge pressure, this calculation being based on a normal atmospheric pressure of 14.7 lbs. per sq. in.?

Answer—The area of the water gauge is 30 sq. ft.

\[
\text{Gauge pressure} = \frac{18,000}{30} - 14.7 = 507.7 \text{ lbs. per sq. in.}
\]

Question—How many sq. ft. of air will pass through a circular shaft 10 ft. in diameter, when the air enters with a velocity of 30 ft. per sec. through the shaft opening?

Answer—The sectional area of this shaft is 78.54 sq. ft.

\[
\text{Number of sq. ft. of air} = \frac{30 \times 78.54}{30} = 78.54 \text{ sq. ft.}
\]

Question—What is the horse power of the air when 70,000 cu. ft. per min. is exhausting at a water gauge of 1.7 in.?

Answer—The pressure corresponding to a 1.7-in. water gage is 5.2 \(\times\) 6.84 lb. per sq. ft. The horse power of the air is, therefore,

\[
H = \frac{70,000 \times 5.2 \times 6.84}{38,000} = 18.75 \text{ hp.}
\]

Question—What is the horse power of a 2.64-in. diameter water gage when 97,000 cu. ft. per min. is exhausting at a water gauge of 1.7 in.?

Answer—The pressure corresponding to a 1.7-in. water gage is 5.2 \(\times\) 6.84 lb. per sq. ft. The horse power of the air is, therefore,

\[
H = \frac{97,000 \times 5.2 \times 6.84}{38,000} = 22.67 \text{ hp.}
\]

Question—A 3-in. air pipe is 6 times larger in diameter than a 1-in. pipe. How much larger is the volume of water flowing in the former, under a constant head, in 1 ft. of each pipe? Thus, if 6.75 cu. ft. of water will flow in a 3-in. pipe, what volume will flow in a 1-in. pipe? Therefore, in this case, the head remaining constant, it will require twenty-three 3-in. pipes to discharge the same quantity of water as one 15-in. pipe.

\[
H = \frac{6.75}{15} = 0.45 \text{ sq. ft.}
\]

\[
H = \frac{6.75}{23} = 0.30 \text{ sq. ft.}
\]

Question—What is the breaking strain of a good steel hoisting rope 1 in. in diameter? (b) How will you find the safe working load for this rope?

Answer—(a) The breaking strain of a 1-in. cast-steel, 6-strand, 19-wire, hoisting rope is 32 tons. This is used as the basis for calculating the breaking strain of similar ropes of different diameters, since the strength of similar ropes varies as the square of their diameters. Thus, the breaking strain of a 1-ft. rope of this kind is 32 \(\times\) 1.25 = 53.125 tons.

(b) The safe working load of a rope must be determined by the conditions under which the rope is used. For example, when hoisting in a vertical shaft it is common practice to use a factor of safety varying from 5 to 10, depending on the depth and diameter of the shaft. If the weight of 75 or 80 yds. of the factor of safety of 5 may be used, making the safe working load then 53.125 \(\div\) 5 = 10.6 tons. At a depth of 1,000 ft., a factor of safety of 8 may be used, making the safe working load, in that case, 53.125 \(\div\) 8 = 6.6 tons. In each case, however, the working load should include the weight of the rope itself, hanging in the shaft.

Question—Explain how you would arrive at the cost for hauling the coal, in a mine of which you might be manager.

Answer—The cost of hauling coal in the mine, from the working face to the shaft or slope bottom, must be based on the output or daily tonnage and the number of men required on the mine road and for gathering the cars at the working face. This will determine the expense for wages of motormen and trip riders, to which must be added the wages of any trappers, trackmen and timbermen employed on the haulage roads. An estimate must also be made of the cost of maintenance, including all supplies and labor required in the upkeep of the machines and power line.

In addition to this, there must be added the cost of power, if purchased; or the wages of the men employed in the power plant together with the cost of supplies and maintenance of the boilers, engines, generators and machinery forming the equipment of the power plant, making due allowance for the power consumed for other purposes, in the same period.

Finally, dividing the total cost of labor, supplies and maintenance, by the total tonnage consumed during the period, will give the average cost of haulage, per ton of coal mined. This assumes that the overhead charges include depreciation, interest and insurance and are not included in the cost of haulage.
Production of bituminous coal in the United States in 1921, according to final statistics issued by the Geological Survey, totaled 415,921,000 net tons. The Survey's preliminary estimate, published Jan. 7, 1922, or nine months ago, was 407,000,000 tons, which was an error of 2.2 per cent. Several interesting features of these statistics, pointed out by the Survey, are given here in full.

The mines included in these figures, the Survey states, do not embrace the output of country banks and of some wagon mines. They include, however, many small operations that fall within the definition of wagon mines but that operate steadily year after year. The tonnage not included, it will be agreed, would amount to little in a year of acute depression such as 1921. Were statistics available for the small mines not included, the total output would be raised by not much over 1,000,000 tons.

The value of the bituminous coal produced in 1921 was reported to be $1,139,000,000, as against $1,160,000,000 in 1920. The average value per ton f.o.b. mines declined from $3.75 in 1920 to $2.89.

Contrary to what might have been expected, the number of men employed increased in 1921. There was less work but more men to share it. The total employed at bituminous mines was 663,754, an increase of 24,000 men. This figure is not the average number of men at work at any one time, including the weeks in which mines may have been shut down; it is rather the number of men on the working force of the mine when it was in operation. Since the effect of the business depression upon the demand for coal did not become acute until February or March, the great majority of commercial mines got at least a few weeks' operation during the year, and their working forces were thus counted in the total number of employees. By August, 1921, so many mines had closed down that the total number of men drawing wages in one week had fallen to somewhat between 500,000 and 520,000.

The increase in number of employed was confined to the tonnage workers. The number of daymen decreased in almost every state. The total number of surface employees dropped from 110,000 to 96,000, and of underground daymen from 174,000 to 158,000.

This reduction in number of day workers was one cause of a remarkable increase in the output per man per day. In 1920 the average production per man employed per day worked was 4 net tons, a new record for the bituminous industry. Yet in 1921 the average rose to 4.20 tons, an increase of 5 per cent. Other factors contributing to this increase, in addition to the change in proportion of day workers, were the natural tendency to restrict development work in a time of depression, an apparent tendency of the miners to work harder when running time is poor and, most important, a remarkable increase in the percentage of machine-mined coal. Average productivity in a machine mine ranges from 20 to 30 per cent above that in a mine where coal is undercut by hand or shot from the solid. Now in 1921 the proportion of coal mined by machines was 65.6 per cent against 59.8 per cent in 1920 and 55.9 in 1918.

Higher productivity per day tended to reduce the number of days worked. The average time worked by all bituminous miners in 1921 was 144 days, 4 days lower than the history of the bituminous industry. In the calculation of this average, as in earlier publications of the Geological Survey, the size of each mine is taken into account, and each affects the average in proportion to the number of men it employs. The days reported are tippie days, the best single measure of productive time. The use of tippie days gives rise to a tendency to understate the time when repair work or development is being done on underground work and when the tippie is not working. As this condition was more prevalent in Utah and some other districts during 1921 than formerly, the average for the year is not strictly comparable with earlier years, although the form of question used was exactly the same.

Examination of the figures by states shows that the business depression was felt in every important coal-producing region. Omitting the states of insignificant tonnage, such as California, Georgia and North Carolina, the lowest number of days worked was 112, in Arkansas, and the highest, 196, in Michigan. No important producing state reached the 200-day mark. In Illinois the average was 152 days; in Kentucky, 152; in Pennsylvania, 151; in West Virginia, 149; and in Alabama, 166.

(c) Includes also shatterers. Statistics compiled by M. C. Geological Survey, Sept. 23, 1922.
Coal Consumption by Utilities at Peak in December, May Is Low Month

Coal consumed by public utilities during 1928, 1929 and 1930 averaged 3,450,000,000 tons per month. Using also an 189 per cent, the average consumption rate fluctuated from a high of 4,327,758 per cent in December (January 1.16 per cent to a low of 28.49 per cent in May. The spring and summer months falling below the average, and the autumn and winter period exceeding it, as shown in the accompanying diagram. The April-September average consumption was 46.85 per cent of the total. October-March consumption averaging 53.05 per cent. Some of this variation, of course, is due to the seasonal dullness in general industry during this spring and summer.

More Mine Fatalities in August, 1922, Than A Year Ago but Fewer Than in July

Accidents at coal mines during August, according to reports received by the U. S. Bureau of Mines from state mine inspectors, resulted in the death of 98 men, of whom 96 were killed at bituminous mines and 2 at anthracite operations. The total output of coal, including a small amount of steam sizes of anthracite, mostly from river dredges, was 25,776,000 tons. Thus the fatality rate for August was 3.80 per million tons as against 3.69 for the corresponding month last year. The average fatality rate for August over a nine-year period (1913-1921) is 4.15. For bituminous mines alone the August rate was 3.75, as compared with 3.39 for August one year ago and an average rate of 3.78 for the nine years 1913-1921. Thus for bituminous mines alone and for bituminous and anthracite mines combined, the August, 1922, rate is slightly higher than for the corresponding month last year but lower than the nine-year average rate for the same month. In July last there were 74 fatalities, or 4.31 per million tons produced.

During the first eight months of the current year accidents at coal mines have killed 1,025 men, 159 at anthracite mines and 866 at bituminous mines. During the corresponding period last year there were 1,318 fatalities, of which 366 were at anthracite mines and 953 at bituminous mines. For each million tons of coal mined the current fatality rate is 4.07 as against 4.09 for the eight-month period last year. For bituminous mines alone this year's rate is 3.77 as against 3.66 last year; for anthracite mines alone the 1922 rate is 7.16 as compared with 5.90 one year ago.
New Coal Legislation Presents Opportunity to Air Causes of Instability in the Industry

BY PAUL WOOTON
Washington Correspondent of Coal Age

The coal industry is waiting in suspense to see what the new Federal Fuel Distributor will do and what policies may be adopted by the Fact-Finding Commission. The feeling in official circles is that the predominant sentiment within the coal industry is hostile to both of these agencies. There are many evidences of a tendency to hold back and oppose, although there are many coal operators who are waiting with open minds and some who see in these agencies new opportunities to improve the industry.

The consensus of opinion in Washington is that, everything considered, the coal trade is getting off easy with the dose of legislation it is receiving after such a major disturbance. Some operators think the industry is particularly fortunate in that the spoon is in the hands of Secretary Hoover and Fuel Distributor Spens. When it is considered that the trouble within the industry practically wiped out the nation's coal reserves and nothing more serious than this legislation has followed, there is reason for the coal trade to be thankful, some think.

The public was forced to suffer inconveniences and real annoyance and was forced to play the galling role of bystander. Despite all that there was no great demand for even this legislation. Many are surprised that the public did not receive something more drastic. The feeling in official circles is that the coal industry should accept this legislation in good grace and do all it can to cooperate fully with each of the agencies set up by the new legislation. In this connection it may be said that officials have had striking evidence of friendliness from the smokeless operators. If all groups would do as much, there would be every reason to believe, it is said, that the situation could be met and all industries allowed to obtain the fuel requirements of the increasing tide of prosperity.

Obstructive Tactics May Prove Disastrous

If, on the other hand, the coal industry starts to fight those agencies with injunctions or suits to test the constitutionality of the laws, it is believed nothing constructive will have been accomplished. It is felt that the industry probably will bring down upon itself a form of regulation which will soon place it in the public utility class. It is contended that the purpose of this legislation is a legitimate function of the government, and if by any chance Congress may have exceeded its power, there is every reason to believe that the strength could be mustered to increase its power.

It is certain that Secretary Hoover and Mr. Spens will not use the powers which have been vested in them any more than they have to. If all will pull together, at least until the lake program has been filled, it is believed that the situation will be left largely to the good sense and the self-restraint of the coal producers. An evidence that Mr. Hoover does not want to use any more power than necessary to handle the situation is the fact that he recommended for the post of Fuel Distributor a man who was connected with the Food Administration. The Food Administrator had almost unlimited authority. Very little of that authority had to be exercised. Mr. Spens was one of the principal officials who helped carry out that policy. With that training Mr. Hoover undoubtedly selected him as a man who would react in the same way in the matter of coal distribution.

While fact-finding commissions have a reputation of being possessed with an immense amount of inertia and of being distinguished principally by their ability to compile dry reports of great length, there is reason to think that this commission may be an exception. At least the commission gives the coal industry a chance to obtain some of the constructive things it long has been striving to get. Has there ever been a better opportunity to place an entering wedge to effect the amendments to the Sherman law which the coal industry needs so badly?

If coal operators think something should be done in the matter of assigned cars, an opportunity now is presented to obtain a recommendation in line with their views. If anyone has an idea as to improvements in reaching wage agreements or for meeting the waggon mine problem, here is the chance of a lifetime to convince a body vested with all authority to handle a formal act of Congress. A plan is offered to air the thousand and one causes for instability in the industry. A chance is presented to cooperate with the consumers and with the carriers on such things as the promotion of storage. The government has created an open forum. Many friends of the coal industry believe it should be thronged for the next several months by men within the coal industry who have constructive ideas. An unprecedented opportunity is given to procure a friendly hearing.

Purchasing Agents Adopt Coal Policy to Facilitate Equitable Distribution

Following the conference on coal held by Secretary Hoover on Sept. 15 at Washington, which was attended by Mark Kuehn, chairman of the Fuel Committee of the National Association of Purchasing Agents; E. H. Hawkins, former chairman of that committee, and H. R. Heydon, secretary of the association, the members of that organization were requested to adopt as the coal policy of the association the following:

1. Buy only for current consumption.
2. Adjust deliveries on contract, so that they will not exceed current consumption.
3. Play the game according to our respective actual requirements and not try to beat our neighbor to it.

It was stated that much could be accomplished through the cooperation of the part of all purchasing agents. Every member was mailed a declaration of the coal policy of the association and asked to buy only in sufficient quantities to meet current consumption and "thus voluntarily to assist in ameliorating the coal situation by preventing a fictitious demand that will increase prices and prolong the period of coal shortage, thereby affording an opportunity, in the hope of normal days, to obtain supplies of coal which are so desperately needed."

Should this voluntary method fail to accomplish its purpose, the declaration says, it is probable that industry generally will be asked to cease production or operation for a period of two weeks. It therefore seems essential that all industry should immediately co-operate in this present coal policy.

Bethlehem Corporation Gets Permanent Injunction Against District Union

In a lengthy decision handed down by Judge John N. Langham at Indianapolis, the temporary restraining order obtained by the Bethlehem Mines Corporation against District No. 2, United Mine Workers of America, John Bragg, its president, and others, is made permanent and absolute. The plaintiff coal mining company employees are not named. Apparently they were satisfied to remain at work during the strike period when other companies went into the district and, it is alleged, attempted to coerce the miners into joining the strike. An order restraining the union was obtained and Judge Langham now makes it imperative that the same organizers remain out of the field and permanently refrain from the defendants.
Miners Win First Skirmish in Herrin Case

Every year at the United Mine Workers of America have won a point in the court room in the case the great interest in the Herrin, Ill., coalfield for the treatment of the injured be they become acquainted
with each other and the members of other teams. A bond of common sympathy is thus fostered. Even the physician.

After Many Years' Rest Coal Is Being Mined
Within the City Limits of St. Louis

By E. J. WALLACE

A coal mine has been opened within the city limits of St. Louis. This is the first coal mine in many years to be operated commercially within the city limits. It is in the Clifton Heights district, off Southwest Avenue, where a 4-ft. seam has been opened up with extensive acreage. The coal is soft and is of fairly

First-Aid Contest at Norton, Va., Shows
High Proficiency of Contestants

Some remarkably high scores were made at the fourth annual skilled and unskilled coal operators' contest held at the ball park in Norton, Va., Sept. 18, 1922. Ten teams took part in the contest, which was

HOW COAL MINING IN ST. LOUIS LOOKS TODAY

by the southeastern part of the city this 4-ft. bed under an

good quality. It is estimated that there is a considerable acreage

This is one of the few acreages that were not mined out

in the years 1850 to 1860 prior to the building of the East Bridge in St. Louis. All the coal used in the city at that time was mined in the southwestern parts of the city. One of the miners of that period is still living today. He is

The two companies in existence today that mined coal at that time in St. Louis are the Garber Coal Co. and the Pepper-Russell Mining & Manufacturing Co.
Spens Orders Daily Reports on Kind, Amount and Price Of Soft Coal Shipped and to Whom Sent

Federal Fuel Distributor Spens' first official act is Order No. 1, issued on Sept. 27. This order divides the soft-coal fields into 17 districts and directs every producer and shipper to make detailed, signed daily reports showing with respect to each car of coal the kind or grade, tonnage, consignee and price, and whether shipped on a contract. Until offices in the field have been designated to which these reports can be mailed they are to be sent to Washington.

In making the order it is pointed out that the Fuel Control Act requires the Federal Fuel Distributor to ascertain many things with regard to production, distribution, prices, shortages and character of consumption. Accordingly, Mr. Spens for administrative purposes has divided the coal fields into 17 units and calls for daily reports from all shippers.

Paragraph 2 of the order thus sets forth the requirements as to reporting:

1. The total number of carloads of each class or grade and size.
2. Names and addresses of consignees, with car numbers and initials, destinations and amount of each class or grade and size of coal shipped to each consignee.
3. All to each shipment, the prices or prices f.o.b. mine as contracted for, charged and (or) received for each grade of coal shipped. In the case of coal sold at a delivered price at destination the destination price less transportation cost shall be used as the mine basis.
4. A designation of such of said shipments as shall have been made under time (or period) contracts for periods of more than one month's duration.

The 17 "producing districts" each to be under the management and direction of a district representative, yet to be appointed, are described as follows:

**PRODUCING DISTRICTS DESIGNATED BY MR. SPENS**

1. Alabama; headquarters, Birmingham.
2. Tennessee; headquarters, Knoxville.
3. Virginia; headquarters, Richmond.
4. All of Kentucky east of the 85th meridian; headquarters, Cincinnati.
5. All of Kentucky west of the 85th meridian; headquarters, Louisville.
8. Fairmont, Coal and Coke, and Upper Potomac districts in West Virginia, with all other districts in said state not otherwise included, and Maryland; headquarters, Fairmont.
9. Central Pennsylvania, including the Somerset district; headquarters, Altoona.
11. Pittsburgh district, and all other districts in the State of Pennsylvania not otherwise included; headquarters, Pittsburgh.
12. Ohio; headquarters, Columbus.
13. Indiana; headquarters, Evansville.
15. Franklin, Williamson and Saline counties, the Bellefonte and Mt. Olive districts and all other districts in Illinois not otherwise included; headquarters, St. Louis, Mo.
17. The United States west of the Mississippi River, except the States of Iowa, Montana and North Dakota, reporting directly to the Federal Fuel Distributor at Washington, D.C.

Assurances of cordial co-operation in the execution of measures deemed necessary to insure an equitable distribution of coal in the present emergency are being received by Mr. Spens from the governors and fuel administrators of the various states. Governor F. E. Morgan, of Virginia; Hugh J. M. Jones, State Fuel Distributor of Vermont; William J. Grier, chairman of the New Jersey Fuel Commission; Major Alex. Forward, Fuel Administrator of Virginia; J. W. McCardle, chairman of the emergency fuel commission of Indiana; Ivan Bowen, Fuel Director of Minnesota; Governor Len Small of Illinois, the Pennsylvania Fuel Commission, and W. H. Woodin, head of the New York State Fuel Commission, are among those heard from.

**NORTH CAROLINA PUBLIC UTILITIES FACE SHUTDOWN**

R. O. Self, director of the North Carolina State Coal Distribution Committee, reports that a number of public-utility gas companies are facing a shutdown unless gas coal supplies can be furnished at an early date. The difficulties of these companies are due to the inadequacy of the car supply in the Southern Appalachian coal-producing districts.

Foreign-owned vessels are urged to take on all coal supplies possible at foreign ports. Fuel Distributor Spens has declared that, in his opinion, the existing reconsignment rules should be permitted to stand without revision for the present. "It is true that at about the time the coal strike was ended there was at certain terminals quite a quantity of coal on hand awaiting disposition, but this was due largely, I think, to the fact that this coal had been purchased at high prices with the result that the breaking of the strike made it difficult for the operators or shippers to find customers," said Mr. Spens in a letter to the interstate commerce commission. "Today there appears to be approximately one-third of 1 per cent of the total loading of cars held for reconsignment, and I am inclined to the opinion that, with the big demand for coal that now exists and with the instructions that you have extant that consignees must unload within twenty-four hours or be embargowed, we need not, just at this time, have much apprehension that the privilege will be dangerously abused."

An urgent appeal to concentrate on a drive to expedite coal movements, especially during the month of October, has been addressed by Fuel Distributor Spens to the executives of the various coal-carrying railways.

"I appreciate fully the current conditions on the railroads; the ravages of the strike, the fact that today the offerings of tonnage of all character are large, and the further fact that, in spite of those circumstances like carriers, in the aggregate, are making a splendid showing in the transportation of coal," says Mr. Spens. "In these circumstances I am loath to suggest the possibility of even better performance."

"Due to the dual strikes there is, of course, a dearth of coal. Consumers, domestic as well as industrial, have been urged only to purchase coal for immediate requirements. Current transportation is adequate for current needs, but not sufficient to permit of reserves. An early cold snap
Ohio Begins Regulation of Coal

Production, transportation and distribution of coal in Ohio from the time it is loaded at the mines until it is dumped into consumers' bins, must be reported to the Ohio Fuel Administrator, including prices received by producers, wholesalers, jobbers and retailers, according to a statement issued at Columbus. A comprehensive system of reports from all dealers, jobbers and shippers of all the coal shipped, received or sold in any quantity and form must be made direct to the fuel administrator.

This event that any violations or apparent violations are found, civic organizations are at once to make a report to the administrator so that an immediate investigation of the case may be made and the violators subjected to the penalties provided for in the emergency act," reads the announcement. "Producers will be required to report the quality of coal mined, loaded and shipped, with the prices obtained for it. Wholesalers and jobbers must report shipments received, from whom they came and the prices received. This class of dealers will not be required to make a report of each separate transaction, but will lump their sales. All these reports are to be made daily, and are mandatory under the act. Thus Administrator Neal and his staff will have a hand on the pulse of the situation at all times."

Output of Smokeless Coal Fell Sharpily in July. When Rail Strike Began

West Virginia produced and shipped 2,630,565 net tons of smokeless coal during July, 1922. This is approximately 500,000 tons higher than for July last year, but is the lowest of any month since the strike began and a sharp decline from the June output of 3,777,588 tons.

The total for the first seven months of 1922 is 22,018,974 tons, as compared with 16,170,355 tons during the corresponding period last year.

The output from open-shop mines in the Connellsville coal region continues to increase steadily. Many men are coming into the region from other sections and a number of old men are returning to work. Two additional plants of the H. C. Frick Coke Co., the Shamrock Coke Co., Grindale No. 2 plant of the Halman Coal & Coke Co. and the Connellsville Coke Co. have resumed operations on an open-shop basis during the past week. This means that all the Frick plants and all the Halman plants are mining.
Peace Between Operators and Mine Workers in Sight: District Committees to Work Out Wage Contracts

By E. W. Davidson

Cleveland, Ohio, Oct. 3—Peace appears to have made its entry at last into the long conflict between miners and bituminous operators. Tuesday night, after two days of the mine-operators' conference looking toward the next wage agreement, fighting points between men and employers seemed to have been partly removed, and a plan for adjustment of future controversies was under way and operators from fifteen mining districts, representing about two hundred and seventy-five million tons production, had almost ceased showing their teeth at each other. It was expected by both sides that the conference could end Wednesday afternoon.

It was practically decided Tuesday after considerable sparring that the operators of the two sides and among operators themselves that the method of making future contracts between operators and miners would be worked out by a committee made up of miners and operators from each district, that no joint fact-finding commission should be appointed by that conference and that the request of Washington for a suggested panel of names from which the federal fact-finding commission might be appointed would be answered in the negative.

All this developed during Tuesday following a notable peace speech by John L. Lewis, president of the miners' union. This speech, along with a parallel one by T. H. Watkins, president of the Pennsylvania Coal & Coke Corporation, appeared to pave the way for real accomplishment by the operators, who up to that time had shown not the slightest sign of unity on any subject.

Lewis Bids Both Sides "Bury the Hatchet"

It was apparent when the conference started Monday that no harmony prevailed anywhere among the operators. Part of Ohio and a scattered few operators from Pennsylvania were regarded as ready to "play the miners' game" as they did at the August Cleveland conference which ended the strike. Many operators present were divided about taking part in the conference, notably Illinois and the Pittsburgh and Central District men of Pennsylvania, who did not agree in the pacts they signed in August to join this conference. Many of the operators from elsewhere also were of doubtful status. It seemed necessary for them to unite on some common ground, but they couldn't do it until after Lewis' speech in which he bade both sides "bury the hatchet; bear in mind that it is essential for them to put their own house in order" and that the miners were ready to meet their employers half way.

"That sounds mighty good; if the miners only will live up to that, things will smooth out," declared more than one operator. Then they proceeded to compose some of their differences. It was made distinctly understood at the outset of this process that neither Illinois nor the two Pennsylvania regions would proceed unless it was distinctly understood that no decisions were to be dictated by any minority and that in the matter of creating a joint wage committee nobody was to be bound by the recommendations it might make Jan. 3.

When this understanding was finally reached the operators had taken their highest hurdle. They then proceeded to do business among themselves. The two main objects of this conference were to create a joint fact-finding committee and to set up another joint committee to recommend wage scales, and then for future agreement.

The request from Washington for a panel of twenty names for the new federal coal commission was a new element. At first it appeared important, especially when the operators decided Monday to answer it with a message signed only by themselves, but later it was lost when it became known around that Lewis might not insist upon helping to make up such a panel, though he would insist that the reply to Washington be signed by both sides.

The joint fact-finding committee also appeared a less important issue as the conference wore on, for the operators got the impression that Lewis was willing to cancel that part of the program on the ground that the Federal Coal Commission would do just as well or better.

By Tuesday night the operators agreed among themselves that the federal commission should be left the entire field of coal investigation, so that it could not be said that the coal industry was hampering the people in their effort to correct coal evils.

This left the creation of the wage committee as the principal business to be done at the conference. Some were for organizing it by regions but it was finally concluded that it should be by miners' presidential districts. It was distinctly understood, however, that this committee if created should make no recommendations until after the new federal fact-finding commission has brought in some results. On Tuesday night Phil. Penna., chairman for the operators' separate sessions, and W. D. McKinney, secretary of the Southern Ohio Coal Exchange, declared that the operators had reached a common ground and that if the miners were as reasonable as they sounded the conference would succeed easily.

Expect to Heal Many Schisms in the Industry

John Lewis said the war was over. Thus it appeared on Tuesday night that the operators and miners of the fifteen principal districts of the land had only a day of calm deliberation before them to finish the conference and that possibly many a schism in the coal industry might eventually be healed.

It was undecided whether the joint wage committee should contain one man or two from each side for each district, and it was not definitely decided what the conference reply to Washington would be, but most of the conflict is over.

Practically every producing district in the country was represented when the conference assembled Monday afternoon. T. K. Maher was named temporary chairman and William Green, of the Miners' International Union, temporary secretary. Adjournment was taken almost as once until 10 o'clock Tuesday upon motion of Phil Penna, secretary of the Indiana Coal Operators' Association. He said the operators needed time to "get acquainted" and to review the situation. They remained in session all afternoon, deeming the next time the President Harding's wire asking for a panel of names of men suggested for the federal fact-finding board. It seemed obvious that the operators will not favor sending such a list, since many names have already been proposed by coal men. The discussion the rest of the afternoon indicated that the leaders among the operators' faction which led the settlement in Cleveland in August were going to stand pat.

Tuesday morning the committee which the operators had appointed to draft a diplomatic reply to Secretaries Hoover and Davis declining to suggest names for the President's fact-finding commission did their job of drafting, but they did not send it. The message was held because "developments of Tuesday made it seem futile" to wait, even though Washington expected a reply by Tuesday at the latest. The "developments" of Tuesday were that President Harding's wire asking for a panel of names of men for the fact-finding board had collapsed. The miners held that the request which was received by T. K. Maher was addressed to him not as an operator but as temporary chairman of the joint conference.

As first drafted the message set forth that the operators, "having full confidence in the wisdom and fairness of the President of the United States" and suggesting willingness to abide by whatever choices he should make, were ready to pledge "harmful co-operation" with such a federal commission. Herman C. Perry, of the 8th and 9th Districts of
Jobbers’ Executive Board Meets at Buffalo; Many New Members Elected

G. H. Mergyweather, secretary-treasurer, of the American Wholesale Coal Association, announced the following: The Executive Committee of the American Wholesale Coal Association held a very successful and constructive meeting at Buffalo on Sept. 28 and 29, 1922. At this meeting many new members were elected and the activities of the association were discussed at length. The members of the association were entertained at luncheon by the Buffalo District Wholesale Coal Association. It was presided over by John T. Roberts, of Buffalo. Address were made by Seth W. Morton, president; J. W. John, vice president; G. H. Mergyweather, secretary-treasurer; and J. A. Fisch, of the Cleveland, Ohio. Charles L. Dering, of Chicago, H. J. Huydend, of Toledo, and Ira C. Cochran, who was at this meeting appointed acting commission. As well as trade manager, which latter position he has occupied for some time. The association is making excellent progress in solving the problems which confront the industry from day to day.

Western Fuel Corporation and Coal Miners Sign Two-Year Agreement

A 2-year agreement has been entered into between the management and the employees of the Western Fuel Corporation of Canada, Narrows, Ca., effective Oct. 1, 1922. A minimum daily wage of $1.42 is set. The superintendent of mines is to be the judge as to the ability of each man to do the minimum. The company agrees to pay all employed a bonus of $1 per day worked. It is mutually agreed to have a company and its employees that any decrease in the district wages as set down shall be governed by competitive conditions. The agreement states: Moreover the bonus has been 25¢ per day worked. The price of coal to employees is set at $1.40 per ton.

Fundamental Business Conditions Sound

No clearer demonstration could be asked to indicate the soundness of the fundamental conditions underlying the present business revival, the Department of Commerce reports, than the persistence with which commerce and industry have progressed in the face of recent serious obstacles. The extremely serious labor difficulties through which we are now passing would, under many conditions, have completely demoralized business; instead, real progress continues to be made. There is reason to suppose that the economic losses occasioned by the coal and railroad strike will make themselves felt for some months to come. Disturbances of this character affecting basic industries cannot take place without having to be paid for in the long run. It is possible that the full force of these losses will be felt more severely in future months.

Figures now available on business movements during July show that the rate of progress was materially slackened in that month. In the majority of industries production and sales were less than in June. A part of this is to be attributed to the usual midsummer seasonal slump and a part either to approaching over-production or to increased prices and increased production costs.

The extent of the real progress of industry on the road back to normal is seen when current figures are compared with those for a year ago. In almost every instance production is on a much higher level than in 1921. Perhaps the most favorable feature of the present situation is the prospect for a bountiful harvest this fall. This will do much to offset the other less favorable factors.

Under the appended schedules mining and yardage pay is given as follows:

MINEING
Wakesiah and Reserve Mines and No. 1 Upper Seam—91¢ per ton.
No. 1 Lower Seam—61¢ per ton.
No. 2 Upper Seam—Coal under 4 ft. in thickness, $1.68 per ton.
No. 2 Lower Seam—$1.05 per ton.

YARDAGE—UPPER SEAM
Leaves—$3.37 per yard and coal.
$2.70 per yard and coal.

Leaves—When less than one-half of height is in white rock.
$2.13 per yard; coal to company.
$1.70 when more than one-half of height is in white rock.
$10.50 per yard; coal to company.

Tumbling Stalls—Five yards long by 4 yards wide, $13.50 per yard.
Brashin; rock—One foot thick, $1.35 per linear yard.

The day rates range from $3.714 for muckers to $4.994 for machine foremen, plus the bonus.

Trading Loss of £550,000 Shown in British Coal Mining Industry in June

Collation of the proceeds and costs of the working of the coal-mining industry of the United Kingdom for June, for the purpose of determination of wages in August, shows a gross trading loss of about £500,000 in that month for the whole of the coal-mining industry throughout the country, equivalent to about 9d. per ton of coal. The average earnings per shift worked in June, taking into account all persons in the industry,—men, women and boys,—were 9s. 84d., or about 50 per cent more than the 1915 figure of 6s. 5d.

Fuel Distributor Spence’s order requiring daily reports from coal producers, printed on page 537 of this issue of Coal Age, is now being served on operating companies by mail.

The Geological Survey and the Department of Commerce are sending out questionnaires requesting information on stocks of coal as of Sept. 1 and Oct. 1. The report of the canvass, which will be the first since March 1 of this year, is expected to be available by Nov. 1, 1922.
Coal Strikes Unknown in Near East, but It Has Fuel Problem

Cold weather does not spell "coal" to the American relief worker in the Caucasus district of Armenia; it spells "candles," for the fuel question is just as vital in the Near East as it is here, but the answer is different. In the chilly Caucasus area, where the mercury often creeps down to 16 deg. below zero and there are more than 30,000 shivering youngsters to be kept warm in the orphanages of the Near East Relief, wood is the fuel on which relief workers must depend, according to the Near East Relief.

The accompanying illustration shows a caravan of camels carrying wood fifty miles overland to keep these people warm this winter. That is how the answer to cold in Armenia comes to be camels. Camel ox teams, for the latter do just as well, carry the fuel over many miles. A caravan of seven hundred ox teams was organized last year by an enterprising worker, and rendered remarkably good service.

The Ending of the Coal Miners' Strike

It is some time since the August conference at Cleveland wound up its proceedings with a great victory—for whom? At this time of writing it would appear that honors are fairly well divided; the miners can still claim their seven and a half a day and the operators are getting a good price for their coal to enable them to pay it.

When work was sent out to start work at once did the miner rush down to the mine with the same smile on his face he had when he brought his tools out on the last day of March? If anyone who was not around the mines at that time thinks he did, he is very much mistaken. He took the news very calmly. Many of them still sit with their feet on the front porch rail, pulling at their old pipe, praising Mr. Lewis for the glorious victory.

After our mines had been running a week I noticed that the coal did not rush up the slope (as we fondly anticipated), and found on inquiry that the men were not going to work and those who were going were not loading much coal. At this information I ventured among the miners' houses and, seeing several of the men, I began timidly to ask them if they knew the strike was finished. Most of them somehow thought there was some change, but they would talk about anything but work. Another superintendent came to me in a great state of mind, saying they were not loading one tenth of the coal they were before the strike.

The miner foreman spends most of his time showing them places with the result that 99 per cent try another mine the next day and every boss (they know) is standing with open arms to meet them. This strike has made men more dissatisfied and less inclined to work than ever they were before. They have gone five months without work and it seems a lot of them feel they can go on indefinitely without work, and if a superintendent or boss ventures to remind them that those big wages will not always prevail and tells them to make hay while the sun shines, they tell him he does not know what he is talking about.

I cannot help but wonder what is going to be the end of all this. It seems to me that we shall have to have a five months' strike every year to keep production down and prices up on purpose to pay the miner the big wages he is receiving. Mr. Lewis knew what he was doing when he refused the arbitration clause, but it seems to me he either will not or cannot see that it is a mistaken kindness to keep the miners' wages inflated above the rest of the workingmen.

INDIANA, PA., Sept. 5, 1922.

T. HOGARTH,
Superintendent.

Independent Anthracite Prices Give Concern: 1920 Level Allowed Temporarily

Independent producers' prices on anthracite are still giving the official bodies of Pennsylvania and Washington some concern. Governor Sproul of Pennsylvania on Sept. 20, 1922, issued a proclamation establishing $8.50 as the maximum price on prepared sizes of anthracite, conferred executive authority on the Pennsylvania Fuel Commission, of which Wm. D. B. Ainey, is chairman, and announced that a Fair Practice Committee would be appointed to deal with prices of coal.

Independent operators at once let it be known that they could not produce and sell at the $8.50 maximum, and on Sept. 22 they were informally advised by Mr. Ainey's office that pending the decision of the new Fair Practice Committee they would be allowed to charge prices that were considered fair by the Fair Practice Committee of 1920.

Edgar F. Felton has been appointed chairman of the Fair Practice Committee and has been engaged in the last few days in a study of costs of production of anthracite. A meeting was held on Oct. 2 but no conclusions were reached and no announcement was made other than that everyone concerned with the distribution of coal would be called in an effort to lower the price to the consumer.

It is understood that one large independent held to the $8.50 maximum for a short time, but has now advanced his price to $9.15. Little independent coal is quoted in Philadelphia over $9.50. Quotations in New York, however, are more general at $10.50@12.50.

At an executive session held Sept. 22 at Harrisburg the Pennsylvania Fuel Commission spent considerable time discussing the appointment of a fair-practice committee, to be established as provided for in the proclamation of Governor Sproul, and the methods to be followed in determining promptly and fairly the cases coming before it.

The commission also met representatives of some of the independent anthracite coal companies and it is understood that the base price some of the companies originally asked for was considerably lowered during the discussion. No decision relative to prices of independent companies' coal was reached, except that it was agreed that the new committee would have to deal with each company individually.

A statement issued by the commission follows:

"The handling of the situation between the present and the time when this committee can function so as to hold up production was likewise discussed. The commission arranged to have representatives visit immediately some of the larger cities to make plans for local distribution."

No meeting of coal operators was called, but representatives of three companies who desired to discuss informally the situation of their particular companies and the methods to be used under the Governor's proclamation were heard. "The personnel of the Fair-Practice Committee is being canvassed and will soon be announced."

"Several of the companies which have announced selling prices higher than the $8.50 basis are prepared to withdraw these and make some reductions in their base rates until the Fair Practice Committee can hear their cases."

"Chairman Ainey stated that there was no confirmation of the commission's purpose to keep a semblance of coal price to the lowest point consistent with a fair margin of profit in output. In this respect the commission stands unwaveringly on its former utterance and the policy of the Governor that there shall be no strike bonus or bonus from mine Idleness carried into the present coal prices."

The new "no to coal" has some interesting form, among which we notice "shall we call it? 'We will call it.' It all ends, however, with 'we may be sold.'—New York Sun."
Production and the Market

Weekly Review

From hopes on the recovery of demand, steam coal prices have receded but domestic fuels are advancing with the advent of cool weather and the usual seasonal household demand. This demand is not yet in full swing, but today’s domestic situations have all the earmarks of further increases, as the short supply will be accentuated by orders placed as a substitute for hard coal. This demand will fail largely in producing districts not so much called upon to furnish coal for domestic use, but will doubtless also lead to emergency shipments outward of high-grade domestic from fields west of the Alleghenies.

Coal Age Index of spot bituminous coal prices declined to 109 on Oct. 2, as compared with 118 the week before. This represents an average spot price of $4.89 at the mines. The decreases were spread over nearly every district, only the Hocking field showing an increase. Cherryfield (Pa.) and Springfield (Ill.) coals holding firm.

STEAM CONSUMERS CONSIDERABLY “BACKWARD”

The steam consumer is purposefully staying out of the market and is taking little coal aside from current needs. In the Middle West he is able to obtain this tonnage by picking up bargain bids which are still sent in on consignment, often being sold under pressure of heavy demurrage. Screenings have been selling on a par with mine-run, but with the sympathetic steam market, and the better domestic call more operators are increasing their output, and this is fast softening the resultant price.

Recent press notices, “is Ford,” have advised buyers “to delay purchases as prices must drop further.” The coals traders generally fail to see how deferred demand can spell anything but higher prices, especially with transportation conditions as they are and will be this winter. An argument advanced by buyers in the Lake coal-producing zone is that it is unwise to enter stocking orders at a time when they must compete for tonnage with deck buyers.

With 25 per cent of their motive power out of commission, the railroads of the country are now attempting to handle the peak of the year’s business. There are no signs that the crest has been reached. Traffic men generally believe that business will be offered the railroads in increasing amounts more rapidly than its loco-motives can be restored to the service.

The effect of the Lake sailors’ strike which began Sunday at midnight was still doubtful Monday night. Coal laden vessels continued to load and clear for upper ports. The Lake Carriers’ Association asserted that no boats are tied up and that few men have struck. On the other hand E. J. Sullivan, secretary of the Cleveland local of the union, said most union men had quit and that boats that cleared from there went out with “cruelly short crews.” The Lake Carriers’ Association states it is going to handle all the coal that can be dumped at the docks and that it will be moved for the special benefit of the Northwest. Railroads originating coal for the Lakes have issued temporary embargoes, until congestion is cleared or the effect of the strike determined.

All subject to revision. (1) Revised from last report.
Normal production of anthracite is being retarded by the same conditions that hamper the soft-coal industry—lack of cars and poor transportation. There also is a dearth of labor. The effect of the car shortage is only just now beginning to show. During the last four days of September the supply began to be "spotty," incurring delays at collieries located on the Lehigh Valley, Erie and D. L. & W. lines.

The anthracite price situation is confusing. Retailers have received independent quotations ranging from $9.15 to $13 and even higher and are loath to pass this on to their trade. The $8.50 price recommended by the Pennsylvania governor has not been effective and the commission now urges that, pending further investigation and adjustment, operators refrain from charging prices exceeding those established in 1920 by the Fair Practice Committee, which prices ranged up to $12.50, averaging around $10.50.

BITUMINOUS

"Production of both bituminous coal and anthracite appears to have found a temporary level, bituminous at around 9,750,000 net tons, and anthracite at 1,850,000 tons a week," says the Geological Survey. The total of all coal raised is therefore about 11,600,000 net tons, still somewhat less than the amount required to meet current consumption and the heavy movement up the Lakes, and at the same time to rebuild coal company stocks.

"The output of bituminous coal for last week is estimated at from 9,600,000 to 9,900,000 tons. Heavy loadings in the early part of the week—35,804 cars on Monday and 33,396 on Tuesday—were largely offset by a decline later in the week. By Thursday loadings had dropped to 28,862 cars as against 29,036 on the preceding Thursday."

The all-rail movement of soft coal to New England increased to 3,255 cars during the week ended Sept. 23.
From L. C. C. reports for the preceding week. That market, however, is said to have industry has sufficient coal on hand to last well through the year.

On the West Coast, figures show there were 6,786 tons of anthracite and 209,551 tons of bituminous coal on hand Sept. 16, compared with last year's figures of 88,081 tons of anthracite and 828,335 tons of bituminous; on the Ashland-Washington docks 871 tons of anthracite and 44,417 tons of bituminous were on hand, as against 21,616 tons of anthracite and 238,625 tons of bituminous a year ago. On upper Lake Michigan docks there were on hand Sept. 2, of this year 49,162 tons of anthracite and 156,535 tons of bituminous, compared with stocks of 56,323 tons of anthracite and 218,014 tons of bituminous on those docks on Oct. 1, of last year.

Favorable orders for the movement of coal are being received only rarely. The Federal Fuel Distributor is unable the L. C. C. to issue such orders only in cases of real necessity where it is impossible to relieve an acute fuel situation by any other means.

### Coal Age Index 104, Week of Oct. 2, 1922
Average spot price for same period $4.83. This diagram shows the relative, not the actual prices on fourteen coals, representative of nearly 99 percent of the bituminous output of the U. S. weighted in accordance first with respect to the proportions each of stock, prepared and run-of-mine normally shipped and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June 1914, as 100 after the manner adopted in the report on "Prices of Coal and Coke, 1913-1915," published by the Geological Survey and the War Industries Board.

The total dumped for the year to date is 10,185,210 tons, as compared with 18,843,148 tons in the corresponding period of last year.

Numerous complaints are reaching Washington from coal operators who are not being given assigned cars. It is asserted that railroads generally are misinterpreting the L. C. C. service order and are assigning cars for railroad fuel. These complaints point out that it is flagrant discrimination when a few operators are allowed to absorb all the transportation in a coal-producing district. Several instances were cited where certain mines are receiving 100 per cent car supply whereas the complainant is being given only 29 per cent of the cars he requires.

### Anthracite
Production of hard coal was 1,856,000 net tons during the week ended Sept. 23. Preliminary reports for last week indicate an output of 1,500,000 to 1,500,000 tons. The approach to normal production, however, was checked in the last few days of September by a growing car shortage. Movement of loads is also slow and deliveries uncertain.

### Coke
With hectarite production increasing—135,000 net tons during the week ended Sept. 23—the car shortage has overshadowed the strike. It is now apparent that the strike will no longer be the dominant factor in curtailing the production of coke. The market is stiffer, furnace coke being in demand for domestic purposes, while foundry coke is steadily higher.
European Coal Markets
Show Signs of Revival

France Feels Effect of Withdrawal of British Fuel for American Emergency
—With Unfilled American Orders, British Prices Hold—Coal Shortage in Germany and Buying Power Crippled.

Foreign coal markets show some improvement. The emergency American demand removed an embarrassing volume of British offerings from Continental markets, stimulating prices and production. The French industry felt the effect of this immediately. British exports to France were stopped or greatly reduced and French mines cleared away their heavy pithead stocks with the disappearance of these competitive offerings.

Great Britain still has many unfilled orders for North America and producers are not inclined to reduce prices to attract Continental buyers. They feel that these orders, having been delayed for many weeks, will soon be forthcoming.

Germany is suffering from a coal shortage. Her buying power is reduced by the exchange rates and she must take steps to increase her production.

Prices Firm on Best British Coals; Dock Congestion Still Acute

There is more activity in the superlative Admiralty coals and the best drays. Canada is still in the market and is now inquiring for 60,000 tons for Montreal delivery before the end of November. Continental demands are also good. With the exception of these quality coals, other descriptions show an easier tendency. The output during the week ended Sept. 16 dropped to 4,955,000 tons, according to a cable to Coal Age. This is the first week since Aug. 12 that production has been below 5,000,000 tons.

The position in the Welsh fields now is that the pits have an abundance of contracts to carry them into October. Leading operators are not inclined to make any cut in prices. On the other hand, Continental and South American buyers are holding back orders because they believe that now the heaviest American demand is over operators will have to reduce prices to get rid of their coal. The demand for the lower grades of coal is extremely poor and stocks are accumulating.

In the north of England, American inquiry is still heard, although there is not much actual business. Here again the chief operators are well sold up and have little to offer. The coke market is strong. Among the contracts recently fixed are 4,000 tons of high-grade Durham gas coals for Malmesbury at 21s. 6d. f. o. b., 2,000 tons of gas coal for Esbjerg and 90,000 tons of Durham coking coal for Oxlund at 20s. 6d. f. o. b. An inquiry was made for 30,000 tons of Durham coking coals for immediate shipment, but the quotations were too high and the inquiry was withdrawn.

The new arrangements for the loading of coals cargoes at the Northeastern ports, under which two hours' overtime are worked at the end of the second shift, is proving a success. Congestion of the docks has undergone no appreciable relief; in fact, the conditions are so unsatisfactory that a considerable amount of trade is being diverted from these to other ports.

Under the circumstances, it is likely that a further attempt will be made to induce dockers' representatives to agree to a reduction to the three-shift system. When the two-shift system was introduced during the war, it was provided that there should be a return to the old arrangement if the volume of trade justified such a move. It is undeniable that the time has arrived for the change. Thousands of tons of ships are being held up, thereby incurring heavy losses in demurrage, and sidings are crowded with loads.

The result of this congestion has already been felt at some of the collieries, which have been forced to close down temporarily owing to wagon shortage. The aggregate loss to the miners in wages is very considerable, and their resentment against the attitude of the dock workers' officials can be well understood.

French Coal Is in Good Demand: Miners Deliver Ultimatum

French coal is finding a ready market, with the exception of the Saint-Etienne field and other minor districts of the Center of France. The National Congress of French Miners, which met recently at Angers, voted a resolution declaring that should the French government or the French Parliament make the action of modifying any of the fundamental provisions of the Act of June 24, 1919, on the eight-hour working day possible, a general strike of French miners would be the immediate response. The possibility for intensifying the present conflict between operators and men in such a resolution is quite evident.

During July France also produced 355,244 tons of coke and 226,544 tons of coal. The output was 985,242 tons of coal and 22,049 tons of coke. Her pit-head stocks were 593,810 tons of coal on July 31, as compared with 619,285 tons on June 30.

The comparatively heavy shipments to Spain in July followed the strike of the American miners.

The quantities of coal to be exported by Germany on special contracts in July and August have been reduced, as follows: France, 3,170,000 tons; Luxemburg, 111,000 tons; Belgium, 257,000 tons; and Italy, 216,000 tons.
Coal Paragraphs from Foreign Lands

ITALY.—The market continues dull. Coke supply is somewhat better. There is no demand from the mills and railroads. Stocks have increased to about 30,000 tons and more steamers are expected soon. The prices are: Bengal coke, 35s. L. Bengal good 2s. 6d. Rs. 27; British Rs. 35; African, Rs. 275.

SPAIN.—The first deliveries of Asturian coal for Barcelona after the miners’ strike have put an appearance. Orders have been large in consequence of the low level of stocks and the rise in quotations for foreign coal. In a certain number of mines the return of the workers has not yet resulted in a full output, owing to the necessity of restoring workings.

BRITISH COLUMBIA.—The market is improving every day. Coke is very firm, especially metallurgical coke. Briquettes are also strong. The state has laid in large stocks and the partial revival of the mining industry has led to an improvement in demand.

Unusual Dullness at Hampton Roads

Circular dullness featured the situation last week. Dumperings fell off to a point far below the minimum in the last twelve months, and demand, particularly in the coastwise trade, receded rapidly.

Spot prices have returned almost to the level which existed before the railroad strike. Steamers engaged for the coastwise trade are being laid up.

Dealer expect very little more business from New York, because of the closing of the Pennsylvania trade which makes competition from this market unfavorable. Some revival in the export trade is being predicted, as indicated by the sailing of several foreign ships with coal, made possible by declining prices.

Advances over previous week shown in heavy type; declines in light type.

A. G. W. JEROME, Secretary of the International Miners’ Union.
North Atlantic

Consumers Apparently Set

On Depressing Prices

Market Continues to Reflect Indifference of Users—Car Shortage Such
That Lower Prices Are Unlikely, save Temporarily—Fuel Comes from
Divers Sources.

The consumer is close to a buyers’ strike in his determination to
depress prices. The market so far has retained its indifferent aspect, from
the consumers’ standpoint at least. There is, however, a growing feeling that
the car shortage has reached such proportions that lower prices
cannot be expected except as a temporary measure. Coal men realize that
a slight return to buying would quickly wipe out spot offerings and
they are extremely cautious about quoting futures.

Coal from all sources can be had at lower figures than last week.
British cargoes have sold off, Southern coals are not so easily salable
and Tidewater piers have a good supply at hand.

CENTRAL PENNSYLVANIA

Car shortage is seriously curtailing production. Figures show a loss in
output of 700 to 800 cars daily.

The situation is fairly good so far as the Pennsylvania is concerned, par-
ticularly in the eastern part of the district, but farther west where other
resource points are located, it is exceedingly bad, not only due to the scarcity of
cars but also to the lack of motive power.

Spot prices are as follows: Pool 11, $3.60; members Pool 10, 11, $4.10@$4.25; Pools 9
and 71, $4.25@$4.50, and Pool 1, $4.50@$5.

BALTIMORE

Prices here are well maintained, especially as to the better grades, as the
continued car shortage is holding down production and delivery. While industries
have been running on the hand-to-mouth basis, or at least have made no
attempt to stock up at the high prices prevailing, the near approach of colder
weather is making some of them consider this necessary. Purchasing agents
are showing greater desire to get under cover, and this has meant that little
coal of the better grade is to be had below $5.25.

Heavy importations of British coal continue to be received, and in fact
there was one diversion of a cargo to New York City after it had been re-
ported as reaching this port. During September fourteen steamers arrived
here with a total of 79,836 tons of Bri-
tish coal. The steamer diverted to New
York City after arriving in Baltimore
was an American ship, with a total of
8,232 tons cargo.

FARIMONT

Transportation conditions are somewhat better here than before the B. & O. will be able
to handle anything like normal quantities and congestion is still so general that
the margin to the West is badly upset, and embargoes have been con-
tinued. Much of the output is moving to Eastern markets. Mine run is
quoted $4@$4 a ton.

PHILADELPHIA

It is an indifferent market, at least from the consumer’s standpoint, as
many concerns needing coal are simply holding off, insisting that their
gues as to much lower coal is bound to come true. These have so far do seem to have
the best of it.

All houses are extremely cautious about promising delivery, as they fully
realize how serious is the coal situation. Naturally the consumer reasons that if
the operator urges him to take coal it must be plentiful, but the actual truth
is that the small floating supply that is available for all is market is extremely
small, and would be wiped out almost in an instant with but only a slight in-
crease in ordering.

On the Pennsylvania, the mines east of Altoona were reported receiving the
best service this week, while the New York Central was quoted as in trouble.
The B. & O. out of the Fairmont region, has not improved, and shipment via
Connellsville from Somerset County is now in almost the same condition.

There has been some decline in prices, and in some instances there have been
dead stops due to the necessity to move a limited tonnage for some reason or
another. Producers predict that the competition has been keen, and that
there is much of a moot question, with some consumers close to a buyer’s
strike in their anxiety to depress the market.

UPPER POTOMAC

Injunction proceedings in the Georges Creek field have been dropped under an
agreement with striking miners who have promised not to molest the miners
who desire to return to work and the feeling exists that this will go far to
break the strike. Considerable progress has been made in getting back to
normal in the Upper Potomac, where
there is no prospect that the labor
status will be changed.

NEW YORK

Coal is becoming so plentiful that contracts are being talked of and in
some instances have been closed at $3.60
$4.50, the latter figure having to play
with Pool lung coal.

Quotations show no improvement. Buyers are apparently willing to take
their chances with the poor car supply and the approaching winter months
before they believe prices are going
to be lower.

The showing up in the receipt of British coal is noteworthy. During last
week about 8,000 tons of this were
reported. At the office of the

Fuel Administrator it was announced
there was a cargo in the harbor which
could be bought to sell at about $10. At
about the same time it was announced by dealers there was a cargo of
foreign coal in the Red Hook dock which was being offered at $10.50 per
ton on wagons. Local houses were offered coal anchored off Boston on a basis
of $7 per ton. It being stated there were in the neighborhood of sixteen
cargoes awaiting buyers.

Southern coals are not causing much competition however, being sold
at the same as for coals usually found at
this Tidewater.

Activity along the line prevents high coal prices from Tidewater. How-
ever, coal is coming forward in suffi-
cient quantities to take care of the
local demand. On Sept. 29 there were
1,583 cars reported at the local docks, a
gain of 200 cars over the day previous.

West

DENVER

The labor situation is much improved with the readjustment of the wage
scale. Cars are still scarce and there is a great lack of power to move the coal.

Denver is not suffering from a coal
shortage, as it is close enough to the
mines to get a fair supply of both bitu-
minous and lignite coal. Prices are the
same at the mines as previously when
the same wage scale was in effect. Re-
tail prices in Denver are 75c, lower than
a year ago on account of lower freight
rates.

SALT LAKE CITY

There is very little domestic demand. People are waiting to see what the
grand jury, now in session, will decide about alleged price fixing by operators
and dealers. A prominent dealer, who is also interested in the wholesale end
of the business, states that the retailer,
in spite of the contention that the raise
from $9 to $10 for lump coal has per-
mitted him to draw an abnormal profit,

in getting 50c to 70c on domestic
sizes and 25c, a ton less on slack than
he did a year ago.

Canada

TORONTO

A little anthracite is now coming forward and is being sold in small lots
as low as $15.30, the old price. The
market has a limited supply of
coal obtainable and it is being freely bought by
domestic consumers in small quantities until anthracite becomes generally
available. Quotations for June are
$10.50 for 3-4. lump and $9.50
for slack, wholesale. Coal is

The city on Sept. 27 announced the
distribution of coal certificates to
residents, who had a rush of orders and during the day
1,100 tons were disposed of in car lots at $16.50 per.
The only anthracite to be procured in Pennsylvania was
found in Sullivan County.
Anthracite

Diverse Independent Prices Disturb Retail Dealers

Little Coal Offered at $4.25—Range from $7.15 to $7.50 on Family Size—Packing Adjustment on Canadian Bovine Tub Shovels Available at High Distinction to Producers.

Retailers are quoted by the variety of independent quotations being made. Very little of this coal was offered at the $5.50 price which had been established in the Pennsylvania anthracite region and prices now range from $3.15 to $4 on the family sizes, following the commission's recommendation that prices be kept within the limits fixed by the Fair Practice Committee in 1929, pending further consideration and adjustment. Canadian buyers are appearing in large numbers, taking any coal available at the high end of the range.

Production is being slowed by scanty car supply and some labor shortage. Loads are moving slowly and deliveries are hampered by unsatisfactory transportation conditions. Shovel roads are rolling off.

BOSTON

Practically all the large Tidewater retailers have received their first cargoes and all-rail shipments have been scattered around about as well as could be managed under the various unmeasurable complications that prevail. Retail distributors are working overtime to fill orders and making deliveries as soon as possible. On the old orders, Boston dealers are charging $15 for all cars down to peat, much as they did in the spring. We are interested to watch sales of independent coal during the next month or so. Quotations range from $8.50 to $11.25, f.a.b. mines, but it is not easy for these retailers to pay those prices without undergoing serious losses before the season ends.

ANTHRACITE FIELDS

Production would have almost reached normal this week if it had not been for the instance of a coal shortage seems to have hit the mines on the D. & H. and the D. L. & W. more than on any of the other roads. In several cases, the miners had not enough of striking strain. An outlaw strike was called at the Pettibone Colliery of the Glen Alden Coal Co., because some of the men had not paid their assessments to the union and because some of the firemen were not members of the union. It seems strange after a long idleness and only sixteen men of work the men would be in a position to strike or that they would want to strike. The miners are asking of backing the railroad shops and it is estimated that a sympathetic strike might be called.

NEW YORK

Independent producers as well as some of the larger companies have difficulty in disposing of the steam carbon coal. Many instances of the larger coal concerns are being asked to include some of the smaller coal in their orders. Many smaller independent operators are selling their product over the counter, buyers from various sections of the country and Canada spending most money this week at the mines. Business is being done mostly on a cash basis, the coal being paid for before shipment.

Many stocks of bituminous coal in the Netherlands and in other industrial countries and in some other places where the anthracite steam coal has been purchased as well as the installation of coal basins in the Bahamas as is given as one reason, for the lack of demand for the small coal at this time.

Retailers are getting a fair supply of the small coal and are careful to follow the orders of the State Fuel Administrator regarding distribution. While mines are quoting $1.50, recorded as a fair price by the Fuel Ad-

PHILADELPHIA

While the matter of price is still much of an annoyances to the coal dealer, nevertheless his chief concern is to get sufficient coal to meet the orders he has on his hands. Consumers are becoming insistent that they be given prompt service, and at the same time complain of the price charged.

Larger retailers are for the most part asking $1.50 for egg, stove and nut, but a considerable number who quote $14 for the large sizes and $11.25 for peat. Perhaps a few dealers did charge $15 for prepared coal during the past week they had coal, but it is doubtful if any one is charging this price now.

At this time it seems to be much more than a rumor of coal shortage at this time in the mines in the southern field have not been affected, but to the north there has been some last time on this account. All roads have been asked against loading line equipment to foreign roads, and have requested shippers to take some box cars.

All companies have an active market in buckwheat, rice and barley, and of the former size there is very little to be had on the spot market, with a fair amount going into the domestic trade.

South

BIRMINGHAM

Demand for steam coal is only moderate, consumers appearing not concerned except in regard to movement and car supply, which continues a principal factor. Any shortage in coal supply is attributable to these hindrances which are holding production down to a figure which closely approximates the demand. However, there is a strong demand for lumps and other sizes. The supply of lump is necessarily depleted largely by the casing off in the steam requirements. When prices were at top notch during the recent heavy demand from Western and other foreign territory little domestic coal was produced at the steam coal operations, hence this served to curtail the movement.

Quotations are practically stable at the maximum fixed schedules, although limited amounts of steam fuel have been sold during the past week somewhat under the figures above referred to, though it is not thought there will be any serious depletion against these prices. Open market will prevail on domestic coal in many instances where contracts with dealers do not extend beyond September.

VIRGINIA

The pendulum has begun to swing in the direction of a somewhat larger production, bringing the output up to 144,000 tons. Cars are beginning to get more plentiful, with C., C. & O. mines producing 42 per cent of capacity and with production on the Southern also on a larger scale. N. & W. supply, however, is not quite as adequate.
Chicago and Midwest

Steam Market Remains Weak in Middle States

Gluts Here and There Force Screenings Prices Lower—Domestic Demand Fair—Rail Service Improves Slightly in Certain Regions.

Steam coals continued in no demand during the past week, everywhere except in Kentucky and even there the call was not heavy. It weakened enough in St. Louis to send heavy shipments of screenings up to be dumped on Chicago where that class of coal got into demurrage difficulties by the hundreds of cars and sold down to $2. Domestic demand continues fair in all regions, although there is so much protest against high prices that nobody is buying heavily.

Some fields have been getting better railroad service. The L. & N., in Kentucky, has raised its average car service from about 15 to 30 per cent. Northern and central Illinois service is at least 50 per cent and even in the Carterville region of southern Illinois there is some improvement, but most of the southern Illinois mines are complaining of discrimination against them in favor of other fields.

SOUTHERN ILLINOIS

A slightly improved car supply is the most interesting development of the week in the Carterville field. The efforts of the roads to give the coal the preference in movement is getting some results. There are orders on hand for domestic sizes that will take 90 days to clean up. The steam sizes are giving some worry. This has even affected the minerun market. Steam users are not stockpiling. Somehow, somewhere, they have a hunch that "coal is coming down." Motive power is not far from normal, but the Illinois Central has shown rapid strides in getting back to nearer normal than any other midwest coal carriers.

Miners who have been away since last summer are beginning to drift back and the mines are filling up. Very few minor disputes are reported that cause loss of time. Somewhat similar conditions prevail in the Duquoin and Jackson fields that depend on the Illinois Central alone for cars. The Mt. Olive field shows up with better car supply on the trunk lines, but short on the local coal roads, due to congestion in the St. Louis terminals. A good movement is noted to Chicago and Omaha markets, with some to Kansas City, although the bulk is going to St. Louis. All mines show a steady increase in daily tonnage. The Standard field is as usual afflicted with the thought that "coal is coal" and that anything goes. A better coal carry may bring normality and save operators there from being the first "objects" of federal investigation.

INDIANAPOLIS

Prices continue about the same, though there has been some easing off on some grades of foreign mined coal. Indiana coal seems to be as strong as ever and the prices range $4.50@ $5 and more. Because of rail conditions the Indiana mines have been able to work only about half time. The East is buying coal, generally the biggest buyers, are purchasing spot coal in just as small quantities as possible. The utilities are making a determined fight to eliminate brokerage fees. Coolers are better and the retailer demand is a little more active. One retailer in Indianapolis has announced he will sell no more than three tons to any one customer and officials of the retailers' organization are urging purchases in small quantities.

CHICAGO

Few changes are noticeable in the Chicago market since last week. Steam sizes continue a drug with the heaviest consignments still making a success of their policy of holding out and picking up coal that gets into trouble. The heavy consignment shipments that have been coming in this city have amply filled their needs. The prices paid have varied from $3 on good Illinois and Indiana stuff down to as low as $2 on some northern Illinois and Standard screenings and the effect of this has been to compel a softening of the circular price list on screenings, for circular no longer can be maintained on steam coals. Buyers have been hammering so hard on steam prices for so long that coal men are now charging many of them are refusing contract shipments in order to further embarrass the producers.

Demand for domestic sizes continues fairly strong and likely to burst upward at the first cold snap, carrying prices with it. To date it is difficult to get $5.50 for good 6-in. lump from both the Fourth vein field of Indiana and the southern Illinois counties. Sizes of domestic coal are strong and bring $5@ $5.50. Very little mine run is shipped except on contract. Screening plants are fully justifying their investment and operations. They recently ran out the amount of coal that must either be stored on the ground at the mine or be sold at a loss.

LOUISVILLE

As a result of better production of steam coal in all producing sections the shortage is being rapidly relieved, and the big question now is in supplying retail dealers.

Most operators are handling the domestics freely but in Louisville, however, it looks as if the retail business will be late and heavy. Operators are producing very little prepared size coal. However, with the let-up of steam demand there should be better production, especially with a better coal carry, but until Lake demand is filled prepared production is not promising.

Retailers are asking a margin of about $2 a ton between eastern Kentucky and mine run, which is causing retailers to do a lot of biding. Eastern Kentucky coals start at $5 for mine run and sell down to a low of $8 for lump. Western Kentucky starts at $3.50 for screenings and goes as high as $6 for lump.

Locally retail prices are $10.50 for eastern Kentucky or West Virginia lump, $10 for mine run or screenings, $9@$9.50 for western Kentucky lump, and $8.50 for mine run or screenings. Eastern Kentucky, this week reports about 30 per cent car supply—the best for some weeks—and there is a chance of three days operation. Western Kentucky exports 15 to 30 per cent, the L. & N. doing better, and averaging close to 30 per cent.

ST. LOUIS

Reasonable weather is helping up the domestic demand. This, however, is not as pronounced as was expected. Dealers complain about too much rain, "weathering out of stock like Ford" from sources ignorant of coal conditions. This has resulted in delayed buying and small orders.

Carterville tonnage is small. Plenty of substitution of other make by jobbers is reported. Mt. Olive is best, with poor call for Standard, whose price is high. Small town domestic buying is delayed. Low priced croakers and generally the recent labor troubles, make high-priced coal a luxury. Steam locally is slow. Buying is light and is forcing prices down, and aside from the phenomenon of storage is not marked. Country steam is somewhat similar. Oil retail is held locally and pretty well throughout the St. Louis outlying territory.

Chicago market is bumping ground for steam sizes that won't sell here. Coke is scarce and hard to get and there is no promise of West Virginia or South Carolina coke here. A few cars of anthracite have been shipped, but the tonnage will be small and not a factor. Retail prices in St. Louis are: Carterville lump, $8.50, net; $9@$9.50; Mt. Olive, $7.50, Standard, $6.75.

WESTERN KENTUCKY

It is reported that retailers are demanding prepared sizes all the way from Michigan and Wisconsin to Mississippi, and that prices are stronger there being very thin. $3@$3.50 this week, with the price going as high as $6 in western Kentucky. Steam coal is shipped, however, demand is a little off and screenings have been reported at $5.50, $6.50, $7.75 in clays to the miner. Miners are weaker and prices are quoted at $3.50, with some here as low as $3.25. Coal that was far too expensive is not likely to bring such fancy prices, as they will be largely for lump to the domestic custom. The improved shipment of some standard and weaker grades in these is causing a heavy outside and for runs for railroad use, and many industrial uses screenings and "Slippery Downs."
Eastern Inland

Consumer Waits, Placing

Orders at Receding Prices

Coal Shortage Is Controlling Factor—Continuing at Free Coal Prevents Further Decline—Lead Jam Causes Temporary Embargoes to Lakes—Sears' Service Feared.

The consumer continues to play a waiting game and each order placed last week went at a lower price. Car shortage now controls production and the curtailed amount of free coal is falling in all that holds spot prices from a further decline. The only market strength is shown in domestic coal. Steam buying is hand to mouth, industry refusing to compete with Lake buyers for current offerings, in the belief that with the close of navigation the release of this tonnage will bring about an easier market.

A jam of loads has caused temporary embargoes to the Lakes. Dealers are still the highest in the history of the traffic and while the casualty strike is not yet felt the trade fears its possible effect at the peak point of the season.

COLUMBUS

Buying is limited to present needs only. With few exceptions the National Chamber of Commerce and other agencies advising the people to hold off orders are placed for west is necessary. They are particular to the eastern trades and dealers are buying in limited quantities. Retail prices are being quoted from $4.50 up, and $4.00-$4.75 for lumps. Hocking Valley coal West Virginia, and southern coal are selling around $4.75-$5.00, while Pocomoke when available is quoted at $4.75.

There is a setback in the Lake trade due to the embargo announced as the result of the threatened wage strife. These men are in a fair accumulation of coal around lower ports and with the larger a good supply will be available.

Pittsburgh

Prospects are substantially the same as formerly. Car supplies are limited all around, but are much more plentiful on some divisions than on others. The Pennsylvania has developed an embargo, Oct. 21 to 11, on receipts from connecting roads, to go coal, and all coal products, etc. Thus the supply is checked, but apparently the trade continues. In a few cases supplies are with all the cars they can handle.

Cleveland

Prices are higher. Coal supplies are limited all around, but are much more plentiful on some divisions than on others. The Pittsburgh had been in an embargo, Oct. 21 to 11, on receipts from connecting roads, to go coal, and all coal products, etc. Thus the supply is checked, but apparently the trade continues. In a few cases supplies are with all the cars they can handle.

Exports continue to be the ruling price. For 2,000 tons or more, 1.026 is the stated standard for the grade of coal, and prices are quoted accordingly.

The coal market is one of whole sales. Coal supplies are limited all around, but are much more plentiful on some divisions than on others. The Pennsylvania had been in an embargo, Oct. 21 to 11, on receipts from connecting roads, to go coal, and all coal products, etc. Thus the supply is checked, but apparently the trade continues. In a few cases supplies are with all the cars they can handle.
Heavy Volume of Coal Reaches Northern Docks

September Cargoes Exceed Best Previous Month of 1922—Some Rail Anthracite Is Welcomed—Looming Lake Strike Is Cause for Worry

The upper ports are jubilant for the time being. Soft coal receipts are heavier than at any time during the present shipping season which means that enough bituminous coal is arriving to remove all danger of immediate distress. This region is counting on—and getting, to a certain extent—a good deal of rail coal from Illinois and Indiana. So the principal thing that worries it now is a strike of boat crews. Only sixty days of the shipping season remain.

The first hard coal of the fall has reached Milwaukee—by rail, not by boat. This coal is selling at the old retail prices while cities further north are talking about $22 rail hard coal—if it ever reaches them. The coal men at the ports are struggling to make up their minds whether to sign long contracts at present prices.

MINNEAPOLIS

After prolonged travel over the coal supply for the Northwest, there appears to be some real action. The month of September sees around 1,000,000 tons of coal delivered at the Lake Superior docks—all soft coal. But some hard coal is now reported en route. The dumpings at the Lake Erie ports for the Northwest promise the equal or better showing for October, if the lake seamen's strike does not block things. Altogether, the coal supply situation looks the best that it has this season.

It is well established that barring transportation troubles the Northwest can get all the coal—at least soft coal—that it is willing to pay for. To get it, the current price at the mines must be paid. If the market or going price is above the "fair price" figure, it is a certainty that the coal will go to those who will pay the ruling price.

So dock men and jobbers generally are working to determine how much coal they will be safe in buying at the price now ruling, for it is felt that just as soon as the rush is over for the immediate needs for coal, there will be an easing of prices. But the dock season ends in less than eight weeks. If, in the course of five or six weeks, the use of coal stored on the docks, bought at higher prices, will have to absorb the decrease. Much less than the usual amount of hard coal is expected by Lake. It is possible that there may be some brought up all-rail, but it might have to retail for $22@23 as against the old price of $17.50@18.

MILWAUKEE

The arrival by rail of the first anthracite of the season was the outstanding feature of the coal market last week. The consignment consisted of about 1,000 tons of chestnut. It is being charged at $16, with an extra charge of 75c. for carrying in. Another shipment of 119 cars is in transit.

No anthracite has been received by Lake as yet though an allotment of 2,100,000 tons has been made to Great Lakes ports. A conference is being held in Washington to determine Wisconsin's share, which is expected to be about 1,000,000 tons.

The general coal situation has been considerably brightened by liberal receipts of coal, forty-eight cargoes aggregating 377,000 tons having docked in September up to the 26th. It is safe to predict that September receipts will aggregate at least 425,000 tons. Up to this time June has held the record for receipts for the season, with 303,401 tons. Illinois and Indiana coal is coming in freely by rail.

The City of Milwaukee has absorbed all coal contractors from the thermal unit requirement of their contracts so long as a federal pooling order remains in effect. The city contemplates buying its own coal in the Eastern market in future.

New England

Well Stocked in Advance.

Consumers Not Buying Now

Price Trend Confirms Disinclination to Buy Now for January Use—Congestion at Railroad Wharves Fails to Strengthen Spot Market—Oversupply at Roads and British Receipts Softening Factors.

There continues no improvement in the current market. Buyers have so generally anticipated their wants during the summer that with few exceptions they are well stocked for months to come. They are still disinclined to make purchases that will not be needed until after Jan. 1, and price development from week to week only confirms their attitude.

High-grade Pocahontas and New River have been offered down to $9.50 per gross ton, on cars Boston, and notwithstanding congestion at railroad wharves there is no sign of firmness in the spot market. Hampton Roads shippers now have an oversupply; the all-rail carriers are actively seeking business, and continued receipts of British coal are further softening market factors.

At Hampton Roads the deficit of a month ago has been changed into a surplus of upward of 100,000 tons, coal in excess of boats waiting, and while the situation just as such would be but it is feared there will be little storage. The volume via the Philadelphia and New York ports is still light, and the northern engineers report that there are only a few masts of bituminous coal in the State that are expected to be needed during the week of the Holiday.

The demand for coal is reported good through the week, with shippers' receipts to the east running about an average daily of 250,000 tons. Over 400,000 tons are expected to move this week.
Cincinnati Gateway

Situation Made Obscure by Railfing Cross Currents

Several firms of Prizes for Nowadays—Weekends on Streets Shown by Horse—Lake Halting Cause of Sooner's Strike Improves—Barge Movement on Ohio Grows.

Cross currents without leaving any indication of their significances have been noticeable here for the past week. The sudden situation is hardly identified. Three or four dissimilar signs of present prevalentSteam has shown a greater tendency toward flood conditions and has dropped the coal price a few cents, while following a slight decline, is still in demand. Late buying practically caused with the business forcing the trend to a strike. Railroads are badly operated. A further volume in coming down the Ohio by large than has been handled for months. The supply of supplies on the mines has decreased. Coal on the water is estimated to amount to more than the large number of loads going into all the surrounding coal fields and will result to movement to the gateway.

CINCINNATI

More retail buyers are on the market than usual. They are pre-occupied with the early demand for large for shipments, which are being called for. In mid-week, four railroads were making calls for transportation. Other railroads have been on the water, the number has increased. Lines have been on the water and one railroad has been on the water and has been on the water. The market is of the average.

There are three reasons which are making for volume on the Market. October prices are changing, and the shorter than will be handled. Others hope for the price reduction. It is the theory that the price will be $4.50 for prepared grades. Coal has been handled at the following price, $5.00.$50 for prepared grades, but little coal is on the market to be had.

LOW-VOLATILE FIELDS

New River and the Gulf

Although an agreement has been reached between the C. & O. and its striking shippers, not enough men are available to materially change conditions. Mines in the New River region are struggling along with a very slender supply, not averaging over 300 tons. Western prices are holding, but there is little equipment available for those shipments. With so much coal going to Tidewater, the price is softer there. There is a strong demand for prepared grades.

Pocahontas and Tug River

Although more coal is being produced in the Pocahontas field yet the output is not over 20,000 tons. The trouble is due to accomplishments of lands on the N. & W. Tidewater and other Eastern operators. There is a paralyzing effect on demand for prepared grades. Western shipments are partly suspended. Coal will supply not exceeding 30 per cent of capacity. The river mines are not prepared west of the 48th parallel. Under existing conditions it being to be expected that matters will get coal through to Western markets. There is a strong demand, however, for all grades. Most companies are making themselves to the production of mine run, which ranges $4.50-$5.50 a ton.

Coke

CONNELSVILLE

Complaint of car shortages is louder and more widespread. Apparently the places are fully as large as formerly, probably somewhat smaller, but with greater working forces the operators find the restrictive influence more keenly. The supplies are also very irregular, causing irregular drawing of ovens.

There are still thousands of "strikers" in the region but the strike as a general industrial factor was eliminated some time ago, the region's production being entirely a matter of car supply. Many plants are still closed on account of strike, but if these plants were to attempt resuming that would not increase the total car supply of the region.

The market is stiffer, with prices on the whole a shade higher. Demand of retail dealers for furnace coke is widespread and mounts up to quite a tonnage. Small lots are taken, such as would hardly interest a blast furnace, but in the aggregate this competition is a matter of making it still more difficult for any furnace to pick up enough coke to base an operation upon. Foundry coke is in somewhat wider demand, with refinements quite limited. The market is quotable at $11.50@$12.50 for furnace coke and $13.50@$14.50 for foundry.

The Courier reports production during the week ended Sept. 23 at 80,950 tons by the furnace ovens, and 24,900 by the merchant ovens, making a total of 105,340 tons, an increase of 5,550 tons.

UNIONTOWN

Inability of railroads to provide cars is now the only factor curtailing production. The H. C. Frick Coke Co., largest employer of labor in the region, has increased production to 80 per cent of capacity and could further add to the output were more cars made available.

Strange as it may seem with the known coal shortage the market softened last week and operators and brokers are not finding it too easy to obtain quotations. The situation is declared especially soft on so-called "line shipments" and operators report that the Great Lakes, destination of much tonnage in the last few weeks, is jammed and cancellations are in order. Most sales were closed this week upon a basis of $3.75@$4.

Deficiencies are occurring daily in the ranks of the strikers but the drift back to the mines is yet lacking substantial proportions. Operators announce that practically all strikers have been evicted and that production is re-organized upon a permanent basis.

BUFFALO

The supply is very light and demand is only moderate. Jobbers quote 72-hr. Connelsville at $12.50@$13; 48-hr. furnace, $11.50@$12. Add to this $3.28 to cover freight.
News Items From Field and Trade

ALABAMA
Announcement has been made of the appointment of Joseph Youmans as general manager of the Warrior River Service of the Alabama Coal & Coke Co. Youmans will have complete jurisdiction of all operations of the company west of Decatur. Youmans will have complete jurisdiction of all operations of the company west of Decatur. He assumed his duties Oct. 1st, succeeding Henry T. Doolard, who resigned some time ago.

The Alabama Fuel & Iron Co. has provided electric safety lamps for its mine families, west of Decatur, St. Clair County, in order to minimize the danger of gas explosions at these operations.

COLORADO
The Rocky Mountain News reports that Capt. James J. Smith, its mining editor, and Harry F. Nash, general manager of the Colorado Fuel & Iron Co., have been appointed by Gov. Oliver H. Shoup and Mayor Dewey Co., officials of the state, to assemble at Denver to the meeting of the American Mining Congress to be held in Cleveland early in October.

The Turner mine, near Walsenburg, until recently under lease to the Turner Coal Co., has been taken over by the lessees, the Calumet Fuel Co., and will henceforth be operated under the name of Calumet mine, the Calumet company is a part of the Utah Fuel & Coke Co., and will operate the mine as a branch of the company.

I. T. Robinson has resigned his position with the Danson & White interests in Rount County, and has returned to Billings, Mont.

ILLINOIS
R. W. Arms, of the department of mining engineering of the University of Illinois, Urbana, will leave the university Nov. 1st and join the staff of Robert & Shaefer, contractors engineers. He will have charge of the design of the new year's crop of Southern Illinois, and Davenport, Iowa, is the president. Hugh Shuler, of Des Moines, and Jacob Schelb, of Rock City, Iowa, are the other stockholders.

Five men were killed and two injured Friday, Oct. 5th, when an explosion occurred in the Lake Creek mine of the Consolidated Coal & Coke Co. of Collierville, Ill., and Davenport, Iowa, is the president. Hugh Shuler, of Des Moines, and Jacob Schelb, of Rock City, Iowa, are the other stockholders.

NEW YORK
Bids were received by the board of purchase of the city of New York on Sept. 27th for 1.5 million tons of coal for the year 1922. The rebates for each ton of delivered coal are $0.03 for each ton above 6,000 pounds, and $0.05 for each ton below 6,000 pounds. The bids were received from fifteen concerns, and the rebates were not granted for coal delivered under the range of 0.03 to 0.05 per cent. per ton. The bids were delivered at the harbor between July 1st and September 1st.

NEW MEXICO
The miner's strike in the Gallup-American River coal field has been recently completely destroyed by fire. The company has not yet decided on future plans.

The Grenko Coal Co. has just installed the first low-volt shaft in the Gallup-American River coal field. The installation is successfully cutting in a 20-in. vein.

OHIO
The Atzinger Coal Co. has been chartered with a capital of $10,000. Incorporators are Robert Petz, John P. Prentes, and Charles T. Craig.

The Uhlig Coal Co., Niles, has been chartered with a capital of $10,000 to mine coal near Youngstown. The incorporators are Harry H. Armstrong, A. B. Schudy, R. W. Maugh, C. O. Arman, and E. H. Davis.

Pennsylvania
The Lehigh Valley Coal Co. has filed an appeal in the Pennsylvania Supreme Court against the tax levied against it under the mining tax act.

The company has also filed an appeal against the order of the Pennsylvania Supreme Court which held that the company was not entitled to the tax exemption for coal sold to individuals.

The company claims the valuation of $5,000,000 for the purpose of the sale of a considerable portion of the property to other companies.

WASHINGTON, D. C.
Donahue R. Cong of Pennsylvania has been appointed manager of the President's Club of the American Railway Association for the year 1922. The resignation of A. G. Dutriaux, who has been the manager for the past year, has been accepted.

The Dominion Fuel Corporation of Montana has been organized for the purpose of engaging in the coal business. The company has an authorized capital stock of $50,000, which will be organized by Frank E. Brown, Frank L. Brown, and Anna M. Trost.

Washington, D. C., Sept. 27th—The interest of the Dominion Fuel Corporation of Montana has been organized for the purpose of engaging in the coal business. The company has an authorized capital stock of $50,000, which will be organized by Frank E. Brown, Frank L. Brown, and Anna M. Trost.

The Railroads and Coal

Adequate coal for this winter in this country depends on the railroads. The deficiency in anthracite cannot be made up by calling on the mines for extraordinary production, for these mines have no surplus capacity and are short of mine labor. But soft coal can and must be substituted for hard coal. The soft coal that will be required for this purpose and to fill empty bins and stockpiles, supply the Northwest and meet current requirements may be had and still more if the railroads are able to supply the empty cars, haul them to market when loaded and return the empties.

The President, Secretary Hoover and Federal Fuel Distributor Spens have joined in saying that transportation is the key to the coal situation this winter. The shortage, whatever it may be, is due to the coal strike, for which the railroads were in no way responsible, and to the rail strike, for which the coal miner may have had a degree of responsibility. The fact remains that, whoever may be at fault for the present lack of coal, the limitation of transportation is the only bar to recovery of that lack.

What right has the public or the coal industry to ask that the railroads give coal preference, to set aside other and more profitable freight in favor of coal? If the question be turned only on the basis of a fair proportion of annual transportation, the coal industry is warranted in demanding unusual preference at this time. In the first nine months of this year the total loading of freight was some 2,000,000 cars in excess of the same period of last year. Grain and grain products, live stock, coke, forest products and ore all show small increases, and loadings of merchandise and miscellaneous freight were nearly three million cars in excess of last year. The only commodity shown by the figures of the American Railway Association to have declined is coal, which stands a million cars below 1921.

While portions of the coal industry were at a standoff with other industries at work. In the first nine months of 1920 and 1921 coal cars represented 20.3 and 21.7 per cent respectively of the total; this year but 15 per cent. The ratios for 1920 and 1921 may be taken to show the relative proportions of total business sustained by coal when things are in balance. When one-fifth of the cars of freight loaded contain coal, then industry is marching ahead, four abreast. Coal stumbled this year; it is not in step with the rest of the country. Business cannot proceed normally until coal catches up in the procession.

One way to make up the arrears is to let the railroad business proceed as usual, coal getting what transportation it can and coal-consuming industry bidding for the available supply, shutting down when it cannot pay the price—a disorderly and unnecessary method. Or the railroads can hold back the other marchers, giving to coal the preference that will bring its percentage of the whole from the present 15 to the needed and normal 20.

This is the sensible, orderly process—the one that President Harding has urged on the railway managers. If the carriers will conscientiously divert motive power and cars to the movement of coal they can raise the level of production to 12,000,000 tons per week of bituminous coal and possibly 2,000,000 tons of anthracite. Then, if the commercial interests will call off their buyers’ strike and take the extra tonnage into storage, the situation can be tranquilized.

Unsatisfied demand can be impounded for a time, but eventually the dam will break. The machinery of the Fuel Control Act will be found insufficient to handle the flood when the dam breaks. From now forward the responsibility is the railroads'.

Ohio Tries Price Fixing

Price fixing by law is a doubtful enterprise at best and full of possibilities for failure; but Ohio is attempting it. The ambition is laudable enough, but there is an insurmountable difficulty. The state can fix mine prices on Ohio coal but it cannot interfere if Ohio producers choose to sell all their coal outside the state, or in whatever available market pays best, leaving Ohio dealers to buy outside coal wherever they can at whatever prices prevail. The fixing of retail prices within the state would be no material protection of the public in a case such as this, for if they do not allow a fair margin above mine price plus freight and cost of handling, then the dealer simply withdraws, leaving the Ohio public without coal.

Naturally there are substantial and conscientious producers in Ohio who will consider it good business to look after the most urgent needs of their old reliable trade in Ohio, whatever the prices, but this will not be meeting the coal demands of Ohio. That state may suffer more by its own weapon of protection than it would have suffered had it not armed. Indiana made a fruitless effort of the same sort in 1920.

Encouraging Signs at Cleveland

No one need be surprised that immediately after concluding arrangements at Cleveland for negotiations for a new wage contract next year, the United Mine Workers let it be known that they would demand a continuation of the present scale for two years from next April, the six-hour day, and five-day week. To maintain their prestige it is essential for the officers of the union to convey to their constituents that their interests have not been forgotten, that there is something to look forward to next time.

The union that met the operators in Cleveland last week is the same that won the strike this summer; it has had no change of heart. The provisions in its constitution demanding the "full social value" of its labor and the six-hour day and five-day week have not been
How Shall the Public Be Protected?

IN THE current issue of the Atlantic Monthly, Director Smith of the Geological Survey, writing to the thinking consumer on "What Coal Means to Us," says: "It is society that gives value to coal and opportunity to the coal industry." At our invitation he expanded that thought in an article in Coal Age last week (Oct. 5, page 225), in which he charged that the coal operators have been blind in one particular—"They have failed to see their duty to the general public." In large measure this is the burden of thought of present-day critics of the coal industry.

The production and distribution of coal is still private enterprise. Management, whose voice is the expression of the industry, owes certain obvious duties to stockholders, to customers and to labor. If in the sale of its product the coal company charges only such price as will return a reasonable wage to labor and a reasonable profit to stockholder, then that company is most assuredly a desirable member of society. Transgression of any of these duties brings its own measure of censure. For the industry as a whole the part of the consumer is taken by the general public.

The majority of coal producers and distributors so conduct their business that they maintain the good will of their customers, if for no other reason than that this good will is their cheapest asset in business. Every stable coal company has its back log of steady, dependable trade, served year after year, leisurely guarded, protected and satisfied. In these individual relations of seller and buyer there is a minimum of violation of the terms of good citizenship. But the relations of the coal industry to the public in the sum of all relationships and to this whole there are many variations from the general rule. It is largely the advantage taken by the intermittent producer, and by the regular producer with his tenant trade, during disturbed market conditions that has given rise to the charge that the coal industry has failed in its duty to the general public. The many are called on to account for the transgressions of the few.

Price and supply are the two points of contact of the public with the coal industry. In the last 25 years there have been four marked peaks in the price curve, corresponding to shortages in supply, excluding, of course, the periods of war control of both. Two of these have attended protracted strikes of coal-mine labor in 1902 and 1922; one was an after-effect of a coal strike negotiated by a railroad strike, in 1920; and the other was the development of extraordinary demand when stocks were low in 1917. In the intervening periods the bituminous-coal industry has served the general public with ample coal at the lowest prices in the world. Three of these upheavals have been in the past 6 years, a part of the war turmoil that has, and is yet, shaking the world.

If the production and distribution of coal were public business the peaks of high prices and corresponding profits would be leveled off and the more frequent hollos of low prices and corresponding losses filled up, at public expense. Can it be that the duty of the coal industry to the general public is to wipe out its best profits and continue to absorb its major losses? That certainly is not in the public interest in the long run. It is plainly of far more advantage to the coal producer than to the coal consumer to maintain steady operation at moderate price and profit than to "vibrate between bankruptcy and high profits." What Mr. Smith and others charge as the duty of the coal industry to the general public is first of all of the duty of the coal men to their own industry.

We cannot but conclude that it is not the blindness of the coal operator but his impotence that prevents him from making his industry function in a more ideal manner. There is no such thing as majority rule in either the soft- or the hard-coal industry. The Sherman law, which regulates the coal industry, is more stringent than any proposed by modern reform legislators. It says that no two in the business shall get together in any way to regulate the trade, either for or against the interests of the public. There is no method, either direct or devious, by which the "good" operator or wholesaler can control the "bad." There have been occasions, not without notable results, when the organized voice of the coal industry has been raised to stop the rising price of coal.

Summed up, Director Smith's indictment of the coal industry rests on the assumption that coal is a public utility and that without being so declared by law it should function as such. We submit that it is too much to expect that some ten thousand individuals engaged in the private business of mining and distributing coal should march up to the counter every time the price of their product passes a certain profitable point, and voluntarily rebate to the public the increment of profit, large or small, as it may be, that is offered by circumstances not of their making. Considered as a whole the reputation of the industry in profit taking has not always been creditable, but if one will but examine individual records he will find that many—the majority as respects tonnage if not numbers—have a definite sense of responsibility toward that part of the general public with which they have contact—their customers—and that they have lived up to that responsibility even as Director Smith would have them do.

Coal operators are fast developing a national consciousness of their collective relationship to society; they are learning self-government. For four years they have been on the defensive against "an unfriendly press, a distrustful public, and the threat of socialistic legislation." We have no doubt that every honest-minded coal man will agree with Herbert Hoover in his New York address of Sept. 12, that "When these various rights [to strike, to lockout, to work or not to work, etc.] infringe upon the public right, then the dominant right is the public right." The points yet to be decided concern the methods by which the public right shall be protected without socializing a basic industry.
Calculation of Horsepower Required for Unbalanced Uncounterweighted Hoist in Shallow Shaft

Radius of Gyration and Radius of Drum and Their Relations—Average Moments—Frictional Resistance—Acceleration and Retardation Moments and Horsepowers—Horsepower Torque—Energy in Hoist and Check on Result

By F. L. Stone†

Schenectady, N. Y.

In this article will be elaborated the main calculations for the selection of the machinery for hoisting in a shallow shaft unbalanced and without counterweight. Under the classification of "shallow shaft" may be included all those which have hoists the total travel of which is 300 ft. or less. The hoist thus to be considered is what would ordinarily be termed a "supply" or "man-and-material" hoist.

The capacity of this machine will be based on its ability to raise rock, and, as stated, the assumption will be that it is to be operated unbalanced and without a counterweight. A later article will deal with the same hoist using a counterweight and when serving a double-compartment shaft with cages in balance. The following conditions are assumed:

<table>
<thead>
<tr>
<th>Total lift</th>
<th>210 ft.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Weight of cage</td>
<td>9,000 lb.</td>
</tr>
<tr>
<td>Weight of ore</td>
<td>2,100 lb.</td>
</tr>
<tr>
<td>Weight of rock</td>
<td>2,000 lb.</td>
</tr>

</tbody>
</table>

It might be well at this point to discuss some detail in the various ways in which the weight of a rotating mass may be manipulated. The radius of gyration is such a radius that if the entire weight as recorded by the scales could be located at its extremity this weight multiplied by the square of its velocity (2πn)^2 when rotating about its axis, and divided by 2g would represent the stored energy in foot pounds.

The formulas for determining the radius of gyration of bodies of most ordinary shapes may be found in almost any standard engineering handbook. For example, consider a plate wheel weighing 10,000 lb. and 8 ft. in diameter. The radius of gyration of such a wheel is

\[ r = \sqrt{\frac{I^2}{2}} = 0.707r \]

where \( r \) is the outside or extreme radius. In the example the radius of gyration would be \( 4 \times 0.707 = 2.828 \) ft. This means that a ring of no thickness could be made 5.656 ft. in diameter and weighing 10,000 lb. It would have the same stored energy when rotating as has the plate wheel.

The \( \text{tor} \) of such a wheel would be

\[ 10,000 \times 2.828^2 = 9,600 \text{ ft.-lb.} \]

†Other articles on hoist design by F. L. Stone may be found in Coal Age, Vol. 8, p. 216, and Vol. 9, p. 921.

†Power and mining engineering department, General Electric Co., Schenectady, N. Y.
The \( w^2 \) is of great value when considering rotating masses, for, having this quantity, the effective weight at any radius may be determined by dividing the \( w^2 \) by the square of the radius at which the effective weight is required. Thus, in the drum under consideration in the above problem, the effective weight is given as 17,000 lb. at the rope radius. The \( w^2 \) of this drum is 17,000 \( \times 3^2 \) or 153,000 ft.-lb.

This, incidentally includes the gear.

The radius of gyration of a cylindrical hoist drum, break tread and gear is about 20 per cent of the outside radius, and 80 per cent at 3 ft. 2.4, therefore the actual weight of the drum and its attached parts as registered by the scale would be about:

\[
\frac{153,000}{2.4} = 63,750 \text{ lb.}
\]

As an indication of the accuracy of the above calculation, it is noted that the drum and parts are turning at 160 r.p.m. or 1,666 r.p.s. The stored energy then will be:

\[
\frac{w^2}{2} = \frac{1,666^2}{2} = 13,260 \text{ ft}-\text{lb.}
\]

\[
\frac{17,000 \times 3^2 \times \frac{1,666^2}{2}}{32.1 \times 2} = 17,000 \times 31.4 \times \frac{1,666^2}{2} = 290,500 \text{ ft.-lb.}
\]

Using the actual weight and the radius of gyration above found:

\[
290,500 \times \frac{1,666^2}{2} = 260,500 \text{ ft.-lb.}
\]

The above is, of course, elementary and intended only for refresh the memories of those who have not used these fundamental formulas for years. It shows, however, that the \( w^2 \) the effective weight can be found for any radius within knowing the actual radius of gyration.

To proceed with the calculation:

The time required for one round trip = 16 sec.

Half, top and bottom = 7 sec. + 7 sec. = 14 sec.

Total running time up and down = 50 sec. - 14 sec. = 36 sec.

Running time one way = 36 sec. / 2 = 18 sec.

Assume 6 sec. acceleration and 6 sec. retardation.

\[
\frac{t}{2} + \frac{t}{6} = 13.26 \text{ revolutions per second or } v \text{ at full speed}.
\]

\[
D - \frac{v^2}{2} + \frac{v^2}{2} = \text{ space passed over during retardation.}
\]

\[
T = t_a + t_r = \text{ time of full-speed running.}
\]

\[
D - \frac{v^2}{2} = \text{ space passed over during acceleration.}
\]

\[
\frac{v}{2} - \frac{v}{2} = \frac{T - (t_a + t_r)}{2} = \frac{v}{2} = \frac{D}{t_a + t_r} = \frac{t_a + t_r}{2} = \frac{t}{2}
\]

In the present case as \( D = 13.26 \) turns

\[
\frac{13.26}{6} = 2.2 = 0.78 \text{ r.p.s.}
\]

The number of turns passed over during retardation

\[
\frac{v}{2} = \frac{2.2}{2} = 2.34.
\]

Similarly the turns passed over during acceleration

\[
\frac{0.78 \times 6}{2} = 2.34.
\]

The moments will be determined as follows:

<table>
<thead>

</table>

The value to be assigned to friction will have to be estimated, as there are no reliable test data available to the knowledge. Experience has shown that 50 per cent of the average net moment (for single gear reduction) is sufficient. In the case of an unbalanced hoist this efficiency probably is a little low but safe.

57,900 + 59,400 = 59,900 = average moment

57,900 + 0.8 = 73,300 = average moment including friction. Deducting the average moment, which is 57,900, leaves the friction, which is therefore 14,650. Net moments including friction then become:
October 12, 1922

Acceleration and retardation are calculated as follows:

Velocity in feet per second of moving parts at end of acceleration = 0.78 × 6 × π = 14.68 ft. per sec.

Force = mass × acceleration

Acceleration (a) = \( \frac{v}{\text{Time}} \);
Mass = \( \frac{w}{g} \);
\( a = 14.68 \)

2,446 ft. per sec. per sec.

As the drum is cylindrical and its weight is given as the effective weight at the rope center, all the moving parts may be considered as a whole and the acceleration force calculated at one operation.

Cage. Car. Rock. 9,000 lb. 2,300 lb. 8,000 lb.
Rope (250 ft. in shaft and 200 ft. between the cage and the drum when the cage is at the top of the shaft) 9,600 lb.
Total 20,200 lb.
Drum Head sheaves. 17,000 lb.
Heel sheaves. 7,000 lb.
Total 44,200 lb.

Accelerating force = \( \frac{44,200}{32.2} \times 2.446 = 3,360 \) lb.

As this force is applied at the drum surface, the moment will be

\( 3,360 \times 3 = 10,080 \) ft.-lb.

Retardation is to be accomplished in the same length of time and, as the v of all parts is the same, the retardation force and moment will be the same as that of acceleration, except that, as energy is being given up, the value will have a minus sign.

* From plotted curve.

Having determined the moments and plotted their values it is necessary only to change the moments to horsepower and plot against time.

The horsepower may be determined by substituting in the equation

\[ HP = \frac{2\pi \times \text{r.p.s.} \times M}{550} \]

This formula is derived as follows:

\[ HP = \frac{\text{Force} \times \text{velocity in feet per sec.}}{550} = \frac{\text{Force} \times 2\pi \times \text{r.p.s.}}{550} \]

\[ \text{Force} \times \pi \times 2\pi \times \text{r.p.s.} \]

\[ M \times 2\pi \times \text{r.p.s.} \]

\[ \frac{550}{550} \]

\[ \frac{550}{550} \]

† These values are not actual horsepower, as the speed is 0 at these points, but they indicate values proportional to the torque. This value is, therefore, called horsepower torque. In other words, the motor must develop such a torque that if it were running at full speed it would produce this horsepower.

HORSEPOWER-TIME CURVE OF DUTY CYCLE.
HOIST NOT BALANCED

The horsepower used and the horsepower demanded are different quantities, for at the start the horsepower used is zero, but the hoist must be designed with that point in mind, for the horsepower torque at that point is at a maximum.

Having plotted the curves of moments and horsepowers it might be well to consider what they mean. The moment curves are self-explanatory and mean that at each turn of the drum an indicated torque must be applied to the shaft. The horsepower curves, however, mean a little more when analyzed. As a help in discussing the duty cycle the following definition of terms used may be in order.

Force is pressure, pull or resistance to motion in the line of motion and its unit is the pound. Velocity is the rate of motion and its unit is one foot per second. Work is the product of force in pounds, resisting motion, multiplied by the distance traveled in feet, the unit being the foot-pound. Energy is the ability to do work. It may be potential, that is, the energy stored in a body due to its position, such as a weight carried to an elevation; or it may be kinetic, or that due to the motion of the body. The unit is foot-pounds as in the case of work. The formula for the stored energy in a moving body is \( \frac{mv^2}{2} = \frac{mv^2}{2} \). Power is the rate at which work is done. The most common unit is the horsepower, which is equal to 550 ft.-lb. per second. Thus, if 10,000 ft.-lb. of work is to be done in, say, 5 seconds at a constant rate, this rate will be 2,000 ft.-lb. per second or 2,000 \( \times \frac{1}{2} = 3.64 \) hp. If the same work is done in 2 seconds it will have to be done at the rate of 5,000 ft.-lb. per second or 5,000 \( \times \frac{1}{2} = 9.1 \) hp.

In the problem just solved we have made a duty cycle, plotting horsepower against time.

In lifting the cage, car, rock and rope, we have expended much energy; that is we have raised a weight.
Eight-Ton Cars Will Be Built for Mines

For many years past, the railroads of the United States have continually increased the size of their rolling stock. They have built larger and larger locomotives and cars. Back in 1870, only about fifty years ago, coal was not infrequently shipped in small four-wheeled cars, each holding about five tons. Today steel hoppers of 140,000 lb. capacity are not uncommon. This increase has been made necessary by the larger and ever larger tonnage that must be carried over one set of rails.

To a lesser extent the same tendency is manifest in the mines. The output of individual operations has been continually increased. Almost every mine is now producing more coal than in the past. To meet this increased output, mine locomotives of various types have been designed, each succeeding model being capable of pulling a greater number of cars at a higher speed than its predecessors, thus adding capacity to the haulage roads already existing. Mine cars likewise have increased in size. With a larger car it is unnecessary for the mining company to furnish each man with as many wagers as were formerly required, thus reducing the number to be gathered and hauled in any one mine in order to maintain a given capacity and reducing the number of times during any one day when the miner must wait for cars.

SIZE OF EQUIPMENT DEPENDENT ON CONDITIONS

Certain considerations, however, limit the size of equipment that can be used in any particular mine. With railroad equipment the size is not so definitely fixed, but in mining, as most of the haulage roads are underground, and as many of them were laid out years ago, when the equipment was small, the limitations to the size of cars are sometimes unavoidable.

Many, if not most, mine roads have been driven within the coal bed itself, the height of the bed thus dictating the height of the car. It is, of course, not possible to use a car that is the full height of the bed unless the bottom is to be lifted or the top braced. Consequently a car must be so designed that room for the miner to load it with ease is readily available. It is well to make this space between the top of the car and the roof as large as is conveniently possible.

In addition to the height of the car, its length and width also are limited. The length and wheelbase are fixed by the degree of curvature of the tracks that must be traversed. The width is limited by the width of the heading and the requirements of the state mining laws. As a result, any device or arrangement of car that will permit a greater carrying capacity in a given size of coal bed is of more than passing interest to the whole mining profession.

The Chicago, Wilmington & Franklin Coal Co., of Illinois, recently desired to use, in one of its mines, larger mine cars than any hitherto designed. It accordingly requested Allen & Garcia, of Chicago, to prepare plans for a new mine car that would have a capacity of 8 tons of coal, and about 10 to 12 tons of rock. The great weight of the material to be carried necessitated a specially designed truck. This truck, furthermore, must be provided with springs in order to reduce the shock on the axle as the car passes over inequalities in the roadbed. The introduction of such
springs, however, must not increase the height of the car when it is loaded. To meet the conditions imposed, J. R. Fleming & Sons Co., Inc., of Scranton, Pa., have designed a special truck.

This is being tested out at the coal company's mine. It is designed to carry a load on each axle of 4 tons in addition to the weight of the car itself. The axles are 3 in. in diameter and the journals are 3x7-in. Hyatt roller bearings. The spring pedestal is so arranged as not to increase the height of the car. Two springs are employed at each journal box, one on either side of the axle. When the car contains its maximum load, the springs will be so compressed that the load will just miss the stop on the top of the bearing.

**AXLES ARE MADE OF HEAT-TREATED STEEL**

Wheels of 14 to 16 in. in diameter are employed. It being advantageous to use as small an axle as possible on these cars, the diameter of the axle has been made only 3 in. The steel is of 30 to 40 points of carbon, heat-treated to a hardness of 240 to 250 Brinell. Heat treating in this manner raises the tensile strength to from 135,000 to 140,000 lb. per square inch.

Aside from the special arrangement of the truck and bearings, these journals are similar to the regular Fleming-Hyatt self-aligning roller-bearing journal boxes. Use of these bearings eliminates all bending and cutting of the axle.

With the use of springs the load can be handled with greater ease. Shocks to a certain extent will be removed from the drawbars or drawheads, and these will not be pulled out as frequently as sometimes happens around the mines or on railroad equipment. The roadbed also will be relieved of shock, and a decrease in low joints and bent rails should result. The springs in like manner relieve the axle and wheels from shock, and, consequently, there should be fewer bent axles and broken wheels.

These advantages will permit higher hauling speeds, while the cars will take curves easier and derailments will be fewer. This should reduce appreciably the frequency of wrecks on the haulage road, thus saving much valuable time as well as permitting a freer movement of traffic. Higher speed, larger car capacity, and a decreased liability to wrecking will mean greater mine output with less rolling stock.

Much interest attaches to the actual use of spring journal boxes of this kind in the mines. If they are successful, it is probable that similar equipment will be employed in the future, and much of the present rolling stock may be subject to overhauling. In installing such equipment the mines are merely taking a step that the railroads found it advisable to take many years ago.

**France Makes Much Use of Compressed-Air Locomotives in Coal Mines**

BY FRANCIS P. MANN

Paris, France

FRENCH regulations forbid the use of electric or gasoline locomotives in all mines or underground work where firedamp would cause explosions, so that compressed-air locomotives have been much used in France. For other reasons also they are often preferred for certain classes of work. For instance the Paris subway, which is always under extension, is now making use of an up-to-date locomotive of the Renault type. The latter has been designed in general for all classes of tunnel or mining work, and runs upon a 24-in. track. It is made in three principal parts, vehicle frame, air tanks and back cab, and these can be dismounted so as to be let down separately into a mine. The engine is of a new type which is claimed to be quite an improvement over those which have preceded it.

A high-pressure cylinder is disposed on one side of the vehicle and a low-pressure cylinder on the other side, the wheels being driven as shown in the illustration. Above the cylinder is the slide valve, which in
How to Make Portable Electric Cable Last

By H. M. McEORLAND

Vol. 22, No. 15

COAL AGE

THE replacement of broken and worn-out low voltage and portable electric cables can be greatly aided by attention to five vital factors, which are as follows:

(1) Use of conductors of proper size.
(2) Proper working voltage; all proper uses of operating reels of current size for the speading of cables.
(3) Proper stranding of the copper conductor.
(4) Care in the handling of cables.

Let us consider first why it is important that all conductors should be of proper size. Practically all underground cables have Para rubber of varying percentages of vulcanizing next to the copper. This rubber starts to deteriorate when the vulcanizing temperature is reached. For this reason the temperature of the proper melt be kept at less than 220 deg. F. This cannot be done unless the conductor is of the proper size.

From actual tests made by the manufacturers of all rubber cables having a high percentage of Para rubber the operating temperature of such cables is less by about 25 per cent than the same size of braided cable carrying the same current. This is because of the greater heat conductivity of the high-grade rubber. Table 1 shows the size of conductors recommended for various mine locomotives and mining machines operating at both 200 and 550 volts direct current. The recommendations are based on the maximum allowable copper temperatures.

**TABLE 1.—SIZE OF CABLE FOR LOCOMOTIVES AND CABLE CUTTERS**

</table>

The difference in cost between any two sizes of cables is only 8 to 12 per cent and the larger size of cable has 25 per cent more copper than the smaller size and will last it from 30 to 50 per cent, so that an actual saving in dollars and cents is made by using the proper size. This is particularly true on the all-rubber cable, as the rubber is hard to cut while cool, but cuts more readily when the temperature rises.

As to the proper working voltage, attention may be called to the fact that the work done by any direct-current electric motor is the product of volts and amperes. When the voltage goes down the amperage goes up—not in exactly the same ratio but depending on the way in which the motors on the various kinds of equipment are wound. This tendency to draw increased current from the line at low voltage is greater on series-wound motors, as the entire current is carried around the field of the motor. Practically all mine locomotives have motors of this kind and over 50 per cent of the winding on the compound-wound motors of the mining machines in general is in series. Therefore the cables may be expected to heat up when, owing to low voltage, they have to carry an excess of current.

Now as to the size and method of operating reels for spreading cable, the larger the diameter of the reel, the less the copper conductor is bent and the less likelihood there is, therefore, of breaking the component wires. Of course, there is a practical limit to the size of reel to be used, but the manufacturers could greatly improve their reels in this respect.

The method of operating the reel is even more important than its size, for a mine locomotive while gathering frequently reels and unreels its cable one hundred times per day. When doing such work it is easy for the cable to get foul of any of the many obstructions in the mine. If there is no protective device on the reel to slip and protect the cable from excessive tension when it thus becomes entangled, the copper wires are likely to be stretched and reduced in diameter, thereby decreasing their conductivity, if not actually breaking some of them. Soft-drawn copper will stretch about one-quarter of its length before it will part.

As to the correct stranding of copper conductors, nearly all manufacturers regard the three-strand cable as standard. Now the number of wires in each strand should be sufficient to give the cable enough flexibility for the service intended. As locomotives reel and unreeil their cable three to four times as often as mining machines the cable used on mine locomotives must necessarily be much more flexible if it is to have long life. The standard practice now with reliable manufacturers is to put at least 19 wires to each strand for locomotive cables, giving a 7x19 cable or 133 wires all told, and on the mining machines a 7x7 or 49-wire cable is found to give good results. A 49-wire cable will not have as long a life on a locomotive as would a 133-wire cable, yet the difference in cost is only 5 per cent.

**LIFE OF CABLE Depends on CAREFUL HANDLING**

Another important factor in the life of cable is the manner in which it is handled. This is a problem for each individual operator and in the main depends on the experience of the motorman or machine runner who handles the cable. Green men invariably abuse the equipment they handle, but with proper supervision they can be made to take care of their cables; some really remarkable records in fact have come to my notice.

For your information and also a mark to shoot at I will give you herewith a record of an all-rubber-covered cable in use at No. 2 mine of the Clinchfield Coal Corporation at Dante, Va. Mr. Booker, chief electrician of this company advises that he put a No. 3 all-rubber cable on a 5-ton locomotive Sept. 8, 1921. This locomotive gathered coal in the daytime and handled a mining machine at night. The current for this machine was fed through the same locomotive cable, giving a day-and-night service.

Up to Sept. 15, or in a little over one year, this locomotive has hauled 42,500 tons of coal and the machine has cut 47,000 tons of coal, giving a total hauled and cut of 89,500 tons of coal. The first cost of the cable was $70 and 7 splices in that time will add $3.50, or a total cable cost of $73.50.

Dividing this sum by 89,300 tons gives a cost per ton of $0.0008 or $ of one mill. This is about 1 of 3 mills, which was the cost per ton of braided cables given by C. E. Rogers in the excellent paper of his committee on gathering locomotives.

*Part of a discussion at a meeting of the Committee on "Standard Codes for Portable Electric Locomotive Cables," presented at the West Virginia Conference on Electrical Engineering. This report was used as the basis of a report of the Committee on Cable Age.

**"Wire & Cable Co.**
Rubber-Covered Vs. Braided Cable for Mine Work

Beware of Short Cotton Fiber in Braid—Kink Test—Though Rubber Covered Cable Lasts 75 to 100 Per Cent Longer, Mines Getting Ten Months’ Service Out of Braided Cable Should Not Abandon It

ONLY such cables will be considered in this article as are used for connecting conductor-cable-reel gathering locomotives, coal-cutting machines, loading machines, portable lamp cords and other mining equipment to trolley wires. Until recently rubber-covered cotton-braided cable was in general use. Approximately two years ago all-rubber-insulated cable made its appearance, and for mining service it quite largely has replaced cotton-braided cable.

For a long time the question as to the kind of cable to be employed usually was left to the discretion of the salesman. The order called merely for No. 3 or No. 4 locomotive or mining-machine cable, as the case might be, and the conductor thus loosely specified often gave unsatisfactory service. In some cases the cable lasted only two or three months and sometimes an even shorter period, whereas the average life should be from six to eight months.

All cables of the braided type have a rubber insulation and a woven covering of cotton, either single, double or triple braided. This braiding is saturated with an insulating compound, the purpose of which is to keep water out of the cotton, thus preventing the fiber from loosening or rotting. It also gives to the cable a certain degree of slickness which helps it to resist abrasion. The chairman of this committee has made extensive tests on different forms of this type of cable and has found that some manufacturers use an inferior grade of cotton in their braid. The fibers are short and hard, and the life of cable of this kind is, of course, not as long as it should be.

BEWARE OF CABLE COMPOUNDS THAT PEEL OFF

The braid in some cable is not fully saturated with compound. Other cables show a beautiful glossy surface, giving the appearance of having plenty of impregnating materials, but the compound will chip off when the cable is bent. Consequently the braid becomes bare and presents a dull and ragged appearance. When this type of cable is used on gathering motors or mining machines the cotton braiding soon breaks and unravels and much tape is necessary to keep the conductor in service until at last so many splices have been used that renewal becomes necessary.

The chairman of this committee has had manufacturers submit samples of different makes of cables to which he has applied various tests in order to ascertain the strength of the cotton braid and rubber insulation. Among others he has used a “kink” test, in which the cable is bent into a short loop and then pulled out straight again.

None of the cables with ordinary woven braid would resist this test, as the insulation would tear under the stress. Most of the cables where the covering of cord construction would come through the test in good condition. Some of the manufacturers are insulating their cables with heavier rubber than is found on ordinary braided cable, and when they do so the cable gives better service than any of the other cotton-covered cables.

In making a choice between all-rubber-covered cable and braided cable, attention should be paid to the fact that all-rubber-covered cable costs from 75 to 150 per cent more than cotton-braided cables with the braiding of either weave or cord construction. Therefore, a cable with all-rubber insulation should have at least twice the life of ordinary braided cable.

For any mine which is getting from 8 to 10 months of service out of ordinary cotton-covered cables a change to all-rubber-covered cable is not advisable. The life of a cable as used on gathering reels on mine locomotives or loading machines, etc., usually ends when an excessive number of splices has been made, and it has been observed that a cable which with very careful handling would have only three splices after 8 months in service, would require, after that time with the same careful handling, to be spliced not less than once a week. After 10 months’ service it would need splicing so frequently that to avoid loss of time it would be advisable to install new cable.

NUMBER OF REELINGS DETERMINES LIFE

It is apparent, therefore, that the life of the insulation and of the copper itself is limited by the number of times the cable has been reeled, especially if it is subjected to long hauls and is bent around sharp corners. Another factor which enters into the life of the cable is the voltage which is maintained at the entries on which the equipment is working. If the voltage is not kept within a reasonable range of the normal rating of the machine the cables are subjected to heavy currents and consequently to heating. This is likely to make the copper brittle. Furthermore, if the cable gets too hot so that the insulation warms up, the rubber separates from the copper strands, and on braided cable the insulating compound also melts out.

The life of cables subject to such treatment is very short, but under such conditions life proportionate to value cannot be obtained from either type of cable. Another factor entering into the life of such conductors, especially on gathering locomotives, is the type of reel in use. At this point I would call the attention of manufacturers of gathering locomotives to the fact that...
while they have made wonderful progress in the development of the new type of gathering locomotives, the development of the real task has not kept step, and the cable reel is a subject which should have further consideration from the West Virginia-Kentucky Association of Mine, Mechanical and Electrical Engineers.

On some locomotives the spooling device will not accommodate No. 2 cables even when properly spooled, and in consequence toward the end of the spooling the cable is wedged and pressed on the reel. This injures the insulation and the stranding of the cables just as it injures the strands of a hemp rope when it is not wound properly or evenly.

The manner in which the cable is handled by the miners when gathering has much to do with the length of its life, as the man often gets too much slack and then runs over the cable and sear or whip it. This is done when the men are either not familiar with the type of reel to use or are not taught as to the proper operation of the reels. It also occurs on some types of reels if the clutch has not been set at the proper interval.

The mains look in the type of all-rubber-covered cable now in general use is that the insulation stands up well. After the cable has been run over or kinked severely the copper strands will part when subjected to strain, yet the rubber insulation will show almost no signs of injury. To find such a place in a 500-ft. cable will consume from one to three hours of a man’s time. If he found it in less time he would be fortunate enough.

When such gathering locomotives is required to haul a certain weight of coal every day, the minerman cannot reach this quota if he is obliged by an inefficient search for hazards in his cable. The man at the Stowega plant for this reason took such a dislike to all-rubber-covered cable that at one time a brand new one was found all dropped to pieces. For this reason the claim that all-rubber-covered cable resists frequent and expensive interruptions cannot be substantiated. It will seldom take a man more than 30 minutes to find and repair a break in braided cable. For this reason the Stowega Coal & Coke Co. has hesitated to accept all-rubber-covered cable as standard in its various operations. Another reason for not standardizing on this cable is that the Stowega Coal & Coke Co. is getting an average life of 6 to 9 months out of all-rubber-covered cables.

At the last convention and industrial mining exposition the chairman of this committee told some of the representatives of the cable manufacturers that cable of No. 3 conductivity and cord was wanted with the cable strength of No. 2, and cords of No. 4 conductivity and cord was wanted with the tensile strength of No. 3. To obtain these I recommended the use of a steel or similar reinforcement of high tensile strength.

Some of the manufacturers of all-rubber-covered cable are following this suggestion and have brought out during the last two months different types of reinforced locomotive cable. At the present time a cable of this type has been in service approximately two months and the results obtained are quite satisfactory. The Stowega Coal & Coke Co. will receive in the near future cables of various kinds all thus reinforced and will continue its experiments on this type of cable.

For extension cords around mines and mine shops all-rubber-covered cable should be used. The wire should be of not less than No. 14 gage, for the majority of electricians break or injure the fine strands when skinning the wires and thus reduce the carrying capacity of the cable and its ability to withstand the pulls and strains to which extension cords are subjected.

The committee would suggest to the manufacturers rubber-insulated cable from No. 4 to No. 1 gage should have 133 wires. For ordinary braided cable up to No. 3 size the limit should be set at 49 wires, as the danger of puncturing the rubber insulation with the finer sizes of stranding would be too great. For the larger sizes No. 2 and No. 1, 133-wire cable is necessary to insure flexibility. On the cables where the brailing is of cord, the strands for No. 3 can contain either 133 or 49 wires. Not more than 49 wires should be used, however, in No. 4 cable.

The committee would suggest to the manufacturers of all-rubber-covered cable that they reduce the cost of their cables so that they will come closer in line with the cotton-braided cables, as it believes that in many cases the additional service obtained from the all-rubber-covered cable over the braided cable does not warrant the 80 to 150 per cent high cost.

It believes that all-rubber-covered cable is a step forward to a better insulated and more serviceable cable and would like to see wires and cables of this and similar construction manufactured for installation work, as it believes that it will give excellent service in conduit, where the cable is subjected to much vibration, as in tipples and breakers. It also thinks that fire hazards will be greatly reduced by the use of this type of cable, as rubber is not as easily ignited as a cotton weave saturated with compound which is at present used to insulate wires and cables for installation work.

Though this paper does not mention the multiple-conductor mining-machine cables, attention is called to the fact that all that has been said in regard to the insulating and wearing properties of the cable as used...
by gathering locomotives applies also to this cable. There remains the question whether to use concentric or twin cables, but the opinion of all who use cable for this purpose is so greatly divided that no conclusive arguments can be brought forward to decide the question, because, after all has been said, each one uses the type of cable, concentric or twin, that meets his own peculiar conditions best.

Engineers Detail Experience with Machine Cable, Resistors and Insulating Oils*

As at the third session of the West Virginia-Kentucky Association of Mine, Mechanical and Electrical Engineers, on Thursday, Sept. 21, F. M. Reigher, of the American Coal Co. of Alleghany County, Bluefield, W. Va., made the report for the committee on cables. Mr. Reigher proved a firm advocate of braid-covered cables, not so much on the ground that they were better than rubber-covered cables, which he did not claim, but because the latter were more expensive and would have to be cheaper to receive his indorsement. He asserted that the wires inside a rubber-covered cable were likely to break, and when they did it was sometimes extremely difficult to ascertain just where the defect occurred.

Reuben Lee, of the Elkorn Piney Coal Mining Co., Stanaford, W. Va., said that cars could be run over rubber-covered cable without any trouble of the kind described. He himself would use nothing else. His company had used that type of cable for seven or eight years. N. A. Johnson, of the Buffalo-Eagle Coal Co., Braeholm, W. Va., declared that he had no trouble with concealed broken wires. At his mine he had never been able to get, like Mr. Reigher, seven or eight months of service out of braid-covered cable. He preferred an all-rubber coating. He found difficulty in holding enough cable of adequate size on certain types of reels.

C. E. Rogers was afraid that the rubber of rubber-covered cable would deteriorate before he would get sufficient life out of it to justify its greater expense. He found that foremen and superintendents were quite willing to pay the greater cost if thereby they could get better service out of the cable, certainty in operation being in their belief more important than ultimate length of life. Mr. Johnson said that the saving in splicing reduced delay and justified the higher cost.

Deterioration Vs. Wear Factor in Cable Life

Mr. Reigher stated that in estimating the life of a cable consideration should be given not merely to days of life but to the number of reelings and unreeelings during that period. Some men reeled out the cable twice as many times a day as other men, thus inevitably shortening the life by increasing the daily service. A. Fred Phelps, of the Post Glover Electric Co., said that rubber-covered cable would last two or three times as long as cable covered with braid, but nevertheless it might not last ten months where the conditions of service were peculiarly trying.

Mr. Reigher urged that 133-wire cable was made up of excessively small wires and said that such wires punctured the covering. He believed that rubber-covered cables with steel reinforcement in the rubber could be guaranteed for twelve months. He could not see that rubber-covered cable could be expected to last long enough to make the investment profitable. Mr. Phelps said that no guarantee of the life of a cable should ever be given because a "short" might at any time overhear the wires and insulation. Furthermore at some places cables would last eighteen months and at others not more than thirty days.

H. M. McFarland, of the Simplex Wire & Cable Co., said that much depended on how the strands were disposed. He found seven and nineteen strands better than thirteen and seven. Mr. Reigher remarked that he was opposed to the use of such fine stranded for a No. 4 cable, whatever might be used in those that were larger. Mr. Phelps amplified his previous statement by saying that the compensation rules in Pennsylvania made favorable insurance provisions wherever fuses were provided in the cable. One objected, however, that fuses were useless, as machine men would take ample care that the fuse was provided with a conductor that would not fuse at any lower current than that which would melt the wire in the cable. For this reason fuses would be little or no protection.

Cable Larger Than No. 4 to Have 133 Wires

E. S. Simkins, of the Standard Underground Cable Co., declared that the whole matter had been discussed at a hearing held by the Bureau of Mines and it had been decided that 133-wire cable should be used for the larger cables but that No. 4 and smaller should have only 49 wires.

Mr. Lee said that the grades at Stanaford were so heavy that the cables heated and the rubber came off on the braid-covered cable. Someone remarked that the insulation in braid cable varied greatly and some specification should be made as to the amount of rubber used. Mr. Simkins said that every kind of insulation was used by unscrupulous manufacturers. Some of it, he jokingly asserted, was a mixture of Jersey mud and molasses.

He said that when reeled in three layers cables had only about one-half their unreeled capacity. The mine locomotive builders admitted that their reels were too small for an adequate size and length of cable, but with that admission they rested. They had done nothing to increase the size of their reels.

Roscoe Woltz, for the committee on the use on mine locomotives of resistance grids made of rolled steel plate as compared with cast grids, made a report on that subject, as published in the issue of Coal Age of Sept. 11. Mr. Reigher declared himself a believer in the steel grid. Nevertheless he said he had cast grids in use that had lasted six years.

Mr. Phelps said that the steel grids would occupy no more space than cast grids and that standard grids
R. R. Webster, chairman of the committee on the Proper Handling and Care of Insulating Oils, read the report on that subject. This report appeared in Coal Age in the issue of Sept. 28. The chairman said that the subject was one of considerable importance, as many transformers had been in use now for quite a few years and the oil had not been changed or filtered. He also read the following statement:

"The following are tests on the oil of three General Electric 65-kva. 2,300 206-volt single-phase transformers, used inside a mine substation to supply a synchronous converter. The two tests are about two years apart, the oil not being filtered or renewed in the meantime. The day load on these transformers has been averaging approximately 60 per cent of full load. However, the short-time peak loads often exceed 175 per cent of full load. A temperature test taken during the summer, when these transformers were reported to be running warm, showed the oil to be 114 deg. F. Note that the decrease in the dielectric strength of the oil during the two years is considerable:

Mr. Crenshaw wanted to know how the "sweating" properties of a steel transformer differed from those of one made of cast iron. He was told that a transformer case if properly prepared by drying for the reception of the oil would not permit of an accumulation of sweat, providing the oil itself was free from moisture.

It being learned that the Coal and Industrial Exposition would not be held in Huntington next year, the association concluded not to set any place for the next meeting until it was ascertained where the exposition would be held.

THE U.S. BUREAU OF MINES does not make life tests of batteries used on electric lamps, but the performance of the batteries is studied during a short period while the lamp bulbs are being tested for life and uniformity. Also, field inspections are made by the bureau's electrical engineers, and reports are obtained from both users and lamp manufacturers. As a result of this general information the bureau believes that lead cells will give 300 shifts of 12 hours each, and alkaline cells 600 such shifts, without failure.\n
Ventilation of Mines with Flexible Conduits

Brattice Cloth, Sollars, Windboxes, Metal and Flexible Pipe as Means of Ventilating Blind Entries—Method of Suspending and Coupling Pipe and Erecting Ventilating Machinery

EVERY coal mine requires some sort of ventilation. As a rule the circulation of air through the various headings and rooms of ordinary workings is not difficult, as every mine is, or should be, laid out with this end in view. When it becomes necessary, however, to ventilate long stretches of single heading or various other dead-end operations a more serious problem is introduced.

Common means of carrying air to dead-end faces include the brattice, the sollar, the windbox, and various kinds of pipe, either rigid or flexible. The brattice is well known to all coal miners. It consists of a partition built up of boards or canvas, or both, extending through-out the length of the place to be ventilated, dividing it longitudinally into two sections or compartments. In one of these the air travels inward and in the other outward.

A large volume of air may be handled by the brattice. It is nevertheless subject to many shortcomings. In the first place it is always liable to more or less leakage. The brattice itself as well as the joints at floor and roof seldom can be made tight. If carried to a point near the face it is subject to injury from shooting. This is particularly true if the passage to be ventilated is in rock which must be blasted from the solid, this of course necessitating heavy loading. It also reduces the width of the roadway unless the place driven is specially widened for that purpose.

DIVIDING THE AIRWAY BY HORIZONTAL BRATTICE

Sollaring air to the face as a rule is more expensive and less satisfactory than bratticing. Whereas the brattice divides the heading or driven passage vertically the sollar divides it horizontally. Thus a bratticed heading contains two compartments side by side, while the sollarhed heading has two passages one above the other. The sollar has all the shortcomings of the brattice so far as leakage is concerned with the added disadvantage that it is applicable ordinarily only where timber framing such as post sets are used.

The windbox is a modification of the sollar. Here air is carried into a working by means of a wooden box laid, usually, on the floor at the side of the driven passage. Such a box, even though effective, is difficult to make airtight and requires much lumber, as a rule being made of tongued-and-grooved flooring. It also adds appreciably to the fire hazard and is not an efficient means of carrying air, as the frictional resistance is considerable.

Sheet-iron pipe often is used to convey air to the remote faces of headings and rooms. This may be either black or galvanized and usually ranges from 8 to 24 in. in diameter. Though fairly tight and losing much less air from leakage than any of the devices previously mentioned, it is somewhat difficult to handle, as it cannot be collapsed in any way. The maximum length that can be transported conveniently is about 10 ft., so that many joints have to be made in its erection. In addition to all this the sheets from which such pipe is made are thin and subject to rapid corrosion. Galvanizing will protect them from water but not from acid, which many, if not most, mine waters carry in solution. Consequently such pipes, though affording excellent results for a time, are as a rule short-lived.

Another disadvantage of such pipe is that it becomes dented, causing a loss in carrying capacity, and if this occurs near the joints the leakage is considerable.

During recent years another form of piping that possesses many advantages over the devices previously mentioned has come into more or less extensive use. This is a tube of canvas or fabric that is marketed under various trade names. Such tubing is manufactured by at least three makers—two in this country and one in England. Thus the Bemis Bro. Bag Co., of St. Louis, Mo., manufactures a canvas tube known as Flexoid; E. I. du Pont de Nemours & Co., Inc., of Wilmington, Del., makes a fabric tube similar in many respects to the product just mentioned but known as Ventube; and the Telephones Co., Ltd., of Vaughan Road, West Harrow, Middlesex, England, manufactures a canvas pipe known as Ventwal.

All the tubes manufactured by the above firms are circular or elliptical in cross-section. An Australian device of similar nature is made with a rectangular section. Inasmuch, however, as this shape does not lend itself readily to manufacture at low cost and as a conduit of this section must be supported by a framework of light wood or metal this device has not met with extensive application. The circular forms also oppose less resistance to the air current.

In ventilation by means of flexible conduit the joint between sections has always presented difficulties. In the Flexoid and Ventube pipes this has been overcome by fastening a light spring-steel slightly collapsible ring at either end of each section of tubing. In joining two sections together one of the end rings is slightly
TUBE CAN BE PATCHED LIKE A RUBBER TIRE

A special cement is used for patching, the part to be patched being deflated and the torn section to be covered being carefully cleaned with gasoline. Two coats of cement are placed on the pipe and on the patch and left to dry. When completely dry the cemented portions are hammered together on a flat surface, giving instant adhesion. For temporary repair underground a small patch can be sewed on, and this usually will give entire satisfaction.

“Fittings” for this kind of tubing are exactly analogous to those available for wrought-iron or steel pipe. They include elbows, tees, wyes, reducers and the like as well as a connection to join the tube to the rectangular discharge nozzle of a fan or blower. A blasting piece also is sometimes used next to the face if heavy charges are to be fired. This is drawn back before the shots are detonated, and pulled forward again after the blast, thus avoiding the injury to the fabric which frequent removal and dragging over the ground would inevitably cause should the end tube be unhooked every time before a shot was fired.

As a rule a fan or blower will be used to furnish the air current. Where compressed air is available, however, a small jet may be led within the outbye opening of the pipe and a ventilating current induced on the principle of the injector. Tests made in South Africa some years ago showed that 5 cu.ft. of free air per minute escaping under pressure from a 6-in. nozzle opening induced a current of 210 cu.ft. per minute; 80 cu.ft. of free air escaping under pressure from a 9-in. opening actuated a current which delivered 1,080 cu.ft. of air. These experiments were conducted on a 538-ft. length of 9-in. pipe, and the figures on the resulting current just given were the discharges measured at the outlet opening and included, of course, the input of compressed air.

In most cases, however, as above stated, a fan or blower will be employed. This may be mounted either permanently or temporarily. For a permanent foundation no material, all things considered, appears to equal concrete. Brick or stone masonry may, however, be employed to advantage. In emergencies or in cases where the fan and tubing are to be used for only a short time a wooden foundation may be employed. This can be built up of mud sills and cross-pieces, bolted, drift-bolted or spiked together. Any timber that is
convenient, such as posts, ties, chock lumber and the like may be used, provided an even foundation surface is secured. Sawd lumber, of course, is preferable. If properly made a fan may be operated on a foundation of this kind for a long time.

In work of this nature the motor and fan, if possible, should be direct-connected. If this is done both elements may be bolted on a common base, which in turn is bolted to the foundation as a unit. For large volumes of air, however, belt or chain drives have their advantages, as the motor and fan may then be readily separated and moved into place with greater ease than if joined rigidly together. This arrangement, however, necessitates two foundations. Many companies manufacture fans suitable for this kind of work. Many motors also are available.

Although ventilation by this means will hardly be used in the ordinary operation of a well-regulated coal mine it may advantageously be resorted to for special work or in time of emergency. Thus it will find application in driving long passages, such as drifts or slopes from one bed to another, under streams and the like. The accompanying illustration shows some of the dead-end faces that can be ventilated by this means.

So far as coal mining is concerned it is in time of emergency that this type of ventilating equipment will be found most valuable. Its light weight—one man can carry 100 ft. of 16-in. tubing without serious inconvenience—and the rapidity and ease with which it may be erected are considerations of high value after a disaster, such, for instance, as an explosion. Furthermore, in fighting mine fires it may in many cases be used to good effect. This will be particularly true in those instances where the exact location of the fire is unknown and where it is desired to attack it from above. Under such circumstances sometimes thousands of feet of narrow passages must be driven. As every mining man knows, these are extremely difficult, if not impossible, to ventilate by ordinary means.

In such emergencies also time is, or may be, an all-important element. No man can do his best in an atmosphere depleted of its oxygen or vitiated by smoke or explosive fumes. Pure air in adequate volume delivered at or close to the working face will not only promptly clear away powder smoke and the like but will assure a maximum of effort from the workmen employed. With an outfit of this kind such an emergency can be met without delay.

State Geological Surveys 
and Mining Bureaus

Coal Reserves of Cambria County, Pa.

By John F. Reese

Cambria County, Pennsylvania, has six coal beds that are now of economic interest. In order of their present importance as shipping coals these are the Lower Kittanning, Upper Kittanning, Lower Freeport, Upper Freeport, Clarion and Brookville.

The many mines working the Lower Kittanning bed and exposures of its outcrop have furnished many measurements of its thickness, thus making possible an accurate and reliable computation of the quantity of coal contained. The "B-Rider" coal of the Bens Creek area has been computed along with the Lower Kittanning coal in this report.

The Lower Kittanning is the most persistent bed, contains the greatest coal reserve and is the largest producer within the county, yielding more than 8,100,000 tons annually.

A fair amount of information as to the thickness and persistency of the Upper Kittanning bed is available. This measure is best suited for mining in the Patton, Portage, South Fork and Johnstown areas.

A fairly accurate estimate of the quantity of coal in the Lower Freeport bed is made possible by many measurements at mines and outcrop. This measure attains its best development for mining in the Barnesboro-Spangler area.

The extensive outcrop of the Upper Freeport bed throughout the county, and its mine development in various localities, furnish a fair number of measurements for an accurate estimate of its quantity. It is

mined most extensively in the Barnesboro, Hastings, Gallitzin and Cresson areas, where it attains its best thickness.

The Clarion or A coal has been computed as of economic interest in Reade and Richland townships, where it has been mined. Little is known of its thickness and extent, and only areas surrounding mining developments or proven ground have been computed.

The Brookville or A coal has been considered as of interest in five townships, namely, Adams, Cresson, Dean, Gallitzin and Richland. Only areas surrounding operations or proven ground have been computed, as little is known of the extent and persistency of this coal.

Cambria County has a total area of 697.4 square miles. The result of computing the coal reserves in this county based on the latest maps, engineering data, and methods is shown in the accompanying table. The figures are here given as computed. It should, however, be distinctly understood that while the acreage of each of the beds has been accurately calculated, the reliability of the average thickness of the coals employed in the computation of tonnage decreases for the various beds in the order following: Lower Kittanning, Upper Freeport, Lower Freeport, Upper Kittanning, Brookville and Clarion. Thus, while the figures for the Lower Kittanning bed are conservative and probably reliable, those for the Clarion coal may be much too small or many times too large.

Detailed tables of the coal reserves in each township have been prepared and will appear in printed form in a report now being written on the bituminous-coal fields of the state. They can be consulted in the office of the Topographic and Geological Survey; or figures for a single township will be mailed from this office on request.

October 12, 1922  COAL AGE  589
Valuation of Coal Land Leaseholds
In Tax Returns

BY W. B. REED
Washington, D. C.

In every coal field there are operations on leased land. Many companies make both from leaseholds and from land owned in the field, but not all of those who work under leaseholds appreciate the value of the lease or consider that they are entitled to establish on their books and before the Internal Revenue Bureau a recoverable value for this form of property. In particular, the operators who had substantial earnings prior to March 1, 1913, or who have preferential royalty rates or favorable conditions are in position to profit by taking advantage of this failure of the tax law and regulations.

Under the revenue acts of 1918 and subsequent years the value of a lease may be amortized. The procedure is comparatively simple. The Treasury Department has a Form 7, rather formidable it is true, but one that most companies find it necessary to file. The facts necessary for a lease to establish the value of a leasehold are assembled when Form 7 is issued. But the Treasury Department does not make the deduction in tax that corresponds—the lessee must make it himself.

Whenever a lease was vested in the ownership of any property on March 1, 1913, prior in the event of a subsequent sale of that property be regarded as capital, and is assessed to the lessee from income tax, regardless of the fact that that value may have increased during the term of its contract. Consequently revenue legislation has provided that profit in the sale of such assets shall be apportioned by taking the fair market value as of March 1, 1913, or as the basis of value. Therefore, it has always been recognized that the taxable profit from the sale of a mining lease shall be in excess of the March 1, 1913, value. This being the case, the importance of establishing such values in the case of such property is obvious.

SUPREME COURT DECISION WITH INTEREST

It would have seemed natural for Congress to provide for deduction of depletion, or, more strictly speaking, for the amortization of such leasehold values as allowable deductions in ascertaining taxable income under the revenue laws, but it was not until the passage of the act of 1918 that proper consideration was given to this situation and an allowance provided for the same. The Supreme Court has decided that, since the 1918 law the lessor is not entitled to such a deduction. Nothing before has ever been paid in such a case. If such a lease would be amortized, but the amortization in value was not therefore recognized.

The Bureau of Internal Revenue has issued voluminous regulations as to how values may be established. They may be summarized as: cost, sales or transfers of similar properties, royalties and rentals, values for capital stock or local taxation, records of litigation, probable court inventories, and disinterested appraisals, and present value of eventual earnings.

Because comparatively few representative transfers of operating coal-mining property took place around the basic date of valuation, March 1, 1913, and because the other methods offer little for comparative value, most valuations in this field are determined by the present-value method. This method is one generally recommended by the engineering profession and is equitable in that it gives recognition to the value of management as a factor. Two properties may be or apparently similar nature, yet one be a failure and the other a success. As a former official of the Internal Revenue Bureau put it: "A dollar of capital which will earn a quarter is worth more than a dollar which will earn a nickel."

R. V. Norris Defines "Present Value"

A leasehold is a property right and to appraise its present value requires first a knowledge of the proper method and second certain basic facts. R. V. Norris' defines present value as follows: "The total value of a property at any date is the value of the future earnings of such property discounted to that date. The value of the mineral in the ground at any date is the total value of the property as above, less the value of the present and prospective expenditure for plant, development and equipment necessary to recover such mineral discounted to the same date."

The Treasury Department has held that taking into consideration the hazards of mining and marketing, a fair basis of valuation in the bituminous coal industry is obtained by using a discount factor of 8 per cent with a sinking fund provision of 4 per cent. Many engineers, however, will not agree with this basis.

Let us illustrate the theory of the valuation of a leasehold on the basis of earnings in the period prior to March 1, 1913. Assume that in the period prior to 1913 the average earnings were 30c per ton, that the life of the reserves after the date of valuation was twenty years and that the average annual production is 100,000 tons. This would give an annual profit of $30,000 and prospective profits in twenty years of $600,000. The present worth of the eventual earnings, $600,000, discounted on the basis of 8 per cent and invested in a sinking fund at 4 per cent is found, by using Hoskold's formula, to be $264,126. If from this is deducted the cost of plant, present and prospective, assumed here to be $125,000, we find the present value of the leasehold to be $139,126. On the basis of the 2,000,000 tons unmined at date of valuation, this gives 6.956c per ton, which may be deducted as depletion. If the annual production is 100,000 tons we have $6,956 allowable depletion and therefore a decrease of that amount in the taxable income.

Using the 1918 income tax rate for corporations of 12 per cent, plus 65 per cent, the highest bracket of the
excess profits tax into which many of the coal companies rates ran, we have possible a 77 per cent tax. Taking 77 per cent of our $6,956 we have $5,556 as the maximum saving through proper valuation of leasehold. Of course if the earnings in the period before 1913 were higher than the assumed average of 30c. or if the life of the coal is less than twenty years the per ton value would be correspondingly higher and the saving greater; if lower, the reverse would be true.

If the lease have a preferential rate of royalty as compared with neighboring properties made under similar conditions and at approximately the same date, values may be assigned upon the basis of such preferential values, without the necessity of proving on the basis of earnings.

It is possible that at times a value may exist in a leasehold for the purpose of invested capital. These cases are the most difficult to establish, but if the lease was a proven tract and was turned over to a corporation in exchange for capital stock of the corporation, the value of the lease may be "paid in surplus" within the meaning of the law and be capitalized as such at its value at date of acquisition, subject to the limitations, for the year 1917, of the par value of the stock or shares specifically issued therefor.

Recloses Instantly Circuits Temporarily Short-Circuited or Overloaded

AUTOMATIC reclosing equipment for use on direct-current circuits of 300 and 500 volts has recently been designed and constructed. Its function is to protect apparatus in case feeders become short-circuited or overloaded, and at the same time to insure a continuity of service when the trouble is only temporary.

This equipment, which is constructed by the General Electric Co., is designed for use on circuits supplying stub-end feed, a combination of stub-end and multiple feed, or in combination with a sectionalizing switch or sectionalized feeder.

The manner of its operation on a stub-end field—that is, one where the load is supplied by current from a single source—is so typical that once described the reader will have a clear idea of the manner in which the apparatus functions under other circumstances. The various devices that go to make up the equipment are a shunt contactor, an instantaneous overload relay, a reclosing relay, a control power switch and a load-indicating resistor. These devices are connected in accordance with the accompanying wiring diagram.

The sequence of operation of the equipment in case of a short-circuit or heavy overload on the feeder is as follows: The overload relay opens its contacts, thus de-energizing the coil of the contactor, which opens instantaneously, disconnecting the load from the power supply. When the contactor opens it closes the auxiliary switch (b; see diagram) which energizes the coil of the time-delay circuit-closing relay, which starts to close. The time delay is inserted at this point in the sequence in order to allow conditions on the feeder line to become stable. Closure of this relay completes the circuit through the lower coil of the reclosing relay.

OPERATES SOMewhat LIKE A VOLTMETER

The reclosing relay has two coils, both of which must be energized before the device will function. Its operation somewhat resembles that of a voltmeter, the lower coil being analogous to the permanent magnet of the meter while the upper one furnishes excitation to the movable element on which the contacts are mounted. The relay contacts will close only when the voltage drop across the load, with which the upper coil is in parallel, is enough to cause that coil to excite the movable elements sufficiently to close them. When the load resistance is zero, as in case of a short-circuit, there is no voltage across the upper coil, but when the load resistance is infinite or when open-circuit conditions exist, practically full voltage is impressed across the upper coil, because its resistance is much greater than that of the load-indicating resistor. Consequently it is possible to obtain an intermediate point and calibrate the reclosing relay so that, with a definite value of resistance in the load-indicating resistor, the equipment will not close on a load in excess of a predetermined value.

As long as the trouble on the feeder continues the reclosing relay will remain open, even after the time-delay relay has closed, because the voltage across the load is not enough to close the contacts. As soon as the trouble has cleared, however, and the load resistance has passed the predetermined point, the relay will close, energizing the coil of the feeder contactor which then closes, in turn closing the auxiliary switch (a) which seals it in. Closure of the contactor reconnects the load and de-energizes the time-delay relay which opens its contacts.

The equipment for circuits having a combination of stub-end and multiple feed makes use of a contact-making voltmeter to indicate when the potential difference between the feeder and the source of supply has fallen to a safe reclosing value. When the voltage has so decreased, the feeder contactor recloses in the same sequence as in the former instance. A relay connected in parallel with the contact-making voltmeter determines whether the equipment is to operate on multiple or a stub-end feed.
Examples of Successful Gravity Planes

Three Rail System, Top to Bottom of Plane, with Four-Rail Passing Tracks - Arrangement Wholly Eliminates Switches—Tipple Set on One Side of Incline as a Safeguard Against Runaway Cars

Referring to the inquiry of C. W. Shaffner, regarding the proposed installation of a gravity plane, Coal Age, Aug, 10, p. 211, kindly permit me to give a brief description of an incline that has been in successful operation for some time, and of any mines.

In using Table I, I will refer only to a few of the general features that have a particular bearing on the successful operation of the plane. Without knowing the exact conditions that brought the situation to which reference was made, it is clear that any plan proposed would have to be modified in detail to fit the case in hand.

Three-Rail System Assures Many Practical Advantages

With one reservation, not one of which I would hesitantly recommend a three-rail system extending the full length of the mine, except for the passing tracks midway of the plane, where there must naturally be four rails provided.

The important advantage of a three-rail system is that such an arrangement, when used as the normal arrangement of the incline, eliminates the need of switching at any point on the incline. It provides separate loading and empty tracks to be used exclusively by the loaded and empty cars, respectively.

This is accomplished by the installation of a vertical type of incline, formed in the drumhouse, which is located from 5 to 7 ft. above the head of the incline, as indicated in the accompanying figure.

Equipment, Guard and Track Arrangements

There are different types of three-rail machine, adapted to very different conditions, and a machine should be selected, not only from the standpoint of equipment, but also in regard to the weight of cars to be handled, and the service intended. It is important to consider the cost of handling of cars and the maintenance required. These factors will determine the efficiency and economy of the three-rail machine, and a careful study of the conditions will be necessary.

Referring to the figure, a portion of the track is shown at A. For a short distance from A to B, the grade is such that the incline, as shown in the figure, is 40 ft. above the plane, which is to be level. The portion of the track is shown at B and C, and at C to D, the grade is much steeper than the surrounding grade of the incline, reaching from B to C. These, from C to D, the grade is much shallower. This is an important feature, as the leading cars descending the steeper grade add force to overcome the friction and accelerate the incline.

At the same time, the descending empty cars are passing over the lesser grade from D to C.

Evidently, both tracks, at B and C, must be on the same level. Above the knuckle at A and below the knuckle at D, the tracks are graded to favor the movement of the loaded and empty cars respectively. At the various points marked x in the figure, there are provided short lengths of 2 x 4-in. oak pieces, for the purpose of lifting the rope over the rails.

The movement of the cars on the incline is controlled by a brake, as shown in the drumhouse. This brake is operated by a man stationed at the knuckle. A wire-rope cable reaches from that point to the brake in the drumhouse.

Further information regarding the operation of this incline will be gladly given if desired. One important point re-

Another Letter

In connection with the suggestion offered by D. S. Allison, Coal Age, Sept. 14, p. 415, regarding the use of three rails to replace the single track, above the passing point, on a self-acting incline, it may be of interest to state that such a system has been installed by the American Manganese Mfg. Co. of this place, at one of their mines.

At the head of the incline is located a set of tandem wheels, or gravity sheaves, of the type commonly known as "Figure 8." The machine is placed directly under the tracks leading into the mine. As has been stated the three-rail system is only used above the point where the cars pass each other halfway up the incline. Below this point a single track is used.

Plane Equipped with Permanent Cars and Automatic Switch

The automatic switch, at the lower end of the passing tracks, in this case, is operated by a weighted lever that keeps the switch set for the empty track, except as it is forced open by the loaded cars passing down the plane.

On this incline, there are but two permanent cars used, which are attached to the two ends of the rope, respectively. These cars are equipped with drop doors, at their lower ends. As a car reaches the foot of the incline the door is automatically raised by the movement of the car and the dump its load, after which the door again closes, locking with a spring catch.

At the upper end of the incline each car passes under a bin, located at the entrance of the mine, where it is loaded and then is ready for another trip. While only a small car is used at the present time, this arrangement is capable of handling an output of 500 tons in 8-hr. Its operation has given complete satisfaction.

Dunbar, Pa.

John Stannis.

Room Timbering

Cantilever action of roof follows extraction of coal—Permanent posts should not be carried too close to the face—Temporary posts there will often avoid breaking of timbers—Systematic timbering advised.

Referring to the question asked by "Timberman," Coal Age, July 27, p. 136, asking the best method of timbering rooms in a 6-ft. seam under 250 or 300 ft. of cover, with a good roof and bottom, I would like to make the following suggestions:
It is important, of course, to use timbers of a suitable size. In this 6-ft. seam the small diameter of the posts should not be less than 6 in. Good cap pieces from 3 to 4 in. should be used over the posts, but it will not be necessary to use foot boards.

Assuming that these conditions have been complied with and that the rooms are driven systematically, the continued breaking of the posts under this cover would seem to indicate that there is a greater pressure operating than that due to the weight of the overburden alone.

CANTILEVER ACTION OF ROOF FOLLOWS EXTRACTION OF COAL

The extraction of the coal always develops a cantilever action in the roof. In my sketch I have tried to illustrate the effect of this action. The gradual settlement of the roof on the timbers causes the strata to break a short distance back from the face of the coal. In the figure the portion A represents the area of complete settlement, while that marked B indicates where settlement is in progress.

As explained in the reply to this inquiry, the unbroken strata above overarches the opening, causing the weight of the overburden to rest on the ribs, and the weight of the loosened portion A above rests on the permanent timbers beneath it.

POSTS AT THE COAL FACE MUST NOT BE SET TOO TIGHT

The point I wish to emphasize is that temporary posts should be set under the solid portion B close to the face. If these posts are set tight between the hard roof and floor they will be broken by the weight coming on them, being subjected to a much greater pressure than the permanent posts farther back from the face.

If the breaking of the posts is more pronounced and continuous within a limited distance of the face it would seem that the posts have been set too tight under that portion of the roof. On the other hand, if the breaking of the posts extends further back from the face we must look elsewhere for the cause.

It is a good plan to drive several rooms abreast of each other and at a uniform width and distance center to center and watch the effect in producing a more uniform distribution of pressure. It might be well to use a line of light pegs up the center of the room instead of the middle line of posts. This would be expensive, however, and can only be advised as a last resort.

CAPS BEING CRUSHED SHOW POSTS ARE SET TOO SOLID

From the statement that the caps do not appear to serve their purpose when the posts take the weight, I infer that the trouble occurs at the face rather than down the length of the roof. I naturally conclude that the compression of the caps is not sufficient to allow for the settlement that must take place.

That being the case, it is not strange that the posts are broken since, as stated in the reply to the inquiry, the weight of the overburden is far in excess of the strength of the timber. Since this settlement is irresistible, the most practical course to pursue is to make the posting at the face temporary and not drive them tight.

The conditions described would also suggest the advisability of adopting a systematic method of posting by which the roof pressure will be more equally distributed.

Washington, D. C.

Testing of Safety Lamps

Every lamp must be tested—Opinions differ in regard to character of test—Use of lamps approved by the Federal Bureau—Blowing test effective if properly made.

In his letter regarding the testing of safety lamps, Coal Age, July 13, p. 60, Joseph Cain raises the question as to whether the method of testing a lamp by blowing against it, as he has described, should not be adopted at all mines where such lamps are in use. Mr. Cain also asks whether it is possible to tighten a lamp to such an extent as to endanger the bleaching of the glass through an excess of air blown upon it due to the heating of the lamp.

It requires no argument to prove that a safety lamp should be tested for any defects, either of construction or assembly, before being entrusted to a miner. However, the manner in which this testing should be done is a question on which all may not agree. Before the lamp is assembled, it must be carefully examined in every part to ascertain if they are in perfect condition and there are no defects that would render the lamp dangerous.

PURPOSE OF FEDERAL BUREAU OF MINES TESTING OF SAFETY LAMPS

When a lamp has been assembled its further testing is for a twofold purpose: 1. To demonstrate that it will not pass the flame in a current of high velocity. 2. That it will not pass the flame by an internal explosion, under any conditions that may reasonably be expected to arise in the daily operation of the mine.

As far as I have been able to observe, very few mines have facilities for making a test to demonstrate the first of the two conditions mentioned. In fact, such a demonstration is not necessary, inasmuch as all approved lamps have been subjected to such tests at the Federal Testing Station. The fact that they have been approved by the Bureau of Mines is evidence that they have stood those tests successfully.

My point is that no mine should be worked with any other than approved safety lamps, if safeties are required at all. Then, if these lamps are maintained properly, there will be no necessity of their being subjected to a further test to ascertain if they will pass flame in a current of high velocity.

TESTING FOR INTERNAL EXPLOSION MORE IMPORTANT

Personally, I consider the testing of a lamp, for the second purpose named, of far more importance in determining its safe condition. As a matter of fact, there are few mines in which the velocity of the air current is as great as that to which the lamp has been subjected in the Federal Bureau test. Such velocities, if they occur at all, would only be found on the main intake and return airways of a mine.

Now, regarding the blowing test mentioned by Mr. Cain, it might be said that custom has sanctioned this practice, which has been in use a long time, in most localities, chiefly owing to its thoroughness and reliability, which is apparent to everyone. My experience is that when a lamp has been properly examined and assembled there is little danger of its being unsafe, except that it may leak air against the asbestos washers and these gaskets should receive careful inspection.

HARDENING OF GASKETS

At times, the gaskets become hard from long use and continued compression, which gives them a glazed surface and makes them ineffective, particularly if they are dirty. To remedy such a condition, the washer should be scraped to remove the compressed dirt and produce a soft surface that will form a better contact with the glass; or new gaskets must be used in place of the old ones.

In regard to the flame of a safety lamp being extinguished by the carbon dioxide contained in the breath, as suggested by one writer, it should be remembered that the purpose of the blowing test is to ascertain if the flame is at all deflected by reason of the air blown against it as it enters the combustion chamber. If the flame is at all disturbed or deflected, the lamp is unsafe. It seems to me that the distinctive effect of the breath is immaterial, in respect to ascertaining the security of the lamp.

MAKING THE BLOWING TEST

In making this test, I have found that the lips should be placed in close contact with the lamp, at the suspected points. If the lamp is held even a short distance away from the lips, the air blown against it is deflected by the circular form of the lamp, and the extinguishing effect of the flame is destroyed. This may not seem material, but it makes
The lamp has not been put to practical use in any mine. It has always been my understanding that nothing is so right when a light can be contemplated by breathing only the lamp base, that, today, many safety lamps are not put in this manner. It appears doubtful that statement, let alone the nuisance of the lamp, just below the glass.

From Letters Abroad.

While it may not have a direct bearing on the subject matter of this discussion, I think it will be well to draw attention to two features that have not yet been mentioned regarding the construction of safety lamps. The first has reference to the air entering the lamp at a joint below the base, so that the circulation within the combustion chamber and the chimney of the lamp will be in opposition to the body of the lamp. It is well known that where the air enters a safety lamp through the lower part of the lamp chimney and above the base, it soon escapes in order to reach the flame. This is the trouble with the old type of chimney lamps. The air will not enter the lamp, even though there is a lamp base. Moreover, there is a risk when a lamp will cause the base to "pop" and give off fumes, which are very liable to happen when the lamp is in the hands of a careless miner.

Owing to the regulating devices, in many safety lamps in use today, a fire lamp is apt to be less careful in making note for gas. He will often run the risk of an explosion within his lamp. However, most of the lamps equipped with regulating devices enter the air below the flame, thus creating an upward circulation within the lamp and clearing the combustion chamber of explosive gas. The construction, I believe, reduces the liability to danger from internal explosion.

The second feature to which I want to refer relates to the size of the gauze chimney. To my notion, a small lamp is stronger and better able to stand hard usage. It occupies less space, is easier to handle and a thin layer of gas at the top is more readily reached when the height of the lamp is reduced. As a result, Davy, with a large number of his fireboxes, is to carry an electric lamp in their cap, which has a good light and helps to expedite their work. This is the custom that has given rise to a desire for small testing lamps.

Listed, Led. W. H. LUXTON.

The reference of this correspondent to the desire of some firebosses to use a small lamp recalls the attempt made years ago to introduce a minia-

true Davy lamp, for the purpose of testing for gas in mines. When the knowledge of this came to the late James E. Roderick, then chief of the Department of Mines, in Pennsylvania, it brought from him a prompt protest against the use of such lamps, as being dangerous for many reasons.

STANDARD SIZE OF LAMP DETERMINED.

First, the size of the lamp and the small space enclosed within the gauze chimney, it was claimed, made the little lamp a menace to safety when exposed to a body of gas in the mine. Again, its small size made it an object that would naturally be tucked away in the pocket of a fireboss or foreman, where it would accumulate dirt, be upset and leakage of oil would render it unsafe for testing.

As the result of protracted experiments, the eminent chemist Sir George Humphry Davy, found that the best results were obtained in the use of what has since become a standard gauge for safety lamps, containing 28 wires (No. 28 B.W.G.) to the inch, or 784 openings per square inch. Davy drew attention to the danger arising from the use of gauze chimneys of too large a caliber as in the old Scotch Davy; or a chimney that was too high, as in the Pielier safety lamp. Similar danger also exists in the use of too small a gauze chimney, by restricting the volume within the lamp.—EDIT.]
 הפרטים על צבע האיטלקי נלקחים ממקור ידוי. כלlarınızı בטוחיםijing. כותרת: "A large percentage of electric gathering reels are of the single-conductor type. In mines where the rails, on room entries and in the rooms turned off those entries, are laid with fair amounts of care and the fishplates bolted up so as to afford a good rail return for the electric current, there is no true reason why a single-conductor cable will not give satisfactory service. The double-conductor cable has been used largely, in the past, where wooden rails were laid in the rooms; or where iron rails were used but improperly laid and the fishplates loose or missing. Under these conditions, it is quite evident that a single cable could not be used to advantage, if at all. Today, most of the mines realize the importance of keeping their tracks in fair condition, as derailments are not only expensive but affect the output to a very considerable extent. There are two types of conductor cables; namely, the twin-conductor cable, consisting of two parallel wires bound together to form a single cable, and the concentric type of cable. I regard the latter as being much superior to the former. Most of the double-conductor cables manufactured have been of the twin-conductor type, which is very difficult to reel up evenly, and makes the operation even harder of accomplishment when it becomes necessary to use a cable that has been spliced. During the last few years, I have been recommending the concentric type of double-conductor cables, wherever it is necessary to use a double cable owing to poor track conditions. The concentric type has the advantage that it needs much more evenly than the twin-conductor cable. In the concentric type, the ground side being outermost, no particular damage is done if the outside layer of insulation becomes worn off in operation. Though, in the case of this type of cable, repairs may be a little more difficult, this disadvantage is more than counterbalanced by the advantages gained. Allow me to advise that wherever possible the single-conductor cable should be used, with a type of reel having a small inertia in the drum, which will insure easy winding and prevent the heavy stresses caused by a type of drum having a large inertia. It is my belief that money spent in providing a fair rail return, on side entries and in the rooms, will more than balance the extra cost of double-conductor cables and the consequent high cost of maintenance and additional delays.

Examination Questions

Answered

Indiana Mine Bosses' Examination
Indianapolis, 1922

(Selected Questions)

QUESTION—Discuss the subject of mine ventilation, setting forth the purposes; mechanical devices and their uses; quality of air required and how determined; quantity of gas and how determined; humidity and temperature, how determined; mine gases, how detected; their danger and how prevented; and give the law respecting mine ventilation.

ANSWER—Brieferly stated, the purpose of ventilation is to furnish pure air throughout the mine, by conducting it from the air shaft in one or more splits so that it will sweep the working faces, in quantity and velocity to dilute and carry away the noxious gases that accumulate in the workings.

Many small, non-gaseous mines are ventilated by a furnace constructed near the foot of the air shaft. In all the larger and up-to-date mines, however, either a centrifugal or a disk fan is used to force the air into the mine or exhaust it from the mine. In either case, a free circulation of air is produced in the airways and throughout the workings.

The Indiana Mine Law requires the circulation of 100 cuft. of air per minute, for each person, and 300 cuft. per minute, for each mule, employed in the mine. The air is measured by means of an anemometer, which shows the velocity of the current, and that multiplied by the sectional area of the airway gives the volume of air in circulation.

The percentage of gas in the return air current is first estimated by observing the height of the flame cap in a safety lamp exposed to the current. Taking this percentage of the total volume of air in circulation gives the quantity of gas generated in the mine.

The humidity and temperature of the mine air are ascertained by observing the readings of the wet-and-dry-bulb thermometer. This instrument is often called a hydrometer or psychrometer. The reading of the dry-bulb thermometer determines the temperature of the air.

Mine gases are detected mostly by observing the effect of the gas on the flame of a safety lamp. Methane or carbon monoxide causes a flame cap, while carbon dioxide makes the lamp burn low or puts it out entirely. Carbon monoxide is generally detected by observing its effect on small birds or mice confined in a cage. Hydrogen sulphide is detected by its smell.

Carbon dioxide is dangerous when accumulated in low and badly ventilated places. In mines, because the gas contains no available oxygen for the support of life, and its presence depletes the oxygen of the air, causing suffocation and death. The other three gases named are inflammable and form explosive mixtures with air.

These dangers are prevented, as far as possible, by providing adequate ventilating current to sweep them from their lurking places in the mine.

The Indiana Mine Law (Secs. 255, 261, § 265) requires that 100 cuft. of air, for each person, and 300 cuft. of air, for each mule, be kept in circulation, in all main and cross-entries and working places in the mine, to an extent to keep it free from standing gas and in a fit state for work. The law further provides for the examination of the mine by a competent fireboss using a safety lamp, the examination to be made before each shift.

QUESTION—Discuss the subject of mine warning devices with respect to gas, weight of rails, ties, nails, fishplates, curves, grades, switches, ballast, drainage; and give the legal respecting width and refuge holes.

ANSWER—All tracks on haulage roads must be well bedded and drained by a suitable ditch at the side of the road. Main roads should be well bedded with good material. Weight of each rail, weight of rails, ties, fishplates, and fishplates must be determined by the size and capacity of the mine cars used. This is largely modified by the height of the track as determined by the headroom on the roads. In general, in locomotive haulage, a 3 or 4 ft. track gauge is used, with rails weighing from 10 to 50 lb. per yard, fastened by spikes or rivets, bedded with ties and fishplates, and the fishplates, with the proper spikes and bolts, tightly fitted to the rails. The grades on the main roads, as far as possible, should favor the movement of the loaded cars, a 1 per cent grade being preferable. It is quite impossible to make tracks entirely without tracks where the track is to be avoided and all switchings must be carefully laid by competent trackmen.

The Indiana Mine Law (Chap. 197, § 11) provides for a clearance space, 8 ft. wide, for the passage of railroad cars, and 4 ft. wide, for the passage of hand cars. The space must be free from all obstructions, except proper fences and other material. This does not apply to mines in the Black-Creek field, working Sesquicetna, and other一律 known as the Low Carbon and Upper Sesquicetna in Indiana. Chap. 255, Sec. 12 provides for refuge holes, 4 ft. deep, measured from the side of the car, and 4 ft. wide, at distances not more than 20 yards apart, to be constructed on all single-track haulage lines not more than 600 ft. long, where the distance from the mine mouth to the head of the track is 1,000 ft. or more.

Peace Prevailed to the End at Cleveland; Reorganization Committee Starts Work Nov. 14 at Chicago

What the Conference Did

Enabled operators to compose many violent differences and to discover much "common ground," leaving them more nearly unified than at any time in years.

Created a "reorganization committee" of two miners (one a district president) and two operators from each of the 15 districts whose operators attended the conference, with a vague understanding that other districts can come in.

Instructed this "two-by-two" committee to suggest a method for negotiating future wage contracts. It is understood that the committee is not to report until the new United States Coal Commission does and that nobody is bound to accept its recommendations, though all parties hope to.

"Peace to the end!" was adhered to with determination in the wind-up of the joint miner-operator conference in Cleveland, Ohio, last week, as forecast in these columns. The bitterness among operators on Monday, Oct. 2, the opening day of the meeting, was smothered into the background on Tuesday, a day of give and take, and on Wednesday the partly settled program of conference decisions was put through calmly and with doors open to the public. The fighting was all over.

So the conference proceeded to set up its joint committee to work out and suggest a method for future negotiations; it agreed not to comply with the Washington request for twenty names for President Harding to consider in appointing the United States Coal Commission, and it simply "omitted" to set up any joint fact-finding commission of its own because it was the desire of the conference to do no act that would appear in the light of interference with the people's investigation of the coal industry. Since the miners wished to supply President Harding with a panel of names, they were permitted to do so after the conference adjourned. But the operators, many of whom have already submitted lists in response to requests from the administration, declined.

When the conference adjourned, about the middle of the afternoon on Wednesday, both sides agreed that no such display of harmony between miners and operators, and among operators' groups, had been seen in many years. They all declared that a new era of good feeling might easily be starting from this conference. There was some difference in tone in some of the after-conference statements, however.

WATKINS COMMENDS LEWIS' CONCILIATION SPEECH

T. H. Watkins, president of the Pennsylvania Coal & Coke Corporation, declared that the spirit displayed by both sides had been splendid and that he had never seen such harmony prevail in a joint meeting. He said the conciliatory speech of John L. Lewis, president of the miners, on Tuesday morning, was a fine declaration and went a long way toward harmonizing the whole conference. Mr. Watkins felt very optimistic for the future of relations between miners and operators.

T. K. Maher, of Ohio, who with Mr. Watkins and W. H. Haskins, of Ohio, was largely responsible for the settlement of Aug. 16 with the miners, agreed that a fine spirit pervaded the meeting and that the conference was entirely satisfactory.

"There was carried out here," said he, "not only the letter but the spirit of the Cleveland agreement. The first factor that contributed to produce harmony was the speech to the miners by Mr. Haskins, in which he made it plain that the little group which first signed the Cleveland agreement intended to stand by it here, even if they had to do so alone. The second factor was Mr. Lewis' speech and the third was Mr. Watkins' able analysis of the problems that confront us and what this conference ought to do."

In the test of strength between the "small group" of operators who broke the strike in August and the majority there was much belligerence. Mr. Maher, of the "little group," finally was conceded the temporary chairmanship of the joint conference, but Phil Penna, of Indiana, was made chairman of the operators' separate sessions, with W. D. McKinney as secretary, and also was chosen permanent chairman of the conference.

There was difference of opinion as to whether the letter and spirit of the Cleveland agreement had been carried out. Many operators and groups who went to the conference uniting for a strike, finally did so when it became apparent that no minority was to dictate policies as it did in the making of the Cleveland agreement and that therefore the spirit of this conference differed widely from that of the Cleveland meeting in August. They felt that the harmony of this conference was no result of bludgeoning by anybody but resulted from a realization by operators and miners alike that the only hope of doing business in the future lay in unity groups. Therefore the operators effected what chairman Penna called "a cohesion."

COMMON SENSE, NOT THREATS, DID IT

"Common sense, not threats, and Lewis' speech were responsible for our final harmony," said H. N. Taylor, president of the Central Coal & Coke Co., of Kansas City, a man who was an outstanding figure throughout the conference, and the outcome of it all was most satisfactory." When he was asked how permanent he felt the new harmony was, he replied: "I think it is as permanent as the harmony effected in 1898. Operators went into that meeting with such hatreds that they didn't know each other. They made peace. It lasted for twenty years or even longer." Said Phil Penna: "The operators never can be as united as the miners for they are competitors among themselves and have far more conflicting interests than any union groups have. However a real unity was accomplished among them here."

"Both sides saw the necessity for harmonious action," commented John L. Lewis, miners' president, and, "my heart is gladly heart that it was taken. The manner in which the business of the conference was dispatched augurs well for the future of the coal industry."

Peace at the conference was so infectious that it pervaded even the relationships between President Lewis and Frank Farrington, delegate president of the Illinois miners, whose bitterness against Lewis has been obvious for a long time. Farrington received committee appointments at the hands of Lewis and the two appeared to make it a point to meet several times and converse pleasantly in public.

The joint conference was called by President Lewis and T. K. Maher, chairman of the August Cleveland meeting, thus following out the terms of that meeting. Under the agreement which ended the strike, the two main purposes of the joint conference were to choose a joint committee to set up machinery for future wage agreements and to name a joint fact-finding commission within the industry. If the conference failed by Oct. 10 to agree upon this fact-finding commission, then President Harding was to be asked to
Operators on the committee are: District 6, Ohio, Michael Callaghern and James H. Pritchard; Iowa, E. C. Smith and A. E. Kilgore; Kansas, W. P. Bowne, W. A. Johnson and C. H. Jenne; Arkansas, Oklahoma and Texas, M. McWilliams and to be chosen; Wyoming, H. C. Marchant and one to be chosen; western Kentucky, C. W. Taylor and F. D. Rash; Michigan, R. M. Randall and Warren Pippen; Missouri, F. W. Lukens and H. N. Taylor; Indiana, Hugh Shirkie and M. L. Gould; Washington state, J. H. Campbell; Illinois, central Pennsylvania, Pittsburgh and Montana are yet to name their members.

On motion of President Lewis this "two-by-two" committee will have its first meeting at the Great Northern Hotel in Chicago at 11 a.m., Nov. 14.

Thus the main scheduled business of the joint conference was finished and the conference adjourned to be reconvened at the call of the "two-by-two" committee whenever that board is ready to report. It was the general understanding throughout the conference that that committee is to wait until the new United States Coal Commission produces some results before it completes its plan, for the whole feeling of the conference was that the federal investigation is to be given a clear field and that its recommendations are to be adopted as far as possible.

As Phil Penna put it: "Everybody in the coal industry has tried to put our own house in order in the past and failed. Now the people should be given a chance to do it for us."

It was also understood that whatever recommendations the "two-by-two" committee may make are not necessarily binding upon either miners or operators though everybody recognizes the value of any work which is being done and that the recommendations will stand. President Lewis of the miners said as a final word from his side that he "hoped" the committee would be successful in working out an acceptable plan.

Miners Stick to 1922 Demands; Lewis Almost Sure to Be Re-elected

Immediately after the "peace conference" of miners and operators in Cleveland, which ended Wednesday afternoon, Oct. 4, the policy committee of the miners' union assembled, conversed briefly and announced that the platform of demands for wages and conditions which was adopted at the Indianapolis convention in February, 1922, had been reaffirmed. Thus whenever the time comes for the presentation of demands for the next wage agreement the miners will demand a continuance of their present wages, as well as a six-hour day, five-day week, time and a half for overtime, double time for Sundays and a correcting of machine inefficiencics and certain other elements of the existing working agreement. While this program was adopted early this year the miners have never presented it. The reaffirming of this set of demands eliminates the necessity of another miners' convention to formulate new demands.

It became known at the end of the Cleveland conference that President Lewis' re-election as chief officer of the International United Mine Workers was assured. Nominations for the next election, which was now in, made Lewis the choice of between 1,600 and 1,700 union locals, while George Mercer, statistician in District 12, generally referred to as a "Farrington candidate" of the rebellious element in the union, won the nominating votes of only about 128 locals. The names of Lewis and Mercer are the only ones to go for the ballot for the election. While a number of locals attended to nominate their candidates in Texas, to run against Philip Murray, of Pittsburgh, for vice-president, it was officially stated that Howat's name would not be permitted on the ballot because he is not recognized as a member of the union, never having been reinstated after his ejection with his entire group of Kansas officers nearly two years ago. William Green is guaranteed the nomination and election to continue as secretary-treasurer.

F. R. WADLEIGH, who now is devoting most of his time to matters connected with the office of the Federal Fuel Distributor, has been looking into the anthracite situation during a visit to Pennsylvania fields.
Fact-Finding Commission Should Seek Improvement of Coal Industry, Not Act as Tribunal

By Paul Wooton

Washington, D.C., Oct. 9.—Developments of the last week have caused officials concerned with coal to take a much less encouraging view of the situation than at any time since the strike was settled. There is a general belief that the peak of production has been reached and that a decline in output may be expected. The public believes the shopmen's strike is over. As a matter of fact it is continuing on a number of roads and some of those roads are vital in effecting the maximum coal production. Even on those railroads where the strike is settled, unusual difficulty is being experienced apparently in effecting an equitable distribution of available cars. Car supply is spotty and uncertain. The non-union districts are suffering particularly. Their cars were sent broadcast over the country during the strike and great delays in their return are occurring. Incidentally as a result of that situation, Western mines have a proportionately better car supply. The fact that the surplus of empties has been exhausted and the increasing pressure of other freight along with the difficulties in obtaining compliance with service orders and car rules and regulations make for increasing difficulties in supplying mines with coal cars.

It is clear that the more critical part of the situation is to obtain the distribution of household fuel. Every effort is being made at the office of the Federal Fuel Distributor to meet that situation. It is known that there has been no extensive substitution of anthracite. It is recognized that that situation is one in which the operator can do little. It is entirely a problem of inducing the retailer to exert his influence with the consumer to induce him to lay in a supply of bituminous coal or coke.

While the coal strikes still in progress have only a small influence on coal production, they are having serious consequences in creating a shortage of gas coal and in their influence on beehive coke production. The strike in the Greensburg-Westmoreland district is chiefly responsible for the bad situation with regard to gas coal, while the strike in the Connellsville district is so limiting the output of beehive coke that there is no surplus, which was being counted on to substitute for anthracite.

There is general disappointment that production at its apparent peak fell short of the 10,000,000-ton mark. If no better showing was made in September under certain advantages that will not exist in October or again this year, there is little hope of producing enough coal to meet the full requirements of the winter. The entire September production was necessary to meet current requirements. It is believed that very little of it went into storage. If surpluses are not made available in October the dangers of the situation are increased, particularly if severe weather conditions should occur during the late autumn and early winter.

Officials generally are pleased by the developments at Cleveland. To have had another commission studying the coal situation would have been embarrassing in many ways and would have been a distinct burden on the industry. At the same time the decision to study the wage agreement problem meets general approval, as it is regarded as certain that the government's fact-finding commission will fail in bargaining within the industry rather than the setting up of a coal labor board.

As is evidenced by several provisions in the act creating the fact-finding commission, the framers of the law—for the most part lawyers—could not get away from the idea of a court. Those officials closest in touch with the coal situation hope that the commission is not going to devote too much of its time to the calling of witnesses and the taking of testimony under oath. They prefer seeing the problem approached in a student-like manner with emphasis on the desire to give sympathetic attention to any proposal which has as its object benefit of the coal industry.

The hope also is expressed that the commission will not divide itself into two parts, one to consider anthracite and the other the bituminous situation. It is believed that the two industries should be studied together since the problems of one have their counterpart in the other. Anthracite, for instance, would be a most instructive exhibit in considering the overdevelopment of bituminous mines. There would be much gained by viewing the industries side by side, so that full advantage could be taken of their contrasts. It is also hoped that the commission will possess a sufficient aggregate of courage to recommend whatever drastic policy may seem best to meet the situation. It is being called upon to provide a constructive program for two generations to come. The thought is that few problems on the horizon are as important as that of coal. Heat is essential to life. Power is essential to industrial civilization. Each must be had in quantities sufficient to meet all requirements and must be cheap if the nation's progress is to be maintained. There is much more before the commission than an effort to work out a plan whereby capital and labor may live in the same house without demolishing it as an incident to internecine strife.

Spens Simplifies Order on Daily Reports

Under date of Oct. 4, 1922, Fuel Distributor Spens modified his order No. 1 calling for daily reports of coal shipments. The modifications permit the omission of names and addresses of consignees and car numbers and initials by all who will keep such a record in their offices. Instead of being required to note the number of carloads of coal shipped to designated classes of consignees, as “steam railroad,” “public utility,” etc. Shipment to tidewater and the Lakes may be so designated. Shipments to other than consumer, as to tide, to wholesale, or to scales, must be reported as such and the producer is to be held responsible for the ultimate reports from the middleman as to the destination of the cars.

The order follows:

ORDER OF FEDERAL FUEL DISTRIBUTOR, Oct. 4, 1922

Paragraph IV

1. To facilitate reporting and assure the earliest possible reporting by the Federal Fuel Distributor of the latest and most complete information immediately required, compliance with the provisions of Regulation II requiring the daily report of names and addresses of all consignees, with car numbers and initials in问-place wanted as to all producers, who shall continue to keep and preserve full and detailed records showing all movements in each form so as to enable them promptly to furnish such information as to any shipment if and when required in any particular case, or as to any entry in the columns to be employed in answering the following questions:

"Consignee" and "Office Address" apply to consignees, "Car Nos. and Initials" authorize the number of carloads shipped and the names of consignees or shippers;

The "Nature of Consignee's Business" should be designated, where applicable, as "Steam Railroad," "Public Utility," "Wholesale," "Dealer for Domestic Use," "Industrial Use," "Farm and Stock," etc. and like designations.

In giving the "Destination of Shipment," state place of shipment or "Tidewater" or "Lakes" as the case may be.

1. In all cases where the coal is shipped from the mines to the middlemen, or to tidewater or lakes ports for transmission from there to the ultimate consumer, the producer shall keep daily account of all sales shipments upon the form required by Regulation XI; giving in all of the following information:"

Washington Correspondent of Coal Age
Pennsylvania's Estimated Coal Reserve Cut Almost in Half; Enough for 290 Years

According to a survey of the bituminous coal fields of Pennsylvania, just completed by the bureau of topographic and geological survey of the state department of internal affairs, there are 48,830,860,000 net tons of recoverable coal in the state. At the present rate of consumption this supply will last 290 years. The department has announced that prior to this survey it had generally been believed the bituminous fields held at least 75,990,000,000 tons of recoverable coal.

The report says: "The original bituminous coal deposits in Pennsylvania reached a total of 75,250,055,000 tons and thus far only 5,519,655,000 tons have been mined out. Waste and unrecoverable coal leaves a total of 45,830,860,000 tons which can be mined out and used.

"The largest original deposits were found in Washington and Greene counties. Washington originally held 10,526,003,000 tons and Greene 10,030,094,000 tons. Thus far only 42,490,000 tons have been mined in Greene and 557,765,000 tons have been mined in Washington County. The largest supply still recoverable is in Greene County where it is estimated that 7,011,400,000 tons of mineable coal still remain, a supply approximately 40 per cent more than the total mined in the entire bituminous coal field up to the present time.

"Westmoreland County thus far has furnished more coal than any of the other counties, a total of 1,218,141,000 tons having been mined to date. Allegheny County stands second with 969,200,000 tons and Fayette ranks third with 899,544,000 tons.

"The summary of the coal reserves was worked out from detailed county reports in which the area, thickness and quantity of coal in each bed was computed by townships. The work was done by Major John F. Reese, mining engineer, who has had wide experience in the bituminous coal fields of Pennsylvania."

Morrow and Callahan Resign as Officials of National Coal Association; to Form Selling Company

J. D. A. Morrow, vice-president of the National Coal Association, and John Callahan, its traffic manager, have resigned from these offices and will establish the Morrow-Callahan Coal Co., which will act as a selling agent for a few well-known coal producers who will be associated with the firm.

While it is believed that these officials of the National Association would have taken this step sooner or later, regardless of the situation within the National Coal Association, it is evident to the officers and members that there was no inducement to embark in business for themselves at this time by the lack of support being given that organization.

At the present time the National Coal Association represents less than 50 per cent of the country's bituminous production. Mr. Morrow frequently has urged upon bituminous operators the necessity of having within the organization the maximum possible amount of the country's production. It always has been recognized as impossible to have 100 per cent of the production represented in any organization of operators. This is due to the fact that many mines are owned and worked by manufacturing concerns or other consumers as a mere incident of their business. Such operators of coal mines as public utilities or steel makers, for instance, are not immediately concerned with the welfare of other producers of coal. In many instances they are particularly anxious not to align themselves with the operators whose principal business is the production of coal. Nevertheless there is at least 75 per cent of the country's production which reasonably might be expected to join in a national association.

One of the outstanding results of the study of trade associations which has been made since the Supreme Court's ruling in the Hardwood case is that industry must have a practical point of contact with the federal government. Coal is too essential to the public welfare for the government to have to turn to several thousand individuals in an effort to secure information. It is admitted almost unanimously that there must be someone in Washington authorized to represent the bituminous industry. Such a representative must be supported by a staff.

Unwilling to Occupy False Position

Mr. Morrow is believed to have felt that the association is such an obvious necessity that it should have the unanimous support of no less than 75 per cent of the country's bituminous production. When it became apparent that this measure of support could not be obtained, Mr. Morrow is thought to have been unwilling to pose as the representative of the industry when as a matter of fact he was representing only the minority portion of production.

While it is admitted that Mr. Morrow's resignation has precipitated something of a crisis in the affairs of the National Coal Association there is every indication that the organization will continue. It is known that certain coal operators are so convinced of the need of the association that they would be willing to finance it themselves in order to keep it in existence. It is certain that there never has been in the history of the coal industry at which so great a need for some organization exists as at present. What the government has done in the way of regulating distribution and in the creation of a commission, which within a year will recommend legislation and other action of great moment to the industry, well may be the entering wedge for drastic federal regulation unless there is evidence that the coal industry is competent to work out its own salvation. The coal industry confronted with such a situation it is apparent that a point of contact with the federal government will continue to be maintained. It is fully expected that the resignation of Messrs. Morrow and Callahan will emphasize the need for a wider measure of support for the association.

Mr. Morrow first came to the attention of the coal industry in a national way when he wrote the report on coal for the Bureau of the Census, based on the returns of the 1909 census. He was on the point of leaving Washington after the completion of that job when E. N. Hurley was made chairman of the Federal Trade Commission. Mr. Morrow had formerly worked with Mr. Hurley and at his earnest request Mr. Morrow consented to remain to serve as personal assistant to conduct the initial research, which resulted later in the Webb-Pomerene Act, making legal combinations for purposes of export trade. By the time the export investigation was out of the way the coal situation had come in for serious attention, with the result that Mr. Morrow stayed with the commission to make a study of the bituminous-coal industry.

Organized Pittsburgh Producers' Association

Mr. Morrow left the Federal Trade Commission to organize the Pittsburgh Coal Producers' Association. In 1917 he was called to Washington to organize the National Coal Association. In January, 1918, he accepted an invitation from the Federal Administration to reorganize the distribution division of that organization. He continued as head of that division until it was dissolved, when he resumed his position with the National Coal Association.

Mr. Callahan began his career in the train service of the Pennsylvania R.R. Promotions carried him into the traffic end of the work, where he specialized in the problems of coal transportation. His activities as traffic manager for the National Coal Association have brought him into the front rank of the country's traffic specialists.

Governor Davis Signs Order Fixing Coal Prices in Ohio at $3.56-$4.86 at Mine

A schedule of fair prices for coal mined in Ohio and sold to Ohio consumers has been formally approved by Governor Harry L. Davis following a week's investigation of the question by State Fuel Administrator Clarence J. Neal. The prices as announced by the administrator are based on those established by the Federal Fuel Administration in 1918. The new price list is to become effective Oct. 10.

The prices as fixed are for mine-run and provisions are made for a charge of 25c per ton more for lump and 25c per ton less for 'light slack.' The Administrator Neal reports that the price list is to be considered only temporary and will be maintained until a study of the cost of producing and distributing coal now under way is completed, when it is proposed to issue a revised price list. Dealers' and jobbers' prices are likewise to be announced as soon as the necessary information has been compiled. The price list as announced follows:

Dealers' and jobbers' prices are likewise to be announced as soon as the necessary information has been compiled. The price list as announced follows:

District No. 1—Meigs County and Cheshire and Addison townships, Gallia County, $3.66.
District No. 2—Vinton Jackson, Lawrence, Athens, Pike and all of Gallia County, except Cheshire and Addison townships, $3.94.
District No. 3—Butler and Athens mining districts, Coal and Morrow townships, in Perry County, and Homer townships, Morgan County, $3.72.
District No. 4—Wallington and Washington townships, Morgan County, except Homer township and Perry County, except Coal and Morrow townships, $4.24.
District No. 5—Muskingum County $3.94.
District No. 6—Holmes, Tuscarawas, Carroll and Columbiana counties, except Harrison and Harrison township in Harrison County; Washington and Youngstown townships, Columbiana County, and Brush Creek, in Jefferson County, $3.57.
District No. 7—Trumbull, Mahoning and Valley townships; Jefferson county, except the 4A coal in New Alexandria township, Jefferson County, $3.64.
District No. 8—Monroe County, Bolivar County except Warren townships and operations in the 4A coal, in Harrison Township, Jefferson County, $3.64.
District No. 9—Greenup and Warren townships, Jefferson County, except the 4A coal in Newton Township, Jefferson County, $3.57.
District No. 10—Greene County and Warren Township in Butler County, $3.64.
Special prices for coal mined by the Wayne Mining Co. $3.51.
Maryland Householders Bulk at Price of Bituminous Coal for Domestic Use

In a communication from the Maryland Fuel Distribution Committee, alluding to the Federal Fuel Distribution Act, it is stated that no really abundant coal is available for sale. The coal on the market is claimed as a weapon for the control of coal prices. The committee have urged the Government to impose a coal tariff, but the effects of the tariff are not likely to be felt for some months. The Government is urged to use its influence to keep the price of coal down.

State Fuel Administrator Depreciates Move To Enact Coal Legislation in Michigan

Governor A. J. Greenough, issuing the call Oct. 2, saying that his action was encouraged by information from the mines, states that it would be unwise to accept coal distributions after shipments leave the mines. Governor Greenough believes present conditions indicate a serious coal shortage during the winter and he wants to prevent excess-cost prices.

The Detroit Ex-Servicemen supports the position of Mr. Greenough. One of the senators says Detroit dealers have done a profitless trade but and would not seek to impose the same upon others. The Government, he is informed, has been asked to buy coal in order to keep the current price lower.

Willard Makes Suggestions to Railroads To Speed Up Distribution of Coal

At a conference held with Mr. Spens in Washington on Oct. 1, Governor Willard made a report of the distribution of coal throughout the country. The report was unanimous that the national coal companies are unable to meet the demands of the country, and a larger number of coal distributors would be needed to meet the demands of the mines. Governor Willard also gave a general statement of the importance of the coal situation, and he said that the railroads are unable to meet the demands of the mines.

Lake Strike Does Not Halt Flow of Coal

The second week of the strike of miners employed on the Great Lakes by the Lake Erie Steamship Company opened with practically all services still on the water, although the flow of coal over Lake Erie slowed down as the week wore on. The railroads are unable to meet the demands of the mines, and the coal companies are unable to meet the demands of the railroads.

Locals of District 26 Protest Against New Wage Agreement

Phalen local of the United Mine Workers has formally protested at the wage agreement between the U.M.W. for District 26 (New Brunswick, Nova Scotia and Prince Edward Island) and the soft-coal operators, principally the Dominion Coal Co. (British Empire Steel Corporation). This local was instrumental in starting the recent strike which ended in the agreement following the defeat for re-election of the old board of officers including Robert B. Van Cauwenbergh, president of the district. The new board is composed of twelve national board members for the district. The Springhill local also is in the field against the agreement.

The United Mine Workers for District 26 are leading in an attempt to found a labor college. If the college is opened it probably will be in either Glace Bay or Sydney. The officials of the district assert that such a college is a necessity. The labor college, say the union chiefs, would preserve democracy and instruct in coal mining and other occupations.

Due to the large volume of shipments by river, output of coal and coke in the Connellsville coke region is increasing in spite of the car shortage. All operating mines are increasing in man power and output. A couple of union mines on the river nearby in Washington County struck Oct. 4 — the Diamond mine of the Diamond Coal & Coke Co., because the men were ordered to load cars of the Mather Collieries Co., an open-shop operation, and the Lily mine of the Lily Coal & Coke Co., because they were asked to load barges for the Pittsburgh Steel Co., which operates open-shop mines. The miners tried also to get the Pike mine of the Diamond Coal & Coke Co. out, but failed, and the Diamond mine returned to work Oct. 5.

Loc's D. Tracy, of Edgewood, Pa., has been appointed superintendent of the central experiment station of the Bureau of Mines at Urbana, Ill. Mr. Tracy was educated at the Sheffield Scientific School and at Yale University. He holds degrees as both mining and civil engineer. He joined the staff of the Bureau of Mines on July 15, 1918. Since that date he has served the bureau continuously as a coal-mining engineer. Mr. Tracy takes the position made vacant by the recent resignation of J. J. Rutledge, who now is chief mining engineer of the Maryland Geological Survey. J. L. Lamson has been transferred from the Geological Survey's New England district to the New York district, with headquarters at Albany. Harry I. Granger was at the same time transferred from Albany to Boston.

Reports reaching Washington are to the effect that difficulties are being encountered in the burning of the British coal now being imported. The importers contend that this is due to lack of familiarity with the coal, but those who have purchased some of the British coal maintain that poor quality coal has been shipped to America. One of the British cargoes, 7,000 tons, was shipped to Norfolk, which is cited as the latest instance of carrying coal to Newcastle. As this is written, no determination has been reached as to what to do with the shipment.

Very few permits are being issued under Service Order 25. Outside of the Lake movement, only seven permits have been allowed. These cover less than 400 cars. Even these permits are limited to a comparatively small movement.
Mining Congress in Cleveland Is Laying Down National Program for Entire Mining Industry

The American Mining Congress, in session this week at Cleveland, is discussing problems vital to all branches of mining and its affiliated industries with the purpose of laying down a national or even international program for the coming year. The first general aim of the congress is to arouse a protest against "any further encroachment of governmental paternalism in supervising and restriction individual enterprise in the development of mining." The second is to inaugurate a national policy of industrial cooperation which will help to solve the problem of relations between capital and labor and further eliminate needless waste caused by industrial strife. The third is to advance the cause of standardization in methods, processes and equipment.

The congress opened Monday evening in Cleveland's magnificent Public Auditorium with much formality, including an address by Newton D. Baker, Secretary of War in the Wilson administration and now president of the Cleveland Chamber of Commerce. Tuesday's program provided for a discussion at the time that conditions of union and the operators Wednesday morning was devoted to coal. Thursday was to be national standardization day with parallel sessions on industrial co-operation. On Friday, the 13th, metal mining problems are to be foremost. The "silver anniversary banquet" of the congress Friday night is to be the final event of the convention.

All through the convention the program was shaped to eliminate "spread eagelism" and hold every session down to essential facts and matters of real importance to mining. As the convention opened it was predicted that more than 3,500 miners face mining's daily problems would attend and listen to the speakers. In all, there were about 300 meetings.

In all its 25 years the congress never met in more beautiful surroundings than in the new auditorium. The main arena or ground floor of the great building provides a floor 247 feet long and 120 feet wide without a post or obstruction of any kind and is illuminated largely through an 80-foot ceiling made mostly of glass. The permanent decorations are in a soft shade of gray with blue in the balcony trim and highlighted in gold. The same colors prevail in Machinery Hall, which is directly below and reached by a winding staircase and several ramps of easy grade.

The exhibits of machinery and equipment are shown artistically in this building. There are about 200 displays of one sort or another, including a demonstration by the Bureau of Mines of new breathing apparatus and other approved appliances, a working model of a Hudson Coal Company's anthracite mine by explosive plant, a state exhibit by Colorado, a small display by the Mexican government and row after row of booths showing the most modern types of mine equipment.

Highlights in the entertainment of the week were the smoker and carnival of Wednesday night, daily organ recitals throughout the convention and much singing by the famous "anthracite sextet" which so often has entertained visitors underground in the Pennsylvania hard-coal region.

Union May Abandon District 29 Because of Partiality of Miners to Open Shop

Abandonment by the United Mine Workers of District 29, which covers the New River field and a small part of the Winding Gulf field, understood to be contemplated by the union organization, is regarded as the logical sequence to developments within the district during the last two years. The proposed relinquishment is due to the fact that there are now so few union miners in the district that a district organization can no longer be supported financially. If District 29 loses its identity as such, it will either be combined with District 17, of which C. F. Keeley is president, or the territory will be looked after by the International Auxiliary in District 28, which the union now has the right of in District 29.

That it has not remained such is due to two factors. In the first place the check-off has never been popular among the miners. That was demonstrated by the opposition to that feature of the Sept. 1, 1919, contract when it was submitted to the miners in a referendum. It was freely stated at the time that a majority of the miners voted against ratification but that the votes were counted for ratification. The other factor which has led New River operators to adopt the open-shop plan is the frequent strikes and lawlessness displayed by an element among the miners.

When the 1919 contract was agreed to by most of the operators President William McKell and other operators representing about one-tenth of the tonnage of the field refused to become a party thereto and continued to operate on the open-shop plan. Some of the more radical union miners in the district sought to prevent such operation by attacks on McKell plants and did succeed in closing down the Willis Branch Coal Co.'s mine after almost two years of violence. A number of union miners were tried and convicted for such violence and are serving terms in the penitentiary.

No sooner had the operators of the New River field signed the new contract than the men went out on strike on Nov. 1, two months after the new contract became effective. The miners themselves started the move for open-shop operations, early in 1921 asking the operators to resume on a wage scale lower than that of the union. Many of the miners at that time returned to work without any union agreement. Although some of them responded to the strike call of April 1, 1922, mines in the New River field continued at work throughout the strike under the protection of a federal injunction. When an agreement was reached elsewhere by the union no move was made to force the New River field operators to sign an agreement, simply because no sentiment existed among the miners and because they were receiving wages as high as those paid union men without having any agreement or without having to pay money to the union through the check-off.

SEVERAL IGNITIONS OF MINE GAS which might have led to explosions and at least one mine fire attributed to heated leg wires of electric detonators have occurred at mines in which outside shotfiring is practiced. Photographs taken at one mine indicated that the wires became red hot during firing. These results having been called to the attention of the electrical section of the U. S. Bureau of Mines, a series of tests were made at the Pittsburgh (Pa.) experiment station to determine, if possible, the cause of the ignitions and to aid in preventing future trouble of this kind. The investigation, which is considered preliminary, included tests to determine the conditions that cause gas ignitions from heated leg wires of electric detonators, possible remedies for such heating, and the relative behavior of iron and copper leg wires. Details of these tests are given in Serial 2385, "Ignition of Gas by Electric Detonators," which may be obtained from the Bureau of Mines, Washington.

H. F. Bell, Foreign Freight Traffic Manager for the Erie Railroad Co., has been given a leave of absence at the request of Fuel Distributor Spens to assist his organization during the existing emergency. Mr. Bell was associated with Mr. Spens in his work for the Railroad Administration and also was one of the traffic staff of the War Industries Board during the war.
Weekly Review

Prices are on a continued movement to stay out of the market as coal prices seem slow. Industrial coal is being held on a hard-to-smooth basis, for immediate requirements only. Industries throughout the country have responded to the suggestion that business buy coal according to its current needs during the present emergency and the practice is now general.

The effect of the curtailed demand is read in the last two weeks’ decline in spot prices of bituminous coal, as shown by Coal Age, Index, which stands at 330 on Oct. 5, representing an average spot price at the mine of $4.00. This is a drop of 25c. as compared with the previous week and 46c. below the average price of $4.00 on Sept. 25.

Post transportation conditions and the growing car shortage tend to modify the price break. Were it not for these factors the present market would range lower all around until the so-called buyers’ strike had pro-

ized the price level which would tempt the consumer to order heavier orders.

IMPORTANT TO END INDUSTRIAL BUYERS’ STRIKE.

The coal industry has a very definite deficit to overcome before reserve stocks can be brought up to anything like normal. Right now current requirements are absorbing current production, but the approach of real-burning weather with its attendant transportation difficulties always spells increased demand. If industries call off their buyers’ strike and if the railroads give the preference to coal movement that the occasion demands this situation can be met without a reversion to the boom market of two years ago.

Worse weather has reduced the call for domestic coal. Dealers are now having trouble in moving supplies and are inclined to reduce their orders to the mines. Too many people are waiting for household coal to follow steam sizes down in price. The result is producers are feeling the pressure for a reduction on domestic mine prices.

New England is in the heaviest supply of any section of the country and the Northwest, of course, is the shortest. In the former market both all-rail and water-borne fuel is selling off and receipts are dropping. Lake business is very heavy, but the tremendous dock receipts of the past few weeks have so completely dispelled fears of a fuel famine that it has reduced consumer demand and threatens to affect the placing of additional orders at the mines.

The second week of the strike of sailors employed on the Great Lakes shows practically all vessels still on the move, although dumpings at the lower ports declined in the last week. The sailor’s union has protested to Secretary Hoover that vessels were leaving port undermanned.

Breaks in the price of steam sizes of anthracite are reported from several of the larger markets. This is due to oversupply and large producers are running this coal to mine storage. Warm October weather together with the great quantity of soft coal flooding the market has been responsible for a remarkable shrinkage in orders for the smaller coals.

Demand for the larger sizes of hard coal is, of course,
The market for coal, however, has been affected by the unseasonably warm weather and the inevitable rush to cover has been delayed at a time when dealers welcome every day's respite to enable them to get in more adequate supplies. Mines are handicapped by ear shortage and rail delivery is very slow.

**BITUMINOUS**

"A slight decrease marked production of soft coal during the first week of October," says the Geological Survey. "Over three weeks in succession the output had been slowing, reaching 9,776,000 net tons in the week of Sept. 30. During last week (Oct. 2-7) the returns so far received indicate a total of about 9,600,000 tons. Although the aggregate shipments of soft coal have increased gradually during September, the shipments from individual producing districts have fluctuated irregularly. In Pennsylvania there was a slight decrease each week since Sept. 15, and the week was begun with shipments a lower rate than the previous week. In Maryland and parts of northern West Virginia there has been a steady increase, but in southern West Virginia there has been a steady decline. In Kentucky there had been little or no change up to last week, for which, however, a decline is indicated. In Alabama daily shipments have been falling off since the close of the first week of September. In Ohio, Indiana and Illinois there have been gradual gains, which now appear to be checked. West of the Mississippi shipments have in the main steadily increased."

New England is the target for heavy tonnage. Western congestion is diverting much coal eastward, forcing it on an unwilling market, with softening quotations. All-rail shippers are pushing sales in an attempt to keep up their production. During the week ended Sept. 30 there were 3,541 cars of soft coal forwarded through the Hudson gateways, as compared with 3,255 in the preceding week.

*Figures furnished by the Massachusetts Fuel Administrators subject to revision.

Westbound coal movement through the "Soo" during September was 2,364,550 net tons. Of this amount only 10,805 tons was hard coal.

Hampton Roads is in oversupply for the same reason and pier tonnage is increasing. Dumps during the week ended Oct. 6 were 262,945 net tons as compared with 288,053.

**NOTE:** Smokeless prices now include New River and southeastern.
HOW THE COAL FIELDS ARE WORKING

Popular demand has increased during the past weeks on account of the weather, which has been mild, and the increased demand for coal for home heating and cooking. The production of bituminous coal has been steady, with a slight increase in the past week. The price of coal has remained stable, with no significant change from the previous week.

Coal Age Index 289, Week of Oct. 9, 1922. Average spot price for same period, $1.68. This diagram shows the relative, not the actual prices on fourteen coals, representative of nearly 50 per cent of the bituminous output of the U. S. weighted in accordance with the proportions of each ton of black, prepared coals, and non-coal tonnage normally shipped and received, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1921, as 100, after the manner adopted in the report on "Price of Coal and Coke, 1913-1918," published by the Geological Survey and the War Industries Board.

Independent prices show a wide range. The family sizes are going as high as $14 at $15 in the outlying districts and in Canada, while Eastern centers are paying around $10.50. This is especially true in Philadelphia where high-priced coal is being little quoted and rarely, if ever, taken. New York market prices have dropped from the high range quoted last week. The steam market has been extremely hard hit by the heavy tonnage and the strong competition of bituminous coal.

Unless coal reaches the bins shortly, the only place many Americans will be warm this winter will be under the collar. —Indianapolis Star.
Foreign Market And Export News

British Obtain Orders from Continental Markets; Prices Held Firm

Best British coals continue to strengthen. There is a good demand from Germany, Canada and Italy. The lower grades are more freely offered, however, and with less price firmness. A cable to Coal Age places the output during the week ended Sept. 23 at 5,144,000 gross tons as compared with 4,995,000 tons in the preceding week.

Much anxiety is felt over the threat of Welsh miners to give notice to terminate all contracts on Nov. 5, unless the non-union miners join the Miners' Federation.

The outlook in Durham and Northumberland is considerably brighter. The past few days have been marked by a revival of Continental inquiries and orders, which are more welcome than the American orders. The special feature of the European awakening is the interest taken by the Continental gasworks. The European railways are taking more British steam coals, and 150,000 tons have been sold on German account.

The same feature is found in the Yorkshire fields, where the export trade has picked up appreciably. Forward ordering has attained a level which leads the operators to believe that the Continental market is regaining the pre-war standard. Another feature of the Yorkshire area is better business in the home markets.

Coal Freight Rates Reduced in France

French coals from the Nord and Pas-de-Calais area have still a favorable market. There is now quite a rush for domestic. Industrial coals also are in a favorable situation. Gas coals are very scarce.

On the other hand, the situation of the minor fields of the center of France, which are feeling the pinch of the competition of Lorraine and Pas-de-Calais, is far from being satisfactory and more small mines are closing.

The various reductions on rail rates for coal from the Nord and Pas-de-Calais have been approved by the French Minister of Public Works for a provisional period of three months from Sept. 20. These are deemed insufficient by French collieries, all the more so as they are offset by a similar reduction granted on the transportation of Sarre and Lorraine coals.

No progress is to be reported in the conflict between operators and men, but a general strike of miners about the middle of October is not at all impossible. Mines of the Nord and Pas-de-Calais are said to be already preparing for it by shackling down their shipments.

Representatives of the Swiss Federal Railways are now negotiating with French reconstructed collieries for a briquet contract.

Hampton Roads Market is Weaker

The market was dull last week, a slight movement in export business providing the only redeeming feature. For the first time in many months the piers reported only about 10,000 tons of vessels waiting for cargo. Prospects for increased movement in the immediate future were very slight.

Prices continue downward, and shippers express the hope they might drop far enough to permit a stronger movement of export coal. Large stocks are on hand at the piers.

Coal Paragraphs from Foreign Lands

ITALY—The price of Cardiff steam first is quoted at 39s. 6d., according to a cable to Coal Age.

AUSTRIA—The output of coal and lignite during the first half of 1922 was 1,874,000 tons, a falling off in the second quarter ($10,000 against 86,000,000 tons in the first) due to serious labor troubles.

INDIA—The tendency of the coal market is weaker. Supplies are adequate. Mills and railways are out in the market and quotations are unchanged.

BELGIUM—The market is very firm, both in the domestic and industrial sections. Briquets are in great demand for home consumption and for export.

GERMANY—Production in the Ruhr region during the week ended Sept. 24 was 1,892,000 metric tons, according to a cable to Coal Age, as compared with 1,847,000 tons in the preceding week.

Heavier Offerings in East

With Western Railway Jam

Lake Superior and Shipping Conditions—Average Central Still Water on Price Decline. Deal in Warning of Shortage—Railroads Buying Heavily.

Coal competition to the West and Greater overseas offerings overseas. The movement is very slow, as there are many shortages and shipping conditions are becoming more complicated each day. British coal suppliers are active, but in smaller volume.

Prices are dropping slowly and such decline measures the average assessment of the wisdom of his buying policy. He is due to warnings of a shortage in some and maintains his attitude of aloofness, covering only at current requirements. Railroads, however, are taking heavy tonnages, assuming so many pairs for this railroad that the supply for loading commercial coal is very heavy.

There is almost no loyalty at Timidwater. Long shipments are slow in getting through from the mines and sellers are devoting much of their attention to local cars to indication.

PHILADELPHIA

There is lack of market activity. Effect of the shipping house being promptly and directly in the way of prices. Price is not doing a broad deal of the business at present, and the bulk of the business in the local coal is very much lower in the local market.

There is no steady Scholars of various kinds to affect that shipping house is unable to keep track of these prices. The sale of the local coal is in the hands of the producer, and the dealers are too busy with other concerns to keep them in track so many pairs for this railroad that the supply for loading commercial coal is very heavy.

The market is not doing a broad deal of the business at present, and the bulk of the business in the local coal is very much lower in the local market.

There is no steady Scholars of various kinds to affect that shipping house is unable to keep track of these prices. The sale of the local coal is in the hands of the producer, and the dealers are too busy with other concerns to keep them in track.

There are no steady Scholars of various kinds to affect that shipping house is unable to keep track of these prices. The sale of the local coal is in the hands of the producer, and the dealers are too busy with other concerns to keep them in track.

Baltimore

A carload twist has arisen in the local situation for the reason that car supply is becoming more complicated. A check in the order of procuring has been reformed in evidence of this. The car shortage, particularly in the West, is becoming more and more evident. On the line of the Western Maryland in the Potomac field. The curtailed supply of reduced production at a time when the rate of output was about 60,000 tons a week, or not far from normal. The curtailed supply of empties, however, found mines with less of a demand to meet owing to the large tonnage in Eastern markets, the effect of which has been to reduce prices.

New York

There is practically no inquiry at Timidwater. Long shipments are slow in getting through from the mines and sellers are devoting much of their attention to local cars to indication.

South

Birmingham

The problem of the trade continues to be one of car supply. The quota furnished the past week ranged from 30 to 40 per cent of the number needed, and the market of speculation is in the near future not bright. Much of the equipment of local carriers found its way into foreign territory during the period of shortage and the strikers coal has never been returned to the owners.

There is a strong and urgent domestic demand from every direction. Dealers with contracts are not purchasing their quota by any means, due to car shortage. The easing off in the demand for steam coal is also affecting the supply. Quotations are remaining fairly stable on steam grades though some seams have been selling 25c. @ $35c, under the maximum schedule the past week.

The output is holding up well considering the acute car shortage, a total of 345,000 net tons being reported for the week ending Sept. 30, the last figures available. The week of Sept. 30 will probably show a decrease, as transportation conditions were not so favorable.

Virginia

So far mines have not been able to overcome the handicap of a car shortage which is curtailing production to the extent of 50 per cent. It is not so much the strike of shippers as it is the fact that few of the roads are able to put their hands on enough demand to keep the mines supplied. The demand for coal is weaker, and as a result, the price of coal has softened somewhat.
Anthracite

Rush in Domestic Business, Steam Sizes Drug on Market

New York harbor terminals are heavily congested with steam loads of anthracite. Railroad officials fear that the tying up of these cars will seriously affect the fuel situation at New York. Steam sizes quickly became a drug on the market following the resumption of mining, and those producers who have such facilities are now storing these grades.

Domestic business is, of course, rushing. Coal is being portioned out to consumers in small lots and the unseasonably warm weather has fortunately delayed the inevitable rush of householders. Independent quotation show a wide range but the extremely high-priced coal is going to small towns or Canadian points, as Eastern distributing factors are loath to pass on these premiums to their customers.

NEW YORK

Lack of demand has resulted in an accumulation of steam coals here. At the end of the week there were about 3,500 cars containing upward of 175,000 tons on the various railroad terminals adjacent to the New York harbor.

Because of the failure of consumers to take this size and the ever mining companies have reduced the output of these sizes by closing down various washeries and are again storing the present production. That there should be an oversupply at this time is attributed to the supply of bituminous.

Dealers predict that unless the weather becomes unusually colder during the next four weeks and with production continuing at or about the same basis as at present, the situation will be comparatively easy. In the West, however, users of anthracite will be forced to take soft coal.

Quotations for independent domestic coal cover a wide range starting at $9.25, most of the big operators going as high as $9.50.

PHILADELPHIA

Moderate shipments to retailers are coming in and as a result deliveries to consumers are going along quietly. The remarkable run of warm weather has temporarily held up this business.

There is much speculation as to the relative scarcity of peat, as most dealers had an idea it would be plentiful. Numerous dealers have put in requests urging prompt delivery of this size, probably not with the idea of moving it at once, but to get some stock ahead. Retail prices are unchanged. Wholesale quotations show no appreciable change in the last week. Independent prices higher than $9.50 are heard repeatedly, but sales are rare.

The State Fuel Commission is hearing the arguments of independent shippers to establish their right to get more than $8.50. It is likely the present prices will be approved in all cases, and in few instances even higher figures will be allowed later.

Steam sizes are moving along nicely, although there is just the slightest tendency for a slowing down on rice, but all shippers are easily able to get full prices. Some retailers are taking a small tonnage of buckwheat, generally at the urging of the shippers.

BUFFALO

Demand is rash. It would be impossible for a while to satisfy the consumers with five times the ordinary supply.

The independent mines are trying to ask $12 up, but jobbers are afraid to buy, because they have to report their sales to the fuel administrator and the prices they have to ask look bad. It will be a long time before the trade comes around.

The effort of the Lake seamen to tie up the fleet by a strike appears to have failed. The steamers move as usual. The west-bound coal movement is tight. Shippers have to date since the beginning on Sept. 23 have been only 91,500 tons, of which 46,600 tons cleared for Milwaukee, 31,300 tons for Duluth and Superior, 15,700 tons for Chicago and 7,700 tons for Sheboygan. Rates are 40c. to Duluth, 50c. to Milwaukee, Sheboygan and 50c. to 55c. to Chicago.

BOSTON

Shipments are coming forward steadily. There are large retail distributors who have not yet had cargoes of prepared sizes, but there seems less anxiety than a fortnight ago. Rainy weather has delayed the on-coming rush, but in another fortnight there will be heavy pressure on all the anthracite channels to provide increased supplies.

No change has yet been made in retail prices. What coal is being passed out is at figures that prevailed during the spring, except in peat sizes which is either sold mixed with other sizes or commands a price on an equal-

BALTIMORE

Receipts are light and dealers are sticking to their resolve to deliver not more than one or two tons to a customer. Additional receipts are expected as a result of the announcement of a new freight rate of $3.28 on coal from the Schuylkill field of Pennsylvania. This rate was arranged by agreement with the P. & R. and the Schuylkill schedules. The R. & O. will carry coal from the Schuylkill field at the same rate charged by the Pennsylvania for coal from the field which they tap.

The Maryland Distribution Committee has taken up with Pennsylvania producers the question of supplying peak and bushel men in this city who claim that they are unable to get any. The committee has planned to work out some measure by which the poor of the city who buy in bushel and peak lots will be able to get supplies.

Coke

CONNELSVILLE

Connelsville coke remains as scarce as ever and prices on an average are a shade above those of a week ago, with furnace at $12@$12.50 and foundry at $13.50@$14.

An additional furnace has resumed on coke bought in the open market, a second Shenango stack, while Struthers furnace blew in Oct. 7 on coke obtained through an old contract. In general there is not enough coke in the open market to enable any furnaces to resume by simply buying coke, while most furnaces would probably hesitate to pay present prices even if they were sure of getting a steady supply.

Consumers have shown such an inclination to pay present pig iron prices that furnaces are now getting into bush as might be supposed from a mere comparison of coke and pig iron prices.

There is a good bit of inquiry for foundry coke, but the majority of foundries seem unwilling to pay present prices. Enough are willing to buy to support the market at present level, with offerings relatively limited.

The Courrier reports production during the week ended Sept. 30, at 90,000 tons by the furnace ovens, and 28,430 tons by the merchant ovens, a total of 118,430 tons, an increase of 13,340 tons.

UNIONTOWN

Despite an acute car shortage, raw prices have slipped off several notches, with $5.25@$5.50 prevailing and probably sales made at lower figures. Business and orders are steady in finding destination for large shipments but encounter very little trouble in placing small lots. That would infer that buyers have placed their coal requirements upon a hands-to-mouth basis.

The union intends continuing its fight in the Connells ville region, seems indicated by the erection of barricades by the Lake furnaces against evicted miners who are now living in tents. At both Uniontown and Connells ville there are evicted families living with other families. At Uniontown with authority and shear families out of an old warehouse because of health conditions as well as the menace of fire. Many of the families are reported to be in straits and the drift back to the mine has increased.

BUFFALO

Demand is light, but the supply so small that high prices are generally maintained. But for the fact that we have a good line of supply in present prices of beet coke would still sell more.
Chicago and Midwest

Bottom Softens Under Midwest Coal Trade

Even Domestic Demand, Which Has Been Strong, is Weakening—Steam Prices Sag Lower—Rail Service Continues Harder—Cold Snap Desired.

The outlook Midwest is getting drier and deeper in the grip of the winter weather. Reports from Kentucky and Tennessee, however, show that rail tonnages remain steady. The eastern coal market continues active.

STEAM SCRAP RAPIDLY

Steam coal prices displayed a downward trend recently. A report stated that the price of steam coal in the eastern markets dropped to $2.75 per ton. The price is based on 6,000 tons per shipment. This price is $0.25 per ton lower than the price three days ago. The drop in steam coal prices is expected to continue.

WESTERN KENTUCKY

The demand for steam coal in Western Kentucky has recently increased. The demand is driven by the colder weather, which increases the need for coal to generate heating in homes and businesses. The supply of coal in the area is sufficient to meet the demand, and the prices for steam coal remain steady.

LOUISVILLE

The demand for coal in Louisville has been strong, with prices remaining stable. The market is expected to remain active due to the colder weather. The supply of coal in the area is sufficient to meet the demand.

ST. LOUIS

The demand for coal in St. Louis has been strong due to the colder weather. The market is expected to remain active due to the demand for heating in homes and businesses. The supply of coal in the area is sufficient to meet the demand.

INDIANAPOLIS

The demand for coal in Indianapolis has been strong due to the colder weather. The market is expected to remain active due to the demand for heating in homes and businesses. The supply of coal in the area is sufficient to meet the demand.

SOUTHERN ILLINOIS

The demand for coal in Southern Illinois has been strong due to the colder weather. The market is expected to remain active due to the demand for heating in homes and businesses. The supply of coal in the area is sufficient to meet the demand.

The demand for coal in the Carterville field has increased, and the supply is expected to increase in the near future. The demand is driven by the colder weather, which increases the need for coal to generate heating in homes and businesses. The supply of coal in the area is sufficient to meet the demand.
Eastern Inland

More Pressing Need of Coal Gives Market Better Tone

There is a slightly better market tone. Under pressure of growing coal needs and more firmly held prices industries are showing signs of interest. There is no snap to the market but it has lost some of its apathetic tone of the last few weeks. The general policy has been to buy for current needs only, but more of such takers are in the market.

Governor Davis’ announcement of the temporary Ohio fair price list has caused some operators to say that if it is enforced they must send their product out of the state, where higher figures can be obtained. The establishment of these prices is causing shippers to force the Lake market, which is paying $4.25 for good No. 8, as compared with Ohio’s list of $3.56.

Lake dumpings are still heavy, although rail congestion is reducing the movement somewhat. Vessels are clearing quickly and but little effect of the Lake seamens’ strike has been felt as yet. Dumpings at the lower ports during the week ended Oct. 9 were 1,087,265 net tons, as compared with 1,245,373 tons in the preceding week.

The Pittsburgh market is still distinctly dull. Consumer requirements seem to have been over-estimated. However, the sluggish market is not a factor in controlling the output as yet, as cars are far too scarce to permit prompt loading of the orders in hand.

PITTSBURGH

Demand has fallen off in marked fashion and the market is commonly described as being distinctly dull. Prices have declined 25c. to 50c., but are now practically stationary.

All told, consumptive requirements do not seem to be as heavy as was predicted. The average buyer is quite content to cover his immediate requirements, showing no disposition to buy even for a short time ahead. Demand from retail dealers is fair, but seems to be for current distribution only, the dealers being unwilling to put in any stocks. Truck mines are still doing considerable business in domestic fuel and in some cases are making prices well below what can be done on rail coal.

Production is not affected by the dull market as prices still show a wide margin. The limiting factor in production is car supply, which is hardly as good as 30 days ago and is of course far below mine capacity. The market is quoted at $3.50 to $3.75 for good grades of steam coal, $4.50 for byproduct, $4.50 to $4.75 for good gas, and mine run, and $5.25 to $5.50 for best grades of domestic 11-in. lump.

BUFFALO

Shippers are urging consumers to buy, pointing to the fast-growing shortage of cars, but the advice is not much heeded. The talk is called mere effort to work off coal. So the prices are high and the more the consumers refuse to buy the movement is declared to be less than consumption, but the consumer does not mind that, so long as he believes that $5 is pounding down the price. The decline is not likely to last. In fact, the shipper is unable to see how the opposite is not the case. One result is the general overlooked. The natural production is large and somebody is managing to get his coal to destination.

As to prices there is naturally a wide range. Some shippers manage to get as high as $4.50 at the mines for gas or Pittsburgh lump and some mines are offering good coal below $4. A fair average is $4.50 for Allegheny Valley run as being equal to No. 8, and $5.25 for Pittsburgh lump, with a little more for gas lump. The freight to be added for Buffalo delivery is $2.00 for Allegheny Valley and $2.25 for Pittsburgh.

CLEVELAND

A slightly better tone in the market is reported. There is nothing resembling activity, but operators and dealers are somewhat encouraged by what they believe is a growing disposition of buyers to come into the market at prevailing prices. For some weeks consumers have been holding out for lower levels.

Under the pressure of growing coal needs, and with the price showing no further evidence of important declines, industries are giving indications of buying. The state fuel commission has announced the usual scale of “fixed” prices. The level of $3.50 for No. 8 mine run is regarded by most operators as unreasonably low. Since there is a fairly good market in the Lake is $4.25, as much coal as possible will be sent out of the state. The shortage of cars is becoming more and more pronounced in this district. Current quotations are shown in the Weekly Review.

The Lake movement continues at high speed, apparently undisturbed by the walk-out of the union seamens. It is now believed that it will be possible to ship the Northwest more than 15,000,000 tons, which was regarded as the limit a month or so ago. Fears of shortage in the Northwest are greatly diminished and there is no panic of buyers apparent.

NORTHERN PANHANDLE

Accumulation at the Lakes constitutes the most serious interference with the movement and is having a tendency to check production. Although there is not quite so string a demand for steam coals, nevertheless more coal could be moved if the transportation situation permitted but terminals are congested with cars. There is more of a demand for lump than any other grade.

COLUMBUS

While the “buyers strike” is not over, still there is evidence of a disposition to buy. Lake shipments are going forward, many embargoes having been removed.

Householders are coming into the market more and more, but the continued warm weather is still delaying them. Retail prices are rather steady at average levels, with Hocking lump, $8.75 to $9.50, and semi-lumps grades up to $11.

The Pennsylvania has removed its Lake embargo and the same is true of the lake-carrying roads. The New York Central is still holding its own and little coal is going through on either the K. & M. or the T. & O. C. H. V. Rys., shipments are not interfered with.

DETROIT

Not very much interest is being manifested in the market. Summerlike temperatures during the week have soothed the household consumers into lethargic indifference. Detroit’s receipts are still far below the amount which dealers estimate as the city’s average daily consumption.

A theory advanced by some that the strike of the sailors’ union of the Great Lakes against the Lake Carriers’ Association effective since Oct. 1, would not handicap the shipping interests as to reduce coal loading and increase the quantity available for shipment to Detroit, has not developed into actuality, as the boets of the Lake Carriers’ Association are being maintained in operation, apparently unaffected by the strike, and the volume of loading of the last week approaches 1,000,000 tons.

The larger part of the present supply is coming from mines in Ohio. Hocking lump and run is quoted at $6.50 to $6.75, Allegheny Valley run, $7.25 to $7.44, Allegheny Valley and slab, $3.25 to $3.50. Pittsburgh No. 8, run, is $5 to $6, lump is $3, mine run, $4.10 to $4.33, slab, $3.75 to $4.75. Fairmount lump is $4.50, mine run, $4.25, $4.40, $4.55, slab, $4.25. West Virginia and Kentucky lump and run, $6.25 to $6.30, mine run, $4.75, slab, $5.50. The draft coal, arriving in small amount, Jardine, are receiving independent quotations of $3.75 to $4.10 at the mines. The freight charge is $4.95, making the retail price very high.
New England

Heavy Reserves Postpone
Big Buying Till January

Large Volume of British and Southern Coals Depresses Market—Receipts Ahead of Same Period Last Year—Consumption Lower—Prices Drop.

There is very little buying power left in the current market. The avalanche of British coal, together with heavier receipts of Southern coal, has increased reserves to so great an extent that there is hardly a chance of any comprehensive purchasing before January. Throughout this territory receipts have been much larger thus far this year than during the same period in 1921, while consumption has been notably less. It is very difficult to see, therefore, how there can be any improvement in trade conditions the next 30 to 60 days.

Prices are materially lower. Hampton Roads accumulations have reached 150,000 tons and receipts of Pennsylvania coal are declining with the market.

This week prices have slumped all along the line. From $9.15 asking price on cars Boston for Inland delivery the spot market has eased off already to $8.50 and less. At Hampton Roads 50c has been quoted as soft coal, the wholesale prices of both sorts have being $8. Other grades of soft coal remain unchanged. Hard coal is down to $7.50, the lowest it has been for some time. The danger of a fuel shortage is now rapidly dissipated by heavy receipts. It is evident, however, that many hard-coal consumers will have to turn to soft coal. There is some talk of rationing the anthracite as it arrives. Thus far in October, 20 cargoes have been docked, aggregating 50,000 tons of anthracite, and 150,353 tons of soft coal.

September cargo receipts aggregated 63,343 tons of soft coal, making the receipts of cargo coal for the season 720,561 tons of soft coal, and 1,250,955 tons of soft coal. During the same period car-ferries brought 20,794 tons of anthracite, and 77,633 tons of soft coal. Rail receipts aggregated 50 tons of anthracite, and 162,746 tons of soft coal, making the grand total of hard and soft coal from all sources since the season of navigation opened up to Oct. 1, 1,246,679 tons.

No Fear of Famine in Upper Lake States

Boston-Buffalo-Rocky Mountain traffic on the Great Lakes has been maintained at high rates. The Cleveland Electric Illuminating Co., which had a large number of units off the grid, has been busily working on the purchase of additional service, and will probably begin to reduce the current of units on the output. The amount of traffic in the region has been increasing at a rapid rate, and the coal companies are making every effort to keep up with the demand.

MINNEAPOLIS

The Northwest’s tone of a coal famine is about gone. It now appears evident that enough coal will have arrived early in the new year to meet all requirements, and that the situation is well in hand. The coal trade has learned that it could handle the situation if it would be accorded some time to get things right. The buying and selling done during September and the early part of October is to be expected. It will only be a short time, with the new year on the way, before the market will begin to recover. The demand for coal, both current and future, is expected to be sufficient to keep the market well supplied.

There has been a great number of coal dealers dealing for future coal, and the amount of business has been considerable. This has been due to the fact that the price of coal has been high and the expectation of a further rise has kept their prices high with their customers.
Cincinnati Gateway

Trade Watches Prices in Other Producing Fields

As Quotations Recede and Rejections Increase, Byproduct, Gas and Domestic Coals Are Market Bulwarks—Some Still Base Hopes on Car Shortage

With quotations slipping a bit more rapidly, rejections increasing in volume and reports piling up of Northern terminals being clogged with coal—the first time that such a situation has obtained since last April—it can well be said that by-product, gas and domestic coals are the mainstays of the market at this writing.

Lake buying has temporarily ceased and with this highly competitive feature playing little part in the bidding for coal and on top of this many buyers discriminating against shipments that will not come up to grade, the trade has been looking about and there has been a disposition to keep a weather eye on what other producing fields are doing in the way of naming prices. Those jobbers and wholesalers who believe that the cream can be skimmed forever are still holding tight to their estimates based upon a scant supply of empty cars, but this feature can no longer be taken as a barometer.

LOW-VOLATILE FIELDS

New River and the Gulf

Buyers are trying to maintain control of the market by declining to buy until prices reach a lower level but are unable to dominate the situation as much in the West as in the East, according to conditions reflected in the New River field. The continued shortage of cars is preventing more of a break in prices. Most of the coal has been moving to the coast, since it is difficult to get smokeless through to Western markets where there is a strong demand for prepared sizes. The car supply is not averaging over 30 per cent.

Winding Gulf mines were greatly hampered during the final week of September by the extremely poor car supply. It was not possible to produce more than 100,000 tons representing less than 40 per cent of capacity. Even under normal conditions little coal from this region moves westward and now that these lines are congested less tonnage than ever is going west. Tide water is soft owing to the large volume of receipts.

Pocahontas and Tug River

Pocahontas coal is being diverted to Tidewater and the East, the Pennsylvania

vania and the Hocking having imposed an embargo on coal originating in the Pocahontas region owing to conditions at Lake piers. The car supply is holding back production to a material extent. The greatest difficulty is in getting empties back from Western lines, much equipment being under load at the Lakes.

Tug River mines are not producing more than 75,000 tons a week, owing chiefly to a poor car supply. Buyers are showing a disposition to remain aloof from the market and to "bear" prices but a poor car supply is modifying the downward pressure.

CINCINNATI

So many mines are pouring out mine run with little or no attention to preparation that domestic business is still the keener feature of the Cincinnati gateway. Lump coal is scarce, but on the other hand the retail buyers are shying at taking any great amount. They are buying only a few in small deliveries until the price comes down to a lower range.

The smokeless situation is hardest to fathom. The situation is good even though $6@6.50 is the price on mine run and this in the face of the fact that Tidewater prices are $1.50 and more below. The rub of the situation seems to be that the Western embargoes are holding this back while the seaboard is getting more of this coal than it will absorb. Producers are still rolling at the Hoover price if you wait your turn in filling the order. Jobbers and wholesalers force the price to the limit when they have car numbers to offer.

There has been no change in the retail situation. A large tonnage is on its way down the Ohio in barges, but less water is being sent in ton per ton. It will take a couple of hundred thousand tons by water to make any visible effect on the present retail prices being charged here.

HIGH-VOLATILE FIELDS

KANSAS

Although buyers in general were showing an inclination during the closing days of September to stay out of the market in the hope of securing fuel at lower prices, yet the scarcity of coal due to a poor car supply and congestion at terminals was tending to keep up prices. For domestic coal there was a strong demand. Although striking shopmen of the C. & O. are all back at work, the improvement in the transportation situation is not marked owing to the heavier movement of general freight.

LOGAN AND THACKER

Logan mines are still confronted with such poor transportation facilities that the output is not as much now as in the earlier days. River mining has been almost a thing of the past and thus buyers were holding aloof there was more than enough demand to absorb the output. Although mines are supposed to ship a large tonnage to the Lakes, little headway was made in getting coal through owing to congestion at piers. Prices were softer on fuel for Eastern delivery and comparatively little tonnage was being consigned there, and especially to Tidewater.

More than half the full time output of the Kenova-Thacker district is being lost through a shortage of cars. The best demand is in the West but difficulty is experienced in getting fuel through owing to embargoes. Lump is not to be had although prospective buyers are willing to pay almost any price for it.

NORTHEASTERN KENTUCKY

In the face of a demand somewhat restricted owing to the effort of buyers to force prices downward, prices are not so far as yet are on a lower basis, the coal bringing a little more than steam. Inasmuch as operators are experiencing no difficulty in marketing mine run, no effort is being made to produce lump and egg. There has been little change for the better in the transportation situation.

West

SALT LAKE CITY

The coal price probe continues. Many operators and retailers have been examined. Sessions are behind closed doors and there is no indication as to whether or not they will be prosecuted.

Retail business is quiet as a result of the grand jury examinations and warm weather, but mines are still behind on orders. Cars are in crop sections in the local yards are low. A retailer declared that instead of coal coming down he looked for another reason, the weather sets in cold. This would be necessary to keep the coal from going out of the state.

KANSAS CITY

The coal situation here is anomalous. Dealers expected a strong demand for domestic grades and they are not having it. This is because oil has displaced coal in many plants and because people expect a price drop. Steam coal is in good demand, however, and prices have held up but those for domestic coal are lower than costs of production would justify.

One contract for Arkansas slack was closed recently at $1.50 f.o.b. mines and as Arkansas mines market at least 350,000 tons a year it will be readily seen that the operators must get a price for their lump to break even, as the cost of production is around $2.75.

Some operators do not think the coal will hold up at the present cost or below. This is hard to understand. Outside competition is not serious as railroads have embargoed most coal from Illinois, and when there is no coal here is not strong enough to draw that coal.

DENVER

The report of operators for the week ended Sept. 23 showed a loss of 40.2 per cent production or 53,751 tons, an account of the car shortage on railroads in Colorado and northern New Mexico. Coal tonnage came to 128,592 tons and "market" 77.7 per cent. During August, 1922, a total of 950,818 tons of coal was produced in Colorado compared with 777,638 tons in August, 1921.
News Items
From Field and Trade

ALABAMA

The Friedley Coke & Burden Co. of Jemison, Ala., announce that they will begin operations about the middle of this month at their new plant. The furnace has a capacity of 1,200 tons per month.

COLORADO

The Spring Valley Operations Co. said yesterday that it has received its first shipment of coal from its new mine at Marijuana. The mine is expected to produce 50,000 tons per month.

IOWA

The City Coal Co. at Jermynville, near Charles City, are completing the building of a tank to hold about 2,000 tons of coal. The tank is expected to be in operation within the next week.

ILLINOIS

The Freeman Fourth Vein Coal Co. has completed the lease of a new mine, the Dragon Coal, located near Beardstown. The mine is expected to produce about 50,000 tons per year.

INDIANA

The city of Evansville is planning to build a new coal plant to handle the increased coal production expected in the area.

MINNESOTA

Hibbing, Virginia and Eveleth, three iron range towns near Duluth have filed their initial coal claims for the Winter, according to reports. They purchased an aggregate of several tons of palomino ore claims at a cost of about $5,000 each.

F. W. R. Coleburn, formerly of the City Fuel Co. of Minneapolis, is reported to be in charge of the local office of the company.

A report to the fuel committee named by the mayor of Minneapolis stated that there would be no shortage of coal on the market and that the expected shortage of coal was largely due to the strike of the steel workers.

MISSOURI

"Gopher hole" mines are opening up all over Missouri, from St. Louis, in the east, to the Missouri River, and as far west as Joplin. These various new operations are opening up new fields and getting out from 5 to 100 tons per day. Some of these little mines have long been known but have not been developed until recently.

The old-time coal landlords are now resuming their activities, and the old-time coal buyers are now moving north where it is a present rumour that all of the activities are active. The Central Missouri Coal & Mining Co. of Jefferson City, G. H. Meeker and Herbert L. Hough, of St. Louis, in the Coal Co., have been operating the coal company for many years, and are known as the old Hubbard coal mine.

The coal company now plans to employ 300 men and to build a new plant at a cost of $500,000. The coal will be shipped from Taylor Bros. and will be a shift on the St. Louis and Illinois road.

The Jones Coal Co. of Rich Hill, has announced that it will go into the coal business and clean up the slack at the mine, south of the town, and get the coal on the market soon. About fifty men are employed.

The Leland Coal Co., of St. Louis, has been operated. The headquarters for F. Sullivan, an old-timer in the wholesale trade.

E. Bryan Tucker, connected with the power and mechanical department of the Consolidating Coal Co. of Pittsburgh, W. Va., has resigned, and is now connected with the Ohio Coal Co., of St. Louis, importers and manufacturers of engineering instruments and supplies.

NEW YORK

Two new coal concerns have recently set up business in Buffalo. Edward J. Proctor, formerly with E. T. Mclntire, now in the Manufacturers' Fuel Co.; and Henry E. Stokes, a former member of the city's leading coal trade, in the new Lafayette Coal Co., under the name of the Continental Oil & Supply Co.

OHIO

Columbus becomes an important center in coal distribution under the ruling of Federal Authorities, who designate Columbus as the headquarters for the Ohio district. Assistant Commander H. H. Boswell of Columbus has been appointed in charge of the Ohio district. Cincinnati, Columbus, and Cleveland, are the three important points in the distribution of coal.

Kentucky coal has increased in price from $35 to $40 per ton, while coal from the T. L. Young Mine is quoted at $35 per ton.

The Kentucky Coal Co. of Danville, Va., has increased its price from $35 to $40 per ton. The company has been in business for several years, and is the largest producer of coal in the state.

The Central Kentucky Coal Co. of Danville, Va., has increased its price from $35 to $40 per ton. The company has been in business for several years, and is the largest producer of coal in the state.

COAL AGE

October 12, 1922

The Douglas Coal Mining Co., Nashville, Tenn., has also completed the planning and development of the mines at Island, Ky., which will mine both steam and coking coal,

some of the operators of northern West Virginia who signed an agreement with the United Mine Workers of America for an assurance of having unlawful strikes to deal with. Two of the first was that during the summer of September at the Morgan mine of the Virginia & Pittsburgh Coal Co., in Virginia, in which 140 miners participated after two cutters had been discharged. These cutters had failed to live up to their agreement. When a running was made it came out that the discharge was warranted.

At the Bees mine of the Buffalo Eagle Coal Co. in the Logan field, a deman-

ers had been made of the real landlord manufactured by the American Coal Leasing Machinery Corporation of Hunting-

ton, with operation on a southeast course of way for 400 feet.

Coming in the same direction is the Rolling Stony field, consisting of 1,000 acres of land with 60 operating shafts and the Santa Fe. Eight miles east of Rockdale, which owns 1,000 acres of land, the Colorado & South Fork mine, has a mine and is using the equipment of the Dallas mine.

OKLAHOMA

The Welch Coal Co. is removing dirt on the Etowah field, five miles west of Welch, which will arrive soon. A tractor and several scrapers are on the job. The company will employ 24 men and will have four machines.

W. H. Fugle has opened a new strip pit outfit of the Mill Creek Coal Co., Mingo county, W. Va., near Welch. Most of the coal from this mine will go to the Miami lead and zinc mining district.

WEST VIRGINIA

The Eagle Mine Coal Co. has been operating at Huntington, W. Va., with a view to operating in territory adjacent to Huntington, this company having a capital stock of $750,000. Offices for the time being will be at Huntington. The company is organized by E. B. Winters, W. E. Tomkins, R. C. Taylor, O. Bowers and N. P. Douglas.

The organization of the Stanley Coal Co., for the development of additional coal in Monongalia County, with a capital stock of $100,000, has been completed. The leading figures in this company are: Charles W. Ream, Stanley Askin, R. C. Sumner, M. R. Hoffman Jr., John W. Kendall, of Meyersdale, Pa., and I. Kendall, of Pittsburgh.

The officials of the union in sub-district 4 of district 15, claim that all but six of the companies in the district have entered into an agreement with the union. Five companies not parties to the agreement are in Monongalia County and one in Harrison, the one in Harrison being the Hubbell & Ream, the company which declined to sign when there was no assurance given by the union that men who had worked during the strike would be protected. In sub-dis-
tinctly the district where the union is not strong is the Charleston district, which has been acquired by the United Mine Workers of America and the Grand Coal Co., and numerous other companies are organized and are in conflict with the union. The officials of the union are not satisfied with the number of companies in the district and they are prepared to meet all companies that are not satisfied with the activities of the union.

There were a good many fatal accidents among the miners with the mining industry of West Virginia during August, twelve meet-
ing death in or around the mines, with thirteen deceased due to falling rock, timber, and state. Mine car accidents were responsible for five deaths, and one miner was killed by electrical shock. Two were killed in accidents outside the mines, one miner was killed in a mine car accident, and one mortality was caused by miscellaneous causes.

Governor Morgan named the following men to serve as members of the coal commission of West Virginia at the annual meeting of the American Railway Union: J. W. Chane, chief of the West Virginia Department of mines; Charles W. Chane, Everett Brecken, president; W. H. Steele, vice-president; C. C. S. Smith, secretary-treasurer; and R. H. E. K. Irvine, secretary-treasurer.

The commission is authorized to examine the coal companies, and to make reports to the legislature; and to make recommendations to the legislature with respect to the laws and regulations affecting the mining of coal in the state.

The United States Civil Service Commission has announced that the examination for the position of Assistant Paymaster has been opened. Those desiring to enter must be United States citizens, of good moral character, and have the ability to read and write English. The examination is to be held on November 22, 1922.

Association Activities

Fayette-Greene Coal Producers' Association

The annual meeting of the organization was held recently at the headquarters of the organization, held at the organization's headquarters, and the following officers were elected for the ensuing year:

President, John A. Smith; Vice-President, Robert W. Parshall; Secretary, William E. Ralston; Treasurer, John D. Brown.

The purpose of the organization is to promote the interests of the coal producers in this area, and to work for the betterment of the industry as a whole.

The National Coal Association

The annual meeting of the National Coal Association will be held on the 15th of this month in Chicago, Ill. The agenda for the meeting will include the following topics:

- Discussion of the current coal market
- Presentation of the annual report of the organization
- Discussion of the organization's plans for the coming year

The meeting will be attended by representatives from all parts of the country, and is expected to be a successful event.

Coming Meetings

Kentucky Mining Institute will hold its annual meeting on Nov. 3 and 4 at Seaboard. The meeting will be attended by representatives from all parts of the state. The keynote address will be given by C. Rogers, Lexington, Ky.

The National Industrial Coal League will hold its annual meeting on Nov. 15 and 16 at the Hotel Commodore, New York City. The meeting will be attended by representatives from all parts of the country. The keynote address will be given by J. H. Bickell, Chicago, Ill.

The Coal Mining Institute of America will hold its annual meeting on Nov. 13, 14 and 15 at Pittsburgh, Pa. The meeting will be attended by representatives from all parts of the country. The keynote address will be given by C. W. Bickell, Binghamton, Ala.

The American Gas Association will hold its annual meeting on Oct. 23-25 at Atlantic City, N. J. The meeting will be attended by representatives from all parts of the country. The keynote address will be given by H. F. Davis, New York City.

Canadian Institute of Mining and Metallurgy will hold its annual meeting on Nov. 17, 18 and 19 at Vancouver, B. C. The meeting will be attended by representatives from all parts of the country. The keynote address will be given by C. G. Mackenzie, Montreal, Quebec, Can.
More—or Less—Unionism

INTERESTINGLY written is James W. Cain's recital of facts in "The Battleground of Coal," in the current issue The Atlantic Monthly. But it is not with his facts but with his theories and his cures that the public is justified in taking issue. He shows that before the strike the union mines were idle for lack of orders and the non-union mines were working, their activity being due to lower wages. Then he adds:

From the foregoing it would seem that the solution of the problem lies in putting the whole country on a non-union basis. This is just what the operators are trying to prove. Not only the non-union operators but the union operators as well distribute this propaganda; newspapers are flooded with it. Yet it is clear that the argument of the operators is valid only in a superficial sense, even though present conditions lend it considerable plausibility. For obviously the prosperity of the non-union fields prevails not through any superiority of non-unionism per se but from the artificial advantage they have on account of their lower wage expense.

Mr. Cain is right; the enslavement of part of the industry to the United Mine Workers of America and the freedom of the other part from it is the cause of the wage differential and of the inequality of operation in the two districts which existed before the strike. But he has taken on himself to oppose the cure that many operators suggest, and the one which he himself admits is the more obvious outcome of the facts he has presented. Eliminating the cure of national non-unionism he says:

There is one plan left—short of a big government corporation to run all coal mines—which promises some sort of solution. This is to put the whole country on a union basis and give all operators an equal chance at the market and all mines an equal chance at regular work.

Miners are now reported as making, where they get sufficient railroad and mine cars and are willing to work, as much as $500 and $600 a month. Surely they would not be willing to pay as much as $20 or $25 a day to those who would work for them.

Are they no demanding by the power of their union that other men work in mills and factories, on the high roads and on the railroads and at the desk for less money than they are willing to accept for themselves? We do not put any figure as being a fair wage for any man. We do not condemn labor profiteering. Nor does the law condemn it. Doug Fairbanks, Fender Chaliapin and Babe Ruth may make their millions or hundreds of thousands or tens of thousands yearly so long as they do it without a combination in restraint of trade. We do condemn them, however, if they obtain high wages by deliberate conspiracy, by murder and other violence, by arson and violation of pledges, by the enactment of laws which while purporting to be for the public good are framed solely to sustain their monopoly and to give them an unfair advantage.

But mark this. The complete unionization of the mine worker would mean the complete unionization of his employer, legal or illegal. The union in fact demands a co-operative bargain between all the employees and all the employers. With all operators paying a scale fixed by a single conference, the employer could laugh at high wages. He would have no incentive to fight to keep wages down, for strikes would be extremely expensive to him as a capitalist. The higher the wages, the more men would flock to his mines. He would have no difficulty in filling the working places no matter how irregularly he worked.

Consequently complete unionization of the mine worker would do great injury to the public unless the government stepped in to prevent it. Mr. Cain does not want that, nor do the operators, but it would be the inevitable result of 100 per cent unionism.

Mr. Cain goes on to say that "it would be a step back to the Dark Ages to put the whole country on a non-union basis. The miner would be reduced almost to peonage." In this he is absolutely wrong. Just before the strike came to an end the non-union United States Steel Corporation, anxious to get men, had to raise wages. The Anaconda Copper Mining Co., at Butte, Mont., now a corporation employing non-union men, is paying $4.75 a day to miners and would, if it could afford it, raise the wage still higher to get men to operate its plants. The Cour d'Alenes are paying $5 a day.

The wage of non-union men is usually lower than the pay of union men, but that is because the profits of any trust are higher than those of a competitive industry. The profits of a trust, whether a commodity or a labor trust, are sure to be excessive unless the prices of the commodities or the wages of the laborer are set so high as to discourage industry.

It is an ill time to talk of giving Mr. Lewis and his men a firmer hold on the throat of the public when they are demanding a six-hour day and a five-day week in order to furnish men with excessive opportunity in the coal industry when they are needed more elsewhere.

A Maligned Industry's Opportunity

THE announcement of the personnel of the U. S. Coal Commission has been met with mingled cheers and jeers by the coal men. Few appear to evidence hope or anticipation that the commission will or can do much for the soft-coal industry. The public has been led to hope that this agency will lower the price of coal and stop strikes. It, of course, can do neither. The coal men are today in about as pessimistic a mood as they ever have been. Battered between the forms at Indianapol and Washington they entertain little hope of finding their way out of trouble.

Many there are who hold with Mr. C. M. Hager of the Cleveland address last week, that since the United Mine Workers will not arbitrate and will not take a reduction

617
Progress at the Mining Congress

A LOOSE, unorganized write-up. The American Mining Congress is making progress in taking on some of the functions of earlier organizations. Not a few of those who attended the Cleveland meeting last week commented on the excellence of the programs and discussions on mine taxation and standardization of mine equipment and mining methods and did not hesitate to compare them with similar efforts conducted under the auspices of the American Institute of Mining and Metallurgical Engineers. In fact, the so-called standardization conferences are engineering discussions; while the everyday problems of mining are taken up by young men not afraid to be trite at times if they can talk about the things that concern them in the routine of their business.

The mine-taxation conference this year called together many of the country's authorities and the interest in the discussion proves that this subject is gaining in popularity every year. Such open discussion of the tax questions of the day as characterized the Wednesday morning session, when J. G. Bradly, of West Virginia, and C. E. Mature, of Ohio, had the floor, has never been heard at a meeting of real men—at least a public meeting.

As the advertising pages of a magazine are in the reading pages as the editor of mining machinery and equipment complemented the meetings and discussions. To none in attendance it appeared that the management of the day, and regarded necessary, to return a profit to its and legislative importance on the behalf of the miners, gave value to this belief. The exhibit, of course, added interest and value to the congress, but care should be taken not to add to the burden that these conventions are merely gatherings of salesmen.

A queer conglomeration of coal mining institute, coal operators' gathering, meeting of economists, Institute of Mining Engineers and county fair, at which no particular attention was paid to the advance slogan, "Greater Prosperity Through Lower Production Costs," the silver anniversary of the American Mining Congress was a success. To this success the coal men of Ohio in particular contributed no small share.

Efficiency vs. Reduced Wages

In 1921, when coal was in slack demand and prices falling, the operator of a coal mine was offered a railroad-fuel contract for a tonnage representing more than half full-time operation, but at a figure which would not return cost. Business was difficult to get and his men needed the work. He called them together, told them the situation, said that he was willing to take the contract if he could be assured of sufficient margin to cover interest, depreciation and depletion—that is, fixed charges, but no profit. He told the men he was not willing to ask them to take a reduction in wages, but he was asking them to increase their efficiency.

After some debate the proposal was made and accepted by the men that 10 per cent be deducted from each pay envelope and held in escrow, as it were, this amount representing approximately the difference between cost and price. It was put up to the men to increase their efficiency, thereby lowering costs, and it was agreed that if they did their part the 10 per cent held out would be returned.

Now, of course, to increase efficiency here meant the exercise of hearty co-operation between men and management, particularly with the daymen. It meant studious avoidance of preventable mine failures, derailments and mechanical breakdowns. It meant working with a will, getting cars to the diggers, shooting loads to the shaft bottom—for this was a shaft mine—it meant steady application to the daily task, whether track laying, dumping coal or any of the many jobs about the coal mine. On the part of management it meant keen appreciation of the value of the time of the tonnage man, giving him a proper place in which to work and such prompt service as his ability to load required.

By the end of the first pay the preliminary cost sheets indicated that it had been done—that costs had been lowered in sufficient amount without cutting wages. Every pay thereafter the men received two envelopes, one the full rate less 10 per cent and the other deducted 10 per cent in accordance with the agreement with the men.

It is needless to say that this was a non-union mine. It is also needless to say that this mine was an exception among the non-union mines in 1921. There was nothing particularly humanitarian about the course pursued by the management of this mine, for there were cogent reasons for the method followed, reasons found in union mines in close proximity on every side. The fact remains, however, that in the absence of a union it was possible to get close enough to the men to substitute efficiency for reduced wages.

With the coming of a coal peace there remains nothing to worry about except the delivery of coal and the arrival of the bill.—Brooklyn Eagle.

No system of government will work in a land where everybody tries to work the government.—Illinois State Register.
United States Coal Commission

United States Coal Commission Named

Judge Samuel Alscher, a noted labor arbitrator

Judge Samuel Alscher was born in Chicago and has practiced law in Aurora and Chicago. He has been active in Democratic politics throughout many years, having served in the Illinois Legislature, and has been his party's candidate for Congress and, in 1920, for Governor. In 1915 he was appointed by President Wilson to the circuit bench of the Seventh Circuit on which he still is serving. Judge Alscher in 1918 was named by the Secretary of Labor as arbitrator of the labor disputes between the Chicago printers and their employees, and his handling of the business has been recognized as one of the notable labor arbitrations in this country.

The Peabody Coal Company, a native of South Carolina, but has lived most of his life in Georgia. He joined the Constitution staff and became managing editor when Henry W. Grady died; later he succeeded him as editor in chief. He served in the Georgia Legislature and for many years as Democratic National Committeeman for Georgia.

George Orin Smith, Director of the U. S. Geological Survey, was named at Colby College and at Johns Hopkins. His interest in coal began in 1895 and 1896 when, as an assistant geologist of the U. S. Geological Survey, he was working in the vicinity of the coal fields of West Virginia. It was in the field season of 1895, 1896, and 1897 that he made the trip to the coal fields of West Virginia, and the results of these trips were the basis of his later work on the coal fields of the United States.

In the first complete treatment of the United States coal fields by the U. S. Geological Survey in 1903 Dr. Smith contributed a detailed chapter on the Pacific Coast coal fields. As Director of the U. S. Geological Survey since 1917 he has taken special interest in the development of the statistical laboratory, and since 1915 has been the University of Pennsylvania professor emeritus of the subject of coal geology. In 1917 Director Smith was a member of the Committee of Coal Policy, one of which the late Francis Peabody was chairman. In 1920-21 he prepared a "Survey of the United States Coal Commission."
Mining Brown Coal in Germany, Briquetting It and Extracting Its Byproducts

BY HUBERT HERMANNS
Berlin-Fankow, Germany

Growing Importance of Brown Coal—Mining and Stripping Methods—Large Percentage of Moisture—Drying with Exhaust Steam—Briquetting and Baking Coal for Byproducts—Producer Method of Utilization

In no country has the production and utilization of brown coal, or rather brown lignite, had more development than in Germany. This substance has of late years become of greater importance to the Republic by reason of the decreased output of coal due to the decreased efficiency of the miners and to the loss of the important coal fields in Upper Silesia and the Saar valley. Moreover, large quantities of coal have to be delivered regularly to France, Belgium and Italy.

Table I shows the development of the production of coal, brown coal and brown-coal briquets in Germany between 1913 and 1920 and 1921.

The character of the brown-coal deposits in Germany varies greatly. Faults, folds, thrust faults, ruptures and interstratified layers of sand and shale often make the mining of the deposit quite difficult. The thickness of the bed varies from a few inches to 300 ft. The method of mining, whether by strip pit or by underground mining, depends on the depth of the deposit over the coal, the overburden consisting chiefly of sand and clay. When underground mining is adopted the coal is reached by a shaft and less often by a drift. Before the war a miner working underground in coal mines could be relied upon to mine 260 short tons per year, whereas the yearly production of brown coal per miner was between 350 and 400 short tons.

By the use of the land dredger the production in strip pits has been raised to more than 1,500 tons per miner. Unfortunately the heat value of this lignite is only about one-third that of coal. However, even making due allowance for the lower calorific value of lignite, each man in a lignite operation will produce many more heat units than a man in a German coal mine. Whereas a coal miner would produce 2,000,000,000 calories per year, the yearly production for a miner working in brown coal is now 3,200,000,000 calories.

When brown coal is mined by underground methods an entry is driven through the deposit to the further property line with side entries on either side at regular distances and cross roadways between these; thus the coal is divided up into pillars measuring 4 meters (13 ft.) square. The coal obtained from these pillars is transported through the side entries to the main entry and up through the shaft.

The roof of the area thus excavated is allowed to

![Image of mining scene]

How the German Miner Avoids Use of Backbreaking Shovel

Another scene in a brown-coal strip pit. Note that the miners are forming a chute in the coal that will feed into the car without shovelling and have erected a chute with a gate so that the coal will be stored and the car will move away without delay. Thus the men will be able to work without cessation while cars are being placed.

*1 Metric ton equals 2,240 lb., or 1,013 short tons.
*2 Lignite, including Saar District and Pfalz. Though from 1913 to 1921 the coal production declined from 196,000,000 metric tons to 136,000,000, the brown-coal production increased from 37,000,000 to 123,000,000 and the brown-coal briquet production from 21,000,000 to 25,000,000.
the mineral by underground mining methods. The difficulty in daylight mining is in disposing of the impurities mixed with the lignite. These are thrown into the areas already mined.

When the coal is mined by hand in these strip pits it is directed into cars by chutes laid close to the coal, or holes are dug in the face of the coal in the shape of a semi-funnel, and by these the coal is chuted into the car. (See headpiece.) This method is known as rolllochbetrieb. The narrow end of the "rolloch" is closed by boards and is placed so high above the level of the top of the car to be loaded that the latter can be run under it and filled by gravity, the loose coal in the funnel being released as desired. Usually the sides of the rolloch are made so steep that the loosened lignite will run down them without any assistance from the miner.

As Table I shows, most of the coal is burned without being briquetted. The use of this coal in its natural condition is limited because it contains from 25 to 50 per cent of moisture. The freight rates, figured on the basis of its heat value, are too high to encourage the use of such fuel. The heat value sometimes falls as low as 2,000 calories, or 3,600 B.t.u.

The difficulties encountered in burning this wet coal have been overcome in course of time by the construction of special furnaces in which the coal is dried before reaching the grate, but the principal way in which the economic value of brown coal can be increased is by its use in the manufacture of briquets. The cars are mostly conveyed by continuous chain haulage from the mine to the briquet plant. Three separate operations have to be performed. The lignite must be prepared, dried, and briquetted.

First the coal is discharged from the car by a rotary dump. It falls into a funnel-shaped bunker, from which it goes to the crushers. The broken coal from these drops on an inclined shaking screen 13 to 20 ft. long and about 4 ft. wide. This allows particles less than 1 in. in diameter to fall through, the larger pieces going to rollers or a centrifugal mill. The finer coal is screened again, and the lumps coming from the screen are guided to a belt conveyor by which the coal is transported to the boiler house. The wet coal is dried either in tubular driers or on shelves heated by exhaust steam, this process usually being continued until the water content falls to 15 per cent. For tubular driers the pressure of the exhaust steam should be from 2 to 3
PLANT FOR CRUSHING, SIZING, RECRUSHING, RESIZING, DRYING, COOLING AND BRIQUETTING BROWN COAL

atmospheres absolute. When shelves are used the pressure should range between 1.5 and 2 atmospheres.

The tubular driers consist of a sheet-iron shell 8 ft. 2 1/2 in. to 9 ft. 10 in. in diameter and 23 ft. to 26 ft. long and two strong ends in which are inserted tubes of 3 1/2 in. diameter such as are used in tubular boilers. The coal slides through the tubes, which are surrounded by exhaust steam. The center line of the drier is at an angle of 6 deg. with the horizontal.

The shelf drier (teilertrockner) consists of twenty-five to thirty-six circular shelves of 16 ft. 4 in. diameter placed vertically above each other at regular distances. These shelves are each made of two circular iron sheets riveted to a frame, the space between them forming a chamber for the exhaust steam. By means of rotary shovels the lignite is constantly turned over and pushed alternately toward openings in the middle and on the outside which connect the separate shelves.

The dry coal goes to a trommel, or revolving screen, and is separated into fine coal and coal dust. It is then cooled in a jalousiwerk. You have seen the small shutters on a Venetian blind; in Germany the latter is known as a jalousie (or jealousy) because it allows one to look out without being seen. In the cooler just named the coal falls on shutters similar to those in a Venetian blind, and between them cool air circulates. The lignite is cooled because it can be better pressed in briquets when its temperature has been lowered. Conveyors bring the dried and cold lignite to a bunker placed over the briquet presses.

Brown-coal briquets were manufactured as early as 1858, the coal briquetted being from the Von der Heydt mine. Many technical difficulties were encountered, however. In particular the pulverizing and drying apparatus both proved inefficient. All equipment and methods have been so greatly improved since that date that no more technical questions remain for solution.

Today plunger presses driven by steam are used almost exclusively for briquetting. Electrically driven presses are seldom seen; not because the drive is unsuited to that purpose but because exhaust steam is needed for the drying apparatus. The steam engine and press are combined in one heavy frame with a heavy crankshaft, common to both, in between. On this fly-wheels are mounted.

The stroke varies from 61 in. to almost 11 in., depend-

ing on the condition of the coal and the desired density of the briquet. A rod transfers the crank movement to a heavy slide to the other end of which the plunger of the press is attached. The principal part of the press is the head in which is placed the mold consisting of a passageway 3 ft. 3 in. long open at both ends. The sides of the mold are of interchangeable steel plates so that the free opening is of the desired dimensions for the briquet being manufactured. The plates are so formed that the opening on the press side is a few millimeters wider than the rest of the passageway.

BRIQUETTING PRESSURE MANY TONS PER SQUARE INCH

The difference in width depends on the nature of the coal and the desired firmness of the briquet. The opening can be regulated while the press is in operation. The plunger, fitting closely in the widest end of the channel, pushes a quantity of dry coal into the mold and forms a briquet with every forward movement.

On the return stroke the space left by the retreating plunger is filled again with another measured quantity of coal, which is formed into a briquet at the next stroke. Each briquet is pushed forward in the mold by the one that succeeds it. On passing the narrowed part, the briquet is again subjected to pressure, causing much friction and consequently back pressure on the plunger. Leaving the passageway the briquets land in a trough, through which they are pushed in a continuous string by the action of the plunger. The trough can be adjusted horizontally and vertically. The briquets usually fall directly into the railroad cars by which they are

STEAM PRESS FOR MANUFACTURE OF BRIQUETS

So much exhaust steam is passed for the driving of the machinery in the brown coal that steam engines are produced to generate it. The briquetting presses run from 3 to 4 times per square inch and the revolutions per second from 30 to 35.

October 19, 1922  COAL AGE  623
taken to market. An illustration shows the pressroom of a briquet plant with eight presses. The construction of the press and the trough can be clearly seen.

Not only the length of the stroke but the speed of the press depends greatly on the condition of the coal; the speed is from 80 to 125 r.p.m. The pressure required for the forming of a briquet is from 1,200 to 2,600 atmospheres, 17,640 to 23,000 lb. per square inch. The presses must be built so that the flywheels are capable of exerting such a pressure.

The dry coal is held together without any added binder, partly as the result of the high pressure exerted on it, and partly through the heat generated in the press which softens the coal and the substances it contains, such as paraffin and resins.

Naturally the capacity of a press depends on the number of revolutions per minute and the weight of the briquets. In about twenty-four hours one machine will make from 90 to 100 long tons. The shape of the briquet varies greatly for industrial purposes, preference being shown for small cube or flat-shaped briquets.

**Some Bruine Coal Cokes Quite Readily**

Although brown coal is used mostly in the form of briquets, it can be utilized in other ways. Where it will coke, like the brown coal from Halls, Zeltz and Weissenfeld, it may be used in that form. The lignite, having baking qualities, can be readily distinguished from ordinary brown coal. The best baking lignite has a bright yellow, almost white, appearance. When burned it melts like sealing wax and cannot be used at all in grates, as the molten coal would fall between the bars.

This pure and rich baking coal, however, has all been mined. What remains, though more like brown coal, has a lighter color than the non-baking lignite. One of the illustrations shows a pit in a deposit of this character. The lignite is caked slowly so that the water is first separated from it, and later, at a higher temperature, the gases and tar. As a residue a porous and brittle coke remains, which is mostly used for domestic purposes.

The oven in which the brown coal is baked are vertical shafts lined with firebrick, heated on the outside and provided with rings arranged like shutters, over which the coal slides, losing its moisture gradually. In the hotter part of the shaft the brown coal is decomposed into tar and gas. The coal is taken out at the bottom. The tar is drawn off with the gas and precipitated in a condenser. The gas from which the tar vapors have been extracted serves as fuel for the ovens.

Of the tar, the paraffin, which is extracted by distillation in iron retorts, is the most valuable constituent. By distillation also the oils are freed from the paraffin; those of lower boiling point, forming “solar oil,” are freed first. The heavier oils, containing paraffin, are then collected and cooled rapidly, and the paraffin is separated thereby. This is pressed and purified. The oils from which the paraffin has been extracted form cheap lubricating oils and oils for driving Diesel motors.

For some time, especially during the war, experiments were made to increase the production of oils and fuels of high heat value by the distillation of brown coal in producers. The tar in that case is not obtained by a baking process but by distillation. No coke remains but all the combustible materials are transformed into gas. Large quantities of tar were produced by this method during the closing months of the war.
Calculation of Power Required for a Counterweighted Hoist and One in Balance, Shallow Shaft

Moments Required for Lifting Load Reduced by Moments of Falling Counterweight or Descending Load—Acceleration Moment Must Be Large Enough to Increase Speed of Descending as Well as Ascending Bodies

By F. L. Stone
Schenectady, N. Y.

In last week's issue shaft calculations were made for an unbalanced, uncounterweighted hoist. In this article will be developed the calculations for a counterweighted hoist and one operated in balance. The counterweight that will give the best motor rating is one the weight of which is equal to that of the cage plus half the weight of the load. In the example given the following conditions were specified:

- Total lift, ft.
- Weight of cage, lb.
- Weight of car, lb.
- Weight of rock, lb.
- Trips per hour
- Drum, cylindrical
- Weight of rotating parts at rope center, lb.

From these figures it can be deduced that the counterweight for this hoist should weigh 15,300 lb. in all. The closer this condition is approximated, the closer will the two cycles, hoisting the load and hoisting the counterweight, coincide.

As 60 trips per hour are required and all other data are the same, the moments of the up load will be exactly the same as in the first case, except for acceleration and retardation moments, which will be increased by reason of the fact that the counterweight has also to be accelerated or retarded.

We will, however, proceed as if this were an entirely new problem as far as moments are concerned.

<table>
<thead>
<tr>
<th>Up Load</th>
<th>Counterweight</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cage</td>
<td>9,000 lb.</td>
</tr>
<tr>
<td>Car</td>
<td>2,300 lb.</td>
</tr>
<tr>
<td>Rock</td>
<td>8,000 lb.</td>
</tr>
<tr>
<td>Total</td>
<td>19,300 lb.</td>
</tr>
</tbody>
</table>

Assuming 80 per cent efficiency as before, 12,000 — 0.8 = 15,000 ft.-lb. Substracting the average moment from 15,000 (that is, 15,000 — 12,000) we get 3,000 ft.-lb., which is the frictional moment. The acceleration and retardation may be calculated as follows:

<table>
<thead>
<tr>
<th>Tums</th>
<th>9</th>
<th>11.26</th>
</tr>
</thead>
<tbody>
<tr>
<td>Load</td>
<td>57,900 ft.-lb.</td>
<td>57,900 ft.-lb.</td>
</tr>
<tr>
<td>Hold</td>
<td>1,300 ft.-lb.</td>
<td>1,300 ft.-lb.</td>
</tr>
<tr>
<td>Darum</td>
<td>45,500 ft.-lb.</td>
<td>45,500 ft.-lb.</td>
</tr>
<tr>
<td>Total</td>
<td>59,400 ft.-lb.</td>
<td>59,400 ft.-lb.</td>
</tr>
<tr>
<td>Down</td>
<td>47,400 ft.-lb.</td>
<td>47,400 ft.-lb.</td>
</tr>
<tr>
<td>Net</td>
<td>12,000 ft.-lb.</td>
<td>12,000 ft.-lb.</td>
</tr>
</tbody>
</table>

Average moment = 12,000 ft.-lb. / 2 = 6,000 ft.-lb.
The sumation of moments in lifting the counterweight will be as follows:

**SUMMATION OF MOMENTS (LIFTING COUNTERWEIGHT) IN FT-LB**

As the counterweight moment is reduced by the moment of the cage and car the total moment is less than the counterweight moment. The net moment equals the difference between the sum of the up-counterweight and up-rope moments and the sum of the down-cage, down-car, down-load and down-rope moments.
October 19, 1922

Glancing at the duty cycle it will be seen that the motor required for this work is much smaller than that necessary for hoisting a totally unbalanced load. The actual work done is that of hoisting the active load, rock or coal.

We have lifted 8,000 lb. of material through 250 ft., the work being done at an assumed efficiency of 80 per cent.

\[
\text{Work done} = 8,000 \times 250 = 2,000,000 \text{ ft.lb. or} 2,000,000 \text{ ft.-lb.}
\]

\[
\text{Horsepower-seconds} = \frac{2,000,000}{0.8} = 2,500,000 \\
\]

3,636

Then \( \frac{3,636}{4,545} \) hp. sec., which should equal the area of the total duty cycle. Thus:

\[
\begin{align*}
\text{Loaded Car Up} & = 269 + 266 \\
\text{Accelerating} & = \frac{6}{2} \times 2 = 802.50 \\
\text{At full speed} & = \frac{1,07-1.83}{2} = 1,467.95 \\
\text{Retarding} & = \frac{6}{2} = 1.14 \\
\text{Total horsepower-seconds} & = 2,269.31
\end{align*}
\]

Adding the horsepower seconds of work performed in the two cycles—namely 2,269.31 and 2,271.39—the result is 4,540.21, thus checking with the result previously obtained.

We will now consider the last case for this set of conditions—namely, hoist in complete balance. That is to say, we will assume a double-compartment shaft, cages and cars in balance and the same output, a trip per minute, as in the first two cases, that just calculated and that considered in Coal Age on pages 577 et seq. of this volume.

The up moments of the cage, car, rock and rope will be the same as before, that is, Turns 0 = 59,400 ft.-lb.; Turns 13.26 = 57,900 ft.-lb.

The down cage and car have the following weights: Cage 9,000 lb.; car, 2,300 lb.; total 11,300 lb.

\[
\begin{align*}
\text{DOWM MOMENTS} & = 11,300 \times 3 = 33,900 \text{ ft.-lb.} \\
\text{Turns 0} & = 11,300 \times 3 = 33,900 \text{ ft.-lb.} \\
\text{Turns 13.26} & = 11,300 \times 3 = 33,900 \text{ ft.-lb.}
\end{align*}
\]

\[
\begin{align*}
\text{MOMENTS OF DOWN ROPE} & = 10,600 \times 2 = 1,060 \text{ ft.-lb.} \\
\text{Turns 0} & = 10,600 \times 2 = 1,060 \text{ ft.-lb.} \\
\text{Turns 13.26} & = 10,600 \times 2 = 1,060 \text{ ft.-lb.}
\end{align*}
\]

\[
\begin{align*}
\text{SUM OF MOMENTS DOWN} & = 33,900 + 1,060 \times 2 = 35,900 \text{ ft.-lb.} \\
\text{Turns 0} & = 33,900 + 0 \times 2 = 33,900 \text{ ft.-lb.} \\
\text{Turns 13.26} & = 33,900 + 1,060 \times 2 = 35,900 \text{ ft.-lb.}
\end{align*}
\]

The down moments must now be deducted from the up moments.

\[
\begin{align*}
\text{Up moments} & = 33,900 \text{ ft.-lb.} \\
\text{Down moments} & = 35,900 \text{ ft.-lb.} \\
\text{Total} & = 69,800 \text{ ft.-lb.}
\end{align*}
\]

Adding the horsepower seconds of work performed in the two cycles—namely 2,269.31 and 2,271.39—the result is 300.
Coal from Peat or from Drifted Matter?

Speaking before the British Association for the Advancement of Science, Sept. 6, of this year the president of the geological section, Professor Percy Fry Kendall, declared that true coal seams — those, that is, that were unshaken — were generated where found, that is, from peat — had the following characteristics: (1) Wide extent, (2) uniformity of thickness and character over extensive areas, (3) freedom from intercalated detrital mineral matter, (4) constant presence of a soft earth or vegetable level, (5) entire absence of remains of aquatic animals within the seam. Substitutes, he said, negative for alternatives and affirmative for negatives and the characteristics of coal, which he regards as drift or alluvial matter, are truly set forth.

If, coal, he added, scales, teeth and bones of fish are almost invariably present, and it is from coal that our largest collections of coal-measure vertebrates have been obtained. Amphibian remains are more rare, reptiles are crowded to some places and partly fresh-water plants such as Chara, Equisetum are represented commonly ent by the plants themselves, but by the flattened wrinkle-silicified, the chaff-covered shell having evidently been dissolved by the acids generated by decomposing vegetable matter. The last content always 20 per cent before reaching the point at which it would be regarded as shale. The characteristics of coal are consistent with the view that it originated from a mass of vegetation macerated in pools of water somewhat after the manner in which flax is retted.

Sometimes the coal is in unconformable relation to the underlying beds, as at the Abram colliery, Wigan, England, where it rests in one district upon true coal and in the course of about a mile encroaches first on the coal, then upon its underclay and, finally, having become 7 ft. in thickness, it rests upon a bed of shale underlying the underclay.

It commonly happens, added Professor Kendall, that the presence of a patch of coal as a constituent of a coal seam is accompanied by an increased thickness, even out of proportion to the magnitude of the coal, and this irrespective of whether the coal is above, within or below the true coal. This may be explained by the fact that the process of fermentation by which the coal was produced reduced its volume more rapidly than the ordinary clay reduced that of the adjacent peat and so maintained a depression in which the plant debris of the peat bog could accumulate, but the ultimate effect of this fermentation was a less complete loss of hydrocarbons and, consequently, both because its contemporaneous loss was greater and its subsequent loss was less, the presence of a coal component increases the thickness of a seam.

A check on the area of the plotted cycle can be made as follows:

\[
\begin{align*}
116.2 + 115.3 & = 231.5 \\
\frac{2}{2} & = 1 \\
100.5 + 92.9 & = 193.4 \\
\frac{2}{2} & = 96.7 \\
100.5 & = 97.7 \\
\frac{2}{2} & = 48.8 \\
\end{align*}
\]

""
Huntington Show Suggests Modern Ways of Reducing Coal Cost—I

Typical West Virginia Mine Cars—Low Cars Permitting Use of Side Loading—Use of Band Brakes—Machine for Electrically Heating Rivets—Hoist for Long Slopes and Inclines

Much interest was exhibited in the Coal and Industrial Exposition held at Huntington, W. Va., Sept. 18-23, in the Chamber of Commerce Building. Lightning, it is said, seldom hits twice in the same spot, but the coal exposition has ventured for two consecutive years to descend on so small a town as Huntington. The rest of the country needs some of the enlightenment that has been so generously bestowed on this West Virginia town and it is certain that some other city will get it, as it was decided at a meeting of exhibitors to hold the show elsewhere in the coming year. The West Virginia-Kentucky Association of Mine, Mechanical and Electrical Engineers, thus deserted by their exposition, decided to withhold a decision on next year’s place of meeting till they found where the exposition was going to be held.

Prominent among the exhibits were four mine cars of mammoth proportions. They probably will carry but little coal, however, for apparently payment of coal by the carload instead of by the ton results in the filling of cars but little more than level full. The cars are, however, constructed to carry a maximum quantity of coal for a minimum height of body.

The American Car & Foundry Co. had a big all-steel car that was constructed for the Little War Creek Coal Co., at Maier, W. Va. Its weight is 4,400 lb., its length is 9 ft. inside and 10 ft. 8 in. over all, its width is 6 ft. and its height from the top of the rail to the top of the car, 3 ft. 2½ in. Its capacity is 107 cu.ft. and its gage 44 in. The wheels, which are fitted with Hyatt roller bearings, project above the bottom of the car and are hooded with steel covers; to stiffen the sides three steel gusset plates are set on each side. They connect the sides of the car with its bottom. It will be dumped on a rotary dump.

Across the way might be noted a rival car constructed by the Kenova Mine Car Co. for the Red Jacket Consolidated Coal & Coke Co., at Red Jacket, W. Va. This, which was a composite car with sides of steel and a bottom of wood, like the other, had hooded wheels and two angle stiffening plates on each side. It holds 2½ tons when level full. Its dimensions are as follows: Weight, 3,800 lb.; inside length, 10 ft. 6 in.; width, 6 ft.; height above rail, 29 in.; capacity, 90 cu.ft.; wheels, 14 in. in diameter; track gage, 48 in.; wheelbase, 40 in. A spring drawbar, a swivel hitching and a Timken roller-bearing wheel of the exposed Lynch-pin type were notable features.

Only slightly smaller is the car made by the Watt Mining Car Wheel Co. for the Island Creek Coal Co. This car has a gage of 44 in. for a track gage of an even 44 in. It has an 18-in. wheel, a straight-link hitching, Hyatt roller bearings and lifting end gate being intended, unlike the other two cars, for easy dumping. Its weight is 3,700 lb., its inside length 9 ft. 12 in., its over-all length 10 ft. 6 in., its inside width 5 ft. 5 in., its height above the rail over all 3 ft. 4½ in., its wheel...
It will be noted that modern mine cars are frequently riveted—not bolted. Rivets are less likely to become loose. Properly driven, they will hold permanently until a wreck of some sort subjects them to strains for which they have not been designed. Then the cars come to the shop, and the riveting must be renewed.

In this work the electric riveter of the American Car & Foundry Co. exhibited in the company's booth offers opportunities. The heat is, of course, not of the cheapest but it is confined to the rivet and not dissipated as to a furnace. There is no risk of burning a lot of rivets by leaving them in the fire. The heat is from the center out and not from the outer surface inward. Hence it lasts longer or else does not have to be made so intense to last as long. The rivet is in full view of the operator.

In a booth near the entrance to the show was exhibited by the Hocken-Smith Wheel & Mine Car Co., a car built for the Pond Creek Ry-Product Collieries Co., of Leekievile, Ky. Several illustrations are shown of it because, although it has certain qualities all its own, it is typical of the cars being used in West Virginia, a state where large loadings per man are made at most of the mines. The cars are quite low, this one being only 28 in. high. The height is kept low, usually not at all because the coal is thin, but because ease of loading favors a low car. It also saves injury to the coal in loading.

The band-friction double-reduction single-drum hoist of the Thomas Elevator Co. occupied another booth. It is intended for such work as sinking shafts, hauling cars up slopes or inclines or for other purposes where a machine with large drum and ample cable capacity is desired. It is fitted with a band friction on one end of the drum and a composition-lined band brake on the other. A band friction puts no end thrust on the bearings and is therefore especially advantageous on long hauls. The brake is of ample proportions and as it is placed on the opposite end of the drum from the friction any heat generated by it does not affect the operation.

These machines are furnished with a smooth drum face and cut gearing. When made with machine-cut grooves on the drum the friction may be locked in engagement and the machine used for operating skips, cages or cars in balance. The brake and friction shafts are fitted with babbitted bearings and the control levers are banked in a quadrant conveniently located for the operator. Speeds and capacities range up to 12,000 lb. rope pull and 600 ft. per minute. Either alternating or direct current may be employed.
Every Big Mine Should Have Its Locomotive Inspector

To Be Always "Fit" a Locomotive Must Be Inspected at Regular and Frequent Intervals—If Continuously Kept in Good Condition, with Hauling Loads Commensurate with Capacity, It Should Last Indefinitely

By W. M. Johnson*
Woodward, Ala.

ELECTRIC locomotives are now largely employed both in gaseous and non-gaseous mines for hauling coal from the working face to the pit mouth. These machines form the key to present-day coal production. They vary in size from four to thirty tons. Without them the output of some of the larger mines would be so seriously reduced that coal could not be mined economically. In fact to revert to mule haulage or other modes of transportation would mean disaster to the coal-mining industry.

Considering the thousands of electric locomotives that are put into the mines each year, the question naturally arises what percentage replaces worn-out equipment and what is installed in new development? This is not easily answered, as other considerations are immediately involved such as "What is the average life of a mine locomotive?" as well as many others.

Of course everyone experienced with mine locomotives will immediately answer that the life of an electric haulage motor depends entirely on the service it is called upon to perform. They believe that they have thus effectively answered the query. However, even if we restrict the scope of the question and limit the work of the locomotive to that commensurate with its size, so that the machine hauls loads proportionate to its capacity only and over track such as is normally found in coal mines, the question is not easily answered in a satisfactory manner.

ANCIENT LOCOMOTIVES ARE RARELY SEEN

From time to time the technical papers have published photographs of electric locomotives of ancient vintage that have been in continuous service for twenty or more years and that are still as good as new, or are doing as much work as ever. Here again is an answer to the query, but is it not rather the exception than the rule that a locomotive should operate for twenty years and be as good as ever, without any change in structure, or with little or no expense for repair parts during that time?

As a matter of fact, coal company records of cost of operation and repairs to electric locomotives are for the most part average costs and cannot be used in a comparative way to estimate the life of such a machine. Neither can a yearly depreciation method be employed.

Again if new parts are being continually added to a locomotive, is it fair to estimate the life of the machine at twenty years, when as a matter of fact probably twice the cost of a new haulage motor or a capitalisation amounting to the price of three locomotives has been spent during this period and its end finds the company possessed of a half or completely worn-out locomotive?

On what then does the life of an electric locomotive operating at normal load and over average trackage depend? The answer is: "On the thoroughness and regularity with which it is inspected and the promptness and excellence of the repairs made." The old adage, "It is easier to keep up than catch up," applies particularly to electric mine-haulage locomotives.

Consider your own mine. Are the electric locomotives used in it always in first-class condition, or are they over the pit a large part of the time? Is it cheaper to operate them in a hit-or-miss fashion until they go out of service for want of repairs, with the accompanying interruptions to haulage schedules and loss of tonnage or to keep them in such shape that they will maintain a 100-per cent efficient haulage schedule?

RAILROAD LOCOMOTIVES RIGOROUSLY INSPECTED

Look at the great steam-railway systems on which the very existence of the country depends. Are they run in a hit-or-miss fashion? Decidedly not. A fast freight or passenger locomotive after a run of 100 or 200 miles is thoroughly examined, oiled and passed by competent inspectors before it is again called upon to perform service. Are electric mine locomotives, many of which travel 100 miles per day and some of which cover an equal distance both day and night, treated in a similar manner? Or are they run until they fall apart? Again I affirm that "the life of an electric locomotive varies directly as the completeness of inspection and the quality of repairs made."

Most mine owners will say: "Of course we inspect our electric locomotives. Our mine electrician both inspects and repairs them. In fact he does everything but operate them, and he could do that if necessary." But should the man who makes the inspection be the one to make the repairs also? Emphatically not. Man's characteristic tendency to do as little physical work as possible and "get by" is the reason for so saying.

ELECTRICIAN SHOULD NOT INSPECT OWN MOTORS

The old biblical admonition to the effect that "a man can see the mote in his neighbor's eye but cannot see the beam in his own eye" is familiar to all. The same reasoning applies to permitting an electrician to make his own inspections. He soon will be making his inspection reports to suit his own convenience. And a report that does not embody a true statement of conditions is of less value than none at all, for it will convey an erroneous impression to the management.

In large operations with twenty or more electric locomotives in service an inspector is a necessity and will save his wages many times over in the course of a year. In the case of smaller companies working one or two mines and employing only a few locomotives, the proper scheme is to have the electrician from one mine act as the inspector for the other and vice versa. With a little friendly rivalry, it will be surprising to see the close scrutiny the locomotives will receive and to observe how delays, armature failures and kindred

*Electrician Superintendent. Woodward Iron Co.
troubles will decrease slowly and steadily until, instead of being an accepted daily occurrence, they will become unusual.

An inspector, where the mines operate daily, can handle about twenty locomotives per week as a maximum allotment, provided these machines are not scattered over too great a territory. He can report on each machine twice weekly. My inspector handles thirty locomotives per week equally divided between three mines. He works 10 hours per shift at night, six nights per week. He can thoroughly inspect, on the average, eight locomotives per shift, so that each week I have on my desk a complete statement of the actual condition of each machine. The mine electrician also receives a carbon copy of the inspection report the morning following. In this manner no time is lost in replacing any parts found needing attention.

To make the work of inspection as easy as possible, especially so far as writing is concerned, a printed form has been prepared arranged in pads so that a carbon copy is easily made. The form accompanying this article is an actual copy of an inspector's report. As may be seen, it requires little writing, yet conveys a complete record of conditions. These reports are likewise easily examined, as the status of any part requiring attention stands out prominently while that of those in good shape is automatically passed over at a glance.

This form is intended for use with a straight two-motor locomotive without reel attachment. It can easily be modified to meet the needs of any type, however, using the same symbolic scheme to reduce to a minimum the writing that the inspector is obliged to do.

I adopted this inspection system about a year ago. At that time one of our mines was producing 1,400 tons of coal per day with twelve locomotives in service. These machines were continually in and out of the pit for the renewal of armatures burned out by poling, for hot bearings, controller and brake trouble and numerous other misfortunes peculiar to electric mine locomotives. At the present time the same mine operates only nine locomotives, yet produces 2,300 to 2,400 tons per day. During the past six months not a single armature has failed, whereas prior to the adoption of this inspection system an average of one to two locomotive armatures were burned out per week. The same inspection scheme has been adopted for our coal-cutting machines, and the results obtained in the past half year have been highly gratifying.

How long will a locomotive last in mine service? At the present time we cannot estimate the life of our machines. As we are keeping them in first-class operating condition they should last indefinitely.

By the installation of means for the control of air currents, by the installation of instruments of precision and by making a long series of calibrations, the experimental coal mine operated by the U. S. Bureau of Mines at Bruce- ton, Pa., near Pittsburgh, has been put in condition for a study of some fundamental factors that govern the ventilation of mines. In one of the rooms of the mine a lead disk 3 ft. in diameter has been placed against the coal. Thermocouples have been placed in this disk and also at various depths in the coal and shale roof for the purpose of studying the rate of flow of heat through coal and shale. Such data, when obtained, will be of value in the control of ventilation in deep metal mines. This work is under the general direction of G. S. Rice, and under the personal supervision of J. W. Paul, assisted by G. E. McElroy, H. P. Greensward and H. C. Howarth.
American Mining Congress Considers Standardization, Taxation and Industrial Relations

Twenty-Fifth Annual Convention Held in Cleveland—Coal in Limelight
—Seek Laws to Prevent Interference by Organizations of Employers or Employees with Production or Distribution of Necessities of Life

COAL was easily the headliner at the twenty-fifth annual convention of the American Mining Congress in Cleveland, Oct. 9 to 14. The cataclysmic events in coal's history during the past year and the present general movement, both internal and external, to reorganize the coal industry are responsible. During the five days of the convention, held in connection with a striking national exposition of mining methods and equipment in Cleveland's new and magnificent Public Auditorium, much was said which may have a lasting effect upon coal and its relations with the public. The convention program directed much attention to standardization throughout all mining, upon mine taxation, better industrial relations within all branches of the industry, and to oil shale and its future, but there is no gainsaying the fact that coal was in the spotlight.

Sidney J. Jennings, of New York, was elected president; D. B. Wentz, of Philadelphia, first vice-president; H. W. Seaman, of Chicago, second vice-president, and E. L. Doheny, of Los Angeles, third vice-president. Directors elected were D. B. Wentz, W. C. Doring, president of the Southern Wheel Co.; W. H. Lindsay, of Nashville, and A. J. Nason, of Chicago. The convention and mining exhibition in 1923 will be held in Milwaukee.

At the closing session on Friday the convention adopted a ringing resolution on the labor question, declaring that "laws should be made and enforced by all the power of the government that shall forever strip labor organizations as well as employers of the ability to interfere with production and distribution of the necessities of life." A resolution was adopted putting the influence of the American Mining Congress behind the Federal Coal Commission and authorizing a committee of seven from the congress to co-operate with the commission and with the coal operators.

CROWDS FLOCK TO NEW AUDITORIUM

The convention and exposition drew mining men and others interested less directly from all over the country. A total of over 500 delegates registered but the throngs which flowed through the two immense floors almost full of exhibits in the Public Auditorium when the doors were open to the public would have indicated a much greater attendance. Cleveland itself contributed heavily to this crowd, for the great building is new and most of the taxpayers whose $6,500,000 built it have not yet seen its beautiful and spacious interior. It was generally admitted by exhibitors that they had never shown before in such a handsome and well-appointed building. Many of their displays were novel and most of them interesting and instructive.

Delegates began to register for the convention as early as Sunday morning, Oct. 9. The next day enrolment boomed as engineers and mining men arrived from everywhere. Short meetings of the boards of governors for the Southern and the Western divisions of the congress were the only program events of the morning, but in the afternoon the taxation conference, one of the important branches of the congress, began its series of meetings, which ran through the succeeding three days.

Monday evening the convention and exposition was formally opened with a program on the immense stage of the auditorium after a musical prelude on the municipal pipe organ played by Edwin von Krafft and sung by Miss Rex Haller, soprano, and the famous "Anthracite Quartet" of hard-coal miners from Pennsylvania.

Newton D. Baker, Secretary of War during a part of Woodrow Wilson's presidency and now president of the Cleveland Chamber of Commerce, made the address of welcome, in which he declared than an obligation rests upon those in the mining industry to devise means of cooperating with each other, to take the public into their confidence, especially in matters relating to coal.

President Harding, unable to be present, sent a letter to Michael Gallagher, of Cleveland, chairman of the speakers' committee for the convention, in which he assured the mining industry of his interest in it and his confidence in the wisdom and leadership of the congress. The President's letter is shown in another column.

Most of Tuesday morning, when the second general conference of the convention was held, was devoted to the interests of metal mining. W. R. Woodford, president of the Rail & River Coal Co., presided. W. J. Loring, president of the congress, who was scheduled for an address, was absent, serving on a committee investigating the Argonaut mine disaster in California. Carmi Thompson, vice-president of the Tod-Stambaugh Co., of Cleveland, iron ore operators, and now a candidate for Governor of Ohio, spoke on "Some Requirements of the Iron Ore Industry." Gold was treated by H. W. Seaman, of Chicago, Ill., and Bruce C. Yates, of Lead, S. D., and a paper on prospecting methods was read by Walter H. Trask, of Denver, Col.

In the afternoon the first of the convention series of all-some conferences, presided over by Victor C. Adelson, of the Colorado School of Mines, was held, running parallel with the second mine taxation conference and the first of the standardization conferences. That evening the general session was devoted to "Industrial Co-operation," with John A. Benton presiding.

The principal address of the evening was delivered by
GOhioal, L. D. WENTZ
Editors First Vice-President, American Mining Congress

W. A. Graves, vice-president of the Jeffrey Manufacturing Co. of Columbus, Ohio, a man well known for his firm belief in the value of encouraging a spirit of mutual helpfulness and co-operation between employer and employee. He urged his hearers among employers of labor to remember the importance of the human element in their industry and to earn it in good account by educating their men in the principles of mutual dependence. He said unions have their place and should not be antagonized unnecessarily, but that their helpful effort can be offset by proper methods and a wise attitude by men in the board offices and down the line.

Arthur Young, vice-president of the International Harvester Co., described the works punch system his company uses throughout its twenty-four plants, declaring that in three years only five appeals had been taken from the decisions of the joint council of workmen and bosses.

An important social conference took place Wednesday morning, as reported elsewhere. The manufacturers' division of the congress handled together that day at noon. In the afternoon both the mines taxation and the shale-oil conference continued.

Wednesday evening, amid much joy, the exhibitors told a similar in a temporary dancing room at the end of Machinery Hall, the lower floor of the auditorium. A troupe of entertainers, including an orchestra, a cartoonist, a dozen singers and dancers, and five hundred boys who sang and danced bravely on the floor in the center of the room were much applauded.

Municipality was given the floor on Thursday. Companies reported the meeting of which does not survey the interesting nature of their contests, occupied most of the day and were reported elsewhere, but not in the exclusion of special addressees by reason.

Colonel H. H. Longino, who is chief of the technical staff of the assistant secretary of the War Department, passed on all matters of standardization, spoke on the aftermath of standardization as a factor in industrial mobilization. He advocated a draft law for near ten to which would take in every man from twenty to forty and a scheme of fixing wages and profits that would "foster wages and profits at figures obtaining when war was declared." That evening W. S. Culbertson, of the Tariff Commission, explained the new act, saying that in his opinion the provision permitting the President to change the schedules and make adjustments would do more to take the tariff out of politics for good than anything that has ever been done. Judge Crawford, of the Industrial Relations Court of Kansas, told of the progress made by that novel experiment in handling labor trouble and pointed to Alex Howat in jail as what they do in Kansas to stop strikes.

G. A. O'Reilly, vice-president of the Irving National Bank of New York, on Friday morning painted an optimistic picture of business conditions in this country and put himself on record as favoring the payment by European countries of their debts to the United States. F. W. Fenn, of the National Automobile Chamber of Commerce, spoke on the importance of motorized transport in mining. Herbert Wilson Smith, of the Mining Congress staff, spoke on the relation of a protective tariff to the mining industry. Friday afternoon was devoted to viewing the exhibits and to dressing for the banquet that night.

The banquet, always a feature of the annual gathering of the Mining Congress, was a gay affair, despite the greatly mentioned and greatly bemoaned absence of pre-Volstead refreshments. The toastmaster, Richard F. Grant, of the M. A. Hanna Co., waved his opening remarks around the old familiar saying, "You are the days." After he had everyone saddened he turned Elisha Lee, vice-president of the Pennsylvania R.R., loose. Mr. Lee reviewed the shopmen's strike and said that decentralization of the labor problem offered the only permanent solution. He urged that when a man entered the railroad service he give up the right to strike, and pointed out that the stockholder never has a strike when his earnings fall lower than he likes.

Ira E. Robinson, of the Interior Department, gave the assembly what he described as a "good, old fashioned" talk in the old Fourth of July, spreadagle style, depreciating every modern tendency and extolling the Constitution and the liberty-loving patriots of the past.

LETTER FROM PRESIDENT HARDING

The Executive's message to the twenty-fifth anniversary of the American Mining Congress, Cleveland, Ohio, Oct. 9-14, 1922.
How Remedy Tax Evils That Beset Mine Properties?

Keen interest in mine taxation was well sustained throughout the twenty-fifth annual convention of the American Mining Congress at Cleveland, Oct. 9 to 14. In the series of taxation conferences running through the first three days the troublessome question of how to remedy tax evils which exist in most mining regions was threshed out from many angles, and committee reports, some of them voluminous, were read. As a general result the congress veered its course from state action to federal, on the theory that while the root of a good deal of the evil in mine taxation may be local the first remedy lies largely in the federal government.

So the congress after resolving that the load of federal expenditures be greatly reduced, realized itself for future taxation activity. A committee is to be appointed made up of at least one well-informed representative in each mining territory to act with the division of taxation so as to better maintain the congress' contact with tax matters everywhere, and the division is to proceed with the collection of a comprehensive library on the subject, to be maintained at Washington headquarters. Already a bibliography has been compiled by McK. W. Kriegh, chief of the tax division, which will be used as a basis for the building of the library.

The congress considered it a healthy sign of federal right-mindedness that two government officials were sent to the tax conferences to encourage better co-operation between mine owners and Washington. E. H. Batson, deputy commissioner in charge of the income tax unit of the U. S. Bureau of Internal Revenue, was one of these. He explained in great detail the workings behind the income tax, and which previously have puzzled many mine men. He showed how the bureau slowly had built up a working system which at last is able to cope with the involutions of mine taxation and said that by 1923 the government will have cleaned up all of the excess profits tax cases. Mr. Kriegh said this would release approximately $200,000,000 capital now tied up. This release, he declared, would prove a great boon to the mining industry. The second government tax official present was Albert H. Fay, chief of the natural resources division of the Bureau of Internal Revenue.

MINING CLASSIFIED AS A GOING BUSINESS

Carmi Thompson, of Cleveland, an iron-ore operator, who is candidate for Governor of Ohio, paid high tribute to Mr. Fay. "Mr. Fay does all that a good man in his position can," said Mr. Thompson, "but he is handicapped by an unfair law—a law that is unfair because it classifies mining as a going business when it really is a liquidating one. The more successful the mining operation, the faster it liquidates.

At the Monday taxation conference, which opened the tax program at the convention, reports on various state tax methods were read and discussed. The central unit of the congress' tax committee reported its inability to recommend any uniform system of mine taxation for the whole country because of the wide variations of method now in use by states. But it suggested that a uniform general system be worked out to include the taxation of mines, property owned, and profits. While interwoven with property taxes is such that separation is out of the question. The committee declared that the immediate need of tax remedy is great, remarking incidentally that there is much understating of the amount of taxes paid by mines, and that the industry suffers by reason of such estimates. It suggested that while it is difficult now to combat such errors made in defence of high mine tax rates, a library of tax information such as the congress contemplates creating should end this embarrassment.

Hammering home the idea that the present rather chaotic condition of mine-tax matters is expensive to the industry, an estimate was made that the 18,000 mining companies of the country paid out more than $2,000,000 to prepare and make their income and capital stock tax returns in 1921, and that adjustments cost the companies a total of approximately $23,000,000 more, bringing the total cost to at least $25,000,000 for that one year. The remaining sessions of the conference were intended to bring out possible remedies for the tax situation, so that this cost could be reduced.

Paul Armitage, of New York, who presided at most of the tax conferences, on Tuesday read an exhaustive paper on "Distributions from the Depleting Mines' Under the Federal Tax Laws," elucidating the laws on the subject passed since 1913 and now controlling. He remarked that there still is some doubt as to whether a quota of the capital invested in mines must be debited against annual profits to calculate net profits, but that this is not vital because since 1916 the government income tax laws make complete allowance for depletion. There is so much difference of opinion, however, on methods to be used in arriving at the proper annual allowance for depletion that Mr. Armitage suggested a committee of the Mining Congress take up the question with the U. S. Commissioner of Internal Revenue and the Division of Natural Resources. R. V. Norris, a well-known mining engineer of Wilkes-Barre, Pa., presented a discussion on the valuation of mine properties.

PROGRESS IN MINING ACCOUNTING METHODS

At the same session T. O. McGrath, of Bisbee, Ariz., a recognized authority on mine accounting, presented a progress report of his committee on mine accounting methods in relation to federal taxes, and W. R. Ingalls, of New York, addressed the conference on "Mine Taxation in Louisiana." Mr. McGrath's committee hold that since the mining industry has never standardized its accounting and costing methods, it was only natural that the Treasury Department go ahead and crystallize its regulations whether the mine men agree with them or not; so the committee recommended that uniformity be arrived at within the industry. On Wednesday George E. Holmes, of New York City, author of "Holmes— Ferris'" and chairman of the congress' committee on state taxation, spoke on "Invested Capital of Mining Corporations." Robert N. Miller, a former solicitor of internal revenue for the Treasury Department, explained a series of special and significant cases under recent revenue acts and Mr. Kriegh, of the congress' tax division, clarified many points on proper procedure in effecting settlements and compromises with the Commissioner of Internal Revenue.

The following resolution on state taxation was introduced by the tax conference:

Resolved that the report of the special committee on state taxation be accepted as read at this conference and that the thanks of the American Mining Congress be extended to the members of said committee and to those who cooperated with them.

Further resolved that since it seems impossible to obtain uniformity in mine taxation until such time as the various states agree to uniformity in the principles of general property taxation, the subject of improvement in methods of local taxation of mines be referred to the tax committees of the several chapters of the American Mining Congress.

Further resolved that subjects of general interest in mine taxation be referred to the standing tax committee, with power to confer and aid the tax committees of the several chapters; and

Be it further resolved that a general tax committee be created to be composed of one member from each state, to co-operate with the standing tax committee of the American Mining Congress on all matters of general interest in taxation. The members and officers of the standing tax committee of the national organization shall be ex-officio members and officers of such general committee; and

Resolved that the Board of Governors of the several divisions appoint at this session, or as soon thereafter as practicable, from each state within their jurisdiction, one man to be a member of such general tax committee, and that where a state is beyond the jurisdiction of the Board of Governors the standing tax committee be authorized to select from each of such states one man to sit on such general committee.
Problems of Operating Men

Regarding the Use of Booster Fans in Mines

Insurers Where the Use of Booster Fans Becomes a Necessity—Other Cases the Result of Bad Management

Need of an Efficient Mine Superintendent or Manager

FROM time to time there have appeared, in Coal Age, numerous articles in the use of booster fans for overcoming the ventilation in certain mines. In offering the following remarks, it is not my desire to repeat statements that have been advanced as to the advantage gained by the installation of such fans in any particular mine.

Undoubtedly, there are instances where it becomes necessary to use a booster fan in order to obtain all the benefits that are available. But, as a rule, the use of booster fans in all mines is likely to be abandoned, and where it is impossible to install any necessary apparatus to improve the ventilation in that section, the air being lost, it is realized that something must be done to counteract the unhealthy conditions which have resulted from the lack of proper ventilation.

Power Plan and Management Will Distinguish Need of Fans

On any occasion of a mine in property being sold and its air-currents being changed, Complied, cleaned and kept free of all obstructions to the flow of air, an inspection will always result in the installation of a booster fan or fans in order to maintain the required amount of air in the working places.

Without knowing the actual condition of a mine, or whether booster fans have been in use there, it would appear that the operation is a cheap and efficient method of ventilation. The mines that are operated by the same company and that have been in operation for years and years and years must have some factors in common other than those that have developed with a booster fan in the usual arrangement.

Some of these factors, however, have developed the ventilation system on the whole, although some of them may have been responsible for the development of others. In other cases, it may simply have been a good man in charge, with a thorough knowledge of the practical operation of the mine, and the needs of its future development.

The chief desire of a temporary foreman of this kind is to keep a low cost-sheet and put out cheap coal. In order to do that, he allows dirt to accumulate on the roads; falls of roof in the air-currents go unheeded; timbering of entries is neglected and complaints of bad air in the working places are frequent.

Under these conditions, there is sure to be evidence of bad management everywhere throughout the mine. This continues until affairs take a turn and the officials wake up to the idea that a change of foremen is necessary. It is wholly to the advantage of a coal company to employ an efficient and reliable foreman—one whom they can retain in permanent charge of the mine.

BUSINESS FOREMEN NEEDED

If a business man of intelligence and experience is needed in any position in a coal operation, it is in the position of mine foreman. Personally, I have seen much money wasted through the management on the part of the foreman in charge. For one reason or another, foremen are often prone to retain more men than they require and, yet, the mine is not kept in the best working condition.

No foreman is efficient unless he retains the mine in his charge and has a good working condition at all times and plans the work with a view to the future development of the property. As the workings of a mine are extended, the foreman must be able to provide and organize his crews that will insure good ventilation in the working faces. To do that, he must have a thorough knowledge of the theory and practice of ventilation.

EFFICIENCY QUICKLY SHOWN

As may be inferred from my previous remarks, the position of a foreman in charge of a mine will show itself quickly through the bad results obtained by his operation. This may not appear in a day or a month. In most cases, it may require a year or more to prove the inefficiency of a foreman. Unless the management are thoroughly familiar with the practical operation of the mine, and the needs of its future development,

The shrinkage of output and the daily mounting of the cost-sheet are, of course, warnings of breakers ahead; but often, present fears are allayed by the plausible excuses of the mine foreman. It is then up to the management to form their own independent opinions, and determine whether the fault lies with the foreman, or that the condition is unavoidable.

In closing, let me say that dirty tracks, falls of roof blocking the air-currents, accumulation of water at the working faces, or on the main haulage roads, cannot be explained away by excuses, provided the foreman has the means at hand for doing the work required.

O. KENNETT

Hillside, Ky.

Mine Foreman.

Relation of Foremen and Miners

Need of training all miners to have confidence in themselves—Two types of mine foremen—Two types of miners.

READING the article "Gaining the Confidence of Men," by G. W. Breedon, Coal Age, Aug. 24, p. 290, it occurred to me that it would be a good idea to inspire our miners to have more confidence in themselves, and rely more on their own judgment in the placing of their shots and the standing of their timbers. Teach them to take proper care of their working places, and not to depend on the foreman to tell them how and when to do these things.

In my opinion, it is a good thing for a miner to confer with his boss when he visits his place, and ask for his ideas regarding timbers or timbers under dangerous top. But a miner should never wait for him to point out where timbers should be stood to make the place safe.

TRAIN MINERS TO INDEPENDENCE

Miners should be trained to be careful and watch for any dangerous conditions that may appear. Then, without waiting for the boss to tell them what to do, the miner should proceed at once to make himself safe.

It seems to me that the efficiency of miners who stand timbers only when approved by the foreman, or who depend on him to arrange their shots, cannot be estimated very highly. It is all right for a miner to have the utmost confidence in his foreman's judgment, in regard to standing timbers and arranging and charging shots; but every miner who is in a charge of timbers should have the ability to take care of himself without being told to do so.

The foreman should be a man of experience, whose judgment can be re-
lied on in almost any emergency arising in connection with the mine work; but that does not signify that he should know where timbers are needed in a working place any better than the old experienced miner who works there every day.

Training a miner to depend on his foreman to tell him what things he must do to keep his place safe has a tendency to cause him to lose confidence in himself in that respect. A miner who has no confidence in his own ability to stand timbers and arrange his working place is worthless as a mine worker.

**Type of Foreman on Whom Miners Learn to Depend**

Competency and ability on the part of the foreman to fill the position he holds and honestly in dealings with his men will gain their abiding confidence. Consider two foremen, for example: Of one it can be said, he is a kind and pleasant fellow; but he does not know anything about practical mining. Can you rely on his judgment, or on anything he may say regarding the work? His opinion may be of some use, and as ready to forget them. Such a foreman cannot gain or long retain the confidence of his men.

Of the other foreman it can be said, he is rather an unsocial man, or distant in his manner; but when it comes to handling the work he stands very well. His word is as good as his bond. He talks but little, but means all he says. His judgment about the work is good; and he gives it when and where it is needed. Miners will have confidence in such a foreman, though he may be close and strict in his dealings with them—friendly but never intimate.

**Two Types of Miners Compared**

In a certain coal mine, there are two miners employed. One of these is not skilled in his profession, although he has been in the mines for years. He is incompetent to do work where care and the exercise of good judgment are required. The other miner has not been in the mines many years, and yet he is skilled and competent to do any kind of work pertaining to the mine. He is a good workman.

If in a section of this mine there is a dangerous and difficult piece of timbering to be done, which of these men will the foreman choose for the work? Will he select the miner first named? Can he have confidence in his judgment and ability to perform such work?

The answer is, No!

Some miners possess great friendship and respect for their foreman as long as they are shown special favors; but when there are no favors coming, their regard for him wanes. The better element of miners, however, have confidence in the foreman who is honest and capable and who, in a business way, looks after the welfare, interest and safety of all and treats all his men with equal fairness in his dealings. A foreman who sacrifices honor and principle to gain the favor and confidence of a few of his men will soon lose the respect and confidence of the better and more intelligent element.

**Practice of the Golden Rule the Key to Mutual Confidence**

In the article previously mentioned, Mr. Breeden says in substance that his experience as mine foreman has taught him to treat every man as he would have them treat him under similar circumstances. Let me add, the practice of that principle is the key that will unlock the door to a mutual and abiding confidence between men and officials. The hope of industrial peace is to be found in the practice of the Golden Rule.

**John Rose**

Former State Mine Inspector.

Dayton, Tenn.

**Longwall Retreating in the Panel System**

Butt headings driven up the pitch—Panels worked out by the retreating method of mining.

**Referring to my previous letter** describing a method of handling a fire situation in a longwall mine, Coal Age, Aug. 17, p. 248, it appears I did not make myself clear in regard to the method of working out the panel.

Starting on the main headings, each panel is worked by driving three pairs of butt headings directly up the pitch. Each pair of headings was driven on 50-ft. centers, leaving 245 ft. of solid coal on each side of each pair of butts. It is stated that these pillars were to be worked out on the longwall retreat system. In my opinion, the area within the panel could not be worked on the retreating system, until other developments had been driven to the outer edge of the panel area.

My idea was to drive longwall advancing faces across the pitch, starting left and right from the butt entries and leaving gateways for switches, at suitable intervals, on each pair of butts.

**Thomas Allen**

Mine Rescue Station, Mt. Harris, Colo.

**It is difficult to understand how working out a panel, by extending a longwall advancing face across the pitch, starting left and right from the butt entries and leaving gateways for switches, at suitable intervals, on each pair of butts.**

**Charging Holes With Steel-Headed Tamping Bars**

Steel tamping bars dangerous under any conditions. Danger greatly increased if coal containing naphtha.

Charging a hole with loose powder is a dangerous practice. Tamps all holes with clay.

**Reading a recent reference to the blasting of coal in mines, in respect to the dangers attending that work, I am reminded of one or two dangerous practices to which I believe attention has not as yet been drawn.**

The first point I would mention in this connection, is the use of steel-headed tamping bars. In spite of all
In my opinion, it should be the duty of the district mine inspector, in making his rounds of the working places when Booster fans are in use, to see that the miners are supplied with a suitable tamping bar. He should urge that these be kept on hand in the supply house, and sold to any miner who is not already supplied. The bars should be sold to the miner at cost, with freight charges added.

In the case of a ventilation, let me suggest that coal companies should supply their miners with clay or other incombustible material for tamping their shafts. This will go far to obviate the use of fine coal dust and slack for that purpose, which is too often the practice of miners where other material is not available.

It is hardly necessary to repeat what has been so often urged in Coal Age, that competent shotfiring men should be employed whose duties it would be to examine, charge and fire all shots in the mine, except such shots as are, in their judgment, for any reason unsafe.

Every miner should be instructed to remove the fine coal cuttings, after drilling a hole in his place. In most cases, arrangements should be made for taking these cuttings out of the mine. Where dustproof cars are in use, the cuttings can be loaded out with the coal.

In closing, let me say that when these and a few other precautions necessary for safety are followed by miners and the officials in charge of the mine, we shall see a gradually decreasing percentage of mine accidents. What is needed is the strict enforcement of rules for safety.

OSCAR H. JONES,
Wilder, Tenn.
Fentress Coal Co.
in dangerous quantities in the working faces. Therefore, at the best, a booster fan should only be regarded as a make-shift, for the purpose of avoiding expensive repairs in a portion of the mine that is about finished.

It is unnecessary to dwell further on the dangers that follow in the wake of installing a booster fan at any important point in the mine. In case of an explosion in the mine, such a fan is of little or no assistance to the rescuers who would enter the mine. The sparking of the motor is an added danger, in a mine generating gas. It is a safe general rule never to place any ventilating apparatus at any other point than on the surface where it will be subject to constant supervision and accessible at all times.

## Examination Questions Answered

### Indiana Mine Bosses' Examination, Indianapolis, 1922

(Selected Questions)

**Question:** Give five causes of accidents that occur on haulageways, and state the method to prevent them.

**Answer:**
1. Accidents to persons walking the road and being caught by a car or trip. 2. Accidents due to men and boys riding on loaded trips, contrary to the regulations of the mine. 3. Accidents to motormen and trip riders when cars are derailed, causing a wreck. 4. Accidents due to cars standing on a room switch where the track is supposed to be clear for the motorman. 5. Collision of cars by reason of faulty schedules, or disobedience of orders by motormen and drivers.

To prevent these accidents from occurring:
1. Provide ample clearing space on one side of the track and refuge holes at short distances apart, kept whitewashed and free from obstructions. Every trip should have a warning gong or other means of telling the approach of danger.
2. Enforce strict regulations in regard to persons riding loaded trips, and provide suitable penalties for violation of the rules.
3. Have a good schedule for the running of cars or trips and enforce strict regulations regarding the maximum speed of hauling.

**Question:** Give five safety precautions that a miner should observe on going to his working place at the face.

**Answer:**
1. A miner should enter his place with caution, observing carefully the condition of the roof and timbers as he proceeds. 2. If he has brought his powder with him, on coming into the mine, he must first put it in a safe place before proceeding.
3. He should look for the mark left by the fireboss, showing that the place has been examined and found safe.
4. Unless the mine is known to be free from powder in blasting the coal; failure to remove the fine cuttings in machine mining; neglect to clean up roads and air-courses and remove accumulations of dust on the working places. To prevent these occurrences, the required powder should be used and the blasting performed by competent shotfirers. No accumulations of dust should be permitted at the working faces throughout the mine. Roadways and air-courses should be cleaned, at regular short intervals, and an effective spraying system installed in dusty mines where the coal is highly inflammable.

**Question:** In what way would you provide for the protection of your men from falling roof?

**Answer:** Frequent careful inspection of the working places, by the foreman, assistant foreman, safety inspectors and fireboards; and the enforcement of strict rules and regulations regarding the setting of timber in working places, will go far toward protecting miners from the falling of the working face. Particular attention must be given to the work of drawing pillars. All workers must be carefully instructed in respect to making themselves safe. In addition, an ample supply of suitable timber should be kept in all working places, ready to use when needed. The most effective safety device known, however, is a careful man.

**Question:** What is the best and safest way to detect the condition of the roof?

**Answer:** Besides the usual method of sounding the roof with a pick, holding one hand against the roof while striking the blow, to detect any tremor or hollow sound that would indicate an unsafe condition, it is important to make thorough inspection to see if any slips or fault lines are present. If these are found they must be carefully studied and means taken to avoid accidents therefrom.

**Question:** What is the danger arising from working a mine adjoining an abandoned mine?

**Answer:** The abandoned workings may contain accumulations of water or gas that would flood the live workings and endanger the men should a place break into the old workings. In order to minimize this danger drillholes must be kept in advance of the faces of all places approaching old workings that have been abandoned. No reliance can be made on the accuracy of surveys of such mines.

**Question:** Give method of procedure in case an explosion occurred in a mine of which you had charge, and the ventilating devices have been injured and men must be rescued.

**Answer:** Call for volunteers and select the most experienced men to form rescue parties. Make such temporary repairs as are necessary to restore the ventilating current. The rescuers, equipped with safety lamps and wearing breathing apparatus, if such is available, must enter the mine with the air and proceed with caution, making only such repairs as may be necessary to restore the current. Send at once for physicians and other assistants.
British Household Coal Prices Now 63 Per Cent Higher Than Before War

Although 18 lb. pieces of three qualities of coal were formerly used at the rates of £1, £2, and £3 per ton in British households, the present rate is considerably more than that of the last, as shown in the following:

<table>
<thead>
<tr>
<th>Quantity</th>
<th>Present Price</th>
<th>Last Price</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 lb.</td>
<td>£0.05</td>
<td>£0.03</td>

<td>£6.00</td>
</tr>
</tbody>
</table>

The distribution charge includes delivery and fuel costs, storage charges, handling, and profit. Today's prices are sold as an additional freight per ton, the final price being a hundred more than that of the last previously mentioned. In 1906 the average price of this coal was 6, the service and wage cost was 50, and the total making 58. The current prices are about 63 per cent above those quotations.

Kentuckians to Consider Mine Problems

Under the leadership of A. G. Spillane, general superintendent of the St. Bernard Mining Co., Earlington, Ky., their president, the Kentucky Mining Institute will assemble, Nov. 3 and 4, in the昶ch Park Hotel, Louisville, Ky., to discuss mine problems with special reference to the needs of their industry at the mines of their state.

Two sessions will occupy one on the preparation of coal and the other on small mining machinery, the latter being presented on behalf of the institute by Alphonse F. Brophy, superintendent editor of Coal Age. This will occupy the first session, opening at 10 a.m. The second session, at 10:30 a.m., of the same day, will hear papers, one by Graham Bright, chief engineer of the Westinghouse Electric & Manufacturing Co., of Pittsburgh, Pa., on "Catering Lunchrooms for Coal Mines," another by C. D. Franklin, district superintendent of the Portland Cement Association, on "What Good Results Mean in Mining Districts," and a third by T. M. Uddom, coal broker and coal agent of the Louisville & Nashville H. R. Leavitt, Ky., on "Present Coal Trade Problems and Prospects for the Future."

The same evening at 8 when a mahogany will be held at which the subject to be discussed will be "How to Make an Operators' Association of Mine Value." In this discussion the following are scheduled to discuss the problem: R. A. Hook, general superintendent, Lexington, Ky.; H. B. Clayman, attorney, Harlan County, Ky.; J. E. McCay, secretary, Southern Appalachian Coal Operators' Association, Nashville, Tenn.; J. E. Butler, general manager, Stearns & Lumber Co., Stearns, Ky.; G. E. Richardson, president, West Kentucky Coal Co., Sturgis, Ky.; R. C. Tway, president, R. C. Tway Coal Co., Louisville, Ky.; Munro B. Lanier, president, Munro-Warner Coal & Coke Co., Birmingham, Ala.; C. S. Sneed, general manager, Pioneer Coal Co., Kettle Island, Bell County, Ky.; K. A. Muckley, president, the Harlan Coal Co., Louisville, Ky.; Harry E. Bullock, president, Carri Fork Coal Co., Lexington, Ky.; Frank D. Hurlburt, president, St. Louis & Missouri, Earlington, Ky.; F. P. Wilson, general manager, Crampton Coal Co., Reivier, Ky.; James D. Overall, general manager, Reinecke Coal Mining Co., Madisonville, Ky.; C. J. Norwood, University of Kentucky, Lexington, Ky.; R. Dawson Hall, Engineering Editor, Coal Age, New York City.

On Saturday a business session will be held at 9 a.m., after which the meeting will be adjourned.

Cliftonville Case Involves 218 Union Men 71 Charged with Murder

Two hundred and eighteen union miners were placed on trial at Wellsburg, county seat of Brooke County, W. Va., on Oct. 9, charged with complicity in the death of Sheriff H. H. Duvall, of Brooke County, who was killed while repelling an attack on the Cliftonville mine of the Richland Coal Co., on July 17. Seventy-one of the defendants are charged with first-degree murder. The indictments range from murder to conspiracy and aiding and abetting. As many as half a dozen indictments are pending against some of the defendants, all of whom, if it has been announced, will be prosecuted to the full extent of the law.

Prosecuting Attorney W. S. Wilkins of Brooke County will be assisted by John J. Coniff and J. B. Handlan, of Wheeling. Charles J. Shuck resigned as Assistant District Attorney to engage in the case as counsel for the defendant and has associated with him D. A. McKee, formerly prosecuting attorney of Ohio County; F. A. O'Brien and M. J. Cullinan, all of Wheeling, and John D. Gardner, of Steubenville, who was once a miner. One of the most interesting phases of the case is that John J. Coniff, who was the principal attorney for the defendants in the Matewan case, will act as one of the principal attorneys for the state in the Cliftonville case.

Martial Law Lifted in Mingo County

Martial law, established in Mingo County, West Virginia, June 27, 1921, more than fifteen months ago, after a series of outbreaks, which resulted in several deaths and the flight of considerable numbers of people ordered by Governor Morgan. Peace has been restored along the Tug River, where war between union and non-union miners spread terror and resulted in the intervention of federal troops.

Total coal produced in Indiana in 1921 was 36,500,000 tons.
New England has made strenuous efforts to avert a domestic coal shortage before the advent of coal-burning weather. Despite all the warnings of an impending famine, there are several encouraging factors in the situation in that section which indicate that household consumers may "get by" with a minimum of inconvenience this winter.

Unseasonably warm weather has delayed the lighting of furnaces. This has proved a welcome respite to retail dealers and has enabled shippers to spread a thin veil of anthracite over the territory as a bulwark against the insistent demands which will come with the first cold snap. More coal went into cellars just prior to the anthracite suspension than has been generally realized. New England got a fair proportion, at least, of the mine storage stocks that were moved during April, May and June. Substitute fuel is plentiful; little has been distributed at retail, but it will be available when wanted. Lastly, economy in fuel consumption can always be expected during a period of shortage with its attendant high prices.

Conditions in Massachusetts are typical of New England as a whole. That state, through its Fuel Committee, is taking active steps to safeguard the fuel supply and protect its citizens from extortion. In urging upon the Federal Fuel Distributor, at Washington, the necessity for adequate supply and reasonable prices, James J. Phelan, Massachusetts Emergency Fuel Distributor, describes the situation in that state as follows:

"Bituminous reserve stocks for industrial purposes are not in excess of the line of safety, considering our remoteness from the mines. Anthracite deliveries by dealers to households so far this season, commencing April 1, are carefully estimated not to have exceeded 25 per cent of the total quantity customarily distributed by dealers to households within the same period of time in normal years. "In view of the fact that the people of New England and of Massachusetts have always used anthracite for their household needs, and we have this year lost five out of twelve months' anthracite production, it follows that our people will be unable to secure adequate anthracite supplies. We shall, therefore, be compelled to use considerable substitute fuel to take the place of, or mix with, such supplies as we may be able to secure.

WOULD NOT HESITATE TO ISSUE EMBARGOS

"I am glad to observe that you are exerting every effort to secure the fullest transportation services in order to provide the maximum quantities available as promptly as possible. I, therefore, trust that you will not hesitate, whenever the occasion requires, to issue embargos, and establish priorities that shall maintain constant and equitable distribution between states. In this connection may I point out that in my order of Sept. 21 'all dealers and consumers receiving fuel in carload lots must unload such cars within the twenty-four hours following the receipt thereof. Every day saved in the use of coal cars should be a gain of several tons in production."

"There exists to-day a variation of approximately $5 in the nine prices being charged Massachusetts retail dealers above the costs prevailing last March for anthracite, resulting in increased costs to our householders. I can, and shall, control the gross margin which may be added by dealers to the cost of coal to them, in order to prevent extortion within the state, but it is obvious that the cost of coal at its sources is beyond my control. You will understand that our earnestness in this matter is based upon the desire that the federal and state governments shall fully co-operate in such a way as will secure to the citizens of Massachusetts the best results possible under the present difficult conditions."

New England is getting more than its fair share of current anthracite shipments, when the greater Western and Lake movements are considered. Requirements for the winter in Massachusetts are estimated at 4,000,000 tons. By Oct. 1 all-rail shipments of anthracite by this section were averaging 300 cars per day. The normal movement during the month of March, if this movement and shipments by water can be maintained, the estimated shortage of 1,500,000 tons will be reduced materially. However, this shortage will never for the most part at the beginning of the season, therefore the main problem is to overcome this difficulty for perhaps 60 or 90 days, after which it is expected that the conditions will gradually become normal before the season has ended.

---

**«..tmi & M. R.R. Takes Much British Coal**

Unloading cargo directly into railroad cars, shown in foreground.

*Coke is finding a better market for domestic purposes than for years past. The present emergency also has produced a strong market for Rhode Island coal, which is being sold not only at points adjacent to the mines but is finding its way to more remote New England points. The public has lost much of its faith in this coal, partly because of its weight, which made it appear small in bulk when delivered, and partly because of its excessive ash content, but mainly because of the difficulty in kindling it. This coal is extremely variable in character and quality, ranging from anthracite to graphite and, unlike Pennsylvania anthracite, its high content of water necessitates a special drying process. During the last year or so extensive experiments have been made in preparing and firing this fuel, and at the present time one company at least is putting it on the market in sizes and condition that makes it an excellent substitute for Pennsylvania anthracite and at a price which is attractive. New methods of firing are necessary; the coal needs considerably more draft than other fuels, but once one becomes acquainted with its peculiarities it is said to be far more satisfactory as a domestic fuel than bituminous coal.*

*Anthracite receipts are making inroads on the shortage with every day's delay of cold weather. With the practice of economy and a plenitude of substitutes at hand when wanted, the worst that New England householders should experience this winter is the necessity of adapting themselves to the use of unfamiliar fuels. At that the substitute tonnage will not be large and its use will be confined to the early part of the season.*

**British Fuels, Though High Grade, Do Not Ship Well**

British shippers also made an attempt to push their Admiralty Large for domestic purposes, but, like the Welsh semi-anthracite, this coal has not cut much of a figure in the domestic market. Both are high-grade fuels, but do not ship well. The New Englander has been so accustomed to the use of our clean and uniformly sized anthracite that the physical appearance alone of the British coal has been against its sale at retail. The following analyses were made from recent receipts in New England:

The U. S. Bureau of Mines, in co-operation with the U. S. Public Health Service and the Society of Heating and Ventilating Engineers, is engaged in a study of the relative importance and correct correlation of the many individual factors concerned in the problem of the physiological effect of different conditions of temperature humidity and air motion. A special room has been constructed for this purpose at the Pittsburgh station in which the air conditions are controlled by apparatus outside the chamber and entirely separate from it. A comprehensive program, which includes a quantitative study of a considerable number of bodily functions, is being carried out. The work has not yet been completed, but enough has been done to demonstrate the importance of determining the physiological reaction to environment as a measurement of the harmful effect of heat and humidity, and to show that feelings of discomfort as a standard of measurement cannot be depended upon because there is a certain adaptation of the sense organs to an unchanging environment, and individuals differ in their sense reactions.
Smokeless Operators Will Sell Domestic Sizes at $6; Spens to Probe Anthracite Prices Over $9.25

Prepared sizes of smokeless coal for domestic use will not be sold at a price in excess of $6 a ton, an agreement to that effect having been reached by the Federal Fuel Distributor and operators representing 80 per cent of the smokeless production. Fuel Distributor Spens gave out the results of the conference in the following prepared statement:

"The Federal Fuel Distributor had a conference on Oct. 14 with four operators in the 'smokeless field' of West Virginia relative to coal prices. This field comprises the Pocahontas district, the New River district, the Winding Gulf district and the Tug River district, and the estimated total coal production in these four districts is 36,000,000 tons per annum. The operators that were present at the conference represent approximately 80 per cent of the commercial production.

"The maximum price f.o.b. mines on prepared sizes for household use that was observed by the operators, through co-operation with federal and state authorities, prior to cessation of the miners' strike, and at a time when the coal supply in the 'smokeless field' practically equalled the demand, was $5.13 per ton, including sales agency's commission. With the settlement of the miners' strike in union coal districts, the operators in the 'smokeless field' found it necessary to advance the wages in their mines materially, resulting in an estimated increased cost of production of the prepared sizes of approximately $1 per ton. In addition, with the ending of the strike, the coal supply commenced to diminish, due to distribution of equipment that naturally had resulted from a wider distribution of this 'non-union' coal, the immediate demand for cars from 'union' mines, and the retarded transportation incident to the railway strike, until today the coal supply in the 'smokeless field' is appreciably below current requirements and quite below the supply available at the time the former price was established.

Smokeless Coal Now Much in Demand

"The demand for 'smokeless' coal is very great, and since the termination of the miners' strike, at which time this understanding as to prices was cancelled, f.o.b. prices at the mines on domestic coals have ranged as high as $8.75 per ton plus 8 per cent sales agency's commission, or a total of $9.45 per ton. These operators, however, in appreciation of the present emergency and in a desire to continue to operate with the federal government in the accomplishment of its purposes, indicated a willingness not to exceed a maximum price f.o.b. mines of $6 per ton on the prepared sizes of coal for domestic use, this price also to include the sales agency's commission. Therefore, effective at once, this will be the maximum price f.o.b. mines that wholesalers, retailers or other purchasers of these coals will be asked to pay.

"While, as stated, the entire production of the 'smokeless field' was not represented at the conference, we have been assured that the action taken by the very large majority will undoubtedly be followed by the remaining interests.

"Conferences on the matter of coal prices are being arranged by the Federal Fuel Distributor with representatives of mine operators from each of the states coal-producing districts east of the Mississippi River. Fuel Distributor Spens is giving attention also to the price situation in certain coal-producing states where it is reported that coal is being sold within the state at a certain maximum figure agreed upon with the state authorities while it is being marketed outside the state at figures in excess of this maximum.

"Lieutenant-Colonel Hatch, U. S. Marine Corps, retired, has been designated with the permission of the Navy Department to act as the representative of the Federal Fuel Distributor on the fair practices committee of Pennsylvania, an organization which functions as a part of the Pennsylvania Fuel Commission and which is giving its special attention to matters affecting the price and distribution of anthracite. Lieutenant-Colonel Hatch's residence is in Philadelphia. He succeeds E. M. Durham, Jr., who is resuming his duties with the U. S. Railroad Administration. Arrangements have been made for a conference between the federal distributor and a special committee of the National Coal Association, of which J. C. Brydon, of Baltimore, is chairman, to be held in Washington, Oct. 18, for the purpose of discussing matters relating particularly to transportation conditions and earnings.

"The following statement summarizing developments in the anthracite price situation was issued Monday night by the Federal Fuel Distributor:

"Approximately 75 per cent of Pennsylvania's anthracite is produced by the larger, or so-called 'company' operators. The balance is produced by the so-called 'independent' operators. On the 75 per cent production a price of $8.50 per ton f.o.b. mines, established by Pennsylvania state authorities prior to the creation of this office, applies as a maximum, although on a goodly percentage of the production prices ranging from $8 to $8.35 per ton have tarily been observed. On the remaining 25 per cent production prices range from $9.25 to as high as $14.25 per ton f.o.b. mines.

"The fair practices committee of Pennsylvania was appointed several weeks ago to investigate cost of the 'independent' production and to determine fair f.o.b. mine prices. The Federal Fuel Distributor is represented on this committee.

"This committee commenced to function about Oct. 1, and since that time, pending a more thorough investigation and final conclusions, 'independent' operators, representing approximately 20 per cent of the total production, have signified a willingness to observe a maximum price of $9.25 per ton f.o.b. mines, the prices theretofore on this production having ranged in some instances as high as $10.50 per ton.

"In order that the fair practices committee may concentrate its efforts on the remaining approximately 5 per cent, on which production prices are today ranging as high in some cases as $14.50 per ton f.o.b. mines, the Pennsylvania Fuel Commission and the Federal Fuel Distributor have agreed as a temporary expedient to defer investigation of these independent operators whose prices will not exceed $9.25 per ton f.o.b. mines. The Fair Practices Committee have been advised by the Pennsylvania Fuel Commission and the Federal Fuel Distributor that their findings as to fair prices that should obtain for the 5 per cent production should be completed by not later than Oct. 31."

Jobbers' and brokers' commission charges on sales of coal to retailers and consumers must not raise fuel prices above maximum levels fixed for coal at the mines by the state, under a ruling by C. J. Neal, state fuel administrator of Ohio and approved Oct. 11 by Governor Harry L. Davey. Under this ruling the "fair prices" of $3.36 to $4.80 established in Ohio include the merchant's profit. Mr. Neal's announcement reads:

"Effective Tuesday, Oct. 10, prices received by producers in Ohio for coal sold to jobbers, brokers or wholesalers under a ruling by C. J. Neal, state fuel administrator of Ohio and approved Oct. 11 by Governor Harry L. Davey. Under this ruling the "fair prices" of $3.36 to $4.80 established in Ohio include the merchant's profit. Mr. Neal's announcement reads:

ARTICLE IN THE newspaper was to be composed before the Interstate Commerce Commission on Oct. 15. The decree in the matter of mine rating and coal distribution rules will be considered at the same time. Commissioner Atchison will preside.
Maurer Foresees Repetition of This Year's Trouble Next April*

Until this week a thing on a sort of a real advantage in the Central Competitive Field had almost been unheard of. But now the coal interests are doing something about it. That is, when the demand is so great that the operators are finding that it is more economical to do business by giving the miners a wage than to keep the mines idle. This has been going on for some time, but it is only in recent weeks that the operators have taken it up in earnest.

The operators in the Central Competitive Field, which includes West Virginia and the neighboring states, have been increasing wages, and it is said that this has been a great move on the part of the operators. They are paying more than double what they used to pay, and the miners are getting more than double what they used to get. The result is that the miners are getting more than double what they used to get.

The miners have also been working harder than ever before. They have been working for more than double the time they used to work. The result is that the miners are getting more than double what they used to get.

The operators are also paying more than double what they used to pay. They are paying more than double what they used to pay. The result is that the miners are getting more than double what they used to get.

Bradley Defends Policies of Non-Union Operators*

During the long depression of 1921, when coal was a drug on the market, when the coal industry was ready for the bandit receiver, the great Southern district was producing 80 per cent of its maximum.

That illustrates a very important point. There must have been a reason for that, and what was that reason? It was the ability to adapt itself to changing economic conditions. You travel through those fields and you will find enormous collieries, tremendous operations, wonderful mining towns, adapted to the comfort and the convenience of the employee such as you will find in no union field, where the bitterness and distress of class hostility has been injected, so that the operator doesn't feel like giving that man a place to work.

There in the South, where we have this co-operative spirit, you will find the cheapest living, the cheapest rents, the cheapest store prices; you will find co-operation in reducing wages and in raising them. We know when we should pay our men more and we do it. We are not tied up by a contract, running through every conceivable up and down of economic depression and keeping the men from getting a decent wage in good times, and taking the work away from them in bad times.

We only wish that you had the same advantages.

When I think about it I feel that I simply can't express to you what it means to the operator who is on that basis with his labor. It is a partnership, and that is what it ought to be. It is a man-to-man relationship. There is no third party to come between telling the thrifty workingman that he is being cheated; no third party to come in and tell the honest, hand-saving son of toil: "Don't work so hard."

Why is it necessary to have an investigating commission for the coal industry when the coal industry has been investigated by a public committee every eighteen months for the last seven years? Why can't they take some of that somewhat experiment for it? To a man like George Otis Smith and have him compile it and tell the story, with the affidavits to back it up? It wouldn't be enough of a smoke screen.

Now, this is what we are getting out of Washington. This coal labor problem—I feel very much about my coal business as I do about my garden. I have been fighting bugs and insects and plagues in that garden from early spring to late fall every year; my only bill for insecticide is more than almost the pleasure that I get out of the garden. And that is just exactly what I have been doing with my coal business. I have been fighting the pests, the diseases, the assailants, and in West Virginia, by God, we fight them with a rifle, and so would you. You wouldn't let a sneaking skunk steal up and put a wire through your garden, whereas, if you didn't want to do it. Now we come to the crux of the labor problem. It is a question of the enforcement of the law that we have got. Labor courts, boards of conciliation—put them in the waste-
paper basket! Give the man who wants to work and who has the right to work the protection which he deserves—to work. There wasn't a time during this strike in the anthracite and bituminous coal industry that the mines couldn't have been manned by men who wanted to work, but they were afraid—a fear that they would be massacred, as they were at Herrin.

The public of the United States doesn't realize the crime that your union operators and the United Mine Workers have perpetrated on you. The public of the United States doesn't realize that the price of fuel for the future is today in the hands of the labor oligarchy, which has every intention of emulating Lenin and Trotsky; they are jealous because they haven't beaten them to it. And when you get the entire fuel resources of a nation in the control of such an unscrupulous, small group of men, you can sit around the table and say, "Now, John, you shouldn't do that," but it will get you nowhere.

Why should the public allow us to operate our mines if we haven't got the gumption to fight for our customers? They had better make their deal directly with the labor oligarchy; no use in counting us in. Why give us our profit? What have we done to earn it?

Before there is any other situation such as we have just come through, before another first of April, let us pray to God for the sake of the 110,000,000 people of the United States, who were held up by those controlling that traffic, just as the highwayman in the night holds up the express crowded with people, so the leaders of this labor oligarchy have held up that 110,000,000—yes, let us see, that these high-paid public officials enforce the law; let us see that the public knows the situation so that they will demand that that law be enforced for their own protection.

Michigan Legislature Expected to Pass Fuel Bill Similar to New York's

Michigan's Legislature assembled in special session Oct. 10 to consider legislation to regulate distribution and cost of coal in the state and the Senate on Oct. 12 by a vote of 24 to 4 approved the measure submitted by the state's administrative officers, after slight amendments. One of the modifications limits application to coal and coke, releasing wood, oil and other forms of fuel, and another change eliminates authorization for appointment of a salaried fuel administrator.

The administration bill encountered rougher going in the House. It is predicted, however, that the House will pass the bill in modified form and that House and Senate will then harmonize the efforts of the two bodies.

The measure is modelled quite closely on the New York law, though its provisions are said to be less drastic. It contemplates a system of licensing dealers and provides for seizure of coal or coke in possession of dealers.

SPENS WILL NOT ATTEMPT TO FIX PRICES

The Federal Fuel Distributor has no intention of attempting price-fixing. This was brought out at a conference between John W. Davis, special counsel for the National Coal Association, and the law officer of the Fuel Distributor's office. Mr. Davis in a telegram to A. M. Ogle said: "Counsel for the Fuel Distributor assures me that the Fuel Distributor has no intention now or hereafter to attempt the fixing of prices. All efforts will be directed to moving coal.

DENIES OHIO COAL WILL BE FORCED INTO MARKETS OUTSIDE THE STATE

Emphatic denial was made by Commander H. H. Rouss, federal representative in Ohio of the Federal Fuel Administration, to reports that Ohio-mined coal will be forced into interstate channels, thus compelling Ohio dealers to buy from other states at exorbitant rates, because of the Ohio emergency control system.

"Statements to the effect that Ohio's fair-price law would deprive the people of this state of coal are not founded on fact," Commander Rouss avers. "Definitive instructions on that very point reached us recently. State Fuel Administrator Neal, on his recent visit to Washington, was assured that any effort to evict the Ohio law through interstate channels would meet with a sharp check from the federal authorities."

ON PAGE 561 of Coal Age last week the Ohio fair-price schedule by districts contained an error in District 7, which should read as follows: "The counties of Trumbull, Portage, Summit, Mahoning, Medina, Wayne and Stark and the County of Columbiana except the townships of Washington and Yellow Creek, $4.86."
Coal Wholesalers Express Satisfaction With Personnel of Coal Commission

Residential and industrial users generally regard with satisfaction the personnel selected by the President to constitute the United States Coal Commission and believe thatComposition can thoroughly expedite good will results from the fact-finding proceedings. The President’s choice of the following commission members: Honoring. General. Arm. J. Mead, chairman; Honoring. General. J. P. Morgan, Jr.; Honoring. General. E. J. Hall; Honoring. General. W. R. Grace; Honoring. General. J. H. Foraker; Honoring. General. E. M. Shaw; and Honoring. General. H. F. Coats are good signs that the coal situation is on the point of being properly decided.

Transportation is a definite factor, as reported by the President, in ameliorating the situation, and Acting Commissioner Coatsman expressed the belief that the railroads as a whole have been performing remarkably well under the conditions with which they have had to contend.

Positioning of the Federal Fuel Administration thus far has been highly pleasing to the associations of wholesalers, since the movement of traffic has been preserved without the confused conditions that some feared might result.

Rehearing of Coronado Case Denied

Rehearing of the Coronado coal case was denied by the U. S. Supreme Court in a ruling from the bench Oct. 9. Unless the original plaintinity institute a new suit in the court, no other move is possible in the case.

In this suit, the United Mine Workers of America brought the Coronado Coal Co. and others because of obstruction of mine property in Arkansas during a strike. The Supreme Court on June 5, had handed down a decision of far-reaching importance, holding that labor unions, although not incorporated, are liable and liable for damages which result from acts of their members or an authorized strike in matters affecting interstate commerce. The court held, however, that it could not sustain an award of damages in this case because it had not been established to the satisfaction of the court that the acts were in restraint of interstate commerce during an authorized strike.

Argument has been heard in the case of the Corona Coal Co. vs. the Southern Railway, involving assignment of cars and the coal movement.

The case of the Hillbam Coal Co. has been passed to be

Floating Coal Down the Ohio on Artificial Waves Leaves Many Barges Stranded

Government engineers have had considerable success at various times in creating artificial waves in the upper Ohio River by firing coal down from West Virginia mines toward Cincinnati, but this month a 30,000-ton coal was a failure as the water was lower than at any time in fifteen years and when the pools of water above the various dams were released they spread out and moved so rapidly that the artificial stage did not hold long enough to enable the boats to make headway.

Out of ten steamers one but one boat got into trouble. The Kasaawoa, No. 17 in the list, was scattered at various points on the Ohio River, and will have to wait for a considerable time before proceeding. In the meantime they may be out in for the winter, as there have been seasons when there were no heavy rains on the river rises until after the first of the year.

One steamer lost two barges near Dam 28. When they hit bottom and sunk. The steamer Mitchell went aground off Ironton, Ohio. The Island Creek—a towboat, which had been stranded on a bar below Maysville, Ky., for a week, managed to get off when the artificial wave reached her. She had a line of barges carrying between 5,000 and 6,000 tons, and at last reports was expected to reach Cincinnati. The R. F. Gilham reported tied up at Lock No. 65, near Martinsville, W. Va., where she had made two trips down the river when the wave of water is available. Handling a coal tow is no easy matter with a good river, but with shallow water and an artificial wave, creating a strong current, towing becomes a serious problem. However, previous efforts to bring out a lot of coal through artificial waves created by manipulation of locks and dams have been successful.

Railroads Consume 300,000 Tons Less of Coal During July Than in June

Class 1 railroads consumed 6,886,000 net tons of coal during July, 1922, as charged to account 204, compared with 6,892,000 tons in July last year, according to a report of the Bureau of Statistics of the Interstate Commerce Commission covering 182 steam roads. June consumption was 6,787,000 tons. For the first seven months of 1922 these roads consumed 51,061,000 tons as compared with 52,514,000 tons during the same period in 1921.

The delivered cost per ton in July was $4.32, or 38c. above the same period last year. The per-ton cost for the year to July 31, however, was only $3.67 as compared with $4.37 during the corresponding period of 1921.

Fuel-oil consumption continues to gain. During July 120,626,000 gallons were used, as compared with 114,911,000 gallons in July, 1921. The figures for the first seven months of 1922 and of 1921 were $31,923,000 and $11,719,000 gallons respectively.

End Strike at Connellsville Union Mines

Non-union mines in the Connellsville coke region are all gaining substantially in output and man-power and the car supply is improving. The Taylor Coal & Coke Co. at Searight resumed operations during the past week.

The strike at the Diamond mine of the Diamond Coal & Coke Co. went out because they were asked to load Mather Colliery Co. (open-shop) cars, and the Lilly Coal & Coke Co. men quit because they were loading Pittsburgh Steel Co. barges. The Diamond miners stayed out only one day, but as a result of meeting Sunday several mines along the river—the National Mining Co. mine, below the Lilly, went out Oct. 8, and stayed out three days. They went back to work Oct. 12 and the men at Lilly went back the following day. The National Mining Co. is a union subsidiary of the United States Steel Corporation and the men quit rather than load Carnegie Steel Co. barges.

According to unofficial information there has been a steady return of men to work at the leasing No. 1 plant of the H. C. Frick Coke Co. during the last two weeks.

Restrictions on Bunker Coal Raised

An order raising the restrictions on bunker coal was issued Oct. 13. During the time that the restrictions were in force some 200,000 tons of coal which ordinarily would have gone to foreign ships has been diverted for American use. The accumulation of coal at ports and the sharp decline in prices at tidewater are regarded as sufficient indications that the regulation, which frequently imposed a severe hardship on shipping and on dealers and operators, could be cancelled.

The Navy Department has given permission to the City of Boston to use the coal unloading facilities at the Boston Navy Yard for coal consigned to the municipal coal yard. The plans for this municipal enterprise have been laid before the Federal Fuel Distributor and he has interposed no objection to the project.
Coal prices are still slipping downward and demand is but little improved, though signs are not lacking that the bottom will be reached before Nov. 1. Colder weather has strengthened the demand for domestic bituminous coal and this has been reflected in a better steam call. Industries normally go into the winter with increased stocks as a bulwark against poor receipts when transportation conditions are bad. This year has been the exception and buying has been on a hand-to-mouth basis. The prospect of still lower prices is now delaying purchases, but the recent touch of cold weather has shaken this resolve in a manner which indicates further buying action in the near future.

Demand has not yet revived sufficiently to hold prices. Coal Age Index of spot bituminous coal prices stood at 368 on Oct. 16 as compared with 380 a week earlier. This corresponds to an average mine price of $4.45, a drop of 15c. in the week. The previous week registered a decline of 29c. The trade expects the end of the price drop, which has been in progress since the middle of August, to await the advent of real cold weather, bringing with it deferred industrial and domestic demand.

Realizing Values, More Consumers Enter Market

Some large consumers have realized the good values now offering, and the past week has seen heavier takings by the railroads and utilities. The rank and file of buyers, however, have not yet appeared in the market, except for day-to-day requirements.

The market ranges from excessive dullness in New England to mild activity in the Chicago territory, which appears to be awakening to the fact that the time is short to obtain additional tonnage before the usual seasonal transportation difficulties appear. New York and other North Atlantic sections are experiencing better coal receipts via Tide and all-rail, offsetting the declining volume of British coal. Hampton Roads is in over-supply because of transportation congestion in the West, and coastwise factors are plying New England and North Atlantic centers with all the tonnage the market will stand, to the detriment of the all-rail fuels. Pittsburgh, Cleveland and Detroit are in more comfortable supply and inquiries are picking up with the recent cold spell.

Much transportation progress has been made during the past week. It has been possible to move large amounts of coal which were being held on sidetracks and in yards between the mines and destination. This accumulation has not been cleared up by any means but most of the railroads are beginning to make an impression on their accumulation of loaded cars.

Despite the large amount of coal still being held on railroad sidings, reports to Washington indicate that there are many cases throughout the country where coal is being sold for demurrage charges. Demands for priority have practically ceased.

Retail distribution of anthracite is progressing smoothly. Strict rationing of supplies has spread considerable tonnage over the East, but Western markets are obtaining little fuel. The Lakes have taken approximately 200,000 tons of hard coal since the strike ended, and it is not expected that the Northwest can
COAL AGE  Vol. 22, No. 16

BITUMINOUS

"Continuous returns on coal at present are not expected for the week ended Oct. 14, with an average of about 3,092,000 tons," says the Geological Survey. "During the five weeks just closed the average has been at an almost uniform rate varying little from an average of about 3,750,000 tons."

The number of cars dumped on Monday, Oct. 8, reported by the railroads, was 69,850, the largest reported this year; but on Tuesday thousands fell off to 39,289, a figure obtained on several Mondays since the close of the strike. The total cars dumped on the first four days of this week shows an increase of 3.9 per cent as compared with the same days of the week before. Full returns on loadings for the week are expected to show an output of 9,800,000 to 10,000,000 tons."

Coal Age Index 358, Week of Oct. 14, 1922. Average spot price for same period, $4.45. This diagram shows the relation and actual prices on fourteen coals, representative of quality and percent of the bituminous output of the U.S. ( excluding run-of-mine normally shipped and used, with respect to the tonnage of each normally produced. This average is compared with the average for the seven preceding weeks, June 12, 1921, as 100, after the same was adopted by the Department of Commerce as "Prices of Coal and Coke, 1913-1918," published by the Geological Survey and the War Industries Board.

The week ended Oct. 12, practically unchanged from the preceding week. Coastwise markets— the bulwark of the Roads shippers—are in much softer condition and prices are being shaded to close sales. New England especially is in such comfortable supply that it is difficult to see where any considerable inquiry can develop before Jan. 1.

Last week's dumpings were 1,493,273 net tons during the week ended Oct. 16, as compared with 1,179,218 tons in the preceding week. The season's Lake movement to date is 12,432,474 tons; last year it was 20,382,948 tons.

ANTHRACITE

Production of anthracite continues to increase. The output during the week ended Oct. 7 was 1,959,000 net tons, and loadings for the first four days of the week indicate an output of about 2,000,000 tons in that period. Much inconvenience is being caused by the slowness in the movement of steam sizes. There are now more than 150,000 tons of these coals between the mines and Eastern cities.

COKE

Production of coket coke continues to increase. The output during the week ended Oct. 7 was 171,000 net tons, 11,000 in excess of the preceding week. Coke prices are at last breaking, but the supply is still too costly and limited to tempt additional blast furnaces to resume.

And Export News

Continental Orders Replace American Business
On British Market: Prices Strong

French Fear Domestic Coal Shortage

Coal of the Nord and Pas-de-Calais has become more active still and domestic demand is especially pressing. A few collieries are restricting their shipments in provision for a strike which may break out before Nov. 1. A shortage of domestic coal is apprehended as soon as winter sets in.

The outcome of the present conflict between operators and miners may be determined when the French Parliament reassembles. Should, however, collieries of the Nord and Pas-de-Calais obtain no relief from their present plight, they may again be in no man's land in the situation as soon as British competition reasserts itself.

Miners of the Nord and Pas-de-Calais have published their schedule of prices for the fourth quarter, which is the same as for the third quarter, with summer bounties which are now off.

The adjusted price of German coke delivered to French blast furnaces by the Société des Cokes de Hauteriveaux has been maintained for October and November at the same limit as for September—59fr. at the Franco-German frontier. On the other hand, French collieries of the Nord and Pas-de-Calais have reduced the price of the metallurgical coke they supply to the said Sociétés, in view of its being pooled with German coke, to 92fr. for November from a previous limit of 95fr.

Coal Paragraphs from Foreign Lands

France—The government has been notified of the latest developments of the current strike at the works in the Pas-de-Calais. The present strike is more serious than the preceding one, which was last summer. A more general strike has also been notified at the mines in Pas-de-Calais.

Spain—A report from Madrid states that the national government has issued an order for the immediate withdrawal of the troops from the Asturias, where the miners’ strike is still continuing. The government has also ordered the immediate discharge of the miners who have been arrested for looting.

Cooler Weather Fails to Stimulate Coal Market

Prices Firm Only on Good Grades—With Car Shortage Acute, Shippers Confine Efforts to Regular Trade—British Coal No Longer a Market Factor.

Colder weather has failed to cause much stir in the coal market. Only good grades are salable at firm prices, while the poorer qualities are forced to sell at lower figures. Shippers are not active in soliciting orders, as they are barely able to take care of their regular trade, so acute has the car shortage become.

Some large consumers have realized the good values now offering and are taking in a limited tonnage for storage, but the average buyer is still restricting his orders to current requirements. British coal has ceased to be a market factor, but this has been replaced by heavier American receipts, both by Tide and all rail.

PHILADELPHIA

No improvement is noticeable in the bituminous trade, the consumer holding off as usual, while the producer is not soliciting trade, being busy distributing tonnage to his regular trade. Car shortage is still a very serious problem. Quite some complaint is heard of poor quality coal coming into the market, but this usually springs up when coal of the better grades is not to be freely had. With the consumer's attitude of waiting for lower prices, he is at the same time inclined to become more critical as to quality. The railroads now seem to be accumulating better stocks of engine fuel and are reported to have close to a month's supply ahead, or in prospect.

Prices are still inclined to weaken. Nothing seems to shake the consumers' confidence in much lower prices and they congratulated themselves that they are slowly achieving this result. Contrasted to this attitude we know of some large consumers who have contracted for blocks of tonnage of the best coal at prices that closely approximate the present spot market. At Tide there is only ordinary business in bunkering, and only a minimum of shipments for export. British coal also seems to have ceased to be a factor in the market.

CENTRAL PENNSYLVANIA

Car shortage is about the only thing interfering with production. On the lines entering the central region and in the region reached over the New York Central, the supply of cars is only 30 per cent of requirements. The miners are working in full force throughout the union areas. The non-union mines are rapidly gaining in the strike and to all intents and purposes the strike in the non-union operations is over. The Berwind-White Coal Co., at Winding, where the battle was most bitterly contested, is making daily gains in production.

Prices quoted at the mines are: Pool 10, $4.20@$4.50; Pool 9, $4.50@$4.75; Pool 1, $4.75@$5. Lower grades are quoted at $4.

Baltimore

Now that winter is approaching rapidly the seasonal jump in demand for storage in anticipation of traffic congestion to come later might well be expected. So far this has failed to materialize and even the larger industries are going ahead without much reserve.

The easy market has had the tendency of preventing any further jumps in prices, as the buying there has been a recession, this being especially true of gas coals. With the call for soft coal coming from sources that normally get it at a premium, there is noted a particularly strong demand for lump but there has been so little screening done that dealers are at a loss to know where to get the lump for this trade as they recommend.

The situation has strengthened the call for English coals, even though they are selling much above the American lump. Following the importation of 88,789 tons of British coal at Baltimore from the latter part of August till Oct. 15, it is reported that other ships will shortly arrive. The October arrivals were two with a total of 13,580 tons. The first export movement noted since last April came on Oct. 9 when a schooner sailed for Cuba with 2,816 tons. The last previous export movement was on April 10, when 2,916 tons cleared for Cuba.

New York

No buying to amount to anything has come into the market and prices show little tendency to advance. At the same time the decline seems to have been checked, in the better grades of coal at least. There has been no improvement in the situation. If anything, it is worse.

With such a state of affairs prevailing when the railroads have nothing to contend with in the way of adverse weather conditions, it is easy to surmise what will happen when low temperatures make their appearance. Yet the average consumer is making an effort to get stocked up against such a time. The hope of getting coal cheaper by waiting is the acting motive of many car owners.

Few of the operators are willing to commit themselves over a period of months at the prices now prevailing in the spot market. They are fully as confident as the buyers when it comes to predicting the future course of prices, the only difference of opinion being as to which way the cat is going to jump on the all-rail territory, owing to the scarcity of orders, shippers have been sending somewhat more coal to Tide-water than the local market can absorb readily. Some of it has got on dehur- rage and is causing some unsettlement. Between 1,500 and 1,600 cars were reported standing at the piers at the end of the week.

Anticipation quotation are shown in the Weekly Review.

Upper Potomac

Mines are not troubled so much by a shortage of cars as they were during a part of September and hence it has been possible to increase output somewhat on the line of the Western Maryland. Georges Creek production is not being increased materially but the de- standing sold for heating fuel. On the Meyersdale field where many strikers are working. Aware of that fact, Georges Creek operators are bringing eviction proceedings as to make room for men who will work. As it is necessary to dump all coal produced into Eastern markets the price is off.

Fairmont

Changes in the Eastern market have been very rapid and peculiar. Much coal billed to the Lakes is being thrown back on producers who have to find a market for it in the West and that is creating confusion. The B. & O. is assigning cars and that is only aggravating conditions connected with an acute coal shortage. Coal demand is extremely light. Coke production is being increased.

South

Birmingham

Buyers of steam coal are maintaining a rather critical attitude toward the market. Consumers are placing orders for immediate needs only with requests for prompt shipment, and are apparently obtaining a stock of coal. The principal demand is coming from small industries and utilities in Alabama, Mississippi and Georgia, while some run of mine is filling the special orders for the higher grades. A few days of cool weather has created a more insistent demand for domestic. Conditions incident to an increased supply have not improved the situation. Consumption of both production and movement very materially. Price for all grades of domestic are at a standstill. Quotations on steam have eased off to some extent.

Car supply on the Southern lines last week has shown some little improvement, but the situation is little or any better than a week ago. Production is around 345,000 tons per week.

Virginia

Virginia mines are recovering in a measure from the handicap of a car shortage. The sales are up to 90 per cent, with C. C. & O. mines leading all others. Although there is not a stiff demand for coal, no losses have been sustained on far cars, owing to the shortage of equipment.
**Anthracite**

**Rigid Domestic Rationing**

Eases Tension in East

Western Markets Wait Awaits Hard Coal—Lake-in-Arrow Shortage in Northwest—Independent Quotations Are Modified—Steam Sacks Harden

The industrial situation is more reassuring as strict rationing has distributed a little coal over a wide area of the East. Western producers are not expected to receive much tonnage for another 60 days. The Lakes are beginning to get hard coal—200,000 tons since rationing was resumed—but it is realized that winter will find the Northwest in short of its requirements.

Independent quotations show a lower range. There is less tendency to buy 112-coal, and the majority of the independents are adhering to the 3525 maximum for the family coal. Steam prices are in heavy over-supply and the market has softened perceptibly.

**Philadelphia**

Coal weather has brought a snap to the retail trade that is not desired by the dealers. The consumers are asking for hard-sensory for coal. Most prices are on the range of exceptions. To compensate, the independent dealers are quoting the highest prices. The tendency has been toward those that have shipped orders and offer rebates when it is possible.

The high prices seem to be reaching a visible point now, as the efforts to keep the independent into the coal market seem to be nearing a close. Baltimore has not sold a ton of the small independent will continue to charge $4. So far nothing has been given out as to the fact of two or three orders that are reported to be coming in.

The company prices seem to be reaching a stable level now, as the efforts to keep the independent into the coal market seem to be nearing a close. Baltimore has not sold a ton of the small independent will continue to charge $4. So far nothing has been given out as to the fact of two or three orders that are reported to be coming in.

The company prices seem to be reaching a stable level now, as the efforts to keep the independent into the coal market seem to be nearing a close. Baltimore has not sold a ton of the small independent will continue to charge $4. So far nothing has been given out as to the fact of two or three orders that are reported to be coming in.

The company prices seem to be reaching a stable level now, as the efforts to keep the independent into the coal market seem to be nearing a close. Baltimore has not sold a ton of the small independent will continue to charge $4. So far nothing has been given out as to the fact of two or three orders that are reported to be coming in.

**New York**

The substitution of all burners and soft coal is burned in part for the accumulation of steam coal. They are buying in all directions, although it is realized that the turnover of steam coal will create a better market in the fall.

**Baltimore**

Dealers are being swamped with orders now that there is a snap in the atmosphere. Less than 60 per cent of immediate needs, entirely outside of any coal for storage, and the winter is over. Dealers are sticking to their lot deliveries but even this does not meet the situation as consums generally are refusing to take 112-coal as a substitute. In view of the fact that Baltimore dealers are still getting practically only independent coal at high prices the majority of dealers are still forced to sell the more popular grades at $16 per ton.

Officials of the Maryland Distribution Committee who have been investigating conditions have openly said the greater part of the trouble to this fact.

**Anthracite Fields**

The mines are all working to capacity and they have not been hit as badly by the car shortage this week. There are no labor disturbances anywhere in the region.

There is no demand for the steam *bars.* Some of the companies are complaining about this.

**Buffalo**

The demand keeps up, but people understand the situation and do not try to get coal in quantity. Nobody is getting more than about half as much as was needed a year ago. Lake shipments are cut down.

Lake shipments last week were 71,970 tons, of which 22,500 tons cleared for Milwaukee, 22,500 for Duluth and Superior, 14,500 for Chicago and 7,500 for Buffalo. Freight rates are 50c. C. to Chicago, 50c. to Milwaukee, 45c. to Sheboygan and 40c. to Duluth.

**Boston**

Shipment of coal is slowly dribbling through all rail, and practically every well-connected dealer has had a fair quota since mining was resumed. Dealers have perhaps had better receipts in proportion, but this is due rather to eccentricities of car supply than to any design on the part of the railroads.

Prepared sizes are being distributed in sparing amounts, but during the mild weather there was very much less public anxiety in evidence than was expected. Householders have apparently concluded that somehow or other they will manage to get through the winter and they are gracefully accepting the situation. Or, if it be so, the situation is not as distressing as has been made out.

**Coke**

**Uniontown**

Coal buyers are retaining their advantage in the market by limiting purchases. In addition, and operators, faced with the problem of keeping their working forces together are forced to close sales at figures they claim out of production costs. The car situation is a bit easier. Because of the railroad situation, the carriers are keeping close check on cars placed for loading and are demanding that a consignee be named as shortly as possible after a car is loaded. That condition also helps to soften the market.

The strike of Connellsville miners has ceased to be a matter of public interest. At practically all the larger plants there are groups of "hold-outs" but at the present time many of them have returned to work.

The trade is quoting $3@4 50c for steam coal. Three-quarter lump is $3.25@4 50c with byproduct, 95c@1 50c.

**Connellsville**

The break in Connellsville coke prices has begun at last. A few days ago sales were $6@6 75 while they were quoted freely at $7 25 per ton. The market has ample room for further declines, since coke has not been sold for less than its natural ratio to coal, according to the formula of 114 tons of coal at the market price plus the cost of coking. With the coal market at $10.50, the coke is made at $1.00, and the formula would make $6.50 as the coke price.

Foundry coke has also declined, but somewhat sluggishly as some foundries, not well posted, have been paying close to the old prices. The market is now quoted at $12.50@13.50.

The condition no longer obtains of there being an indefinite number of blast furnaces waiting to resume and willing to pay the open market price. Pig iron consumers evidently are unable to pay present prices, while furnaces could not make lower figures except with cheaper coke. As furnaces get into operations, deliveries are made on old contracts and thus the need of consumers to buy pig iron in the open market is reduced.

The Courier reports coke production during the week ended Oct. 7 at 91,100 tons by the furnace ovens and 35,250 tons by the merchant ovens, a total of 126,350 tons, an increase of 7,670 tons.

**Buffalo**

Demand continues light, for the local plants are running actively and they are able to supply the furnaces pretty well. At the same time the coke situation at the big Pennsylvania oven centers is not good.
Regional Market Seems Ready for Upturn Now

Domestic Demand Continues Heavy and Steam "Buyers' Strike" Gives Signs of Breaking—Car Service Improves Only Slightly.

Continuance of a heavy domestic demand and very little, if any, improvement in car service by the roads keep the markets of this region about on the level of last week. While it is true there is no rush of steam buyers and a good deal of those grades are getting into distress almost daily, yet railroads are taking heavier tonnages for their own use and other big steam consumers are displaying more interest in deliveries on contracts. With the approach of colder weather the coal industry gets into a better position temporarily—only to prepare gloomily for greater difficulties later on.

Car supply throughout southern Illinois is still in the neighborhood of 30 per cent, while northern and central fields are down to 45 or 50 per cent—and that the service is no better. West Kentucky is running about 20 per cent of the time and Indiana fields somewhat less than half time. Prices generally throughout this section are unchanged from last week, except in Kentucky where a slight weakening of mine run and screenings was noticed.

CHICAGO
A tinier opening up of the domestic market, after the slight softening, and a certain uneasiness on the part of some of the big steam buyers who are still "on strike" are signs which coal men are reading just now. Many retailers who have not attempted to stock anything, are trying to do so now, finally concluding that domestic prices are not due for a drop. Householders who have been following to the letter the retailer's advice to buy only in small quantities, are now asking for a good deal more than the yards can deliver. The result is a considerable backwatering of orders followed by an epidemic of coal prescriptions signed by many doctors.

Some hard coal has reached here but on a restricted scale. The anthracite mine price quoted here ranges from $9.50 on buckwheat and pea and up to $12 on the larger sizes. Smokeless mine run and lump sells for $6.25 or $7 except the little which is jobbed.

Several elements are combining to take some of the rigidity out of the "buyers' strike" among big consumers of the steam grades. It is that a good many short contracts for oil expire at once and many may not be renewed.

Another is that few industries are stocked with coal and the third is that it seems more apparent every day that the strengthening of rail transportation will not be relieved soon and cold weather with an inevitable rush of demand is due at any moment. For these reasons there are fewer coal contract cancellations nowadays.

WESTERN KENTUCKY
The general markets are weaker and with industrial consumers refusing to stock, and retailers buying only for immediate needs, producers are finding it harder to sell coal. Unless there is material improvement soon in demand for either for domestic or steam, many in concern will have to look to the heavy demand will develop for prepared. Right now there appears to be an increasing tendency for domestic consumers to take up better grades of clean mine run for heating use.

Lump coal which has been strong at $5 and over, is now quoted at $4.75 in some instances for off-grade, while supplies are plentiful at $2.75 to $3.25 in quantities. Mine run has broken to $2.75 @ $3.25 and screenings, $2.75 @ $3.

SOUTHERN ILLINOIS
Lack of rail equipment and failure to sell steam sizes stand out strong as obstacles in the Du Quoin and East Jackson field. At one or two places a little steam is held without billing and if cars were plentiful there would be a lot of this stuff on hand. Railroads are buying again, however, and the car situation is just a trifle better than strong demand for lump, egg and nut is unusually good.

Somewhat similar conditions prevail in the Du Quoin and East Jackson field. At one or two places a little steam is held without billing and if cars were plentiful there would be a lot of this stuff on hand. Railroads are buying again, however, and the car situation is just a trifle better than strong demand for lump, egg and nut is unusually good.

In the Mt. Olive district working time is two or three days a week. The railroad tonnage is heavy. Several trunk lines have trouble in getting cars and demand for lump, egg and nut is unusually strong.

Somewhat similar conditions prevail in the Du Quoin and East Jackson field. At one or two places a little steam is held without billing and if cars were plentiful there would be a lot of this stuff on hand. Railroads are buying again, however, and the car situation is just a trifle better than strong demand for lump, egg and nut is unusually strong.

ST. LOUIS
A little more reasonable weather has started to develop and demand on the cheaper grades. The light tonnage of Carterville is going at a premium of $3.50 to $5.00 @ $6 at the mine. The retail price is $6.50. Mt. Olive, which is available as a rule, is $8 at the mine and retails at $7.50. This makes Mt. Olive the popular coal.

Country domestic and steam demand are both picking up. Locally steam is not selling, except from day to day. Very little coal is piling up in storage. Railroad movement has shown some improvement though hundreds of cars are held in East St. Louis on account of the inability of the Illinois and Missouri Pacific to handle them.

INDIANAPOLIS
Demand has been more active during the past week, due largely to the imminence of cold weather. Most of the domestic coming from the domestic consumer and retail dealers generally are limiting their sales to three tons in order to have enough to go around.

There has been no particular strength in the price situation during the past week, although there has been a fairly ready market at the established prices. Domestic coal of the Indiana grades is retailing around $7 @ $8.50, while foreign mined coal, such as Pocahontas, Kentucky and West Virginia, is retailing around $11.50 for the prepared sizes, with about $5.00 lower for mine run. Demand for steam coal is fair.

LOUISVILLE
Heavy rains for the past several days are resulting in better river stages and packets are resuming operations. A number of coal trains are leaving up. Ohio is expected to reach Cincinnati on the rise and some of this coal will come to Louisville and sister cities. General demand is slow. Everybody appears to be getting immediate supplies and at present prices there is no stocking demand reported. When the Lake movement steps this will throw more production to the industrial and domestic consumers, and may ease prices.

Retailers are hot over the fact that there is a range of $2 a ton and more between mine run and lump. A few retailers who have the new screening equipment are taking advantage of the fact, but others are endeavoring to get some domestic users to take mine run.

It is hard to sell coal now, not only locally but north of the river and in other sections. There is a lot of railroad demand but there has been, but it appears as if the country generally is anticipating lower prices and is not worrying. Car supply is reported at about 20 per cent on most lines, with the Illinois Central remaining about 50 per cent.

Canada

TORONTO
The volume of business is light with conditions unsatisfactory and prices variable. Limited shipments of anthracite received from the line companies are being retailed at $13.50 per ton, the price in the Freeport market. Dealers are obtaining supplies from independent producers and selling considerably higher. Several new longs have been run. The price is $11.25 to $11.50 for 100, 200 and 300 car lots, especially in Ontario. The sales of the new lots are not encouraging.

Eastern Inland

Seasonal Temperature
Tends to Stabilize Market

Pittsburgh

Production continues at much the same rate as for several weeks past. There is somewhat faster sampling and coal shortages, this being due, apparently, rather to operators' wishes than to lack of buyers. There are no great changes in the number of buyers of the forward kind.

The hammer in the open market has been further. Consumption of coal by industrial plants and apparently also for household consumption is not so heavy as it was early in the month. Car shortages have been causing much difficulty in receipt of coal by local industries. Supplies are continuing to be adequate, but difficulties are experienced in making freight adjustments. The market stands at about $6.25 for large grades of steams, $6.25 for $6.00, $5.75 for $5.00, $5.25 for $4.75, and about $5.00 for $4.50.

Pittsburgh

No. 6 coal is the fuel of coolers and serving as a substitute for steam heating. Prices are $10.50 for No. 8, $9.00 for No. 7, $8.75 for No. 6, and $5.00 for $4.75 for lump.

COLUMBUS

A reaction has taken place and all grades are stronger. Demand for lump is the strongest feature with sales made at record prices. The regulations of the Ohio Fuel Administration relative to maximum prices are having the effect of driving the lump out of the state. Retailers in all sections are trying to buy stocks at the same price, and the equal spelt has forced the consumers into the market.

Retail stocks are almost nothing and the public is apparently waiting up in order of the situation. Many of the dealers are compelled to buy West Virginia and Kentucky lump at high prices to take care of the demand. Retail prices are strong and some deliveries with Hocking lump selling around $8@9. West Virginia splints are $10@10.50, and Pocahontas, when obtainable, is higher.

Steam business is not as active, although railroads are taking a large tonnage. The Lake trade is now booming with a large tonnage moving. Ohio mine to the Lakes.

Much of this is mine run which is bought around $3.25. Some mine run which is incapable of being screened is selling at slightly less figures.

DETOIT

Receipts are rather more liberal. According to railway figures, 1,396 cars were received in 48 hours ending at 4 p.m. Oct. 11. Average daily requirements, excluding railroad coal, are approximately 550 cars, and there is not a very active demand. The greater part of the business is apparently on a more or less continuous to-month basis, representing purchases by industrial plants that have exhausted their reserves. Assuming that a reduction of prices is limited, it is likely to come after the close of the Lake movement, the retailers are striving to guard against being caught with too much coal in anticipation of present prices. The householder demand represents a makeshift to tide the buyer over to a time when he hopes to find anthracite available.

EASTERN OHIO

NORTHERN PANHANDLE

Prices vary as widely as ever. The range is $6@$6.50 for Pittsburgh gas lump, and Allegheny Valley mine run, $3.75@$4.25, with some No. 8 at $4.75 for lump. Slack is not as high as mine run, about $3.25@$3.50.

Mines are experiencing difficulty in securing all the cars they need, and in moving coal in the usual channels even when received. Lines to the Lakes are choked with loads. The fact that so many mines load railroad fuel is helping to maintain an output. Prices are lower all along the line in view of the large presence of coal turned back from the Lakes.
Northwest

Coal Cargoes Up Lakes—Not So Numerous Now

Unprecedented Shipments Fill Demand
During Past Weeks—Rail Coal Is Arriving Too—Low-Grade Stocks on Hand Worry Dealers.

The tremendous flow of cargo coal up the Lakes gave evidence, at the end of last week, of slacking off considerably and the keen edge of Northwest demand was somewhat blunted so that nobody worried much even though cold weather is arriving and household demand for hard coal is getting brisker with small shipments to satisfy it. In some markets the price of anthracite continues to stick around last year's scale. Since the general advance on smokeless coals a short time ago there have been no further ascents of quotations on any domestic coals.

A fair flow of rail coal continues, some of it crossing Lake Michigan by carferry from the East, some coming up from Illinois and some from the lignite fields of North Dakota. The result is so much coal is here that dealers who stocked lightly on lower-grade fuels during the summer anticipating a worse October condition than prevails, are having trouble unloading.

MINNEAPOLIS
The wholesale trade is pretty well over its fears of a serious shortage and is now studying the opposite danger of having too much of the high-priced but lower-grade soft coal, which had to be bought when coal first became available.

The better coal is now available, and it is a commercial puzzle what to do with the poorer grades on hand.

The fuel distributor has made an announcement that the Northwest is reasonably assured against any serious shortage of soft coal. This has been realized for some time past, since it became apparent that there would be a reasonable functioning of the railroads. It is true that the interior has not been buying heavily. So far movement from docks is some 20 or 25 per cent lower than a year ago.

It is anticipated that prices on both soft coal and hard will average at least $1 a ton higher than a year ago, although no new hard coal has reached these cities, and no new prices have been announced.

The demand for steam coal is limited. Buyers are awaiting lower prices.

DULUTH

Official figures just made public confirm reports that there was a heavy falling off in shipments from the docks during September. Only 16,178 cars went out, of which approximately one-third were loaded at Duluth and two-thirds from Superior. Last year 18,735 cars were shipped.

Receipts of bituminous coal during September were gratifying. A total of 1,828,900 tons were received as compared with 657,170 during the same month last year, but anthracite receipts were only 10,600 tons as against 182,600 tons in September last year.

For the season to Sept. 30, receipts of anthracite aggregated 27,500 tons, as compared with 1,380,000 tons last year, and bituminous receipts were 1,963,800 tons against 7,186,492 tons last year.

Prices on anthracite have been set as the same as during the latter part of 1921. Coal will go from the docks as follows: Stove, $12.50; nut, $12.75; egg, $12.90; peat, $11; buckwheat, $8.50. Anthracite is being allocated by the fuel administrator at St. Paul. The four cargoes which were received this week were sent to North and South Dakota, the Mesaba iron range cities and villages and to Duluth and Superior. Bituminous prices remain firm as last quoted.

Besides the four anthracite cargoes 52 of bituminous arrived here this week. It is thought that this will prove the high water mark in shipments as only 19 vessels are reported on the way.

New England

Steam Demand Still Quiet; Prospects Not Very Bright

Light Industrial Production and Use of Oil and Electricity Make Gaging of Requirements Difficult—Only Scattered Inquiry Expected—British Receipts Wane.

Demand for all grades of steam coal is extremely quiet. Inquiry is restricted to small users, and apparently there is little prospect of any comprehensive business for some weeks to come. The textile and other industries are still on light production and so much tonnage has been replaced by oil and electric power this year that it is more difficult than ever to gauge probable requirements.

The trade seems to have settled down into an attitude where every sale is as much to the good, and only scattered inquiry is expected the balance of the year. Receipts of British coals are slowing down.

They may win in their position, for there is accumulating a certain amount which will doubtless have to be offered at reductions.

Steam for the Pennsylvania grade and the remainder of bituminous and anthracite coals is practically sold, and for seven or eight weeks there will be no business in British coal. The only outlet is for the heavy steams, and these are limited to a few orders to New England with a few cars for the New River.
Cincinnati Gateway

Domestic and Smokeless Exceed Gas-Coal Values

Despite a drop in steam and gas demand, the market in Colorado remains too stiff to allow a slackening in the condition of the Western fields. The demand is too intense to allow of the slackening in prices that the market is showing. The tendency to cut out and to cut prices is being met by the production of a large quantity of coal from the Western fields. The result is a further fall in the price of coal in the West, and the tendency to the low price range of a ton or less than $1.00.

VOLATILE RANGES

As long as the market remains strong in the West, the tendency to fall in prices is being met by the production of a large quantity of coal from the Western fields. The result is a further fall in the price of coal in the West, and the tendency to the low price range of a ton or less than $1.00.

LOW-VOLATILE FIELDS

NEW RIVER AND THE GULF

With an inactive market for smokeless coal in the East, a slight falling off in the production of gas coal is being noted. The demand is too intense to allow of the slackening in prices that the market is showing. The tendency to cut out and to cut prices is being met by the production of a large quantity of coal from the Western fields. The result is a further fall in the price of coal in the West, and the tendency to the low price range of a ton or less than $1.00.

KANSAS CITY

The Kansas coal fields are getting better running time than the average of other fields and as a result the market is fairly easy and prices steady. Fuel oil continues a great factor. Some steam plants are still changing over to oil and some are changing back to coal. Operators have been ordered to stop coal without any exception in the market in order to reduce the slack, and operators are being required to produce more coal to meet the demand.

SALT LAKE CITY

Business is still quiet. The weather continues summertime and those who would buy coal for storage purposes are waiting for reductions of the grand jury, which set out a few weeks ago to examine the price-fixing charges preferred against the operators and dealers by a local newspaper. It is hoped that no indictments will be made.

The car shortage is hampering the mine and mine operators have decided to hold the price on the basis of the run of mine. It is estimated that Salt Lake City has about 10,000 tons in its yards now.
News Items
From Field and Trade

ALASKA

The Alaska Agricultural College and School of Mines opened at Fairbanks Sept. 15, with a student body number has made arrangements to enter. Miners all over Alaska with the school, organized and headed by Charles Ernest Hatcher of New York, the territory, opens with the largest college in Alaska, made up of gifts by individuals.

CONNECTICUT

The Elm City Coal Co., New Haven, has recently been incorporated to engage in the coal business. The capital stock is $25,000, and the incorporators are: Jacob Roddey, M. Y. Fisher, and A. J. White, all of New Haven.

The Capital Coal Co., of Hartford, has filed articles of incorporation under the laws of Connecticut to engage in the retail coal business. The capital stock is $5,000, and the incorporators are: Jacob Benson; Joseph J. Benson; and Joseph J. Trachtenthorn; all of Hartford.

ILLINOIS

The Callaway County Coal Co., which has been developing the Callaway County, Mo., for nine years, but which was reorganized last year, has just begun operations, and equipment to F. L. Crosby and Lester J. McLenin, both of Illinois, L. W. Hite, of Farmer City; H. G. McCullough, Canton, Ill., and Carter Norris of Fulton, several companies, by which they will own and operate a new corporation under the name of the Callaway County Coal Co. The company has purchased 89 acres of land near Cuba, Ill., which, according to a government survey, will be a good location for a coal field. The field is now being worked, and a mine is expected to be in operation by the middle of November.

Coal has been found near Mt. Vernon, in Posey County, at a depth of 75 ft. A 30-in. vein was struck at 32 ft., but the thickness of the lower vein is more than 4 ft. The prospect is said to be a good one, and Girdler & Broome, who have mines in Illinois, work on the mine proper will be started in a short time. The Verona Coal Co., of Verona, has been incorporated with a capital stock of $50,000. The incorporators are: C. H. Fell, Keokuk, Fred Harford, R. J. Glenn, J. F. Harford and William Earl.

Coal hoisting at the Littlefield mine, purchased several weeks ago by receiver’s sale by Harry Turner, will be in progress within a month. The mine has been sunk 200 ft. deep, and is a capitol stock of coal. The present vein is six feet thick.

INDIANA

A petition for articles of incorporation for the Chicago, Attena & Southern Coal Co., which will take over and operate the Illinois & Southern Coal Co., as the Indians coal road, will be filed with the secretary of state on Oct. 15. Soon. While the mines in the southern section have been abandoned, the northern part of the line have been developed. Brick and clay plants are strong along most of the line and many plants were threatened with extinction when the line was abandoned.

Felix M. McWhirter, president of the People’s State Bank in Indianapolis, has been asked to become a partner in a coal and coke distributor, to serve as a member of the board of directors of the coal and coke distribution problem in Indiana with keeping in touch with the Indiana fuel situation and informing the federal fuel administration of the needs of industry.

Moyer Shank, of Indianapolis, has named five citizens to serve as a committee to work with the government in regulating distribution and prices of coal. Among the five named, two are out of state, and one is out of the state. Two have announced that he will serve on the committee. The mayor has announced that he will appoint others who will serve on the committee.

A consolidation is taking place between the Indiana Bituminous Coal Operators’ Association, which is the old labor organization of shaft mine owners, and the Indiana Coal Producers’ Association of strip mine men. The question of representation in plans on the new organization Committee of the joint operators’ and mine’s conference is now being disposed of. The state has two representatives, but since the strip association fuses with the operators, there is nothing in the way of the Brazel Block region for the president of the state to unite will in reality have three seats because Phil. Penna., permanent chairman of the joint conference, is a member ex officio.

KENTUCKY

In western Kentucky when strikes tied up other mines, there was so much money that roads were full of miners who were traveling to their work in automobiles. One miner was reported as buying a big car. Used cars bringing 40 to 50 cents in 1921 were selling at 100 cents in the cities. Today the coal car shortage is so severe that it is hard for miners to keep up even a "Liz" on surplus earnings. Reports of actual starvation conditions among miners has been a fact so well known.

B. H. McCormack of Cincinnati, E. McCrann of Dayton, and C. H. Carson of Lexington have all been at the Coal Operators’ Conference here to confer with the above concern. Mr. Heffern and associates have formed the Heffern Elkorn Coal Company to operate 150 miles on Marrowbone. This company plans on opening up to the Allied Coal Co. by adding equipment and installing an instillodine in all respects.

The Jacqua Mining Co. has been formed by W. H. Cottingham, W. C. Burch and Ed. Harney. The Smith-Abston Coal Co., has been capitalized at Hazard, Ky. for $25,000 and the incorporators are: M. V. Abston, G. B. Smith and G. H. Abston.

MISSOURI

The Carter Coal Co., of Wellington, has been incorporated with a capital stock of $25,000 in Missouri as well as a Missouri establishment. The incorporators are: Fred D. Dresser, Charles G. Brown, John H. Lumsden, W. E. Woolley, Edward H. Brown, George H. Drewell and Adolph H. Kubman.

MONTANA

An operating held late in September, at Butte, that has the miners strike their own in a position to the National Coal Strike, which was called to end with the recent rates for the present.

NEW YORK

In order to give greater attention to C-H business in western New York and Ontario, a branch office has been opened by the Cuyler-Hannans Co. The office is located in Buffalo. A. A. Hansen, formerly located in New York, has been placed in charge.

J. B. Clark, Jr. has recently become associated with the Pennsylvania Trust Co., as sales engineer, and will make his headquarters in New York office. For a number of years, Mr. Clark has been associated with the Koppers Company of Pittsburgh, Pa., and the United States Steel Corporation, doing business in the coal industry. The new office will be known as the Pennsylvania Trust Co., of New York.

Grant B. McLaughlin & Co., on Oct. 1 opened a coal office at 713 Mutual Life Iron, Mr. McLaughlin formerly connected with the Donner Steel Co. and will also look after the iron trade.

OHIO

C. A. Clyborne, president of the Three States Coal Co., with headquarters at Bluefield, W. Va., has opened an office in the Cincinnati office of his company.

For the third time, the Columbus Board of Trade, Sumner Coal Co., has filled the last date for opening bids has been fixed at $5,000. For the former occasions all of the bids were refused.

Quite a few coal companies, mostly for mining and distribution purposes, have been chartered recently under the laws of Ohio. Among the number are: Windsor Coal Co., New Philadelphia, has opened a mine in Jefferson County, incorporators: H. W. Thomas Rock Coal Co., of Columbus, A. Barakat and S. S. Hill, The Hughes Coal Co., of Byesville, capital: $25,000, incorporators: R. G. Barnard, Jacob Wamsler; James W. Bird, L. W. Morgan; E. E. Solomon.

The Grove Coal Co., of Akron, capital: $75,000, incorporators: E. A. Milton; C. A. Mason Co., of Columbus, capital: $25,000, incorporators: Katherine Wynne, Rose Darling and George W. Coble.

PA, PENNSYLVANIA

A State charter was granted at Harrisburg to the Deerfield Hill Coal Co. of Pottsville. It has a capital stock of $10,000, and David Dr. Griffiths, president. The corporation is incorporated for the purpose of purchasing and selling coal for the market and the purpose of mining and developing coal fields. Incorporators: Alexander and Albert Mays, all of Pottsville.

The Shaffer Coal Co., of Johnstown, has received a capital stock of $75,000, and Pottsville, and in the management of the company. Incorporators: W. J. Minnich, Mrs. and C. A. Minnich.

The Delaware Lackawanna & Western R. R. Co., of the Anthracite, has been incorporated with a capital stock of $10,000, and W. J. Minnich, president, and C. A. Minnich, treasurer. Incorporators are: W. J. Minnich and Thomas Hanfman, T. A. Johnst,

TEXAS

United Mineworkers of America have opened a new office in Houston. A branch office was opened in the American Labor Union Building. The office is under the direction of J. R. Minnich and has been furnished with new quarters.

The American Fuel Co. is said to be doing an active business in the fuel market out of this office, and they have a large supply of fuel available for immediate shipment.

Albert Griffin has severed his connection with the Keene Mine, Balf-Collins Coal Co., Roundup. Mr. Griffin was superintendent.

When and Where to Apply Self-Restraint

WHAT a lesson the public is teaching itself on coal! A most remarkable demonstration of the great axiom that the destiny of the coal trade is in the hands of the consumer is being staged. There have been buyers' strikes on coal before but never under the conditions of today. Previous general withdrawals of consumers from the market, to the discomfiture of the coal producer, have always had a background of large stocks and were explainable as the normal result of falling prices on an overstocked market. They have always gone too far, it is true, and reacted in the end to the disadvantage of the buyer. Hitherto these long sweeps have had no guidance; they have simply been the expression of uninformed mass psychology.

Six years ago this week the country awoke to the realization that consumers' stocks were low, consumption was increasing and that a nationwide car shortage had developed. Prices at once reacted to new high levels. The coal shortage then begun lasted until the armistice. Conditions with respect to stocks, consumption and car supply are essentially the same today as in the autumn of 1916. The differences are only in degree; the relative positions are the same. Yet the price is falling.

The United States Chamber of Commerce has just completed a survey of the country and reports that although reserves of soft coal are "less than normally carried," the bituminous-coal situation "is becoming easier," and that there is no "general complaint as to price." Production of bituminous coal is no more than sufficient for current consumption and permits no stockpiling. "It should be borne in mind, however," says the Chamber, "that this is an average figure of stocks of small plants and large plants, and covers stocks varying from a few days' to two or three months' and in some instances even longer."

The self-restraint of the buyer is being intelligently directed. The mine price of soft coal is even yet high enough to call forth all the production the railroads can carry. The buyers are taking all the coal they can possibly get, but they are buying it without panic. From the standpoint of supply and requirements—as contrasted with demand—this is a sellers' market. Yet the buyer is so largely in control that he is really making the price on a large part of the output.

In 1919 the positions were reversed. The country was overstocked with coal, consumption was falling sharply. The coal producers, fresh from the lessons of the fall, having been forced by the Fuel Administration to learn their costs, refused to be stampeded into price cutting. It was a buyers' market in the summer of 1919. If ever there was one, but the price was maintained by the self-restraint of the seller.

If it be granted that steady prices and absence of violent fluctuations in the market make for stabilization of the coal industry, then the obvious conclusion is that self-restraint should be preached to and practiced by the side that will be benefited thereby. Teach the public its responsibility in a two-sided game, as well as the coal operator. It is easier and more sensible to drive home to the buyer his selfish interest in not going wild and paying prices for coal that cannot encourage production and thus to prevent high-price scandals, and to give the operator the right and opportunity to protect himself against the ruinous low prices that obtain at other times, than to campaign against the natural and human instinct of the buyer to treat the price to the lowest level irrespective of consequences, or of the producer to refuse to take a handsome profit when it is offered to him.

The present concerted restraint of the coal buyer is not an accident. It is the result of broad national planning, conceived in advance of the fact. It exhibits a phase of the national coal situation that we trust will not be overlooked by the Federal Coal Commission in its study. It is true that the chapter is but opening, that the experiment may fail, but it is certain that future chroniclers of the coal question will look back on the buyers' strike of 1922 as a well-conceived stroke of national policy, carefully executed, and that credit for its conception and execution will be placed where it belongs.

Solving Hard Coal's Commercial Problem

COMMERCIAL production of large sizes of anthracite, including peat, averages around 50,000,000 gross tons per year. Of this, in normal years, the railroads take about 2,500,000 tons: gas plants, 700,000 tons, mainly the egg and broken sizes, and industrials, some 1,800,000 tons, a total of 5,000,000 tons, or about 10 per cent of the prepared sizes. This represents a substantial and desirable trade.

It was generally recognized during the war that household use should have preference in distribution of the larger sizes and the allotments of the Fuel Administration to other than domestic consumers were cut as much as possible. The allowance for railroad use, for instance, was cut half the normal taken for this purpose. Somewhat the same situation has arisen this autumn. With retail distribution of the favored sizes largely on a hand-to-mouth basis and consumers' reserves at a low point, hard-coal shippers are holding back other consumers and discriminating in favor of the small user.

A small industrial consumer of egg coal recently called on the president of an anthracite producing company to inquire as to the prospect of getting 500 tons of his winter's requirements. He was told that he had not the slightest chance, that he was "out of luck," that in fact he had "had his chance" in some way and raises the question. The buyer mildly stated that he well knew that he was a "non-essential" but that during the war...
Today and Yesterday

NEW occasions bring new duties, and the mining engineer should be as vigilant of this as anyone. A great change has come over the mining industry in recent years. A few years ago the need for exploration dominated every other need. Every mining man in the coal regions of Pennsylvania and later of West Virginia and Kentucky was a geologist, and the residents of those sections were hardly, if at all, behind. Every farmer had coal land to sell, every lawyer and real estate man (they did not then term them realtors) had coal land to lease or dispose of, and every merchant had in mind making options on coal land or had already hit it cornered and for sale. The mining engineer’s intensive study of geology, consequently, not only solved everyday problems but gave him a standing in the community that he could capitalize.

The day of exploration is largely past. A little of the matter interest and need for coal geology remains and will always remain. There are still outcrops to be traced and drill holes to be bored; there are still a few unexplored areas in the more important fields; there are still possible extensions of old fields; there are waste and faults, but these matters do not stand where they once did as the leading problems of the engineer. It is a day not so much of exploration of doubtful, as of development of known, deposits.

In mining today we are no longer satisfied to use the natural forces of nature aided by mechanical appliances. The study of mechanical engineering therefore is the greatest need of the mining man. He no longer can satisfy himself with geodesics, with the geometry of the coal measures, the chemistry of mine gases, the physics of coal and dust, as was once his wont. He has now to delve and delve deeply into electricity; he has to attain a mechanical mind. He cannot safely let the industry move away from him.

For a while he may be able to regard his mechanical brethren as a man in an inferior branch of the service and “make away with it.” Or again, for a season he can hide his ignorance of electricity by relying on the advice and plans of the admiral of an electrical house. But let him not deceive himself; he cannot do it forever.

Let him study now when he has the opportunity; let him ask questions today, when ignorance of electrical lore is still regarded with tolerance; let him gain experience while the chance offers, or the time will come when so much has to be learned that a busy man cannot hope to acquire it and when his mind, no longer as retentive and flexible as in early years, will fail to grasp what is presented to it. The coming executive is going to be well booked on electrical methods. Are you hoping to become an executive or are you expecting to continue in that position? You cannot do it if indifference to such matters prevents you from studying electrical methods.

How Nicely They Do It

A PAPER from DuBois, Pa., contains the heading “Road Work Suffers as Back-to-Mine Move Grows” and describes how the men are leaving their labor on the high roads to work at the mines. The road contractors, if they ever give a passing thought to the irregular way in which their industry functions, need not worry about their men being idle in the winter. The mines will take care of them at good pay, which is about three times as large as the contractors on road work are offering.

The reason why the employees of road contractors do not have an idle season is that they are willing to work at low wages and so can readily drift from one kind of a job to another. If the coal mines paid $2.80 a day to their men they would be deserted in slack periods, and the miner, finding work elsewhere, would make no complaint about the layoff. But because he gets about $8 a day he can find no place to go where he can do as well. He is therefore disposed to stay, working part time at the larger sum and making as much as if he worked steadily at the smaller. Thus he continues his residence around the mines and finds fault with the operator if for several days each week the working whistle is not blown.

If wages dropped at mine workings to $2.80 per day the last would be heard about the overmanning of the industry. Why is it overmanned? Because it pays best, because it is desirable work—cool in summer, warm in winter—also because, unlike most rough work, it is reasonably steady. Most routabouts have to spend several evenings each month hunting for jobs. They are laid off for every rain and sometimes do not have a chance to return to work till the roads dry. They do well to average an even 200 days a year and then only by eternal watchfulness for odd jobs.

The mine appears to serve as a good opportunity for reasonably steady labor at a high rate. With the present pay the men cannot be driven away from the mines, but should it fall to road-making levels it would be easy enough to wash one’s hands of one’s men. They would be gone within a day after the work stopped, for then any other job would be at least as remunerative even if not as reliable or as easy as coal mining. The mine workers are always protesting to the public of their hardships, their great hardships—low pay, bad working conditions, irregular work, w'ood charges, house rent, doctor and hospital check-offs—but the overmanning of the industry proves that they stay, that once they have joined the coal-digging confraternity they will not leave the mines. By this sign they surely make a more conclusive answer to their allegations than anything the operators can say.
Detection of Waste of Time
And Current at
An Anthracite Colliery

BY D. C. ASHMEAD
Kingston, Pa.

Few Know Just How Many Hours Their Breaker or Tipple Runs—John Conlon Colliery Measures Idle Time with a Recorder—Also Checks Current Used by Hoists—Care in Detecting Grounds

NEAR the city of Wilkes-Barre is the independent colliery of John Conlon with an output of about 300 tons a day. It is supervised directly by members of the Conlon family with a supervision probably more careful and competent than is customary with a mine of such an output.

The Conlons have long recognized that one of the greatest sources of loss in operation arises from broken time during working hours. Delays in one section of the operation often tie up the whole plant, for nearly all the plant operations are dependent, not only ultimately but almost immediately, on one another. Without storage-provision division of labor inevitably produces great loss of time and in mining operations each department must do its work with unerring schedule or almost all other departments will be obliged to wait for the slow department to come up to the mark, thus entailing considerable monetary loss.

Frequently the length of time wasted is far greater than is recognized. Delays are vexatious and we rather like to minimize them when estimating their importance. Because their length is rarely a matter of record, few steps are taken to reduce their number and duration. Hoists are not used to their full capacity, locomotives stand idle, breakers fail to operate. Everywhere are men and machinery on the job yet without doing work of value, adding to the payroll but not to the product.

To detect the wasted time in their collieries the Conlons purchased a number of Servis Recorders. The interior of one of these simple recorders is shown in Fig. 2. The recorder consists in part of a clock to which is attached a recording chart. This paper is graduated to show 10-minute periods. In the other half of the recorder is a pendulum to which a pencil is attached. The recorder is hung vertically, so that the

FIG. 1—RECORDERS SHOWING WHEN PLANT WORKS
Illustration is of interior of instrument. The right half is a paper chart which is revolved by clockwork, it rotates once in 24 hours. On the left is a pendulum in the form of a half disk, and shows turned on one side. When the recorder is properly hung, the pendulum swings with the vibration of the breaker or mechanism to which it is attached. A pencil makes a mark on the chart whenever vibrations are to be recorded.

*Anthracite Field Editor, Coal Age.
North—Headpiece shows the John Conlon Colliery, near Wilkes-Barre, Pa. This is a long established, independent operation with offices at Hudson, Pa. About 100 men are employed.

FIG. 2—CHART SHOWING WHEN BREAKER WORKED
From this chart the actual time of any delay and its length can be ascertained. When operations are to be made and various laborious, this story is already half told. From this chart it is known the colliery can be found and the problem understood. What suggests why and why some time was allowed can be ascertained
The pendulum swings freely. The case is then closed and locked. As the machinery or the breaker on which the recorder rests vibrates the pendulum swings, making with each swing a mark on the recording dial. When there is no movement because the machinery or the breaker is also no mark appears on the dial. In consequence, the exact time during which the machinery is working is registered on the revolving plate. Every day these dials are collected and the time of full operation or its converse, the time of idleness, is measured.

Not only is the full time of operating shown but each stop also, and it is possible therefore to check up the entire operation of the breaker or motor by inquiring into the reasons for the particular shutdown. Finding out the reasons of delay, some rearrangements may be made that will make such delays unnecessary in the future. Just the manner in which the records of this meter are made and used is shown in Figs. 2, 3 and 4. The first shows the actual performance of the breaker in one of its regular runs, the second shows how the results are tabulated day by day and the third expresses by means of a curve the operation of the breaker. By comparing the hours worked by the breaker and the number of cars loaded each day it is easy to determine if the breaker when working is at all times equally efficient.

So much for saving of time; now for savings of current. Two men employed to do the same work under precisely the same conditions will do it with entirely different expenditures of current. One man will be more efficient than another, and even where the efficiency of the least efficient has hitherto satisfied the management and is above the average, comparison with officials and the man himself to see how his efficiency can be raised.

At this mine a hoist is installed which raises the coal through a short slope up a plane to the top of the breaker (headpiece). It was decided that the efficiency of the men operating the hoist should be tested. A Westinghouse graphic meter (Fig. 5), showing the current used, was hooked to the line. This was done without the engineer being informed. From the two charts thus obtained, parts of which are shown in this article, one engineer can be seen to be considerably more efficient than the other. In the first chart the engineer is shown to have used at times as much as 240 amperes and without did not bring his loads as rapidly to the surface. It is evident that he threw the controller fully on when starting. On the other the other engineer used barely 160 amperes as a maximum and in most cases less than 144 amperes, and yet his hoisting time was shorter.

From these diagrams it can be readily deduced, therefore, that one engineer got out more coal with less power and in less time than the second engineer. Evidently with proper instruction the less efficient man could learn to do his work as well as the other man; if not he could be given work where his lack of cooperation or skill would not so greatly injure the company.

The use of electric power without the performance of work is one of the most unnecessary wastes of power around a mine. This type of waste is caused by short-circuits and grounding. At the Conlon Colliery much care is taken to prevent loss of power due to grounding, and for this the simple device illustrated diagrammatically in Fig. 8 is shown. A bank of four lamps (shown also in Fig. 9) connected in series is placed above the switchboard. Lamp No. 1 is connected to wire No. 1 from the transformer and lamp No. 4 with wire No. 3. A connection is made from the ground to a Westinghouse voltage relay. Another terminal of this relay is connected to a point between lamps Nos. 2 and 3. The other two terminals are connected with the leads to wires Nos. 1 and 3. One of these connections is in series with the no-voltage release coil on the main switchboard.

If there are no grounds on any of the lines, then the voltage of the ground lead is 186 volts. An increase
FIGS. 6 AND 7—RECORDS OF TWO MEN HOISTING
SIMILAR LOADS ON INCLINE

The engineer whose power consumption was recorded in the upper chart, Fig. 6, used little power and, as can be seen by the frequency and regularity of his peaks, made many runs per hour. The second man was a current waster and did not land as many trips as the first man. He evidently needed instruction.

of potential of 4 volts in this ground will open the contacts on the relay and release the circuit breaker, on whichever line it happens to be.

In case of a ground in line No. 1, lamps Nos. 1 and 2 will light up; if in line No. 3, lamps Nos. 3 and 4 will light up, but if the ground is in line No. 2 all the lamps will burn brightly, in all cases increasing the voltage, which when normal is at 186. When the voltage rises

in the ground above 186, the relay will open, breaking the circuit in the series coil on the circuit breakers and opening the circuit.

Having a system of this kind it is possible to detect instantly whether there is a ground in any of the circuits. Knowing this the electrician can locate the leak and make the needed repairs. It also tells him when the repairs have been made satisfactorily. When the lines have no grounds the lamps burn with a dull-red light.

By being able instantly to detect losses due to grounds and to ascertain what power is lost in electric machinery by inefficient operation this company has been able to keep its power bill down to about 9c. per ton of coal mined. No steam is produced at this mine. All the power is electric, and therefore with the proper testing apparatus and a man who understands its proper use large savings have been made. There are many

FIG. 8—ADJUNCT TO SWITCHBOARD LOCATES LEAKS

Short-circuits and grounding cause many current losses preventing the power being used for useful purposes. To that device the Cordon colliery gives much credit for lowering the cost of current to 9c. per ton.

FIG. 9—WIRING OF LEAKAGE DETECTOR

In case of a ground in line No. 1, lamps Nos. 1 and 2 will light up. If one occurs in line No. 3, Lamps Nos. 3 and 4 will light up but if the ground is in No. 2, all the lamps will burn brightly, in all cases increasing the voltage which, when normal, is at 186.

When the voltage rises in the ground above 186 the relay will open, breaking the circuit in the series coil which forms part of the circuit breaker and opening the circuit.

operations in the anthracite region which show a power cost running many times the figure given here. For anthracite unfortunately cannot be mined with as small a power consumption as most of the bituminous coal of this country.

STUDY OF THE PHENOMENA of coal-dust explosions has been continued by the U. S. Bureau of Mines during the present year in a specially designed steel laboratory gallery. This gallery is 10 in. in diameter and 14 ft. long, and is provided with a bresleth that has a small cannon and relief valves. Dust under test is injected into the gallery at points spaced 1 ft. apart throughout the length of the gallery and compressed air is used for projecting the dust.

A study was made of the interval between the time of projecting the dust and firing the cannon and the influence of the temperature and humidity of the air within and surrounding the gallery was determined. More than 20 tests have been conducted with standard Pittsburgh coal dust, in a part of which inert shale dust was used to limit or prevent the propagation of flames. The gallery has been equipped with the necessary pipes and meters to admit of the use of natural gas for the study of the influence of low percentages of gas on the explosibility of coal dusts. A number of dust samples from industrial plants and from coal mines have been tested in the gallery in connection with explosive hazard reports made by field engineers of the bureau.
Problems of Bituminous Coal Washing and Measures Now Being Taken for Their Solution

Review of Washery Methods—Trouble with Wet Coal in By-product Coking—Why Wash Fine Coal?—Preferably Screen It Out, Wash the Course and Mix Washed Coal with Unwashed Fines

BY G. R. DELAMATER
Harrisburg, Pa.

I N THE last three or four years only a very few coal washeries have been constructed in the United States and it is not difficult to find the reason for this fact. During the past twenty years many washeries have been built employing the wet process with a wide variation in the method of its application. It would seem that a marked prejudice against this process in general is now held by practically all who are engaged in the washing and preparation of bituminous coal.

Until about ten years ago the jig in various forms was almost the only type of concentrator employed in the washing of bituminous coal. An exception was the Campbellumping table, which has been installed in several of the largest washeries in the country. That the results obtained were quite satisfactory in many instances is proved by the recent construction of a second plant for the Cambria Steel Co. at Johnstown, Pa., which is one of the few washeries built in the last four years. Some effort has been made to introduce trough and drag washers, but these proved unsatisfactory and attracted but scant attention.

Wet concentrating tables of various types, although extensively employed in ore-dressing plants, had never been used in this country for the preparation of coal, as it was quite generally felt that their capacity, considering the coal involved, made them impracticable for such use. Furthermore, their employment in ore concentration was confined to the small-mesh material, jiggling of the larger sizes being the usual practice. We should like to see a field generally conceded to be well advanced in the art of concentration had the effort of fixing the concentrating table in the minds of coal men as being unsuitable for treatment of the coarse sizes.

STUD CANNIN FUEL CO. INTRODUCES WET TABLES

The Stud Cannin Fuel Co. of Davisen, N. M., probably was the first firm to attempt development of a wet table for the concentration of coal, both small-mesh material and some of the larger sizes. The results obtained attracted the attention of manufacturers of wet concentration tables and resulted in the development of several new types suitable for coal treatment.

Possibly the next development of importance was the introduction of the Farr thickeners to replace the old drag-conveyor sludge-tank equipment used as the first step in the reclamation of the washed coal from the water. Closely following this came the introduction almost simultaneously of the Wendell and the Elmore centrifugal continuous washers.

Rapid replacement of the beehive by the byproduct coke oven imposed an even greater need for improvement in coal-cleaning methods. For example, exceedingly wet coal charged to the beehive oven was not deemed objectionable and at times was even considered desirable, but coal with a moisture content in excess of 8 per cent charged to a byproduct oven usually resulted in a loosening of the carbon deposit on the walls of the cooking chamber, thus creating leakages which seriously affected the yield of byproducts. It was found that in some instances the centrifugal drier so successfully overcame this difficulty that it was no longer necessary to store the washed coal in draining bins before it was charged. It should by no means be assumed, however, that the centrifugal drier always can be used successfully, as many conditions may be encountered where it would not be at all suitable.

BONSON TABLE GAVE QUITE PROMISING RESULTS

Various methods of dry concentration developed but probably the first to attract serious attention was the Bonson dry concentrating table. Promising results were obtained in its first application to coal, but, unfortunately, those in control of this process failed to co-operate with men of the coal industry thoroughly familiar with the requirements and conditions to be met. As a result the improved table failed to accomplish results equal to those achieved with the original device, and interest in this process died out completely.

The next development of note was the introduction of the “Chance Process” by the T. M. Chance Co. of Philadelphia, Pa. In this process sand is introduced into the water in a suitable container and by agitation is maintained in suspension, thus creating a liquid of high specific gravity. Separation of the impurities from the coal is accomplished in a manner similar to that employed in the laboratory float-and-sink test, where zinc or calcium chloride is used to produce a liquid of the desired specific gravity.

It would be well to mention here that some ten or twelve years ago J. R. Campbell, chief chemist of the H. C. Frick Coke Co., patented and experimented on a commercial scale with a calcium-chloride process, but while the separations were exceedingly satisfactory other objectionable features developed which caused the abandonment of this effort.

When the T. M. Chance Co. started development of their process on a commercial scale in the Pennsylvania anthracite field gratifying results were obtained; but it was found that with the rectangular tank which they were using they could not obtain a constantly consistent separation of the impurities from the coal. Upon adopting the old and well-known inverted Robinson cone tank, however, this trouble was overcome.

H. R. Conklin has under development at one of the breakers of the Hudson Coal Co. at Scranton, Pa., a process quite similar to the Chance method except that in place of a coarse granular sand a fine material is
used, preferably of high specific gravity and ground to pass a 200-mesh sieve. This process necessitates the employment of a Dorr thickener to reclaim the solids by which the desired gravity of the liquid is maintained. This process has shown some highly encouraging results. Its development and introduction is now controlled by the J. V. N. Dorr Co., of New York. No effort has as yet been made to apply either of these processes to the cleaning of bituminous coal on a commercial scale.

Coincident with these developments came the introduction of the Trent process. This is a radical departure from all other methods employed in the cleaning of coal. By agitation the pulverized coal is mixed with water and a suitable oil. The oil has an affinity for the carbon but not for the non-combustible particles. An amalgamation of the oil and carbon results. The ash reductions accomplished are quite remarkable as compared with results obtained by other systems of concentration. Some difference of opinion exists concerning the reliability of this process for the reduction of sulphur, also as to its practicability for cleaning coal to be used in the manufacture of metallurgical coke.

**Diy Tables to Be Operated at McComas**

Almost simultaneously with the introduction of these various processes Sutton, Steele & Steele, of Dallas, Tex., introduced a dry concentration table. The general apathy existing with regard to any wet process resulted in almost immediate interest being taken in this new table. A plant was built and put into operation in Oklahoma, another in New Mexico and testing plants were constructed both at Dallas, Tex., and at Welch, W. Va. Finally, a contract was given for a completely equipped plant to be built at McComas, W. Va., for the American Coal Co. This should be ready for operation about Jan. 1, 1923.

The present inactivity in coal-washery construction probably arises from the uncertainty in the minds of coal men as to whether a more satisfactory dry process has at last been found. Many coal companies are ready to contract for coal-cleaning plants but are patiently waiting for conclusive proof of the efficacy of the dry process through its additional commercial application before deciding between wet and dry processes for their own operations.

Within the past year two additional dry processes have appeared, one known as the Seagrave dry concentration table, now controlled by Walter J. Sykes, of Danville, Ill., and the other known as the Stebbins dry concentration table, being introduced to the coal field by Briscoe & Stahl, of Detroit, Mich.

While much is claimed for the Seagrave table, based on results said to have been obtained in ore concentration, no machine yet has been built and tested on coal, and therefore its value to this industry is unknown. The Stebbins table also is a Western development. It is reported that this table is being quite extensively and successfully used in ore and borax concentration. Testing and development has been under way at Detroit on both bituminous and anthracite coal with gratifying results. This table doubtless will be heard from in the future.

At present, therefore, the situation seems to be one of uncertainty, first because of dissatisfaction with old wet concentration methods and second on account of the incomplete development of both the new wet and the dry processes. Much of the dissatisfaction with any wet process arises not so much from any inability to accomplish satisfactory reductions in ash and sulphur content as from difficulty encountered in dewatering the washed coal, also from attendant coal losses and undesirable operating conditions resulting from wet coal of the smaller sizes.

The use of the thickener greatly diminishes coal losses in the smaller sizes, yet a question may be raised as to its suitability to coal-washing work as compared to that of the old drag-chain sludge-tank method on account of the moisture content of the reclaimed coal. As a water clarifier the thickener is far superior to the sludge tank, but the reclaimed coal product is in a fluid state while that of the sludge tank is a wet solid and in better condition for intermixing without further dewatering with the rest of the coal product of the plant.

By simplifying the equipment needed in wet concentration and by reducing the number of the operations needed, the objection to the use of water for that purpose will be removed, especially if the dewatering difficulties and coal losses can be eliminated. Granting this, wet concentration may yet hold a most important place in the cleaning of coal.

I have purposely neglected to mention another development introduced by myself about four years ago in which the screening of the coal plays an important part. Before taking up the details of this process I wish to emphasize the importance of the screen in the future of coal concentration. In many instances it will be found that sufficient ash-and-sulphur reduction may be accomplished if the coarse coal only is washed, thus necessitating the screening out of the smaller sizes before the washing process is begun.

With dry concentration close sizing of the coal has been found advantageous. Scant success has resulted from efforts made to dry-concentrate coal below 16 mesh, and the difficulties and expense encountered in eliminating obnoxious dust where attempt is made to clean such sizes make dry concentration of fines of doubtful value.

**Jig for Lump, Air for Slack, Use Dust Raw?**

While fair success is reported in dry concentration of the larger sizes it has yet to be proved that such sizes can be more cheaply cleaned in this manner than by a jig. In many respects the intermediate sizes would seem to be the legitimate field for the dry process. While it may ultimately appear that some coals can be more efficiently and cheaply cleaned by wet processes and others by dry, it is more than probable that a combination of the two will suit the majority of cases. Thus the screen is sure to enter the coal-cleaning problems of the future.

Prior to the introduction of screening equipment of a type wherein the screen cloth is electrically vibrated at great rapidity without movement of the heavy frame of the machine, the cost of screening coal in large quantity and through comparatively small mesh made consideration of such a process prohibitive. The data presented herein, however, will show the possibilities of the use of this type of screening equipment.

Attention is particularly called to the fact that instead of washing all the coal, the fines were screened out ahead of the washery and only the oversize from the screens treated. The unwashed fine material being bypassed and mixed with the washed oversize coal.

Instead of this resulting in a higher ash and sulphur...
not only applied to coals of the Eastern states but also those of the Rocky Mountain district. Later experiences with coal from various parts of the country and from the Argentine Republic and Alaska have brought this situation more and more to my attention, with the result that the tests were made, the results of which will be set forth in a succeeding article. I have also recently made a study of this situation in the Alabama field. David Hancock, consulting engineer and chemist, of Birmingham, Ala., has made extensive studies of the result of which quite conclusively prove this contention as regards much of the coal in that district. He has devised a special chart upon which are graphically shown in a surprisingly effective manner the results of float-and-sink tests made upon the raw coal, and the washed coal and refuse products of various coal washeries in that district. Others in that field also have proved by similar investigations that it would be advantageous to bypass the fine coal around the washery.

Sandstone Dykes Through Whitehaven Coal

As usually interpreted a dyke is an igneous intrusion passing across the geological strata. Thus defined a sandstone dyke is an absurdity. The material could not be of igneous origin but the crack in which the sand was found might have been formed by an earthquake and so be due directly to volcanic action. If, then, the term may be permitted, dykes of sandstone have been found in the coal beds of Whitehaven, Cumberland, England.

They were described at a meeting of the British Association for the Advancement of Science by Professor A. Gilligan. The Whitehaven sandstones, extensively exposed in the cliffs along the sea front, show no such signs of cracks and sand fillings. The sandstone probably rests somewhat unconformably on the Lower Productive Coal Measures, and it is believed that the earthquake action occurred shortly after the period of deposition of the Lower Coal Measures and not later. Only in one case is the crack a true fault, and then the displacement is only 2 ft.

The average width of the dykes is from 2 to 4 in., but sometimes they increase to 10 in. or dwindle down to mere films. The dykes are sometimes split. Veins of calcite and barite traverse the dykes longitudinally and transversely and lenticles of shale and coal also are of frequent occurrence in some portions of the dykes. Professor Gilligan said that he believed that the dykes were filled by deposition from the unconsolidated sands that ultimately formed the Whitehaven sandstone. In the discussion Professor Kendall mentioned one or two examples of earthquake dykes which he asserted had been filled by sand forced up from below.

For the Purpose of Determining Specifications for the construction of concrete stoppings in coal mines that may be developed on the public lands of the United States, the U. S. Bureau of Mines, in cooperation with the Bureau of Standards, is constructing in the experimental mine at Brueton, Pa., a chamber in which it is proposed to conduct tests to determine the strength of reinforced concrete stoppings when subjected to a pressure up to 50 lb. per square inch, suddenly applied. The tests require the construction of a permanent stopping, which was completed at the close of the fiscal year, and a test stopping, which is under construction in accordance with a design prepared by the Bureau of Standards. The work is under the personal direction of J. W. Paul, chief coal mining engineer, assisted by H. C. Howarth.
Crested Butte Field Produces Four Kinds of Coal From a Territory Five Miles Wide

Anthracite and Three Grades of Bituminous Coal Are Mined in This Cold Timber-Line Region—Lava Flows Have Maturated the Coal, Leaving Three Per Cent of Volatile Matter

BY CHARLES M. SCHLOSS
Denver, Colo.

NOWHERE, perhaps, in the world can a greater variety of coal be found in as small an area as in the Crested Butte field of central Colorado. Four kinds of coal, ranging from a bituminous of low rank to an anthracite of high rank, are all mined within a circular area five miles in diameter.

Crested Butte lies in the Elk Mountains on the western slope of the Colorado Rockies. The field is handicapped by its isolation and by the fact that all it produces and all it ships in must travel by a narrow-gage railroad and be transferred to or from standard-gage equipment. It prospers nevertheless, distributing its anthracite over the entire western half of the United States as well as north into British Columbia and south into Mexico. The transference point is Salida, on the Denver & Rio Grande Western R.R. Here the Rio Grande Southern narrow-gage road commences its 316-mile stretch to Crested Butte.

That region at its five plants mined in 1921 only 197,228 tons of coal, a little over 2 per cent of the total output of Colorado during that year, that output being 9,141,947 tons. The four coals mined are all high-grade coals. They are respectively non-coking bituminous, a bituminous making a strong coke, semi-anthracite and anthracite. They will analyze as in Table I.

The non-coking coal is an excellent domestic fuel, the coking is the equal of any heavy-draft locomotive bituminous coal in the United States, and the anthracite fully equal to that of Pennsylvania. The latter has the advantage over the better known coal in that Eastern state in being much freer from dirt, rock and bone. It is, further, with one exception the only commercially developed anthracite west of Pennsylvania, the one exception being a small bed at Los Cerillos, N. M., near Albuquerque.

Because of its excellence, Crested Butte anthracite enjoys an unusually broad market, bounded by the Pacific Coast on the west, Mexico on the south, Kansas City and Omaha to the east, and Canada to the north. Some goes to Mexico, some to British Columbia; one car found its way as far north as Nome, Alaska. Denver consumes more than any other city, San Francisco is next, and Kansas City third. Kansas and Nebraska, however, are the large consumers.

The operators in the field have standardized on the following sizes: Nos. 1 and 2, 24 in. to 5 in.; Nos. 3 and 5, 14 in. to 23 in., and No. 6, 8 to 11 in. Nos. 1 and 2 are adapted for large domestic furnaces and open grates; Nos. 3 and 5, for base-burners, kitchen ranges, small domestic furnaces, and open grates; No. 6, for domestic furnaces with small openings in the grates, kitchen ranges, laundry stoves and for banking furnace and range fires. On the refuse piles of Crested Butte a third of a million tons of anthracite dust have accumulated. It is only in recent years that a market for this "carbon dust" has been found. Smelters manufacturing zinc oxide for paints find it a prime fuel and reduction agent.

To the one who seeks the why and wherefores of natural phenomena the Crested Butte field gives much material for investigation and study. Geologists basing their hypotheses on the presence of porphyry masses and eruptive mountains credit the variety of coal found here to a flow of eruptive rock emanating from the main range and covering much of the sedimentary strata. The intense heat of the incandescent liquid rock meta-
morphed the bituminous to anthracite wherever it came anywhere near the coal. No trace, however, of the lava flow remains; it has been entirely removed by erosion.

Due to various rock movements the coal beds are more or less irregular in thickness. Many local, but not serious, faults are present. The roof and floor are either sandstone or shale. The bituminous beds vary in thickness from 4 ft. to 16 ft., the anthracite from 2 ft. 6 in. to 4 ft. The coal beds are either horizontal or on a moderate pitch. Many props are used, but their cost is not high. They are cut on the hillsides around the mines.

The coal at Crested Butte was discovered in 1879. Lack of shipping facilities delayed exploitation until 1881, when, upon the advent of the railroad, the first bituminous mine was opened. This same property has been producing ever since—more than 40 years.

From an engineering or mining standpoint Crested Butte offers nothing extraordinary. Its methods and machinery are not unusual. Two of the mine openings are so much higher than the railroad that gravity planes are necessary to land the trips at the dumps. The remainder are at tipple level. One mine sank a shaft but later abandoned it and began taking coal from another bed through a slope; the other openings are either drifts or slightly pitching slopes; the steepest has an inclination of 7 deg. Two are gaseous and use electric lamps; open lamps are used in the others.

In 1921 two shortwall coal cutters cut all the machine coal—only 3,641 tons. Longwall advancing methods are successfully applied by one company, room-and-pillar by the remainder. The machines operate in room-and-pillar workings. In 1921 55,323 pounds of black powder were consumed, that being used more than any other explosive. However, 5,415 lb. of permissible and 4,650 lb. of dynamite also were used. Haulage motors are conspicuous by their entire absence. Mules and hoisting drums substitute for them. Coal washeries and cleaning plants, likewise, are not found. Some refuse is picked out at the faces and the remainder in the screening plants.

Old Ruby Anthracite Mine, Now Abandoned

Note the trees around the plant growing up to levels near the timber limit. Climate is so cold that Japanese, Greeks, Mexicans and negroes avoid it.

Cable Cut by Rock from Bottom Shot Fires Crevice Gas

Ignition of Gas in Atmosphere Filling Longwall Face Fatally Burns Eighteen Men, Doing Hardly Any Damage in Mine of Canadian Collieries, Ltd.—Shot Said to Be Flameless—New Electrical Regulations

EXCELLENT as were the safety provisions at the No. 4 Mine of the Canadian Collieries (Dunsmuir), Ltd., at Cumberland, Vancouver Island, Canada, gas nevertheless collected in it and exploded on Aug. 30, killing eighteen men. A report made by George Wilkinson, former chief inspector of mines for British Columbia, who was given a special investigation commission by William Sloan, Minister of Mines, details the circumstances and gives advice as to the manner in which a repetition of such a disaster may be avoided. Of those fatally injured on this occasion only two were British, one being a Russian, six being Japanese and nine Chinese.

Briefly, Mr. Wilkinson finds that the source of the trouble was a flash, or open sparking, caused by an arc in the electric trailing cable at the socket used to connect this cable with the main electric circuit. This electric cable furnished the necessary power for the operation of a coal-cutting machine. The latter, a Sullivan alternating-current chain cutter, was of a type approved by the U. S. Bureau of Mines for use in gaseous mines.

NEW RULES FOR ELECTRICAL OPERATIONS

"After giving the matter careful consideration," says Mr. Wilkinson, "I would recommend the adoption of the following rules as part of the Coal Mines Regulation Act and would further suggest that the use of electricity be fully investigated by the Department of Mines, so that, if possible, definite conclusions may be reached as to the conditions under which the use of this power underground in coal mines may be permitted." The rules recommended are:

(1) The terminals of main feed lines in no case shall be located within 50 ft. of any coal face. (2) The current shall be cut off and the cables made dead in that vicinity when blasting, and the current shall not be switched on again until blasting is finished and the places are examined and pronounced safe and until the cables have been examined and found free from any defect. (3) All permanent electrical installations and transforming stations underground shall be made fireproof. (4) All switches and terminal connections shall be protected or enclosed so as to prevent persons coming accidentally into contact with them, to avoid danger from arcs or short-circuits resulting from fire or water. Where there may be risk of igniting gas, coal dust or other inflammables, all parts shall be so protected as to prevent open sparking. (5) All cables used underground shall be covered with insulating material, and, where high voltages are used, properly armored cables of standard thickness shall be provided. (6) All trailing cables shall be of properly armored construction whatever voltage is used.

Confidence is expressed that these rules will give an additional margin of safety. Rules 1, 2 and 3, it is asserted, should be put in force at once. As for Rules 4, 5 and 6, it probably will require three months to obtain and install the armored cables and other material required to make them effective. Mr. Sloan already has taken the action necessary to give these recommendations the effect of law. Orders in council have been passed and from Oct. 2 the rules enumerated have been a part of the Coal Mines Regulation Act. In the course of "general remarks" the report reads:

"It was a small explosion to take such a heavy toll and only a combination of circumstances made it do so. Occurring on a longwall face many men were in the path of the flame despite the short distance it traveled. As most of these men were working at the face and the seam was not thick, they could not escape. It is my opinion that if the current had been cut off the cable while the shot was being fired there would have been no explosion, and the fireboss erred in not requiring this to be done seeing that the terminals of the feed cables were in such close proximity to the shot.

"The terminals of the main feed line should not have been located so close to the face and fixed flameproof terminals should have been used. I do not mean to infer that an arc could not have been created if the terminal boxes had been installed, for if the blow had been of sufficient force to draw the bare end of the connecting cable clear of the insulated material an arc might nevertheless have been created, but the chances of this happening would have been decreased. It is questionable whether, owing to the quantity of gas liberated by the strata and the peculiar conditions existing, it would be wise to continue the use of electric mining machines in this section.

"Up to the present, because electric power has been used to only a limited extent in the mines of British Columbia, no specific regulations governing its use have been made. No doubt it will be used more extensively in the future as it already is in the coal mines of the United States and Great Britain.

DANGER LURKS IN THE CABLE CONNECTION

"These electric coal-cutting machines were installed by the Canadian Collieries (Dunsmuir), Ltd., nearly seven years ago, and the recent accident is the first recorded. Though the machines are approved by the U. S. Bureau of Mines, their safety must be judged by the weakest link, which in my opinion is the cable and especially that connection which is in close proximity to the working face.

"Edison electric safety lamps are used throughout the mine. The only exceptions were the few flame safety lamps used for testing purposes. No one was permitted to blast the coal in this section, and most of the bottom lifting was done without blasting. Explosives were used only in places where the rock was so hard that it could not be lifted without it. Even then only permissible explosives were used.

"It is hard for the higher officials and the inspector to watch every detail in a mine of this size. The terminals of the main lines are being moved from time to time, and this detail comes mainly under the control of the under officials. Enough electricians were employed to do this work, and an adequate number of certificated officials were employed to supervise it. In
addition to the large staff of register officials, the company employed a safety engineer who holds a first-class certificate of competency. He constantly patrols the works in an end, keeping up and pointing out any defects that may imperil accidents.

The floor has two main entries from which at a point 75 ft. from the portal two slopes diverge, No. 1 slope being 7,000 ft. long and running due north, and No. 2 slope being 9,000 ft. long and running north 45° east. Levies have been turned off the latter slope in an easterly and westerly direction.

The explosion occurred in what is known as the main剥离 district off No. 20, East Level, No. 2 slope. Part of the face is machine-quarried, the coal from that part being shoveled into cars by loaders. Another part was worked by hand miners. A trailing cable 200 ft. long connects the main circuit to the machine.

With reference to the condition of the mine as to gas, Mr. Wilkinson quotes the daily reports of firemen from Aug. 20 to Aug. 22, the inspectors' reports for the months of June, July and August, and the gas committee’s reports for the same three months. From these reports, he observes, it is plain that much gas is being made in this section of the mine, chiefly due to the roof ‘breaking through to a small seam of coal about a foot thick which lies about 15 ft. above.

The inspectors' reports show that explosive gas has been found in small quantities in No. 3 level and other places in that vicinity and that a 1-in. gas cap was obtained at points along the roof line, but that it was less as the lamp was lowered and probably did not exceed 1 in. from No. 3 level to the end of the longwall face. No explosive gas or gas caps have been reported below No. 3 level.

According to the length of the flame caps and their relation to percentage, as shown in a pamphlet issued by the Department of Mines, the above-mentioned caps of gas are equivalent to 2.08 per cent and 1.08 per cent respectively. The low explosive limit is 5.5 per cent. The withdrawal point as set by the Coal Mines Regulation Act is 2.0 per cent, leaving a margin of safety of 3 per cent. But the margin in this case appears to have been 3.42 per cent.

**Many Deaths but Little Explosive Violence**

Mr. Wilkinson states that conditions as he found them in his examination of Sept. 1 indicated that the mine had been little damaged by the explosion. He goes on to tell in detail of the conditions in each level visited. Regarding No. 1 slant off No. 4 level* he says:

"About a 1-in. gas cap was obtained in this place and an atmosphere that was explosive in a cavity on the right side of the roadway above the terminals of the main circuit of the electric power line. The trailing cable from the mining machine is connected with the main line at this point.

"A shot had been fired in the floor of this place, and it was almost simultaneously with the firing of this shot that the explosion occurred. A rock flying from the shot came in contact with the trailing cable with sufficient force to break the insulating and bare wire wire and had also torn one of the three connecting wires from the socket where they were connected with the main circuit. The shot had done its work well.

"No damage was done in this place but much dust was deposited on the timbers. The shotlighter with two of the workmen out of the place stood in No. 2 roadway off this slant about 30 ft. distant from the shot. They were slightly burned on the face, hands and arms. A car standing about 45 ft. from the face had not been moved. In No. 3 slant, No. 2 level, No. 1 place, there was no damage. A car was standing at the face and apparently had not been moved. The badly burned body of John Johnston, a miner, was found on the slant about 80 ft. back from the face.

"In No. 2 place, off No. 3 slant, No. 2 level, there were signs of considerable heat from flame. Two shovels were standing against a cog on the face line in this place. There had not been sufficient force to move them. In No. 3 slant a 5-ft. post was found with the saw in position for cutting. A car was standing undisturbed."

**IGNITION OF GAS RATHER THAN AN EXPLOSION**

Commenting on the evidence Mr. Wilkinson asserts that the outbreak may better be termed a burning of gas than an explosion. He adds: "It would appear as if the percentage of methane had bordered on the lower explosive limit. The flame passed up the longwall face with the air current. The shotlighter, who was standing 30 ft. below the point where he was firing the shot, was only slightly burned. E. McAdam, who was working in No. 1 level, about 700 ft. up the face, did not see any flame, consequently the distance it traveled along the longwall face did not exceed 750 ft."

It is stated that conditions point to No. 1 slant of No. 4 level as being the point of ignition. It was in this place that a shot was fired in the bottom, as described. The roof in the place is broken and full of slips and crevices, and there is a cavity which has a length of 8 ft., a width of about 1/2 ft. and a height above the roof line of about 12 ft. Fissures and crevices extend back into the gob; to what distance and height is unknown. A fault with an approximate downward displacement of 3 ft. had been crossed by the place above this. It had run out before it reached this place, but it extended for some distance in the opposite direction. This resulted in a considerable area of exposed roof being badly broken, and no doubt the breaks in this roof continued upward to the small seam which overlies the one being worked. The crevices made by these breaks would provide a large storage space for methane, as the ventilating current could not be diverted to clear them. This gas also would be out of reach of anyone testing, as a safety lamp could not be got into the crevices.

Small quantities of explosive gas had been found in several places on the return side of No. 1 slant for some time prior to the explosion. This being so it is not safe to presume that the crevices higher up, which could not be examined because of their inaccessibility, also contained methane. The distance traveled by the flame was not great, and it died out after passing the working places in the disturbed area, showing that there was lack of explosive material elsewhere.

Commenting further on the cause of ignition it is stated that the main three-phase circuit was carried up No. 1 slant, No. 4 level, to a point approximately 16 ft. from the coal face and about 4 ft. from the end of the bottom lifting. The top cable was about 1.7 ft. below the roof line and the bottom of the cavity. The lower cable was about 3 ft. above the top of the rock to be lifted. Mr. Wilkinson speaks again of the break-
ing of the wire by flying rock following the firing of a shot and asserts that there must have been considerable flash from the arc so created. The break occurred only about 2 ft. from the cavity.

There were only two possible sources of ignition; one, the arcing of the electric circuit, and the other, flame from the explosive in the shot. The shot was a good one, according to Mr. Wilkinson, and the chances that any flame resulted are remote. It was some 8 ft. from the cavity, whereas the junction point of the trailing cable was only about 2 ft. distant. He adds: "From conditions as seen after the explosion I have to conclude that actual ignition must have been from flame or sparking from the electric wires."

References are made in the report to the evidence of the fireboss at the inquest to the effect that he had carefully examined the place before firing the shot and found no gas and also that he had examined the cavity in the roof with similar results. Mr. Wilkinson expresses doubts of this. It is possible, he says, that this was done, and that there was a change between the time of examination and the firing of the shot. However, assuming that the cavity was clear, so far as could be ascertained by the fireboss, the crevices above it no doubt contained gas.

On June 26, 22,000 cu.ft. of air were provided for the use of sixty-two men and eight mules; on July 25, 20,000 cu.ft. were supplied, and on Aug. 11, 25,000 cu.ft. were circulated for the same number of men and mules. The amount passing is nearly three times that required by the Coal Mines Regulation Act under normal conditions, according to Inspector Jackson's reports. Since the installation of a booster fan, electrically driven, for augmenting the ventilation the quantity passing in this district has been increased some 6,000 cu.ft. per minute.

Officials of the Canadian Collieries are said to have been faced with unusual difficulties in the ventilation of the mine, which is of large extent, having been operated for thirty years or more. Large extraction of pillar areas in the earlier days of operation, without any thought for the future, has made many difficult problems which the present-day management is endeavoring to solve. Thomas Graham, the superintendent, and his staff have made many improvements in the past five years. Among these are "the building of permanent stoppings with a gunite finish on main airways practically throughout the mine, the installation of a second fan of the Sirocco double-inlet reversible type with a rated capacity of 200,000 cu.ft. per minute against a 6-in. water gage and the construction of a new and separate return airway through the old works for practically the whole length of the slope."

Work Both Wood and Metal on One Machine

ONE of the “side issues” of every coal mine—one of those things that contribute nothing directly to the extraction of coal yet without which little coal would be produced—is the mine shop. In the old days this was a blacksmith shop pure and simple—a place where mules were shod, picks sharpened and drills and augers dressed. With the passage of years, however, the equipment of the mine has changed and similarly the needs of the shop. The electric locomotive, the coal cutter and various mechanical appliances of a similar nature necessitate a type of repair impossible with only forge, anvil and possibly hand drill press.

Of all the machine tools yet invented it is well recognized that the lathe, being the most flexible, possesses the greatest possibilities. American manufacturers have developed this machine to a high state of perfection; that is, they have developed many special lathes adapted to special uses. In the mine shop, however, particularly if this shop be small, the special tool is the type to be sedulously avoided. On the contrary, the kind of lathe most to be desired is an “all around” machine or what might be termed a jobbing lathe—that is, one upon which a great variety of operations may be performed without its being specially designed or adapted for any one in particular.

In the accompanying illustration is shown a lathe recently placed on the market and well adapted to the small shop having a variety of work to perform. This lathe is designed for turning either wood or metal and is made rigid enough to withstand the possible high-speed vibration of the former and the heavy cuts of the latter.

Possibly of most interest to mining men, however, is the large number of attachments with which this machine may be provided. For metal working these include grinders, buffers, millers, gear cutters, etc., and for woodworking they embrace sanders, grinders, buffers, polishers, bandsaws, jig saws, jointers, planers, saw tables, mortisers and the like. Of course, the procurable equipment includes raising blocks, a compound rest and a turret. Many others also are available, built especially to fit this machine.

Thus it will be seen that this machine is adapted to the performance of many operations. The attachments, such, for instance, as the band saw, take up far less floor space than would separate machines performing the same service. When not in use these may be taken off and set to one side out of the way. This machine is being built and marketed by the Little Giant Co. of Mankato, Minn.

![Diagram of lathe](image-url)
Huntington Show Suggests Modern Ways of Reducing Coal Cost—II

Abrasive for Keeping Tires in Condition—Self-Renewing Water-Softening Material—Means of Ridding Mine Towns of Typhoid—Bucket Conveyors—Helical Gears

In an article regarding the Huntington Coal and Industrial Exposition, Sept. 15-23, appearing in Coal Age last week, the wide, low, spacious mine cars of the West Virginia mining region as shown at several booths were described as well as an electric rivet heater and a mine hoist of large rope capacity.

At another booth was an exhibit of "feralum," the substance which, set in a brake wheel, wears off false flanges and so makes it unnecessary to take the wheels off their axles, to turn down the tires and replace the wheels, to lay off mine locomotives temporarily while this work is being done, and to renew shoes. Moreover, wear and tear on frogs and switches are prevented by this grinding, as also the derailments that are the result of false flanging. The cutting of fishplate bonds is avoided and electric welded bonds if attached to the upper part of the rail are protected from injury.

When the brake shoe with abrasive material imbedded in it has ground down the false flange, the body of the shoe that has no cutting abrasive rests on the main portion of the wheel, the part that runs on the rail and is worn by traction and sparking, and the cutting substantially ceases except as much as is necessary to keep the wheels true. Abrasive shoes are put also on new wheels to prevent them from getting out of shape. The keeping of false flanges off tires saves the rail surfaces from much wear.

Interesting also was the exhibit of the Permutit Co. Permutit is a zeolite (so called because it intumesces or acts so rapidly as to be said to boil when acting on the hardness in water). It is a sodium aluminum silicate that exchanges its sodium for lime or magnesia when those elements come in contact with it in the form of the hardness in water. It has the advantage that it can be regenerated by passing through it common brine (sodium-chloride solution). In consequence when permutit is used to soften water before its introduction into the boiler of feedwater heater, the chemical after change need not be thrown away but can be used again and again after it has been regenerated by brine. The regeneration cycle is ordinarily arranged to take place at night, when the plants are closed, or two softeners are placed in parallel to give a 24-hour continuous serv-
as a softener of permanent hardness, cannot compete in cost with lime as a means of removing temporary hardness. Therefore the best practice is often to use lime for the latter and Permutit for the former. Whether to do so is a matter for expert determination.

The Kaustine Co., Inc., exhibited its line of sanitary products and here it may be said that one cannot be favorably impressed with the sanitary conditions in mining villages with the houses perched often above one another and sewage seeping down from the imperfect vaults now in general constructed. The evil is perhaps not painfully apparent. It takes a medical man to realize it. There has been little objection made by the residents of mining villages, though they are the persons subjected to the evil effects just described. Still, many mine operators have sensed the dangers of seepage and flies and wondered whether they could not make their village more typhoid-proof.

I am told that the owners of many mining plants in West Virginia are not only aware of the danger but are
All the illustrations shown are for single units, but multiple units are provided where these are desirable for schools, stores, bathhouses, churches, assembly rooms, ballrooms and like places.

Coal soda has a demineralizing effect on galvanized vessels, so these are made of Armco iron, which is 99.84 per cent pure. This is covered with an enamel that is unaffected, it is said, by acids, alkalis or the elements. The top of the tank is fitted with a revolving trap which serves to keep the tank reasonably tight, but the nature of the contents after reaction by the caustic soda renders this quality less necessary. In one illustration will be seen the agitating paddles which are set in motion automatically by the closing of the lid. Where sewers are laid throughout the village and the sewage is conducted to a central point septic tanks are used instead of chemical tanks.

The Egyptian Iron Works exhibited an eccentric having instead of the usual eye a self-acting ball. This eccentric is intended for use with shaker screens. With such a connection between the shaft and the screen no harm results if the eccentric bearings are not in alignment. The ball forms a joint so truly universal that no ordinary misalignment can bring improper stress on the eccentric.

Both the Hyatt and Timken roller bearings were well represented in the Huntington show both directly and in the use of bearings for mine cars. The Timken Roller Bearing Co. lays stress on the ability to take up wear in the bearings while eliminating that in the running gear.

The Joy Machine Co. showed a full-sized loading machine which loaded coal all day long. The Westinghouse Electric & Manufacturing Co. had a bar-steel conductor-cable-reel locomotive running on tracks and both the Westinghouse and the General Electric Co. had an exhibition of their automatic substations equipment.

A. Leasen & Sons Rope Co. had a model illustrating its equipment at the mines of the Bradshaw Coal Co. at Bradshaw, W. Va., on the Dry Fork Branch of the Norfolk & Western R.R. The coal is 600 ft. above the railroad, and the point nearest the railroad is 1,200 ft. distant therefrom. This company had been using a surface incline to reach the bottom of the hill and mules to haul the cars over the Dry Fork of the Tug River. The rope is supported only at the ends and it has a rated capacity of 125 tons per hour, or 1,000 tons per day of eight hours. However, one man can readily lower 50 per cent more and do it safely. The span is 1,320 ft. and the fall 380 ft., the cost for operation being approximately 1c. per ton.

The R. D. Nuttall Co. had a booth where were displayed the helical gear reduction units by which continuity of contact, reduction of noise and vibration are attained. With such a gear the load is transferred from the pinion teeth to the gear teeth progressively, gradually and without shock regardless of how badly they are worn. They do not drive by a series of impacts, as is inherently the case when an ordinary pinion drives a spur gear. It is asserted that the wear being uniform permits a new pinion to be applied to a worn gear with satisfactory results. Compared with ordinary spur gearing the teeth have a greater rolling contact and are provided with a large quantity of metal at their roots. Unlike a herringbone gear the pinion can float across the main gear without injury. These gears are suited for many purposes, among them for driving hoists and pumps. At the Carnegie Coal Co.'s plant at Atlasburg, Pa., a helical gear of this kind has been installed for driving a 12-ft. exhaust mine fan, replacing the steam drive.

The Nuttall firm also showed a trolley and pole head for holding it. This trolley is provided with a centering spring that brings the wheel back to its normal position. Instead of the pole head covering the sides of the pole it covers the top and bottom. In consequence when the trolley escapes from the trolley wire and hits against an offset in the roof or on the edges of cross beams, the blow falls on the steel fork and not against the wood of the pole. This prevents it from being shattered. The cable is firmly clamped to a grooved plate, using bolts instead of set screws. The motorman is almost sure to have a wrench with which he can tighten up the connection should that be necessary, yet is quite likely not to be provided with the wherewithal to tighten setscrews where these are used to clamp the connections to the trolley-pole head.

AT THE PITTSBURGH (Pa.) experiment station of the U. S. Bureau of Mines, J. D. Davis, fuels chemist, and J. F. Byrne, research fellow, Carnegie Institute of Technology, have investigated the relative tendency of Pennsylvania coals to ignite spontaneously. The research consisted largely in the development of methods for the determination of the comparative sensitivity of coals to oxygen.
Where Coal-Mining Practice Could Be Materially Improved

Examination Started Too Long Before Men Enter the Mine for Work—Practice in the North of England

—Economy in Handling Coal at the Working Face

Born in England and starting work at the early age of 13 years, for ten years I labored there as a miner's helper and doing various kinds of work about the mine, before deciding to come to this country.

Looking back over that early experience in England and judging it by what I have seen in American mines, I find there is much to be learned by way of comparison. In the fifteen years that have passed since I came to America, I have worked in many coal mines from southern Illinois to British Columbria. During that time, my eyes have not been closed to what has been going on about me and I find that many lessons can be learned through close observation and comparison of the means and methods employed in different localities.

Firebosses Start Examination Too Long Before Men Enter Mine

It was reading the numerous letters that have appeared in Coal Age, regarding the fireboss’ identification mark, that leads me to offer a few comments on this work. I am deeply impressed with one fact; namely, in the large majority of cases, the fireboss starts his examination too long before the time for the men to enter the mine for work.

In Illinois, it was a common thing for a fireboss to start his examination eight hours before the beginning of the morning shift. I found that this was wholly in compliance with the coal mining laws of the state, where the mine examiner is required (Sec. 21) to examine the underground workings of the mine within eight hours preceding the time the dayshift goes on duty.

Let us assume, for example, that a fireboss begins, say at 1 a.m., to examine a section of a mine in his charge. In his examination, we will suppose that he finds a small quantity of gas in several of the places, but not sufficient to render work in those places dangerous.

Now, we will assume that a big cave has been opened by a rockfall, and coal has been exposed in several places. As a result, the circulation is choked and gas accumulates in the section. Believing everything to be safe, the men are admitted to the mine and proceed to their several places. It is nothing strange that conditions such as these bring calamity.

At other times and places where the fireboss starts his examination only two hours previous to the entrance of the miners to work, I have known of places that were found to be clear of gas at the time the examination was made; but a cave occurring a little later would knock down a brattice and short-circuit the air, allowing gas to accumulate at the face in a very short time.

Booster Fans Installed in Mines, Menace to Safety

Again, I have observed gaseous places that were hard to ventilate and required a small blower or booster fan to keep them clear of gas. Let me ask, Who knows when the belt driving such a booster is going to slip or break; or when a cave will tear down the wire that conducts the power to operate the fan? Either is liable to occur at any time and the fan be put out of commission.

In some localities, bumps are frequent, causing roof falls that destroy brattices, airways, and short-circuit the air. This may take place at a time between the examination by the fireboss and the entering of the men for work.

Practice in North of England

Allow me just here, to refer to practice in the North of England, where the firebosses enter the mine only an hour previously to the beginning of the miners' shift. The mine manager is at the shaft bottom to receive the firebosses and give them any orders that might be necessary. He starts the shift together with the fireboss.

The examination by the firebosses being completed, if everything is reported safe for work, the men are allowed to enter the shaft bottom. Every lamp has been examined and locked, and the men are searched for matches before being permitted to enter the mine.

It goes pretty hard with a man who is caught with matches on his person. The officials are sure to make an example of him, by imposing a fine or hauling him to court for imprisonment. At the entrance of each section, the fireboss in charge awaits his men and there is no chance for a man to enter his place when it has been found to be in an unsafe condition for work.

When a fireboss has admitted his men to their respective places, he devotes the balance of the shift to an careful examination of the shots and timbering, in each working place. All shots must be properly mined and tamped before they can be fired.

Improvements in Loading Coal Adopted in Montana Mine

I was pleased to note a reference made in Coal Age, Aug. 24, p. 288, to the improved method of loading coal at the working face, as adopted by the Keene mine management, at Roundup, Mont. It appears that the company has been studying for economical methods of mining and handling the coal at the working faces, in the rooms.

The plan adopted of standing from three to five cars at the face of a room, the cars to be loaded at one time, will expedite the work and reduce the cost of gathering cars in the workings. The new plan has also reduced the investment of several hundred dollars for extra mine cars; but this expense will be more than offset by the reduced cost of operation.

Coal Face Conveyor System

In the mining of a seam of low coal overlaid with a good roof, allow me to suggest that there is much economy in the use of a conveyor system laid parallel to the coal face. Such a conveyor, operated by a small electric motor, will afford easy loading all along the face and will be found a profitable investment.

Not the least of the advantages of a conveyor system is the fact that little or no brushing of the roof is necessary. As the conveyor works along the floor, miners can load commercial coal with the greatest ease. A skip of coal, that requires two men to load it, under the conveyor will generally be carried along without further trouble.

A conveyor system of this kind is generally protected by a series of rods. As the face is advanced, the conveyor line shifted forward, new rods are built and the conveyor is moved along the casing area to save. Whether a conveyor is installed or a track is laid along the face of the coal, there is provided an ideal long-wall system that will prove a source of great
Steel Guides and Buntons in Mine Shafts

Steel cage guides and shaft buntions in use in Europe fifty years ago are described in a modern Belgian coal mine report.

In describing the equipment of the Remondile SHAFTS, in Coal Age, Sept. 1, p. 224, George A. Richardson points to the advantage that the use of steel rails as cage guides in these shafts, is something novel. He calls it a "revolutionary development."

As a matter of fact, steel rails have been used as guides in the deepest coal shafts for well over fifty years. Since such rails have been rolled commercially, and that is, since the early stages of the Bessemer process development, which would put me back fifty years or so in the seventies.

But, even before that time, when iron rails were being used, there were wood rails as cage guides in Belgium. In the sixties, Alphonse Briart, a famous Belgian mining man of those days, replaced iron rails with wood guides in all the hoisting shafts of the Mariemont-Bassompaille area. There were eight or more of those shafts, none of which were deeper than 1,500 feet.

Use of Iron Rails as Shaft Guides Fifty Years Ago

From the beginning, Mr. Briart used steel as the heaviest rails procurable. At that time, there were not many kinds of rails being manufactured, and, consequently, the conditions of the heaviest rail with which we are familiar in this country and the two-headed type, which still survives in the British Isles. Mr. Briart used the former as cage guides, while the latter, placed at the bottom of cages. More than a century ago, therefore, rails were not only used as guides, but for hoisting, as well.

That mining men had their doubts about safety catches being effective on iron guides is proved by a certain amount of literature that flowed its way into the publications of the Mining Engineering Society. However, it was soon demonstrated by tests that guides not only helped a cage more promptly on iron guides than on wooden ones, but that in almost eliminating them. The same kind of catches, acting on wooden rails, always slipped down on them for quite a number of feet, drawing the rolling body with them and making them unfit for further use.

Tests Prove Steel Guides More Effective Than Wood

During the seventies, when steel rails became available on the continent, they were employed as guides in preference to iron, and it was then very promptly and conclusively demonstrated that all the types of safety catches in use were effective on steel as on iron.

In the accompanying sketch (Fig. 1), I have shown how steel guides were sometimes installed in deep shafts, at the time when I gained my mining experience in Belgium, in the early nineties. The drawing is made from memory, the dimensions given are the only ones I am able to remember definitely.

Heaviest Rails Used for Guides: In 1890, shafts 3,000 feet deep were quite numerous in Belgium, and there were a few, in regular operation, at 39.3 lb. per yd., which is manufactured continuously in Belgium ever since the late eighties.

The buntions shown in Fig. 1 were, I think, 30-em. (12-in.) channels. I am certain they were not less than 25 cm. (10 m.). There was nothing cheap about such work. There could not be, considering the speed with which hoisting had to be done, in order to reach the outputs of 800 or 900 tons, in eight hours, from shafts 2,500 or 3,000 feet deep. Hoisting speeds of 10 m. (about 33 ft.) a second were then reached. Today, they hoist at speeds even greater than this, say 19 m. (about 61 ft.) a second being often maintained during 65 per cent of the hoisting operation.

Details of a Modern Shaft in the Belgian Campine Region

In Fig. 2 I have shown how a modern Belgian coal shaft is equipped. The example I have selected here is a shaft in the Campine region. I was in that shaft recently. There are two pairs of four-deck cages and two hoisting engines. Each cage engine carries two cars. The dimensions given are the only ones I have noted, besides the following data:

Shaft is 2,350 ft. deep. The eight cars hoisted in a cage contain a total of 4.8 gross tons of coal. The cars themselves weigh 2.4 tons. A cage weighs 4.5 tons. The rope hanging in the shaft weighs 6.6 tons. The total weight hoisted is, therefore, 18.3 gross tons.

As is usual in Belgium, this shaft is lined with cast iron, being concreted all around as indicated in the figure. The cast-iron lining, in this case, is 220 m. high (700 ft.), because of a corresponding thickness of quicksand which had to be frozen before the shaft could be sunk. The same sinking process has been used for all the shafts of the Campine region, on account of this quicksand formation, which is nearly constant over that part of Belgium.

While I was there, the double hoisting outfit, shown in Fig. 2, made seventy-six hoists, bringing to the surface 658 cars and 364 tons of coal in one hour, from a depth of 2,350 ft. I was told that this was less than the record, which then stood at 5,056 cars and 3,034 tons of coal, in a day of eight hours; or at the rate of 632 cars and 379 tons of coal per hour.

New York City. F. C. CORNIT.

Driving Wide Rooms

Loading contest shows record output, per man, per day—Influence of width of rooms on output—Discussion asked.

In the issue of Coal Age, Aug. 10, p. 216, is given an account of the results of a loading contest that took place between two mines of the Standard Island Creek Coal Co., located at Cora and Taplin, W. Va., respectively.

The account gives the average daily output of two men, working at these
respectively, as being 50.5 tons of coal, per shift, in the one case, and 45.9 tons, per shift, in the other; or, practically, the capacity of a 50-ton railroad car, per day, of each sectional elevation.

This is a record output for a miner working in 4-ft. coal and drilling, shooting and loading his own coal without assistance. It is stated that one of these men was working in a double-track room, 36 ft. wide, while the other was driving two places, each 18 ft. wide.

Reading this account interested me, particularly as I have lately been endeavoring to convince our foreman at Coral, Indiana County, Pa., that he should widen his rooms from 20 to 36 or 40 ft., believing as I do that this would increase the daily tonnage, per man.

We are working coal 78 in. thick and overlaid with from 200 to 390 ft. of cover. The seam which is the upper Freeport seam and is very soft, consists of 26 in. of top coal and 42 in. of bottom coal, separated by 10 in. of binder. The roof is mostly sandrock and taking the mine as a whole, it is considered very good. Occasionally, we strike a "cutter," where the roof will cut or shear from 3 to 10 ft. The floor of the seam is solid and very regular.

I would like to have the question discussed as to what influence, if any, the width of rooms have on the possible daily output, per man. It would be interesting to hear from some of the men of the Standard Island Creek Coal Co., on this question, giving their roof conditions and other data that would bear on the subject.

L. F. KLINGENSMITH,

**Inquiries Of General Interest**

**Triple-Compartment Hoisting and Airshaft**

**Double Compartment Hoistway and Airshaft Combined—**

**Effect of Movement of Cages on Circulation of Air—**

**Suggestions Regarding Design of Shaft and Its Equipment**

HAVING in contemplation the sinking of an airshaft, at a point some distance in advance of our present workings and desiring to design and equip this shaft in a manner that it can be used as the main hoisting shaft, at some later time when the underground development has proceeded to an extent to make that advisable, we solicit the advice of Coal Age and its practical readers, in hopes of gaining information that will enable us to avoid mistakes that might otherwise be made.

In order to make clear the situation, I have prepared the accompanying sketch showing the cross-section of the proposed shaft, and outlining the headframe and hoisting sheaves above the shaft, together with the fan and fan drift connecting with the air compartment of the shaft. Below the sectional elevation is shown a plan of the shaft with its three compartments, comprising two hoistways for the cages and an air compartment in one end of the shaft.

As indicated by the arrows, the two hoistways are made downcast and the air compartment is then the upcast for the mine, the fan being operated as an exhaust fan. In accordance with our best practice, the fan is set back from the shaft a short distance, as a safeguard against its possible destruction by the blast of an explosion should one occur in the mine.

The shaft is to be lined with concrete throughout its entire depth and a 12-in., reinforced concrete curtain wall will separate the air compartment from the hoistway adjoining it. This curtain wall will extend from the top to the bottom of the shaft, thus providing separate intake and return airways in the shaft.

It is assumed that the ultimate quantity of air circulating in the mine and passing through this shaft will be 200,000 cu. ft. per min. It is the intention to operate the cages at a maximum speed of 900 ft. per min. Briefly stated, this shaft will serve the following purposes: 1. Ventilation. 2. Hoisting and lowering men and supplies, and hoisting coal and rock from the mine.

As shown in the sketch, there are three beds of coal cut by the shaft; namely, beds B, D and E. Hoisting operations will include the following: (a) Lowering supplies from the surface to the several levels, E, D, B. (b) Hoisting coal and rock from bed B to the surface. (c) Lowering coal from the two upper levels to bed B. (d) Hoisting and lowering men working in several levels.

Having made this explanation, I would like to ask three questions, as follows: What effect will the presence of one of the cages at either of the upper levels have on the circulation of air in the hoisting compartment? 2. What effect will the travel of the cages up and down the shaft have on the air in the hoisting compartment? 3. What suggestion has any one to offer in the matter of design of the shaft, with a view to realizing the most satisfactory result from a ventilating standpoint?

It should be further stated that of the 200,000 cu. ft. of air, which is the proposed maximum circulation that will pass through the shaft, 130,000 cu. ft. will be required in the lowermost seam, Bed B, while the remaining 50,000 cu. ft. will circulate in the two upper levels, Beds D and E. I trust that this will make the proposition clear to all and hope for many good suggestions.

—, Pa. Chief Engineer.

This is an interesting proposition that we are glad to present to the practical readers of Coal Age, knowing that they will respond by giving many helpful suggestions respecting the design and equipment of this shaft. Before introducing to your readers the most economical and satisfactory results in its operation. By way of opening the discussion, we offer the following brief suggestions:

First, it is not assumed that this shaft is sunk so far in advance of the present working face in the old mine, that connection with the new workings will provide a way of escape in case of accident in the new shaft, which would be necessary to comply with the Pennsylvania mine law.

While it is a common practice to sink a triple-compartment shaft providing a double-compartment hoistway, and airshaft combined in one, there are serious objections to this plan. First, and chief of all, is the fact that an accident occurring in the shaft endangers the circulation of air in the mine.

It is true that, in this case, a 12-in. reinforced-concrete curtain wall separates the airway from the hoistway. But it is a question whether this curtain wall would withstand the terrific force of an explosion in the mine should one occur. In our judgement, a far better arrangement would be to sink two separate shafts, making one a hoisting shaft and using the other as an escapeway in the later operations of the mine.

Answering the question regarding the effect on the air due to one cage being at the upper level and practically closing that compartment of the shaft to the free passage of air, or the effect on the air due to the travel of the two cages up and down the shaft, our experience has been that neither of those conditions have any material effect.
Kentucky Mine Foremen's Examination.  
Lexington, May 30, 1922

(Selected Second-Class Questions)

Question—Explain how natural ventilation in a mine is affected by the change of seasons.  

Answer—In the winter season, the outside temperature is generally lower than the inside air, and the intake air, being heavier than the warm return current, an air column is produced which assists the circulation of the air produced by the ventilator.  

In the summer season, the outside temperature is generally higher than that of the mine.  The result is, then, that the warmer intake air, being lighter than that of the mine, an air column is produced which opposes the circulation induced by the fan.  

In general, therefore, a mine is more naturally ventilated in the winter than in the summer season.

Question—What kind of inrush of air may start a ventilating fan at the face of such working place?  

Answer—At the first place, a visible mass of producing the circulation of air on the mine must be adopted.  

Again, the air must be carried forward by means of well-built shafts, doors, air headers and hitches, that it will be made to move the face of the mine, or raise the place.  Frequent inspections are necessary, but not only to keep them in good condition, but also to remove a constant resistance of air in the workings.

Question—What are the greatest advantages in regard to the distribution of air in mines, and what must be considered in order to get the greatest effect?  

Answer—The total inrush area must be divided into two or more shafts, and the capacity of air in each shaft must be proportioned to the working.  The number of sections must be built in the mine in order to comply with the requirements of the mine law so that the number of men working on a single split will not exceed what the law allows.

Should the current be seriously interrupted, the men must be promptly notified and withdrawn from the mine.  They must not be permitted to return, until the trouble has been removed and the mine examined and found safe for work.

Question—If the velocity of an air current is 75 ft. per min., in an airway 31 x 51 ft., what is the quantity of air passing per minute?  

Answer—The sectional area of this airway is 6.3 x 5.5 = 35.2 sq. ft. The quantity of air passing is then 725 x 55.25 = 40,455 cf. per min.

Question—The air in a mine when the downcast temperature is 60 deg. F., and the upcast 300 deg. F., the barometer being 30 in.  

The depth of both shafts is 300 ft.  

Answer—The weight of 1 cu. ft. of air in the downcast shaft is 1.3273 x 30 = 0.07657 lb.  

Likewise, the weight of 1 cu. ft. of air in the upcast shaft is 1.3273 x 30 = 0.06033 lb.

Therefore, the difference of pressure, for a single shaft of depth in this shaft is 0.07657 - 0.06033 = 0.01624 lb.  

The depth of both shafts being 300 ft., the unit of ventilating pressure, in this case, is 300 x 0.01624 = 4.872 lb. per ft.  

To find the ventilating pressure, or the pressure producing circulation in this mine, it would be necessary to know the sectional area of the airway, which is not given.

Question—What is the pressure per foot of air?  

Answer—The term "absolute pressure" describes the total pressure exerted on the air, which includes the atmospheric pressure (14.7 lb. per sq.in., sea level) and any additional pressure due to the height of the mine.  

Therefore, the unit of ventilating pressure (in feet, lb.) would be either positive or negative, according to the fan is blowing or exhausting air from the mine.

Question—(a) What is meant by ventilating pressure, in mine ventilation?  

(b) What is the unit of ventilating pressure?  

Answer—(a) The ventilating pressure, in mine ventilation, is the total pressure producing the circulation of air, in a mine.  

It is equal to the mine resistance, and is the difference of pressure between the intake and return airways.  

(b) The unit of ventilating pressure is the pressure per square foot of sectional area in the airway or fan drift.  

It is found by dividing the ventilating pressure or mine resistance by the number of square feet in the sectional area of the airway.  

While the ventilating pressure is expressed in pounds, the unit of ventilating pressure is expressed in pounds per square foot.  

The unit of ventilating pressure is sometimes expressed as "ounces per square inch," 1 oz. per sq. in. being equal to 9 lb. per sq. ft.

Question—Explain the difference between ventilating pressure and absolute pressure.  

Answer—Ventilating pressure is the difference between the pressure on the air in the intake airway of a mine and that on the return air, in the same mine.  

It is this difference of pressure that produces the circulation in the mine.

Question—An airway, 16.7 ft. wide and 8.9 ft. high is passing 65,000 cu.ft. of air per minute.  What is the velocity of the air current?  

Answer—The sectional area of this airway is 16.7 x 8.9 = 148.63 sq. ft.  

The velocity of the air current is then 65,000 / 148.63 = 447.3 ft. per min.

Question—If powder smoke requires 2 min. and 17 sec. to travel 149 yd., in an airway 10 x 12 ft., when in position, what quantity of air is passing in the airway?  

Answer—The time, 2 min. 17 sec., is 137 sec. and 149 yd. is 3 x 149 = 447 ft.  

The velocity of the air indicated by this observation is, therefore, 60 (447 / 137) = 195.76 ft. per min.  

The sectional area of the airway is 10 x 12 = 120 sq. ft.  

The quantity of air passing in this airway is, therefore, 120 x 195.76 = 23,491 cu. ft. per min.

Question—With a pressure, at sea level, of 14.7 lb. per sq.in., and the barometer 30 in., how far can you set a pump above the surface of the water, venting and not use rods for pumping?  

Show by example.  

Answer—The theoretical height of water column supported by an air pressure of 14.7 lb. per sq.in. is, 14.7 x 0.434 = 6.4 ft.  

Owing to friction and leakage of valves, it is safe pumping practice to make the vertical height of the pump, above the surface of the water in the sump, not to exceed nine-tenths of the barometric pressure; or, in this case, 0.9 x 30 = 27 ft.
Seven-Hour Day Causes Increase of £30,000,000 a Year in Production Cost of British Coal

A great deal of publicity has been given to the subject of miners' wages in Great Britain. There are other branches of productive activity in Great Britain, however, in which unemployment and short time are so prevalent and earnings so low that a great percentage of employees are compelled to subsist for long periods on the "dole." The latest official figures show that in such great industries as iron and steel, shipbuilding, and engineering, unemployment is much greater and employment itself more broken and paying more than those paid up to the period immediately preceding the war. This is a misconception. The average earnings of miners throughout the country work out at approximately 45 per cent more than the pre-war scale. Piece workers are allowed 14 per cent more than their old rates to enable them to earn as much in a working day of seven hours as they formerly did in one of eight. The miner also is privileged in respect to housing and fuel. At a time when accommodation is still difficult to obtain many miners pay nothing for their dwellings, or receive an allowance in lieu of rent. House coal, which is a fairly substantial item in the miners' domestic economy, is given to them either free of charge or at a price which little more than covers the cost of carriage. These two items have to be taken into account in considering the miner's position in comparison with that of his co-workers in other callings.

Leaders allege that miners' earnings are too low.

The miners' leaders fully recognize that wages absorb the vast bulk of the proceeds from the industry, leaving the owners with a profit much less than the minimum provided for them in the terms of settlement of June, 1921. Nevertheless they persist in the claim that the earnings of the mine workers are below the "subsistence level" and need augmentation.

They now propose that the owners raise prices to the general body of consumers as to provide a sufficient revenue from the sale of coal to afford the miners what they deem a living wage. This can only mean that there be some sort of selling combination by which coal prices shall be maintained at an artificial level. The principle is one diametrically opposed to the present methods and to the traditions of the mining industry, which before the war provided cheap as well as abundant coal. In other words, it is proposed to substitute for healthy competition a system of trufistification entirely alien to the traditions of British commerce.

This expedient is like to find little favor in the eyes of the consumer. It is directed to the same end as the proposal for a government subsidy—viz., the placing of a further burden on the community to extract an unreasonably high wage for the miner at a time when every section of the public is handicapped by high prices and overtaxation.

One of the most serious effects of any arbitrary regulation of selling prices would be the crippling of overseas trade. The coal industry experienced the disastrous effects of foreign competition during and immediately subsequent to the period of coal control. If an artificial price is to be substituted for the open market price in international trade, nothing is more certain than the re-entry of competitors, and much, if not all of the good effected during the past twelve or fifteen months will be undone.

In considering the position of the British miner it is necessary to realize that even in these days of industrial depression he enjoys privileges denied to other workers. Relatively his lot is little worse—in some cases it is distinctly better—than that of workers in certain other trades—railwaymen and municipal workers excluded.

It is a popular assumption that miners are in receipt of wages only 20 per cent above those paid up to the period immediately preceding the war. This is a misconception.

The introduction of the seven-hour day at a time when a return from artificial to economic conditions was foreshadowed was a measure which could not have been recommended had its advocates foreseen results. During this period of bad trade and uneasy markets, co-operation and solidarity have become more necessary than ever before in the annals of the coal trade.

The statutory reduction of working hours has had the effect of increasing the costs of production to an extent which has left its mark on the whole trade. This measure has necessitated the employment of large numbers of extra day-workers, and at the same time it has added to the cost of piece work in wages by 14 per cent. Wallace Thornycroft and other authorities upon coal-mining matters distinctly estimate the greater production cost due to the act at from 2s. to 2s. 6d. per ton. At the present rate of output this saving would produce about £30,000,000 in a twelve-month, of which 83 per cent would be available as a supplement to mine workers' wages under the terms of the existing agreement.

While the relations existing between the mine owners and their workpeople are by no means unsatisfactory, it is obvious that much benefit would be derived by closer co-operation between the two parties. The employers are anxious to restore the industry to economic health and feel that if the men's accredited spokesmen take the long view and join with them in their efforts to this end, the most serious obstacles would be overcome. There are some factors, such as the exchanges and conditions abroad, which are beyond the control of the industry; but others are amenable to control, and if these are approached in the spirit of conciliation much can be done to make the position of the trade more tolerable.

The deliberations of the National Coal Board will have proved valuable if they merely serve to elucidate the truth that better times for the miner and the industry generally are not to be obtained by schemes which are economically unsound and socially undesirable.

U. M. W. International Board Takes Steps to Restore Kansas to Good Standing

Steps to restore the autonomy of the Kansas district, No. 14, United Mine Workers, whose charter was revoked more than a year ago after district officers and a number of members of the district had been expelled from the union, have been taken by the International board of the Mine Workers, which is in control in Indiana. The charter of the Kansas district members has been called for Pittsburg, Kan., Oct. 25.

A constitution for the district will be drawn up at the convention and arrangements made for an election of district officers to take the place of the others. The question of reinstatement of membership in the union is to be considered separately. The charter of the Kansas district was revoked and Howat expelled after he had called strikes in violation of contracts.

Federal Coal Commission Names Hammond Chairman
And Proceeds to Map Out Program

BY PAUL WOOTON
Washington Correspondent of Coal Age

The first act of the United States Coal Commission at its initial meeting, Oct. 18, was to designate John Hays Hammond as its chairman. The commission immediately plunged into a discussion of a program for its work. No formal announcement has been made as to how the work will proceed, but certain of its policies already are apparent. It is the intention of the commission to keep the public informed as to each step of its progress. It recognizes that in this way the public will be able to absorb more knowledge as to the problems of the coal industry. The commission recognizes that the only chance that it has to accomplish anything is to obtain public support for its recommendations. It is believed that if the public mind goes through the same processes that the minds of the commissioners will go through, they will be prepared to pass intelligent judgment on questions. Frequently when conclusions constitute the first knowledge that the public has, much time must elapse before their real purport is understood. Thinking takes time. Recognizing that fact, the commission hopes to be able to carry the public along with it as the study progresses.

LEWIS INVITED TO INFORMAL CONFERENCE

The problem is so intricate that the commission expects to call to its aid each subdivision of the coal industry. One of its first acts was to invite to informal conference John L. Lewis, president of the United Mine Workers of America; Alfred M. Ogles, president of the National Coal Association; and S. D. Warriner, a leading anthracite operator, and to ask each to appoint a consulting committee, which is to maintain close contact with the commission and assist it by presenting such facts as may be called for from time to time.

Since E. E. Hunt is secretary of the commission, it is reasonable to suppose that he will resort to much the same form of organization that functioned so successfully during the President's unemployment conference—the plan also used at the conference on limitation of armament. At those conferences advisory committees composed of representatives of the varied interests concerned were used with great success. For instance, an advisory committee on storage would be composed of representatives of coal operators and of large consumers—those most likely to benefit or be interested in storage. This plan, if acceptable to the present commission, would be carried out in such a way that an advisory committee would be formed for each of the important problems within the industry. In this way the committee would be saved a large amount of work and would be furnished with much predigested material.

Since the commission must make its preliminary report on Jan. 15, advantage must be taken of all means to expedite the study. It is probable that the commission will call upon those most concerned to lend it some of their specialists. Only in this way can the commission procure the requisite skill necessary to its work.

Now that the commission is in action an opportunity has been given to judge as to its capability and as to the ability of the individual members to work together. The first sessions indicated that President Harding's mixture of two engineers, two lawyers, two economists, and a newspaper man is less discordant than some critics might expect. Apparently they will work well together. Judge Acheson gave early evidence that he is experienced not only in weighing evidence but, as shown too in his packing-house experience, is skilled in obtaining evidence for himself.

Mr. Marshall is so well known for his quaint philosophy and his Hoosier directness that sight frequently is lost of the very practical way in which he reasons on problems which come before him. It already is apparent that any policy to win his support must be 100 per cent American. One of his acid tests is whether or not a man puts his American citizenship first.

Dr. Smith brings to the commission not only his own large store of knowledge acquired from having kept abreast with the coal situation day by day for a long period of years but his knowledge of the federal machinery and his acquaintance with the government personnel in Washington has made it possible quickly to co-ordinate the commission's work with the coal activities of the various federal departments. This is in direct contrast with the experience of numerous new boards and commissions, where there has been an exasperating loss of time before actual work could start.

Mr. Howell has a wide acquaintance with men and has an accurate knowledge as to the part coal plays in the industrial South. He has demonstrated a keen appreciation of the public's equity in coal.

No one could approach a task better prepared to serve efficiently than Mr. Neill. It has been just twenty years since he began his work with the Roosevelt Anthracite Commission. His connection with the anthracite industry has been almost continuous since. He also brings to the commission a knowledge of transportation, but above all he has a sympathetic understanding of each side of labor disputes.

Mr. Hammond, in addition to his understanding of the engineering phases of the inquiry, has a genius for organization which he is applying actively to the plan for the commission's staff.

An analysis of editorial comment in more than one hundred newspapers reveals that the New York Call, a socialist organ, is the only one commenting unfavorably on the personnel selected for the commission.

E. E. Hunt, Coal Commission's Secretary, Has Had Broad Economic Experience

E. E. Hunt, of Springfield, Ohio, has been selected as secretary of the President's coal commission. Mr. Hunt has been in charge of the study of intermittency in the coal industry which the Department of Commerce has been pursuing since last March. For the purposes of that study a sizable contribution was received from the Cabot fund. The study was an outcome of the unemployment conference, of which Mr. Hunt was secretary. Mr. Hunt had been associated with Mr. Hoover throughout the preparation of the report on waste in industry.

Mr. Hunt was graduated from Harvard in 1910. From 1910 to 1914 he did editorial magazine work. With the outbreak of the war in Europe he was sent to Antwerp by the Committee for Relief in Belgium. He was in charge of the entire Antwerp district, in which he superintended the work connected with feeding and providing fuel.
During the recent years the coal industry has been the charge of the Commission and has become a larger task. For this reason an increase of personnel has been necessary, and this has been attended by some difficulties. The Bureau has been under the direction of the Secretary of the Interior, who has been assisted by a staff of experts, including engineers and scientists, and has worked in close cooperation with the Bureau of Mines.

The United States Coal Commission has started to use all the available resources of the Government in its fact-finding work. How large in this supply of authoritative information is in part indicated by the reports prepared by the Bureau of Mines and the Bureau of Standards, the latter being under the direction of Secretary T. R. F. Cook, U. S. Comptroller, and the former being under the direction of Secretary T. R. F. Cook, U. S. Secretary of Commerce and Labor.

The Bureau of Mines has been working on the mining industry for its 12 years, and its chief, W. S. L. Rankin, has prepared a report on the coal industry in the United States. The report covers the history of the industry, including its development, its present condition, and its future prospects. The report is a valuable source of information for students of the coal industry.

The Bureau of Standards has been working on the coal industry for its 12 years, and its chief, W. S. L. Rankin, has prepared a report on the coal industry in the United States. The report covers the history of the industry, including its development, its present condition, and its future prospects. The report is a valuable source of information for students of the coal industry.

Seven Injured by Slate Fall in Mine at Brownsville, Pa.; Three May Die

Seven men were injured, three probably fatally, in a fall of slate Oct. 10 in the Maxwell mine of the H. C. Friek Coal Co., near Brownsville, Pa. Pinned under the debris of the first fall, the seven men were helpless when a heavier second fall of slate enveloped them.

Fifteen others, injured slightly, were rescued by Rankin, mine foreman; Steve Ritsky, assistant mine foreman, and Edward Queen, all of whom may die as a result of their injuries. Others injured are Peter M'Kenna, Fred Reynolds and two unidentified foreigners.

In a short time the men were dug from beneath the slate and carried to the surface.
A Public Policy for the Coal Industry

BY JAMES A. EMERY†

What does the outsider see in the coal industry today—not the prejudiced, nor the impassioned, nor the embittered, nor the merely selfish observer of your industry, but the citizen who has a sincere interest in the relationship of your great industry to the social and political problems that it is creating? During six months of deliberately suspended production he has perceived upon the one hand a solid, unified organization of workers, so powerful that it has been able to successfully resist not only economic argument but official persuasion and threat. And upon the other hand, he has perceived a great industry of highly intelligent and responsible operators disintegrated and disunited, with no single responsible group or spokesman who could speak the collective thought and the collective judgment and state the collective policy of a great American industry!

Does that not suggest that there never was a more favorable, a more desirable, a more necessary moment in which this great industry should enter upon a highly systematic, organized self-examination, self-analysis and self-declaration of policy for self-government?

All the forms of government that we have had any experience with in this world must live under restraint and authority, and they either take that authority from without or impose it from within; and the difference between popular and autocratic institutions is that the one finds its rule imposed upon the outside and the other imposes its rule upon itself by voluntary self-restraint established from within. Doesn't the coal industry need today a scientific, self-examination of its own facts?

It is essentially in the public interest that the control of private property shall be preserved within the limits of public interest; and these change with the intensity and complexity of public life, because government is no longer a mere maintainer of order. It must, under the circumstances of modern life, undertake to carry out production and distribution against arbitrary interruption, and these high obligations have fallen upon it with an intensifying degree of necessity.

APPOINTMENT OF COMMISSION DUE TO PUBLIC OPINION

The public view of this thing, as I see it today, has been very fairly expressed in the appointment of a special fact-finding committee. Any anxiety is whether it will discover the facts or whether it will merely paint a picture of its theories. But no industry is so well fortified to meet the facts of life today as the one that knows itself, and by a critical examination is prepared to present, as occasion arises, an accurate picture of its own operation. And that is what American industries have been doing.

I would venture to urge upon the coal industry (to urge not only in its own interest but in the interest of the public as well, that ultimately will be the terrible sufferer if a public policy is established for the coal industry that does not correspond with the facts) the establishment of a public policy based upon facts. There is nothing that the American people have paid so terrible a price for, or have suffered for so much in the past ten years of their life, as the substitution of political answers for economic answers to economic questions, and no policy will succeed with the coal industry that is not predicated upon its facts.

First of all the coal industry cannot do better at this time, cannot fortify itself more successfully, than to undertake to organize for its own self-examination in the determination of facts with respect to itself. Until it knows itself, it cannot relate itself to others. And, secondly, it is for the industry to establish its public relations and its economic position by that knowledge of itself, and no policy will succeed with the coal industry that is not predicated upon its facts. It is an easy matter to "cuss" Congress; we all do it, and then we rest ourselves by "cussing" the state legislatures or the local Board of Aldermen. But representative government is a mirror in which we reflect ourselves, because it not only pictures our virtues but it very accurately defines our defects—and the besetting sin of American business has been indifference to politics. God help the man who says that business ought to keep out of politics. Business ought to get into politics, because if this nation is going to endure it isn't going to have its policies determined by a mob, but it is going to continue to be what its founders believed it would be: an aristocracy of intelligence and character, directing a democracy of right and extreme opportunity.

Who can organize and give direction to a public policy for the coal industry better than the men who know it? They will be listened to exactly in proportion to the breadth of enlightened selfishness with which they commend themselves to public attention. Remember, that if you don't sit in the saddle to correct evil and guide the horse of reform, there are many willing riders who think they can ride the beast better than you can.

The country has suffered from the social advice of gentlemen who could not fill pulpits to the satisfaction of a congregation. It has been advised on employment relations by men who never hired a domestic servant except in their wife's name. It has had great public policies established for it by gentlemen who had no responsibility for their utterance except that they were gentlemen, and that the advice was from a gentleman. A people like ours, gentlemen, will live when we meet our public responsibility and take upon ourselves the responsibility to honestly perceive and undertake to accurately define, first, our obligations, and then I say with equal sincerity, and determination to assert and enforce our rights.

ADVISER FACING EMPLOYMENT RELATIONS

I believe that with the coal industry demonstrating its sincere interest in the public welfare, it is in a position to present to the public, and its representatives, through self-organization and self-examination, an accurate picture of what it is and what its relationship to the public ought to be. But, gentlemen, I don't believe that we will ever accomplish for the coal industry what we hope to see accomplished—to preserve it from not only incompetent and unwise but invalid regulation—unless the industry is ready in an organized way to frankly face the problem of its own employment relations. I say that it faces invalid regulation. Why, I think that the field of coal regulation today is the last great battlefield of social self-government, as opposed to the remaining federal control. The people of the United States have had ample warning of the situation that was bound to develop in the coal industry. Year after year the danger signs were lifted in the public sight, and year after year an indifferent and apathetic people refused to heed them. And now we come to emergencies, and emergencies always excite governmen't intervention. The popular pressure and exercise of unusual power. The neglect to establish social controls in the public interest, that would insure the protection of public rights, protected in the person of private agents performing a semi-public service, has led us to the situation in which we are today, but not without considerable assistance from within the industry itself.

Now we can read the history of employment relations in the coal industry, as spread upon the records of the courts of the United States, without perceiving that gentlemen found the miners' union at times a convenient means of equalizing what it termed competition. You will recall that Aesop wrote a fable about the fox who lost his tail, and having lost it he spent a good deal of time in recovering other foals that a tail was a real property in. And these other foals and their operations, under union control and domination, have not only undertaken to persuade others that they needed it and didn't need the freedom that they enjoyed, but encouraged the union, without realizing what it was they were encouraging.

Today the field of employment relations in the coal industry represents a condition that threatens the economic
Retail Margin of Profit on Coal Fixed in Ohio Averages $1.36 Per Ton

Retail margins of profit on each ton of coal sold in Ohio, whether Ohio-mined or imported, have been fixed by Fuel Administrator Neal and approved by Governor Harry L. Davis. The average profit permitted retailers under the schedules is $1.36 and there are approximately 106 different margins fixed. This completes the first entire regulation by the state from the mine to the consumer under the emergency legislation recently enacted. Price margins are effective as of Oct. 20, giving five days for publication of notice to various dealers. The margin applies to the price at the mine plus the freight rate to the dealer's yard. The lowest retail allowance is 65c., in Gallia County, while the highest is $2.75, permitted in Cleveland. Under the new order where the customer makes his own delivery he is to have a reduction of 75c. per ton from the margins allowed.

Prices Ohio consumers must pay for West Virginia smokeless range from $9.99 to $11.34 a ton, in accordance with the official price list given out by State Fuel Administrator Neal. The prices are based on the federal maximum fair price of $6 a ton for West Virginia coal at the mines. Variance in transportation charges to Ohio points is responsible for the range in price, and to be $10.09 to $10.29 a ton. In other cities they are: Cleveland, $10.74@$11.34; Sandusky, $10.64@$10.84; Toledo, $10.54@$10.74; Canton, $10.07@$10.84; Youngstown, $9.99@$10.94; Akron, $10.07@$10.84; Dayton, $10.39@$10.49; Marion, $10.04@$10.24.

Michigan Governor Seeks Aid of Congress To Fix Reasonable Prices at Mines

Legislation designed to regulate distribution and cost of coal and coke in Michigan having been approved by the Legislature and signed by Governor A. J. Groesbeck, the latter has arrived at the conclusion that the most direct way of holding down prices is to be found in establishing reasonable prices at the mines. He is urging the governors of various other states to join him in appealing to Congress for action to that end.

The Governor also is conferring with Conrad E. Spens, Federal Fuel Administrator, in the effort to obtain more reasonable prices on anthracite than are quoted by some of the independent operators, seeking business in Detroit with quotations of $12@$14 at the mine.

Retail coal prices in Wayne County are required to report on the quantity of coal they sold last year, the amount they have sold so far this year and how long they have been in business. This information is expected to supply a basis for computing the fuel requirements of the state and for determining the eligibility of the dealer to be classed as a legitimate coal merchant.

The new Michigan legislation similar to the legislation enacted in New York State, though the Michigan law is said to be less drastic in some of its provisions.

Coal Consumption by Utilities in August Highest of Any Month Since February

Electric public-utility plants consumed 2,814,141 net tons of coal during August, according to a recent report of the Geological Survey. This is the largest tonnage for any month since February and compares with 2,565,607 tons in July. Production of electricity in 1922 has been accomplished through steadily increasing use of fuel power, while water-power production has declined gradually from the high mark of the year attained in May.

Evidently the scarcity of coal has increased the use of oil and gas, as August saw a record-breaking output of electricity, averaging 131,100,000 kw-hr. per day, exceeding the June record by 2½ per cent and July by 5 per cent. The heavier production no doubt was due to the increase in the domestic and commercial lighting load brought about by the activity in the building industry and by the demand by industries who were forced by lack of coal to turn to public-utility plants for power.
German Coal Situation Proves Not as Bad as Pictured

BY H. O. HERZOG
Berlin, Germany

The annual report of the German National Coal Association, dealing with the production, evolution of prices, consumption and supply between April 1, 1921, and March 31, 1922, has just been issued. Of special interest is the balance of loss drawn after the final division of Upper Silesia. Of 75 mines which produced 43,800,000 tons in 1912 and approximately 30,000,000 tons in 1921, representing 75 per cent of the total production, 59 have gone to Poland. Measured by the production of 1913, the loss to the national wealth thus incurred is 400,000,000 gold marks per year. The actual loss of coal to the supply of the interior of Germany is, however, not so large as has been commonly stated in public. The fact that the province itself consumed the third part of the output, while another third part was exported under Entente control to surrounding countries, having more or less been kept from public attention. Actual shipments to the interior of Germany have averaged 12,000,000 tons during the last two years. The output of the mines remaining to Germany may for this year be assumed at 8,000,000 tons. Deducting therefrom the non-greatly reduced local requirements, which probably will be 2,000,000 tons, 6,000,000 tons will remain for the supply of the German interior. The net loss to the latter, therefore, is only 6,000,000 tons per year.

The National Coal Association is an institution called into existence by the law of March 30, 1919, regulating the control of coal; it forms part of the organization provided for that purpose, the other members being the Coal Commissary and the National Coal Council. The first named is the executive and the latter an advisory body, best described as a coal parliament. In this organization the Coal Association represents the producers; it is formed as a joint stock company with a nominal capital of 250,000 marks, in which the coal syndicates of the various districts and the States of Prussia and Saxony in their capacity as mine owners are shareholders. It does not transact business in the proper sense, having nothing to do with sales or distribution. Its object is the adjustment of coal prices in conjunction with the other members of the organization of control, and eventually to assume the function of the coal commissary.

SUMMARIZES COUNTRY'S COAL SITUATION

Although a few representatives of the labor class are sitting on its board of directors and also are represented in the board of managers, the Coal Association is more or less a combine of the producers' interests, wherein lies its chief importance as a public institution. This is reflected in the annual report of the association, which goes far beyond this official object and is a summary on the whole coal situation.

The picture presented by a review of the production at the present rate and that of the past years is not all hopeful. In no mining district has the pre-war average been attained, or the average of the short-handed war time been reached. The best result so far reported is that of Lower Silesia, where the output in 1921 was 81.5 per cent of that of 1913. The next best was Saxony, with 80.6 per cent, and the Ruhr district, with 81.2 per cent. The worst case is that of the Aix la Chapelle fields, with only 64.2 per cent. Upper Silesia, with 67.7 per cent, was only a trifle better. Considering that the output of 1913, upon which these figures are based, is the highest on record, these figures do not make a bad showing.

In nearly all cases, with the exception of the Aix la Chapelle district, a considerable recovery has taken place since 1919; in the Ruhr district, for instance, it was from 61.9 per cent to 81.8 per cent of the 1913 output. When, however, the means whereby this recovery has been achieved is taken into account, these figures have a sinister significance.

Over 1,000,000 men were employed in 1921 in German coal mining, including brown-coal mining, as against 660,000 in 1913. The increase of employees in bituminous-coal mining from 1913 to 1921 was no less than 263,000, or nearly 50 per cent. The output of the inside workers per hour in 1920 dropped to 116 kg. as against 136 kg. in 1913. During 1921 the average was even a trifle lower, showing a slight recovery during the first three months of this year. According to consecutive reports this recovery was only temporary. The efficiency of labor in the Ruhr district is at present about 85 per cent of pre-war standard and in Upper Silesia it is only 77 per cent. When it is considered that 400,000 men employed in coal mining produce now only 80 per cent of what 580,000 men produced in 1913, the standard of efficiency appears to be still lower or approximately only 55 per cent. Almost identical conditions prevail in brown-coal mining.

The quantity of coal at disposal for the supply of the country within the present frontiers, after deducting the Entente tribute and the compulsory export from Upper Silesia and ignoring small quantities of free export, averaged in 1921 75 per cent of that of 1913. The increased production of brown coal, amounting to 36,000,000 tons, is one of the few favorable aspects of the situation. The efficiency of brown coal has been estimated at 2/9 of that of bituminous coal, which is entirely too low, considering the progress made with brown-coal combustion. The report leaves out of discussion how the financial situation of the mines has been affected by the prevailing price policy. In touching upon the evolution of coal prices in comparison with those of other minerals, large increases in both parts of cost and production the report leaves it to the reader to draw his own deductions.

COST AT MINES MOVES SKYWARD

The increase of the net cost price at the mines exclusive of taxes and other levies is 49.76 times that of 1913. The cost of labor for one ton of coal during the same time has increased 51.83 times. It is interesting to learn that in pre-war times the ratio between wages per shift and cost of labor per ton was 5.50 to 6.20 marks, while in April, 1922, the ratio was 177 to 322 marks. The relation has, therefore, charged from 1:1.2 to 1:1.82. Other details of production cost have increased above pre-war prices in a still larger proportion, as, for instance: Rails, 84 times; iron ties, 77 times; oil, 100 times; and 77 times; structural steelwork, 100 times; boilers and piping, 110 times; electro-technical equipment, 65 times.

This demonstrates that the level of coal prices is maintained to a certain degree at the expense of the prosperity of the mines, leaving them hardly any margin for renewal and extension. As a consequence the equipment is largely run down, especially in the case of cooking plants.

While the National Coal Association is loyal enough in public to attribute these unfavorable circumstances to the general unfortunate situation, in private conversation bitter complaints are heard of the short-sighted price policy which prevented the accumulation of sufficient funds for renewal and extension while they were still possible. The time for economy was presumably over. The only way out of the existing difficulties is the reduction of the number of large districts. For instance, the entire production of the miners to overtime has lately ceased, but the concession made lately for three extra shifts of two hours each per week is, unless considered only as a start, entirely insufficient.

To sum up the situation, in 1915 Germany had a surplus of coal, and in 1921 only 6,000,000 tons; in 1913 76,500,000 tons of coal was left for the country's consumption as against 119,000,000 tons in 1914. The total deficit in the supply compared with the latter year, taking into account both bituminous and brown coal, was on 1921 38,500,000 tons, which, when added to the export surplus, shows a total loss of 73,000,000 tons. The deficit in supply has to be made up by imports as long as it is not reversed by increased production. The next few months will show what
Some interesting results of the working of the national wage agreement which has been in force in Great Britain since the first week in April have recently been given out by the Mining Association, which body represents the operators on the United Kingdom.

The first quarter, Co., immediately preceding the great stoppage, resulted in a loss to the owners of £14,984,936. This was the position when the strike began. The cost to the man of the stoppage is estimated at a minimum of £1.15,624. The following table gives the results of colliery operations during the first year (to June, 1922) of the national agreement:

If the last trading profits are not offset against the loss during the strike it is seen that the net loss was £1,328,962. In the corresponding period of 1913 the profits were £28,000,000.

From last November to June this year the owners have paid out £22,000,123 to make the wages up to 20 per cent above the standard.

During the year under review the tonnage and profit or loss were:

Engineers to Become Coal Operators.

The Brotherhood of Locomotive Engineers is to enter into the work of the coal operators, according to a statement of Albert F. Cary, editor of the Brotherhood of Locomotive Engineers' Journal. The locomotive engineers are ready with investment in West Virginia and Kentucky for coal for the miners but have not invested capital for the mining of coal. The leading officers of the brotherhood have obtained the United States patents on coal River, in Boone County, Big Spring coal district, near Pittsburgh, Ky.

The Coal River Collieries, as the new company is called, is owned by hundreds of locomotive engineers throughout the country, who have subscribed in small amounts to the capital stock of $5,000,000.

The engineers are not only going into the business of mining coal; they are also planning the establishment of retail yards to sell their coal at reasonable prices to railroads and other workers in the large cities. Locomotive engineers and their friends have already organized these auxiliary coal yards in Ohio and Michigan, and have placed contracts with their coal companies for delivery direct from the mine pits to consumers. It is estimated that the mines will have a capacity exceeding 6,000 tons a day.

Smokeless Output in August Exceeded That Of a Year Ago, Despite Car Shortage.

Notwithstanding the handicap of a car shortage, 2,847,728 net tons of coal was produced in the four smokeless districts of West Virginia in August, according to figures just compiled. Output during the first eight months of 1922 exceeded by six and a quarter million tons that of the corresponding period of 1921. If production can be continued at the same rate during the remainder of the year, there is every prospect that 1922 will eclipse the banner production year of 1916, when 36,000,000 tons was produced. The following is a showing of smokeless production for August and for the eight months of the year:

| District          | 1922 Tons | 1921 Tons |增(-)%

Forty-Eight More Men Indicted for Murder in Connection with Herrin Massacre.

The special grand jury at Marion, Ill., finished its work on the Herrin massacre case Monday, Oct. 23, by indicting forty-eight more men for the murder of Ignace Kubenis, a victim who died of wounds since the jury recessed last month. Circuit Judge Hartwell says the indictments are illegal because returned at a term of court subsequent to the one at which the jury was impaneled. State's Attorney Delos Duty disagrees with him.

Only a few witnesses were heard on Monday, and they are said to have told of wounds inflicted on Kubanis, and which are said to have resulted in his death. This makes 494 persons the grand jury has indicted in connection with the rioting in which twenty-three men were killed.

Most MEN's IDEA of a living wage is about two dollars more than they get.—Portland Oregonian.
Colder weather has strengthened the domestic market. Industrial buyers, however, are as yet unchanged in their attitude of aloofness. Cars are so short and the steam market so weak that the net result is a continuation of the price decline which has been in effect for the last 60 days. Coal Age Index of spot bituminous coal prices receded to 352 on Oct. 23, a drop of 16 points from the preceding week; the average price corresponding to this index number is $4.26—the week before it was $4.45.

Car shortage is prevalent everywhere and poor transportation conditions make deliveries slow and uncertain, but circumstances indicate that there would be a heavy surplus of coal if the carriers were able to give better service. As it is, production is becoming more evenly balanced with current demand, and even the slight upturn in general industrial buying which has been brought about in the last ten days discloses the narrow margin between supply and demand.

**EVEN RAILROADS HAVE DELAYED STOCKING**

The stocking program has not yet started. Even the railroads are not building up any appreciable reserves. The feeling seems to prevail that with the end of the Lake season and more seasonable domestic weather there will be plenty of tonnage then available to care for current needs and to build stocks. Day-to-day requirements constitute the main market activity and prices show a wide range. Some coal, caught on a poor market, sells off, while on the other hand a consumer in need of coal pays the higher quotation without a murmur. There is no complaint heard about the ruling prices, nor is the consumer evincing any apprehension about the state of the market when colder weather may be expected to interfere with the movement from the mines.

New England is deaf to the offerings being made to that market. Large consumers in that territory have sufficient coal on hand to await developments in November and December. The smaller buyer is taking some additional tonnage that he has been considering since last July, but the amount is not sufficient to check the declining current quotations, whether all rail or coastwise. British coal is still a factor along the Atlantic seaboard, but receipts are falling off daily.

The Cincinnati gateway is feeling the competition of coals from outside territory and prices have softened all along the line. Eastern inland markets, however, feel the heavy drain on production made by the Lakes and railroads, and this section presents the firmest market of today. Chicago and Midwestern points are saturated with steam coals, produced in an effort to meet the onrush of domestic orders.

Anthracite domestic sizes are, of course, in heavy demand and the cold weather has brought urgent orders to the retailer. Movement still centers on the East, although Lake business is increasing. Western and more distant points are receiving meager shipments, much of it at high independent figures.

Steam sizes are burdensome. Sales are slow and companies are running these coals to storage, while various railroad embargoes have been placed against their movement, as the congestion of these loads threatens to affect production of the much-needed family sizes.

*Gross tons, f.o.b. vessel, Hampton Roads.

Advances over previous week shown in heavy type, declines in italics.

Coalingage Vol. 22, No. 17

"Complete returns on coal production in the third week of October show an increase of almost 1,000,000 tons of product, says the Geological Survey. The number of cars handled on Monday, Oct. 24, was reported by the railroads at 81,836, marking a new record for this year. On Tuesday holdings declined to 81,029 cars, and on Wednesday to 80,590. These were the highest daily figures of the year and third working days of a week about the close of the month. On Thursday there was a further decline to 80,374 cars. Shipments of Lake coal were 100,130 net tons during the week ending Oct. 28, as compared with 1,090,369 tons in the preceding week. This movement has been steady during the third week being 10,481,130 tons, compared with 10,481,130 for the week ending Oct. 19. The figures for the season to date stands at 10,481,130 tons, during the corresponding period of 1920 it was 10,481,130 tons. The recent heavy receipts of soft-coal cargoes has reassured the Northwest, and while domestic business is strong the supply-demand has fallen off. When navigation closes, the other sources of supply will be drawn on to help out the shortage of the docks. North Dakota lignite and Montana coal on increased production can keep the Dakotas going; southern Minnesota and southern Wisconsin can use Illinois coal, and northern parts of Minnesota and Wisconsin only need be dependent on dock supplies. The utilization of the Western coals may have a lasting competitive effect on the future dock trade.

New England all-rail receipts of soft coal were 3,636 cars during the second week of October, as compared with 3,272 cars in the preceding week. A low price of $3 was offered last week to railroads in this territory, but no takers are recorded. British cargoes and coastwise fuels leave little space in the market.

room for all-rail coal in this apathetic market, and when the present high freight rate from the mines is considered it is realized that Hampton Roads is in excellent competitive position for what little business is offering.

Hampton Roads dumpings have held around 260,000 net tons for the last three weeks. During last week 260,358 tons were dumped as compared with 262,957 tons in the preceding week. Coastwise trade has dwindled of late but coal on hand at the piers is not gaining, as car shortage and transportation troubles have affected receipts. The stage appears set for a considerable resumption of coastwise shipments, both on spot and contract, as soon as the congestion of boats is cleared up at New England ports.

ANTHRACITE

Production of anthracite has passed the 2,000,000-ton mark. The output during the week ended Oct. 14 was 2,075,000 net tons, and early reports for last week indicate that production in that period will again be in the neighborhood of 2,000,000 tons.

All-rail shipments to New England were 3,226 cars during the second week of October, as compared with 2,759 cars in the previous week. The East has fared the best since mining was resumed, and the domestic situation, while still troublesome, shows marked improvement. Western points are taking a little coal, much of it at high independent

Coal Age Index 355, Week of Oct. 23, 1922

COKE

Beckley coke production continues its slow but steady upward trend. The output for the week ended Oct. 14 was 183,000 net tons, as compared with 173,000 tons in the preceding week. The present rate is nearly double that of a year ago, when the business depression was acute.

Connellsville prices continue to break and only an occasional purchaser is coming into the market. Softening bituminous coal prices cause coke buyers to feel that they are due for lower quotations. Pig iron is an uptrend that furnaces are conservative in making arrangements for reopening.

COKE
Continental Buyers Appear
As American Orders Abate

In recent weeks a temporary setback in the demand from American buyers has been noted, as a result of which the entire British coal trade is more unsettled, though some brightening is evident during the past two weeks owing to a revival of the shipping in American waters, as a result of which the entire British coal trade has improved. The drop in prices following the filling of American contracts has had the effect of attracting Continental buyers, especially Germany, France, and Italy.

The Scottish market is marked by a general upward trend of prices, and round sorts have advanced by as much as 2s. 6d. to 6. 1 tide. per ton. The chief customer is Italy, though some cargoes are still being booked to the U. S. and Canada.

The miners have threatened to strike on Nov. 5 in Wales with the object of forcing the non-unionists into the ranks of the Miners' Federation. Extensive propaganda work is to be undertaken by the Miners' Federation with the object of bringing the non-unionists into line.

Business Slumps at Hampton Roads

Business is generally poor throughout the coastwise trade, with bolder business scarcely holding its own, in the face of continued decline in prices. Export business is practically non-existent.

While the supply of coal on hand is large, it is distributed through the trade in such small amounts that few dealers have any considerable cargoes on hand. The general tone of the market is off, and little prospect of immediate revival is in sight. Dealers are hopeful, however, of better business later in the season, when shipments by rail to the West begin to lessen.

World Production of Coal in First Half of 1922

In spite of the great strike in the United States the world's production of coal in the first half of 1922 was greater than in the corresponding period of 1921. The total output in the six months, January to June, 1922, according to reports collected by the United States Geological Survey, was approximately 858,500,000 metric tons. Continued for twelve months this rate of output would yield a total of 1,157,000,000 tons. Settlement of the strike in this country insures that world output in the second half of the year will be greater than the first, but unless so, it seems unlikely that the total for 1922 will exceed 1,800,000,000 tons. This is an increase over 1921, but a decrease of nearly 140,000,000 tons from 1920.

*Estimate included in total. b includes scrap and blast furnace. c includes 1,775,000 metric tons estimated produced during June in Polish Upper Silesia.

German Miners Get Wage Increase

The award conceding an increase of 150 m. per man per shift to the Ruhr miners for October has been made binding by the government, despite the opposition met to accept it.

The Ministry has also decided that the wages of miners under the Rhenish Brown Coal Syndicate shall be increased to the same extent as those of the Ruhr miners, and that the increases for the other brown coal districts shall be in the following proportions of that amount: Duren district, 91 per cent; Mid-Rhenish Brown Coal Syndicate, 92 per cent in the central district, and 90 per cent in the marginal districts; Bavaria, 94 per cent for the large pits and 90 per cent for the small concerns.

It is stated that to the end of September the Westphalian pits had not derived any advantage from the introduction of overtime at the beginning of that month, but only additional financial burdens, as only 52 per cent of the underground men have worked the additional hours. The average daily production is estimated to have increased by only 7,000 tons, or from 305,000 to 315,000 tons, whereas a daily advance of at least 30,000 tons was expected from the overtime system.

Production throughout Germany in August was 10,200,000 metric tons, as compared with 11,700,000 tons in the same month in 1921, which included 1,550,000 tons in East and in Polish Upper Silesia. For the eight months ended with August the output amounted to 89,280,000 tons, as compared with
88,990,000 tons, including 13,890,000 tons in East Upper Silesia. Production of lignite in the eight months was 81,482,000 ton (80,550,000 tons in the corresponding period in 1921); coke 19,500,000 tons (18,500,000 tons in 1921), and lignite briquettes, 19,510,000 tons (18,760,000 tons).

Production in the Ruhr region, including the iron and steel deep wells of the Rhine, during the 26 working days of September is estimated at 8,260,000 tons as compared with 8,300,000 tons during the 27 working days of August and 7,900,000 during September, 1921. Production of coal in the Ruhr region during the week ended Sept. 30 was 1,888,000 metric tons and in the week ending Oct. 7 it was 1,855,000 tons, according to a cable to Coal Age.

Strike of French Miners Is Averted

There continues to be a very active demand in the Nord and Pas-de-Calais fields, both for industrial and domestic coal. The demand for the latter exceeds the supply. In the Loire field there is also a strong inquiry for house coals, but industrials are rather quiet. Lorraine and the Sarre are now in a favorable position.

The strike fears have been dispelled by a letter written on Oct. 7 by the owners to the Nord and Pas-de-Calais to the Minister of Public Works, in which the owners withdrew their previous decision to reduce the wages as from Oct. 15, if in the meantime they had not obtained sufficient relief on their coal prices. The owners state that they will continue to assume the sacrifices in favor of their men, hoping that Parliament will soon amend the Act of June 24, 1919, on working time in mines, as to permit the French collieries to adequately meet the competition of foreign coals.

**Coal Paragraphs from Foreign Lands**

**ITALY—The price of Cardiff steam first is quoted at 39s. 6d., according to a cable to Coal Age.**

**BELGIUM—The coal market orders for all domestic description are numerous.**

**AUSTRIA—Widespread cessation of work in the New South Wales collieries has already commenced, but the shipping community is not disturbed.**

**INDIA—The Bombay bunker coal market is dull.**

**BRITISH OWNERS BEAR HEAVY LOSES**

The manner in which the Wage Agreement in the coal industry operates is seen in the certificate of the joint accountants setting forth the financial results of the South Wales collieries for last July, upon which wage rates for September were determined.

It is shown that the costs of production, i.e., the miners' minimum wage, wages, and unemployment payments per ton of coal, were only 3.0s. 6d. in September, and the cost of production including the losses from the miners' disruption, was only 4.6s. 6d. per ton, whereas in April, before the miners' disruption, it was 7s. 6d.

**THE DECREASE IN COKE SHIPMENTS, WHICH CAUSED SUCH MUCH INDIRECTLY TO THE UNJUSTIFIED REDUCTION OF RUHR COKE DELIVERIES BETWEEN AUG. 19 AND 29.**

According to French Custom's returns, France received from Great Britain in August 854,089 tons of coal, as against 215,872 in July and an average monthly quantity of 663,183 tons during the first seven months of 1922.
Large Consumers Active: Others Buy Hand to Mouth

Despite Low Stacks and Car Scarcity, Bargain-Hunting Tactless Are Common—All But Best Coals Sell Off Under Pressure—British and Southern Fuels in Less Demand.

Haying activity is still confined to the railroads and large consumers. Others are still on a hand-to-mouth policy and many have no stacks worth mentioning. Cars are short, but these consumers refuse to worry about the situation and are employing bargain-hunting tactics to procure their current needs. Only the best coals are readily salable—the others are selling off under the pressure.

Late receipts of British coals are still offered at low figures, but with heavier home production these sellers are having a hard time to dispose of their free cargoes. Southern coals also are less in demand. Rail deliveries are slow but enough coal is moving to more than fill all current demands.

BALTIMORE

While the car supply is at present running as low as 18 and 25 per cent, and weekly approaches rapidly, the coal trade here is faced by the rather unusual condition of declining demand, and at times a condition of car supply such as has existed for the past two or three weeks would have dumped the price to $4.50. As it is, there has been a return to $4.75.

The past of the trouble probably lies in the fact that, while these prices were hardening near as high as they have been several weeks, they have not been high enough to make producers hesitate in stocking against fall and winter roads. Thus the shippers have held off the buyers until they have seen a little indication of a more decided movement and the railroads have apparently failed to satisfy them.

This movement on the railroad side is shown by the fact that fuel coal is running near $3.50, and the phraseology at Baltimore has increased on this week and on the 20th, 21st, and 22nd of October, 23rd and 24th of October, 25th and 26th of October, 27th and 28th of October, 29th and 30th of October, 31st of October and November 1st.

PHILADELPHIA

The situation is from every view that the coal supply in the east coast regions is not as low as it has been since the close of last year. At this time the index of assigned cars orders for the loading of railroad fuel is believed to be somewhat higher than in the same period of last year. The demand continues steady and, due to the large number of orders, the price of carload lots continues at $3.25.

COAL AGE

Vol. 22, No. 17

North Atlantic

To the railroads companies have urged the acceptance of these offers, as they realized that the conditions which are confronting the trade. There is no question that the roads realize that the purchase of fuel at the ruling prices in recent weeks is not paying them now sharing in the production with the utility plants and other large consumers.

Prices are still easy, with just the slightest tendency toward a firmer condition. One house which has endeavored to make a survey of the field has reached the conclusion there is at this time not more than a five weeks' supply of coal on the ground in this district. The ships which visit the ports are therefore careful to make it clear to the buyers that the coal is not in excess.

As yet there is no diminution in that class of consumer who prefers to wait for lower prices before trying to accumulate a surplus. It may be useless for such concerns to even try to get stock ahead quickly, as they would only succeed in running up the market.

CENTRAL PENNSYLVANIA

Prices are lower now than they have been for a long time. With the exception of the higher grades, they are below the high prices fixed by the state fuel commission following the termination of the action. Pools 11 and 18 are selling $3.25-$3.50 per ton. Pool 10, $3.50 per ton. Pool 9, $4 per ton. Pool 1 and 71, $4.50 per ton.

Production reached the high-water mark in the week ended Oct. 15, when loadings were 19,900 cars. The operator's associations in the district have asked the C. & O. to place a service agent in the field to investigate the placing of cars by the Pennsylvania. It is claimed that certain sections have not received their share and the operators' associations may have to be straightened out at once.

NEW YORK

Lower temperatures did not result in any improvement here. Buyers held off and a reasonable offer could induce them to increase supplies. Quotations have been reduced to a result of the easiness of coal, indicated a downward tendency.

In this harbor on Oct. 20 there were 1,619 cars, which was a slight decrease from the number on hand earlier in the week. In addition there was considerable British coal which was being fairly offered at $3.45-$3.50 per ton. Although it was reported that some had been offered at lower figures.

Reports of foreign fuel who brought cargoes of coal, without orders for it are finding it difficult to dispose of their holdings. During the week ending Oct. 20 there were reported as arriving at the New York harbor six vessels carrying 37,552 tons of coal and one vessel carrying 3,385 tons of coke.

Just now consumers are getting all the coal they need and are not carrying as large stocks as usual. They evidently feel they will have no trouble in getting whatever coal they will need readily and are not worrying about the future.

Southern coal receipts here are smaller. Quotations run about $7 per ton.

UPPER POTOMAC

From a labor standpoint, conditions are now almost normal in the Upper Potomac and are gradually improving in the Georges Creek field. During the week of October, demand was on a somewhat larger scale than had been the case during the preceding week and that had the effect of hardening prices somewhat.

FAIRMONT

Signs were not lacking at the outset of the third week of October to indicate that demand for coal, both here with railroads seeking larger tonnages. The mines in the northern part of the state as a whole, are still seriously handicapped by a car shortage. Western coal is still being moved by way of Charleston.

South

BIRMINGHAM

There has been no change in general trade conditions. Demand for steam coal is only moderate, the market activity as exists being due to some extent to the restricted supply. Although production is being maintained around 35,600 tons per week, shippers are so gas coals, $5.50-$5.75, and high-volatile slack, $3.00-$3.25.

WASHINGTON

The market is at present showing a slight decrease, but the buyers are still in a steady demand for coal. Prices are steady at $3.50-$3.75 per ton, and are not expected to change.

VIRGINIA

The field has been unable to maintain its production, largely because of losses sustained on the N. & W. and the N. & N. On other roads mines have increased their output somewhat. There is a little stronger demand in Eastern markets.
Anthracite

Congestion of Steam Loads
Now a Disturbing Factor
Production of Larger Sizes Threatened
—Brisker Domestic Demand with Colder Weather, Retailers Hard Put to Maintain Yard Stocks—Independents Forced to Distant Markets to Secure High Prices.

Inability to dispose of steam sizes is a disturbing factor which threatens to affect the production of the larger coals. Some companies are running these to storage and various railroad embargoes have been placed against their movement.

The colder weather has brought about a more urgent demand for domestic coal and retailers are barely able to maintain their yard stocks. Independent coals must seek Western and other more distant markets to obtain figures much above the so-called maximum price, as the East will not absorb much tonnage at exorbitant figures.

NEW YORK

The question of how to keep down the accumulation of steam sizes continues to hold the attention of the trade. The terminals are filled and there is estimated to be nearly 100 loaded boats lying in the harbor. Some of the companies are dumping the small coals at the regular storage yards. Embargoes have also been placed on shipments to some of the local piers.

Retail dealers have been getting sufficiently to keep them busy and nearly all consumers have had at least part of their supply delivered. So far as New York goes, it is believed that there will be no extreme shortage and that everybody will be able to get coal.

Independents are not finding it so easy to unload their product on local retail dealers as they did a few weeks back. Along the line and in the West the problem may not be so difficult.

Pea coal is easier and some dealers who have been willing to take fair-sized tonnages in order to get the larger coals have accumulated quite a supply. Stock of buckwheat are not as large as rice and barley. There were some offerings of large growth coal sizes here during the week on a mine basis of $2.25 for buckwheat, $1.90 for rice and 90c. for barley.

PHILADELPHIA

The pinch of fuel shortage is being much felt at this time, following the arrival of actual fall weather. The yards have less coal than at any time since our first shipments came in after the strike. Some of the larger shippers are no doubt spreading their production around, with territory at a distance now getting their turn. If coal had been kept moving but at the same rate it started there would have been insufficient at least to meet present weather conditions.

Mine prices seem now to be fairly well fixed, the companies continuing at their former figures, and with most of the large independents at $9.25. There are, however, reports that quotations on family sizes up to $12 are yet being made, but the general attitude of the retailer is to go without coal rather than pay extremely high prices.

There is also some annoyance in the car supply, and while it is not believed that any time has been lost the number of the cars delivered for loading is growing.

Steam sizes have not improved, but it is hoped with better weather conditions that the surplus will soon be absorbed. There is still buckwheat offering at $3.50, but the bulk of the excess tonnage is now selling nearer to $3.75. Barley continues troublesome. Should the shortage stocks go as far as continue much longer it is quite likely that a fair quantity of buckwheat will be taken in by the retailers, who up to this time have looked with anything but favor on this size.

BALTIMORE

Appeals for consumers to take bituminous as a substitute are failing to defer ears for the main part. Some of the importers have coal in cellars of houses, but there seems to be a general refusal to take much of the American product. The Maryland committee is pointing out to householders that they should use soft coal when they cannot get anthracite.

The hard coal dealers are up to their necks in work. While some coal is being received it is nothing like enough for urgent demands. Receipts are quickly absorbed and still dealers are putting them on every side by insistent customers.

BOSTON

Low temperatures have caused increasing anxiety over the supply of prepared sizes. In view of the relatively short time since mining was resumed the shippers as a whole have done amazingly well. Conditions have been favorable, both water and rail, for heavy movement and thus far New England has fared well.

Dealers are confining themselves to small deliveries in the effort to make their stock for the season possible. In most city prices have not been advanced over spring figures.

BUFFALO

All distributors and retailers are complaining of no coal and the weather is all that seems to be in the interest of the consumer. The fixing of a price for independent anthracite seems to have caused great dissatisfaction.

All shippers claim to be living up to the price, but there is report of more or less claiming to be out of coal when orders are given. Then the shipper says he can get coal for three or four dollars more. The movement by water has increased considerably, but is not up to normal yet. Shipments last week were 117,600 net tons, of which 53,300 tons cleared for Duluth and Superior and 64,300 tons for Chicago and 23,700 tons for Milwaukee. Freight rates remain at 40c. to Duluth, 50c. to Milwaukee and 50c @55c. to Chicago.

ANTHRACITE FIELDS

Things are still peaceful in the anthracite region and competition seems to be on the increase. There is, however, much difficulty in marketing the steam sizes and some of the companies are making concessions as to price.

The car shortage is not affecting the region as much as it has been in the past and it seems as if this difficulty will soon be done away with.

WEST

KANSAS CITY

It is difficult to understand the coal situation. Demand is strong for all grades and there is a rise in prices for some domestic nut coal. The price for nut has held firm at $6 until recently when it was reduced to $5.50 and mine run, from $5 to $5.50-$6. peninsula is not of much importance to Kansas and the present demand is for small quantities of coal for local use.

Prices are as follows: Kansas lump, $6; Kansas nut, $5.50; Kansas mine-run, $3.50-$4; Kansas slack, $2.50.

DENVER

A price war in Weld County between two small coal companies has reduced lignite coal in northern Colorado 90c. to $1.50 per ton. Some operators declare that coal is selling at $2.25-$2.50.

Wild weather has broken the coal spell which struck Denver and the state for three or four days. The car shortage is still a serious problem, even though the city and surrounding communities have not been suffering on account of a lack of coal, being on the main lines of transportation and using system cars which are never rested out of the state.

SALT LAKE CITY

The coal business is quiet. Operators have nearly caught up on their orders and are no longer looking for business unless the weather turns cold. The general coal price has remained level, and the price is still in session and there is no indication yet as to whether they will bring in any adjustments. Some in the business think they will.

The small companies are getting ready for business and many believe that Coal is in for a big industrial era. Carries have been good this year with fair products and transportation facilities, on the whole.
Steam Market Continues
To Suffer Peremptorily

DOMESTIC DEMAND SLOWLY DAY BY DAY

Domestic demand received no particular note during the week, but the trade continues slow and prices ruling about the same. The week ended February 22nd saw the market fairly steady and prices held about the same as in the beginning of the week. Small sales were made in the district.

There are several large shipments of Newcastle coal to the north, and there is some movement of coal from this district to the east. There is some movement from the east to the west, but the market is generally slow.

Prices are fairly steady, with slight downward tendencies. The market is generally slow and there is little movement. Prices are ruling at about the same level as last week.

RAILROAD TONNAGE

Railroad tonnages from all three fields have been fairly good, but the railroads are not storing any reserves. Many mines in this territory have been forced into suspension on account of no-bill screenings and the condition of the steam market is still poor.

LOUISVILLE

Eastern Kentucky, with a car supply steadily at below 20 per cent., is not having much trouble in disposing of production, which is keeping freight rates fairly firm. The Lake movement along with demand for gas coal, and movement to utility and hydropower plants, is accounting for the bulk of production. Screenings are maintaining values at around mine run prices, due to comparatively small production on account of general lack of lump orders.

It is admitted that with the Lake season nearing a close it will not be long before a larger tonnage will have to be disposed of through other channels, which will have a tendency to break down prices, and force operators to make more lump coal and offer it at lower prices.

Prices are somewhat weaker than they were, especially in western Kentucky. That section is quoting lump, $4.75@$5.25, nut, $4.25@$4.50, screenings, $2.25@$2.50 and mine run, $2.50@$2.75. Type coal is slightly lower, as are most grades. The market is about the same as last week.

WESTERN KENTUCKY

Prices are lower on steam coals, due to slow buying and lack of stock, orders from industries; along with the fact that national production is increasing, and competition for business is beginning to be felt. Freight rates prevent movement at the present time to districts which were large buyers during the period of shortage. Mine run is about a dollar lower, and it is now quoted $2.25@$2.50, and some for less. Nut and slack is $2.25@$2.50, and lump, $4.75@$5.25, but with any large business it would probably advance.

Better time is limiting larger movement of coal by water to the lower river markets. Most of the business of the western Kentucky field is going to the local users. Some buyers are disposing of their stocks, and it is generally agreed that the market is firm.

SOUTHERN ILLINOIS

As the demand for lump and egg increases there seems to be a falling off in the movement of steam sizes. This has been so pronounced that several large coal fields in the Carbondale district have had trouble moving steam coal and have cut the price from $5.50 to $4.25 to steam plants in isolated cases, while screenings were cut from $2.50 to $2.25 in some instances.

Working time averages two days a week, with some mines getting better.

Some similar conditions prevail in the Du Quoin and nearby areas. Egg is in a little more plentiful. In the Mt. Olive territory, the mines are getting about as much coal, but most of the shipments are from smokeless plants. The lower coal is in practically no use, and there is more movement of egg and some of the better grades of bituminous and smaller grades of smokeless. The demand is not sufficient to absorb all the coal on hand, but the market is firm.

DOMESTIC DEMAND IN CHICAGO

Demand continues slow, with little activity. Prices are firm and ruling at about the same level as last week. There is little movement, and the market is generally slow.

CHICAGO

The weather is still very cold, with snow and freezing conditions prevailing. We are very much in sympathy with the severe weather in the northern states, and hope that things will improve soon.

The market is fairly steady, with little movement. Prices are firm and ruling at about the same level as last week.

The demand for egg is not strong, with the market generally slow. The demand for steam is not strong, with the market generally slow.

The demand for smokeless is not strong, with the market generally slow. The demand for bituminous is not strong, with the market generally slow.

The demand for coke is not strong, with the market generally slow. The demand for anthracite is not strong, with the market generally slow.
Industrial Demand Gaining;

Output Matching Demand

Market Still Weak—Prices Steady Save on Domestic, Which Feels Cold Weather Stimulus—Fixing of Retailer's Margin in Ohio Complicates Situation.

Industrial demand is increasing slightly. The market is still weak, but production is becoming more evenly balanced with current demands. Prices are not quotably higher except on domestic sizes, which are feeling the effects of cold-weather demand.

Price fixing by Ohio on coal mined in that state is causing considerable tonnage to be shipped to outside markets. The retail situation also is confused by the state ruling which regulates the dealer's margin.

Lakes and railroads are taking much of the current production and little free coal is available. This is gradually strengthening the market as the shortage is apparent with the slightest upturn in demand.

PITTSBURGH

There is no material change in the rate of production. Supplies appear sufficient to meet regular requirements of the line trade together with the Lake trade. Car shortages are practically universal, circumstances as a whole indicating that there would be a surplus of coal if the railroads were able to supply all the cars ordered.

Coal users are showing no disposition to stock coal and evidently expect lower prices. The great bulk of current requirements are being met by a regular movement between mines and regular customers, subject in many cases to weekly or monthly price adjustment according to the state of the market, rather than by outright sales and purchases. This condition leaves little demand for the open market.

The market is not closely quotable, on account of there being quite a price range, according to quality. Ordinary steam coal is generally at $3@$3.25, with occasional transactions at $3.50. A fair grade of byproduct can be picked up usually at $3.50, while good gas runs up to $4 for mine run, with 50c. extra for screened. Domestic 13-in. lump is $4.75@$5.25, according to grade.

CLEVELAND

The market has begun to stiffen. Prices are higher than 10 days ago. Cooler weather and increasing car congestion have combined to bring about a firmer market. Some of the large coal carriers, which were furnishing a supply ranging from 70 to 100 per cent have dropped to a level of 35 to 50 per cent in the last few days. In view of these things a fuel shortage seems almost inevitable in this district. This is the view of Frank H. Biser, traffic commissioner of the Cleveland Chamber of Commerce, who is serving in the state fuel administrator's office.

In addition to present conditions of the turn in the market is found in the fact that many large dealers and operators report they have more orders for their books than they can deliver in three weeks. The price for $3.50 a ton, fixed by the state fuel commission, for No. 8 mine run, much of this fuel is moving out of the state. There has been a distinct quietening in household demand. The colder weather has caused this. Pocahontas is still scarce and hard coal is coming into the city in driblets. Under the new state regulations retail coal prices will fluctuate daily. In the past dealers have averaged their costs so they could quote prices for future delivery. They no longer do this and are charging the cost at the mine to the day of shipment from which the particular order is filled.

COLUMBUS

With colder weather at hand domestic demand is increasing. Producers and jobbers have many inquiries but since Ohio prices are regulated dealers have to be content with buying West Virginia and Kentucky grades as well as Ohio-produced mine run. Practically no Hocking or Pomeroy lump is going to Ohio dealers, producers preferring to sell outside of the state at higher prices. Retail prices as fixed by the administrator allow a margin of $2.20 to the buyer. The state is still active although car shortage and congestion is reducing the tonnage.

The car supply is growing less and this is reducing the output in all Ohio fields. The supply of cars in the Hocking Valley last week was about 40 per cent and in Crooksville and Cambridge somewhat less.

EASTERN OHIO

While the field is showing some improvement in output yet because of the continued inadequacy of transportation facilities some apprehension has been expressed by some members of the Ohio fuel administration that a famine is in prospect. During the week ended Oct. 14 this district produced 135,000 tons or 58.6 per cent of predicted capacity. With approximately 30 per cent of current output being drawn for railroad fuel and some 60 per cent of the remainder going to the lower traffic point to the Northwest, it may readily be seen that as the restricted rate of operating the volume of rail and mine run entering the area market cannot be of any considerable magnitude.

Steam users are daily becoming more concerned and domestic consumers are beginning to feel more apprehensive. This is due to the demand that has developed. Difficulty is being experienced in satisfying the demand. With the exception of slack, which is still and in abundance because of heavy shipping of 2-in. to the Lake, other grades are scarce in the open market. Other spot prices conform to maximum figures set by the state administration.

Receipts of bituminous coal at Cleveland during the week ended Oct. 14 were 1,471 cars, 360 cars under the preceding week. Of these 1,282 cars were for industries and 251 for retail yards.

DETOIT

Bituminous coal is coming into Detroit in fair amount, though the average daily receipts fail to show the quantity which dealers estimate as necessary to meet the requirements. Industrial plants seem to be releasing orders only when compelled to replenish their supplies.

Retail dealers, also, are inclined to proceed cautiously in the matter of building up yard stocks. The waiting attitude of the consumers impresses jobbers and wholesalers as the fulfillment of the expectation that coal will be obtained at lower prices after a while.

Hocking lump and egg is quoted at $5.50@6.75, mine run, $3.75@4.50, pot, pulp and slack, $3.25@3.50. Fairmont lump is $5, mine run, $4.50@4.75, slack, $4.00@4.25. Hocking lump, 14-in. is $5, mine run, $4.25@4.50, slack, $3.75@3.75. West Virginia and Kentucky lump and egg is $6.25@6.50, mine run and slack, $4.50@4.75. Smokeless lump and egg is handled at about $5.50, mine run, $6.75.

BUFFALO

Some shippers report the market stronger, but it is hard to find any advanced prices. The consumers are buying as they please. No sort of warning of coming storms or still warmer weather supply can scare them.

The price was scaled as varied as it is needed. Mine run coal is quoted as much as over our shortage, but in fact that is all that is saving them from a total collapse of the market.

The weather has done what it could to fix the market. The jobbers know this and confess that it has so far done much toward spoiling their arguments. Quotations are: $8 for Heating; $6.50@7.50 for Gas; $4.50@4.75 for Domestic; $4@4.25 for Allegheny Valley and other mine run; $3.25 for slack.

NORTHERN PANHANDLE

Miners are much handicapped by their inability to ship large cargoes to Western markets or to the market world over. Owners, who are suffering if they can, it has been found possible to get sufficient coal, though not in the quantity被认为。
First Cold Worries Few

Folks Around the Lakes

Considerable Flow of Cargo Coal Both
Hard and Soft Alases Worst Fears
but Fuel is Delayed Out Carefully—
Steam Prices Safest.

The Northwest finds little cause
for worry in spite of the inevitable
domestic rush that was started by
the first cold snap. Prices on
domestic are not hiking even though
the supply does not equal the
demand. Heavy Lake shipments con-
tinue and it is probable they will
until Dec. 1. Rail coal from Indiana
and Illinois is coming in in fair
volumes. The general result is no-
body in contracting and steam prices
are hedged downward.

Hard-coal cargoes already in have
decided not in small quantities
but even that does not cause much
concern over the future. It certainly
has not set a demand keen enough
to take out of dealers’ yards some
low-grade soft coal bought at fairly
high prices last summer. Both deal-
ers and dock men have had as much
experience buying high-priced coals
for protection only to have it left on
their hands at the end of the season
that they are not stocking heavily
now.

MINNEAPOLIS

A flurry of “snow winter” with snow
started a rush of material business by the
coal wing, but with the passing of the
storm, none are end to the rush. The
coal market situation has not changed par-
significantly. The dock men have pledged that a certain
amount will be unloaded at the Northwest.

Minnesota is to get 122,912 tons this
quarter, 63,380 tons last year. St. Paul
has 65,470 tons against 147,450
tons last year. This may be increased
on transportation difficulties, although
it is hoped to move it by Lake and rail
routes. In new openings within the
week, the market will get 21,013,100 tons.

The situation is very active.

There is nothing to show
present and early future need,
and buyers are not at all worried.
When the snow arrives, blow by
blow, it is expected that soft coal
will be delivered. The snow
may set them no end of
trouble. All coal men say that
1914 was a good season
of all-coal business into these
regions, especially between
and Coal City.

Already they are having difficulty
in selling the prices they must ask, and
the future gap in the probability of a
larger tonnage coming on a still
larger exponent.

In October is showing a decline in
charges moving in the docks, as com-
pared with September. Some of this is
various yards. The season’s receipts
by cargo to date now total 87,652
tons of anthracite, and 1,764,371 tons of soft
coal. Last year, during the same period,
185,622 tons of anthracite, and 2,149,410
tons of soft coal were received.

DULUTH

The first snow has fallen and cold
weather seems to have definitely set in.
Householders are straining every effort
to get coal into their bins, and dealers
find it impossible to make local de-
lievements.

During the week forty-two cargoes
arrived at the port. Four were of an-
thracite. Twenty-four are on the way of
which four more are hard coal. This,
it is considered, will relieve the situa-
tion considerably, as the volume re-
ported coming from lower ports indi-
cates that the movement will keep up.
Prices throughout the territory are
excellent. Duluth is in a good way
for cars, as grain shipments to the
harbor leave many empties to take
coal back. Despite this there has been an
accumulation since Oct. 1 of about
600,000 tons more on the docks.

A heavy call for Pocahontas has
about wiped out the supply. Prices on
hard coal remain the same as quoted last
week. The market in bituminous coal
is weakening at the usual point—screen-
ings. These are quoted at $7 for Youghiogheny, and $7.50
last week and Hocking screenings are
50c. below this. Prices for lump and
run of pile remain the same but are
expected to drop. Railroads are not buy-
ing much.

New England

Big Consumers Await Events;
Some Smaller Ones Buying

Business Is Light, Close Canvassing
Being Necessary to Place Tonnage—
Hampton Roads Coals Sluggish—
All-Rail Fuels Quoted Lower to Main
Output.

Only here and there is the cur-
rent market at all responsive to sell-
ing efforts. The larger buyers have
accumulated some reserves and have
settled down to await developments
in November and December. The
various trade factors are enjoying
only light business in consequence,
and what tonnages are placed are the
result of close canvassing.

A few relatively small users have
concluded that present prices are
about as low as they could reasonably
expect, and these are now beginning
to talk on the coal they have been
talking about buying since early
July. Hampton Roads coals are
sluggish and all-rail fuels are quoy-
tly lower in an effort to maintain
production.

The $3 level at the mines has been
reached. Locomotive coal of fair grade
has been offered at that figure per net
ton, but no sales have as yet been
reported. The present all-rail tariff
to New England points is still so high
that coal within reach of Tidewater still
leaves by the water route. Coast-
wise freights are now on what is con-
sidered practically a minimum basis
on present costs, and when the delays
in rehandling at Boston, Portland, and
Pewaukee are cleared up, it is expected
that receipts of Hampton Roads coals
will measurably increase.

Cargoes of British coal continue to
arrive in rather more than smaller number.
A few of the large British cor-
porations have the goods to be well satisfied with their
purchases, and are quoting quality and
reasonable prices of those grades as an
argument to force sales with their
home coals. Some of the high volatiles
that originate on the other side have
given fair satisfaction as railroad fuel,
and renewed shipments have been of-
nounced recently at a range of $6.50@$7
delivered alongside.

Buyers in general seem little
disturbed over the threatened car
shortage. They are not willing to
sell coal the past three months have convinced most consumers that orders will be even more
scarce than cars, provided cars are to
be short as predicted.

In closed circles there is more or
less discussion of “assigned cars.”

There are operators who see in this a
deliberate attempt to force prices to
still lower levels, and without doubt
any new prices would be resisted under
anything like present conditions.
Unsettlement Continues, Due to Diverse Causes

Some Steam Coal Sacrificed to Escape Demurrage—Clog in Movement Reported—Outside Competition a Pressing Factor—Price Fixing Boosts Retail Quotations.

Outside competition, shortage of cars and a soft market have been causing a continuation of the unsettled conditions at the Cincinnati gateway. Rejections have grown to the point where some steam coal is being sacrificed where it had begun to pick up demurrage. These cars in distress have sold down to $3, but that is not nearly as ominous as the reports coming in from Russell, Ky., and Portsmouth, Ohio, to the effect that the quick movement is beginning to clog there.

The outside competition, perhaps, has the greatest effect upon this market and reports that byproduct coal and gas coals from the Pittsburgh belt were being offered 50c.@75c. cheaper than the Kentucky and West Virginia products caused anxiety. On the other hand, reports from companies handling high-grade coals show that the slump has not amounted to more than 25c. a ton on the week.

LOW VOLATILE FIELDS

NEW RIVER AND THE GULF

New River producers were unable to take advantage of the better Western market for prepared owing to an embargo on the C. & O., which for a few days diverted more coal to Eastern markets and to Tidewater, where the demand has been none too strong. Gulf producers also had to ship all their product to Eastern markets, where there was a little better demand, although a surplus was reported at Tidewater. Little tonnage was available for spot sales, due to the large number of contract orders to be filled in the face of the car shortage. Prepared grades were still high, with no prospect of an increase in the supply.

POCAHONTAS AND TUG RIVER

Pocahontas production is still being seriously curtailed by the inability to secure an adequate supply of cars, unless movement is of nearly 400,000 tons per week. The output is not much more than sufficient to take care of regular customers. Little smokeless has been reaching markets in the West but notwithstanding the scarcity of smokeless, prices as a rule have been about on a Hoover level.

Tug River mines are slowly recovering from a slump in production brought about by numerous embargoes and a general shortage of cars. Even making allowance for an improvement in transportation conditions, the supply is still short of the demand, so much so in fact, that producers have not been quoting prices.

CINCINNATI

The smokeless situation continues much as it has been. The Pocahontas producers, however, have finally been able to get smaller equipment to their mines, which will result in a heavier tonnage being shipped to the West. Some producers say that they have caught up with their contract orders.

The situation of the steam coals is the weakest on the list. Customers who were taking anything that looked like coal are now discriminating and demanding quality. Lake buying has been a little better with the end of the season in sight and the automobile and steel people seem to have no limit to their capital outlay.

The retail situation has been muddled by a ruling from the Ohio authorities fixing the price of Pocahontas at $11.71. Dealers were selling this lump activity at $10.50@$11 and mine run at $9.50. Split lump is ordered sold at $10.39@$10.49, whereas the dealers had been selling it at $8.75@$9.60, and the slack, $7.25@$8.50.

HIGH-VOLATILE FIELDS

KANAWHA

Claims of C. & O. officials that they were able to furnish open-tops to the extent of 60 per cent of normal were not being borne out by loadings during the three week of October. Mines were not securing more than 30 per cent supply. The Western market was closed to shippers for several days by an embargo on all coal destined for points west. It is said there was nothing to do but let coal accumulate. The embargo may have had the effect of hardening Western prices. At any rate, mine run increased 5c. a ton and stopped the downward tendency.

NORTHEASTERN KENTUCKY

Claims of railroad officials that the car supply is about normal and the expression of public officials that prices are too high are disputed and resented by mine owners. Under present conditions it is impossible to produce anything like the tonnage for which there is a market, and hence production costs are high.

LOGAN AND THACKER

Severe economy continued to handicap Logan mines. The Western market has shown signs of greater energy. With the Western movement stopped for a few days, the Lake movement ceased also. There was more general inquiry for steam coal, however, than there has been, indicating that supplies are running short in some quarters.

Thacker production was only 30,000 tons as against car shortage losses of 150,000 tons, so that Western shipments were materially curtailed. Producers are hardly able to take care of the requirements of their regular customers, much less sell coal on the spot market.

Coke

CONNELLSVILLE

The break in coke prices which began nearly a fortnight ago brings lower prices almost daily, and finds only an occasional purchaser. The market has been under the double pressure of increasing production and of consumers holding off. There is room for at least $2 further decline in coke without the price going below the market price of the coal involved plus the cost of coking, while sometimes coke has sold at less than the price indicated by the usual formula. Coal, furthermore, may decline, and thus furnacemen have good reason for deferring purchases as much as possible.

The large extent car supply has been the limiting factor in production. At the same time many of the strikers have been quite reluctant to go back to work. At certain plants officials of locals have instructed strikers to return to work while at other plants attempting to resume no such instructions have been given, indicating that the U.M.W. has not yet fully call off the strike and would be content to see the men stay out as long as they will.

The market is quoted at $8 for furnace coke, this being an asking over the bid price, and $10.50@$12.50 for foundry.

The Courier reports production during the week ended Oct. 14 at 98,700 tons by the furnaces and $2,010,000 in the merchant ovens, a total of 140,710 tons, in increase of 14,280 tons.

UNIONTOWN

Furnace coke this week struck a downward strike, joining coal in the low price movement. A number of factors contributed to the lowering of the coke prices, principal of which was a considerably increased production, which temporarily at least is more than the market can readily absorb. Coupled with that feature is the sudden delivery of British coal upon a basis of approximately $8, Connellsville. It is reported that some consumers who placed orders for foreign coke while the Connellsville was at the $13 level are now seeking consolidation in order to substitute domestic fuel.

Coal for some time has been described as soft, due to a great extent to the resumption of operations at mine mines, but the coke market since production was resumed has not the extent of establishing in the Connellsville area. Ton has been strong with an increasingly active demand. That insufficient surplus is now being produced to bear down the market is taken as proof that the union has not its effectiveness in curtailing production.

BUFFALO

The trade is dull, with some report of price reduction. Jobbers quote 72-hr. foundry at $13.50,$13.50 for 48-hr. furnace at $11.00,$11.50 and coke at $11, with $2.50 added for freight.

NEW YORK

Maximum prices in New York City for hard coal sold in quantities less than the producer's monthly quota, subject to an announcement by A. S. Learoyd, district fuel administrator of the Greater New York Coal Exchange, have been reduced to 10c per ton. The prices are said to be 10c, per 100 pounds lower than the previous level.

Charles S. Allen, in association with Karl Knox Gartner, of the firm of Baker & Gartner, has purchased the coal mine by the lease of the Tidewater Coal Exchange, Inc., to purchase and sell coal. The transaction has been completed for $600,000 which have been apportioned against members of the Exchange. Mr. Allen will also take up with the debtor and creditor members the matter of settling the outstanding deficit.

The Astel Coal Co. has been established in Buffalo, managed by William C. Strassburger, a local trader of Tonawanda, and William E. Schmidt, a former city coal salesman.

The Haynes Coal Mining Co., of Haynes, has secured a temporary order in the Court of the U. S. District Court, for the reorganization of the mine. The company operated the Central Coal & Coke Co. in that part of the State known as the Haynes mine, which is the object of the present action.

The company has asked for a temporary order in the Court of the U. S. District Court, for the reorganization of the mine. The company has asked for a temporary order in the Court of the U. S. District Court, for the reorganization of the mine.
Traffic News

President W. J. Heineman of the Chesapeake & Ohio and C. J. Murphree of the Southern Pacific and several other lines meet at St. Louis to confer. A new transcontinental railroad was anticipated to be in operation by 1915. The meeting was attended by representatives of the Illinois Central, Atchison, Topeka & Southern, and the Missouri Pacific.

Federal Fuel Control Notes

Amendment No. 1 to Service Order No. 25

The I.C.C. on Oct. 17 ordered that the following amendments be made: (1) All cars for the transportation of coal to points east of the 99th meridian should be covered by Service Order No. 25; (2) All cars for the transportation of coal to points west of the 99th meridian should be covered by Service Order No. 14.

W. J. Heineman, of the Chesapeake & Ohio, and C. J. Murphree, of the Southern Pacific, meet in St. Louis to confer on a new transcontinental railroad.
Co-operating with Hammond Commission

Perhaps nothing has contributed so much to the excellent start made by the U. S. Coal Commission as the very frank admission by its members that they know nothing about the problem they have had thrust upon them and their invitation to both the miners and the operators to jump in and help educate them. Meetings were held last week in order with representatives of the United Mine Workers, the soft-coal operators and the anthracite producers. Each was urged freely to give advice as to how the duties and functions of the commission as laid down by the law should be carried out.

A committee of the bituminous-coal operators seeking to represent not the National Association alone but the industry generally has offered full co-operation. The National Association has levied a special assessment on its members, to which others are to be asked to contribute, to raise a substantial fund to supplement that given the commission by law. That is to say, the bituminous-coal operators propose to contribute the money to finance important research work for the commission, the money to be spent by the operators at the direction of or in accordance with the suggestions of the commission. This, of course, is perfectly proper, for it simply amounts to carrying a step further than the mine office the collection of data requested by the government. The decision to devote its time and money to the assistance of the Coal Commission rather than fight it, to accept it as something that will be of ultimate benefit to the coal industry rather than looking on its activities as detrimental, is the most forward-looking step the National Coal Association has taken.

The United Mine Workers have taken the request of the commission in good faith and have already supplied a 7-page brief expressing their ideas as to the direction that certain parts of the investigation should take. They have suggested, for instance, that careful investigation should be made of absentee ownership, the spread between mine price and delivered price, the possible connection between coal companies and machinery manufacturers, discrimination by railroads in the placement of railroad cars at the mines, thus producing irregular employment, middleman's profits and coal storage.

On the whole, this first document for the record (which we are pleased to note was broadcast to the press) is a series of suggestive questions and implications such as might easily have been compiled by any newspaperman or any citizen who had followed the subject in recent months. This communication and the others that doubtless will follow from the same source will serve to keep the public and the commission posted on what questions should be answered. Its apparent guilelessness detracts none from its interest and value.

The commission has a long, hard task ahead of it, and the very evident willingness of all parties at interest to help without restraint will make its work more certain of success. The friendly spirit that seems to prevail augurs for a happy ending.

Effect of American Demand On the British Coal Trade

Under the caption "The End of the American Coal Spurt" the editor of The Compendium, London, summarizes the effect on the British coal trade of the recent demand on this side for English coal. It is pointed out that buyers on this side did not leave the British long in doubt of their intention of taking only the coal that was urgently needed, and that by the middle of September inquiry was practically at an end and negotiations in progress were stopped.

As has been currently recorded in our market columns, the American demand caused a spurt in British coal production, forcing the weekly output well above 5,000,000 tons from around 4,500,000 tons. Exports climbed from 4,793,000 gross tons in June to 6,146,000 tons in August. Later figures are not as yet available. From practically none in June, the portion of these totals sent to this country rose to 959,913 tons in August. Our own figures show that 606,000 tons reached here during that month.

Prices were affected by the sudden onslaught of American buyers. Increases in quotations ranged from 28. to 6s. 9d. per ton, according to quality. The peak in prices was reached in August, a marked slump being recorded in September. Ocean freight reached their peak in July. When the buying from this side began it soon developed that ships and not coal would be the limiting factor. The charter market responded with jumps of a shilling or more, only to subside when vessels from all over the Atlantic were offered for this trade.

On the whole the British coal industry has much for which to be thankful in the threatened coal shortage on this side inasmuch as it provided a sudden unexpected market for several million tons of coal. The British coal industry had been in the doldrums for many months, wages had sunk to the level common, prices were dropping and as they dropped the usual buyers were holding off waiting for the further. Mines had been closed and the men were suffering—even at the minimum wage the operators could not produce and find a market for their product. But when utilities, railroads and free-lance traders on this side strained off the surplus supplies and called for more, the coal industry in Great Britain took on new life. Continental buyers woke up to demand their share and the trade became brisk.

The impulse has not been lost. The strike on this side not only made a market on this side but rescued the miner on the other side from a winter of dullness.
Excessive Taxation of Coal Lands

ANTHRACITE dealers and consumers, to say nothing of police supervision, would do well to study the evolution of a movement for the excessive taxation of coal lands, reported elsewhere in this issue. There is no desire to alarm, but there are things worse than being an alarmist—for example, being an optimist so cocksure that the most patent signs of the times are ignored or explained away.

The joint issue is that the anthracite industry in the lower hold, where nearly all the reserve lie, is being subjected to the raids of taxation hawks whose program, if carried out, and without underlying philosophy, if generally adopted, will speedily put the hard-coal business on the rocks. The present assault is, in many ways, the most serious of all those directed at the anthracite interests in the accumulating warfare of the last twenty years.

To raise a property for taxation at ten or twelve times what was paid for it or for what it will bring in the open market is nothing short of a levy on capital. It might be heard without emotion as a report from Romeo, but as a report from supposedly conservative Pennsylvania it comes as a shock which should serve as a warning. A precedent which is made in the case of anthracite lands can be applied to other real estate, if not indeed to all other property.

Consumers of anthracite in markets like New York and New England, justly alarmed by the Pennsylvania State tax on anthracite tonnage, should by no means ignore the implications in the Schuylkill County situation. There a community of perhaps 250,000 of which last year collected $2,000,000 from coal-land owners on every dollar raised for general county purposes this year solely proposes to increase the revenue 50 per cent and to collect 11c. from coal lands and only 11c. from the general community. The Schuylkill County proposals involve a much greater amount per ton than does the Williams tonnage tax of 1921, against which public officers in anthracite-consuming states entered a protest.

Consider the cumulative effects of Pennsylvania public policy with respect to the anthracite industry, the only American industry peculiar to that state. As long ago as 1916 Governor Brumbaugh's commission reported that new legislation and continuous investigation were among the causes for increasing coal prices. Yet the Pennsylvania Legislature has not only put a tonnage tax on the anthracite—the only Pennsylvania product as treated—but it has burdened hard coal with hampering legislation like the Kehler act and the Fowler act, purporting to prevent mine taxes, and raising millions, by another tonnage tax, to make good cave damage. Frankly discriminatory legislation of this character has heartened all those like the commissioners of Schuylkill and Northumberland counties to put all the traffic with bear on the backs of the coal companies in the shape of taxes.

One producing company in the upper region gives a rough estimate that its total tax bill—federal, state and local—amounts to about $8 per ton of production. One producing company in Northumberland County last year paid, as county and municipal taxes alone, an amount equivalent to at least 25c. per ton. The new idea in taxation, if carried out, would double that figure this year.

These things are bad enough, but there is an even more dangerous idea buried in this systematic bleeding of anthracite owners. It is the implied, and even expressed, determination to tax the present, potential wealth which should be, and is being, conserved for the future. If adopted, it means farewell to the sound policy of conserving natural resources, adopted by the federal government less than twenty years ago.

Anthracite is a stabilized industry. In normal times a year's production, working at approximately full time, merely meets the year's demand. There is normally no shortage in supply and no carry-over to speak of. If the hope of the shortsighted, with respect to excessive-taxation, is carried out, and lands now held as reserves are forced into premature operation, the result will be too many mines, too many men employed, broken time, wildly fluctuating prices and alternate dearth and plethora of supply. In short, the tendency in this taxation scheme, whether deliberately intended or not, will be to bring about in the hard-coal industry the exact condition of overdevelopment which is considered one of the main faults of the bituminous industry.

When the President's investigating commission gets around to anthracite it might with profit delve into this matter of taxation as exemplified in Schuylkill and other hard-coal counties.

No Assigned-Car Decision

NO IMPORTANT significance is attached to the action of the Supreme Court in the Corona coal case. Acting on the precedent of the Lambert Run case, the court affirmed the decision of the District Court of northern Alabama in dismissing the suit of the Corona Coal Co. against the Southern Railway. No action was taken by the Supreme Court which in any way passes on the merits of the question involved in the practice of assigning cars. The court's action involved only the matter of jurisdiction. An effort had been made to bring the Corona case to the Supreme Court in such form that the country's highest tribunal could deal with the merits of the question, but the case reached the Supreme Court with exactly the same points involved, and the court in its ruling simply applied its action taken in the Lambert Run case.

The case arose during the car shortage of 1920 following the Interstate Commerce Commission's order modifying Rule 8 to define private cars and cars for railroad coal as assigned cars and all others as unassigned cars. The Corona company filed suit in the State Circuit Court at Birmingham, alleging discrimination against it in not being given a pro rata of assigned cars under the rating system after the company had offered to sell coal to railroads at a competitive figure. A temporary injunction was issued by the state court. The railroad company obtained a transfer to the United States District Court. This court dissolved the injunction and dismissed the suit on the ground that relief should have been sought from the Interstate Commerce Commission; that the attack was against the assigned-car rule and not against its application, it not having been alleged that the railroad delivered assigned cars contrary to the rule or that the order was unequally applied. The District Court held in effect that the railroad had not discriminated because it had delivered assigned cars according to instructions and had distributed unassigned cars among the mines in proportion to their ratings, although the supply was insufficient to meet fully the ratings.
How Rearrangement of Track Raised the Tonnage Of an Anthracite Colliery

By Dever C. Ashmead*
Kingston, Pa.

After Track Revision and Other Provisions Legitts Creek Coal Co. Dispenses with Five Men and One Mule and Quadruples Tonnage—Savings in a Year's Running Pays for All Reconstruction

Does your track hold down your tonnage? Are you wasting effort in trying to hold up your output under unfavorable circumstances where a slight revision of the trackage as to line, grade and position of switches would not only make it unnecessary in handling trips to have close supervision and a nice co-operation between the men by whom the cars were being handled but would afford an increase in tonnage in a manner almost automatic? Wherever delays are occurring the subject is one worthy of consideration. An ounce of planning of a new track layout may save a full pound of effort in handling a badly adjusted track and give better service into the bargain.

The neck of a bottle determines the quantity of liquid that can be poured from it, or rather it determines the rate of discharge. The shaft or drift mouth, whichever it may be, together with the track arrangement at the bottom or the top of the shaft, constitutes the real neck of almost any mine.

Obstructions or ill-conceived track arrangements may limit the output of a colliery beyond hope of betterment, for no more coal can be prepared and shipped than can be delivered to the outside or to the breaker. A mine may be able to produce and load into mine cars 2,000 tons a day, but if the track arrangements are such that only 500 tons a day can be sent to the surface then the capacity of the mine is limited to that quantity.

About three years ago the Legitts Creek Coal Co. purchased the mine at Scranton, Pa., that it is now operating. At the time of purchase the output was about 200 mine cars of coal and forty of rock. The mine was awaiting the happy thought as to surface tracks that would bring its tonnage to a profitable figure, for a small tonnage means a heavy cost. Previous foremen had labored in vain against the insuperable difficulties of a faulty layout.

The coal was brought up through three openings—two shafts and one slope. One of the shafts is right at the foot of the dragline conveyor which leads to the breaker. The other is about 200 ft. distant. The slope mouth was about 400 ft. from the second shaft and its top was about 50 ft. lower than the elevation of the top of the shaft. The coal from this slope was taken on the surface to a short tunnel and through this tunnel to the shaft, where it was hoisted 50 ft. to the surface.

From the shaft to the foot of the dragline conveyor that feeds the breaker is about 200 ft., as has already been stated. About 100 ft. from the shaft the rock track left the main roadway. The grade on this track was insufficient to cause the rock cars to clear the coal cars, and the rock cars collected on the track between the junction point and the top of the shaft. The map shows at this point only the new tracks and the old rock switch consequently is not visible, but it was located at the point marked A on the plan. This layout naturally caused congestion and reduced the quantity of coal that could be hoisted, as no more coal could be handled on the surface than could be passed over the track to the dump. At No. 2 shaft no rock at all could be hoisted, as there was no connection between this shaft and the rock dump. Therefore all this rock had either to be hauled underground to No. 2 shaft or unloaded by hand underground, which latter was a slow, expensive operation and one that caused congestion of the mine tracks.

At No. 2 shaft the distance from the shaft to the

---

*Anthracite Field Editor, Coal Age.
track was laid from the rock bank to No. 2 shaft for the return of the empty mine cars, and the way it connects with the cage track likewise is shown in the accompanying plan.

Another cause of congestion was the handling of ashes from the boiler house. In order to meet the difficulty a dragline conveyor was built to remove the ashes from the ash pit and convey them to an ash pocket which will hold as much as will accumulate in two days. These ashes can now be handled when there is not much rock, and their handling does not interfere in any way with the production of coal. This ash arrangement has another advantage in that it is not necessary now to handle ashes during Sundays and nights, for the ashes can be stored in the ash pocket, and thus it is not necessary to pay men to haul ashes on those occasions.

Another important change was in the empty track from the coal dump to No. 3 shaft. Here the car haul was raised 3 ft., and the gradient from the top of the car haul to the shaft thus increased, so that the cars move more freely. The curves were taken out, and the services of a driver and mule were eliminated.

The method of handling the cars from the slope to the surface also was changed. Instead of bringing them all the way to the surface through the slope they came only to the Four-Foot bed. They are then taken underground to No. 3 shaft and then hauled to the surface by that shaft. This has saved a surface haul such as interferes with operation in the winter. It also saves a mule and a driver on the surface.

The method of handling supplies to the mine also was changed. Instead of sending them into the tunnel that has been mentioned a new track was laid to connect with the empty car track to No. 2 shaft, the supplies being hauled to the shaft level by a small hoist.

The changes that have been outlined were, on the whole, inexpensive, but they saved five men and one mule. Therefore the saving in labor alone in a year's time would amount to the cost of the changes, but not only is money being saved but the obstruction to the neck of the bottle was removed, and the output of the mine could be increased.

After three years of operation the output of the mine has risen from 200 cars of coal and forty cars of rock to 800 cars of coal and 100 cars of rock.

**Improved Mine Car Decreases Costs**

BY L. C. CREWE

EVER since mining began mine cars have been mine cars, yet each succeeding year witnesses improvement in this type of mine equipment. The interest manifested in underground transportation clearly denotes the importance of this phase of coal production.

In the accompanying illustrations Fig. 1 shows the car used until recently by the La Follette Coal & Iron Co. The Rex coal bed worked by this firm averages 12 in. in thickness and, as may be seen, this car was 28 in. high above the rail and held an average of 1.840 lb. Its weight was 1,640 lb.

Fig. 2 shows the new car designed by this company's engineers and now used in place of that shown in Fig. 1. In gage, wheelbase and length over bumpers the new car is identical with the old; its over-all height, however, is 3 in. less and its width 2 in. greater. The new car weighs 1,820 lb. and its capacity is 2,540 lb.

Notwithstanding the increased size and weight of the
The car is only 28 in. high and it has the flare which for many years satisfied those who departed from the wagon-type box car which preceded it. The inside width on top is only about 3 ft. 5 in. and at the bottom only 2 ft. 3 in. These facts account for its meager capacity.

**FORMER CAR OF LA FOLLETTE COAL & IRON CO., FOR USE IN A 12-IN. RIG**

**PRESENT CAR OF LA FOLLETTE COAL & IRON CO. WITH 16-IN. GAGE**

In this car the wheels are placed so that their center is 6 ft. 11 in. above the original floor of the car, which is nearly over the wheels on cars in this department. As a result, the height is raised 4 ft. 8 in. and about the same as in the present car. This makes the length of the car 30 ft. 6 in.

Wheel tines are incorporated into the car, making it a common standard car.
Coal from Behring and Chickaloon Fields, Alaska, Will Be Used on Battleship

RECENTLY the naval collier Jason started on route from Alaska with 6,000 tons of washed coal from the Chickaloon mines and 600 tons from the mines of the Behring River Coal Co. This coal is to be given a test on a battleship. John Bissell, one of the fuel engineers attached to the U. S. Bureau of Mines, will assist in the tabulation of the results.

An application of gold-mine practice has been reported to us washing the Behring River coal. Gold sluices have been put to this purpose and are giving splendid results. They are built in parallel, so that while one is being cleaned the other is in service. The plan is so effective that even the fine coal, which settles in the bins, shows no more than 4 per cent ash. Much of the coal thus far mined has run only 2 per cent in ash. The coal is sacked at the foot of the sluice and then transferred by truck to a canoe landing 41 miles away.

The truck runs over a type of plank road that has been used so successfully that the plan is being adopted elsewhere in Alaska and may play no inconspicuous part in the expansion of motor haulage in the territory. The road is laid directly on the tundra. Heavy slabs are laid down for cross-ties. In lieu of rails a 3-in. plank 12 in. wide is spiked to the cross-ties on each side to form the track for the trucks. Guide rails have been found unnecessary and even in wet, slippery weather no difficulty has been experienced in keeping the trucks on this type of roadway. This particular road has been in service for three seasons and it has been found that the cost of maintenance is insignificant. The original cost was $6,000 per mile. A plank road in the Katala oil fields nearby was built twenty years ago and still is in service.

Some Hoisting!

SEVERAL months ago Coal Age requested information concerning hoisting and production records. Many replies were received and published and much interest was manifested in the results. One great difficulty in considering such data is that it is seldom that the lengths of cage travel in any two cases are the same or even closely similar. This renders a basis of equitable comparison difficult.

Charles F. Sherman, general superintendent of the Groveland Coal Mining Co., Peoria, Ill, writes that on Oct. 16 at Groveland No. 2 mine 274 hoists were made in 60 minutes. The total length of hoist or cage travel at this operation is 202 ft. and the cars hold a net weight of 3,000 lb. of coal.

With cars holding only 1½ tons of coal each, Groveland No. 2 can hardly expect to compete in output with some other operations regardless of the excellence of its hoist or the skill of the engineers that drive it. So far as Coal Age is aware, however, the above figure stands as a record so far as actual number of hoists performed in one hour is concerned. If any mine can beat or has already bettered this number, we would be glad indeed to hear about it.

Inspector Exonerates Lake Creek Miners

IN A RECENT letter W. L. Morgan, State Mine Inspector of the twelfth inspection district of Illinois, writes saying that the unofficial report on the explosion at the Lake Creek mine of the Consolidated Coal Co., near Johnston City on Friday, Sept. 29, in which five were killed and two injured was wrongly ascribed to two miners who were alleged to have been smoking pipes. Mr. Morgan has reported to the Director of the Department of Mines and Minerals that the explosion was due to the surveyors igniting a body of gas in entries that had not been working for two or three years. These entries were in about 300 ft. from the main entries. Owing to a chain of circumstances the ventilation had been short-circuited in these headings. The explosion that ensued ignited a cartridge of powder and then a keg of powder, part full. The explosion occurred just as one miner was loading his car and the other sitting on a pile of coal. The miners were not in any way to blame.
The Mine Blacksmith's Tools and How He Uses Them

Mounting the Anvil—Three Cutting Tools—Flatters and Set Hammers—Fullers and Swages—Punches and Tongs—What They Are Made Of—How They Are Tempered and How Kept in Condition

By Gustav A. Radebaugh*

Urbana, Ill.

EVERY official around the mines should know something about blacksmithing, for much of the successful operation of a mine depends on the prompt and efficient performance of this department.

In Fig. 1 is shown the various parts of the common anvil. The best anvils are made with a wrought-iron or soft-steel body and a face of tool steel about 1 in. thick. The horn and table are not so faced, however, and they are said consequently to be "dead." They do not wear nearly as well as they would if they were faced with tool steel. The size of the anvil is not rated by its dimensions, as being so many inches long or wide, but by its weight, and this weight is marked on the face of the anvil in three numbers. The first records the weight in even hundredweights, the second the excess in weight in quarter hundredweights over the nearest lower even figure and last the excessive weight in pounds over the nearest lower even figure for quarter hundredweights. The usual weight of an anvil for shop use is between 100 and 150 lb. The pritchet and hardie holes are used to hold tools in place and also serve for the making of bends.

The anvil is mounted on a solid wooden block, preferably of oak, hedge* or ash. It should be cut square

*Osage orange.

**Mechanical engineering department, University of Illinois.

Note—The headpiece shows a blacksmith shop at the Delaware Colliery of the Indiana Coal Co.—a regular governor hammer and a makeshift, two forged, a grindstone and a water hammer. Published by courtesy of Ingersoll-Rand Co.
The hot chisel should not be used on cold work for it does not have that sort of edge will harm in use. Cold chisel in much earlier than the hot chisel on its cutting end. As a rule it is removed together with

on each end and should be about 20 in. long. The anvil should be at such a height that a man standing erect and doubling the knuckles of his hand could just touch the face. It should be set 5 ft. from the center of the forge and directly in front of the fire and the floor should be well leveled before the block is placed in position. A piece of 2 x 11-in. soft steel is secured and kept around the waist of the anvil as shown in the illustration. After this steel has been shaped to the outline of the anvil a 1-in. hole is drilled in each end to receive the holding-down spike.

The anvil should be placed in the center of the block, and the strap should be spiked to the block. Though one of the simplest methods for securing the anvil it is one of the best. A wooden block is the best mounting for an anvil, as it gives the necessary cushion for the solid mass of steel. It helps to liven up the tool and makes it much easier to work on. The anvil should be placed so that the horn is to the left of the operator.

Three cutting tools are commonly used about the forge and anvil. The "hot chisel" is used for cutting hot metal. As shown in the view, the tool is held by the smith and the helper strikes the tool with the sledge. When cutting hot metal the chisel should be dipped in water after receiving several blows from the sledge. This is done to prevent the cutting edge of the tool from becoming heated to such a degree that all the temper will be drawn from it and the chisel become so soft that the edge will bend over. Under ordinary treatment the hot chisel does not hold its temper and this is why it should never be used on cold work.

For Heavy Cutting Dip Cold Chisel in Oil

The cold chisel shown in Fig. 4 is used in the same manner as the hot chisel, but the cutting edge is of a thicker cross-section. It is designed so that heavy blows from the sledge can be delivered without injury to the cutting edge. Compare the two chisels as shown in Figs. 4 and 5. It will be noted how much shorter and thicker the cold chisel is on the cutting end. In using this tool in cutting heavy sections the edge should be dipped in oil, which will assist in keeping the edges keen.

The hardie, Fig. 5 A and B, is set in the anvil by inserting its stem in the square hardie hole. It should fit the hole loosely enough so that it will not stick or wedge tight. It is used for light cutting and for trimming hot or cold work. The hardie for hot work is drawn out to a thin edge, but that which is used for cold work is much thicker. The edges are designed somewhat like those of hot and cold chisels, respectively.

In illustration A is shown how a piece of stock is placed on the hardie to be struck by the hammer. When cutting stock a deep cut should be made around the material. The stock is then placed on the edge of the anvil as shown in illustration B. A few blows with the hammer will then break the stock. It will be understood that the material in this operation is worked cold.
The hardie, it will be noted, is a one-man tool, but though it has this advantage over a hot or cold chisel it has the disadvantage that it cannot be used for large work. All three cutting tools are forged from 0.7 to 0.8 per cent carbon steel. The temper should be drawn to a light straw color. When the cutting edges become worn or blunted they can be ground and redressed and tempered. The spoke of an old buggy wheel makes excellent material for the handles of all forging tools that are to be made of wood.

In forging work many tools are needed if a job is to be properly finished. The fuller and set hammer (see Figs. 6 and 7) are used for practically the same purposes—smoothing and flattening work. By using these tools when the material to be forged is at a dull red heat and dipping the tool in water before it is applied to the work, all the rough scale can be removed from the surface, thus leaving a smooth, finished appearance. When making a stock-gate hinge a right-angled bend is made, as shown in Fig. 6. It is good practice in this instance to use the fuller instead of a hand hammer. A more even bend can be made and the surface of the stock will not be made uneven by hammer marks. Fullers for general work have a face from 2 to 3 in. square. The edges of the face are slightly rounded, and because of that provision the tool will leave no marks on the work.

The set hammer is shown in Fig. 7 making an offset on a strap iron. When an offset of the thickness of the stock is desired a piece of the latter is placed on the anvil, and the strap iron is laid over this piece as shown. The work thus offset is then forged into shape by the aid of the set hammer and sledge. The set hammer is useful also when squaring up right-angled bends. These hammers are made with faces from 2 to 2½ in. square.

The top and bottom fullers and top and bottom swages (Figs. 8 and 9) are made in pairs. The bottom parts of these tools are designed to fit in the hardie hole and the tops are provided with handles. As shown in the view, the forging blow is delivered by a sledge, the tools being held in a stationary position. Fullers and swages are both sized by the curved edges. A fuller with a curved edge of ¼-in. radius would be termed a ¼-in. fuller, as the curved edge would be the same shape as one-half of a 1-in. bar.

The fuller is made in several sizes. The top and bottom fullers are used for forming depressions or shoulders on opposite sides of materials, as shown in Fig. 8. They will also be found useful when drawing out metal between shoulders or projections. The top fuller is sometimes used singly in making scars for welds, forming grooves, smoothing fillets or forming shoulders on only one side of the forging.

The swage (see Fig. 9) is used for rounding up work or forging round shapes to a smaller size. When forging stock to a circular section the swages are conveniently used for smoothing up after the stock has been drawn to the correct size. After welding a rail the swages are used to smooth up the weld.

**When Tool Mushrooms It Should Be Redressed**

If an extra-smooth job is desired the top swage can be dipped in water occasionally. The operation is known as "swaging." These tools are not tempered and the best grades of them are made from drop forgings out of 0.8 to 0.9 per cent carbon steel. After these tools have been in severe service the head of the tool mushrooms, and chips of steel may fly when the tool receives a blow from the sledge. This can be avoided by redressing the head of the tool. To redress these tools, remove the handles and work the steel at a cherry-red heat. After the operation is complete, permit the head of the tool to cool slowly by placing it in ashes.

The small repair shop uses two methods of punching holes in hot metals—the hand punch and one of a heavier type, as shown in Fig. 10. This latter punch is provided with a handle and driven by a sledge. The hand punch is made from octagonal or round tool steel and is about 8 in. long. The end is forged as a taper...
When the handling is important the hole in the stock should be bored and a few punch holes turned out the exact length of the jaw of the tongs. Note how carefully the last hole has been made in this stock. A bit turned from the handle will form a part of the stock, and all the backgrounds will have to be ground to prevent the stock from falling.

When punching, as shown in Fig. 10, the hole is started by boring the work flat on the anvil and driving the punch almost two-thirds through it. The work is then turned over and the punching is continued from the other side. The hole can be located easily by the bulge in the metal caused by the punching already accomplished. When the punch is driven through, the work is held directly over the round hole, as illustrated in Fig. 10. If the hole is punched in this manner it is left clean and to size.

When punching thick stock, after the punch is started the rod is removed and the hole filled with powdered coal. This prevents the punch from welding. Tools of this kind are tempered and they should never be left in the heated work any length of time, as the end will become soft and will enlarge in the hole, which makes it nearly impossible to withdraw it. This enlargement is called "pitting." The size of these tools is determined by the size of the hole which the punch will make.

When an irregular shape, such as is shown in Fig. 11, is to be forged, it is necessary to take a pair of hollow-bit tongs and heat the short to a bright red. The jaws of the tongs are then forged to fit the piece of stock which is to be held. Sometimes the rivet in the tongs tightens up in this operation. This may be relieved by first cooling the tongs and then delivering several blows with the head of the hammer on the head of the rivet, which is held over the harden part of the anvil.

The best method of holding square stock is shown in Fig. 12. The tongs have been heated and hammered to fit the stock. In holding stock it is important that the tong jaw fit throughout its entire length. This type of tong is used to hold round stock as well as square. In holding the larger sizes of stock a link can be slipped over the handles. This will relieve the workman from the work of gripping the tongs tightly and allow him more freedom in handling the material.

When welding a head on the end of a rod to make a bolt, the stock is held in the hollow-bit tong, as in Fig. 13. The tong jaws should fit down on the stock snugly so as to insure easy handling of the piece while it is being forged. To make a special bolt, first cut the stock to length, then heat and round up the end of the stock, fit on the blank nut and then weld the nut and rod together. After this operation is complete, cut the thread and the bolt is complete. Using the proper tongs for a welding job of this kind makes the operation much easier and insures a better weld.

The link tong, shown in Fig. 14, is an essential when welding chain links. It is made in such manner that its jaws can be heated and fitted to the link that is to be welded, for only a well fitting tong will hold the link securely. When heating the link to a welding heat, hold it in the fire with a small rod until that heat is reached. The link tongs should be used only to remove the piece from the fire when the weld is to be made and

FIG. 14—SPECIAL TONGS MUST BE USED FOR LINKS
These tongs are carefully fitted to the link that is to be welded. They are not used to hold the link in the fire because they would get too hot. When the broken link is at the right heat, it is seized by the tongs and rapidly hammered into a continuous ring.

FIG. 15—FORGING THE HANDLES FOR READY HOLDING
Sometimes when the tong jaws are not properly offset the handles are so far apart near the ends that no human hand could grasp them. In that event the handles must be bent so as to correct that failing. The illustration shows this being done.
In bending a short piece of steel to make a wagon-bed brace the stock is held while being heated and forged with the flat-jawed tongs (see Fig. 15). These tongs are made in various sizes to hold different thicknesses of stock. In using tongs the handles should be far enough apart only to permit the smith to grip the handles without unnecessary reach. When the tong jaws are not sufficiently offsetted and so are too close together for the stock to be securely held the handles are so far apart that it is impossible to hold them with one hand. This can be adjusted by placing the tong handles on the horn of the anvil as close to the rivet as is permissible and bending the handles to the center until the proper distance is obtained.

When forging a short piece of stock it should be securely held if the best results are to be obtained. The box tongs shown in Fig. 16 are found useful in many repair jobs, as they are designed to hold square or round stock so that it will not slip when being forged. It is important always that tongs should have and maintain a firm hold on the material forged.

Suggests Standard Shatter Test for Coke

COMPARISON between the strengths of coals and the determination of the strength a coke must have to serve for certain purposes make it necessary to standardize the shatter test. To this the Committee D-5, on Coal and Coke, of the American Society for Testing Materials, of which W. A. Selvig, of the U. S. Bureau of Mines, is secretary, has addressed itself.

The committee suggests that the box for holding the coke in this test shall be 18 in. wide, 28 in. long, approximately 15 in. deep and shall hold about 50 lb. of coke. It shall be supported above a rigidly mounted cast-iron or steel plate not less than 1 in. in thickness, 38 in. wide and 48 in. long. The inside of the bottom of the box shall be 6 ft. above the plate.

The bottom of the box shall consist of two doors hinged lengthwise and latched so that they will swing open freely and not impede the fall of the coke. Boards about 8 in. in height should be placed around the plate so that no coke will be lost. To prevent breaking the material when filling the box, the latter shall be constructed so that it can be lowered to a convenient level, which is best done by means of a pulley and counter-weight. For determining breakage of coke, square-mesh screens with the following openings shall be used: 2 in., 1 1/2 in., 1 in. and 1/2 in. Circular screens 2 ft. in diameter are satisfactory for this purpose.

For byproduct coke when determining its freedom from breakage in handling, about 75 lb. of representative pieces of coke, none of which would pass in any position through a 2-in. square-mesh screen, is to be selected from the coke wharf for each test. This is best accomplished by dividing the coke on the wharf into approximately equal areas and selecting an equal number of pieces from each area. Each piece selected shall be approximately equal in length to one-half the width of the coke ovens and should show a "cauliflower" and produced at the walls of the ovens, and an "inner" end produced at the center of the ovens.

For beehive coke, when determining freedom from breakage in handling, about 75 lb. of representative pieces of coke shall be selected for each test as the coke is drawn from the ovens. This is best done by selecting full-length pieces, or their equivalent, as the coke is being drawn from previously determined points in the oven, so that they include pieces from the front, sides, center and back. If the individual pieces as taken from the ovens are too large and bulky, the 75-lb. sample shall be collected by removing three small pieces from each large piece—one from the top, the middle, and the bottom. The sample finally collected should be composed of an equal number of pieces showing top, middle and bottom. None of the pieces comprising the sample shall in any position pass through the 2-in. square-mesh screen.

For byproduct and beehive coke, when determining their fitness for furnace or cupola use, the sample is best collected as the coke is delivered from the railroad cars into the bins. This may be accomplished by inserting a scoop of 10 to 15-lb. capacity in the coke stream at regular intervals during the period of unloading. The sample collected shall be large enough to give about 75 lb. of coke pieces, none of which would pass in any position through a 2-in. square-mesh screen.

As it is difficult to collect a representative sample from coke exposed in bins and cars, care should be taken to take pieces representing the entire exposed area, if sampling must be done in this manner. This is best accomplished by dividing the exposed surface to be sampled into approximately equal areas and selecting an equal number of pieces from each area. Approximately 75 lb. of representative pieces, none of which would in any position pass through a 2-in. square-mesh screen, shall be collected.

About 50 lb. of the sample shall be placed in the shatter-test box, the coke leveled, the box raised, and the coke dropped four times on the plate, the small material produced being returned each time to the box with the large coke. After the fourth drop the material shall be successively run through the screens described.

In screening, care should be taken to prevent breakage of the coke pieces. The screen shall be shaken gently until all of the pieces are in direct contact with the meshes. The coke remaining on each screen, and that which passes through, shall be weighed separately. If the sum of these weights shows a loss of more than 1 per cent the test shall be rejected and another made.

As the average probable error of a single shatter test is approximately 2 per cent it is advisable to make several tests and report the average result.
Gear Economics Effected by Use of New Tooth Shapes*

By E. B. BOWTIELE

From many years stress was laid almost exclusively on improvements in the quality of the steel used in locomotive gears, but in recent years more emphasis has been laid on tooth shape and on the possibility of constructing better gearing through appropriate design. Any fault of incorrect profile will give satisfactory service when new, but we must concern ourselves mostly with the service that the tooth will afford when, in course of time, its face is partly worn.

Until recently practically all locomotive gears had the Brown & Sharpe 141-deg. standard tooth, which operated smoothly, was of a full depth and therefore had more wearing surface than the stub teeth. Being comparatively straight-sided, it showed less tendency to push gear and pinion apart. This 141-deg. tooth is a general standard, easily interchangeable and almost universally used for industrial machinery. The chief objection to it is the fact that when pinions thus formed have a small number of teeth the teeth are undercut in the flank, making them thin and likely to break near their roots. Furthermore, this fault, objectionable as it is in new teeth, tends to accentuate as such pinions wear.

The first improvement used in the railway field was the 23-deg. stub, a tooth which is not so deep and which, therefore, gives the teeth on the opposing gear less leverage at the root of the tooth if driven or by which it is driven. It has accordingly less tendency to break, its sides, moreover, are more slanting and it is provided with a broader base. A 23-deg. stub tooth, therefore, has great strength and, because of its lesser depth, the pinion is strengthened somewhat against bursting, particularly where the bore is large and the pinion small.

The next development was the long- and short-addendum tooth, a type of gearing that for years has been used extensively for railroad service in European countries, particularly Germany and Switzerland, and has been adopted in America for many years in bevel and automotive gear. For application to the electric-locomo-
tive field it was desired primarily because it lacked interchangeability with teeth cut to the old standards.

This type of tooth usually is made with a 20-deg. angle, which broadens the base and increases the strength. Furthermore, by shifting the adden-
dum, one can get teeth, usually the weaker member of the train, in considerable strength added, and this is done without weakening the gear. In making the diameter of the pinion correct the quantity of metal between the root of the tooth and the bore is increased and then it is strengthened at a point where it is most needed, and least be worn. This type of tooth when cut deep or rather thin at the top, and not unusually for this the tooth is some-
times stubbed. The stubbing process removes metal that would otherwise be worn away in service, hence it has a tendency to decrease the life of the pinion, but it makes a more pleasing appearance.

To understand the significance of the long- and short-addendum tooth, we will need to go slightly into theory. The involute curve is the base of practically all our modern gearing, as it represents the ideal curve of contact when two gears are in mesh. Fig. 1 shows three left-hand involutes generated from the same base. The section between the right- and the left-hand involute is a gear tooth, needing only to have the top trimmed off and the bottom shaped up to continue into adjacent teeth.

The farther apart the involutes, the coarser the pitch and the less teeth in a gear of any fixed diameter. The full involute, however, is too long for practical use, so a section is taken out of it for the individual gear tooth. If this section is close to the base circle, as at A, Fig. 6, we have practically the straight-sided tooth of very low pressure angle, which is used where there must be no thrust between gear and pinion. Coming up higher on the curve, as at B, we have the 141-deg. pressure angle, heretofore standard. Higher up, as at C, we have the 20-deg. tooth, and to illustrate by an extreme case, as at D, we could build a gear with about a 30-deg. tooth and yet one which would work smoothly but with a heavy thrust and which would be of no value at all when considerably worn or used with bad bearings. High pressure angles therefore mean forming a tooth on the upper part of the involute curve, farther removed from the base circle. In a gear with many teeth slight changes in pressure angle are hardly measurable, but in a pinion with few teeth they are quite noticeable.
