University of Toronto

1922

Introduction

THE Third Edition of the COAL CATALOG is issued in response to a continued demand for the book. The Second Edition, brought out in 1920, reached a circulation of twice that of the First Edition, which appeared in 1918, while, for the present edition, we feel confident in predicting a distribution of at least 7,500 copies, or triple the number of books published in 1918. This steady increase in circulation attests the value of the COAL CATALOG, not only as a reference work on coal, but also as a publicity medium for those wishing to acquaint the public with the quality of their output or service.

The COAL CATALOG, in three years, has become a standard reference for the producer, seller and consumer of coal. The information it contains as an every-day help to those concerned with the fuel problem, and an examination of the new and revised material in this issue, will bear out the statement that the new volume is of even greater value than its predecessors.

One of the new features is the colored maps, which have been substituted for the outline maps of the several mining states east of the Mississippi river. These maps now make it possible to locate all the principal towns, cities, rivers and railroads, and, in addition, show the boundaries of the coal areas and the geographical limits of the coal fields as fixed by the United States Geological Survey.

The export situation is dealt with fully and in this section are also given the various pools as used at the three Hampton Roads exchanges, together with definitions and list of mines in each pool. Maps and illustrations have been added as a means of impressing the magnitude of the export trade and its possibilities.

A topical index is another of the useful improvements and will aid in finding quickly the information desired. An index of coals, with list of pages on which will be found either descriptive matter on the coal in question, as well as the names and addresses of dealers in same, is also included. In this index will likewise be found listed items or activities having a direct relation to the production or consumption of coal.

Some of the articles in this edition have been entirely rewritten, while nearly all have been revised and enlarged wherever material of value was applicable. Illustrations of an explanatory nature have been inserted in a number of instances. More data are included in the table of Fusibilities of Coal Ash, Analyses of Foreign Coals, Supplementary Analyses, following the various states, List of By-Product Coke Ovens, Etc.

The Directory of Coal Mines, which follows each state, gives a list of operations with such information on each as the purchaser of coal might desire to have. The Directory is the result of 20 years experience in the gathering of statistics in this field, and, while we believe it to be the most dependable information on any of the larger industries, it, nevertheless, is subject to error and change, and cannot be guaranteed.

In the selection of material here presented hundreds of publications have been consulted, consisting principally of reports of the various state mining departments; state geological surveys; reports of the United States Geological Survey; bulletins, pamphlets, etc., of the Bureau of Mines; proceedings of the various mining institutes; books on the coal resources of the country and articles in technical and trade papers. The descriptive matter has been largely compiled from these and we trust that due acknowledgment has been made in each case.

KEYSTONE CONSOLIDATED PUBLISHING COMPANY.

Joseph J. Vigneau, President.

E. B. Day, Vice President and Eastern Manager.

Ralph C. Becker, Vice President and Western Manager.

E. N. Zern, Mining Engineer and Editor.

HOW TO USE THE COAL CATALOG

Since the COAL CATALOG is strictly utilitarian in purpose, a few words of direction in its use will not be out of place.

Finding a Coal for a Particular Use. Let us suppose that a manufacturer of tile and pottery ware in Louisville, Ky., is in search of a coal fitted for kiln burning. The first step is to read the requirements of a coal for this purpose, as mentioned under the head of Tile and Pottery Burning in Part II. Immediately following the discussion we find a list of seams which, by virtue of their chemical composition, are well adapted, in some or all localities, for the purpose. It will be readily apparent that some of these seams are located at a prohibitive distance, and such, naturally, will be eliminated. Let us assume, then, as remaining for consideration, the following coals: Practically all the seams of eastern Kentucky and southwestern West Virginia; the Quakertown and Sharon seams of Ohio; the No. 4 and Block seams of Indiana; the No. 2 and No. 6 seams of Illinois.

Information will now be wanted on each of these coals, and, to obtain this, we will be guided by the page references at the head of the tabulated list of seams. The first reference is to a description of the seams, where will be found information on the thickness of each bed, its physical properties and its general analysis. The second reference is to the list of supplementary analyses, by the aid of which it is possible to select such localities as offer the most favorable coal from the standpoint of chemical and thermal value. The third reference is to the list of operations which enables the selection of all mines at or near the localities previously decided upon as offering the most favorable coal. The fourth, and last, reference is to the DIRECTORY section, where will be found, alphabetically arranged by companies, detailed information on each mine, such as the names of operating officials, sales agencies, size of mine, tippie equipment, railroad connections, etc., etc. By a process of elimination, based on freight rate and quality of coal, the consumer or sales agency is thus enabled to prepare a select list of mines qualified to supply the proper grade of fuel.

It must not be presumed that, because a seam is listed as capable of producing coal for a specific purpose, for instance, the one just mentioned, Tile and Pottery Burning, that all mines operating in this seam can supply a fuel meeting the requirements. This would be true only provided that each seam analyzed the same throughout its entire range, a condition which is rarely satisfied. Volatile matter, sulphur, ash and thermal value, the four factors which determine the suitability of coal for kiln burning, will be found to vary considerably in each seam dependent upon locality, though variations are usually gradual from place to place. For this reason, the list of supplementary analyses should always be replied upon to point out the localities producing coal suitable to the needs. Once this locality has been determined, it is a fair assumption that mines in the vicinity will yield approximately the same quality of coal.

The illustration here given of one service possible with the COAL CATALOG will serve to indicate how the same information may be derived, no matter for what the coal is intended. Public utilities operating gas retorts, metallurgical plants using coal in reverberatory furnaces, cement industries, users of powdered coal, in short, any industry requiring coal, whether for ordinary or for special purposes, will, by following the procedure as above outlined, find the COAL CATALOG an instrument for its location.

HOW TO USE THE COAL CATALOG--Continued.

Determining the Fusion Point of Ash in Certain Coals. An industrial enterprise, let us assume, wishes to know the fusion point of ash in a coal mined from the Lower Hartshorne seam in Pittsburg county, Oklahoma, neither the mine nor the town where the coal is produced being given in the Table, Fusibility of Coal Ash by States and Seams. By referring to this table, it will be noted that the lowest recorded softening temperature of coal taken from the Lower Hartshorne bed at five localities in Pittsburg county is 1980 deg. F., and the highest is 2120 deg. F. The average of all readings is 2034 deg. F., which differs only slightly from the average of the bed throughout the three counties. It follows that an assumption of 2030 deg. F., supplies the desired information and should be correct to within one per cent, no matter what part of the county the coal is from.

Tidewater Pool Lists as an Additional Classification. Inasmuch as chemical analyses and heat value enter largely into the arrangement of mines by pools, at the three Hampton Roads exchanges, there results a classification which serves to define the quality of coal, not only for the pool, but for each mine within the pool. This method of classification approaches closely to the ideal and may be regarded as the forerunner of classifications which will, in time, embrace all the coals of the United States.

Compiling List of Main Offices in Cities. We are asked, sometimes, concerning a list of coal company offices in the principal cities of the country, and the suggestion is made that this information would be useful to the trade. The answer is that, if such a list were inserted for all principal cities and towns, it would require much space, and, further, that it is readily obtainable from the COAL CATALOG, as it is. By turning to the List of Mines by Seams, which follows each state, it will be found that the general, or main, office address is given for each company listed. By scanning this column for all seams and all states, each company having its general office in the city in question may be marked and a list compiled from these.

Tracing Shipments to the Mine. The retail coal dealer is often partial to a certain coal from a certain mine and if, for any reason, he should notice a falling off in quality, or receive complaint from a customer, he may be inclined to doubt whether his pet brand was shipped him. An instance such as this has recently come to our attention where the retailer, in transmitting his order to the sales agency for two cars of his favorite coal, winds up with the following postscript (names have been changed): "Do not ship me anything but Jumping Jack coal from No. 1 Mine, shipping point Nemo, Ky., drift 48-inches thick. R. V. Winkle, Supt." Even were the agency so disposed, it would be difficult to work off an alien car on one who uses his COAL CATALOG so effectively.

Coal Field Directory. The uses to which the DIRECTORY may be put are well understood, being mainly to supply details on a company and its mine or mines. Where steam or domestic coal is wanted, that part which states the equipment in use at the mine for preparation, and the various sizes shipped, will be found especially valuable.

Advertisements In the COAL CATALOG. In this issue, advertisements will be found following the discussion of coals in the various states, and also in the sections on Sampling and Composition of Coals (Analysis), on Coke, and on Export Coals. In every case where advertising follows descriptive matter, it will be noted that the advertisement is likewise descriptive, although not to the extent of excluding sales or institutional matter. On these pages, however, descriptive matter predominates and the advertisement, therefore, becomes an addition to the general information of the section.

The advertisements in the Sales Section of the COAL CATALOG state the coals in which the agency specializes, service features, shipping facilities, etc., and, in many instances, a commendable addition is in the form of institutional data. The information on coal throughout the book, and the pages in this section, are naturally complementary. The sales information on these pages makes them of equal value to the users of the COAL CATALOG as the descriptive pages. Both classes are direct aids to those having to do with the sale or consumption of coal, and, as publishers, we will greatly appreciate mention of this book in every instance where the advertising pages have been of service. Merely add to your inquiry, "Score one for the COAL CATALOG."

GENERAL INDEX OF CONTENTS

PART I.

Divisions of Geological Time	17
Geology of Coal	18 to 36
Explanation of Geological and Mining Terms	37 to 40
Divisions of Coal Areas of the United States	41
Map of the Coal Fields of the United States	42
Preparation of Coal	43 to 51
Storage of Coal	52 to 64
Coal Sampling	65 to 68
Composition of Coal	69 to 74
Buying of Coal on a B. T. U. Basis	75 to 79
Fusibility of Coal Ash	80 to 112
Coke	117 to 120
List of Coke Ovens in the United States (other than By-Product)	121 to 124
List of By-Product Ovens in the United States	125
Export of Coal	138 to 149
Coal Exchanges and Pools	150 to 157
Tidewater Coal Exchange, Inc.	162 to 164
Newport News Coal Exchange, Inc.	165 to 172
Lamberts Point Coal Exchange	173 to 181
Sewalls Point Coal Exchange	182 to 184
Specific Gravity of Coal	185 to 193
Analyses of Coals in Alaska and Foreign Countries	194 to 205

PART II.

Classification of Coals According to Rank	207 to 215
Classification of Coals According to Use	216 to 237
Classification of Coals According to Physical Structure	238 to 240

PART III.

Alabama	242 to 264	New Mexico	581 to 590
Arkansas	265 to 273	North Dakota	591 to 599
Canada	274 to 280	Ohio	600 to 654
Colorado	281 to 305	Oklahoma	655 to 671
Illinois	306 to 371	Pennsylvania Anthracite	672 to 699
Indiana	372 to 417	Pennsylvania Bituminous	700 to 870
Iowa	418 to 435	Tennessee	871 to 892
Kansas	436 to 447	Texas	893 to 904
Kentucky	448 to 532	Utah	905 to 914
Maryland	533 to 545	Virginia	915 to 940
Michigan	546 to 556	Washington	941 to 955
Missouri	557 to 569	West Virginia	956 to 1154
Montana	560 to 580	Wyoming	1155 to 1169

PART IV.

List of National and Local Organizations	1170 to 1177
List of Sales Offices	1178 to 1197
Display Advertisements	1199 to 1350

PART ONE

Divisions of Geological Time *

Geology is the history of the evolution of the earth and its inhabitants as written in hieroglyphics upon the rocks.

Like the history of the human race, this earth history is divided into certain periods, each marked by a change in the animal and plant life, as is evidenced by the fossil remains found in the rocks. The study of these fossils, which is embraced in the science of paleontology, shows that through the countless ages required for the deposition of successive formations, there have been numerous and widespread changes.

In the diagram, different rock systems are placed one on top of the other. The primary divisions, or eras, are five in number, beginning with the Eozoic, in the Archean or Primary or Laurentian system of rocks (not shown on the diagram); (2) Paleozoic, in the Paleozoic, or sometimes called transition system of rocks; (3) Mesozoic, in the Secondary system; (4) Cenozoic, in the Tertiary and Quaternary systems; (5) Psychozoic, in the present system of sediments.

A further division of the history of the earth is by ages, some of which are subdivisions of the eras, while others correspond thereto. When as subdivisions, the ages are separated usually by unconformity and by changes of organisms: They are: 1. Archean or Eozoic age, corresponding to the Eozoic era. 2. Age of Mollusks, or age of Invertebrates, corresponding to the Silurian system of rocks. 3. The age of Fishes, corresponding to the Devonian. 4. The age of Acrogens, or age of Amphibians, corresponding to the carboniferous strata. 5. The age of Reptiles, corresponding to the Mesozoic era and Secondary rocks. 6. The age of Mammals, corresponding to the Cenozoic era and the Tertiary and Quaternary rocks. 7. The age of Man, corresponding to the Psychozoic era and the present sediments.

The further subdivisions of time, known as period and epochs, are founded on more local unconformities and especially of less important changes in the species.

It must not be assumed from the generalized section that all formations are horizontal nor that the order as shown is universal nor even having a wide application. It is rather an ideal section in which the various formations are represented in chronological order. In some localities many of the formations may be entirely absent; in others they may be represented either much or below their normal thickness.

*Diagram from "Coal Fields of America," Macfarlane.

GEOLOGY OF COAL

Treats of the Vegetable Origin of Coal and the Various Theories Put Forth to Explain the Manner In Which Plants Were Accumulated; Combined Oil and Vegetation Theory; Climate of the Carboniferous Age; Formation of Anthracite Coals; Cannel Coal; Erosion of the Coal Measures; Correlation of Coal Seams.

The science of geology offers few problems more attractive than a study of the formation of our vast coal deposits. The methods which Nature used in storing away in the innermost folds of the earth such inconceivable amounts of energy as represented by our fuel beds are not entirely clear, although patient research on the part of geologists, botanists, chemists and palaeontologists has revealed some of the processes by which these wonderful accumulations of mineral wealth have been brought about.

That there is a lack of unanimity of opinion on some phases is not surprising. Investigators are generally agreed on the fundamental conceptions, such as, for instance, coal being the remains of vegetation, that the deposition of this vegetation took place in remote ages and that the original deposits have since been subjected to the modifying influences of time, heat and pressure. On other phases there are decided variances of opinion, thus, the manner in which the masses of vegetation accumulated; whether it be vegetation which grew in situ or whether it consisted of drifted material; whether the vegetation of the Carboniferous period was massive or whether small; whether all coal beds, be they lignite or anthracite, began as peat deposits; how devolatilization of anthracite seams was brought about; the length of time required for the formation of coal beds, etc., etc. These details have all produced opinions more or less in conflict. The entire range of the subject has been well covered by the many able investigators who have given much time and thought to the problem, and it is believed that a presentation of their views on this interesting topic will serve the purpose of this book and help the seeker of knowledge to a better understanding of the processes by which Nature established our bountiful coal resources.

We quote first from the series of Lectures on Coal by Professor Joseph Le Conte:*

THE ORIGIN OF COAL

"It is now universally admitted among geologists that coal is entirely of vegetable origin. There was a time, however, and that not many years ago, when the vegetable or mineral origin of coal was a question warmly contested by the best geologists; but its vegetable character is now so firmly established and so universally admitted that the history of the controversy has lost its interest. I will not, therefore, tire you with its details, but proceed to state the evidence upon which the universal belief is founded.

"First, then the enormous profusion of fossil plants, in the form of impressions of leaves, trunks and branches of trees, fruits, etc., found in immediate connection with a coal seam, affords strong

presumption in its favor. In the second place, this presumption is strengthened, and becomes, in fact, almost certainty in the case of trunks of trees retaining their external conformation, and under the microscope their internal structure even to the minutest sculpturing upon their cell walls, and yet turned to perfect coal. It might possibly be objected that it may be a substitution of one substance for another, similar to what takes place in

Fig. 2. *Stigmaria ficoides* (one-fourth natural size). (Nicholson's Manual of Palaeontology.)

petrification, where we find, also, the external conformation and internal structure perfectly preserved, but the organic matter all gone, that the ancient trunk having been buried in bituminous matter and thoroughly impregnated therewith, as particle by particle the woody matter was removed by decomposition the bituminous matter took its place, and thus perfectly imitated its structure. But this objection is forever set aside, when, in the third place, we subject even the most structureless coal to microscopic scrutiny. The distinguished American microscopist, Professor Bailey, of West Point, has been able to detect the unmistakable evidences of vegetable structure even in the hardest anthracite. In fact, it may be affirmed that there is no coal which, under careful examination, will not reveal a vegetable structure.

"Coal is supposed to be composed principally of the remains of four families,

viz: Ferns, *Sigillariae*, *Lepidodendrons*, and *Calamites*. The abundance of individuals belonging to these families is so great, and their size so enormous, that they must have given character to the vegetation of this period, and may therefore be taken as representatives of its flora."

Fig. 3. Fragments of *Sigillaria Graeseri*. (Nicholson's Manual of Palaeontology.)

*This and all subsequent quotations from Le Conte are from his Lectures on Coal as contained in the Smithsonian Institute Report, 1857.

The vegetable origin of coal, as Professor Le Conte states, is now seldom disputed, though to the practical miner it has ever been a mystery that, in view of the abundance of plant remains so manifestly required, there has been so little visible evidence of organic material in the coal, for in the coal itself we see, with unaided eye, no evidence of vegetation—no trace of leaf or stem.

Dr. James Macfarlane* recognizes this fact:

"Therefore, as to the composition of the coal-slates, you must disbelieve the evidence of your own eyes to deny the presence of vegetable matter, where they had their origin, for you see in them the daguerrotyped likeness of plants, leaves, roots, trunks and branches. But, as to the coal itself, the evidence to the naked eye, of its vegetable nature, is not apparent, as it does not show impressions of plants like the slate-rocks."

Fig. 4. *Pecopteris elliptica* (natural size). Frostberg. (Sir C. Lyell's Elements of Geology. J. Murray.)

Le Conte seizes upon this very point to sustain his theory of the manner in which vegetation has been deposited, as we shall learn later:

"I have already said that a coal seam is made up of the remains of plants, yet it is not in the coal seams themselves that we find the best preserved specimens of coal plants. On the contrary, the vegetable matter is here so thoroughly disorganized that it is only by means of the microscope that we are able to detect its original structure. It is rather in the associated shale strata that the beautiful impressions occur, particularly in the overlying black slate. Between the thin sheets of this slate the stems and leaves are as perfectly preserved, every vein and nerve, as between the leaves of the botanist's herbarium. This fact, viz., that the well-preserved plants are always found in abundance in this position, and never in the coal seam proper has, as it seems to me, an important bearing upon the theory of coal deposit."

But an additional cause of distrust arises to confound such as waver in their allegiance to the vegetation theory, this being the silicified condition of such logs or stumps as happen to be found entirely within the coal. If coal be derived from woody material, they question, how does it happen that all stumps or trees found are either entirely petrified, or else with the bark carbonized and the trunk silicified? Why this discrimination against the one fossil remain possible to recover in easily visible form?

Fig. 5. *Caulopteris primaera*. (Sir C. Lyell's Elements of Geology. J. Murray.)

uncommon occurrence: "A rare specimen of petrification, a stump, found in one of the Pike county coal mines near Whitesburg, Ky., has been shipped to Washington, where it will be placed in the

Fig. 6. *Odontopteris Schlotheimii*. (Nicholson's Manual of Palaeontology.)

Museum of Natural Science. The stump, weighing about a ton, appears to have been of oak. It is in perfect condition and can be easily distinguished, there having been little decay since the hardening process began thousands of years ago. One of the miners found the curio, and after much effort the stump was worked out of the solid body of coal."

Such findings are often reported from the lignite fields of the western states; thus, in a report on the Coals of Custer National Forest, Montana,† we observe that:

"Silicified logs were noted in many of the coal beds. Some of these logs appear as slabs representing but about one-third of the original trunk, the upper side being flat and the lower conforming to the shape of the original log. In some places the logs when partly decayed were undoubtedly crushed and flattened by the load above them, but it is possible that in others as the log lay in the bog the upper portion turned to coal while the lower under different conditions was silicified."

Leaving this phase of the question as one on which more light is needed, we may well inquire into the methods which Nature used in collecting these enormous masses of vegetation which later were to be metamorphosed into our

Fig. 7. *Calamites Canadensis*. (Nicholson's Manual of Palaeontology.)

*This and all subsequent quotations from Dr. Macfarlane are from his Coal Fields of America.

†Carroll H. Wegemann in Contributions to Economic Geology 1908, U. S. G. S.

The following news clipping refers to this not

productive coal beds of today. There is no point connected with coal which has been more discussed, some geologists holding that coal has resulted from vegetation which grew in situ, others that plants were drifted in the forms of rafts to great distances and deposited at the mouths of rivers. The former belief is called the "peat bog theory," the latter the "estuary theory."

PEAT BOG THEORY

Quoting again from Le Conte's lectures:

"It is well known that in many countries, particularly in moist, cool climates, and damp, low grounds, certain plants, such as ferns, mosses, etc., as well as trees which delight in moist places, if allowed to grow undisturbed from generation to generation will, by their decay, accumulate enormous masses of carbonaceous matter. Such a spot is called a peat bog. The theory of this accumulation is as follows: Plants derive all their carbon from the atmosphere. In the annual fall of leaf, and finally their own death, they return to the earth the whole of the matter thus silently extracted from the air. Undisturbed vegetation, therefore, constantly enriches the soil by adding to it what has been taken from the air. Thus worn-out lands improve by lying fallow. Thus the rich black vegetable mould found covering the ground in forests continues to increase from year to year. In all ordinary cases, however, there is a limit beyond which this accumulation will not go. By decomposition the organic matter is again returned to the atmosphere as fast as it accumulates. But if by any means this decomposition is prevented, the organic matter accumulates indefinitely. This is precisely what takes place in peat bogs. The presence of water in a great measure prevents the oxidation of the carbon. The growth of plants now continually takes carbon from the atmosphere, their death as continually deposits it upon the earth. Each generation rises, phoenix-like, from the ashes of the last, to become in its turn soil for the next. Thus the ancestral accumulation continues to increase, the funeral pile continues to rise, until pure carbonaceous matter may in time accumulate to the depth of thirty or forty feet. Such a mass of carbonaceous matter deprived of its water and compressed to the density of coal, would make a seam of perhaps three or four feet in thickness. Now, according to the peat bog theory, it is under such circumstances that the carbon of a coal seam has been accumulated.

"The arguments in favor of this theory are:

"1st. The purity of the coal. It is true that coal is often found largely mixed with earthy matter or mud. As we well know, every stage of gradation may be traced between pure coal and pure shale. But by far the larger portion of coal seems to be entirely free from foreign matter. The amount of ash is not greater than five to ten per cent; that is, not greater than might arise from the earthy matter of the plants from which the coal was derived. This purity of the coal indicates complete absence of sediment in the water in which the coal was originally laid down. Now the water of peat swamps, though discolored by organic matter in solution, is always entirely free from sediment. In fact, this seems a necessary condition of the growth of peat plants—an incursion of water containing

mud is fatal to such plants. If then, a coal seam is the result of carbonaceous matter slowly accumulated at the bottom of ancient peat swamps, the purity of the coal is completely accounted for. But if, on the contrary, it is formed by the accumulation of timber carried down to the mouths of great rivers during freshets, it should always be largely mixed with mud.

"2d. The fine preservation of the tenderest and most delicate parts of plants. We have already spoken of the profusion of finely-preserved leaves and entire fronds of ferns in the black slate overlying a coal seam. So perfect is this preservation that large and complex fronds are often entirely unbroken, and even the minutest variation of the leaves as distinct as in the living fern. This fine preservation of tender parts seems strongly to indicate that these leaves had fallen gently from the parent stem, and been preserved on the spot where they fell. It seems utterly inconsistent with the violent action of currents bearing rafts to great distances.

"3d. The position of the finely-preserved leaves, etc., always on the upper surface of the coal seam (roof of the coal mine). Precisely the same is observed in every peat swamp. The perfect leaves are to be found only on top, for the plain reason that these are the last fallen, and therefore not yet disorganized. But in the case of accumulations of vegetable matter at the mouths of rivers, there seems to be no reason why leaves should not be entangled in all parts alike.

"4th. Coal, like peat, is composed of completely disorganized carbonaceous matter, containing fragments in which vegetable structure is more distinct. This is not inconsistent with what I have already contended to be the vegetable origin of even the most structureless coal being detectable by the microscope. Plants are composed entirely of cells. Both in peat and in coal these cells are generally separated from one another. The vegetable structure is completely disorganized, but the separate cells still bear unmistakable marks of their origin; the organic structure is gone, but the organic origin is still visible. But if a coal seam was an imbedded raft, it should be composed almost entirely of fragments of trunks, branches, etc., instead of a structureless mass containing only a few such fragments.

"5th. It will be recollected that a seam of coal is overlaid by black slate and underlaid by fire-clay. In the black slate, as already said, are found the finest impressions of leaves and other tender parts; in the fire-clay, which underlies the coal seam, are found imbedded in the greatest abundance the roots of plants, and not infrequently the stumps of trees with the roots attached, precisely as they grow. And, what is still more remarkable and significant, trunks of trees are not infrequently found almost entire, standing erect, with their roots still bedded in the fire-clay, their trunks passing through the seam, and far into the overlying strata of shale and limestone. By means of evidence of this kind Lyell and Dawson have been able to make out distinctly nearly 60 planes of successive vegetation in the coal field of Nova Scotia. In many of these, viz., about 20, the trees are still in the position in which they grew; of the rest the evidence consisted in the imbedded stigmata or roots of sigillaria.

"In cases in which these trunks and roots, in situ, are found (and they are by no means common), the evidence is conclusive that the coal was formed on the spot where the trees grew; in other words, that the growth of the trees and the deposit of the coal took place simultaneously on the same spot.

Face of flattened part at top

Root or stigmara of fossil
tree. See Fig. 8.

Fig. 8. Fossil tree found at a depth of 288 feet from the surface.
(Redmayne, *Modern Practice in Mining*.)

This is clearly impossible in an estuary, but is known to take place in every peat swamp.

"To recapitulate the whole argument: If we examine a peat bog which has been for many years thickly overgrown with ferns, mosses and water plants of various kinds, and shaded by many large

trees, we find the soil composed entirely of black carbonaceous matter, wholly destitute of structure but revealing its vegetable origin to the microscope, containing fragments of trunks and branches of trees lying in all possible positions, some prostrate, some inclined at all angles, many, both living and dead, still erect, their roots firmly fixed in the clay at the bottom of the bog, below the peaty matter which has slowly gathered about their lower parts, and over the whole lie thickly strewn the freshly fallen leaves. Now suppose such a peat bog to be deeply buried beneath the surface of water and overwhelmed with sediment of clay and sand, and again, after ages, elevated and exposed by section to the scrutiny of the geologist, and we shall have a complete reproduction of the phenomena of a coal seam.

"The great, and almost the only, objection which has been urged against this theory is to be found, not in the phenomena of an individual coal seam, but rather in the general phenomena of coal basins, in the repeated alternation in the same locality of coal seams with marine and fresh water strata. We have already seen that there are in the same coal basin sometimes as many as a hundred coal seams, one above the other; now, according to this theory, when the coal seam was forming the spot must have been above the surface of the sea, but when the interstratified limestones and shales were being deposited the same spot must have been beneath the sea-level. Thus, argues the objector, we are driven to the enormous assumption that the same spot has been successively upheaved above and depressed beneath the sea-level one hundred times during the carboniferous period, and, what is still more remarkable, that every time it rose above the sea it became a peat swamp; or if the intervening strata are fresh water instead of marine, the difficulty seems only to be increased."

Dr. I. C. White, State Geologist of West Virginia, is clearly an advocate of the peat bog theory, though differing from Le Conte in his conception of the manner in which the peaty deposits have been kept clean from earthy matter.*

"Of course what is now coal was once peat. These peat bogs were drained by streams, nearly free from sediment because of their flowing over sand and gravel, just like the mountain brooks that we now find in the Alleghanies or in the Blue Ridge region, which, even with hard rains, are rarely found muddy. This probably explains the remarkable purity and freedom from ash of our Middle and Lower Pottsville coal beds, because they are very much lower in impurities than the younger deposits. Except for occasional bony coal, these seams are practically pure, that is, they have no more ash than was contained in the woody material from which they were formed.

"It is quite probable that many plants which entered into the formation of coal were capable of existing in very shallow water, but judging from the evidence now at hand, we conclude that the conditions which obtained at the time of these old peat bogs, which later became our coal beds, were very much the same as we now have in the great Dismal Swamp of Virginia and North Carolina, where there

*Proceedings West Virginia Coal Mining Institute, 1910, page 200.

now is a bed of peat in process of formation. There pure peat is accumulating by the growth of vegetation which covers that region and on falling into the shallow water becomes decomposed. All that the Dismal Swamp region needs now for the production of a future coal bed is to sink below its present level, and then be covered by mud, sand and gravel brought in by the rivers. As these sedimentary strata multiply, pressure is produced on the vegetable mass, and as it continues to sink down farther and farther the heat of the earth pervades it. Thus are supplied both pressure and heat, the two factors which seem to be necessary to the change of peat into coal through the loss of volatile matter."

Macfarlane is definitely aligned with those who recognize the peat bog as the starting point of coal:

"The theory that coal was formed by the drifting of large masses of timber into bays, after the manner of the Red River rafts, now finds no advocates. The material could not have been furnished in sufficient quantity, and disposed in layers of equal thickness, extending for many miles, and so free from mud, sand, or other impurities or foreign substance. Coal of the Carboniferous age, when examined, is apparently never found to be formed of the trunks and large branches of trees. The slate-rocks above the coal were so formed, and it is on account of the size of the trees and plants that they have been converted into slate or shale instead of coal, from the introduction among them of sand, clay and mud. The too great preponderance of earthy matter renders them unfit for fuel, although containing some portion of carbon.

"The opinion now held by geologists is that the vegetation from which coal of the Carboniferous age originated was similar to that of the peat-bogs now found in nearly all parts of the world. The examination of coal does not afford evidence of its having been produced from the flattened trunks or more solid parts of trees, but it abounds in fragments of the leaves, and occasionally extremities of branches and fronds, or leaves of the kind which retain the stalk when they fall off. In anthracite coal the process of liquefaction and carbonization, or perhaps it should be called crystallization, has obliterated nearly all traces of the original vegetable matter; but, as we go farther westward, we find some kinds of bituminous coal which appear to be composed of minute leaves and fibres matted together. Large trunks or branches are not found, but thin layers resembling mineralized charcoal are found between the layers of coal when separated, and the material appears to have been of that soft description which must have flourished either in water or when the land was little elevated above the water, and when the climate was moist and warm. Certainly the vegetable matter must have been immediately covered with water as soon as it was formed, in order to be preserved from the rapid decomposition which always takes place in the open air. Sea-weeds and other marine plants are not found in coal, but the plants are all of the fresh-water species, and it has been confidently asserted by Mr. Lesquereaux that there is no coal with marks of marine origin; and, further, that there is no true peat formed entirely of sea-weed and marine plants, although the sandstone and lime-

stone layers between the seams of coal often contain marine fossils.

"The supposition that coal is a true mineral, formed only by chemical agency, and without an accumulation of vegetation grown on the surface, and buried afterward, is an hypothesis to which Nature does not give the slightest support. The analogy of formation between the peat-bogs of our times and the beds of coal of the coal-measures cannot be called a theory, it is a demonstrable fact. We can now see the coal growing up by the heaping of woody matter in the bogs. After a while we see it transformed into a dark, combustible compound that we name peat or lignite, according to its age. We then see it hardening, either by compression or by this slow burning in water. The oldest peat-bogs in Europe have at or near their bottom some plates or thin layers of hard, black matter that ocular examination or chemical analysis fails to distinguish from true coal. We find, besides, in Holland, Denmark, and Sweden, thick deposits of peat separated into distinct beds, by strata of mud and sand, giving the best possible elucidation of the process of stratification of the coal-measures."

"In Switzerland peat grows at the rate of two inches per year, a thickness reduced to one-half by compression. The trunks of trees embedded in peat are generally first softened before being hardened, as Liebig has proved by direct experiment in the process of slow decomposition, or rather slow combustion, of woody matter in water. Hence the flattening of all the stems found in coal or in the shales."—Lesquereaux.

In Bulletin No. 16, Geological Survey of Ohio, Alfred Dachnowski visualizes the occurrence of Ohio coals:

"The well marked order of arrangement, which the coal fields of Ohio present, suggest that at the beginning of the Carboniferous age, an arm of a shallow fresh water lake extended inland, and continued in an unbroken sheet up to the Cincinnati arch, which made its western boundary. Year after year, for many centuries an exceedingly dense, luxuriant growth of vegetation covered the surface of the shallow basins as scattered swamps and bog-like marshes, sometimes running into a long connected chain, and sometimes quite isolated. The vegetation was doubtless of many kinds of trees, especially giant ferns and clubmosses, with an undergrowth of shrubs and plants like grasses and sedges. There were many minor differences between the vegetation of different basins; zones of predominating lycopods alternating with ferns. The vegetation must have moved into the open water of protected bays and inland basins progressively, as groups, distinct in physiognomy and growth-form, the zones varying in width, with the definite conditions of life, and the selective action of the habitat. The plankton association must have been followed by plants nearer the margin and submerged along the gently sloping shore lines. Free floating forms similar to *Azolla*, *Salvinia*, and to various algae, must have existed in great masses, easily transported by winds and currents, at times completely covering the quiet pools. As their debris formed a slowly rising deposit in the basin, the littoral or shore association must have advanced toward the center of the water basin.

forming a mat of interwoven rhizomes and roots, harboring various societies and layers according to the light and water conditions. In time the basin became filled with this debris. In many cases the vegetation accumulated to a depth of more than fifty feet, but this great distance from the mineral substream or the deficiency of mineral substances never rendered it difficult or impossible for the plants to grow luxuriantly. Green plants utilize water and the carbon dioxide of the air to form food, the starches, sugars, fats, and proteins, necessary to their nourishment, and for the successive phases of a normal development. The mineral soil-constituents are not the food of plants; they are indispensable, but their amount is very small in organic substances, and alone they are incapable of sustaining life in plants.

"Trees standing erect within a bed of coal, their horizontal roots still imbedded in the underlying stratum, the corky bark, the wood, branches, leaves, spores, and fruits of many plants, and even the remains of fossil microorganisms,* fungi and mycorrhiza, have given their testimony of what once existed. Though not reported in the Coal Measures of Ohio, the aggregations, and often large masses of resinous substances, amber, fossil coral, and a multitude of similar substances, by their varying quantities, show the exact character of the vegetation. With the plants were many animals, and where they were most abundant, their fossil remains are found."

Dr. Heinrich Ries cites the Dismal Swamp as a possible present-day analogy to the scenes of ancient days, and suggests subsidence and re-elevation to account for a multiplicity of seams:†

"It is a well-known fact that thick deposits of vegetable matter, often covering areas of several square miles, are formed in the peat bogs that in so many places represent the last stage of lake or pond filling in cool, temperate climates. Each of these bogs would, under favorable circumstances, change to a bed of coal, and some of them are extensive enough to form coal beds of large size. But such bogs are, compared to our larger coal fields, far too limited in area to admit of the acceptance of this explanation to account for great fields without assuming far more widespread bog-forming conditions than any at present known.

"Perhaps the most perfect resemblance to coal-forming conditions is that now found on such coastal plain areas as that of southern Florida and the Dismal Swamp of Virginia and North Carolina. Both of these areas are very level, though with slight depressions in which there is either standing water or swamp conditions. In both regions there is such general interference with free drainage that there are extensive areas of swamp, and in both there are beds of vegetable accumulations. In each of these areas there is a general absence of sediment and therefore a marked variety of vegetable deposit. If either of these areas were submerged beneath the sea, the vegetable remains would be buried and a further step made toward the formation of a coal bed. Re-elevation, making a coastal plain, would permit the accumulation of another coal bed above the first, and this process might be continued again and again.

"In support of the theory that coal was accumulated in some such situation as this, are a

number of facts: (1) the coal beds occur over wide areas in sediments which were deposited near land borders and which may therefore have been again and again raised above sea level to form extensive coastal plains; (2) there are evidences of land conditions revealed in the workings of some mines; (3) the enormous area of some coal fields call for some such widespread conditions as coastal plains might provide; (4) the slight admixture of sediment indicates the absence of conditions of sediment supply, e. g., rivers, waves, tidal currents, and wind-formed currents; (5) vegetable accumulations made in such situations would require but slight changes in land level to be buried beneath sedimentary strata as the coal beds have been."

Dr. David White draws attention to several points of difference between present-day and ancient peat bogs:‡

"The processes of peat formation are essentially the same at the present moment as in the ancient epochs, but not so the general physiographic conditions prevailing in most regions of modern peat deposition. Although coal be recognized as fossilized and transformed peat, and the broad analogies or points of similarity between the formation of the coal and of peat now actually forming be considered, it must be remembered that the conditions of deposition of the coal of our great coal fields differ in some very important respects from those of the peat bogs with which most persons are today familiar. Thus it is recognized, as has been already shown, that the widespread coal of the great coal fields was laid down in vast base-level coastal swamps, most of which were at or not far above tide level, and that in most cases, at least, the substratum on which the peat was deposited was either a sinking subaerial old soil or it was so shallowly covered with water that plants, many of arborescent types, were able to take root in it and grow. The peat bogs of the temperate zones usually cited as illustrations are, on the other hand, generally at varying elevations above the sea and amid varying topographic conditions. They are usually of very limited extent, each bog being isolated. In many cases the bogs are immediately caused by locally obstructed drainage or by topographic barriers. In many regions of glacial topography, from which the greater part of the observations recorded are drawn, they occur as inward growth from the margins of kettle bottoms or small lakes between which high hills may rise, in which cases it is manifest that the understratum will not be an old soil and that the peat will not be regularly bedded nor similar in composition, structure, or thickness in passing out from the shore line. In these bogs parallelism of structure will be found generally only in very narrow concentric strips, and even in these the thickness will be constantly variable."

Reinhardt Thiessen gives his view as to the originating point with all coals.§

"It is now an absolutely established fact that coal is formed from plant substances. How they were formed, whether the plants grew where the

*Renault, B., Recherches sur les bacteriacées fossiles. Ann. des. sci. nat. bot. VIII, series, T 11: 1896, pp. 275-349.

†This and all subsequent quotations from Dr. Ries are taken from his *Economic Geology of the United States*.

‡The Origin of Coal, Bulletin No. 38, Bureau of Mines.

§Proceedings Coal Mining Institute of America, 1915.

coals are located, or whether they grew in other places and were later drifted or floated to the place where they now form the coal, is still debated by some. But to my mind, through my own observations and those of others, there is no doubt that the coal beds were formed in an identical manner as the peat bogs of the present were and are still being formed, that is, the plants grew where the coals are now found. Peat deposits, then, are of an inestimable value in teaching us much as to the composition and formation of coal. The transformation of plant substances into coal is quite another problem, and it is not altogether satisfactorily understood."

In view of the clearness of the testimony in its favor, one might be led to suppose that the peat-bog theory had a unanimous support. Daddow and

where cut off by the streams and such local and subsequent causes.

"Therefore, unless we admit that most of our coal vegetables took root deep in the water, we must assume that all the vast area of over 70,000 square miles was level and one vast marsh, which is in contradiction to all fact and in violence of every natural process that we can conceive, and those who advocate this claim an exclusive arborescent or land prodigies of Nature for every coal-seam existing, in order to reconcile their theory with the facts."

A difficulty in the theory of coal formations of course arises in accounting for the succession of strata overlying the coal bed. These consist of sandstones, shales and limestones. The first two mentioned are of fresh water origin, the latter is a

Ideal View of a Carboniferous Forest and Marsh.

Bannan, however, cannot reconcile the vastness of our coal areas with the theory:

"If we assume the vegetation to have been of the peat, or bog, order, we must admit the whole of the vast area of our Appalachian coal formation to have been level, and the gradual subsidence of the land would then conform, in part, to the requirements of the facts sustaining the theory. But even they who sustain this theory of peat-bog formation require the growth of 1,500 years to form the ten-foot Pittsburg seam.

"Our coal-beds are of vast extent, and we find some of the upper seams existing over 14,000 square miles, without a single break or discontinuation of strata, while, in all probability, the lower seams will be found to underlie the entire Allegheny coal-field, without a positive discontinuity except

salt water formation; the former two imply an inland location, the latter requires propinquity to the sea. The "estuary theory" has been formulated in an endeavor to account for the presence of marine strata.

Hugh Miller graphically describes the primeval scene:*

"We have before us a low shore thickly covered with vegetation. High trees of wonderful form stand out far into the water. There seems no intervening beach. A thick hedge of reeds, tall as the masts of pinnaces, runs along the deeper bays, like water-flags at the edge of a lake. A river of vast volume comes rolling from the interior, darkening the water for leagues with its slime and mud, and bearing with it to the open sea, reeds, and

*old Red Sandstone.

ferns, and cones of pine, and immense floats of leaves, and now and then some bulky tree, undermined and uprooted by the current. We near the coast and now enter the opening of the stream. A scarce-pentrate phalanx of reeds, that attain to the height and well nigh the bulk of forest-trees, is ranged on either hand. The bright and glossy stems seem rodded like Gothic columns, the pointed leaves stand out green at every joint, tier above tier, each tier resembling a coronal wreath or an ancient crown, with the rays turned outward; and we see atop what may be either large spikes or catkins.

"What strange forms of vegetable life appear in the forests behind! Can that be a club-moss that raises its slender height for more than fifty feet from the soil? Or can these tall, palm-like trees be actual ferns, and these spreading branches mere fronds? And then these gigantic reeds! are they not mere varieties of the common horse-tail of our bogs and morasses, magnified some sixty or a hundred times? Have we arrived at some such country as the continent visited by Gulliver, in which he found thickets of weeds and grass tall as woods of twenty years' growth, and lost himself amid a forest of corn fifty feet in height?

"The lesser vegetation of our own country, its reeds, mosses, and ferns, seem here as if viewed through a microscope: the dwarfs have sprung up into giants, and yet there appears to be no proportional increase in size among what are unequivocally its trees. Yonder is a group of what seem to be pines—tall and bulky, it is true, but neither taller nor bulkier than the pines of Norway or America; and the club-moss behind shoots up its green, hairy arms, loaded with what seem catkins, above their topmost cones.

"But what monster of the vegetable world comes floating down the stream, now circling around in eddies, now dancing on the ripple, now shooting down the rapid? It resembles a gigantic star-fish, or an immense coach-wheel divested of its rim.* There is a green, dome-like mass in the centre, that corresponds to the nave of the wheel or the body of the star-fish, and the boughs shoot out horizontally from every side, like the spokes of the nave, or rays from the central body. The diameter considerably exceeds forty feet; the branches, originally of a deep green, are assuming the golden tinge of decay; the cylindrical and hollow leaves stand out thick on every side, like prickles of the wild rose on the red, fleshy lance-like shoots of a year's growth, that will be covered two seasons hence with flowers and fruit. That strangely-formed organism presents no existing type among all the numerous families of the vegetable kingdom.

"There is an amazing luxuriance of growth all around us. Scarce can the current make its way through the thickets of aquatic plants that rise thick from the muddy bottom; and though the sunshine falls bright on the upper boughs of the tangled forest beyond, not a ray penetrates the more than twilight gloom that broods over the marshy platform below.

"The rank steam of decaying vegetation forms a thick blue haze, that partially obscures the under-wood. Deadly lakes of carbonic acid gas have

accumulated in all the hollows. There is a silence all around, uninterrupted save by the sudden splash of some reptile-fish that has risen to the surface in pursuit of its prey, or when a sudden breeze stirs the hot air and shakes the fronds of the giant ferns or the catkins of the reeds.

"The wide continent before us in a continent devoid of animal life, save that its pools and rivers abound in fish and mollusca, and that millions and tens of millions of the infusoria tribes swarm in the bogs and marshes. Here and there, too, an insect of strange form flutters among the leaves. It is more than probable that no creature furnished with lungs of the more perfect construction could have breathed the atmosphere of this early period and have lived."

Ries admits the possibility of a more luxuriant vegetation, but finds nothing to support the estuary theory:

"Streams are bringing plant remains to lakes or oceans and incorporating them in their deltas; but nowhere are such extensive accumulations now forming as to make large coal fields in this manner. Moreover, the amount of sediment brought in such places would seem to exclude the possibility of the deposit of large areas of vegetable matter free from a great admixture of sediment. The combination of marine or fresh-water swamp plants in the delta lagoons would increase the chances of the formation of coal beds by this means; but even with this addition, it seems impossible to accept this as a general theory for the formation of extensive beds of coal."

Professor Lewes† suggests that conditions could not have been uniform throughout the entire Carboniferous period, and concludes that both theories are worthy of credence:

"The vegetable deposits which the action of time, heat and pressure converted into our coal seams have many of them evidently grown in situ, as is shown by the underclay, which is loaded with fossil roots (stigmata). These seams as a rule are found extending over a large area and are generally of a uniform thickness, whilst the strata in which they occur also exhibit the same uniformity.

"Other coal-fields, however, evidently owe their origin to enormous masses of water-clogged drift, which have been brought down by great rivers and deposited in the deeper parts of primeval seas or lakes; seams formed in this way showing no fossil roots in the under strata, whilst the fossil remains of marine life are frequently found in both under and over strata.

"An examination of the seam, however, shows it to consist of not one deposit, but twelve or thirteen; very thin deposits, called 'partings,' existing in between the different parts of the seam. These partings, as the seam is traced northwards, gradually open up into wedge-shaped masses of sandstone and shale, clearly showing that the bed has been formed at the mouth of a big river, and that the various parts of the seam represent great masses of floating vegetable lumber brought down by the stream and probably deposited on the silt

*Since discovered to be the roots or base of the gigantic Sigillaria, which always grows in the fire-clays of our coal beds, and therefore could not float down the river into the coal area.

†This and all subsequent quotations from Dr. Lewes are from his work, entitled "The Carbonization of Coal."

bank at the mouth of the river, and that as it has sunk down owing to becoming denser from partial decay, a fresh deposit has formed over it."

Le Conte points out the untenable assumptions in the estuary theory and then artfully combines the acceptable features of both the peat-bog and the estuary theory into a plausible explanation of the ancient process.

"It is to meet this very difficulty, to account for this remarkable alternation of strata, that the rival theory has been proposed. An estuary is the wide open mouth of a river emptying into a tidal sea; it is occupied sometimes by fresh and sometimes by salt water. The deposit at the bottom of an estuary, in suitable positions, is, therefore, an alternation of fresh water and marine strata. In seasons of freshets the river water, loaded with sediment and perhaps bearing rafts of drifts of timber, forces back the sea water, occupies the estuary, and makes its deposit of clay and sand, containing fragments of such drift timber; in seasons of low water the ocean returns and makes its deposit, perhaps of limestone, and so on alternately. A coal field is supposed by these theorists to be the position of an ancient estuary; the limestone strata are the marine deposit, the shale and sandstone the river deposit, and the coal seam the imbedded drift timber brought down by the river from distant forests.

"The objections to this theory are all that has been said in favor of the peat-bog theory. The pureness of the coal, the fine preservation of even the tenderest parts of plants, the position of such well preserved specimens always on the upper surface of a coal seam, the structureless character of the great mass of the coal, and, above all, stumps and trunks of trees still erect, with their roots still fixed in the clay stratum below—all this seems not only unaccountable but impossible on this theory.

"In comparing these two it will be seen that the peat-bog theory explains completely the phenomena of an individual coal seam, but signally fails to explain the general phenomena of a coal basin, viz: the alternation of coal seam with marine and fresh water strata; while, on the other hand, the estuary theory explains well this alternation, but fails utterly to explain the phenomena of an individual coal seam. There is, then, real and substantial evidence in favor of each, and equally substantial objections. If this had not been the case one or the other would have been relinquished ere this. But we find, on the contrary, that they have both found strenuous advocates from the time geology commenced to exist as a science until now. In every such case of vitality in rival theories it will be found, I think, that there is a real germ of truth in both—that both are true and both are false; both true in some sense, and therefore reconcilable; and both false through narrowness of view, through exclusiveness, through mistaking a partial for a general view.

THE ESTUARY THEORY

"Now, it seems to me that the phenomena of a coal seam already enumerated prove most conclusively that the coal was formed in situ, as in the peat swamps of the present day. At the same time

the frequent alternation of seams with marine and fresh water strata prove also most conclusively that the deposit took place at the mouths of large rivers, and therefore subject to overflows by the river and occasional inundations by the sea. We are to look for analogies in existing nature, not among the bogs of Ireland, but among the river swamps of the Mississippi.

"It is well known that such peat swamps, some of them of enormous extent, exist now on the margins and in the delta of the Mississippi and probably many other large rivers, and that pure peat unmixed with mud is constantly forming in these swamps, although they are annually flooded by the river. This seems at first incredible, when we recollect that the river water is loaded with sediment, and that sediment prevents growth of peat plants, or at least would entirely destroy the purity of the peat. But this apparent anomaly has been entirely explained by Mr. Lyell. According to this high authority, although the peat swamps of the Mississippi are annually flooded by river water they are entirely untouched by river mud. These favored spots are surrounded, particularly on the side next the river, by dense vegetation, which, acting as a sieve, completely strains the water of its mud before it reaches the peat swamp. The water of these swamps is therefore pure, and pure peat has been quietly depositing there for ages.

"Let us suppose that there existed during the Carboniferous period a large river, perhaps less than the Mississippi, but with enormous swamps and delta, overgrown with rank vegetation far surpassing in luxuriance anything we know at the present day. In the midst of such swamps there would evidently occur spots of great extent, the waters of which, for the reasons already mentioned, would never be contaminated with sediment, as at (a) in the figure here shown. Here for untold ages pure carbonaceous matter would accumulate undisturbed. In the course of time the surrounding portions of the swamps (b) where the mud is detained would rise by deposit of sediment, while the peat swamp (a) would remain as a sunken

Fig. 10. Showing estuary conditions under which vegetation accumulated.

country, such as exist now in the swamps of the Mississippi. Finally, at uncertain intervals, a more than usually large freshet, or perhaps some change in the level of the land, would deluge the swamp with mud and bury the peat. Gradually the vegetation would return, and the former condition of things be restored, to pass again through the same changes. We have but one other supposition to make, viz: that the whole river swamp and delta were gradually subsiding during the whole Carbon-

iferous period. This is by no means a violent supposition, but one which we have a right in this case to make for two good reasons: 1st. We have the best evidence that many of the large deltas of the present day are thus subsiding. This is proved in the case of the Mississippi delta by cypress stumps in situ below the level of the sea. 2d. The coal strata themselves give indubitable evidence of gradual subsidence during the period of their deposit. The character of these strata and their fossils shows that they were deposited in shallow water, but their enormous thickness (nearly three miles in Nova Scotia) renders this clearly impossible, unless we suppose such subsidence; for, if the bottom was stationary, it must have been three miles below the surface of the water when the lowest stratum was deposited. Now, if such subsidence went on constantly, but slowly, so that, under ordinary circumstances, the delta could be maintained by deposit from the river, but at uncertain intervals, more rapidly than the river could build up, so that the sea would again usurp possession and make its deposit of limestone, and again more slowly, so that the area might again be reclaimed by the river, and become a peat swamp, and so on alternately, we would easily, without any violent hypothesis, account for all the phenomena of a coal basin.

"It will be observed that by this hypothesis the area of a coal basin has, indeed, been successively above and below the sea-surface, but not by successive upheaval and depression, as it has been supposed necessary on the peat bog theory, but by the contention, with various success, of opposing forces, aqueous and igneous, the river constantly building up, the igneous forces beneath as constantly striving to depress; sometimes one force predominating, sometimes the other. Of such contention we have many instances in existing nature. It is evidently going on in the delta of the Mississippi at the present time.

"It may not be possible, in the present condition of science, to picture to ourselves all the circumstances connected with this process. Perhaps I have already gone too far in this attempt; but the general facts upon which the theory rests are incontestible. Coal has almost certainly accumulated in situ in extensive peat swamps at the mouths of large rivers, upon ground which was slowly subsiding during the whole period. Under these circumstances it seems not difficult to account for all the phenomena of a coal basin. All we have to do in future is by study of the peat swamp of the Mississippi and the phenomena of delta deposit to discover the details of the process, to fill up the outline of the picture.

"There is a fact noticed by Mr. Lyell, which is strongly confirmatory of this theory. In the sandstone of the coal measures it is common to find trunks of trees but only trunks—no small branches, leaves, or tender parts. Moreover, these trunks are observed to be mostly pines, highland trees, while the trunks in the coal seam proper are *sigillaria*, *lepidodendron*, *calamites*—swamp trees. Now, when we recollect that coarse sandstone is the deposit of rapid current, does it not seem evident that the sandstone was deposited by the freshet which overwhelmed the peat swamp, and that the

pine trunks are the remains of drift timber, but how different from a coal seam!"

SARGASSO SEA THEORY

While the peat-bog theory and the estuary theory have, between them, the support of the great majority of investigators on the subject of coal formation, there are those who fail to find in either hypothesis a full explanation to some of the visible phenomena of our coal seams.

Partings bearing from a fraction of an inch to several inches, it is argued, would seem hardly sufficient to sustain a vegetable growth ample to provide the superimposed layer or bench of coal. If it be said that the new growth flourished on the remains of the old, why the lack of visible evidence in the parting? Furthermore, the total absence of a fire clay bottom to some coal seams establishes that there could have been no vegetation growing in situ. If it be assumed that the vegetation was washed in, there will need be combatted all the objections to this theory, which have already been stated. Moreover, no one specific manner of accounting for the alternation of strata is universally accepted, nor is it understood how a mass of loose earth could be spread over the accumulated plant remains without the infiltration of more dirt (ash) into the bed, than is generally found. Le Conte answers by asserting that there, unquestionably, is a commingling of dirt with the vegetation, as is proven by the gradual transition from the top of the coal (roof) down toward the center of the bed, or in other words, that there is a high ash zone at the top of the seam with a steady diminution in impurities in going toward the center. But the testimony of the miner is otherwise. He finds a clean-cut line of demarcation between the top rock and the coal, although, manifestly, the upper portion is higher in ash than the coal lying at the center of the seam. If the transition was gradual, as Le Conte avers, why is it the coal parts so readily from the roof? Isn't this in itself proof that the change from the coal to slate is abrupt?

The sargasso sea theory, according to H. W. Althouse, explains many of these moot points.

"Now, instead of our coal beds having been formed from the remains of plant growth that grew in swamps and bogs, a careful investigation into the causes and study of the formation in the coal period shows that our coal beds were formed from minute and microscopic vegetable organisms that then lived and flourished in those ancient seas, and being deposited over lengthy periods of time, became covered by sediments and other materials that are now found overlying the beds of coal.

"In the warm seas of the earth's past, the vegetable organisms that then lived were of the most primitive and simple character, and as these microscopic vegetable particles perished, they sank and formed an ooze, like that of mud, now being deposited on the floors of the deep seas, and this vegetable ooze is what formed our coal of Carboniferous age."

Dachnowski states his objections to any theory which ascribes salt water origin to the vegetable growth:

"The slight admixture of sediment, which indicates the absence of waves, tidal currents, wind-

formed currents and eroding rivers, and the fact that at present only one kind of tree, the mangrove, grows in salt water, is against the view that the coal was formed in salt water or that the characteristic structure and form of the Coal-measure plants was due to a salt water habitat. No records exist to show that in earlier ages the vegetation of the ocean differed greatly in kind from that now predominating. Ferns and mosses are entirely absent from the ocean; the principal marine vegetation is still formed by algae, often highly differentiated, which belong to diverse orders."

VEGETATION—OIL THEORY

Daddow and Bannan are amazed at current estimates on time and refuse to believe Mother Nature so slothful. The time required to accumulate sufficient plant remains to form a coal seam of even moderate thickness is far too great. Surely something must have been present to act as an accelerator, and this the writers conceive to have been oil. While their theory of coal formation is novel, it nevertheless offers a means for reducing by millions of years the time required by the usual account.*

"We have before stated that vegetable matter may, and in all probability did, aid in producing coal, but, we believe, only to a very limited extent. That vegetation grew luxuriantly during the coal era there can be no doubt; and that it grew in the deep basins in which coal was formed is likewise evident; but that the woody fibre of vegetation formed coal is not only doubtful, but contrary to all evidence, and at variance with the concidents of coal formations. It may have formed the impurities—bone and slate—of the coal, but never its pure carbon. The woody tissue supposed to be detected by microscopic examination cannot be determined in pure coal; and that found, or supposed to be found, in the ashes of coal is no criterion, since if the woody fibre of plants formed any part of a coal-seam it must have been the earthy parts thereof.

"We have rarely seen a fossil plant in the midst of a coal-bed or within the coal, but whenever found in this condition it is not coal, but slate or bone. Coal-plants of the Carboniferous era, in a fossil condition, are invariably silicious or calcareous, and partake of the lithological character of the formation in which they are found.

"But we do not intend to deny that the magnificent flora of the Carboniferous era aided in the production of coal. We believe it did, and have before so stated. That the rich and resinous calamites, coniferae, etc., which were fed by a superabundance of carbon and carbonic acid, should yield oil on pressure, there cannot be a doubt; and that they were subject to immense pressure between the rocky strata in which they now exist is evident not only by their flattened forms, but the fact that the superincumbent strata would exert such an influence and expel the resinous oils which they contained. This oil would mingle with the hydrocarbons, and, by evaporation, form bitumen; and this, enclosed in the strata of the coal-measures and subject to pressure, would produce coal.

"We do not consider any of the vegetable theories tenable. We are now positive of the fact, and state positively that all pure coal-beds are

formed from petroleum or oil, resulting from the vapors of carbon directly or indirectly, as above set forth.

"That a gradual depression of our great coal-basins did take place is not only evident from existing facts, but the natural processes of condensation and contraction. It is not, however, necessary that such must have been a condition to account for the formation of our coal-beds and the accumulation of the accompanying measures, since these beds and the rocky strata in which they exist would form as regularly and uniformly in basins of a constant depth as in those of varying depths.

"The fact, in this case, that coal-beds are invariably thin at a great depth, or more so than they are at moderate depth, is explained by the simple fact that they must have existed originally in a soft and plastic condition, and were, consequently, moved by the great pressure of water and sediment resting on them from the centre of deep basins towards their edges—a fact demonstrated in all deep basins, except that of Richmond, Va., where the irregular form of the intermediate basins prevented such a movement.

"It will be found that no conflict exists in the two theories of coal formation here presented, viz: that of vegetation and that of the condensation of naphtha, but, on the contrary, the one is an auxiliary to the other, and clears up some of the most doubtful mysteries in the practical solution of the question. It enables us to shorten our Carboniferous period some millions of years, and give Nature the credit of a rapid worker and a wonderful chemist, instead of being slothful, mutable, complex, and time-serving."

TRUE COAL VEIN FORMATION

Coal formations are frequently referred to as "coal veins." This is incorrect for the reason that the deposits are not in true fissure veins. An instance, however, of what is believed to be a true vein formation is given by William Campbell in *Transactions—The Mining Institute of Scotland*, Vol. XLI. In the province of Yauli, in the department of Junin, Peru, there are two distinct series of veins, 20 miles apart, one of these consisting of bituminous coal and the other of anthracite coal. The bituminous series is made up of three well defined veins or fissures which cut the limestone at nearly right angles to the bedding planes and have a dip of from 60 degrees to almost vertical. They vary from 12 inches to several feet in width and behave in exactly the same way as mineral veins, the coal occurring in irregular lenticular masses. The coal is splendid for domestic uses, and is also used, with a mixture of 50 per cent anthracite from the other series, for making blast furnace coke. The coal burns easily, with plenty of flame and gives off much smoke and a great amount of oil or pitch. The anthracite coal series also occurs in the limestone and is regarded as having the same origin and period as the bituminous series. Both kinds of coal are believed to be of asphaltic rather than of vegetable origin, the theory being advanced that an oil field was in existence, and due to earth move-

*This and all subsequent quotations from Daddow and Bannan are taken from "Coal, Iron and Oil, or the Practical American Miner."

ment setting up great heat, the oil was volatilized, and the ascending vapors in their passage through these open fissures in the limestone condensed or cooled, leaving solids which filled the veins.

VEGETATION OF THE CARBONIFEROUS PERIOD AND CLIMATIC CONDITIONS

The Carboniferous age, it is agreed by all, was favorable to a flourishing vegetation, for the reason, largely, that climatic conditions were conducive to great and rapid growths. Le Conte's explanation sets forth the preponderance of ferns:

"It is probable, from what evidence we have on this subject, that the climate of the coal period was characterized by greater warmth, greater humidity, and greater uniformity than now obtains, and that the air was more highly charged with carbonic acid. Of the greater warmth of the climate we have evidence in the astonishing luxuriance and universal tropical character of the vegetation of the period. One of the most marked peculiarities of the flora of coal everywhere is the great relative abundance of ferns and fernallies. In the present flora of Great Britain the ratio of ferns to flowering plants is about 1 to 35, while in the coal flora of the same country nearly one-half of all the known plants are ferns. In the American coal flora the proportion of ferns is said to be still greater. That this abundance of ferns indicates a tropical climate is shown by the fact that in the existing flora, out of about 1,500 known species of ferns, 1,200 are confined to the tropics, and as we pass from the equator towards the poles the proportion of ferns, steadily diminishes. The same may be said with reference to the club-mosses. It is worthy of remark, too, that although conifers are abundant now all over the earth's surface, still those most nearly allied to the conifers of the coal—such, for instance, as the *araucaria* and *salisburia* of the present day—are found only in tropical regions. Now, during the coal period, this tropical vegetation extended as far as 75° north latitude. Tree ferns and gigantic club-mosses covered the spot now occupied by the *Mellville* island. The evidence of remarkable humidity is no less satisfactory, for it is only in warm, moist climates that ferns and club-mosses grow in the greatest abundance and luxuriance. On some islands in the tropics and in the south seas the abundance of ferns even approaches that of the coal flora. In fact, as a condition of the growth of these plants, moisture seems even more necessary than heat.

"With reference to the highly carbonated condition of the atmosphere, we may suppose this to be the result of the greater activity of carbonic acid producing causes, or else we may refer it to the original constitution of the air—the natural process by which carbonic acid is given to the air, decomposition, combustion, respiration of animals, and volcanoes, carbonated springs, etc. It will be admitted by all that the first three may be neglected, since they return to the air only what had been previously taken from it. The carbonic acid supplied to the air by volcanoes and carbonated springs, according to Bischoff, is so inconsiderable that, unless we suppose these sources much more active than now, it would take millions of years to affect materially the constitution of the air. But even this refuge is taken away, when we recollect

that volcanoes and springs derive their carbonic acid from carbonates, and chiefly from carbonate of lime, or common limestone. But limestones, according to the testimony of all who have carefully studied them, and particularly according to the recent microscopic observations of Sorby, are entirely of animal origin, i. e., entirely made up of broken fragments of shells, corals, crinoids, sometimes recognizable under the microscope, sometimes reduced to impalpable powder. This carbonate of lime is evidently derived from sea-water. Whence, then, does sea-water derive its carbonate of lime? The lime is derived, beyond doubt, from igneous rocks, the carbonic acid probably from the atmosphere, through the animal and vegetable kingdoms, since lime exists in igneous rocks not as a carbonate but as a silicate. It would seem to follow, then, that springs and volcanoes, also, only return to the atmosphere what had been previously taken from it. The only difference between these sources and the three first is, that while decomposition, combustion and respiration return to the air what had been taken from it but a little while before, springs and volcanoes return to the air what had been taken from it during some previous geological epoch. Thus the atmosphere becomes the great original source of all the carbonic acid in the world.

"But whatever be the cause of the excess of carbonic acid in the atmosphere during the coal period, we cannot fail to see an evident and beneficent design in its removal. Carbonic acid, as is well known, is as poisonous to animals as it is nourishing to plants. Previous to the coal period there lived none but aquatic animals of low order. These, on account of low vitality, sluggish circulation, and little necessity for rapid and constant oxygenation of the blood, have great endurance of carbonic acid. But now the earth was prepared to receive air-breathing animals, the atmosphere must be purified for the purpose. This was accomplished by the astonishing vegetation of the coal period. But observe, and never cease to admire and wonder, that the self-same providential act which purified the atmosphere and rendered the earth a fit habitation for reptiles and birds, had references also to the coming of man countless ages after, and laid up materials for his use. In the carbon thus silently extracted from the atmosphere was buried a mechanical energy which, after a sleep of millions of years, was to rise again as the great physical regenerator of the human race."

The versions of A. W. Smith,* Lewes, and Daddow and Bannan now follow in the order named. While a variance in detail will be noted, the accounts are substantially in accord:

A. W. Smith—"It must be kept in mind that all the agencies which contributed to the formation of coal beds worked on a prodigiously larger scale than those which are now in activity for the formation of peat. Then, the deposits of vegetable remains were from an exceptionally exuberant vegetation, favored by the greatest possible humidity of the air, and a superabundance of carbonic acid in the atmosphere. It was a vegetation from

*This and all subsequent quotations from Mr. Smith are taken from the Report of the Anthracite Region, Penna. Geol. Survey, 1886.

which we can scarcely get an idea from anything now visible. Acrogenous plants, Ferns, Lycopods and Equisita (Horsetail) composed nearly the whole flora of the coal period. All the plants of those orders, represented by numerous genera, were then large trees, their trunks measuring from one to three feet in diameter, 40 to 100 feet tall, or even more; growing close together, and forming an impenetrable thicket of stems, branches and leaves; whereas, at the present day, the same kinds of plants are represented by mere herbage of small size, with stems and branches scarcely as thick as a goose quill, and only one or two feet high. Most of the land surface was then a vastness of swamps, in which the first growth, generally floating or creeping plants, was essentially composed of a peculiar species, the *Stigmara*, whose immensely long stems and branches, from 4 to 6 inches thick, were woven together, like the thin, matted, floating stems of the *Sphagnum* of the present age, into an immense woven mat, or thick carpet, over which the luxuriant land vegetation of the coal soon spread itself. And, of course, we must suppose that such an accumulation of ponderous material, such a mass of vegetation, sank of its own weight at times and places into the water beneath and became wholly submerged. This supposition becomes a certainty in view of the superposition of thick beds of sandstone, shale, clay, ironstone, and limestone upon the old beds of coal."

Lewes—"When the monster vegetation of the Carboniferous period grew, it is evident that, although the plant forms were of a simpler structure than is found in their descendants, the actions involved in their growth were the same as those we have considered, the great difference being in the rapidity with which they grew and the size which they attained, which may be taken roughly as twenty times that of their modern types. We know the rapidity with which in tropical regions the marsh plants spring up, attain great size, and then rot down, and it was a similar action, accentuated by heat from the cooling earth below and the richness of the atmosphere in plant food, i. e., carbon dioxide and water vapour, that induced in the vegetation of the coal age an exuberance of growth that has never been equalled since.

"The great vegetable deposits so formed rapidly accumulated, as it must be remembered that during this period decay as we now know it could not have existed—oxygen was only beginning to accumulate in the air, and the processes of slow combustion, by which nature now rids the earth of waste matter, were practically inoperative, so that nothing but what we call today 'checked decay,' i. e., changes at the expense of the combined oxygen in the vegetable matter, could take place, and deposits of a size that would be impossible with the atmospheric conditions now existing were easily formed."

Daddow and Bannan—"It was yet early in the creative periods. The 'third day,' as described by the Mosaic account, had not yet closed, and air-breathing animal life had yet no existence. The air was full of vapor and the floating dust of distant eruptions; carbonic acid loaded the waters and surcharged the air; a sulphurous and heated atmosphere everywhere encircled the earth; and

the waters were tepid with the radiating heat of cooling lava and the condensing earth.

"The temperature that then existed would be insupportable to terrestrial animals, while the carbonic acid that impregnated the air would be destructive to common air-breathing creatures. The vapors of carbon still arose from a thousand sources—smoking volcanoes and smouldering lava; and every crack and fissure of the earth still poured forth its volumes of the vapors of combustion, which here, in the contact with water, formed carburetted hydrogen, and there, with the atmosphere, formed carbonic acid.

"Such a coincidence of favorable circumstances could not fail to produce a vegetation of the most vast and magnificent description, in comparison with which the most luxuriant of the present day would be as a 'drop in the bucket.' The soft and fertile soil, made rich with the decaying matter of the ancient marine life and the resulting bitumen of the carburetted hydrogen gases; the atmosphere, warm and moist with heat and steam, and loaded with the life-giving carbon so necessary to vegetation, all tended to invigorate and give an unlimited growth to that early flora.

"This was the acme of vegetable life. Hitherto those favorable circumstances did not exist, and vegetation could only have flourished to a limited extent."

TIME REQUIRED FOR FORMATION OF COAL SEAMS

Many estimates on the time required to collect vegetation in the enormous quantities necessary to form a coal seam have been made, and of these but a few will be given here:

"In a valuable paper on the 'Maximum Rate of Deposition of Coal,' Ashley gives some most interesting deductions. He concludes that 1 foot of surface peat will at a depth of about 20 feet be reduced to 3 inches consequent to mere moisture loss; that its additional loss by partial decomposition amounts to one-fourth of the vegetable matter, whereas its specific gravity is nearly doubled, so that the original 1 foot is reduced to about $1\frac{1}{8}$ inches, a result in close agreement with Lesquereaux. Again, accepting Bischoff's deductions that one-fourth of the original matter is lost in the formation of peat, and that one-third of that remaining is sacrificed in the conversion of the peat to coal, Ashley applies Bischoff's questionable rate for the reduction of the organic matter in the peat. Thus, he takes from a cubic foot of deep peat, weighing 50 pounds and containing 30 to 40 per cent of water, one-third of the total weight for the remainder, 25 pounds, in round numbers, being regarded by him as the coal equivalent of the cubic foot of deep peat. Hence he concludes that a cubic foot of Appalachian coal weighing $87\frac{1}{2}$ pounds represents $3\frac{1}{2}$ feet of well-compressed peat. In his further computations he uses 3 feet as the thickness of 'well-compacted, deeply buried old peat necessary to produce 1 foot of bituminous coal of the general character of the Pittsburgh coal of Pennsylvania.' According to this rate, the time required for the formation of 7 feet of this remarkable bed was 2,100 years or 300 years to the foot of formation."*

*Origin of Coal, by David White.

Le Conte uses a different basis for his computation, and, as will be observed, arrives at a figure much at variance with Ashley's:

"Let us now attempt to estimate approximately the time necessary to bring about these stupendous results. I believe we should never neglect an opportunity of this kind, because the popular mind has not yet grasped the idea of illimitable time required by geology to the same extent as it has the idea of illimitable space required by astronomy; and, as I believe, this is one of the greatest difficulties with which geology has to contend.

"According to Boussingault, luxuriant vegetation at the present day takes from the atmosphere about a half ton of carbon per acre annually, or 50 tons per acre in a century. Fifty tons of carbon of the specific gravity of coal, about 1.50, spread evenly over the surface of an acre, would make a layer of less than $\frac{1}{3}$ of an inch. Humboldt makes the estimate a little higher, viz: $\frac{1}{2}$ an inch. We are willing to take the higher estimate. It appears, then, that if all the carbon taken from the air was preserved in the form of coal, our most luxuriant vegetation would make but a $\frac{1}{2}$ -inch of coal in a century. But in the coal measures the aggregate thickness of the coal seams in the same basin is sometimes 150 feet or more. In 150 feet there are 1,800 inches, or 3,600 half inches. At the present rate of vegetation, then, it would take 3,600 centuries, or 360,000 years, to accumulate this amount. But it will be objected that the vegetation of the coal period was probably much more luxuriant than the present, and the tendency of this difference would be to shorten the time. True; but it will be recollected that this estimate was made upon the ground that all the carbon was preserved. This is in the highest degree improbable, not to say impossible. Probably much more than half was returned to atmosphere in the form of carbonic acid and carburetted hydrogen. Again, we have taken no account of the enormous periods of time during which there was no carbon deposited on the spot in question, and represented by the intervening strata of limestone, sandstone and shale. The estimate we have given above, therefore, probably falls very short of the truth. Let us try another.

"According to Messrs. Lyell and Dawson the coal strata of Nova Scotia are about three miles in thickness at the South Joggins. At another point, nearly 100 miles distant (Albion mines), they found the thickness nearly the same. There is little danger, therefore, of erring on the side of excess, if we take the average thickness of the strata over the whole basin at one and a half miles. Now, the area of this coal field, according to Mr. Lyell, is about 3,600 square miles. This would give, as the solid contents of these strata, 54,000 cubic miles. But we have already seen that this enormous amount of matter was almost certainly accumulated at the mouth of a great river. Let us see how long it would take one of our great rivers to do the work. I shall select for this purpose the Mississippi and the Ganges, because they are both very large rivers, carrying vast amounts of sediment, and because accurate observations have been made as to the amount of sediment brought down by them. These observations have been made upon the Mississippi by Drs. Forshay and Reddell, of

New Orleans, and by Captain Strachey, British engineer, upon the Ganges. According to these observations it would take the Mississippi 2,000,000 years and the Ganges* 375,000 years to perform the work. And yet the period we are now discussing is probably not one-thirteenth, certainly but a small portion of the entire geological history of the earth.

"It will no doubt be objected to this estimate that it is founded upon a particular theory, and this theory may be incorrect, and the estimate thus falls to the ground. In answer to this objection it is only necessary to state that we are acquainted with no other circumstances under which strata accumulate so rapidly as at the mouths of rivers. Any other conceivable theory, therefore, would only increase the time."

Redmayne† furnishes a basis for estimation of time by citing the rate of peat-bog growth:

"The rate of growth of peat bogs is variable, and our knowledge respecting the same is somewhat indefinite; but it has been estimated that some extensive peat-bogs in Great Britain have increased in vertical thickness by 3 to 5 feet since the date of the Roman invasion."

All that is now needed to arrive at a term of years is to combine Redmayne's observation with Ries's estimate that "from 16 to 30 feet of peat are required to make one foot of true coal."

Lewes finds no modern phenomena by which the formation of thick seams can be explained:

"The conversion of vegetable matter into coal gives a loss in weight of about 75 per cent, and as the specific gravity of coal will vary from about 1.1 in the lignites to 1.4 in the anthracite, the volume of coal can be only from one-ninth to one-sixteenth the volume of the vegetable magma from which it was formed. When one considers the original depth of the vegetable deposit that gave rise to any thick coal seam—say the South Staffordshire 10-yard seam—one feels that no deposit that could form under present conditions would explain it. The Staffordshire coal would represent one-tenth to one-twelfth the volume of the original vegetation, so that the 10-yard seam represents a deposit extending over many square miles and, say, 300 feet in thickness, which, of course, even with the factor of geological time at one's disposal, would appear incredible."

We quote the following from Macfarlane:

"Our thickest beds of peat now measure scarcely 20 feet. By compression and mineralization the thickness would be reduced to one-sixth, or three feet at the most. We have beds of coal of 20 feet of thickness which would make a deposit of peat reach 120 feet. It is true, indeed, that the peat-bogs of old did not extend over the whole surface; that they were of various dimensions, separated by sandy hills or by deep lagoons; that, after the

*This amazing difference in favor of a smaller river is due to the fact that the Ganges, being a tropical river, the rains all fall during six months, and are therefore very heavy. The washing of the soil and resulting sediments are necessarily in proportion. The mountainous country in which the Ganges takes its rise contributes to the same result.

†Modern Practice in Mining, Vol. 1.

deposit of their materials, erosions caused by water or other agency have greatly diminished their size. But it is true also that beds of coal, like the Pittsburgh bed, whose average thickness is about eight feet, may be traced over surfaces more than 100 square miles in width. It is equally true that beds of coal are superposed at intervals, in the coal-measures, in such a way that at the same place a boring of a few hundred feet may successively pass through five beds of coal, or even more, of various thicknesses. So immense, indeed, are the riches of the American coal-measures, that, in their conception of the future developments of our human race, geographers, historians, philosophers, agree in this idea, that in the United States we have, especially in our coal-deposits, the elements for the greatest and most perfect development of the human race."

Daddow and Bannan compute the immense amount of time required for the formation of the Mammoth seam and do not believe that Nature was so slow in her movements:

"It might be interesting to calculate the immense amount of vegetation it would require to form a vein of coal equal to the Mammoth. If we take an average forest of our present day as the base of our calculations, we find that an acre of ground containing 65 trees, or five tons, and containing 20 per cent of carbon, will produce 65 tons of charcoal; or it would require 74 such forests to produce a bed of coal one foot thick, which contains 4,840 tons* of coal. To pursue the subject further, we may assume such a forest of white oak to have been one hundred years in coming to perfection, and we thus find that it would require 7,400 years of our present forest growth to form a bed of coal three feet thick; or 74,000 years to accumulate the mass of coal existing in our 30-foot Mammoth coal-bed.

"We may indulge in some speculation as to the relative time required to produce the same result during the ancient flora. We find the heat, the moisture, the carbon, and the water, all combining to produce an excessive growth; and we may safely assume that each year of such growth would add one foot to the thickness of the vegetable mass, as before described. This might be compressed, in the shape of coal, to one-fifth its bulk or weight, and all that it would lose in the slow combustion, or process of charring, in the bowels of the earth, would be more than supplied by the accession of carbon and hydrogen from the subterranean vapors still pervading the earth, air, and water. This would require five years to produce one foot of coal! or 180 years to form the 30-foot coal of the Mammoth.

"We cannot conceive of any other natural process by which our large veins of coal would be formed direct from vegetable matter."

THE COVERING OF VEGETATION WITH EARTH; SUCCESSION OF STRATA

The manner in which sandstone, shale and limestone strata have been deposited over the coal is one of the phases of coal geology that requires more illumination. The geologist, using lubricated phrases, and either by holocaust or by quiescent

means manages to slide or collect a protecting mantle of earth over the plant remains, in such an artful manner that there is little or no contamination of the underlying coal by the infiltrating earth; the miner, drawing upon his daily observations, accepts subsidence as an explanation of alternating layers, but, lacking details, he continues to marvel at the clean-cut separation of the coal from the overlying rock.

Le Conte's version of the formation of strata overlying the coal has already been given under the heading of "The Estuary Theory." A. W. Smith's account presupposes slow downward movements:

"To account for the succession of coal beds separated from each other by many feet or yards of rock strata, and constituting a mass of coal measures several thousand feet in total thickness, it is necessary to take into consideration those very slow downward movements of large areas of the earth's surface which have taken place in all geological ages, and were nearly continuous on a grand scale during the whole time in which the numerous formations of Middle and Western Pennsylvania were being deposited; ending with the rise of the whole region to its present height at the end of the Coal Measure age. During all the last part of the downward movement the coal vegetation flourished magnificently, but was interrupted by inroads of the sea on an equally grand scale; and these inroads which explain the intermediate sandstone, shale, limestone and iron ore beds, were precisely similar—but vastly greater and perhaps lasting for a much longer time—to those which have been described as happening in the history of the formation of the peat-bogs of our own day."

The deposition of shale immediately overlying the coal, according to Macfarlane, proceeded in a quiet orderly manner, while the higher strata may have placed by violent inundations of the sea:

"The pressure required to transform the vegetable material into coal was applied by the formation of the superincumbent strata of rock, by means of the sinking of portions of the land and the elevation of other portions. Professor Rogers, of the Pennsylvania Geological Survey, seems to attribute these to those mighty movements of the earth's surface called earthquakes, but they are now commonly accounted for by more gradual movements. The present great elevations of the mountains had not taken place, the surface of the earth was not much above the ocean, and small changes of level were sufficient to submerge the continents which were sometimes above and sometimes below the water.

"Dana teaches that contraction of the earth's crust, in cooling, was the one complete, efficient, and universal physical cause of the development of the features of the earth. Certainly, by whatever cause produced, our everyday observation proves that a considerable part of the continent of America was for a long period the bottom of the sea, and was subsequently elevated, as is shown by its abounding in sea-shells and other organic remains, and we find the stratified rocks fractured and

*These figures per foot of coal thickness in seam seem excessive; it is customary to figure 1,725 tons per foot per acre.—Editor.

raised up at various angles, just as they would have been if the crust of the earth had been broken into fragments by some mighty force acting beneath it. The elevation of a part of the earth's surface, and depression of other portions, would cause the sea to roll in against and over the continent. Where slate and sandstone occur over the coal, it is caused by the forests upon the higher ground being uprooted and strewed over the bog or swamp, before described, and the clay, sand, and earthy matter, becoming mingled with these drifting trees, they were spread in a promiscuous mass over the swampy flat.

"The great strata of sand-rock upon the slate, and sometimes directly upon the coal, were caused by more impetuous inundations of the ocean in all its might and majesty, washing away vast quantities of the soil and rock strata of the ancient continent; breaking the rocks into small fragments, carrying them to a great distance inland, and wearing them into water-worn pebbles. These rivers or oceans of sand, gravel and clay, thus deposited, in course of time became hardened into rocks, and their pressure upon the moist and rank vegetation of the coal-bogs buried beneath them has thus, by a simple and natural process, formed the strata of slate, pure coal, and sandstone. The dense, tough mass of swampy growth, with its strong network of roots, fibres, leaves and twigs, from the greater abundance and density of the vegetation, remained in its natural unmixed condition, and, no intermingling of earthy materials taking place, pure coal was formed. Being very compactly matted together, it formed a strong, spongy mass, not easily separated by a current of water flowing over it, and not pervious, or liable to be penetrated by foreign substances borne by such current."

HOW PEAT DEPOSITS WERE CHANGED TO COALS OF HIGHER RANK; PEAT TO ANTHRACITE THEORY

Once the swampy growth had become covered with earthy strata as the result of subsidence, it remains to find some plausible means whereby the woody material was converted into the successive ranks of lignite, bituminous and anthracite coal.

Le Conte explains the transformation in this wise:

"All the stages of gradation between perfect wood and perfect coal may be traced with the greatest certainty. We find the first stage of this process in the blackened semi-bituminized logs of our peat bogs and deltas of the present epoch. The next stage we find in the lignites or brown coal of the tertiary period; the next the highly bituminous coal of the coalite; then the coals of the true carboniferous; and lastly, anthracites of the same and the lower strata. Thus we may trace the whole embryology of coal from its immature to its most perfect condition—may trace and identify all the intermediate links of the chain of conditions of which wood and coal form the extreme limits. But not only in external form and appearance, but also in chemical composition we can trace these several stages. Wood consists of carbon, hydrogen and oxygen; coal consists of the same elements but in different proportions. In coal the proportion of

carbon is greater and of oxygen and hydrogen less than in wood. Now, if we compare the chemical composition of wood, peat, lignite, bituminous coal and anthracite, we find the carbon almost pure, and absolutely pure in graphite, if we acknowledge this as of similar origin. This chemical evidence, it seems to me, is absolutely demonstrative.

"Lastly, direct experiment proves that peat, which we know to be of vegetable origin, may, by strong pressure, be made to assume the hardness, the density, the general appearance and all the useful properties of coal.*

"We have already said that bituminous coal may be considered as a mechanical mixture of carbon and bitumen, and these two may easily be separated by heat. Anthracite is the residue after separation, and bitumen and naphtha is the matter separated by distillation and condensed elsewhere. As in the gas manufactories we find bituminous coal decomposed—a part remaining behind as coke (pure carbon), a part passing off as gas and a part collecting in pipes as coal tar—so in the laboratory of Nature coal beds subjected to heat give rise to the same three substances; anthracite is left behind, coal gas is discharged into the atmosphere and bitumen collects in subterranean pipes and gives rise to naphtha and bituminous springs, pitch lakes, etc. Thus, the enormous lake of boiling pitch in Trinidad is, probably, in connection with the coal strata below. If so, such coal will be left in the condition of anthracite. All the strata of the earth are subject to change under the influence of heat; limestones become marbles, clays become slate. This change is called by geologists metamorphism. Now, the proposition is that anthracite is metamorphic coal. The proofs of this proposition are as follows:

"In the first place, anthracite is never found except in regions very much disturbed by igneous agency, the strata highly inclined, contorted and broken; and even in the same coal field the coal is anthracite or bituminous, according as the region is more or less disturbed. Thus, in eastern Pennsylvania, where the coal strata are very much contorted and sometimes perpendicular, the coal is all anthracite; while in western Pennsylvania, where the strata are nearly horizontal, the coal is bituminous. The actual transition of anthracite into bituminous coal cannot be studied with advantage in Pennsylvania, because the coal strata have been carried away to such an extent that only outlying patches are left; but in Wales the same seam may be traced from the bituminous to the anthracite condition; so that there can be no doubt that, in this case at least, anthracite is metamorphic coal.

"Second. Anthracite is never found except in metamorphic rocks, and conversely all coal contained in metamorphic strata is anthracite. This universal connection of two things proves, as it seems to me, beyond doubt, their community of origin; that they have a common cause. Thus, in the lowest stratified or primary rocks, where the

*Dr. Bergius, of Hanover, in a paper on the artificial production of coal, says he heated peat and cellulose with water to a temperature of 310° C. under 100 atmospheres pressure, and found that both were converted into a substance physically and chemically identical with coal. At 340° C. the process took 8 hours, while at 310° C. it took 60 hours. He estimates, that at the temperature of the earth's crust, it would take eight million years to form coal.

rocks are altogether metamorphic, and even in the Silurian, where a less complete metamorphism is almost universal, what little coal is found is always anthracite. In the coal measures we have coal both bituminous and anthracite, but the anthracite always in altered and the bituminous in unaltered rocks. As we pass upward we find anthracite more rare, because metamorphism is more rare and local; and when metamorphism entirely disappears in the Tertiary rocks we find that anthracite disappears also.

"Third. Trap dykes, as it is well known, are formed by the outbreking and outpouring of melted rock (lava) forced up through the superincumbent stratified rocks, which are altered and rendered metamorphic by the contact. Now, when a dyke passes through coal strata the coal is always thoroughly coked by the contact; that is, it is changed into a substance identical in chemical composition with anthracite. These two substances are doubtless similar in their origin as well as in chemical composition, the great difference in their density being due only to the pressure under which the change took place. Anthracite is produced slowly under enormous pressure, while coke is produced under ordinary atmospheric pressure, and the rapid disengagement of gas renders it light and porous."

Ries attributes the origin of the heat and pressure necessary for the alteration of coal to the folding of the strata; Stevenson holds that devolatilization of anthracite coal was due to long exposure:

"Most of the anthracite coal in the United States occurs in the highly folded Appalachians of Pennsylvania. Such folding must have been productive of much heat and pressure, and that the folding has produced the anthracite is by many believed to be proved by the fact that these coal beds pass into bituminous coal when traced southward or westward into areas of less disturbances. This view is questioned by some geologists, especially J. J. Stevenson, who has argued that the anthracite has not been developed from bituminous coal by metamorphism, but that the volatile constituents were partly removed by longer exposure of the vegetable matter to oxidation before burial."

"There are some cases, as in the Cerillos coal field of New Mexico, where anthracite probably has been produced by heat. Here a bituminous coal has been deprived of its volatile matter and converted into anthracite in those portions of the bed near an intrusion of andesite. A similar change has taken place in the Crested Butte district of Colorado."

Macfarlane and Newberry are definitely lined up in support of the "peat to anthracite" theory:

"The formation of different kinds of coal, such as anthracite and semi-anthracite, semi-bituminous, and the many different varieties of bituminous coal, is supposed to be owing to the different degrees of progress made in the process of liquefaction and carbonization, and to there having been greater means for the escape of the gaseous constituents in some cases than in others. Chemists have actually converted vegetable matter into coal of all degrees of hardness, and possessing all the various qualities of that formed by Nature.

"The combinations formed by the usual affinities of the constituents of coal seem to show that all coal was first formed of the bituminous variety, and that anthracite is the result of igneous action to which it was subjected after it became coal. Anthracite is only found in metamorphic rocks, and all coal found in metamorphic rocks is anthracite."

"Coal, it may be easily demonstrated," says Dr. J. S. Newberry, "has been derived from the decomposition of vegetable tissue, and represents one of the different steps in a progressive change. In peat and lignite, we see the first step in the formation of coal. Peat is bituminous vegetation, generally mosses and other herbaceous plants, which, under favorable circumstances, accumulate in marshes called peat-bogs. Lignite is the production of a similar change effected in woody tissue, and, because it retains to a greater or less degree the form and structure of wood, has received the name it bears. Peat is the product of the present period, and lignite is found in deposits of recent geological age. In the older formations, these carbonaceous accumulations are still further changed, and form bituminous coal. When special and local causes have operated to carry the change still further, as when the beds of coal have been involved in the upheaval of mountains, and heat acted upon it, it is converted into anthracite. When this metamorphosis has been carried still further, the result is plumbago or black-lead.

"The changes referred to consist in the evolution of a portion of the carbon, hydrogen, and oxygen, in the form of water, carburetted hydrogen, carbonic acid, etc., leaving constantly a larger portion of carbon of the plant behind, with all its earthy matter.

"We find that, under peculiar circumstances, Nature has departed from her usual routine, and has locally effected the changes from lignite into anthracite, in a short space of time, as at Santa Fe, New Mexico, where a trap-dike has cut through Cretaceous strata in which are beds of soft and nearly valueless lignite, and where, over a large area, this outflow of melted rock has converted this lignite into a compact and valuable anthracite. So at Los Bronces, in Sonora, Triassic coals are converted into anthracite by the eruption of porphyritic rocks. On Queen Charlotte's Island, south of Alaska, is a Tertiary lignite changed by a similar cause into the most beautiful and brilliant anthracite."

But discordant notes come from the shores of England. Redmayne and Harger have no place in their conception for the peat to anthracite theory:

Redmayne*—"Peat is frequently, and erroneously, regarded as coal 'in the making,' whereas true coal owes its origin neither to peat bogs nor yet to the forest trees, but to forests of cryptogamic plants. Although peat, therefore, properly speaking, is not coal, nor will in the process of time become such" . . .

Harger†—"The hypothesis, once so widely used, that all coals have been derived from the same mother substance, under the same or similar con-

*Modern Practice in Mining, Vol. 1.

†"Coal and the Prevention of Explosions and Fires in Mines."

ditions, must be dismissed as unfruitful and even misleading. There is no doubt that the coal of each particular seam has its own peculiar properties, and these must be taken into account in any scientific theory of its origin. In spite of its attractive simplicity, we can no longer hold the 'peat to anthracite' theory which has, in text books at any rate, held such long sway: so many of the facts accumulated in recent years cannot be explained or related by means of this theory."

CANNEL COALS

Much interest has occurred of that class of coals characterized by their high ash and high volatile content, and known as cannel coals. Macfarlane explains formation in this wise:

"Cannel-coals have usually a more distinctly laminated structure, are finer and more compact in texture, and contain a larger percentage of volatile matter. They produce gas of greater illuminating power, but the coke made from them is of inferior quality. As to the mode of the formation of cannel-coal, Professor J. S. Newberry proved many years ago, in *Silliman's Journal*, that its peculiarities are owing to the chemical and mechanical influence of water in which it is deposited. Cannel-coals are characterized by greater homogeneity than other bituminous coals, as to their physical structure and chemical composition having a more laminated fracture, in pure specimens conchoidal across the planes of stratification. They contain more earthy and more volatile matter, less carbon, and evolve gases having a higher illuminating power.

"Cannel-coals are frequently found shading into bituminous shale, into which they are converted by accessions of earthy matter. Bituminous shale and cannel-coal may, therefore, be considered as the same substance in different degrees of purity, that is, carbonaceous paste deposited from aqueous suspension with different admixtures of earthy matter.

"Plants, when deprived of their vegetable life and exposed to the action of the air, are decomposed by a process of decay which is really a slow combustion unattended by the sensible phenomena of light and heat. Under water, the process goes on more slowly; and the more perfectly the oxygen of the air is excluded, the larger the proportion of the volatile constituents of the wood will be retained. Thin layers of cannel, alternating with others of bituminous coal, are due to the variable quantity of water, overflowing, and saturating the marshes, the cannel layers being deposited during the prevalence of high water."

Harger leaves with his reader the impression that, after all, the formation of not only cannel coal, but likewise bituminous, is far from being satisfactorily accounted for:

"The cannels differ so remarkably from bituminous (or humic) coals that it is supposed they were formed under very different conditions, namely, in inland lakes. Fish teeth and scales are sometimes found embedded in the upper portions of the seams. The fact that cannel is found in actual contact with humic coal, in some seams, adds a further difficulty to the problem of the origin of coal."

EROSION

So plentiful are the coal deposits of the United States that the resources of a state are mentioned by the billions of tons. With these vast quantities remaining, it is hopeless to conceive the original size of our coal areas, when one considers that erosion has removed as much as 95 per cent of our anthracite field alone. Le Conte assures us that most of the original deposits in Illinois have been swept away:

"Coal strata, like all other sedimentary deposits, were at the time of formation horizontal, or nearly so. Sometimes they are found nearly in this their original position, as in many of the coal fields of our own country. More generally this original horizontality has been disturbed by igneous agency, and the coal strata are found in the form of basins. Sometimes the strata are so folded as to give rise to series of basins belonging to the same original field. Whether, however, the strata retain their original horizontality, or are thrown into basins by igneous agency, seldom or never do we find the whole of the original mass deposited. A large portion has been carried away by aqueous agency. From this cause a large coal field, covering many thousands of square miles, may exist only in the form of isolated mountains or detached basins of coal strata. Thus, for instance, nearly the whole of Illinois was originally occupied by a vast coal field, but little disturbed by igneous agency, but by far the large portion of the coal strata of this immense field was carried away by denuding agencies."

Macfarlane and Lesley:

"The fragmentary character of the coal fields is evidently caused by convulsions which took place long subsequent to the formation of the whole of the coal-measures, and we now possess, or at least have only discovered some of the broken parts of a vastly greater field which once existed on this continent. Deep valleys have been formed, cutting down through the coal-regions, leaving sometimes only small patches of coal on the tops of the highest mountains, and extensive countries often lie between, where thousands of feet in thickness of the upper formations, including the coal, have been removed by some mighty agency exposing the Devonian and Silurian rocks on the surface. 'In imagination we can restore those gigantic arches which once carried the same coal-beds high through the air from one mountain across to another many miles apart, and which are now destroyed and buried up, constituting new sand, gravel, and rock deposits in the Atlantic.'—Lesley."

CORRELATION OF COAL SEAMS

The correlation of coal seams is referred to so frequently in treating the geology of the various mining states that an explanation on some of the methods used by the geologist in fixing horizons will be of interest. We quote from Bulletin No. 10 of the Illinois Coal Mining Investigation:

"The correlation of strata from place to place where the outcrops are discontinuous is accomplished by two methods. Of these two the paleontological method is the most convincing. The dis-

covery that a certain fossil or association of fossils is characteristic of a certain bed makes it possible to identify the same bed elsewhere. The presence of a certain species of *Fusulina* in the limestone over coal No. 6, but not found in limestones associated with other coal beds, definitely identifies No. 6. The shale overlying coal No. 2 carries certain fossil plants which identify this horizon from Murphysboro to the La Salle region.*

"Unfortunately our present knowledge of the 'Coal Measures' does not warrant many such definite correlations, so that for the most part we are limited to the second method of correlation, or the comparison of the physical characteristics of the coal and associated strata, to identify the coals in the different fields. Similarity of interval between coal beds is an aid to correlation. Because of the relative uniformity in dip of the Illinois 'Coal Measures' over large areas, identification of strata can commonly be made with reasonable correctness on the basis of similarity in elevation and thickness when points of observation are not separated by more than two or three miles. The greater the number of drillings the greater the safety in this method.

"Fire clays are normally associated with the coal beds, and in a carefully kept log may serve to identify the horizon of a coal, although the bed itself has been removed by erosion. These underclays in connection with the limestones mentioned above afford good key horizons for the correlations of the coals."

From the description of the lignite beds of Montana in Contributions to Economic Geology . . .

1908, we find an additional aid to correlation of seams:

"A feature of the region, especially noticeable south of Missouri River, is the clinker produced by the burning of lignite beds along their outcrops. This material, which is usually red, is an unfailing index to the position of the bed burned. It would, in many localities, be extremely difficult to meander outcrops of beds without the clinker as a guide. To some extent also the persistence and thickness of the clinker give some idea of the persistence, quality, and thickness of the burnt bed, as thick beds of good quality produce thin or impure beds. The distance back from the outcrop of a bed to which burning may take place is governed by the thickness of cover, which, if great enough, smothers the fire by preventing access of air. In this connection it is impossible to give exact figures, as no mining or prospecting has been done where it was necessary to remove the clinker to reach the lignite. To the observer, however, the width of the clinkered zone is often an obvious matter. In prospecting for lignite on an outcrop that has been burned it may be well to keep in mind the fact that the base of the clinker, which is usually well marked, is on a level with the base of the burnt bed of lignite."

The correlation of coal seams by means of examining the structure and composition of thin-ground sections under the microscope has lately been given much prominence and appears to offer the most successful and satisfactory method.†

EXPLANATION OF GEOLOGICAL AND MINING TERMS

In a study of the geology of any region, many terms and phrases are encountered by the lay reader, who, if unfamiliar with the terminology of the subject, finds much of the descriptive matter unintelligible. To assist the reader of the COAL CATALOG in a clearer understanding of the geology of the various mining states, as presented herein, there is here given several illustrations and definitions covering some of the terms that are commonly used in describing coal seams, with explanations to same, these being selected with a view to setting forth the phenomena of common occurrence throughout the various fields.

Unevenness of Bottom; Horse Backs—The floor of a coal seam is never a smooth surface, such as the floor of a house, but consists rather of a series of undulations of more or less vertical and horizontal extent. In some coal fields the floor is very uneven, as shown in Figure 1, undulations of an amplitude of as much as 40 feet being encountered, while in other localities the absence of noticeable

Fig. 1. Uneven character of surface upon which coal was deposited.*

irregularities is quite pronounced. The evenness of the floor underlying a seam as extensive as the Pittsburgh coal is, in fact, one of the astounding features connected with its geology.

While, ordinarily, undulations are so slight as to cause little or no inconvenience in mining the coal, occasionally these rise so high into the top of the bed as to constitute what is known to the miners as a "horseback." See Figure 2. Wherever present,

Fig. 2. "Horseback" in coal seam.*

these introduce a difficulty in undercutting the coal, in blasting, and in making a clean separation of the clay rock from the coal before loading into the mine wagons.

Conformable and Unconformable Strata—When strata have been so laid down that the series is parallel, or else if effected by movements, there will be found a similar deformation to each stratum, the formation is said to be conformable and the structure is called conformity; but if two series, each made up of a number of conformable

beds, are discontinuous, that is, where one seam, the upper, is not conformable with the lower, but rests upon its upturned edges or its eroded surface,

Fig. 3. Some cases of unconformity (Compend of Geology, Le Conte).†

then it is said to be unconformable and the structure is named unconformity. Figure 3 illustrates four cases of unconformity of strata.

Pinch—A local disturbance in the thickness of the coal seam and known as a "pinch" is illustrated by Figure 4. Here the bottom and top of the seam

Fig. 4. Pinch in coal bed.*

are shown swung out of position, often making it necessary to remove both in the normal process of mining.

Clay Veins—These are of frequent occurrences in coal seams. Some beds are so thickly infested

Fig. 5. Clay vein in coal seam.*

*Figures 1, 2, 4, 5, 6, 8, 13 and 14 of this article are from Vol. 19 Iowa Geological Survey.

†Figures 3 and 15 of this article are from A Compend of Geology by Le Conte.

with them as to greatly lessen the value of the coal. It is believed that they are caused by the pressure of the overlying burden forcing the soft clay underlying the coal into fissures extending from the coal seam to the strata above, these breaks having been produced by more or less violent movement of the earth or else by contraction of the earth's crust.

Faults—A fault is a break of the earth's strata, one part of the dismembered section being thrust past the other along the line of fracture. Such occurrences are fairly common and in regions which show evidence of much disturbance they are so frequently encountered, and the throw of the measures

Fig. 6. Fault of small displacement.*

is so great, that it constitutes a serious obstacle to mining. Lesley mentions a fissure in Pennsylvania in which the vertical displacement is 20,000 feet and may be traced for 20 miles. Rogers describes one in southern Virginia in which the displacement is 8,000 feet and may be traced for 80 miles.

Fig. 7. Fault showing complete severance of seam.

The faults in the Appalachian basins are seldom troublesome, the dislocation of strata in nearly every case being small, as shown in Figure 6. The fault shown in Figure 7 has completely severed the seam.

Faults of Erosion, Wants, Cutouts—The miner commonly applies the term "fault" to all disturbances which have placed a barrier of rock at the horizon of the coal, whether or not there has been a fracture and consequent displacement of the strata. Where there has been no displacement of the strata and the coal is found at the same level on both sides of the intruding rock, the proper name becomes rather "fault of erosion," "want," or "cut-

out." The manner of such an occurrence may be attributed to the erosion of streams of water which

Fig. 8. The occurrence of a want in a coal seam.*

have had access to the Carboniferous peat beds. Later in the process of covering, this eroded channel became filled with sand or mud which, on the application of pressure, was subsequently consolidated into sandstone or shale.

Folding—When strata are forced out of their original horizontal position and thrown into more or less curved forms, they are said to be "folded." Folds may be divided into two principal types, called respectively synclines and anticlines. An anticline is an upward fold or arch of strata from the summit of which the limbs on both sides dip downward. The amount of dip may vary from a few to many degrees. The line along which the fold is prolonged is called the anticlinal axis. An anticline may be

Fig. 9. Anticlinal fold (Willis).‡

scores of miles in length or possibly only a few hundred feet. The axis is not horizontal, but is more or less heavily inclined and in the course of travel, the fold disappears. In Figure 9, SS is the line of stripe, D is the line of dip, and the dotted line is the plane of the axis.

A syncline is the complement of the anticline. Here the measures dip on both sides of the trough towards its lowest point. The synclinal axis is the line of lowest depression in the trough. As with

Fig. 10. Synclinal fold (Willis).‡

the anticline, the length of the syncline may be long or short and its shape ranging from the canoe-shaped valley to the saucer-shaped basin in which

‡Figures 9, 10 and 11 of this article are from *An Introduction to Geology*, by W. E. Scott.

Fig. 11. Diagram of folds (Willis).†

1. Upright or symmetrical open folds.

3. Asymmetrical fold, closed and overturned.
4. Symmetrical fold, closed.
5. Closed anticline, overturned.
6. Closed anticline, recumbent.

every section is synclinal. Figure 11 shows several examples of the manner in which folds may occur.

A fold frequently noted in the study of earth formation, particularly in the geology of the western states, is the monoclinial fold shown in

Fig. 12. Monoclinial fold.

Figure 12. This may be defined as a single, sharp bend which forms the connection of a continuous strata lying at different levels.

Erosion—The manner in which part of a coal seam may have been eroded has already been referred to in the explanation of the occurrence of "wants." A second type of erosion is the result of

Fig. 13. Preglacial erosion: Drift occupying small gorge.*

stream action during any period which existed between the last emergence of the coal measures from the sea and the coming of glacial ice from the North. Such an erosion is shown in Figure 13, the

particular glacial channel having been filled with loose unconsolidated material during the icy period and then continuing in this state or being transformed into solid rock by the application of pressure from above.

An additional type of channel is the work of modern streams coming since glacial time. It gives rise to a form of erosion which is so easily

Fig. 14. Postglacial erosion: Gorge of Des Moines River at Des Moines, Iowa.

discernible in all of our coal fields. While it is true that the rivers have, in this manner, washed much of our original deposits from their original location into the sea, they have nevertheless been of some service in laying open a few of the coal beds which now outcrop along their sides.

The great extent is strikingly shown in Figure 15, where by means of the dotted lines we observe

Fig. 15. Section across Middle Tennessee, showing erosion. (Compend of Geology, Le Conte.)†

the arch of a great anticline, most of which, however, has been denuded by the erosive action of streams. It is erosion on the large scale implied by this illustration that has removed over 90 per cent of the original deposit of anthracite coal and over 50 per cent of the bituminous coals of Illinois.

Intrusions of Volcanic Rock—The formation of anthracite coal is generally accepted as the result of metamorphism, the alteration in composition being due to the devolatilizing effects of the heat produced by flexing of the strata. Anthracite coal in New Mexico and Washington has been accounted for by intrusions of volcanic rock, the heat from

Fig. 16. Igneous intrusion through a coal seam.

which has driven off the volatile matter of the coal. Such occurrences as these are fortunately rather infrequent, though they are found in the Deep River fields of North Carolina, in Virginia, and the coal fields of New Mexico and Washington.

Split Seams—Sometimes a wedge-shaped layer of rock of varying thickness occurs interstratified in the seam as shown in Figure 17. Where the rock is thin both the upper and lower members may be worked together, though always at a considerable increase in mining cost. If the thickness of the

Fig. 17. Splint in seam.

rock prohibits operating both benches, the bench having the greatest quantity of coal is generally selected. Disturbances such as these are oftentimes encountered in the Beckley seam of West Virginia, the divider varying from as little as one inch in some places to as much as 120 feet in others.

Band—A thin stratum of shale, slate or other refuse interbedded with the coal.

Bed—Synonymous with Seam.

Bench—(1) When a seam of coal is made up of two or more strata of coal, as is usually the case, each layer constitutes a bench of the seam. The separating material is commonly a band of shale or other impurity. (2) A natural terrace marking the outcrop of any stratum.

Bone, Bony or Bony Coal—This refers to that part of a seam in which the coal is highly charged with ash. In contrast with good coal it has a dull appearance, often resembling cannel coal, from which it may be distinguished by the difficulty in igniting.

Cleats—The vertical cleavage planes in the coal seam are known as the cleats of the coal. Where cleavage is found in coals there are two cleats, known as the face and the butt, and placed at right angles to each other. The face cleat may be distinguished from the butt cleat by its better cleavage planes, the butt cleat being more or less irregular in fracture. Anthracite coal has no cleats and instead, is distinguished by a general conchoidal fracture. The absence of cleats extends to other coals, such as for instance that from the Big Vein of the Georges Creek district of Maryland and from a few localities in Tennessee where the coals are characterized by the absence of vertical planes.

Coal Basin—When seams dip from all directions toward a common center it forms a basin-shaped depression, or a geological basin. It may also be defined as the lowest part of a folded coal seam, that is, that part in the syncline.

Crop Coal—This term applies to the coal which lies along the line of outcrop. It is usually stained

yellow by infiltrating earth and is, therefore, higher in ash and lower in commercial value than coal from the interior of the seam.

Dikes—See Intrusions of Volcanic Rock.

Iron Pyrites—A brass-yellow colored mineral found in coal seams. Though consisting nearly one-half of iron, it is of no value as an iron ore, but is employed for making sulphur and sulphuric acid. From the Fairmont district of West Virginia, Danville district of Illinois, the eastern Ohio district of Ohio, and Cascade county, Montana, it is being shipped to acid manufactories as a by-product of the coal seam.

Marcasite—A mineral having the same chemical composition as pyrite and likewise found in coal seams. It differs from pyrite chiefly in crystallization, color and specific gravity.

Mineral Charcoal—See Mother Coal.

Mother Coal—A soft black substance resembling charcoal in appearance and found along the planes of stratification in the seam, in which the woody character of the material from which the coal has been formed is almost perfectly preserved. Also called fossil charcoal and mineral charcoal.

Parting—Same as Band. Sometimes applied to a thin band of stone in the seam of coal and termed a "dirt parting."

Rash—A soft scaly slate or earth beneath or above the coal seam, often containing much carbonaceous matter.

Roll—An inequality in the roof or floor of a mine.

Rooster Coal—A term used in the Pittsburgh district of Pennsylvania to distinguish the seam of coal lying just above the Pittsburg bed and separated from it by a stratum of rock.

Sag—A depression in the coal seam or mountain range.

Seam—Having reference to a stratum laid down in water. All coal deposits are therefore seams by definition.

Sulphur—The name commonly given by miners to the nodular concretions of iron pyrites found in coal seams.

Throw—A geological fault or displacement of the rock.

Trough—The bottom of a syncline.

Vein—A term often incorrectly applied to deposits of coal. A vein has reference to the filling of a fissure or crack by slow deposits from solution in percolating waters of material leached from the surrounding or underlying rocks.

Divisions of Coal Areas of the United States, Geographical Positions of Provinces, Regions and Fields

As a matter of convenience in considering geologic age, structure, quality of coal and transportation, the United States Geological Survey has divided the coal areas of the country into six large units called "provinces." These are shown by the map on the preceding page, as follows: the Eastern province, Interior province, Gulf province, Northern Great Plains province, Rocky Mountain province, and Pacific Coast province. A sub-division of the province is known as a "region", and the region, in turn, may be made up of smaller units, known as "fields". Some provinces contain all ranks of coal, and the fields are grouped together because of their geographic position, their structural features, or the age of the coal beds.

1. The Eastern province includes all the bituminous and semibituminous coals of the Appalachian region; the Atlantic Coast region, which includes the Triassic fields, near Richmond, and the Deep and Dan Rivers fields in North Carolina; also the anthracite regions of Pennsylvania and Rhode Island. This province contains probably nine-tenths of the high-rank coal of the country.

2. The Interior province includes all the bituminous areas of the Mississippi Valley region and the coal fields of Texas and Michigan. This province is subdivided into the Eastern, Western, Southwestern and Northern regions. The Eastern region embraces the coal fields of Illinois, Indiana and Western Kentucky. The Western region embraces the coal fields of Iowa, Missouri, Kansas, Arkansas and Oklahoma. The Southwestern region embraces the coal fields of Texas, and the Northern region includes the coal fields of Michigan. With one exception, that of Arkansas and Oklahoma, the coals are of low rank, for little

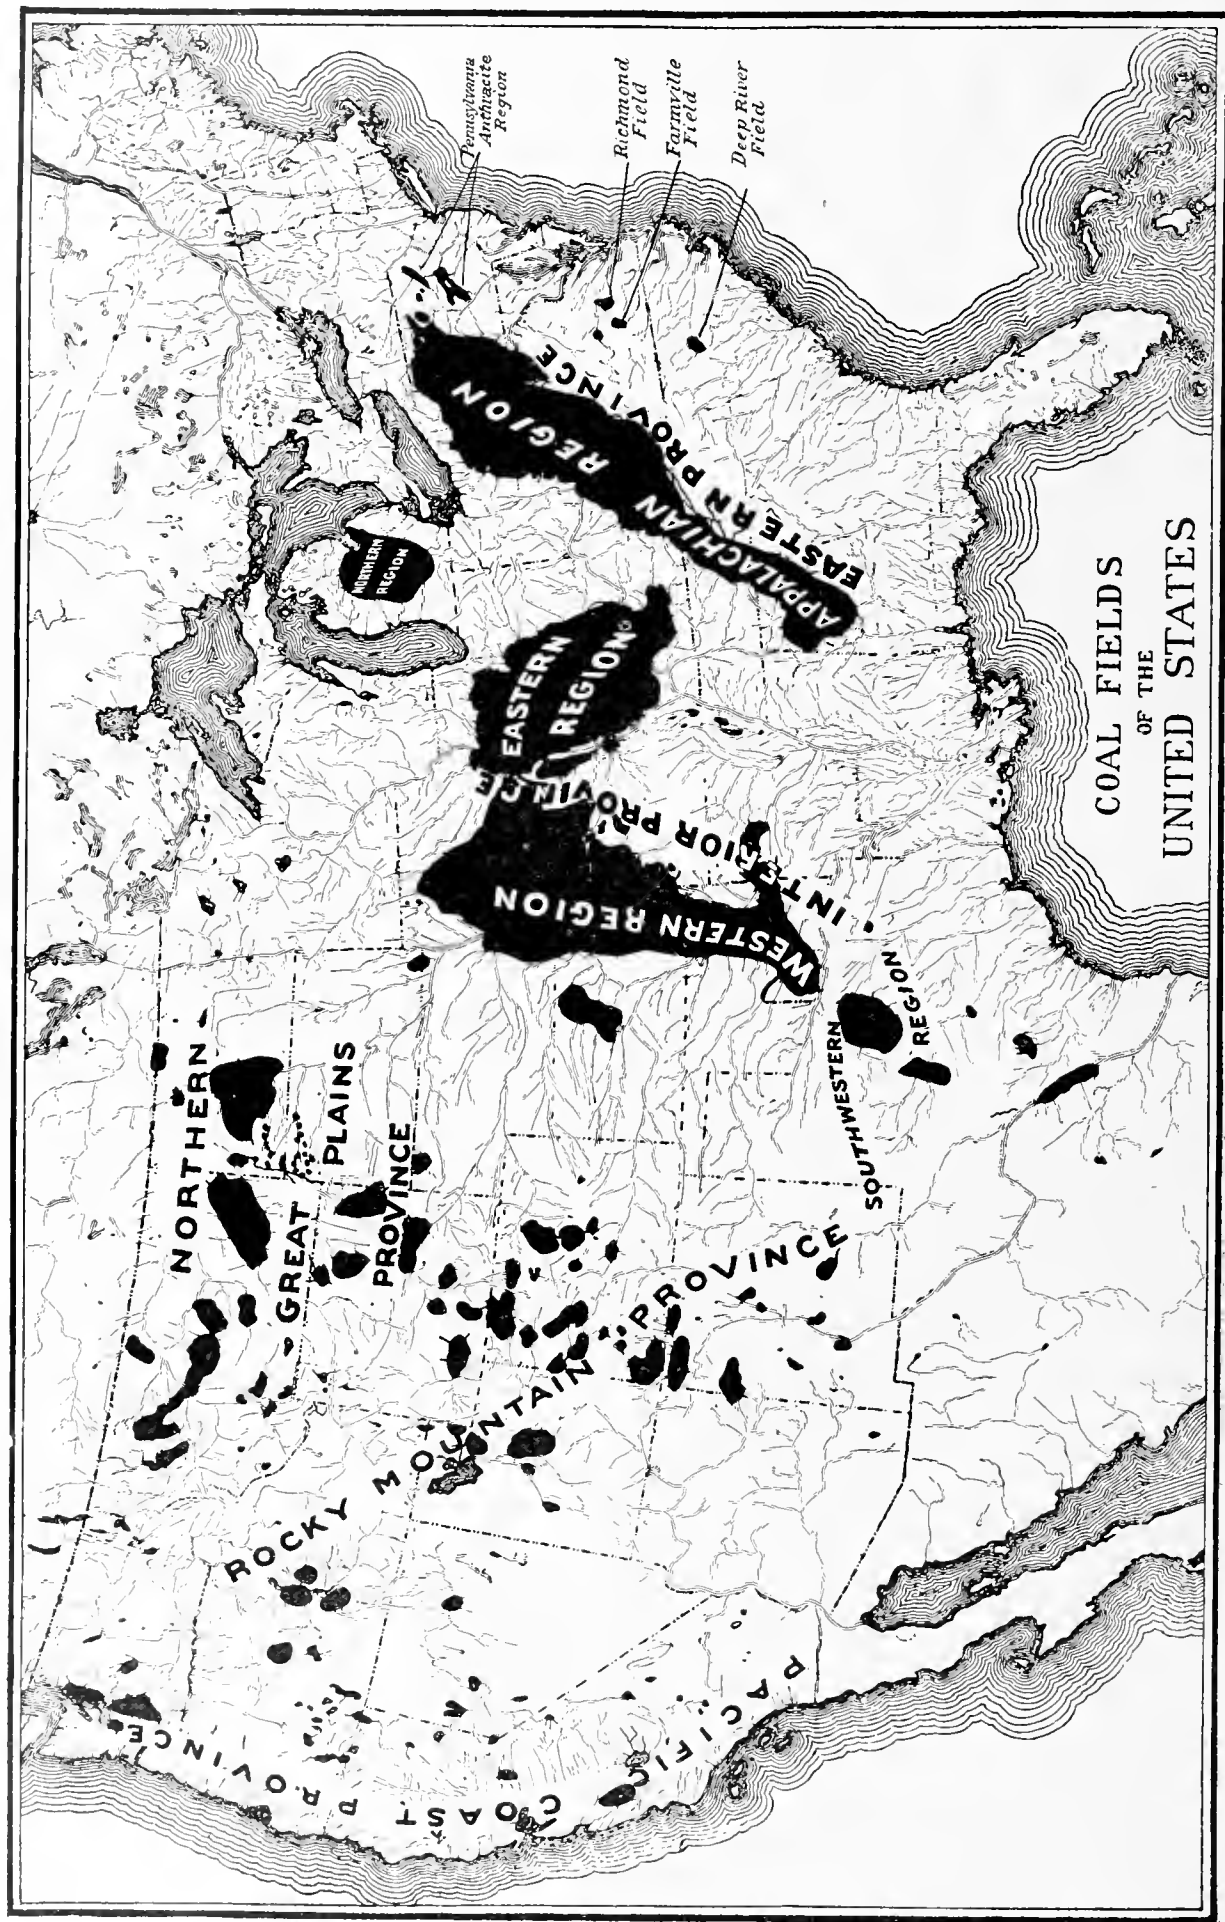

pressure has been exerted upon them. As a whole the coals are not equal in quality to those of the Eastern province.

3. The Gulf province includes the lignite fields of Alabama, Mississippi, Louisiana, Arkansas and Texas. The Gulf province is at present of slight commercial importance, mining being done at only a few points in Texas.

4. The Northern Great Plains province includes all the coal fields in the Great Plains east of the Front Range of the Rocky Mountains. Embraced in this province are the lignite areas of North and South Dakota, and the bituminous and subbituminous fields of Northeastern Wyoming and Northern and Eastern Montana. In this province the rocks generally lie flat or are but little disturbed, and in consequence the coals are of low rank, being either lignite or subbituminous, except in a few of the basins near the mountains, where the forces that caused the upheaval have locally changed the coal to higher rank.

5. The Rocky Mountain province includes the coal fields of the mountainous districts of Montana and Wyoming, and all of the coal fields of Utah, Colorado and New Mexico. This province contains a greater variety of coal than any other province in the United States. The coal-bearing formations are of Cretaceous and Tertiary age.

6. The Pacific Coast province is limited largely to the state of Washington, but includes also the small fields within the borders of California and Oregon. The coals of Washington are of bituminous and subbituminous rank, with a few localities containing anthracite coals. In California and Oregon the coal is of low rank and poor quality, and but little mining has been attempted.

From 23d Annual Report, Dept. of Geology and Natural Resources, Indiana, 1898.

PREPARATION OF COAL

The Factors Which Led to the Present Practice of Cleaning and Sizing Coal; Anthracite and Bituminous Preparation; Kinds of Equipment Used.

Factors Which Brought About Preparation

The separation of refuse from coal and the division of the valuable portion into various sizes originated in England and was first introduced into American mining practice in the anthracite regions of Pennsylvania. Here coal as mined is naturally dirty. Some of the seams are thin, making it necessary to brush the roof or take up bottom, either of which insures that much of the rock material is mixed with the coal in loading. In many localities the seams are pitching and this entails the handling of considerable rock with the coal. A further source of impurities is owing to the natural wetness of anthracite mines, the flow of water washing dirt into the coal when shot down.

It was early to be seen that the product as it came from the mines would not be acceptable to the trade and breakers came into use, wherein the impurities are removed, and the coal graded into its several sizes for shipment.

The second coal producing section, obliged to undertake the preparation of coal, embraced the states of Indiana and Illinois. Here a considerable output came from seams lying under so shallow a cover that percolating waters charged with earthy matter filtered through the seam, and greatly increased the percentage of ash. To compete with the coals shipped in from more favored localities a system of preparation was established, and the coal graded into lump, egg and nut sizes.

It will be observed that preparation and sizing were virtually forced upon the two sections named, owing to natural disadvantages in the seams mined. Sales agencies handling these coals made, as it were, a virtue out of the necessity and were quick to advertise them as specially prepared, and furthermore to emphasize at every opportunity the great bearing which sizing of coal has upon fuel economy.

Trade names were given coals from certain districts, or from certain mines within a district, many of them suggestive of the natural purity of the fuel, or the care taken in preparation to make it clean. The publicity given such fuels redounded to their benefit as the trade came to appreciate more and more those coals which professedly catered to a fine domestic and steam trade.

A survey of the coal fields of central and western Pennsylvania, as well as the Fairmont, Kanawha, New River and Pocahontas districts of West Virginia, made in the early years of their history, would show very little of real preparation and sizing. Much of the coal entered the market as mined, i. e., as run-of-mine, and, even though

heavily charged with fine coal, the high volatile content, as compared with anthracite, permitted it to be readily burned. In the course of time slack was regarded by the trade as objectionable, and at a large number of mines was eliminated at the working face by using a tined fork for loading the coal instead of a shovel. The slack remaining was cast aside into the gob and lost. Where it could be sold—often for as low as 10 cents per ton—the slack was loaded along with the lumpy coal and then separated at the tippie by running the contents of each car over a bar screen, often crudely improvised. At many mines where coke was made the slack was charged into the ovens.

Four factors, at first, served to stimulate a general improvement over this primitive fashion; first, the increasing acceptance by the trade of the statement that prepared sizes of coal are the more economically burned; second, the desire to compete successfully with the well-prepared coals from other sections; third, the rapid growth of the cement industry in America, requiring large quantities of slack coal for the burning of the clinker; and fourth, the increasing number of stoker installations using slack coal. A gradual transition was taking place to meet these changing conditions, so that in due course of time practically every mine of any importance was provided with a tippie from which could be loaded coal in sizes such as run-of-mine, 1¼" lump, ¾" lump, nut and slack. Little attention was given to the elimination of refuse, for the reason that most seams mined cleanly and the increased ash due to rock was small.

The long-discussed possibilities of foreign business in coal became a reality with the dawn of the late war, and gave rise to the fifth reason for a most careful cleaning and sizing of output. Along with the natural desire to excel in the quality of fuel was the knowledge that most of the export business demanded uniform sizing, and to the combination of these causes can be ascribed the installations of shaker screens, picking tables, loading booms, etc., whereby the integrity of the product can be the better maintained.

In the Western states a great many shipments of coal are made in box cars, one of the underlying advantages being the protection afforded from the weather. Box cars, as well as open cars, are used for transporting all sizes, these ranging from the largest size lump to egg, nut, slack, dust or any reasonable combination of these sizes. Loading into open cars is done with the customary boom, while for box car loading the coal is brought by a chute to a specially designed machine which loads the coal evenly from the ends to center of car. Washing is not much resorted to for eliminating waste in Western coals, the picking table having been found more satisfactory.

Preparation of Anthracite Coal

The structure in which anthracite coal is prepared for market is known as a breaker. This term is in reality a misnomer, for while it is true that breakers have crushers or coal breakers as a part of their equipment, it is worthy of note that all efforts in the design and operation of breaker machinery are directed against unnecessary breakage of the coal into sizes smaller than chestnut and egg.

A wonderful change has taken place in breaker construction during the past ten to twenty years. The breaker, as found at the beginning of the present century, was an all-wood structure, black and forbidding in outward appearance, extremely dusty on the inside, and poorly ventilated, heated and lighted. Much of the work of sorting slate from coal was done by hand, boys being employed in large numbers, whose duty it was to pick out rock, bone and slate as the coal traveled past them in chutes leading toward the pockets or storage bins. Due to inefficient methods, much of the coal mined in past years went to the rock pile or culm bank, some of which is being recovered in present years with the help of washeries.

Wood breakers usually end with a common fate—destruction by fire. Replacing them we find a breaker modern in every respect, permanently constructed of steel and concrete, and standing as a testimonial to the combined skill of the mechanical, electrical and mining engineer. In its external design will be found provision for beauty and symmetry of appearance, and internally there is evidence of thought for the health, safety and comfort of employes. As illustrating what constitutes a modern plant for anthracite preparation, the fol-

lowing excerpt from a recent description of the Woodward breaker, shown in Figure 1, is given:*

"Steel, glass and concrete are the materials which make up the present breaker, which is of large dimensions. The building is 213 ft. long, one half of it being 65 ft. and the other half 107 ft. wide. It rises 100 ft. above the ground at its upper end and 145 ft. at its lower end. In its construction were employed 3,000 tons of structural steel, 26,000 panes of double-thick ribbed wire glass as well as several hundred bags of cement, this material being used in the roof as well as in the floors and foundations. As the side walls of the buildings are practically all glass, it is almost as light inside the breaker as it is out of doors.

"During construction the interior of this building appeared like a network of steel beams, girders and columns. It began to take shape, however, with the laying of floors, the building of chute frames and the construction of eighteen large pockets to hold the prepared product. In this work 1,500,000 ft. of 2- and 3-in. yellow pine planking and ceiling was employed. The chute linings required 375,000 lb. of sheet steel. Along the interior sides and ends of the structure are 41,000 ft. of various sizes of wrought pipe, forming a steam-heating system that effectively warms every nook and corner of the building. This insures the safety of the equipment during freezing weather as well as provides for the bodily comfort of the employees during the cold season.

"All the machinery in this building is electrically operated, thirty-two motors being employed

*Dever C. Ashmead in *Coal Age*, Vol. 19, No. 19.

Fig. 1. Million Dollar Breaker of Delaware, Lackawanna & Western Railroad (Coal Department) at Edwarsville, Pa.

for this purpose. Each motor is provided with its own starting box and controller. A central switch-board is installed from which the entire operation of the breaker can be controlled. Fifteen thousand linear feet of conduit pipe was necessary for the wiring. The total installed power of the motors, which were all furnished by the General Electric Company, is 2,185 H. P."

This breaker, which employs the wet process of preparation, has a capacity of 6,500 tons of coal in eight hours. By its construction and the simplification of the methods of coal treatment, a saving has been effected amounting to the services of sixty-three men. The cost of the breaker was \$1,080,000.

The Three Methods of Anthracite Preparation

Dependent upon the nature of the seam and quality of coal mined, there are found in anthracite practice three methods of preparation, as follows: Dry Preparation, Dry and Wet Preparation, Wet Preparation.

Dry preparation is in use in those fields where the seam mined approaches a horizontal position, permitting a first separation by hand of impurities when shoveling the coal into the mine wagon; where the seam is dry; where the seam is practically free from impurities or where the benches of slate cleave free from the coal; where the run-of-mine contains generally not over 7 to 8 per cent of rock or slate which may be removed by hand picking or by dry mechanical separators. This system has the advantage of low cost in initial investment, operation and maintenance. Moreover, shipments of dry coal are preferable to the trade on account of the small percentage of impurities and the elimination of the possibility of freezing and the consequent trouble in unloading.

An objection to the dry process lies in the amount of dust given off in the breaker. In some cases where the coal and slate are very dry, the dust cloud is so thick and constant as to make it difficult to see, and is a detriment to the health of the employees.

Dry and wet preparation is practiced when the run-of-mine contains a high percentage of impurities, including rock, bone and slate. This may run as high as 55 per cent, but the run-of-mine must contain large lumps of pure coal, which can be handled as a separate product using the dry process. The smaller pieces are sized and cleaned with water to improve their appearance, the impurities being removed by jigging. Breakers designed for both processes retain all the advantages accruing to the dry process, but are higher in initial cost and more expensive for operation and maintenance than either wet or dry installations.

Wet preparation is adopted when the run-of-mine is high in impurities, such as results when the seams are highly inclined and the coal loaded from batteries with no opportunity for a preliminary sorting of impurities in the mine, or when the coal

shows a discoloration, as is the case when mined near the outcrop, or when the entire product comes from wet and dirty seams. Such coal must be washed to make it bright in appearance and attractive to the trade. Breakers designed for the wet process permit of no dry shipments and are higher in first cost and also more expensive to operate and maintain than a dry preparation plant. An enormous amount of water is required—in itself an item of considerable expense. Of the three processes, only the last named will be here described.

Wet Process

The wet process is found in the Southern Coal Field of Pennsylvania where the seams are highly inclined with the presence of large quantities of rock, often running up to as high as 800 pounds in weight as the coal comes from the mines. There is very little bony coal, so that the problem in preparation is largely the elimination of the rock.

M. A. Walker* has described the methods used in the Panther Creek valley from which the following is extracted: In general the preparation plant consists of two distinct buildings—the head house and the breaker proper. The function of the head house is to remove all the large pieces of rock and as much small rock as possible down to and including that of steamboat coal size; also to render the coal of suitable size and condition for reception into the breaker. The head house product is carried to the breaker, as a rule, by conveyors of either the scraper or carrier type. These are often inclined in order to gain the height at the breaker end, and frequently 250 to 300 feet in length. All jigging, final sizing and picking of the coal is confined to the breaker.

Figure 2 is a diagram showing the run of coal in a scheme of preparation typical of this region. It will be noted that the scheme of preparation in the head house is in general as follows: A disposition of the mine rock is made, when necessary, at the dump by means of a by-pass gate in the bottom of the dump chute. The coal stream from the dump is passed over a shaker or shakers having 6-inch round mesh, and a consequent separation made into two streams, one of lump size, the other of mixed steamboat and smaller sizes. Following first the lump coal stream, it is seen to descend to the picking table, which is about 20 feet long and has a pitch of 2 to 2½ inches in 12 inches. Here all the rock is removed and the cleaned lump coal which passes off is broken down in crushers to steamboat size and smaller. Steamboat size is removed by shakers which have a 4½-inch mesh, and is subsequently rebroken. All of this stream goes to that one of the two conveyors which is devoted to clean coal.

Following next the second stream, which consists of everything passing through the 6-inch mesh of the platform screens, it is found to be led over shakers having a 4½-inch round mesh. The steamboat coal thus made is hand picked, then crushed and taken to the clean-coal conveyor. Everything passing through the mesh of the

*Preparation of Anthracite Coal, Coal Age, Vol. 1, pg. 71.

shakers is led directly to what is known as the "dirty" coal conveyor, to distinguish it from its partner.

There are thus two streams of coal passing up to the head of the breaker; one cleaned, the other not cleaned, and both a mixture of broken and all smaller sizes, except when it is desired to ship steamboat size, which is done by omitting to break down that size in the head house. The clean-coal stream is usually sized over two sets of shaking screens and is passed directly to the pockets with more or less examination in the chutes.

of pure coal can thus be deflected to the pockets. Buckwheat size is jigged in a number of cases, but more often it passes directly from the screens to the pocket, as do also the rice and barley sizes.

Preparation diagrams, typical of the flow of coal in the dry process, and combined dry and wet processes are shown in Figures 3 and 4.

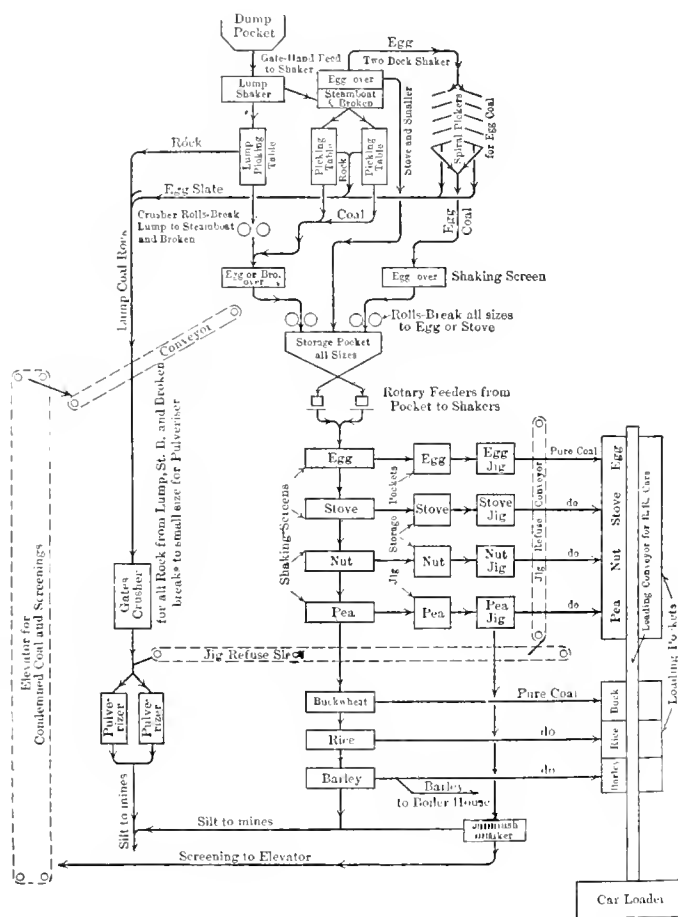

Fig. 2. Diagram showing wet preparation.

The dirty-coal stream is sized over four sets of shakers, or as a rule, double the number used for the clean coal. Broken size from these screens is usually cleaned by spiral pickers or some other mechanical device, supplemented more or less by hand picking. Occasionally it is jigged. Egg, stove, chestnut and pea sizes are usually led directly from the screens to the jigs. It is the practice in some breakers, however, to spiral or otherwise mechanically pick these sizes on the way to the jigs, and it depends a great deal on local conditions whether or not a profitable percentage

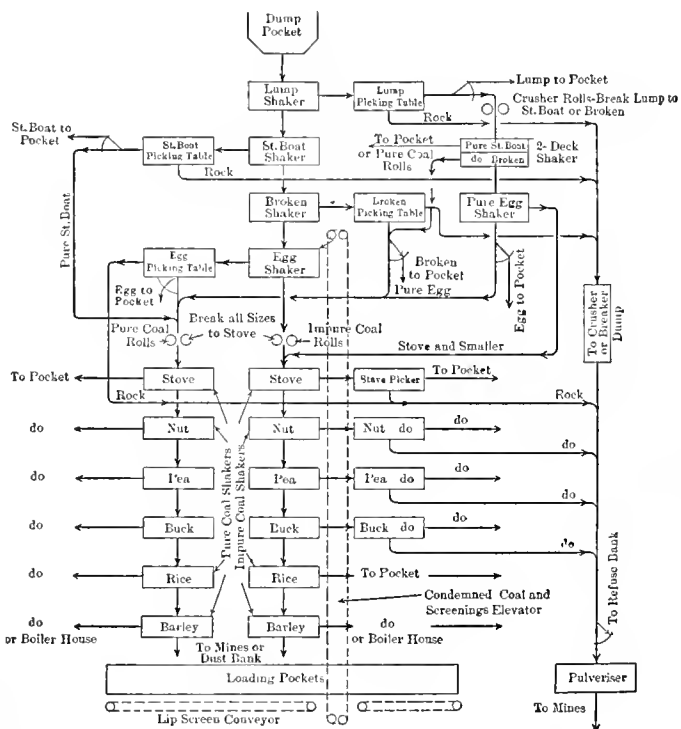

Fig. 3. Preparation diagram, showing typical run of coal during dry preparation.*

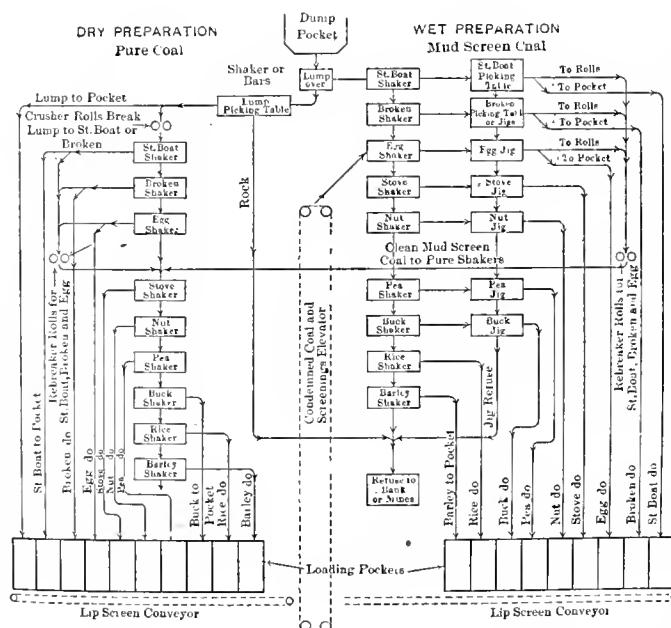

Fig. 4. Preparation diagram, showing typical run of coal during wet and dry preparation.*

*Figures 2, 3 and 4 are from the Preparation of Anthracite by Paul Sterling, Transactions A. I. M. E. Vol. 42.

Standard Sizes of Anthracite; Impurities Permitted

The following dimensions indicate standard meshes, round and square, for screening anthracite coal:

	Through		Over	
	4" square	4 1/2" round	2 3/4" square	3 1/8" round
Grate	2 3/4"	3 1/8"	2 3/4"	3 1/8"
Egg	2 3/4"	3 1/8"	2 3/4"	3 1/8"
Stove	2 3/4"	3 1/8"	2 3/4"	3 1/8"
Nut	1 3/8"	1 7/8"	1 3/8"	1 7/8"
Pea	1 3/8"	1 7/8"	1 3/8"	1 7/8"
Buckwheat	1 3/8"	1 7/8"	1 3/8"	1 7/8"
Rice	1 3/8"	1 7/8"	1 3/8"	1 7/8"
Barley	1 3/8"	1 7/8"	1 3/8"	1 7/8"

The percentages of foreign matter allowed are as follows:

Size	Slate	Bone
Broken (or Grate).....	1 per cent.	2 per cent.
Egg	2 "	3 "
Stove	4 "	5 "
Chestnut*	5 to 7 "	10 "
Pea	8 "	10 "
Buckwheat	10 "	10 "

*An allowance is made on chestnut of from 12 1/2 to 15 per cent. of pea coal.

With regard to the sizing of anthracite during the period of government control, the Fuel Administration set the following standard:

Egg, stove and chestnut coal could contain not over 5 per cent. of the larger sizes.

Chestnut, not more than 10 per cent. of pea or 5 per cent. of buckwheat.

Pea, not more than 15 per cent. of buckwheat and 5 per cent. of rice.

Buckwheat, not more than 15 per cent. of rice.

Influence of Size on Price

Anthracite coal is pre-eminently a domestic coal, and, as such, reaches millions of homes in the United States and Canada. Unlike bituminous coal, which has been lavishly bestowed by Nature throughout all sections of the United States, anthracite deposits are limited to a relatively small portion of Eastern Pennsylvania. Its superiority as a do-

mestic coal is so marked that it has no competition in the New England and Middle Atlantic states. Outside of these groups its monopoly ceases, for, due to high freight rates, more bituminous coal than anthracite is sold for domestic use west of Pittsburgh and south of Washington.

The popular sizes of anthracite for heating are egg, stove and chestnut. Sizes smaller than these, such as buckwheat, rice and barley, amounting to nearly 30 per cent. of the commercial product, are sold as steam coals and must therefore meet competition from bituminous coals in all localities. Since the small sizes of anthracite are inferior to bituminous coal, it follows that they must be priced much lower than the domestic sizes in order to insure disposing of the product. It is for competitive reasons, therefore, that practically each of the ten commercial sizes of anthracite is sold at a different price. These prices are influenced by the demand for each size and by the quantity of each produced. The table below shows the percentage of sizes produced from fresh mined, washery, and combined fresh mined and washery coal.*

PERCENTAGES OF SIZES

Size of Coal	Fresh Mined	Washery	Fresh Mined and Washery
Broken	6.8	0.4	6.2
Egg	14.6	1.2	13.5
Stove	19.6	2.3	18.2
Nut	24.7	10.1	23.5
Pea	9.1	10.0	9.2
Buckwheat	11.6	21.4	12.4
Rice (Buckwheat No. 2)...	3.2	14.9	4.2
Barley (Buckwheat No. 3)...	4.9	27.5	6.8
Boiler	3.9	8.8	4.3
Screenings	1.6	3.4	1.7
	100.0	100.0	100.0

*Anthracite Mining Costs, R. V. Norris, Trans. A. I. M. E. Vol. LXI, page 324.

Preparation of Bituminous Coal

The preparation of bituminous coal is quite simple in comparison with that prevailing in the anthracite fields. The great bulk of the production comes from seams which lie almost or quite horizontally, and, furthermore, it is unusual to find interstratification of rock in any such quantity as characterizes anthracite seams. Partings, of course, are common. Sometimes these may be disposed of by cutting out with machines and casting the dust into the gob, or the rock may be hand picked by the miner when loading his car, or else sorted out on the tippie as the coal travels along in moving conveyors. All of this is properly dry preparation, water being unnecessary, except where the coal is very dirty, or where it is prepared by washeries for such purposes as coking or the manufacture of illuminating gas.

Screens

The sizing of coal is effected by screens having openings between bars longitudinally arranged, by woven wire segments, and by openings made by punching circular, oval, square or oblong holes in the plate bottom, any of these arrangements permitting the fine coal to drop through while the larger pieces pass over the screen.

Gravity Screens

When screens are stationary and set at an angle of, say, from 27 to 35 degrees, so that the coal moves over them by the force of gravity they are known as gravity screens. Such an arrangement is shown in Fig. 6 and represents the type in general use a decade ago, and, in fact, is still quite prevalent in those fields where the coal is free from interbedded impurities and where there are no exacting demands on sizing.

The gravity screen is the cheapest and simplest which can be installed. It is, however, open to the objection that a rough separation only is usually made owing to the dumping of coal in bulk on the screen, there is excessive breakage and there is no opportunity for an inspection of the product and the removal of impurities. Installations of gravity screens have been made recently where the coal is fed to the screens by a conveyor at such a rate that there is a constant flow of coal over the screen in such quantity that effective screening is accomplished. The coal will flow differently dependent upon fracture, moisture content and quality. Weather and temperature also affect the flow. Coal will hang on the screen in the morning due to cold

Fig. 5. A Modern Bituminous Coal Tipple.

or to the rust which has collected during the night; in the afternoon it may run too fast over the polished plates.

The size of openings varies with the grade of coal desired: $\frac{3}{4}$ -inch, $1\frac{1}{4}$ -inch, 2-inch, 3-inch, 4-

inch or 6-inch lump. Where bar screens are used the larger sizes may be obtained by the removal of alternate bars singly or in pairs. The design of the bar is such as to permit the small pieces to fall through without clogging the screen.

The standard size of screen as found in the bituminous regions of Pennsylvania, Ohio, Indiana and Illinois is 12 feet long and 6 feet wide over the screen surface. The screen consists of 6 bearing bars and 39 steel screen bars with $1\frac{1}{4}$ inch of clear space between the bars. In Iowa the same size bar is used, but the space between the bars is $1\frac{3}{8}$ inches.

Lip Screens

Lip screens are those whose perforations are oblong in shape, the upper part of the slot being narrow with a gradual increase in space toward the bottom. This enlargement prevents wedging of coal in the slot. The screen is arranged in steps so that the coal in passing down the screen is completely turned over and away from neighboring

Fig. 6. Gravity Screens.

particles. See Fig. 7. This prevents the fines from riding across the screens on the lumps.

The general practice in the anthracite regions is to use slots 12 in. long and to make the distance between the bends the same length as that of the slots.

Fig. 7. Lip Screen.

When used as a slate picker the bars between the perforations are slightly turned or canted. Coal will flow readily over such a screen, but slate, which occurs in flat pieces, will turn edgewise and pass through the slots. The bend or step has the advantage of spreading the coal, thus insuring a more complete separation, and it also prevents irregular pieces of material from wedging in the perforations, thus keeping the screen from becoming clogged.

This screen can be readily adapted to meet the various different conditions which arise in the preparation of bituminous coal. In some localities the coal is very soft and breaks easily. Here the height of the step is reduced and the end of the slot is made to stop at the bottom of the bend or riser.

Again, if the coal breaks in large cubical lumps the taper of the slots may be changed to suit, and where the coal is in flat flabby chunks the length of the slots is made less, leaving a blank between the rows of perforations for the flat pieces to right themselves on, thus preventing flat over-sized pieces from passing through the screen edgewise.

Shaker Screens

To overcome the disadvantages of the gravity type, the shaker screen was introduced. Here the screens are set at a low angle of inclination, from 5 to 15 degrees, the movement of the coal being not so much dependent upon gravity as upon the forward thrust imparted by the return stroke of the screen which is kept in reciprocatory motion by means of a pair of eccentrics or by a single driving rod located as near as possible to the central axis. The openings in the screen may be made by the spacing of the bars, by cutting circular or oval holes in the bottom plate, or by lip screen. The travel of the coal is comparatively slow, and due to the motion of the screen, the lumps are separated so that no fine coal is carried over and mixed with the larger sizes.

Fig. 8. Shaker Screens in Boissevain Tippie of Pocahontas Fuel Co., Pocahontas, Va., showing discharge of Lump onto Picking Table.

Principles of Effective Screening

The principles of effective screening have been stated to be as follows:*

1. The perforations should be arranged so that each prepared size will pass through one set of perforations and over another. No coal is properly screened until it has passed over a screen.

2. The shape of perforations should be chosen with a view to the sizes to be produced and the fracture and other properties of the coal. Round perforations give the most uniform sizing, oval perforations clear themselves somewhat better, and lip screens clear themselves the best of all—in fact, the latter will screen almost anything. Dry coal having a rectangular fracture is the easiest to screen. Wet coal with a conchoidal fracture is the hardest. A little fire-clay makes the fine coal very hard to screen, and no screening process will separate the fines when the coal is wet, for the small particles stick tenaciously to the larger sizes. Lip screens cause the least breakage and abrasion and should be used where possible for very soft coal. Round and square perforations act like a nutmeg grater in making degradation.

3. The thickness of the plates for producing fine sizes should be chosen partly with reference to the sizes of perforations. When the plates are too thick, the holes will clog.

4. The length of stroke should bear a relation to the size of the largest perforations on the screen. For smaller perforations a shorter stroke can be employed, while for larger sizes it is better to use oval perforations or lip screens than to increase the stroke.

5. The speed of the shaker should be such as will keep the perforations clear and get the required tonnage over the screen.

6. The inclination of the screen should, in combination with the speed and length of stroke, allow screening on the forward as well as on the backward stroke and should be such as will produce an

*Andrew Allen, in Proceedings of Kentucky Mining Institute, 1916.

average flow of coal at a speed of about 100 feet per minute.

7. The flow of coal to the screen must be properly regulated. Roughly speaking, the capacity of a screen is practically doubled by uniform feeding. There is little to choose between types of feeder so far as uniform feeding is concerned; both the reciprocating and the apron type give good results.

8. The thickness of coal on the screen must be limited by "splitting" it where necessary. The relative proportions of the various sizes contained in the run of mine must be carefully studied in designing a screen and its width and the amount of "splitting" determined therefrom.

9. The width of screen must be chosen so as to limit the depth of the coal bed to such a thickness as can be effectively screened over the size of perforations employed. The length of the various perforated plates must be chosen so as to give the coal enough travel to screen out all the undersize without causing a needless amount of degradation. There is no hard and fast rule governing the size of screens, and the proper "splitting" of the coal and arrangements of perforations frequently requires some experimenting.

10. A little vertical as well as horizontal motion of the screen helps to keep the perforations clean. Knockers can also be used where the perforations cannot be kept clean in any other way.

Picking Tables

When merely close sizing is wanted the coal may be passed directly from the shaker screens to the railroad cars, but as preparation of the coal is of equal importance some means must be provided whereby the impurities may be sorted out. For this purpose picking tables are used. These are endless steel conveyors made up of overlapping plates mounted on roller chains at either side and

The use of the term picking tables as applied to travelling belts or conveyors is unfortunately a perversion of the term "table" as applied to the dressing of ores. Revolving tables have, however, been introduced and have been found a very successful substitute for the conveyor form. These are in reality annular rings with a width of about 4 feet and an extreme diameter of about 20 feet, this allowing sufficient circumference to place boys both on the inner and outer circles. Coal from the screen passes directly to the ring, and after completing almost 360 degrees of travel and having been hand picked, it strikes an obstruction placed obliquely to the path of travel and is swept from the revolving table and passes to the railroad cars.

The great advantage of the revolving table over the conveyor lies in the reduced maintenance cost. The conveyor has a large number of parts, such as rollers, links, bushings, etc., all of which are subject to wear and need lubrication to reduce frictional resistance; the table, on the other hand, has a minimum number of wearing parts. The disadvantage in its use would appear to be in that it cannot be applied to tipples already constructed.

The width of picking tables should not exceed 5 feet and they should not travel over 100 feet per minute. This makes it necessary to divide the coal and to use several tables in mines of large capacity. Roughly speaking, a picking table of any type should not be required to handle more than 1,000 to 1,500 tons in eight hours.

Combination Screen and Picking Table

A combination of the two units of screen and picking table is found in those horizontal types where the coal is impelled forward by a differential motion, either vertical or horizontal, and in the inclined type, such as an ordinary shaking pan placed at an angle of from 5 to 10 degrees.

In the horizontal type the screen is arranged in decks, the coal passing first to the upper deck where the nut and slack are first removed; the slack is then removed from the nut on the middle deck and carried forward to a gate in the deck through which it passes to a chute leading to the slack car. The nut passing over the slack screen on the middle deck passes down a sloping plate to the bottom deck and through a gate to the nut car. All sizes above nut are now picked on the top deck after which the egg coal is removed by the egg screen and delivered into the car on the egg track, while the lump coal passing over the egg screen is lowered by a sloping plate onto the bottom deck and passes out over the end of the screen to be loaded into a car on the lump track.

The horizontal picking table may be propelled by a special driving head, by eccentric gears or by short pendulum hangers supported ahead of the vertical. The former operates by a slow forward stroke and a quick return stroke; the latter by giving the screen a quick vertical drop at the end of the forward stroke. The eccentric method of drive is used in the balanced screen. Here there are two screens driven from the same shaft but moving in opposite directions, the object being to balance the vibration.

Fig. 9. Picking Room of Modern Tipple.

travelling at the rate of about 40 feet per minute. They carry the coal from the screens to the cars, are from 4 to 5 feet in width and because of their slow motion offer a fine opportunity to the men and boys stationed on either side to sort out the pieces of rock or bony coal. Belts are largely used for small sizes of coal where it is possible to run them horizontally or nearly so.

Loading Booms

With the use of gravity screens there has always been an excessive breakage in getting the coal from the screens to the cars. To reduce this tendency baskets were designed which might be raised to the edge of the screen, and after receiving one or more dumps of coal, lowered into the car and the coal discharged with a minimum of drop. When shaking screens were introduced it became necessary to combine with these some method of lowering the coal from the screens to the cars so that excessive breakage would be avoided, and for this purpose loading booms are now used.

Frequently the picking table is combined with the loading boom. The conveying picking tables may be readily hinged as a whole, in which case the pickers work on walks alongside the tables and are raised and lowered with them, or the tables may be hinged at some intermediate point, allowing a horizontal portion for picking, with a movable extension for loading.

The discharge end of the boom may be supported on a structural hinged frame or boom which is attached to an electric hoist, thus providing a means of raising and lowering the discharge of the coal to suit the cars.

Loading booms built to operate as a shaker are also employed. They are built in two sections, the

upper section being fixed as regards elevation and placed as close to the screen as operation will permit, so as to prevent any fall and breakage to the coal. The lower section is hinged at the upper end

Fig. 10. View of Lump and Egg Loading Booms.

and is raised and lowered at the lowered end by a power hoist, the same as in the case of the apron type of boom. The coal may be given a final screening in the upper section by inserting a short section of perforated plate which removes the fines.

STORAGE OF COAL

How, Why and When Coal Should be Stored; Causes of Firing and Measures of Prevention; Machinery Used for Storing Coal, Etc.

By H. H. Stock*

The following conclusions and suggestions are mainly empirical and not theoretical. They are based upon an extended personal field study of coal storage practice, upon data secured from hundreds of questionnaires, and by correspondence with engineers and others storing coal in quantities varying from a few tons in the ordinary house cellar to hundreds of thousands of tons as stored along the docks of the Great Lakes and by some of the large industrial concerns such as by-product coke companies and public utilities. These questionnaires and the resulting correspondence included not only all sections of the United States, where bituminous coal is stored, but Canada and Great Britain as well. Without the cordial co-operation of many engineers it would have been impossible to prepare such conclusions, and the author wishes to express his appreciation of the cordial assistance given him in the studies which have been carried on primarily under the Engineering Experiment Station, University of Illinois, and also in co-operation with the International Railway Fuel Association and the United States Fuel Administration. Through the co-operation of Mr. W. D. Langtry, President of the Commercial Testing and Engineering Company, Chicago, Ill., excellent opportunity was afforded for studying 100 fires in coal piles in that city during the summer and fall of 1918.

The details of these several studies will be found in Circular 6 and Bulletin 116 of the Engineering Experiment Station, University of Illinois, and in the Annual Proceedings of the International Railway Fuel Association.

The theoretical considerations connected with the spontaneous combustion of bituminous coal and the results of the experimental work of Prof. S. W. Parr of the University of Illinois, Dr. J. B. Porter of McGill University, Canada, and of Messrs. H. C. Porter and F. K. Ovitiz, formerly of the U. S. Bureau of Mines, will be found in the publications of the Engineering Experiment Station, University of Illinois, of the U. S. Bureau of Mines, and of the Canadian Bureau of Mines.

Although increased consideration was given to the storage of coal during the world war period, the reasons for storage that prevailed at that time prevail with almost equal force at all times in connection with the provision of an adequate and constant fuel supply. Three parties are chiefly affected by the coal storage problem: the consumer, who uses the coal, that railroad that transports it, and the coal operator and miner, who produce it.

The Advantages and Reasons for Storing Coal Are

First. It insures the consumer a fuel supply at all times.

Second. It is often possible to purchase coal for storage at a time of low prices.

Third. It should permit the railroads to transport coal throughout the year, and thus utilize their equipment to better advantage than at the present time, when there is an excessive demand for trans-

portation of coal during the early fall and winter months and very little demand during the spring and summer. A better utilization of equipment should mean lower freight rates, and it is possible that the Interstate Commerce Commission may adopt measures permitting a lower freight rate for transporting coal during the summer months, when it can be done more cheaply by the railroads.

Fourth. It helps to maintain a uniform rate of production at the mines throughout the year and acts as a stabilizer in the daily operation of mines.

The Disadvantages of Storing Coal Are

First. The additional expense due to the additional handling.

Second. The increased breakage due to additional handling.

Third. Loss of heating value due to weathering, which is much less than is commonly supposed.

Fourth. The loss due to spontaneous combustion, which is to a very great extent avoidable.

Practicability of Coal Storage

That it is practicable to store coal is best shown by the experience of those who have tried it out. W. L. Abbott, Chief Operating Engineer, Commonwealth Edison Company of Chicago, who has stored hundreds of thousands of tons successfully, said recently:† "On the whole, I find that for general convenience and security the best coal to store is egg size, which has gone through a 6-inch screen and over a 1½-inch screen. This is a size of coal suitable for most purposes and easy to handle. It is free from fine stuff and does not break up in the handling. I have known of hundreds of thousands of tons of Illinois coal prepared in this way and put in storage in piles 25 feet high during the past 10 years, and in not a single instance has there been a case of serious heating." R. L. Havelik, Chief Engineer of a large power plant at Mooseheart, Ill., in discussing the problem of coal storage, states that since 1915 he has stored Illinois coal in large quantities with entire success.

Every year hundreds of thousands of tons of coal are stored along the Great Lakes for distribution through the Northwest. All of the by-product coke plants store coal in large quantities and the University of Illinois has for years kept from 10,000 to 15,000 tons of Illinois coal in storage with practically no loss. These instances could be multiplied indefinitely.

To be sure many failures have been recorded, but an investigation of these failures has generally shown that in the storage the most fundamental principles of coal storage, as outlined later in this article, have been neglected, such, for instance, as storing a mixture of sizes containing a large amount of dust; storing against a hot boiler or steam pipe; improperly piling the coal so that segregation of sizes takes place, etc.

*Professor of Mining Engineering University of Illinois, Urbana, Ill.

†"Factory," April 15, 1921, "Storing Up a Year of Power," by W. L. Abbott.

Special emphasis is laid on the fact that success in the storage of coal depends upon a very careful and thorough consideration of the problem in advance and attention to the details of storage. Failure to give attention to the details of storage, as outlined later, will often result in losses due to fires. Do not undertake to store coal until you know how to do it properly and safely, and before beginning to store, be sure that you have a definite plan for storage, a suitable place in which to store and adequate appliances to move the coal pile in case heating occurs.

Storage of coal is a very desirable form of insurance for the coal user, but should not be undertaken in large quantities without careful consideration of the matter and unless the party storing is prepared to give due attention to the subject. Before coal is actually stored a suitable place should be prepared for it and a policy to be followed outlined in advance so that all of those who have to do with the storage may receive definite suggestions as to how it is to be done. It is not wise to wait until the coal to be stored is placed on the railroad track at the plant and then to dump it anywhere and in any haphazard way simply so as to release the coal cars promptly. After the coal is in storage it must be watched and provision made to take care of any spontaneous combustion that may develop.

It should be understood that although there is danger of spontaneous combustion that may cause a loss through the ultimate burning of the coal, the fire hazard of stored coal is small, as the heating takes place slowly, and if suitable attention is paid it is easily detected in time to prevent loss of property from fire, excepting sometimes the destruction of the coal itself.

Very often a good storage plan of procedure is mapped out by those in authority, but not followed by those in direct charge of the unloading and storing the coal, who should have authority to reject improper coal and be held responsible for properly unloading it.

Place for Storage

To best insure the user a supply of coal, and to best equalize the transportation problem for the railroads, coal should be stored as near the point of consumption as possible. The householder can usually store in his cellar enough coal to last him through the winter months, but frequently he has not the money to pay for such a supply. A number of schemes have been proposed by banks and co-operative associations for loaning money upon stored coal as collateral, but no definite scheme of this kind seems to have been worked out thus far. The retailer frequently takes care of his customers and protects himself by charging an additional price for coal sold upon deferred payments. In the same way many of the smaller retailers are provided for by the wholesale dealers.

For the office building, hotel, store, etc., in the crowded districts of large cities the space necessary for the storage of any great amount on the property is too valuable for other purposes to be filled by a commodity of relatively low value such as coal; hence only a limited storage capacity is possible in such a building for the current demands of a day or at most of a week or two. This means

that someone should make provision for the storage of large amounts of coal on the outskirts of a city where land is not so valuable, or even outside the city limits, but near enough to be reached by auto truck or even by a short railroad haul. For instance, the Commonwealth Edison Company, in addition to a limited storage supply at each of its power plants in the city of Chicago, keeps a reserve of about 400,000 tons about eight miles from the city. Frequently there are old quarries near a city that are filled with water, and these have been often utilized for coal storage purposes.

Storage at a point intermediate between the mine and the city, either by the mining company or by the purchaser of coal, facilitates the transportation problem for the railroad, and this is recognized by some railroads in granting a through rate for coal stored between the mine and the point of use, providing such coal is not kept in storage more than six months.

A change of only 50,000,000 tons per year from winter to summer would materially help the railroads in equalizing their transportation problem.

The mine operator is interested in storage mainly so that he may operate his mine more regularly, particularly during the summer months, when many mines are compelled to be idle for a great part of the time. Storage at the mine, however, does not help the transportation problem of the railroads, nor does it help the consumer, who has no coal in case of a severe transportation tie-up due to storms or other causes, to know that there is a large amount of coal in storage at the mines. Storage at the mine acts as an operating regulator which permits the mine to run full time on days when there is only a partial car supply or when the car supply for the day is late in arriving, in which case the men are often very loath to go to work. Mine storage may also provide for the storage of sizes for which there is no immediate market. However, the mine is not the proper storage place to relieve the general unequal haulage problem of the railroads or to insure the user a supply of coal when he needs it, and neither the public nor the railroads should consider mine storage as the proper relief for the inequalities of transportation and purchase.

The three parties to be benefited by storage as outlined above should expect to share the expense if there is an increase in price, which should be expected, as it costs to place coal in storage and to take it out from 10 cents up per ton, and this cost is usually considerably more than 10 cents. Coal in storage may mean a slightly higher price to the consumer, but he should not be expected to pay all of the increased price, and this increase should be divided between the three parties benefited. The purchaser may have to pay something for increased insurance, but the railroad should grant a differential freight rate for coal hauled during the summer months and at a time when haulage is done more cheaply and when it can better utilize its equipment. The mine operator should grant a reduced price during the same season if in so doing he is able to operate his mine more regularly and thus better distribute his overhead costs. This has been done for years in the anthracite district, a reduction of 50 cents per ton being made, usually beginning April 1st, with an increase of

10 cents per ton per month until the regular price is reached in September. A similar custom has been tried out to a less extent in bituminous districts.

The Preparation of the Place of Storage

If possible a place should be chosen that is dry and well drained; if not drained naturally, drains should be provided about the storage pile, not underneath it, as a drain beneath a pile may produce an air current up through the pile and thus assist spontaneous combustion.

Coal should not be dumped on ground covered with ashes or refuse of any kind, because often in addition to furnishing flues for the admission of air, such refuse contains combustible material; furthermore, the presence of such refuse will depreciate the value of the coal when it is reclaimed from storage. If possible, the ground should be cleared of vegetation and leveled off, so that the reclaiming of the coal will be made as easy as possible, and so that, in reclaiming, dirt and refuse will not be taken up by the shovel or by other devices used. There is some justification for the objection of firemen to using coal that has been stored, because of the dirt and other refuse that are often mixed with the coal in taking it from the storage pile. A hard clay bottom thoroughly drained is desirable, if a concrete one is too expensive.

If possible, adequate space should be provided so that the coal can be moved, if heating occurs. Coal should not be piled around hot pipes, against a boiler, against hot walls, around a chimney, or in any place where it will be subjected to outside heat, because the liability to spontaneous combustion increases rapidly with a rise in temperature. Coal should not be stored above flues that will permit a current of air to enter the coal pile; hot air such as that from a sewer is particularly to be avoided.

Time of Year for Storage

In order best to equalize transportation facilities, to help stabilize mine operation, and sometimes to take advantage of lower prices, coal should be stored between the first of May and the first of September. However, as these are the hottest months of the year, special precautions should be taken both in storing and in watching the coal after it is placed in storage. Coal is a poor conductor of heat, and if coal that is already at a high temperature is covered by other coal, it retains the heat and is much more liable to spontaneous combustion than coal that is stored at a lower temperature.

Kinds of Coal That May Be Stored

All of the evidence gathered to date points to the general conclusion that all varieties of bituminous coal have been stored successfully, while it is equally true that all varieties have fired in storage. All of the evidence points to the fact that the size of the coal placed in storage, its freedom from dust, and the way in which it is piled, are much more important in avoiding the inconvenience and often the loss from fire due to spontaneous combustion than is the choice of coal from a certain mining district or even from a certain mine. Some think that there are certain inherent qualities in coal

that makes it better for storage than coal from other districts, and some even go to the extent of claiming that coal from a certain mine in a given district is better than coal from adjoining mines in the same district. Evidence does not support this opinion. This statement does not mean that all coals store equally well, as there is a difference in storage qualities in coal from different districts, and even from mines in the same district, but the point to be given chief consideration is not so much the kind of coal or the district it comes from as it is the size of coal placed in storage and the way in which it is stored. The kind of coal to be stored should be carefully considered, and if investigation shows that the coal from a certain district or even from a given mine has frequently fired, common sense suggests not buying such coal for storage if it can be avoided. The data are not available at the present time to classify coals upon the basis of their liability to spontaneous combustion, and it is doubtful if this ever can be done. If there is no choice of coal to be had, greater precautions in piling and in watching storage piles will be necessary.

Clean screened coal, as nearly uniform in size as possible, should be chosen if it is available. The larger and more uniform the lumps the better, as such lumps given an open textured pile that permits an adequate circulation of air. Coal of one size is therefore better than a mixture of sizes, and run of mine coal is the worst of all sizes for storage. Sized coal should not be stored upon a foundation of fine coal, and in the handling of coal into storage care should be taken to prevent breakage as much as possible, as breakage produces dust and also opens fresh surfaces of coal that oxidize more readily than do the weathered surfaces. If there is a choice of coal for storage, the least friable should be chosen, as there will be less breakage and dust as the result of handling such a coal.

It is commonly thought that it is inadvisable to mix coals of different varieties in storage. Although there is no theoretical reason for this, the experience of those storing coal in large quantities is against the practice, which should be avoided if possible.

While many varieties of mine run coal cannot be stored safely under ordinary conditions because of the presence of fine coal and dust, such coal has been successfully stored in small, low piles, and in storing such coal it should always be piled in layers, so as to prevent segregation.

Fine coal, slack, or screenings is more liable to spontaneous combustion than clean, sized coal; hence if placed in storage it should be very carefully watched for evidences of heating, and the only absolutely safe way to store such coal is under water. The more compact a pile of screenings can be made the better, so as to exclude the air.

Spontaneous Combustion

Why should only sized coal from which the dust has been removed be stored? The great enemy of storage is spontaneous combustion, and this is due mainly to the oxidation of the coal which takes place continuously from the time it is mined until it is used, providing the coal is in contact with air so that oxidation of the carbon in the coal is possible. This oxidation is largely superficial and con-

sequently the greater the surface area of coal exposed to air the more rapid will be the oxidation. For instance, a cube of coal 1-inch on the side has 6-square inches of surface exposed to the air; now if this cube be divided into eight equal sized cubes by three planes cutting it at right angles to the original faces there will be eight half-inch cubes and each cube will have $1\frac{1}{2}$ -square inches of face exposed to the air, a total of 12-square inches. Then if each of these smaller cubes is similarly subdivided into eight $\frac{1}{4}$ -inch cubes there will be 64 pieces and 24-square inches of surface, a rapid increase in oxidizable surface exposed to the air. Continue the process so that the coal is pulverized finely and there is practically an infinite surface exposed to the air and the liability to spontaneous combustion is thus very greatly increased.

Sulphur in Coal

Although experimentation has shown that the sulphur contained in coal in the form of pyrites is not the chief cause of spontaneous combustion, as was formerly supposed, yet the oxidation of the sulphur in the coal not only produces heat but also assists in breaking up the lumps and thus increasing the amount of fine coal in the pile. Any considerable rise in temperature from either external or internal sources promotes the oxidation of the iron pyrites. This oxidation produces heat and thus increases the liability of the coal to spontaneous combustion. It is wise to select low sulphur coals for storage if obtainable, but it must not be taken for granted that a low sulphur coal will necessarily store well.

Heating Versus Spontaneous Combustion

A distinction should be made between the heating of coal and actual spontaneous combustion or burning. A coal may heat without taking fire, and unless the temperature rises to such a degree that the composition of the coal is materially changed through the driving off of a considerable part of its volatile content or by the actual burning of a part of the coal, such slow and gradual heating may not materially affect the value of the coal. If the temperature of a coal pile is found to be rising rapidly, provision should be made to move the coal if the temperature reaches about 150 degrees and continues to rise rapidly. On the other hand, if the temperature is rising slowly the coal need not be moved until a somewhat higher temperature is reached, as it frequently happens that the temperature rises for awhile and then remains stationary or decreases.

The period of greatest liability of oxidation or spontaneous combustion is within the first three months after the coal has been mined, particularly if this is during the hot summer months. Observation of a large number of coal pile fires shows that the liability to spontaneous combustion decreases rapidly after the coal has been in storage for three months, and after a coal pile has gone through one summer without heating it is reasonably safe to conclude that it will not heat afterwards, unless it is opened up so that air can get to the inside of the pile, in which case it seems to be as liable to combustion as it was when originally laid down in the pile. This decrease in the tendency to heat is

known as "seasoning" of the coal and is probably due to the fact that the volatile gases that ignite easily are given off from the outside of the pile but not from the interior of the pile. When the pile is opened up the coal from the inside is in practically the same condition as was the freshly mined coal.

Heating may be local or general, that is, it may be confined to a small area from which the coal can be easily dug out and the small amount affected reduced in temperature by contact with the air or by the application of water, but if possible such coal should be used at once and not returned to the pile. If the heating is general throughout the pile and is approaching the dangerous temperature noted above, provision should be made to move the pile, or still better, to use the coal at once if at all possible. If it cannot be used at once it should be spread out so that the temperature may be reduced by contact with the air, unless, of course, the temperature has already reached such a point that the addition of more air will cause actual firing.

It should be understood that although there is danger of spontaneous combustion that may cause a loss through the ultimate burning of the coal, the fire hazard to buildings near the stored coal is small, as the heating takes place slowly and if suitable attention is paid to the coal pile it is easily detected in time to prevent loss of property from fire.

Moisture

The exact effect of moisture in connection with spontaneous combustion is not known, and the evidence of laboratory experiments is contradictory.

The repeated wetting and drying of coal seems to increase the tendency to spontaneous combustion. This may be due to the breaking up of the coal which such alternate wetting and drying occasions, even if there is no chemical reaction between the water and the coal. It is not wise to put wet coal into a pile, or to store on a damp base if it can be avoided. After a rain or snowstorm a coal pile should be carefully inspected and watched.

Water is an effective agent in quenching fire in a coal pile only if it can be applied in sufficient quantities to extinguish the fire and to cool the mass. The water must be applied at the source of the fire, for it can do little good if the stream is only played on the surface. To be sure that the water reaches the fire it is usually necessary to turn over the coal.

It is advisable to have water and hose available for use in case of necessity, but water should be used carefully and only as a last resort after other means, such as moving the coal, have been tried to lower the temperature. An effort should be made to determine the seat of the heating and to remove the coal affected, which should be spread out on the ground and allowed to cool off in the air, if possible. Only in case of necessity should water be used to cool it. If some of the coal is ablaze it is necessary to add water, which very often will so control the fire that the danger to surrounding buildings is reduced, and more time is allowed to move the main coal pile. Coal that has once heated should preferably be used at once and not be returned to the pile.

A fire deep down in a pile may cause the coking of the coal and the evolution of tarry material in connection with coking may form an impervious coating around the fire through which the water cannot penetrate. Such coating must be broken up before the water can reach and be at all effective in connection with the fire.

Decrease in Heating Value of Stored Coal

There is a wide difference of opinion upon this point, and it must be admitted that there is a great prejudice upon the part of many firemen against stored coal, but much of this prejudice is undoubtedly not warranted. Experiments have shown that the heating value of coal in B.t.u.'s is decreased very little by storage, but many think that storage coal burns less freely than fresh coal. This may be so in some instances, but many of those who have stored coal in large quantities report that even where this condition prevails it may be overcome by keeping a thinner bed on the grate and by regulating the draft.

The outside of a pile of stored coal undoubtedly weathers and breaks up into fine particles, so that if stored in the open there will be a certain loss from fine coal blown away, but this amount is very small. The writer has investigated a number of coal piles that have been in storage for some time, the surface of which is very unprepossessing and unfuel-like in appearance, and has found that a short distance under the surface the coal is as bright as when placed in storage. For coal stored under water the deterioration is negligible. Undoubtedly some of the justifiable prejudice against stored coal is due to the fact that in picking up the coal from storage with a clam shell bucket very often dirt and rubbish are mixed with the coal.

The coking properties of most coals seem to decrease as a result of storage, but coals vary greatly in this respect and it is difficult to tell whether any deterioration that may occur is the result simply of storage or of heating that may occur in connection with storage.

Detection of Coal Pile Fires

The common methods of detecting the heating of a coal pile are:

- (1) By watching for evidences of steaming in the pile.
- (2) By noting the odor given off; bituminous or sulphurous odors are evidences of heating.
- (3) By noting places where snow on a pile has melted.
- (4) By inserting an iron rod in the pile, and by noting its temperature with the hand after withdrawal.
- (5) By inserting thermometers into the pile and reading them directly.
- (6) By using a pyrometer or plates connected with an automatic recording device.

The first three methods are so self-evident in their application that it is unnecessary to discuss them in detail, but with a large pile, and particularly one where the heating is distant from the surface, a fire may reach an advanced stage without being detected by surface indications.

Method No. 4, by which the temperature of an iron rod is noted with the hand, is a simple test, and one well adapted to piles not over eighteen to

twenty feet deep. By this means a janitor using a poker may keep informed as to the condition of the comparatively small amounts stored in house or apartment basements.

Temperature readings with a thermometer or pyrometer furnish by far the best and most reliable method for keeping informed on the exact condition of a coal pile.

To get the temperature of the inside of a coal pile it is necessary first to provide an opening into which a thermometer or a pyrometer may be inserted. Such openings may be made after the coal is in storage by driving pipes into the pile, but it is easier to place these pipes when the coal is being stored. Pipes left permanently in a pile are a disadvantage, as they interfere with the appliances used to remove the coal. Instead of leaving the pipe in the coal pile it is sometimes necessary only to drive it and then withdraw it, the hole remaining open sufficiently to permit the insertion of the thermometer. To prevent the hole from filling with coal, an inverted funnel of paper is used in Canada.

Pipes, if used, should be plugged at the upper end, so as to exclude the outside air, for if ventilation is allowed through these pipes, a correct temperature reading of the interior of the coal pile is not obtained.

Reducing Temperature and Extinguishing Fires in Coal Piles

The following methods are employed for reducing the temperature in a coal pile:

The most effective method of combating a tendency to fire in a coal pile is by turning over the coal and exposing it to the air, so that it may be thoroughly cooled. Care must be taken in exposing hot coal to the air, for, if the temperature is too high, as soon as the hot spot is opened out the mass will burst into flame and the fire spread very rapidly. Therefore, if there is evidence of a high temperature the spot should not be opened out unless there are ample appliances at hand immediately to move the hot coal, or water sufficient to put out any fire that may start and thoroughly to cool off the mass.

Whenever the fire has reached the stage where the coal is actually ablaze, it may be necessary to use water, but, in general, water should not be used if it can be avoided.

Water should not be used upon a heating coal pile unless it has reached the flaming stage and until other means have proven ineffective.

A number of attempts have been made to utilize the smothering effect of carbon dioxide gas and solutions of bicarbonate of soda in ways somewhat similar to those used in the ordinary hand grenade or fire extinguishers of the Babcock and of similar types. The effect of CO_2 on fire is certain if it can be localized and applied where needed. The difficulty in a large coal pile is to confine the gases. The evidence as to the effectiveness of these agents in fighting fires in coal piles is by no means conclusive either for or against the method.

Ventilation of Coal Piles

The subject of the ventilation of coal piles is one upon which there is a great difference of opinion, and the evidence is very conflicting. It seems to be quite a common practice of Canadian railroads

to ventilate their coal piles with a great deal of care, and it is the opinion of Prof. J. B. Porter, of McGill University, and S. H. Pudney, Fuel Inspector of the Canadian Pacific Railroad, that by means of proper ventilation spontaneous combustion can be prevented and the temperature of coal piles regulated to a very great extent. Other correspondents in Canada do not fully agree with this opinion. The experience of the railroads in the United States seems to differ widely upon this point, to judge from the replies to questionnaires.

Attention should be called to the fact that many pipes placed in coal piles are intended merely for observing temperatures with no thought of ventilating the piles. Coal is a poor conductor of heat, and it is undoubtedly true that much of the so-called ventilation of coal piles has been inadequately done because only a few pipes have been placed irregularly throughout a pile. If ventilation is to be successful, it must be carefully done and pipes placed near together; but when so placed they interfere with rapid handling of the coal and increase the expense. The writer has not seen any of the Canadian coal piles that are reported to have been ventilated successfully, but a study of storage piles in the United States in connection with power plants has shown that the so-called ventilation is usually not well done and has been ineffective.

Sources of Coal Pile Fires

As the result of a systematic study of fires in coal piles in Chicago made in 1918 it was possible to classify the fires under three heads, as follows:

First. Those due partially if not wholly to outside sources of heat, such as piling coal around a boiler, or above a steam pipe, or above a sewer opening through which hot gases arise.

Second. Fires started by foreign materials in the coal, such as old waste, pieces of wood, etc.

Third. Fires whose origin could not be determined as coming from any outside source, and which could be explained only by the method of piling or the kind of coal used.

Fifteen fires were directly traceable to coal being piled about hot water tanks, against hot pipes, or a furnace, or a chimney, or from hot ashes being thrown into the pile. Thirty-nine fires were apparently directly traceable to materials in the coal pile, such as paper, rags, waste, wood, rosin, or to hot sewer gases rising through the pile. Of course, fires started in this way should not be confused with spontaneous combustion of the coal itself, but they are usually so reported by fire departments, etc., and the storage problem is thus confused through such inaccurate reports.

Method of Piling

(1) Coal should be so piled for storage that any part of the pile can be moved promptly if necessary.

(2) Coal should be so piled that air may circulate freely through it and thus carry off any heat generated, or else so closely packed that air cannot enter the pile, i. e., under water storage conditions should be approximated as nearly as possible.

(3) Stratification or segregation of fine and lump coal should be avoided, since an open stratum of coarse lumps provides passage for air to reach the fine coal, but not in sufficient quantity to keep down the temperature of the pile. Coal should be spread in horizontal layers and not dumped in conical piles, for in the latter case the fine coal stays in the center at the top of the pile and the lumps roll to the bottom.

(4) The depth and area of storage piles will be determined largely by the storage space available and the mechanical appliances to be used. Other conditions being equal, the deeper the pile and the greater its area the greater the difficulty in inspecting it, and in moving it quickly if necessary. Hence, a number of small piles, if practicable, are better than one large pile. Lack of space, however, usually prevents such spreading out of the coal. It is impossible to specify exact heights, as so much depends upon the kind of coal and upon local conditions.

The question is often asked: "How deep may coal be piled?" Piles five or six feet deep have taken fire and many piles fifty feet have not. Experiments in England, confirmed by experience in the United States, show that the highest temperature often occurs at a point five to ten feet below the top of the pile and that in general there is a gradual decrease in temperature downward and below this maximum point. In England a standard depth at which temperatures are tested is seven feet below the top. This depends to a considerable extent, however, upon the way in which the coal is piled, and although there are many instances of high piles that have not fired, the evidence shows that there are more fires in deep piles than in shallow, and this may be due to any one of the following reasons:

Air can circulate through a deep pile less readily and carry off the surface heat.

With a deep pile there will usually be increased breakage and fine coal, and there is also greater difficulty in watching the pile and in detecting incipient fires.

As to the effect of the quantity of coal in a storage pile, the difficulty of storing and watching a large quantity and of moving it quickly may increase the fire hazard, but a large quantity is not of itself more dangerous than a small amount. In all cases the arrangement of the pile so that it can be easily reached by an appliance for moving the coal in case of necessity is of much greater importance than the depth of the pile or the total amount in the pile.

The fundamental consideration where coal is piled by machinery is that there should be the least possible breakage and that segregation of the sizes may be avoided. To accomplish this coal should be piled in layers and not dropped at one point in the form of a cone so that the large pieces may roll to the bottom of the pile and the fine coal accumulate at the top of the pile. In a number of fires investigated in the city of Chicago the point of firing was found to be a short distance below the window through which the coal had been thrown into a bin and at a point where the currents of air rising through the lumps which had rolled to the bottom were restricted by the coating of fine

coal on the top of the pile. The method of piling recommended by the Railway Fuel Administration is shown in Fig. 1.

Fig. 1. Method of Building Pyramidal Pile in Layers. Level of storage pile raised two feet at a time the full length of pile, by lowering the clam-shell to a point just above the surface of the pile before discharging contents.

The breakage will be very materially lessened if the clam-shell bucket is lowered to a point just above the surface of the pile before the contents are dumped. A layer of coal 2 feet in height should be laid down to the full width of the base of the pile and over the entire length of same, the second and succeeding layers, each 2 feet in thickness, being laid down in like manner. This method of unloading will eliminate the accumulation of broken fine particles in the center of the pile, and in addition, give the coal a limited opportunity to season before being covered by the succeeding layer.

Choice of a Storage System

In the choice of a storage system the following points should be considered:

- (1) The location, size, and topography of the available storage ground.
- (2) The capacity of the desired installation, that is, the amount of coal which it is desired to load and unload in a given time.
- (3) The cost of the plant.
- (4) The cost of maintenance.
- (5) The cost of operation.
- (6) The amount of breakage to be permitted in handling the coal.
- (7) The way in which the coal is received, in open or box cars, or in boats.
- (8) The length of time the coal must be kept in storage.
- (9) Climate; in very cold countries under-water storage is impracticable for a part of the year.

The Requirements of An Ideal Plant Are

- (1) Adequate ground area, so that several sizes and varieties of coal may be stored separately. Separation into sizes has not been considered so important for bituminous as for anthracite coal, but it is becoming more important because of the increasing attention being given to preparation of coal for domestic use, and because of the fact that danger of spontaneous combustion is decreased by keeping different sizes separate in storage.
- (2) Adequate facilities for rapidly and economically transferring coal from cars or from boats into storage.
- (3) Adequate facilities for rapidly and economically reclaiming the coal and for rapidly moving any part of the pile which shows evidences of taking fire.

(4) Adequate track facilities, with gravity facilities, if possible, for handling cars.

(5) Means for preventing undue breakage in handling.

(6) Facilities for rescreening the stored coal, which, of course, increase the cost.

(7) Adequate available water supply.

(8) Low cost of installation, maintenance, and operation per ton of capacity. A storage plant is in operation very irregularly and costs are likely to be correspondingly higher because of the heavy fixed charges, especially interest and depreciation.

Few, if any, storage plants possess or require all these ideal conditions.

In a coke plant, for instance, breakage need not be considered, except in connection with spontaneous combustion, since the coal is ground fine before being charged into the ovens. Storage facilities must, of course, be adapted to the various requirements and limitations in coal yards, power plants, railroad yards, boat docks, steel plants, and other establishments.

Usually much of the storage must be done not under ideal conditions, but the fact that the prevailing conditions must be accepted does not excuse the lack of forethought too often observable in connection with storage propositions. In fact it might be said that the more unfavorable the conditions about the plant for storage the greater should be the foresight and care in planning for storage.

Storage Appliances

The simplest form of storage is where the coal is dumped from a car on a trestle into a bin, or else dumped or shoveled upon the ground and wheeled into a bin or spread out upon a pile. The cost of such storage is usually high, but on account of the small amounts handled it should be possible to easily provide against spontaneous combustion. However, some very troublesome fires have occurred in the basements or boiler houses of large buildings where only a few hundred tons have been stored, but where the coal has been piled against the boiler or against hot pipes.

Pile storage from cars which run on a track on the coal pile and which is raised from time to time is probably the method most widely used by railroads. It is also adopted to some extent by commercial plants because it is easy to apply and requires only a small expenditure of money for permanent equipment and because the track can be moved from place to place as desired.

The objections to the method are:

(a) The pyramiding effect; that is, the segregation of fine coal at the center and top of the pile, is intensified as the locomotive and loaded train crush the coal under the track.

(b) It is not practicable to divide the coal by cross-passageways so as to make a number of small piles and thus render each pile easy of access for reclaiming.

(c) When coal is piled in this way adequate track provision for moving the coal quickly is apt to be neglected until it is time to move the coal,

and a track cannot then be put in place quickly enough to save the pile. Where this method is used the track should be moved from the top of the pile to the surface alongside the pile so as to provide for the rapid loading out of the coal, if necessary. The use of a standard railroad ballast spreader to spread the coal on the pile is to be preferred to the ordinary method of dragging a tie through the coal.

Storage by truck is probably next in simplicity to hand and wheelbarrow storage, and one of the best examples of such storage is to be found at the University of Illinois, where, in connection with the central power plant, this method has been used with great success for a number of years. The annual consumption of the University is about 30,000 tons, with a daily use of from 50 to 100 tons. For several years it was customary to stock from 4,000 to 5,000 tons on the ground in piles about 12 feet high, the coal being thrown from the railroad car upon the pile, distributed by scrapers and hauled by wagons to the power house when needed. At times fires occurred in these piles. A new system adopted several years ago is illustrated in Fig. 2. The storage area is about 114 by 196 feet, and as the area was formerly used for tennis

Fig. 2. Placing the First Layer of Coal on Storage Plat at the University of Illinois.

courts, the base is an ideal one, being of firm, smooth clay. The space is surrounded by a plank fence 7 feet high, and although such a fence does not conform to the best practice, unless it is tightly sealed, very little trouble has been experienced in connection with the storage under discussion, and only a few small fires have occurred on the outside of the pile and alongside of the timber fence. The storage plant is about 1,000 feet from the power house, where the coal is received in railroad cars. It is dumped into an undertrack hopper from which it is elevated and delivered either directly into the overhead bunkers in the power house, or, if it is intended for storage, is fed into a chute down to an auto truck, which holds $3\frac{3}{4}$ tons, in which it is taken to the storage ground, where it is laid down in layers about 2 to 5 feet thick. A second layer is laid down by the truck running on top of the pile, and to permit it to do this a track is built of scrap plank, the pieces of plank being kept together by pieces of old iron cable. This track is laid down in sections 5 to 8 feet long and can easily be moved over the top of the pile. This not only serves as a track for the truck, but also permits the pile to be

compacted as the truck runs over it. This method has proven very successful and has been tried out now for a number of years. The coal is reclaimed by a portable loader, into which several men shovel and which in turn delivers it to the truck that takes the coal to the power house. Although successful, the cost of operation has been high and the latest figures show the cost of storage and reclaiming to be 40 to 45 cts. per ton.

Trestle storage, by which the coal is dumped directly from the cars into bins or upon piles, has the disadvantage of giving an exaggerated segregation of the sizes. It also requires an initial permanent investment in a structure which is used only a short time, and the legs of the trestle, if of timber, are frequently starting points for fires. The bents of the trestle also interfere with the loading out of the coal and also the cleaning out of the bin.

A combination of locomotive crane and trestle storage has been satisfactorily used in a number of cases, and probably the most generally used appliance in the storage of coal is the locomotive crane, both because it is very flexible in its operation, can be adapted to a number of uses about a plant, and furthermore many manufacturing plants are already provided with such cranes. Fig. 3 shows two systems of trestle storage and of reclaiming of coal by means of a tunnel which may

Fig. 3. Trestle and Tunnel Systems, Showing an Above-Ground and a Below-Ground Tunnel.

be either above or below the ground level, coal being fed by gravity into a car or by some form of conveyor in the tunnel. The use of a reloading tunnel decreases the cost of handling considerably, but with the tunnel above ground only 35% of the coal may be thus reloaded by gravity and in an underground tunnel only 50 to 60%. The amount of storage space may be increased by building bulk heads along the side of the pile, as shown in Fig. 3.

Where such bulk heads are used it is advantageous to make them airtight by a luting of some kind. As a result of luting such bulk heads the Milwaukee Coke and Gas Company has found the tendency to heat in its very large coal piles to be very greatly decreased.

Fig. 4. Arrangement of Tracks and Storage Piles Employed by the Commonwealth Edison Company in Open Storage.

Where machinery is used for loading and unloading purposes the storage piles are:

(a) Either rectangular, relatively narrow piles continuous in length, or divided up into a number of smaller piles by cross alleys.

(b) Circular piles arranged in straight lines or else concentrically around a central pile.

Fig. 4 shows cross section of pyramidal piles as used by the Commonwealth Edison Company of Chicago, which company, under the direction

of Mr. W. L. Abbott, Chief Engineer, has stored large quantities of coal very successfully for a number of years. As shown by the sketches, the coal is piled between pairs of track which are 80 feet apart, and a crane can operate from either track while loading or unloading cars on the central track. The piles shown in the upper part of the illustration contain about 30 tons per running foot, while the lower part of the illustration shows a newer arrangement adopted by Mr. Abbott and used in the yards recently built by the Commonwealth Edison Company. As shown, the ground is excavated to a distance of 5 feet below

the surface and the soil taken from the excavation is used to raise the tracks five feet above the level, thus giving the coal pile a total depth of 35 feet and containing 45 tons per foot of length. This system, or modification of it, is used extensively in wholesale storage yards and also by a number of railroads. Fig. 5 shows a standard system of the Missouri Pacific Railroad. For coals that are liable to spontaneous combustion the alleyways across the piles are used, otherwise the piles are continuous.

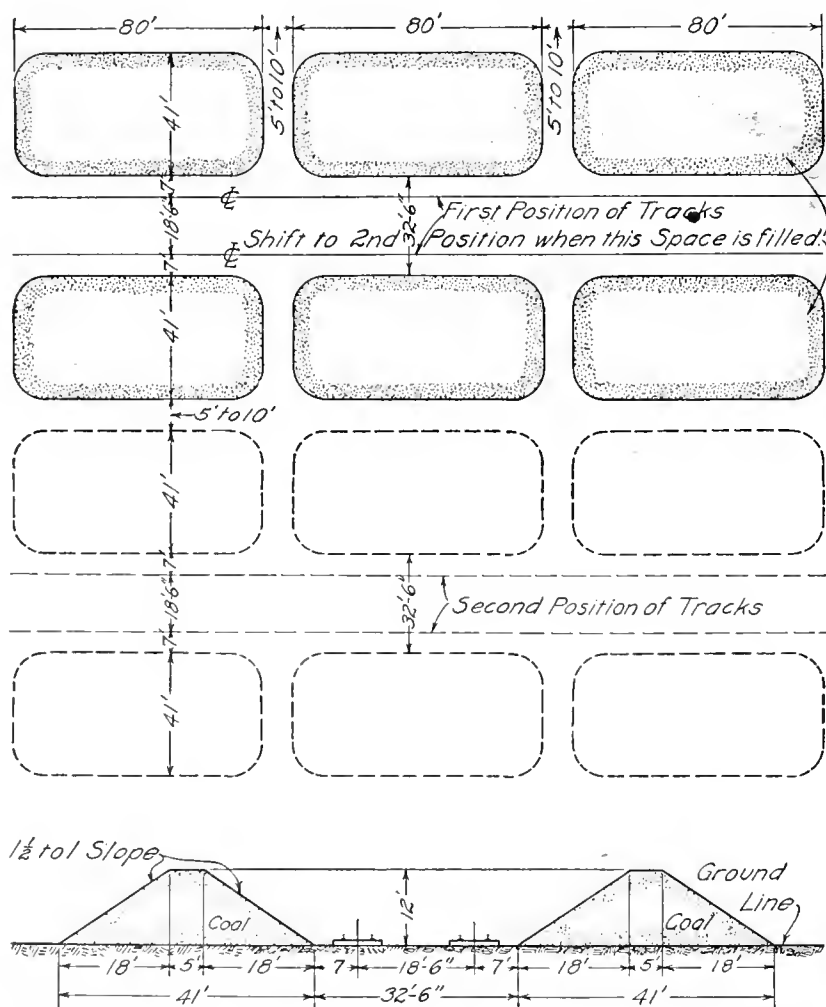

Fig. 5. Plan and Section Illustrating Coal Storage System of Missouri Pacific Railroad.

Figs. 6, 7 and 8 show a circular form of storage patented by the J. M. Dodge Company said to be particularly adapted to the operation of a locomotive crane in a circle. Coal is dumped from the railroad car into a track hopper, as shown, and from the hopper is transferred by a long radius locomotive crane operating a self-filling clam-shell bucket which transfers the coal from the hopper to a concentric circular pile about the track hopper. For reclaiming the coal the crane takes the coal from the pile and loads it directly into the cars. With such a system from 40 to 200 tons per hour can be handled, depending upon size of the bucket and crane used.

Fig. 6. Dodge Type of Circular Storage System.

To give increased capacity concentric piles may be arranged, as shown in Fig. 7, the operation of which is self-evident. By suitable arrangement of tracks a similar arrangement can be applied to elliptical or semi-circular piles where surface is available only on one side of the power house, as shown in Fig. 8.

Fig. 7. Twenty-Five-Thousand-Ton Storage Plant.

Side hill storage is dependent upon the topography of the country and it gives an excessive breakage and segregation of the sizes. It has seldom been used in connection with bituminous coal, but there are a number of side hill anthracite plants.

The portable or semi-portable type of conveyor or elevator, as developed by a number of different firms, seems to be well adapted and very flexible for storage purposes and the machinery is less expensive than appliances of the crane type, either locomotive or gantry. These appliances, as illustrated in Fig. 9, consist essentially of a belt or bucket conveyor suitably supported on a framework, and either temporarily fixed on a light structure, or movable. Some of the semi-portable conveyors have one fixed or pivoted end for receiving the coal, while the other, or discharge end, can be moved about the

Fig. 9. Semi-Circular Storage Adapted to Locations Near Power House or Coaling Stations.

Fig. 10. Circular Method of Piling Coal. Using Both Portable and Semi-Portable Conveyors.

pivoted end, and thus build up a circular concentric pile. Fig. 9 shows the application of such portable conveyors to concentric piles, and Fig. 10 their use at Mooseheart, Ill., for building up a number of small piles concentric to a central pile. The operation of such conveyors is self-evident and does not need description.

Figure 11 is a plan and section of a coal handling plant used by the Southern Railway in which a drag bucket is employed to place the coal and later to gather it. After the coal is dropped from the railroad car into the coal hopper, it is elevated by buckets which may be dumped directly toward the storage bin or else on to a chute on which the coal passes to the coal pile. As the coal accumulates it is spread out by the use of the drag bucket, one end of which is attached by means of hitching lines to so-called pulling poles. It is easily moved into any position. When it is desired to gather up coal for the storage bin, the bucket brings the coal to the coal hopper, after which it is elevated as before explained.

Figure 12 suggests a method of utilizing a large storage space with a small outlay of machinery. The quantity that may be stored will depend on the height of the towers and the length of track upon which the movable tower runs.

Figure 13 is an elevation showing the application of trolleys to the problem of storage. The coal drops from the railroad car into a bin, from which it passes, under the control of a gate, to a standard conveying bucket. It is then elevated by means of a hoist to an overhead trolley which runs on a track held by vertical supports. The bucket can be lowered and the coal tipped at any convenient

point. When the coal is reclaimed the trolley continues into the boiler house and the coal empties into a bin. The same conveying system may be made to remove the ashes, care being taken, however, to have the heat from these well insulated from the coal pile.

Fig. 14.

Figs. 14, 15 and 16 show a method of storage in use at Mooseheart, Ill. Coal is dumped from drop-bottom cars into a hopper, from where it is carried by a pivoted bucket elevator to the boilers. Coal for storage is shunted through a spout to the combination of conveyors, by means of which the coal can be stored in piles, 12 to 15 feet in height, and so arranged that the cross sectional area is small in order to lessen the danger of fire. In the seven piles shown in the plan about 6,000 tons of coal were stored.

In reclaiming, the operation is just the reverse, as shown by the view at bottom of the figure. A mechanical loader may be added for placing the coal on the first conveyor, thus keeping labor cost at a minimum.

The idea back of this plan is to accumulate the maximum quantity of coal on the smallest base in the most economical manner, and at the same time to offer the greatest protection possible against fire.

Storage in silos, Figs. 17 and 18, built of concrete or of wooden staves, similar to those used for

Fig. 15. Plan of Coal Storage at Mooseheart.

Reclaiming Coal As Needed
Same Equipment with Self-Feeding Bucket-Loader Added.

Fig. 16.

grain, has quite recently come into vogue and a number of such plants are now being operated successfully. If the bottom of the silo is tightly sealed when coal is not being drawn out of the silo it serves practically the same purpose as storage under water, as the pile can be made very nearly airtight. Where silos are used, however, air should not be allowed to enter the bottom, for in one instance where this occurred an explosion took place which blew off the top of the silo.

The various forms of bridges used for handling

coal, ore, etc., in large quantities, Fig. 19, are well known and are used for very extensive storage plants. Belts, either alone or in connection with bridges, are also extensively used.

Under water storage has the advantage of completely eliminating the fire risk, but it requires peculiar conditions for its installation and is generally quite expensive in the original installation. A simple example of such storage at the plant of the Western Clock Co., Peru, Ill., is shown in Fig. 20. Locomotive cranes are often used to reclaim the coal

from under water storage pits, the cranes operating either from tracks alongside the pits or running lengthwise of the pits directly above the coal. Sometimes, as at a storage plant near Kankakee, Ill., an old quarry filled with water has been utilized as a storage pit and the fine coal is pumped by centrifugal pumps from the water.

COAL SAMPLING

Methods of Taking Mine Car, Cargo and Wagon Samples

By coal sampling is meant the process of collecting a quantity of coal, either from the seam itself or from a mass of loose coal in the course of shipment, in such a way that it shall be representative of the product. To successfully carry out the procedure requires that the person taking the sample exercises good judgment in order that it will represent fairly both the virtues and the faults of the coal. A knowledge of mining is not essential, but it is very helpful when samples are taken within the mine, as it enables one to better decide on the inclusion or exclusion of impurities.

Coal samples may be taken in several ways, the accuracy of the work, in each case, being entirely dependent upon the sampler. For this reason it is well worth while for all interested in coal to become thoroughly familiar with the various methods of sampling. Since the real purpose of coal analysis is to determine the percentage of the various elements or parts entering into the composition of coal, it is of exceeding importance that every sample should be taken in accordance with well formulated instructions, and it is always advisable, when submitting a sample, that it be accompanied by a statement of how and by whom it has been taken. Nothing is gained by having an analysis made of specially selected lumps, and by its glamour attempting to establish a reputation which the shipped product can never hope to attain. As well might the orchardist hope to perpetually hoodwink the public by artfully using perfect fruit to conceal the decay lying beneath. Far better it is for the good name of a coal, and for the peace of the producer and consumer, when samples are correctly taken, that is, with a proper inclusion of both the good and the bad. An analysis made from a sample so taken will correctly indicate the quality of the coal as shipped and as reasonably possible to be maintained.

Mine Samples

A much used method is that where samples are taken within the mine by hewing a narrow channel from the top to bottom of the seam. This method has been, and still is, much used by the United States Geological Survey, Bureau of Mines,* and the various state geological surveys. It is frequently criticised, and has undoubtedly caused trouble, for the reason that results have not been correctly interpreted. There has been an unfortunate tendency to regard an analysis made from mine samples as indicating the composition of shipped coal, whereas, in truth, it but sets forth the high degree of perfection which the coal may hope to attain. A common illustration of this misunderstanding is shown by the readiness with which shippers occasionally meet complaints by offering in refutation copies of analyses made from mine

samples, a recourse likely to be ineffectual when optical demonstration is to be had of slate, fire clay, crop coal, or bony coal plentifully found in the shipment, and of which no account had been taken in the mine sample. Coal samples taken well inside the mine usually show a better grade of coal than the average commercial shipment from the same mine, the degree of difference depending, as already suggested, upon the amount of removable impurities in the seam and the effectiveness with which they are excluded from the coal. In nearly all cases, however, the shipped coal is inferior, for the reason that the miner who is paid on the per ton basis will not exercise the same care in separating slate or band before shoveling as would the person preparing the sample.

In spite of such difficulties, due largely to a misconception of the real status of mine samples, they are, nevertheless, of much value to the operator, and it is freely recommended that they be taken in every mine, at various places therein, and at various time intervals, for it is only in this way that the operator may know what the inherent quality of his coal is, and knowing this, he can, when confronted with analyses of shipments that are inferior, at once proceed to determine the factors causing undue discrepancies between the coal in the seam and the coal as shipped, and to applying the proper remedies.

In deciding upon the section or sections where samples are to be taken, much will depend upon the development and output of the mine. The larger the mine and the more spread out it is in its development, the more samples will need be taken. Thus, a mine with a daily output of 1,000 tons derived from six active sections would require that at least six samples be taken, with additional samples to be taken in the sections under development for the purpose of indicating any variation in composition in the future sources of supply. A map of the mine will greatly assist in selecting the places to be sampled.

Having decided upon the sections and the probable number of samples to be used, the working places from which these are to be taken is next decided upon. This can be done only after an examination of the mine has been made and such working places selected as represent the average working conditions of each section. It would be obviously unfair to select a place just passing through a clay vein, or one in which water is continuously passing over the coal face. The object at all times should be to strike the average working condition. After the place is decided upon, all loose pieces of coal, stone or dirt should be brushed from the face for a width of two to three feet. The floor is then made smooth and clean and a sampling cloth, preferably of duck material, is spread and made ready to collect the broken pieces of coal produced

*See Tech. Paper No. 1, "The Sampling of Coal in the Mine," by Dr. Joseph A. Holmes.

by a vertical cut, 2 inches deep and 6 inches wide, made with a sharp pick and extending from the roof to the floor, provided the entire thickness of seam is mined. If, as is sometimes the case, top coal is permitted to remain as a protection to the roof, or part of the bottom is unmined because of its impurities, the channel would not include such parts of the seam.

A further point of great importance is that only such of the impurities, including iron pyrites, bone, slate or partings, as are actually cast out by the miner before loading, or are later removed by mechanical or hand processes in the course of preparation, are to be cast out in sampling. It is here that the personal equation enters largely into sampling and it is here that the greatest opportunity for error exists. The best guide, undoubtedly, is a familiarity with both the customs of the miners and the degree of preparation given the coal before loading into railroad cars.

After the cutting of the sample is completed, the lumpy portion is reduced by pounding with a hammer, or the flat of a shovel, until the mass is sufficiently fine to pass through a $\frac{1}{2}$ -inch screen. The sample is then thoroughly mixed, either by turning over with a shovel or by manipulating the cloth. After leveling the mass it is quartered—two opposite quarters being rejected and removed from the cloth. The remainder is thoroughly mixed as before and the method of reducing the sample by first quartering and then rejecting opposite quarters is continued until the sample is finally reduced to about three pounds, or an amount sufficient to closely fill a quart fruit jar or can of approximately the same size. The jar should be shaken to pack the coal, and, after it is well filled, it is ready for shipment to the laboratory. The receptacle used should be provided with a rubber gasket to guard against transference of moisture to or from the coal sample from the time it leaves the mine until ready for analysis, or in place of a gasket it can be sealed with adhesive tape. It is to guard against loss in moisture that reduction and quartering should always be done in the mine and not on the outside, where the coal would be subject to atmospheric influences. All jars or cans should bear a label on which is given the number of the sample. This number should be recorded in the sampler's note book, along with information on the location of the place where sample was taken, and all other details which tend to make its identification easy.

Coal samples taken in openings near the outcrop, or where the coal is more or less weathered, will usually run higher in ash and lower in volatile matter than coal lying farther in, and, wherever possible, such samples should be avoided, as they may not fairly represent the quality of coal commercially possible.

It is always advisable to have the analysis made promptly. Porter and Ovitz* have shown that samples of coal evolve methane and carbon dioxide and absorb oxygen for a period of several months. Parr has found that Illinois coals may lose in heat value from 0.5 to 1 per cent in the first ten days after mining and during the process of preparing the sample for analysis.

Car Samples

Car samples may be taken either while the railroad car is being loaded at the mine, or while being

unloaded at its destination. In either case the object is to procure a mass of coal in such a manner that it shall be a reliable representation of the total shipment. This requires that the gross sample be made up by taking portions of different parts of the mass, and such opportunity is best afforded when the coal is in the course of loading into or unloading from railroad cars. The gross sample should contain the same proportion of lump coal, fine coal, and impurities as the coal sampled.

The Bureau of Mines recommends that when the car is sampled as loaded the procedure be as follows:† “When a shipment of coal is sampled at the mine, shovelfuls or portions of coal should be taken systematically as the coal is loaded into the railroad car, and with such regularity that the sample will represent the entire carload. The frequency of collecting the portion will depend on the number of cars of coal to be represented by one gross sample. If only one carload is to be sampled, a gross sample of 1,000 pounds, or more, should be collected. If two or more cars of coal are to be represented by the sample, proportionate amounts to make up the gross sample should be taken from the coal as it is loaded into each car. The samples should be taken after the coal has been prepared for market; that is, if the coal is passed over picking tables or pickers are employed on the car to remove the impurities from the coal, the samples should be taken only after the coal has had its final preparation.”

When coal is sampled at its destination, the procedure is governed by the type of railroad equipment. If the car be of the flat-bottom type and unloaded by hand, hand shovelfuls should be taken at regular intervals as the coal is being unloaded into wagons or bins. It is usually the practice for the men doing the unloading to go straight to the bottom. Then the same procedure of starting at the bottom and proceeding to the top of the exposed surfaces should be carried over four or five different places on that one surface. This should be done in the ends and middle as the car is unloaded, so that a little coal is taken from practically all parts of the car. Sampling while unloading from drop-bottom cars is likely to be more difficult owing to the rapid flow of the coal from the car. Where possible, shovelfuls are taken at frequent intervals during the drop of the coal, or a sample may be gathered by collecting shovelfuls of coal that has overflowed on the pier or the sides of pockets.

On the size of the gross sample, we again quote from the Bureau of Mines:‡ “For run-of-mine or lump coal, the gross sample must not be less than 1,000 pounds. If the coal contains an unusual amount of impurities in pieces of considerable size, the gross sample should be about 1,500 pounds. For slack coal and small sizes of anthracite in which the impurities are in not abnormal quantities, or are not in pieces larger than three-quarter inch, a gross sample of approximately 500 pounds is sufficient. Whether the quantity of coal sampled consists of 1 ton, 500 tons, or more, the need of the gross sample being of the sizes stated is the same.”

A means sometimes referred to for taking samples of coal on the car is that of driving an iron pipe through the mass, the contents of the pipe

*Technical Paper 2, Bureau of Mines.

†Bulletin 116, “Methods of Sampling Delivered Coal,” by George S. Pope.

‡Ibid.

being used for the purpose of analysis. This method is at all times a troublesome one and is impossible of use in the case of run-of-mine or lump coal. An improved device for taking samples of coal that is 3 inches or smaller in diameter is shown in Figure 1. Figure 2, showing the sampler imbedded in the coal, makes plain that the sample is extracted from top to bottom of the coal as it lies

Fig. 1. Mechanical Coal Sampler.

in the car. After withdrawal, the coal is expelled from the pipe by merely reversing the spiral. The teeth at the bottom of the pipe act as "grip-pers," thus keeping the pipe from turning. These, together with the spiral, act also as a "clipper" and shear off pieces of coal that wedge between.

As many samples may be taken as thought necessary, but if two samples are taken at opposite ends of a diagonal line running from corner to corner of car, and additional samples taken at 10 to 12 feet intervals on the same diagonal line, the gross sample will fairly represent the shipment. The samples at the corners should be taken at least one foot away from the corner and side plates of the car.

Cargo Samples

The methods followed by the Bureau of Mines in sampling coal discharged into ships is as follows:* "Portions of coal should be taken in equal quantities and at frequent and regular intervals so as to represent proportionate parts of the consignment as a whole, either while the car is being loaded or unloaded.

There is no assurance that a sample or a series of samples taken from the top of the cargo represents the cargo as a whole; in fact, it is very doubtful if such samples are ever representative. The Bureau of Mines has charge of the sampling of cargo shipments of coal to the Isthmus of Panama for the Panama Railroad Company. The coal, which is loaded from piers at Hampton Roads, Norfolk and Newport News, Va., is dumped directly from railroad cars into ships carrying from 4,000 to 12,000 tons of coal. The method followed is to collect portions of coal from every railroad car dumped. From 30 to 60 pounds are taken from each car sampled, the quantity taken depending upon the size of the cargo. From 3,000 to 4,000 pounds are usually collected as a gross sample to represent a cargo. The gross samples are reduced in successive stages as collected, rather than accumulated and later reduced to quantities convenient for transmittal to the laboratory.

"The portions making up the gross samples are taken from the coal as it is discharged from the bottom-dump cars by the use of a shovel or a specially constructed ladle. Care is observed to not collect portions of the first or last coal spilling from the car, for the moisture content or proportions of foreign matter in such coal may render the sample unrepresentative."

Wagon Load Sampling

The main idea here, as in all sampling, is to get a fair average of the coal. This is best done by taking the sample from the wagon before it has been unloaded for the reason that the coal, if it is a screening or a size that is made up of different sizes of coal, will not have separated to any great extent. Each shovelful is taken by starting at the bottom of the exposed face of coal and a little taken from the bottom to the top. The number of shovelfuls taken and the loads sampled will be dependent on the number of loads which the gross sample is to represent. The gross sample should contain about the same proportion of lump coal, fine coal, and foreign matter as the coal delivered.

Fig. 2.† Mechanical Sampler Imbedded in Coal.

*Ibid.

†Figures 1, 2 and 3 are here reproduced by courtesy of the Commercial Testing & Engineering Company, Chicago.

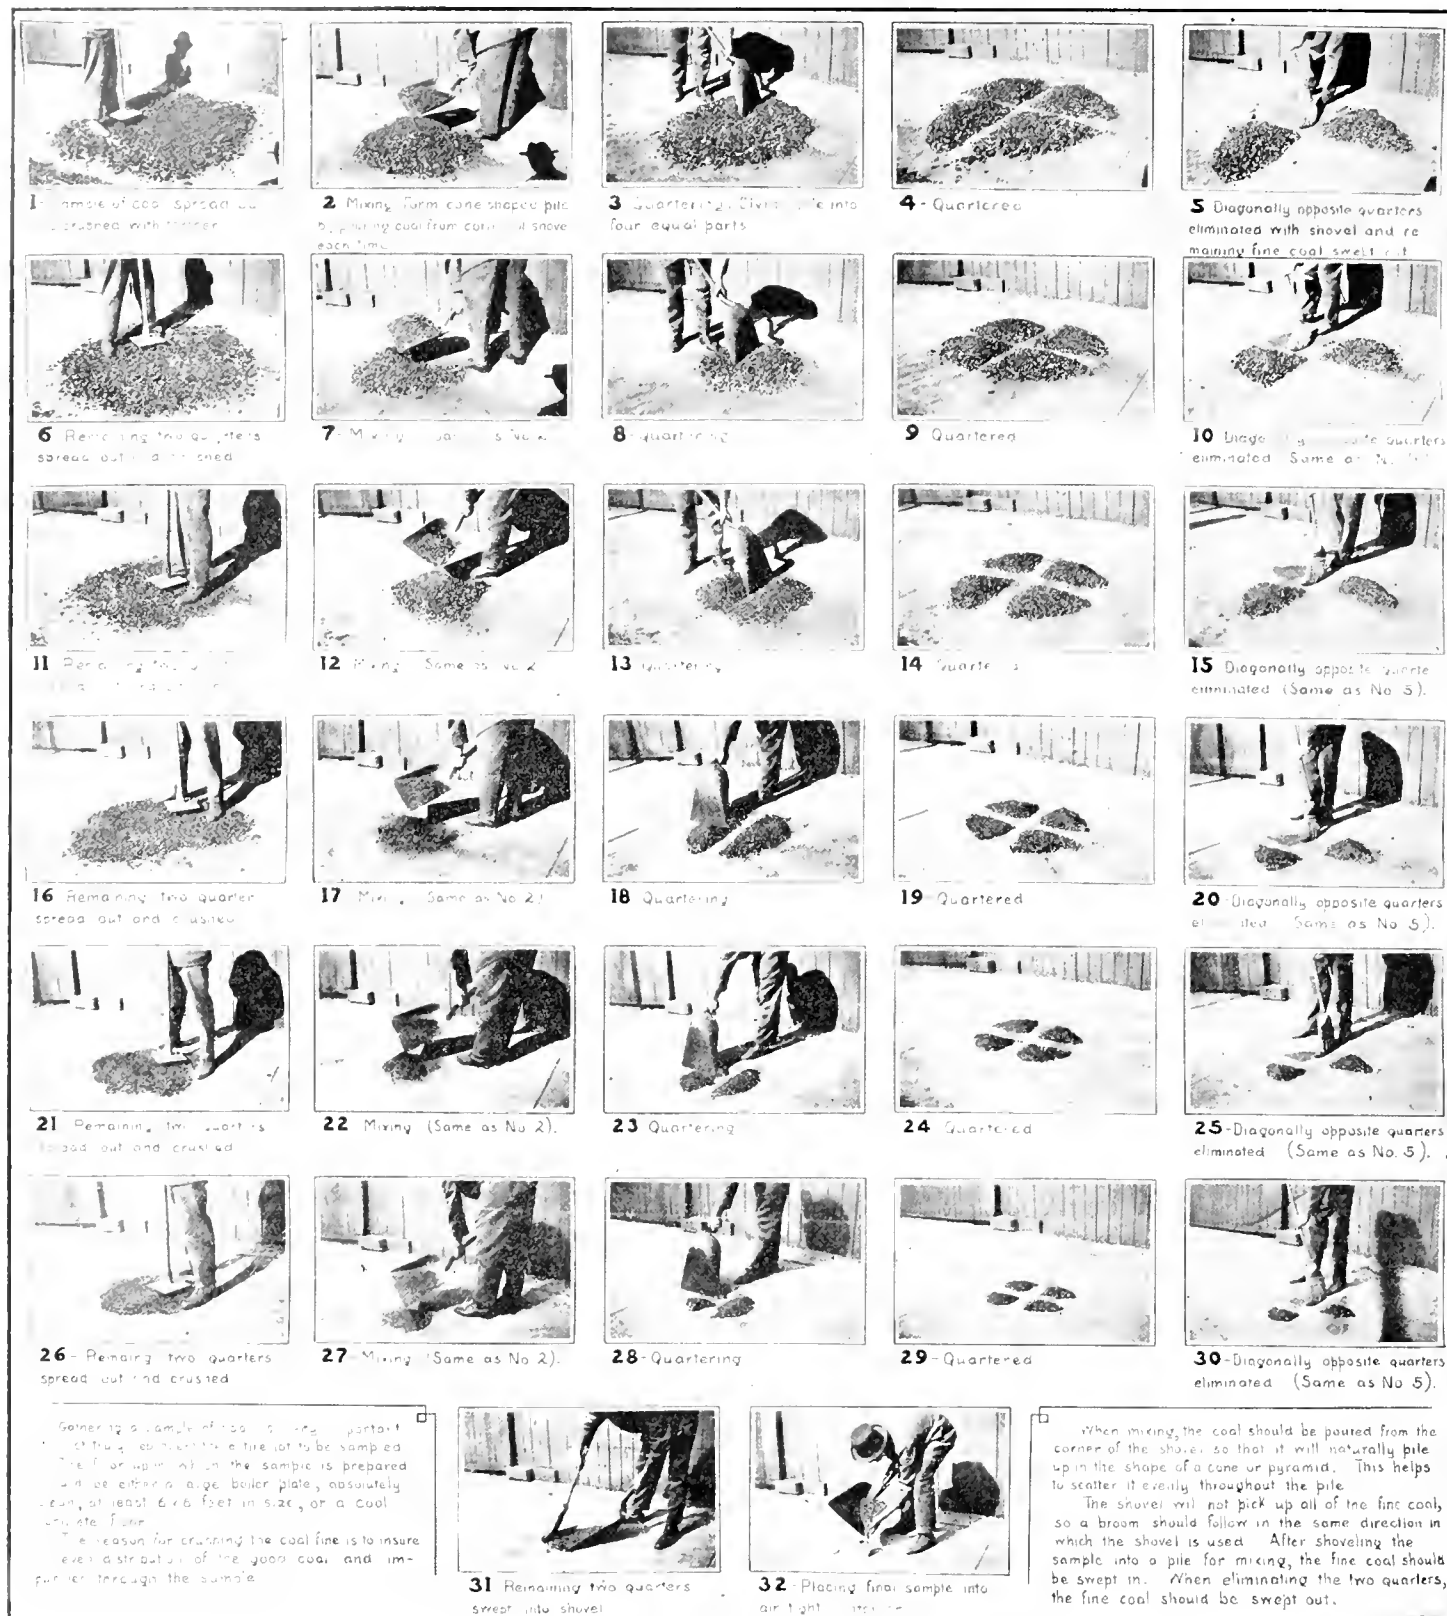

FIG. 3. PROPER METHOD OF PREPARING COAL SAMPLES.

A method of preparing samples taken of shipped, cargo or wagon coal is shown in its various stages in Figure 3. If the metal plate referred to in the instructions is not available, a concrete floor will be found equally serviceable, provided it is hard surfaced so as not to wear off in the crushing of the sample.

THE COMPOSITION OF COAL

Proximate Analysis; The Constituent Parts Entering Into the Composition of Coal; Influence of Each Part on the Generation of Heat; Reporting Analyses; Calculations Involved in Changing Bases; Ratios Used in Comparisons; Heat Value of Coals; Analyses Given in Coal Catalog.

Coal analyses are of two kinds—ultimate and proximate. The first mentioned is a strictly chemical process wherein the percentages of the various elements in coal are determined. It is principally of scientific value, although the amounts of oxygen and nitrogen present in a fuel are of interest to coke and gas makers. For general commercial purposes, however, it is of minor interest and will not be discussed here.

The proximate analysis of coals is of more importance. With the exception of the determination of sulphur, it does not involve chemical processes. Moisture is determined by heating a 1 gram sample in an oven at a temperature of 105 deg. C. for one hour and recording the loss sustained as the percentage of moisture. Volatile matter is found by heating a 1 gram sample in a closed platinum crucible for 7 minutes in the hottest flame of a Meker or Bunsen gas burner and recording the loss as volatile matter. Ash is arrived at by completely burning the sample used for the moisture determination and weighing the incombustible portion which remains. Fixed carbon is the difference between the moisture plus volatile matter plus ash, and 100. The heat units are determined by burning in an atmosphere of oxygen a 1 gram sample in a calorimeter. Sulphur alone is determined by a chemical method.

Moisture

Water in coal may be classed under two heads, first, mechanically retained, or surface, moisture, such as is present in coal loaded from wet sections of the mine, washed coal, or coal rained on; second, hygroscopic moisture, or that which is held within the pores of the coal by capillary attraction, and retained by the coal when air dried. Moisture in the first form may, or may not, be present in coal in varying quantities; in the second form it is unescapable, and it is in this form reported as moisture in coal analysis.

Hygroscopic moisture is present in all coals, ranging from 1 to 5 per cent. in coals of the Appalachian region up to 40 per cent. as found in the lignites of Texas and South Dakota. Almost every percentage between these extremes is found in considering coals throughout the United States, thus some of the Ohio coals reach as high as 7.5 per cent.; Indiana and Illinois, 15 per cent.; Iowa and Missouri, 20 per cent.; Colorado, 25 per cent. These figures represent the extremes met with and are not to be regarded as typical of the coals produced in the various states, but rather as indicative of the variations in moisture content.

The amount of surface moisture in coal varies with the kind and size, the length of time in transit, accessibility of air and also upon the relative humidity of the atmosphere. Slack coal, because of its having in the aggregate a large amount of ex-

posed surface, absorbs relatively large quantities of moisture (as much as 15 per cent. in some instances), but it readily parts with much of this under favorable atmospheric influences. Lump coal, on the other hand, does not retain a great deal of surface moisture. Run-of-mine coal is intermediate between slack and lump coal, the quantity of water taken up being dependent upon the proportion of fine coal. The loss of moisture in shipment from the time it leaves the mine until the destination is reached may vary from practically nothing in the Appalachian coals, to from nothing to 5 per cent. in Illinois coals, and up to 10 per cent. in subbituminous and lignitic coals.

Moisture is a waste product and has no heat value, in fact it is anticalorific and requires a part of the heat liberated by the coal to vaporize it. One per cent. of water represents 20 lbs. in a ton of coal and absorbs 22,380 British thermal units of heat, thereby lowering the efficiency of the coal by an equivalent amount.

Everything else being equal, the coal containing the least percentage of moisture has the highest heat value.

Volatile Matter

Volatile matter in coal comprises mainly the combustible gases, hydrogen, carbon monoxide, methane and other hydro-carbons, together with some inert gas and water formed by the decomposition of the coal, but does not include the moisture expelled in heating the coal for one hour at a temperature of 105 deg. Centigrade.

The exact nature and composition of the gases comprising volatile matter is not yet understood, but for commercial purposes it is sufficient to know that it is that part of the coal which is driven off in the form of gas when the coal is subjected to heat. This gas, in a sufficient supply of air, burns readily and produces heat, in fact, pound for pound it produces more heat than any other constituent part of the coal. It can not be argued, however, that coals highest in volatile matter are the greatest heat producers, for differences in composition of the gas may cause wide differences in the heat produced by various coals. Only a fraction, and a variable fraction at that, depending largely on the kind of coal, is combustible, and a considerable fraction, consisting of water vapor, carbon dioxide, nitrogen and other diluents, is inert or incombustible. Moreover, the rapidity with which the volatile matter is thrown off in burning and the sufficiency of air to insure complete combustion have much to do with the heat value of the coal. High volatile coals, when thrown in large quantities on the fire, produce smoke, that is, the gases have been expelled at a faster rate than they can unite with the oxygen of the air, leaving the unconsumed car-

bon to issue from the stack as black smoke. In all such cases much of the heat energy of the volatile matter is lost.

A characteristic of low volatile coals is that the gases issue forth at a slower rate, affording more opportunity for chemically uniting with oxygen, and a more complete combustion with less smoke. The theoretical heat value of these coals is therefore more nearly attainable in practice than with those of high volatile content, unless mechanical devices, as stokers, are used.

Fixed Carbon

This is the term conveniently, and somewhat loosely applied to what remains after the moisture, volatile matter and ash are accounted for. It does not represent all the carbon in the coal, as a considerable amount, combined with hydrogen, is driven out in the volatile matter, furthermore, the term "fixed carbon" includes some of the hydrogen, sulphur, oxygen and nitrogen of the coal.

Fixed carbon has a high value as a heat producer, one pound generating about 14,544 heat units. While this is low in comparison with the heat produced by one pound of hydrocarbon gas, namely 23,500 heat units, it is nevertheless true in practice that with high volatile coals more effective heat is produced by the fixed carbon than by the volatile matter. The reason for this lies in the tremendous losses of heat energy in high volatile coals, due to the incomplete burning of the gases. According to data obtained by Lord and Somermeier on seventy-eight tests conducted by the U. S. Geological Survey at St. Louis during the World's Fair, the inability to derive full heat value from volatile gases holds true of all coals having 20 per cent. or over of volatile matter; with coals having less than 20 per cent., practically all of the gases can be completely burned. In general, coals ranging from 77 to 81 per cent. in fixed carbon appear to offer the best opportunities for deriving the full heat of both the fixed carbon and the volatile matter.

Ash

Ash is the solid incombustible mineral impurity remaining after the coal is burned. All coals contain ash in varying amounts, and present in two forms, first, mineral matter derived from the original vegetation, plus that which filtered through the vegetation as silt after deposition and became intimately mixed with the other constituents. This is known as intrinsic ash. Second, as shale or fire clay derived from rock above the coal, soft bottom, or from partings within the seam. This is known as extraneous ash. Impurities in this latter form can be minimized by care in mining, casting out refuse at the working faces, or by the use of picking devices at the tippie or breaker. Bony coal, or bone, is found as a part of many seams. This is a mixture of carbonaceous and argillaceous materials, and, unless cast aside, adds considerably to the ash content of the shipment.

Ash is objectionable because it has no fuel value. Each per cent. of ash, representing 20 lbs. per ton, is so much useless matter upon which freight, unloading and cartage charges must be paid. More labor is required with high ash coals

for the removal of ashes, and more coal must be shovelled into the furnace. A further undesirable feature is that ash, in itself, is capable of forming clinkers, in spite of the general impression that sulphur alone is responsible for this mischief. Chemical analyses show that ash consists principally of alumina, Al_2O_3 , lime, CaO , silica, SiO_2 , iron oxide, Fe_2O_3 , magnesia, MgO , and sulphur S . Under the influence of heat, the basic oxides of the ash unite with the silica to form a silicate having a fusion point much lower than the fusion point of the separate constituents entering into the combination. The fusibility of this ultimate product depends largely on the ratio of the silica to the basic oxides found in the slag and also on the properties of the bases themselves. (See further discussion of slagging under the head of "Fusibility of Coal Ash.")

Sulphur

Sulphur is always present in coal, varying in amount from 0.1 per cent. up to 8 per cent. Unlike ash and moisture, it has some fuel value, equal to about one-half that of the coal it displaces. It may exist in three forms: as a sulphide in combination with iron to form iron pyrites and marcasite, in combination with calcium to form calcium sulphate or gypsum, and in more or less unknown states of combination with organic matter. The largest quantity of inorganic sulphur compound is undoubtedly in the form of iron pyrites, FeS_2 , and as such is found in thin layers along the bedding planes, as minute crystals interspersed throughout the mass, and as irregular nodules scattered through the coal. When abundant in this latter form, it is sometimes used as a source of sulphur for the manufacture of sulphuric acid.

Organic sulphur in coal is derived from the protein sulphur of plant and animal life from which coal was formed. Investigations of late date* indicate that the organic sulphur compounds form a large part of the sulphur in coal, some Ohio coals showing as much as 2 per cent. There is a possibility of sulphur existing in coal in an uncombined form as a result of the mechanical mixing of detritus with the early coal material, but sulphur in a free form is undoubtedly a small proportion of the total amount.

Sulphur combined with iron is objectionable because the compound is easily dissociated by heat, the sulphur passing off as gas, and the iron oxidizing to a ferrous state in which it readily combines with other bases to form clinkers. A discussion of this tendency will be found under the head "Fusibility of Ash."

Phosphorus

Phosphorus exists in a coal in the form of calcium phosphate. Its amount is so small that it need not be considered in any usage other than coking where the coke is to be used for metallurgical purposes. All of the phosphorus passes into the coke, and the high limit in the coal is therefore placed at 0.02 per cent. It is objectionable in iron metallurgy for the reason that it makes the steel "cold short", that is it becomes weak and brittle when cold and liable to break under shock.

*A. R. Powell and S. W. Farr, in University of Illinois Bulletin 111, "A Study of the Forms in Which Sulphur Occurs in Coal."

Reporting Analyses

Analyses of coal as reported by the analyst may be under one or more of the following forms, (1) as received, (2) air dried, (3) dry coal or moisture free, (4) moisture and ash free.

The expression "as received" is to be taken literally, and an analysis so reported means that the percentages of the component parts are based on the condition of the coal as it was received at the laboratory and without having been air dried. The condition of the coal as received at the laboratory may, or many not, be representative of the condition of the coal as received by the consumer. Much depends upon the kind of coal, its fineness and upon the weather conditions. The constituent subject to the greatest change from the time coal leaves the mine until it reaches its destination is, of course, the moisture content. The change that may be expected to take place with high-grade high-rank coals is quite small, but will be found to increase with low-rank bituminous coals, and to become quite pronounced with some of the high-moisture sub-bituminous and lignite coals. As an example of rapid moisture loss due to absorption by the atmosphere, may be cited one of the Colorado lignites which is reported losing as much as 200 pounds per wagon load while enroute from the mine to a town seven miles distant. On the other hand coal may add to its normal moisture content while in transit due to weather conditions, thus a car of slack which has been rained upon may contain as much as 15 to 20 per cent of moisture, the greater amount of this being "surface" moisture brought in by the rain. Under like conditions, lump coal would be little affected. For general all-around purposes an analysis reported on the "as received" basis is the most satisfactory.

An "air dry" sample is one that after being reduced by crushing to about 1/4-inch has been allowed to become thoroughly air dry by standing exposed to the air of the room for 36 hours or longer. The same result may be obtained in a shorter time, from six to eight hours, by placing the sample in a drier through which air at a temperature of from 10 to 15 degrees above the room temperature is circulated by means of a small fan. In either method weighings are made at intervals amounting to about one-third of the minimum estimated period for drying, and when two successive weighings show less than 1/2 per cent loss in weight, the process is completed. The total loss in weight is reported as the air drying loss.

Frequently for the purpose of comparing coals freed of all moisture, or in order to calculate the heat balance in accordance with a prescribed code, it becomes necessary to report results calculated to a "dry coal" or "moisture free" basis. This basis is also convenient in comparing boilers burning the same or similar coals.

For making comparisons of the various coal substances coal analyses are usually referred to a "moisture and ash-free" basis, by calculation from the "air dry", "as received", or "moisture-free" analyses. Where a comparison is required between individual coals for practical purposes, the ash and moisture must necessarily be included, rather than to have results calculated on the pure combustible, i. e., on the dry and ash-free basis.

Calculations Involved in Changing Basis

Assuming that the analytical determination has been made on an air dried sample, the various calculations in changing from one basis to another are here given.

Calculations from Analysis of "Air-Dried" Coal to Coal "As Received."*

$$\text{Moisture} \times \frac{(100 - \text{air-drying loss})}{100} + \text{air-drying loss} = \text{moisture "as received"}$$

$$\text{Volatile Matter} \times \frac{(100 - \text{air-drying loss})}{100} = \text{volatile matter "as received"}$$

$$\text{Fixed Carbon} \times \frac{(100 - \text{air-drying loss})}{100} = \text{fixed carbon "as received"}$$

$$\text{Ash} \times \frac{(100 - \text{air-drying loss})}{100} = \text{ash "as received"}$$

$$\text{Sulphur} \times \frac{(100 - \text{air-drying loss})}{100} = \text{sulphur "as received"}$$

$$\text{B. t. u.} \times \frac{(100 - \text{air-drying loss})}{100} = \text{B. t. u. "as received"}$$

Calculation from either "Air-Dry" or "As Received" Analysis to a "Dry Coal" or "Moisture-Free" Basis.

$$\text{Volatile Matter} \times \frac{100}{100 - \text{moisture}} = \text{volatile matter in "dry coal"}$$

$$\text{Fixed Carbon} \times \frac{100}{100 - \text{moisture}} = \text{fixed carbon in "dry coal"}$$

$$\text{Ash} \times \frac{100}{100 - \text{moisture}} = \text{ash in "dry coal"}$$

*All formulas from Wagner, Coal and Coke, pg. 63.
†All figures expressed in per cent.

$$\text{Sulphur} \times \frac{100}{100 - \text{moisture}} = \text{sulphur in "dry coal"}$$

$$\text{B. t. u.} \times \frac{100}{100 - \text{moisture}} = \text{B. t. u. in "dry coal"}$$

Calculations from "Air-Dry", "As Received", or "Dry Coal" Analysis to "Moisture and Ash-Free" Basis.

$$\text{Volatile Matter} \times \frac{100}{100 - (\text{moisture} + \text{ash})} = \text{volatile matter on a "moisture and ash-free" basis}$$

$$\text{Fixed Carbon} \times \frac{100}{100 - (\text{moisture} + \text{ash})} = \text{fixed carbon on a "moisture and ash-free" basis}$$

$$\text{Sulphur} \times \frac{100}{100 - (\text{moisture} + \text{ash})} = \text{sulphur on a "moisture and ash-free" basis}$$

$$\text{B. t. u.} \times \frac{100}{100 - (\text{moisture} + \text{ash})} = \text{B. t. u. on a "moisture and ash-free" basis}$$

Illustration of Analyses Variouslly Reported

Assuming an air-dried analysis to have been made and reported as here given, the analyses on other basis, as derived by formulas just mentioned, would be as follows:

AIR-DRIED ANALYSIS

Moisture	1.12
Volatile Matter	32.16
Fixed Carbon	59.96
Ash	6.76
	<hr/>
	100.00
Sulphur	0.84
B. t. u.	14,420

	<hr/>
	100.00
Sulphur	0.91
B. t. u.	15,653

Ratios in Use for Comparison

Two ratios, the so-called fuel ratio and the carbon-divided-by-oxygen+ash ratio, are much used in arriving at the relative rank and comparative value of coals. The term "fuel ratio" (fixed carbon divided by the volatile matter) has been used by the U. S. Geological Survey in bringing out the decrease of fixed carbon and increase in volatile matter in the several ranks of coal ranging from anthracite downward. Fuel ratio should not, however, be understood as synonymous with fuel value. Any attempt to use it in this sense is sure to lead to error. It is intended merely to designate the rank to which a given coal belongs.

The second mentioned ratio, $\frac{C}{Oxy + Ash}$, furnishes an approximate means for arriving at the relative merits of two or more fuels.

In the specimen ultimate analysis, which will be found on a preceding page, there will be noted two elements that are not combustible, viz., oxygen and nitrogen, and in addition to these, the ash, which is likewise incombustible. Oxygen is not found in coal in the free or uncombined state, as will be found stated under the next subject Heat Value of Coals. Since it has already entered into combustion with either the hydrogen or carbon in the coal, it becomes for all practical purposes just so much ash. In fact, investigation has shown that oxygen and ash are approximately of equal anticalorific value, that is the anticalorific effect of oxygen in coal is nearly equal to that of the same weight of ash. The efficiencies of coals are found to conform fairly close to the order of the ratio of their carbon to the sum of their ash plus oxygen. It will be noted that the third inert substance, nitrogen, is omitted in this ratio, the reason being that the percentage of nitrogen is so fairly constant in coals, and particularly in coals of the same rank, that to include it would be merely to increase the labor of computation without adding any benefit.

Heat Value of Coals

The heat value of a coal is usually expressed in calories or in British thermal units. Expressed in calories, it is the number of grams of water raised one degree Centigrade (from 15 deg. to 16 deg. C) by the heat resulting from the combustion of one gram of coal. Expressed in British thermal units, or as usually abbreviated, B.t.u.'s, it is the amount of heat required to raise one pound of water (at 15 deg. C., or 62 deg. F.) through one degree. Calories may be converted into British thermal units, or vice versa:

Heating value in B.t.u. = 1.8 times the heating value in calories.

Heating value in calories = 5/9 times the heating value in B.t.u.'s.

The heat derived in burning coal is brought about by the oxidation of its combustible elements, viz., carbon, hydrogen, and the unoxidized forms of sulphur and iron. The quantity of heat generated by the complete combustion of these elements is as follows:

	Calories	B.t.u.'s
1 lb. carbon to carbon dioxide.	8080	14544
1 lb. hydrogen to steam.....	34460	62028
1 lb. sulphur to sulphur dioxide	2250	4050

Based on a knowledge of the above heating values, many formulas have been devised to calculate the heat value of a coal directly from its ultimate analysis. The best known of these is Dulong's formula, which is commonly stated as follows:

Heat value (calories per gram) = $(8080 \times C) + [34460 \times (H - \frac{1}{8}O)] + (2250 \times S)$

Heat value (B.t.u.'s per lb.) = $(14544 \times C) + [62028 \times (H - \frac{1}{8}O)] + (4050 \times S)$

It is assumed in Dulong's formula that the various combustible components are completely oxidized. The results obtained, as might well be expected, vary somewhat with results obtained by the use of the calorimeter:

1. The heat value of carbon, hydrogen, and sulphur have not been definitely determined, thus, the calorific value for carbon is sometimes stated as 8100 instead of 8080, and if the higher value is taken the calculated calorific value will be raised from 10 to 15 calories per sample. Sulphur is sometimes given a value of 2220, though the higher value is the generally accepted one.

2. The heating value of a component of a chemical compound is assumed to be the same as in its free state, an assumption which is manifestly incorrect. Thus, some organic compounds, as for instance carbon bisulphide, have a decidedly higher calorific value than that derived by the combustion of equivalent amounts of the elements present. The same is true of the combustion of benzene, C_6H_6 .

3. There is a possibility that some of the oxygen is combined with carbon, and not all of it combined with hydrogen, as is generally assumed. This seems to be particularly likely in the case of high volatile and high moisture coals. Since the calorific power of hydrogen is 4.265 times that of carbon, the assumption, if correct, results in lowering the

calculated value. It is agreed that all of the oxygen in coal is in combination with one or more of the combustible elements; if it were in the free form it would enter into combination with carbon, hydrogen, and sulphur, just as the oxygen of the air does, and thus evolve heat. In Dulong's formula it is assumed that all of the oxygen is in combination with the hydrogen in the proportion to form water, that is, eight parts of oxygen to one of hydrogen. The oxygen thus renders useless one-eighth of its own weight of hydrogen, and the hydrogen which is available for combustion will be $H - \frac{1}{8}O$.

4. Since the amount of oxygen is derived by calculation, it follows that it bears the burden of any errors made in the ultimate analysis, hence its percentage as stated may be inaccurate.

Somermeier* states that the heat values obtained by the use of Dulong's formula are usually within less than 1½ per cent. of the actual value as determined by the calorimeter. About 150 analyses given in Bulletin No. 9 of the Ohio Geological Survey show that the values by Dulong's formula range from about 30 to 100 calories lower than the calorimeter values. High oxygen coals show a calculated value considerable lower than the determined value, and the calculated values, as a whole, are lower than the determined values.

The practical application of Dulong's formula with respect to an analysis of Sewell coal, as reported by the West Virginia Geological Survey,† is here given:

	Proximate		Ultimate
Moisture	1.36	Carbon	80.69
Vol. Matter..	23.14	Hydrogen ...	5.37
Fixed Carbon	70.02	Oxygen	6.49
Ash	5.48	Nitrogen	1.31
		Sulphur	0.66
	100.00	Ash	5.48
Sulphur	0.66		100.00

B.t.u. per lb.

$$= (14544 \times .8069) + [62028 \times (.0537 - \frac{.0649}{8})] + (4050 \times .0066)$$

$$= 11735.6 \quad + \quad 2828.5 \quad + \quad 26.7$$

$$= 14591$$

The calculated result varies by only 21 thermal units from the result obtained by the calorimeter, namely, 14570 B.t.u.'s.

A number of formulas have been devised for the calculation of heat values based on the proximate analysis of coal, but all of these involve the use of coefficients which fail in a wide application of the formula, hence their use is not to be recommended.

General and Supplementary Analyses in the Coal Catalog

The analyses given in this publication have been gathered from various sources, such as reports of the state geological surveys, publications of the United States Geological Survey, bulletins of the Bureau of Mines, technical and trade papers, etc. In

*Coal, pg. 10.
†Report on Fayette County, pg. 875.

all cases it has been the intent to give only analyses of coal "as received," and when not otherwise noted, for mine samples. The general analysis of a seam or field should be regarded as being nothing more than an index to the character of the coals produced. In this an effort has been made to deal fairly with each seam, but it will be borne in mind that a general, or typical, analysis is an attempt to balance the faults and virtues of a coal, and that there will be many mines in a district capable of shipping a better coal, as well as some unable to produce a fuel equal to that indicated by the general analysis.

Following each state will be found a more or less extended list of supplementary analyses in which, wherever possible, the analysis of each seam is given by county, locality and mine. This makes it possible to arrive at a more accurate estimate of the composition of a seam, and to pick out such localities as produce a coal chemically suited to the requirements.

To those familiar with the peculiarities of coal formations, it is well known that, chemically, there may be not only a considerable variation in the coal produced at each of two adjacent mines, but a vari-

ation in analysis from day to day even at the same mine. Thus, coals lying in a basin or syncline may analyze quite differently from those of the same seam lying along an anticline or near the outcrop. In some seams this variation is so great that it affects considerably the use to which the coal may be put, while in others the range is so slight that a general analysis fairly represents the entire seam. The great Pittsburg seam is typical of those whose every constituent is subject to considerable change, while, on the other hand, the Pocahontas seam of West Virginia may be cited as one noted for its constancy.

Usually, however, changes in chemical composition are not sudden, but, instead, take place gradually in tracing the extent of a seam. Thus with the Pittsburg seam, aforementioned, the analysis of a coal in the Connellsville Basin is quite like that from adjoining mines, and the same is true of two or more mines in the Georges Creek Basin, or of a group of mines in the same seam at or near Clarksburg, W. Va., although, as illustrating that the seam itself is not of a constant composition, it will be noted that the coal at Clarksburg differs considerably from that at Connellsville, or at Frostburg, Md.

The Buying of Coal on a B. T. U. Basis

Merits and Demerits of the Specification System

Reason for Introduction of Specifications

So long as coals were produced almost entirely from high grade seams there was little question raised as to the heat value of coal from one district or seam in comparison with the heat value of coal from another district or seam. Stirred by the threatened exhaustion of some of the most favorably known seams, developments were begun in inferior beds, and as these coals gradually became more and more a factor in coal production, there arose a demand from certain quarters that, because of the marked difference in thermal content, coals should be sold on some basis of merit. The fact that coal varies in character through a thousand gradations from the anthracite of Pennsylvania to the lignites of Texas made plain that no longer could it be said "coal is coal".

The marked difference in the preparation given to coal supplied an additional and greater reason why it should be sold in some manner that would take cognizance of both the intrinsic worth of the fuel and the care taken in its mining and loading. Complaint was made that the shipper relied too much on the analysis which adorned his letter head, and too little upon intelligent oversight both inside and outside the mine. The percentage of ash was always in excess of what the consumer was lead to expect. Since ash and moisture, the two principal impurities in coal, have no thermal value, and, in addition, entail expense in the payment of useless freight, the idea was naturally evolved of devising specifications by which the purchase of coal would be based upon its chemical analysis and heat value.

Specification System Fostered by Government

The United States Government readily endorsed the movement, particularly with reference to the purchase of fuel for navy use. The first requirement was to obtain information on the various coals and coal fields of the country in order that specifications might be intelligently prepared covering purchases on a heat value basis. By the year 1907 sufficient data had been collected to start the system and purchasing of coal on specifications continued until stopped by the extraordinary conditions incident to the war in 1917. After being abandoned for almost two years, it was again put into effect by the government in July, 1919, and purchases are again being made on the B. t. u. basis.

Nature of Specifications

The purpose of specifications may be stated to be obtaining for the consumer of coal the lowest cost per million B. t. u., or expressed otherwise, to obtain the greatest number of B. t. u. for one cent. This requires an accurate knowledge of three

things, the ash content of the coal, its moisture content, and its B. t. u. value per pound. All formulae used in arriving at the price to be paid in accordance with specifications should contain these three factors. Specifications usually permit a certain maximum amount of ash and moisture and a minimum value is stated for the heat value. Penalties are laid when the coal falls short of the standards set, and premiums are paid where the requirements are exceeded. The amounts to be paid in either case should be plainly stated in the contract. In the case of ash, the loss due to excess is greater than with moisture, since in addition to being inert it involves freight, labor and cartage expense. This may amount to from 3 to 10 cents or more for each per cent of ash in excess of the stipulated amount. The actual penalty cost should be closely approximated and then stated in the contract. As an incentive to getting clean coal, the penalty in some cases is on a scale that increases rapidly as the percentage of ash increases.

John Howatt* cites two typical specifications which make provision for price adjustment to take care of the ash content in coal, as representing the latest practice in purchasing coal on a test basis. One is that used by the United States Government and the other is that used by the city of Chicago. In the specifications upon which the government is purchasing its coal this year, what is termed a standard ash value on a dry basis for the quality of coal it is intended to purchase is established. For any coal received that tests a lower percentage ash than the standard named, the contractor is allowed a bonus of two cents per ton of coal for each per cent, the ash is less than the standard. This seems to be based upon a cost of \$2 per ton for handling ash. No penalty for ash is deducted unless the ash content is more than 2 per cent, greater than the standard. Where the ash content is more than two per cent, in excess of that named as standard, deductions are made from the price to be paid for the coal on a rapidly ascending scale to compensate for the loss in efficiency in the furnaces. In the specification used by the City of Chicago a deduction of one-half cent per ton of coal for each per cent, of ash on a dry basis is made on the entire ash content. This is based upon a cost of 50 cents per ton for handling ashes and does not increase the penalty for excessive ash to compensate for the loss in furnace efficiency, and therein does not protect the purchaser against coals being delivered with a high ash content as well as does the specification used by the government. On the other hand, it makes a deduction for all the ash in the coal instead of only that in excess of the limits, and in that regard is more scientific but not as practicable in application at the present time.

*Address published in the Journal of the Western Society of Engineers.

Although moisture, like ash, is inert there is less loss to the purchaser for the reason that there is no cost in its removal. Formula used in purchasing coal as a rule provide no penalty for moisture, other than that provided by reducing the coal to a moisture-free basis. Quoting again from the address of John Howatt:

"The two typical specifications considered before, that used by the government and that used by the City of Chicago, differ in their provision for adjustment of price because of moisture only in their method of application. The government specification provides for a payment based upon the British thermal units in the coal as received, the B. t. u. per pound of coal will thus be automatically reduced in proportion to the amount of moisture in it. The City of Chicago specification provides for payment upon the British thermal units in the dry coal, but reduces the amount of coal paid for by the amount of moisture in it. The resultant number of heat units in a ton of coal and the price paid the contractor therefor would be identical under either specification."

The third important factor, the B. t. u. value of the coal, is the point about which all specifications revolve. A necessary provision in writing proposals is to name limits for B. t. u. per pound far enough apart so there will be plenty of opportunity for competitive bidding and still limiting the coal to the general quality desired. The determination of the price to be paid for the coal is a very simple matter after the analysis is known, the procedure being governed in every case by the provisions of the contract.

Advantages of the Specification System

The Bureau of Mines cites the following advantages of the system:

"1. All bidders are put on a strictly competitive basis.

"2. The field is broadened for both coal producer and consumer.

"3. The contract specifies an established standard of quality as a basis for adjusting the price.

"4. If other coal must be substituted, there is a standard for settlement.

"5. If coal is uniformly poorer than the standard set, there is a basis for cancellation.

"6. Where there is need of preparation at the mine (picking, washing, etc.,) the operator, who is largely responsible for variations in the grade of such coal, is stimulated to prepare it better. The quality of coal from a given mine may vary from time to time through the failure of the miners to reject impurities; or the physical or chemical character of the coal in a certain bed may vary from place to place. In some coal fields different beds of coal are mined at the same time and the output is mixed. When there is need of preparation, as by picking slate or other impurities, or by jigging or washing, the quality or value of the coal marketed

depends a great deal on the care taken in the processes employed. The mining companies are responsible in a large measure for variations in the grade of prepared coal. The purchase of coal under a contract that distinctly specifies its quality stimulates the operator to prepare coal better before shipping it to market."

A distinct advantage in the specification method may result to plants where boiler capacity and grate area are small, and the draft is weak. With the information received by taking bids on coals of different quality the probable saving can be determined by the making of radical changes in the plant in order that advantage may be taken of coals offered at a lower cost per million B.t.u.'s.

Reasons for Unpopularity of System

For a considerable period coal consumers were influenced by the specification method of coal purchase, and seemed to regard it as the very essence of fuel economy. That there has been a change in sentiment, more pronounced, possibly, in the East than in the Middle West, must be admitted. The fault would appear to lie almost entirely in the lack of standardization, both in sampling and analyses. One difficulty is that the coal producer is prone to regard the sample taken at the face as an actual representation of shipments, whereas, in truth, it merely sets forth the high state of perfection possible to be attained by that particular mine. That the coal may fall far short of its possibilities is a fact now well known to both the consumer, who puts in the "kick," and to the operator who receives it, but the reason for it is sometimes not clearly understood until an opportunity has been extended for a representative to examine the condemned shipment. The reason for dissatisfaction on the part of the consumer may then be quite plain. Slate or rock from the roof or gob pile may have become intermixed with the coal and loaded into the car by careless or indifferent miners, or fire clay from the bottom may have been cut into and intimately mixed with the finer coal. Plainly in such a case, which is here cited as typical of many complaints, there is much difference between the coal in the seam and the coal as it reaches the consumer, and there can be no agreement between the mine sample analyses, furnished by the operator, and that made on a car sample by the consumer, and which, if correctly taken, must stand as the correct analysis, no matter how much it may vary with the mine sample.

Maurice J. Walsh* cites a number of objections to the specification system, three of which are as follows:

First, chance for misunderstanding arises from the fact that the operator is not familiar with the qualifications of the person doing the car sampling and the related analysis, while, on the other hand, the consumer has no acquaintance with the chemist employed by the coal company—a situation which is not conducive to mutual confidence. Furthermore, it is well understood by both parties that samples can be so taken, either at the mine or at the car, that the results obtained from samples taken by two people may analyze so differently as

*Black Diamond, May 31, 1919.

to make it impossible to determine it as the same coal. Experience has proved that for a given mine there may be greater variation due to sampling than in the coal itself. The price to be determined, which is the very essence of the transaction, can, therefore, be very materially influenced by incompetence.

The second objection, frequently urged against the practice, is that owing to the variation in tests made on coal there is a constant argument between the producer and consumer. The seller of coal contends that there are entirely too many chances for discrepancies in results, and that when such occur he is more or less at the mercy of the consumer, furthermore, that when disagreements arise there follows much misunderstanding and argument between both parties to the transaction. Because of the desire to sidestep trouble there is a noticeable tendency on the part of the shipper to withhold bidding on a contract calling for coal on a specification basis.

A third objection to the use of the specification system lies in delays in settlement. The items of supplies and labor entering into the cost of coal are live charges to the producer who is obliged to meet a pay roll each fortnight, and in addition must satisfy his bills for supplies. In order to provide funds for current needs he bills his coal promptly and expects to have remittance made in a reasonable length of time. When coal is sold on the B.t.u. basis, no settlement can be arrived at until the shipment reaches its destination and each car is sampled, tested, and the proper calculations made preliminary to making payment. This involves a delay of from 30 to 60 days, and works a hardship on the operator or sales agency. If all settlements for coal were as much delayed, the financing of coal companies would become a serious matter.

Importance of Sampling

It is recognized that the correctness of a coal analysis is subject to the care taken at the mine in selecting the place for sampling, in the taking of the sample, in its preparation and sealing, and that when it reaches the laboratory it is again subject to error in reducing the sample and in making the analysis. The old saying that a chain is no stronger than its weakest link applies particularly to the successive steps in coal analysis, and it is quite likely that sampling is the weakest link of all.

Opportunity for Error

Where there is laxity in the method of sampling, calorimeter tests will likewise show a considerable variance in results, even though made by men skilled in this work, and if the chemist be inexperienced in the operation of a calorimeter, or if cheap equipment be used, there is a still further opportunity for disagreement in results, for a heat value determination is no easy thing to make with accuracy. The work should be done by a person skilled in the handling of sensitive apparatus and trained in the observation of details. Such important matters as knowing the exact water equivalent of the calorimeter; having the thermometer correctly calibrated; taking thermometer readings to 1/100 of a degree; making correction for the heat generated by the burning of the fuse wire, for the

amount of nitric and sulphuric acid formed within the bomb, and for the heat generated while the circuit is closed for the ignition of the fuse wire; making the proper application of formula to take care of the heat radiated to and from the calorimeter while readings are being taken, etc., etc., must all be taken into account, as must also the difference existing in the several makes of calorimeters themselves.

The Inconsistency of the Consumer

In the next place it has been observed that in some instances the consumer, who is loudly insistent that his fuel requirements be filled with coal of high calorific content, is, at the same time, grossly negligent in providing his power plants with efficient combustion devices. The coal salesman is plainly nettled at the attitude of the purchaser who demands exceptional value in his fuels, the while dense clouds of smoke are permitted to pour forth from the boiler stacks. He regards it as unreasonable to have a selection limited to premier coals, in face of the fact that coal is being improperly fired, and such important matters as draft and thickness of bed are not regulated in accordance with the character of coal and the design of the furnace. His stand is that a thousand B.t.u.'s made possible by furnace improvements are just as effective as so much heat made available because of the superior quality of the coal; in short, that economy to be consistent should begin at home.

The following aptly illustrates this neglect on the part of the purchaser to acquaint himself with scientific methods of firing so that the B.t.u.'s in the coal might be fully utilized: "A large manufacturer not long ago assured me that he was very particular about the purchasing of his coal, and insisted that all coal must be to a standard of 14,600 B.t.u. In looking over his steam results, I called his attention to the fact that his coal should show an evaporation of 11 pounds of water per pound of coal, but that he was obtaining only 9 pounds, and that by proper firing he would make a saving of at least 20 per cent. in the quantity of coal used."[†]

However, it must not be supposed that power plants as a rule are indifferent to the importance of utilizing to the fullest extent the potential energy in coal. In fact, owing to the curtailment in coal supply during the late war, tremendous strides have been made in the introduction of economical devices in power plants, and for such as these weightier reasons against the specification method of coal purchase must be given to have any force.

Specifications May Run Counter to Conservation

A further reason for opposing the specification method is that, in effect, it may run counter to the doctrine of conservation of our natural resources. As illustrating this we may consider the case where two or more seams are present on a property, the lowest and oldest of which has the purest coal (as is generally the case in West Virginia), and would be the most certain of a market, in accordance with the B.t.u. system of purchase. The coal operator has long since learned that a market is a prime

[†]Edwin Ludlow, April, 1918, Bulletin A. I. M. M. E.

necessity, and with working conditions nearly or altogether equal, the lower seam will quite naturally be the one chosen for operation. In line with good mining practice the engineer is directed to lay out the property so that a good recovery, say from 85 to 95 per cent., can be made. Up to this point the procedure is in harmony with the principles of conservation, but in order to attain this high figure of coal recovery it will be necessary to draw all pillars, and since this robs the overlying strata of its support, these are broken, not only to the seams above, but in all probability clear through to the surface. In the room and pillar system of mining there would be a number of such breaks at varying intervals, and all upper seams of coal are bound to be so badly fractured as to make mining not only much more difficult and hazardous, but, perhaps, impossible. It is quite evident that were all coals bought on specifications, there would be no choice left when it came to deciding between two seams of unlike quality, and equally evident that the fault should not be charged to the operator, but rather to a system which would discourage or prohibit working the upper seams, as should be done in the interest of true conservation.

Can Reputation Replace Specifications?

Strange to say, the operator with a good coal having an established reputation is the one most likely to resent the invitation to bid on a specification contract. He feels that his coal, having been on the market for a long period of years, during which it has been thoroughly tested, should be bought by the customer on its past performance record. Analyses, and all other information on their coals, are always gladly given to a prospective purchaser, and in most cases this information can be relied upon, for the responsible producer or sales agency realizes that an absolutely truthful description of its fuel is a means of instilling confidence and of insuring a profitable business relationship, and that no permanent good can result from a claim that a coal is different from what it really is.

It is true, as often contended, that specifying coal from a certain district is no guarantee, since many districts can supply coal varying easily 10 per cent. in heating value. This is noticeable in some mining sections where as many as two to four seams of coal are exposed, each differing from the other in physical and chemical properties and in thermal value, and where coal from all seams are loaded over the same tipple. But this does not generally hold true where coal from a **certain seam in a certain district or sub-district** is specified. It is well known, of course, that there will be a variation in both analyses and heat value in two samples taken at different places in the same seam and in the same district, due largely to the difference in the amount of ash, but in the case of well prepared coals such variation is usually small and would hardly be sufficient to affect the price one way or another. A large number of examples could be mentioned to establish the fact that there is a fairly consistent regularity in well prepared coals from the same seam and district.

The Real Importance of Analysis

For the reasons given, the B.t.u. method of purchase has not made much headway and is now

chiefly used only by the Federal, state and city governments in their purchases of coal. It does not follow from this, however, that a knowledge of the complete analysis of a coal is without importance. It does, in fact, have a great importance, for in most cases the available heating value of a coal varies directly with its theoretical heat value, and, other things being equal, its purchase price is governed by the total number of heat units it contains. It is, moreover, of much value to the operator. A sample taken in the mine acquaints him with the degree of quality possible to attain; a car sample shows how nearly the maximum quality is approached. But in addition to knowing the calorific value of a coal, there must also be taken into consideration such matters as the adaptability of the coal to the furnace and stokers in use. Anthracite coal, for instance, being very low in volatile matter, and hence slow burning, requires a large grate area, whereas high volatile coals, being fast burning, are best served by a small grate. Furthermore, the design of the furnace will be governed by the coal burned, and an attempt to make the same furnace serve for all types of coal results in either much smoke, or else a failure to develop the full capacity of the plant. No matter, then, how good the coal, waste is sure to result when there is a misfit of coal and plant.

The heat value of a coal is obviously one of its most important properties, especially when it is to be used for steam purposes, and although in practice it is only possible, even under the best conditions, to utilize a portion of the heat units of the fuel, it has been demonstrated conclusively in the U. S. Fuel Tests that the actual heating effect under a boiler is proportional to the calorific value of the coal, as determined in a bomb calorimeter. It becomes, therefore, a matter of prime importance that a knowledge of its B. t. u. content be known before purchase. If the coal is to be used for steam purposes, a point of equal importance is to know the fusing point of the ash, for if this be so low as to cause excessive clinkering there may result a closure of the spaces between the grate bars with a consequent shutting off of the air supply to the fire box.

Practical Method of Estimating Coal Values

In place of the specification system of coal purchasing, the following is advocated by Maurice J. Walsh as a practical measure:*

"The purchaser of coal should know coal well enough to purchase the best obtainable, taking into consideration the quality of the product, freight rates, etc. It should be produced from a well-known producing coal field and from representative companies and reliable shippers. In all well-known producing districts there is a recognized standard of quality that maintains generally.

"The best way to determine the actual value of coal, and its real worth, is by a boiler or plant test where the coal is actually burned or used. This enables the purchaser to learn its good or bad qualities and to know whether or not it is suitable for the requirements for which it is intended. It is more important to find the coal whose physical

*Black Diamond, May 31, 1919.

properties act best in a given plant, and then insist on the same grade of coal continuously. It is the practice of reliable coal companies to furnish the buyer with the coal best suited for his requirements or plant conditions. After the coal is tried and found economical and satisfactory, the right shipper will not fail to deliver what he sells the purchaser."

Conclusion

As is usually the case there is much to be said favorable to both sides of the controversy. It is undoubtedly true that in many instances a wrong impression has been created by the citing of analyses which can not be sustained by shipments. O. P. Hood* in referring to ash in coal shipments said recently: "The sellers of coal in a certain district talk quite freely of coal having three, four or five per cent ash as their regular output. In pre-war times this coal, as delivered at Tidewater for export, was sampled a great many times and by the most approved method. Out of 116 cargoes representing perhaps half a million tons less than 15 per cent of

the coal ran below 5 per cent in ash. Fifty-seven per cent ran between 5 and 7 per cent ash. Placing a limit of 7½ per cent ash on this coal would have included only 80 per cent of the shipments and there was as much coal above 9 per cent as there was below 4 per cent. This shows that in a district which has much to say about 4 per cent ash in coal, a much truer statement would have been that coal from this district was more likely to run between 5 and 7 per cent in ash."

Sampling, as already stated, has been one of the principal reasons for the apathy felt toward the innovation, but it must in all fairness be said that most of the disputes that have arisen over the specification method of coal purchase might have been avoided had the matter of sampling and analysis been entrusted to reliable concerns who specialize in coal analyses and who are by experience thoroughly familiar with the numerous difficulties, not readily apparent to the operator nor to the chemist in ordinary practice.

*Chief Mechanical Engineer, U. S. Bureau of Mines.

THE FUSIBILITY OF COAL ASH

Why Coal Ash Fuses; General Analysis of Ash; Relation Between Sulphur and Clinkering; How Fusion Point Is Determined; Table of Fusibilities

Fusibility of Compounds

In addition to knowing the B.t.u. value of a coal, it is also of great importance to know something of the fusibility of the ash which remains after burning. It has long been known that two compounds, each more or less infusible by themselves, may, by contact or intermixing, form a new compound having a fusing point much lower than that of the separate constituents entering into the combination. The chemical action which takes place in a blast furnace may be cited as a common illustration. The ore charged contains a large proportion of siliceous and other gangue material of a highly refractory nature, and which, in the process of smelting, must be gotten rid of by some cheap means. The problem is to effect a combination of some compound with this refractory material so that the two will form a silicate having a low fusing temperature. At the temperature encountered in blast furnace practice the resulting silicate is readily melted and forms slag. The material used as a flux in blast furnaces is limestone, CaCO_3 , which, by the time the lower zones of the furnace are reached, is reduced to CaO , by itself one of the highly refractory oxides, but which, in combination with the siliceous matter in the ore, produces an easily fusible compound.

A second illustration of the dependency of industry on the property of fusibilities is found in the manufacture of glass. Here quartz sand, SiO_2 , a highly refractory substance, is made to flow easily by mixing with it calcium, sodium, lead, or potassium oxide, according to the kind of glass desired.

An example of the pernicious effect of fusibility is frequently observable around beehive coking plants. If the earth used for filling over the crown is charged with limestone or manganese or ferrous oxides, the union of these with the silica in the crown brick produces a stringy slag, which, in time, may cause the failure of the oven due to eating away the brick.

General Analyses of Coal Ash

So much by way of establishing the easy fusibility of certain refractory substances when closely mixed. Let us now turn to coal ash and see of what substances it is composed. Probably the analyses of most samples of coal ash will come between the following limits:*

TYPICAL LIMITS OF ASH ANALYSES

Constituent	Per Cent.
SiO_2	40 to 60
Al_2O_3	20 to 35
Fe_2O_3	5 to 25
CaO	1 to 15
MgO	0.5 to 4
$\text{Na}_2\text{O} + \text{K}_2\text{O}$	1 to 4

*A. C. Fieldner, A. E. Hall and A. L. Feild in Bulletin No. 129, Bureau of Mines, page 13, "The Fusibility of Coal Ash and the Determining of the Softening Temperature."

It will be evident from the above list of constituents that coal ash contains relatively large proportions of SiO_2 and Al_2O_3 , and smaller proportions of other oxides which, when mixed with the above, as is bound to be the case with coal ash, may produce a condition favorable for fluxing, or, as more commonly expressed, the clinkering of the ash. The fusibility of ash is, however, dependent upon several factors, such as the ratio of the silica to the bases present, upon the particular bases, and upon the percentage of alumina present. Mixtures extremely high in silica, or extremely high in bases, are not readily fusible. Ash which is low in iron is usually so highly siliceous that it is not readily fusible. Ash from coals high in pyrite is necessarily high in iron and the ratio between the bases and silica is often such that easily fusible compounds may be formed.

Some coal ash has such a high fusing temperature that there are practically no fuel bed conditions that will produce troublesome clinker from it. Another ash with a little lower fusing temperature will sinter together and form a porous, spongy clinker which does not seriously obstruct the flow of air, nor is it difficult to remove. Ash with a still lower fusing temperature, say 2100 deg. F., will not only become melted in the average fire box, but it will be heated several hundred degrees above its melting temperature, in which case it runs down like overheated iron until it spreads out in a thin sheet over the grate area. Clinker in this form is hard to get rid of and while on the grates it may obstruct the flow of air so completely that the heat of the fuel bed is localized and causes burning of the grate bars.

Relation Between Sulphur and Clinkering

Sulphur, which, in combination with iron as iron pyrites, FeS_2 , is a common constituent in coal, is sometimes held solely responsible for clinkering. It is not, as a matter of fact, the element sulphur which produces the trouble but rather the element iron.

When coal containing pyrite is burned two chemical changes are possible. First, that all of the sulphur and all of the iron will be completely oxidized, thus, $2 \text{FeS}_2 + 11 \text{O} = \text{Fe}_2\text{O}_3 + 4\text{SO}_2$. That this takes place to any great extent is quite improbable owing to the insufficiency of oxygen. The most likely reaction is the second, which is that the iron bisulphide, FeS_2 , having contact with air at the high furnace temperature, loses one of its atoms of sulphur, which passes off as sulphurous oxide gas, SO_2 , and thus the bisulphide is reduced to a monosulphide (ferrous sulphide), FeS . A still further chemical change now takes place. Some of the monosulphide, in the presence of air, will replace part of its sulphur with oxygen, thus becoming oxidized to ferrous oxide, FeO . In this form there is a ready union with the silica of the ash, produc-

ing a ferrous silicate which has the property of fusing at a comparatively low temperature, thus causing clinkers.

While it is therefore the iron, and not the sulphur, which has the effect upon the fusing temperature, it is well to remember that the percentage of iron usually increases or decreases with the amount of sulphur. Even so, the fusibility of an ash should not be prejudged solely upon the presence or absence of iron pyrites, for it would be possible to have fusion where sulphur is entirely missing in an analysis. One of the lowest sulphur coals in the United States is found in Rhode Island—less than $\frac{1}{4}$ of 1 per cent.—yet the fusing temperature and the clinkering properties of this coal class it amongst the very worst. The reason for this lies in the presence of fluxes other than ferrous oxide. The amount of sulphur in a coal, as shown by analysis, is not a sufficient criterion on which to base the degree of slagging. Sulphur existing in organic combination as a sulphate is likely to be harmless, therefore, to fairly prejudge the clinkering of a coal, the amount of sulphur in its various forms should be known.

Other Factors in Fusibility

The intensity of heat in the firebox also has a considerable bearing on fusion, thus, fuels which are impossible for locomotive use for reasons of clinkering, might give very satisfactory results in the less terrific heat of a stationary steam plant. Conditions of service, grate area, methods of firing, etc., frequently determine whether or not a coal will clinker badly. Upon this point Mr. E. G. Bailey§ advises as follows: "The seller of coal cannot justly be held responsible for trouble due to clinkers when the formation is the fault of the fireman, but the purchaser can specify that the ash of the coal delivered shall not fuse below a certain desired temperature and can see that this specification is filled. This requirement is of equal and often of greater importance than the demand for a given number of British thermal units in a pound of fuel, for the formation of clinkers may retard and prevent development of heat, as clinker affects both the capacity and efficiency of the plant as well as the repairs to the furnace and its equipment."

How the Fusion Point is Determined

The manner in which the fusion point of ash is determined is of no small importance, for unless properly done the results derived may be entirely misleading. Here, as also with coal sampling and analysis, there is much opportunity for intrusion of the personal equation into the results. A common method of arriving at fusion points is by comparing the fusibility of an ash cone with that of Seger cones, the melting points of which are known. Both the ash cone and a series of Seger cones, having a progressive range of, say, 25 degrees in their

fusing points, are placed in a furnace and the heat gradually increased. The temperature at which the ash cone fuses is fixed by noting the fused Seger cone having the highest temperature, which temperature thereby becomes the point of fusibility of the ash. As may well be surmised, it is altogether important that the definition of the term "fusion point" be a commonly accepted one, rather than left to the individual judgment of each observer. The ordinary conception of the term as applied to a compound is a fixed temperature at which transition from a solid to a liquid state takes place. This conception as applied to a test on coal ash is both misleading and inapplicable. The Bureau of Mines offers a definition which tends to make the matter clear. In all laboratory tests it regards the fusion point as the temperature at which the cone has fused down to a spherical lump, as shown in cones 2 and 3 of Plate III. B, page 66 of Bulletin 129.

The pyrometer method of recording temperatures is used by the Bureau of Mines and many commercial laboratories because of its greater accuracy. Thermocouples are also in use. Recourse to these scientific devices enables a close reading in degrees, and, where exact work is a requirement, they are always to be preferred to Seger cones. The latter, however, usually meet the need of commercial work.

It is now well known that results obtained in fusibility tests will vary considerably with the atmospheric conditions under which the test is made, that is, whether made in an oxidizing, reducing or neutral atmosphere. The importance of this is emphasized by results noted by Marks,[†] who found as great a difference as 390 deg. C. in the fusing temperatures reported by two different testing laboratories on the same sample. In an atmosphere that is reducing, that is, where an excess of gas is used, the iron in the ash is reduced to the ferrous state, as already explained, and this gives the lowest temperature at which clinkering will result. If, on the other hand, the atmosphere is oxidizing, that is, where an excess of air is used, the iron is oxidized to ferric oxide and a higher softening temperature may be expected. This same condition will occur where an atmosphere is so strongly reducing as to convert the iron to the metallic state. It will be quite apparent from the foregoing that the result of a test depends largely upon the kind of atmosphere employed, and equally apparent that the most accurate test on a coal is made only after knowing to what use it is to be put, and the conditions under which it is to be burned. In recognition of this fact, the Bureau of Mines advocates‡ that a standard method of testing should be adopted in order to insure comparable results by different laboratories and to obtain the softening or fusing temperature of the ash under conditions similar to those in the fuel bed. A practical method of determining fusibility has been developed whereby the ash is caused to soften and form slags in which the iron exists in approximately the same state of oxidation as the iron in the fuel-bed clinkers.

§From paper "Fusion Temperature of Coal Ash and Its Relation to Rate of Combustion" read before Ohio Society of Mechanical, Electrical and Steam Engineers, 1911, quoted by E. B. Wilson, Proc. Coal Mining Institute of America, 1912.

[†]Marks, L. S., "The Clinkering of Coal," Power, vol. 40, pp. 32-934.

[‡]Ibid, pp. 1-2.

The Table of Fusibilities which follows is compiled from reports issued by the Bureau of Mines. The samples represented are practically all standard mine samples collected by representatives of the Bureau of Mines, the U. S. Geological Survey, or by the various state geological surveys, according to the methods used by the Bureau of Mines.

For convenience in discussion the order of fusibility of coal ash from the various coals of the country may be divided into three groups, as follows:

Class 1—Refractory ashes, softening above 2600 deg. F. Class 2—Ashes of medium fusibility softening between 2200 and 2600 deg. F. Class 3—Easily fusible ashes, softening below 2200 deg. F.

Specializing in

Coal and Coke Analysis

(See Pages 65 to 68 on Proper Methods of Taking and Preparing Coal Samples)

TO THE PRODUCER OF COAL—Coal analyses made on samples taken from the face and tippie will show you whether your miners are careful in eliminating the impurities.

Knowing the quality of coal you are producing will be valuable information for your salesmen.

Coal Sampling in the Mine

Coal Sampling at Mines and Plants—Samples should be gathered so as to be representative of the gross lot of coal upon which the analysis is desired. Face samples represent the quality of coal as it lies in the seam. Samples collected at the tippie or from railroad cars at the mine or at destination represent the quality of coal shipped to the consumer. See pages 65 to 68 of this section for preparation of sample and methods of sampling.

Our trained experts can visit the mines and plants to gather the samples, or, if preferred, we can instruct one of your employees on coal sampling and mail a print showing the "Proper Methods of Preparing a Coal Sample," which will enable him to prepare representative samples.

Let Us Serve You on the Following

Proximate Analysis of Coal—Includes the percentage of moisture, ash, volatile, fixed carbon, sulphur and B.t.u. (heat units).

Fusion Temperature of Ash—This determination is most important, for it indicates at what temperature the ash or refuse in the coal begins to fuse or form clinkers. The furnace we use is so made that we get practically the same condition that exists in the fuel bed of a furnace.

Mine Investigation—We have been retained by numerous operators to go to their mines and gather samples at the face and also at the tippie as the coal passes into the railroad cars and make analyses from these samples. The difference in quality between the coal in the seam and from

railroad cars will show you whether care is being used by the miners.

Besides reporting the quality of the coal, we make a sketch showing the general make-up of the seam.

By-Product Investigation—Do not sell your coal to steam plants if it proves to be better adapted for by-product use. We have a special plant designed to carry on practical investigations showing the amount and quality of gas, ammonia, tar and coke. We are able to furnish a distillation of the tar for the oils and pitch. We also furnish with each investigation a good-sized sample of coke for examination as to physical properties, etc. About 40 to 50 pounds of coal should be sent for this test.

Ultimate Analysis of Coal—This includes determinations for moisture, carbon, hydrogen, nitrogen, oxygen, sulphur and ash.

Coal Washer Test—We are prepared to put through our laboratory, tests that will demonstrate the advisability of washing coal in order to make a cleaner and better product for the market.

Oil Analysis (Fuel and Lubricating)—Flash point, burning point, viscosity, specific gravity, etc.

TO THE CONSUMER OF COAL—The quality of coal must be known in order to obtain high efficiency in your boiler room. Representative samples should be gathered daily from cars and analyzed. (Details sent on request.)

Combustion Engineering—When coal is not giving the desired results in a plant, we are able to find out the reason for the trouble. Sometimes coal is at fault and sometimes conditions in the plant are at fault. We maintain a department that has specialized in demonstrating how coal should

Coal Sampling from Railroad Cars

be burned to the best advantage. We are able to locate the cause of the trouble and make suggestions as to how this can be remedied. We send a representative to the plant and do the actual firing when necessary in order to accomplish the desired results. We have saved trouble in plants for both the consumer and shipper of coal where difficulties have come up in the actual burning of the coal.

FROEHLING & ROBERTSON

Established 1881. RICHMOND TESTING LABORATORY

815 East Franklin Street, RICHMOND, VA.

Laboratory Tests As an Aid to Coal Profits

COAL ANALYSES FOR INCREASED PROFITS

A series of coal analyses representing the output of a mine is indispensable to the operator in the economic production and disposal of his product.

For more than forty years this firm has specialized in coal analysis, following the most advanced methods and employing only modern equipment; it is therefore in position to render complete, prompt and accurate chemical service.

We make Proximate and Ultimate Analysis, determine British Thermal Unit values of Coal, Fusing Temperature of Ash of Coal, and Sample Cargoes at Tidewater.

High Temperature Furnaces for Coal Ash Fusion

Calorimeters for Testing Coal and Gas

Further, we do general analytical and research work, such as the examination of water for boiler and drinking purposes, and the analysis of ores, alloys, oils, paints and food products.

We also conduct a testing bureau for the inspection of structural and road building materials.

Your problems will receive personal study by capable experts. Information and prices on request.

CINCINNATI, OHIO

The Chemist and the Mine Operator

The chemist, by means of his technical skill and knowledge, is able to render service in many ways to coal producers. Most frequently this service consists of **coal sampling and analyses**, and it is quite likely that this will always be the chief means of bringing the work of the chemist to the aid of coal production and salesmanship. Of this service we shall have more to say later on.

There are other ways, however, in which the analyst can serve the operator. One of the chief considerations in present day town planning is to secure an adequate supply of **pure drinking water**, water which is known to be free from disease breeding bacteria and germs. The success of a mining plant is closely bound up in the health of its employees, and a knowledge of this accounts for the very general practice among mining companies of having their drinking water analyzed at frequent intervals. The Louis G. Robinson Laboratories solicit analytical work of this kind.

In spite of the inroads of the central power station, most mines still generate their own power. One of the essentials in steam raising is to use water which is free from scale forming materials, or if such cannot be had, then it becomes of equal importance to know the ingredients of the water, so that proper correctives can be applied to stop the growth of scale, foaming, etc. It is a matter of experience that where water is taken from nearby streams, the quality of the **boiler feed water** often varies with the season of the year or the volume of water flowing. We will be glad to advise with mine officials on their feed water supply, method of taking water sample, etc., and after analysis, to recommend a proper method of water treatment.

One of the big items of expense in house maintenance is the cost of **paints and painting**. Paints vary in quality from good to bad, and in view of the number of houses in mining camps, it is a matter of economy to have your paint analyzed before final acceptance.

The Chemist and the Coal Consumer

Among the services already enumerated, the chief of these to the coal consumer, as a class, lies in the sampling and analyses of coal and coke. It is a matter of record that most coal bought today for industrial purposes is based on the chemical content of the fuel. The purchaser of coal rightly wants to know the amount of the worthless ingredients, such as **moisture and ash**, in every pound, what the **heat value** of the coal is, and whether there will be any interference with combustion through the **fusibility of the ash**.

The Louis G. Robinson Laboratories have been sampling coal deliveries and making analyses for coal consumers in many states, and guarantee satisfaction.

Coal Sampling

Coal samples may be taken (a) as a channel sample in the mine, (b) at the tippie or breaker while coal is being loaded, (c) while the coal is being unloaded at destination, (d) car or pile samples at destination. No matter how taken, the matter of sampling, let it be said here, is of such importance to the correctness of results that it should be entrusted only to an experienced and reliable person.

The Louis G. Robinson Laboratories have been taking samples and making analyses for mine operators and coal consumers for many years; we will undertake your work on the principle that the first step in the process, that of sampling, is just as vital to exactness as is the careful manipulation of the crucible, the balance or the calorimeter. We follow the methods of sampling recommended by the Bureau of Mines and in every case aim to secure a mixture which is representative of the whole.

We recommend to mine operators that channel samples be taken at various sections of the mine at regular time intervals, depending upon the rate of development or tonnage output, and, in addition, that samples at the tippie while the coal is being loaded be taken more frequently. The tippie analyses can then be checked against the channel analyses; the latter represent the perfection to which the coal may attain; the former show how nearly that perfection has been reached. Any unusual discrepancy in the two analyses enables immediate action to be taken for correction.

Coal Analyses

Our facilities and equipment for analysis are scientific and modern in every respect. Determinations of volatile matter, moisture, sulphur and phosphorus, as well as the percentages of various elements as reported in the ultimate analysis of coal, are by the methods of analyses recommended by the American Society of Testing Materials. Fusion Temperature of Ash test is done under furnace fuel bed conditions. The calorific value of coal (British thermal units) is obtained through the use of the Emerson bomb calorimeter.

Tests on Illuminating Gas and By-Product Coals

Where coals suitable for the gas or by-product industry are produced, the operator or sales agency should have on hand full data as to the coke yield, gas yield, heat value of the gas, ammonia and tar yields; also an analysis of the coke, gas, and tar. We are prepared to make all tests and analyses necessary for this information.

Reliability, Service

The first requirement on the part of an analytical laboratory is accuracy, and accuracy is the result of painstaking care. We pride ourselves on the reliability of our past work done among both the producer and consumer of coal. We stand ready to render the same quality of service to others.

SMITH, RUDY & COMPANY

411 WALNUT STREET, PHILADELPHIA

Complete Facilities, Standard Methods, Experienced Chemists, Prompt and Accurate Reports, Reasonable Charges,—THAT'S US

Smith, Rudy & Company, in their capacity as analytical chemists, offer a service to all connected with the production, distribution and consumption of coal. Our laboratories are well and completely equipped with all the necessary scientific devices to insure correct results. Our working staff consists of experienced chemists who by the use of standard methods and the benefit of proper facilities are enabled to do their work with promptness and accuracy.

Our rates are very reasonable—it's a fixed part of our policy to have them so.

Coal Sampling

Taking a coal sample carefully and correctly is as important as extreme accuracy in making the analysis. An analysis can be checked and errors detected, but it may not be possible to secure a second sample. It is well to bear in mind, therefore, that the impurities of coal are irregularly distributed throughout the mass, and both care and judgment are needed in taking the sample if it is to be representative of the coal in question and if the analysis is to be of any value. If the sample is taken in the mine we recommend that it be cut from a channel six to eight inches in width and two to four inches deep, rejecting only such portions as would be rejected in good mining practice. Samples taken while loading or in cars or piles are more dependent on the good judgment of the sampler, but the main facts to bear in mind are

that the sample should be large rather than small, and, second, that it should consist of about the same proportion of lump and fine as exists in the car or pile. After crushing and quartering, the final sample of 5 to 7 pounds should be put in an air-tight can, jar or tin bucket and sent to the chemist.

We have issued a little folder of convenient size on COAL SAMPLING in which complete instructions are given which we will be glad to send you.

Our services for sampling are available, whether for taking sample in the mine, at the tippie, from the car, from boats, or in coal yards.

Coal Analysis

When sending coal samples, it should be stated whether the **Proximate Analysis**, consisting of moisture, volatile matter, fixed carbon, ash and sulphur determinations is wanted, or the **Ultimate Analysis**, consisting of carbon, hydrogen, nitrogen, oxygen, ash and sulphur. Frequently both are desirable for the purpose of presenting more complete information on the coal.

The heat value (British thermal units) as determined in the calorimeter and the fusing temperature of the ash supply data of equal or greater importance in some cases than the proximate analysis.

Proximate Analysis

Consisting of Moisture, Volatile Matter,

WRITE FOR PRICE LIST

COKE

Furnace; Foundry; Domestic, Including Coke Derived from Gas Works, By-Product Ovens, and from Low Temperature Distillation of Coals.

Coke may be described as the carbonaceous product remaining after coal has been subjected to destructive distillation, either in the absence of air or in the presence of a limited supply, in any of the three commercial processes, viz.: beehive coking, by-product coking, gas retort coking. It contains as its chief constituent carbon, and with this minor percentages of moisture, ash, sulphur, phosphorus, and such of the volatile matter as the temperature employed failed to drive out.

The fuel originally employed for furnace use was charcoal, which, in the early days of the industry, served well because of its exceptional purity, due to the almost total absence of sulphur, and also because it satisfied the requirements for smokeless burning and infusibility. With the greater development of the blast furnace industry, charcoal became costly to secure owing to the timber supply on which it depended becoming gradually removed from the centers of iron production, and, further, because of softness of body it was incapable of standing the increased charges incidental to the use of taller stacks. Anthracite coal was also much used in the early days, and, with its natural hardness of body, was well able to sustain the pressure of the highest furnace charges, as well as to resist the dissolving action of hot carbon dioxide gas, but it was high in price and somewhat difficult to deal with in practice due to its denseness. Bituminous coal in its raw state could not be used in the blast furnaces because of its swelling, softening, and tendency to form arches which interfered with the descent of the charges and the ascent of the hot gases. Much of the heat value of the coal was also lost due to distillation of the volatile matter in the upper zones of the stack.

It is not the purpose of this article to dwell on the kinds of coal best adapted for any of the several processes, except as it may be incidental to the discussion of coke. Information referring to adaptable coals will be found under the heading "Classification of Coals—According to Use."

Furnace Coke

Furnace coke, as suggested by the name, is the fuel employed in modern blast furnace practice for the reduction of iron from the ore. A coke to meet this requirement successfully must have certain chemical and physical qualities. Chemically it must be low in ash, sulphur, and phosphorus and high in fixed carbon, which latter is the heat yielding constituent of coke. Ash is undesirable for the reason that it has no heat value, although to it is sometimes ascribed the virtue of supplying strength to the coke cells; sulphur and phosphorus are both detrimental for the reason that sulphur, being readily

absorbed by molten iron, makes the resulting steel "hot short," while phosphorus makes it "cold short."

It is largely physical structure which gives coke its advantage for metallurgical work over other forms of solid fuel. Furnace coke must be uniformly strong in order that it may withstand the weight of the furnace charge. A spongy or porous coke would become crushed and much of it lost by the dissolving action of ascending carbon-dioxide gas. The same difficulty will appear if the cell walls are thin. Fulton gives 56 per cent., the figure of Connellsville coke, as the most desirable volume of cells for American blast furnace practice. It does not follow, however, that the harder the coke the better it is for any furnace plant. By means of mixing coals it is possible to obtain a resulting coke which will be very hard, strong, dense and in large pieces. In certain type furnaces such a coke may not give good results, causing the blast pressure to drop, excessive heat in the upper zones and, worst of all, a high-sulphur iron. With a less dense coke all such troubles might be made to disappear.

Coke, in order to have the required strength, must be made from a coal suited to the coking process and must be properly burned. This requires the exercise of care and judgment on the part of the coke yard supervisor. Sometimes charges of coal are put into beehive ovens in excess of the amount which can be entirely coked in the prescribed period of 48 or 72 hours. When this coke is drawn it shows a mass of spongy-black uncoked coal at the bottom, known amongst coke men as "black butts." The same condition may be caused by careless leveling of the charges in the oven, by poor judgment in the regulation of air to the oven while the charge is being coked, or by permitting the oven to be excessively watered or otherwise chilled after a charge is drawn. Furnace men object to coke with black butts, claiming that it makes it difficult to calculate with accuracy the fuel charge for the furnace and that because of its softness such coke is too easily crushed.

Furnace coke is usually burned for 48 hours in the beehive oven and for 16 to 18 hours in the by-product oven. Coke from the former type of oven is the larger in size, has a higher percentage of cell space, and when drawn has a more silvery lustre, due to being watered in the oven, whereas by-product coke is quenched after it has been discharged from the oven and has a darker appearance. For a considerable period after the introduction of by-product coke into furnace use, a prejudice existed against it because of these differences, and it was with some difficulty that the furnace man was brought to see that it was in no wise inferior to beehive coke. In the early days some trouble was experienced owing to by-product coke

being softer and not so thoroughly carbonized, hence was too easily attacked by carbon-dioxide gas in the blast furnace; others complained that it made furnace operation difficult by preventing a rapid and continuous movement of the stock. All such prejudice and objections gradually disappeared as the usage of by-product coke was extended. It was found to be more uniform in size and harder than beehive coke, with a smaller percentage of cell spaces and, therefore, about 10 per cent. heavier bulk for bulk. W. H. Blauvelt* states that "the by-product oven, with its variable mixture of coals, variable heats, coking time, width of oven, fineness of coal discharged, and other controlling factors, permits a control of coke structure formerly impossible. The problem is to determine, first, what is the structure best adapted to standard furnace practice, while recognizing that special practice requires modification of structure; second, what conditions are necessary to produce it."

Coke used in lead, copper, and other non-ferrous blast furnaces which are run with a low-pressure should be more porous than coke used in iron furnaces.

The heating value of metallurgical coke ordinarily lies between 12,500 and 13,000 B. t. u. per pound. A fair average for a good coke may be stated as 12,900 B. t. u. per pound.

Foundry Coke

Foundry coke is used in cupolas, and since the burden here is more concentrated, larger and tougher pieces are required. The coal charge from which it is made is usually burned in the beehive oven for 72 hours, which produces a denser and stronger coke than that burned for 48 hours and used for blast furnaces.

Domestic Coke

The introduction of coke for domestic use dates back to the close of the eighteenth century, gas house coke being used in grates in England in a small way for a number of years. The use of bituminous coals there, as here, has ever been attended with the inconveniences of smoke and dirt, not only to the household, but to the entire community. The smoke "nuisance," as it is properly termed, has received the attention of investigators for many years. The monetary loss in cities is surprisingly great. According to the Bureau of Mines,† "the cost to the community has been investigated in detail in several large cities. The committee on smoke prevention of the Cleveland Chamber of Commerce in 1909 fixed the annual loss due to smoke in the city of Cleveland at \$6,000,000, or about \$12 for every man, woman and child each year. Similar investigations made by the Mellon Institute in Pittsburgh showed a total annual cost of \$10,000,000, or about \$20 per capita. This estimate does not include such items as depreciation in value of property, compulsory absence of certain industries, injury to health, or impaired mental efficiency." In addition to these losses there must be added that loss due to the waste of fuel as indicated by clouds of smoke pouring forth from stacks and chimneys—indisputable evidence of the incomplete utilization of fuel values in coal. These various sources of loss are so well understood, and have been so much

dwelt upon in recent years that there is no need to make extended references to them here. The fact that stands out prominently through all these years is that in spite of all attempts made to effect improvements in stoves, furnaces or hearths whereby high volatile coals may be burned economically, the smoke nuisance still persists. The point of attack is obviously in the raw coal itself.

Anthracite coal is everywhere recognized as the best type of smokeless fuel, as it is very clean and easy to regulate and control. It is carefully prepared in sizes well suited to all kinds of domestic service and in every respect is the premier coal for the household. An unfortunate characteristic of this coal is that it is found only in a relatively small section of Eastern Pennsylvania, hence its use is largely restricted to a district lying within reasonable freight distance of the mines.

In view of the troubles encountered in burning bituminous coal, and the inaccessability of anthracite coal, the coke industry was early turned to for relief. Gas house coke, already referred to, failed to arouse the enthusiasm of the English household. No great amount of attention was given to its quality by the manufacturer, it being regarded solely as a by-product of little value derived in the making of illuminating gas. Its softness and black dead look were also against it, but the main trouble was in its use, objections being raised against the difficulty in ignition, the dull, cheerless fire, and the fumes given off in burning. All of these troubles were brought about by lack of draught, the result being that coke as a fuel fell into disrepute.

No sustained attempt has ever been made to introduce coke made in beehive ovens into domestic use, although at various places such coke is crushed and separated into sizes for supplying domestic trade. Beehive coke is usually characterized by a hard outer skin of graphitic carbon, produced by the breaking down of the gases evolved in the process with the deposition of carbon. The skin affects the ignition point and accounts for one reason why beehive coke is not so well adapted to domestic use as is by-product coke, as with the latter this hard skin does not appear.

With the rapid growth of the by-product industry, the use of coke for heating and coking received more consideration, with the result that facilities for supplying coke to the household are now very different from what they were in the earlier days when domestic coke was produced in gas works. Coke at present supplied to the trade is derived in the ordinary procedure of coking in by-product ovens, that is, coal is coked at the usual temperature and for the usual period of time. Such valuable ingredients as gas, ammonia, liquor, and tar are distilled from the coal, leaving but a small percentage of volatile matter remaining in the coke. Great care is taken in sizing and preparing the coke for domestic use, and also in the complete removal of breeze and dirt. The following table shows approximately the usual sizes produced:‡

	Size of Square Opening on Screen	
	Through	Over
Egg Coke	3.5 in.	1.5 in.
Nut Coke	1.5 in.	1.0 in.
Pea Coke	1.0 in.	0.5 in.
Breeze	0.5 in.	... in.

*"The By-Product Coke Oven and Its Products," March, 1918, Bulletin, A. I. M. M. E.

†Tech Paper 242, Bureau of Mines, "Why and How Coke Should be Used for Domestic Heating," Henry Kreisinger and A. C. Feldner.

‡"The By-Product Oven and Its Products," W. H. Blauvelt, March, 1919, Bulletin, A. I. M. M. E.

Coke as a domestic fuel has a number of advantages over both hard and soft coal. The locality in which anthracite coal is found is irrevocably fixed, hence distance from the source of supply to the points of consumption will never be lessened. By-product coking plants, on the other hand, may be situated either at the point of coal production or else placed in thickly populated sections and coal shipped to them. Since coals suitable for by-product purposes are widely situated geographically, freight rates are correspondingly less than those applying to anthracite coal. Ton for ton coke also gives more heat than hard coal and is easier to ignite.

In comparison with soft coal, coke is much cleaner and more easily handled because of its light weight. Unless too thin a fire is carried, it will not burn out grates, and the ash produced is of a fine nature without the formation of clinker. "When burning coke a furnace requires much less attention than when burning soft coal. The time usually given to poking fires, cleaning the furnace flues and the house, can be spent much more profitably in some other way. Surely the most disagreeable work a householder is called upon to do is to clean the soot out of his furnace and flues. Moreover, the cleaning is not limited to furnace and flues alone, but extends to the entire house. With hot-air heating particularly, some of the soot may be carried into the house, necessitating more frequent house cleaning, curtain washing, and papering. The cleanliness of coke will appeal especially to the housewife."*

The ignition point of by-product coke is governed by both its chemical and physical conditions. In its manufacture the percentage of volatile matter is reduced to almost nothing, as it is distilled at the temperature employed in the production of metallurgical coke. The ignition of this coke does not depend upon its content of volatile matter, but rather upon its physical condition, that is, its cellular structure. The range of coals, and the possibilities for mixing, permitted by the by-product oven, is such as to produce coke having a very firm structure and at the same time characterized with a sufficient development of cellular space so as to permit of easy combustion. It is, moreover, free from the graphitic coating so commonly noticed in beehive coke, and which acts as a hindrance to ready ignition. Objections are sometimes urged against coke for domestic purposes, but these are based largely upon a lack of familiarity with its use. Coke is unlike both hard and soft coal, but not so much unlike either that the method of firing is difficult to understand. Its cellular structure gives it an intensity of combustion and susceptibility to chill that renders its control different from that usually employed with coals. The rules governing its burning are few in number, centering largely on thickness of fuel bed as a means of draft control, and full instructions are readily gotten, either from the companies supplying coke or from the Bureau of Mines.

Coke Made at Low Temperature

It was suggested many years ago that half-coked coal be used as a fuel supply, and numerous attempts were made to produce a commercial article

by carbonizing coal at the ordinary gas-retort temperature, drawing the charge when half the usual volume of gas had been distilled out of it. All of these attempts resulted in failure, due to the outer portion of the charge being heated to such a degree that it became hard coke and was difficult to ignite, whereas the interior of the charge received an insufficient amount of heat necessary to drive off the smoke and tar producing substances. In 1902 experiments were begun at the University of Illinois, having in mind the modification of bituminous coal in such a manner as to eliminate largely the constituents which tend to produce smoke in combustion and which would consequently give to the material the essential properties of anthracite or semi-anthracite coal.†

Coke resulting from the low temperature process has from 4 to 12 per cent. of volatile matter remaining, but since it has been heated above 750° C. there should be none of the tar constituents remaining. The behavior of this coke in an open grate has been summed up as follows:‡ "The coke ignites readily, it retains its shape through the process of combustion, a bed of glowing coals quickly results, the very indifferent provisions for draft as found in an open grate are sufficient for keeping the combustion lively, there is no smoke produced, and fire is retained over a long period of time, because the interior of the larger pieces hold the fire and continues the combustion until all of the carbonaceous material is consumed. While the temperature commonly attained by a grate fire would not furnish positive evidence as to the formation of clinker, the indications, so far as they went, were altogether favorable. A small amount of coke was at hand for the test, but so far as observations could be made, it was as favorable as the test in the open grate."

While coke made by the low temperature process has not as yet advanced beyond the experimental stages, the ideas involved promise much for the future. It has already been demonstrated that a fuel much superior to the raw coal used can be made, and if the process can be worked out to produce coke commercially on a large scale, a ready sale for the product may be safely anticipated.

Modified Method of Carbonizing at Low Temperature

During the past few years an elaborate series of experiments have been conducted at Irvington, N. J., by Chas. H. Smith in the development of a process whereby coal can be treated by low temperature distillation methods and made to yield a smokeless coal, along with a yield of tar oils double that derived from the ordinary by-product practice. The fuel derived is called Carbocoal. "The essential features of the Smith process are two distillations carried on at different temperatures, first of the raw coal and second of the raw briquets. The raw coal, after being crushed, is distilled at a relatively low temperature, 850° to 900° F., and the volatile contents are reduced to the desired point. The result of this first distillation is a large yield of gas and tar oils, and a carbonaceous product termed semi-carbocoal. The semi-carbocoal is next mixed with a certain proportion of pitch obtained from

*Tech Paper 242, "Why and How Coke Should be Used for Domestic Heating."
†University of Illinois, Bulletin No. 24, "Modification of Illinois Coal by Low Temperature Distillation," by S. W. Parr and C. K. Francis.
‡Ibid.

the tar produced in the process, and this mixture is briquetted. The briquettes are then subjected to an additional distillation at a higher temperature, approximately 1800° F., resulting in the production of carbocoal, the recovery of additional tar and gas, and a substantial yield of ammonium sulphate."[†]

The work begun at Irvington, even though of an experimental nature, was so successful that shortly after the United States became involved in the late war, and the necessity for providing a greater quantity of the by-products derived from coal for munition purposes became pressing, the Government arranged for the building of a large commercial plant at South Clinchfield, Virginia, adjacent to the coal fields. This plant began operation on the first of August, 1920. In addition to the fuel Carbocoal there is produced gas in the amount of approximately 9,000 cubic feet per ton of coal carbonized, a yield of tar more than double that obtained in the ordinary by-product coking

process, and ammonium sulphate equal in amount to that normally recovered in the ordinary by-product coking process.

Carbocoal as it comes from the high-temperature retorts is in the form of hard briquets of a density much greater than that of ordinary coke, and only slightly less than that of coal. It contains only from one and one-half per cent. to four per cent. of volatile matter, and consists mostly of fixed carbon. As a domestic fuel it compares favorably with anthracite. It has a heat value of about 13,000 B. t. u. (based on a coal with 7 per cent. ash). In combustion it is smokeless, it ignites with comparative ease and being of uniform size and quality it burns evenly and freely, leaving under proper firing conditions a clean light ash. In all cases the tendency to clinker is much less than with the coal from which the fuel is made.

[†]"Carbocoal," by Chas. T. Malcolmson, in September Bulletin, A. I. M. M. E.

BY-PRODUCTS OBTAINED FROM COKE-OVEN OPERATIONS IN 1920*

The table summarizes reports received by the Geological Survey from operators of by-product coke ovens covering the year 1920. The statistics are subject to revision on receipt of final reports from two companies for which at present complete information is not available. The total value of the by-products sold including gas used about the works for other purposes than heating by-production ovens was \$93,626,000.

To recover these by-products required the carbonization of 44,234,000 net tons of coal. The quantity of merchantable coke produced was 30,781,000 tons, indicating a yield of coke from coal of 69.6 per cent. In addition, the operators reported a recovery of 2,322,000 tons of screenings and breeze. The yield of coke including breeze was 74.9 per cent of the coal charged during the year.

Product—	Unit	Production	Sales	Value of sales
Tar	Gallons	360,000,000	172,000,000	\$7,400,000
Ammonia:				
Sulphate	Pounds	675,000,000	629,000,000	27,150,000
Ammonia liquor and anhydrous	Pounds NH ₃	65,000,000	63,000,000	8,300,000
Ammonia (a)	Pounds	935,000,000	881,000,000	35,450,000
Total sulphate equivalent	Pounds			
Gas (b)	M cu. ft.	476,000,000	227,000,000	32,050,000
Benzol products:				
Crude light oil (c)	Gallons	109,000,000	843,000	96,000
Benzol, crude	Gallons	8,960,000	1,730,000	430,000
Refined	Gallons	16,890,000	15,580,000	4,030,000
Motor fuel (d)	Gallons	55,100,000	53,200,000	12,070,000
Tolu, crude	Gallons	287,000		
Refined	Gallons	2,740,000	2,490,000	760,000
Solvent naphtha	Gallons	5,420,000	4,530,000	820,000
Naphthalene, crude	Pounds	10,710,000	10,750,000	290,000
Refined	Pounds	3,450,000	3,700,000	200,000
Other products (e)				30,000
Total value				\$93,626,000

*Preliminary figures, subject to revision.

(a) Includes anhydrous ammonia reported as such, and ammonia liquor converted to equivalent in anhydrous ammonia. Of this, the quantity sold in the form of ammonia liquor was equivalent to 19,000,000 pounds NH₃.

(b) Of the 476,000,000 M of gas produced, 237,000,000 M was used in heating coke ovens and 12,000,000 M was wasted. The distribution of the 227,000,000 M shown as "sold" was as follows:

	M cu. ft.	Value at plant
Used under boilers or other coke plant equipment	24,000,000	\$ 2,150,000
Used in steel or other affiliated plant	150,000,000	14,200,000
Distributed through city mains	53,000,000	15,700,000
	227,000,000	\$32,050,000

(c) The quantity of crude light oil reported refined on the premises was 106,000,000 gallons.

(d) The percentage of benzol reported in the motor fuel ranged from fifty to ninety.

(e) Includes coal tar, crude heavy solvent, retort carbon, pyridin oil, etc.

AVERAGE RECOVERY PER NET TON OF COAL CHARGED INTO BY-PRODUCT OVENS IN 1918, 1919 AND 1920

	1918	1919	1920
NH ₃ (all forms) expressed in terms equivalent ammonium sulphate	18.9	20.8	21.2
Tar	7.1	8.1	8.1
Crude light oil	2.4	2.7	2.7
Gas	10.4	11.6	10.8

The progress of and the fluctuations in the coke trade of the Connellsville region, during the past 41 years, or since it assumed importance as an industry, is comprehensively shown in the following tabulation. This gives the total number of available ovens at the close of each year, the annual output, the average price per ton and the gross value, as compiled and published annually in The Courier since 1880:

Year	Ovens	Shipped	Price	Revenue
1880	7,211	2,205,946	\$1.79	\$ 3,948,643
1881	8,208	2,639,002	1.63	4,301,573
1882	9,283	3,043,394	1.47	4,473,889

686 East Catalan Street, ST. LOUIS, MO.

Piette System Belgian By-Product Coke Ovens

With or Without Recuperation or Regeneration

The Belgian-American Coke Ovens Corporation was organized in 1921 by a group of American business men for the purpose of introducing on this side of the Atlantic a thoroughly modern and economical system of by-product oven and recovery plant construction.

This company has acquired all the patents and rights in the United States and Canada from the Franco-Belgian Coke Ovens Corporation of Brussels, Belgium, for the construction of its several types of Piette System By-Product Coke Ovens and Recovery Plants.

The Piette oven is firmly established by virtue of its successful and economical operation. It is not new by any means. It has been extensively used in Europe for the past thirty years and during

the past decade more than 1,500 ovens have been built in Belgium, Russia, France and Mexico. Some of the installations in France are operated by Schneider & Company, the well known steel manufacturers.

During the year 1920 a demonstration battery of eight Piette ovens was erected at the coke station of the Laclede Gas Light Company, St. Louis, Mo., and is now being successfully operated by the latter company.

After the ovens had been in regular operation for three months, very careful tests and measurements of yield were made for a period of thirty days. Information on the remarkable results obtained will be found on a succeeding page. The public is invited to inspect this demonstration plant.

Fig. 1. View of Piette Ovens at St. Louis From Pusher Side.

Principal Characteristics of Piette Ovens

1. The ovens are of the horizontal type with vertical flues, transverse regenerators and reversing arrangement.

2. The construction is very simple and less shape bricks are required than with other constructions.

3. The ovens are built on an absolutely rigid monolithic block, thus assuring a maximum stability.

4. The method of feeding the heating gas by regulation tuyeres permits a distribution at every point of the oven walls of the exact amount of gas required for perfect coking.

5. The regulation sections for the control of the gaseous currents are calculated before construction and exclude the need of numerous dampers and sliding bricks. The simplicity of regulation for these ovens has been nowhere exceeded.

6. The checkerwork of the regenerators, situated in the longitudinal galleries, are crossed transversely by either the waste gases or air, thus securing the equalization of the temperature in the

whole battery and also permitting the isolation of any one oven in case of stoppage.

7. The arrangement of galleries in the foundations for the incoming air enables the extraction of heat from the waste gases, besides reducing the loss of heat by radiation.

The St. Louis Demonstration Plant

Since the methods of coking, the operation of ovens, the silica used in the brick work and the qualities of American coals are somewhat different from those met with in European practice, it was decided to make a demonstration of the technical processes involved in the construction and operation of the Piette ovens in order to prove their adaptability to American conditions.

The Laclede Gas Light Company kindly consented to the construction of the eight demonstration ovens at their coking plant at St. Louis. Numerous tests conducted have shown conclusively that the Piette type of oven is adapted to American conditions, that they respond to every requirement of manufacture, and that they are able to compete with any other oven.

During the thirty-day test, already referred to, the following mixture of coal was charged: Sixty-five per cent. of Elkhorn coal and thirty-five per

Fig. 2. View of Piette Ovens at St. Louis From Coke Discharge Side.

cent. of Pocahontas coal. The analysis of this mixture was as follows:

Moisture	4.43	Dry Basis
Volatile Matter	30.42	
Fixed Carbon	64.20	
Ash	5.38	

This battery has been making coke since the beginning of 1921. It is not too much to say that its yields in coke, gas and by-products are remarkably good. The efficiency of the ovens and the accurate control of the heat have been in no way impaired, although, due to the fluctuations in the demand for coke, the battery has been operated at times on very short coking hours, and sometimes on long hours. It is general opinion that this kind of oven, due to its yield and ease of operation, is called a great development in the United States.

Results of Tests Made at St. Louis

The following tables summarize the results obtained in the tests conducted for thirty days:

A—OVENS AND COAL:

Number of ovens charged and pushed	282
Average coking time.....	20 hrs. 18 min.
Average load per oven.....	26,770 lbs.
Total quantity coal charged in 30 days	7,549,400 lbs.
Quantity of coal charged in 24 hours per one oven.....	31,455 lbs.
Average temperature of the smoke at the outlet of the heat regenerators corresponding to 3.8 per cent. oxygen or an excess of 25% of air.....	642° F.

B—COKE:

	Pct.	
Total yield in coke (coal mixture included and dry coke).....	69.19	
Proportion of foundry coke in the total coke	38.15	
Proportion of domestic coke in the total coke	61.85	
Average analysis of the total coke obtained:	Pct.	Pct.
Moisture	1.936	
On dry coke—		
Ashes	6.900	
Fixed carbon	92.110	
Volatile matter	0.990	100.00
Specific gravity—		
Apparent	0.973	
Real	1.906	
Shatter test	55.57	
Porosity—		
Coke substance by volume	51.03	
Air spaces by volume...	48.97	
Total quantity of coke produced in 24 hours in one oven.....	21,764 lbs.	

C—HEATING GAS:

Volume of gas burnt during the 30 days in cubic feet at 30 in. pressure and 60 degrees F....	20,332,000
Volume of gas burnt per pound of coal charged.....	2,693
Heating value of this gas (B. t. u. per cu. ft.).....	479.3
Consumption in B. t. u. per pound of coal charged.....	1,290.7

D—GAS PRODUCED AND B. T. U. AVAILABLE:

Total volume gas produced during the 30 days in cu. ft. at 30 in. pressure and 60 degrees F....	44,159,000
Volume of gas produced per pound of coal charged cu. ft.....	5,849
Average calorific value of this gas (B. t. u. per cu. ft.).....	564.5
Total quantity of B. t. u. available per pound of coal charged (non-debenzozized gas)	3,301.7
B. t. u. available per pound of coal treated	2,011.0
Average analysis of the gas produced by volume:	

CO ₂	1.703%
CnHm	3.357%
O	0.453%
H	51.817%
CO	6.063%
CH ₄	29.757%
N	6.850%
	100%

Average specific gravity at 30 in. and 60 degrees F.....	0.3888
--	--------

F—YIELDS IN BY-PRODUCTS PER TON OF COAL CARBONIZED:

Ammonia in pounds.....	5.632
Tar in gallons	7.009
Benzol (product distilling below 200° C.)	3.416

The above figures show that the yield of available B. t. u. per pound of coal treated is 60.9 per cent. of the total quantity of B. t. u. produced. This already very satisfactory proportion does not, however, represent the real power of this system of ovens.

It will, of course, be well understood that a small number of ovens cannot give the same yields as a bigger battery of, say, 50 to 60 ovens of the same type. In the case of a big battery the heat lost by radiation in the end walls is distributed over a larger number of ovens, and, as a matter of course, over a larger quantity of coal distilled.

If this heat loss is distributed over a battery of 50 to 60 ovens, which is the average number in a modern battery, the reduction in heat loss, over the figures here quoted, is 6 per cent. Taking this into account, the calorific balance sheet of the Piette ovens under the operating conditions at St. Louis is:

	Per Cent.
B. t. u. produced....	3301.7
B. t. u. per cu. ft....	564.5
B. t. u. in the available gas	2088.4
B. t. u. consumed in the heating gas..	1213.3
	36.75

Fig. 2. Section Through Oven Chamber.

This consumption is the smallest yet realized in the United States, considering the conditions imposed by the tests.

Features of Construction

The ovens built for demonstration purposes at the Laclede Gas Coke Station in St. Louis are the Regenerative-By-Product Oven.

The general appearance of the battery is pleasing. Simplicity and strength is shown in the complete plant as well as in the details.

The foundation is formed by four galleries, running the length of the battery, with wide division and side walls and heavily arched tops. (See Figs. 3 and 4.) The whole forms a structure having a rigidity equal to that of a mass foundation and forms a huge grill to carry the oven walls which run at right angles to the gallery walls.

The galleries in the foundation are the regenerators. They contain checker brick work designed for the efficient absorption of heat. The two outside galleries run the length of the battery and are called the "Primary Regenerators." The two inside galleries run the length of the battery and beyond where they connect to a gallery leading

to the base of the stack. These inside galleries have somewhat less checker brick work than the outside galleries and are called "Secondary Regenerators."

The Primary and Secondary Regenerators on the same side of the longitudinal center line of the batteries are connected through channels (M) in the base of their dividing walls. The sectional area of these channel openings vary, being so designed that each passes an equal quantity of air, even though they are located at different distances from the stack.

The oven proper, or distilling chamber, is 9' 10" high, 37' long between doors and has an average width of 19 $\frac{3}{4}$ '. The oven walls diverge slightly from the pusher toward the discharge side, to facilitate pushing of the coke. Great care has been taken in the design throughout that the oven may give long service and remain leak-proof.

Directly under the distilling chambers are the sole-flues (S). These sole-flues are provided two for each oven, each half of the same oven having its own sole-flue. Each sole-flue (S) connects directly to the primary regenerator on its side of the battery, through a slit in the arch top of the regenerator gallery. (See Fig. 5.)

Fig. 4. Section Through Heating Flues.

Fig. 5. Longitudinal Section Through
Primary Regenerator Secondary Regenerator

The sole-flues connect to the vertical oven wall flue system on the right of the distilling chamber under which they are located, but it will be well to first describe the construction of the oven walls.

The oven walls seat firmly on the foundation, which has already been described. The lower part of the wall, corresponding to the space occupied by the sole-flues beneath the distilling chamber, is termed the sub-wall; the rest of the wall above the sub-wall is the wall proper. The design gives a very rigid wall compared to other types of ovens, as the only unsupported height of wall is just equal to the height of the distilling chamber.

In the wall proper are the vertical flues. The gas is brought to these flues through a system of four small conduit openings (A), built in the brick work of the sub-wall. (See Fig. 4.) Each conduit carries gas to its allotment of either three or four vertical flues, into which the gas passes through carefully calibrated nozzles in the base of each. In the vertical flues, just above the gas nozzles and very close to them, are the openings from the sole-flues.

The top of all the vertical flues open into a header (T) built in the wall. (See Fig. 4.) These headers form the only means of passage for the gases from one system of regenerators and flues on one side of the battery to the second system on the other side. This will be made clear in the discussion of the method of operation which follows.

From without, the battery is supplied with gas and air. Lean gas from the recovery plant is carried by large mains (K) to both sides of the battery. These mains in turn supply gas to four burners, with individual control valves, to the four gas conduits (A) in the sub-wall of each oven, which in turn carry it to the vertical heating flues, as already explained.

A feature of the design is the method employed to utilize the intake air, before it reaches the regenerator, for absorbing heat that otherwise would have been lost through radiation; as in the case of the air channels (H), which pass beneath the regenerators. The intake air is further used to give an insulating effect between sole-flues and secondary regenerators; as in the case of intake canals (G), which run over top of the secondary regenerators and below the sole-flues.

All the air canals (G) and (H) conduct air to a common gallery near the stack end of the battery, from which it is delivered through a fan and reversing mechanism first to one regenerator and then to the other.

Method of Operation

As stated in the description of the ovens, there are vertical flues, regenerators and a reversing arrangement. It is also shown that the regenerators are constructed in longitudinal galleries. However, they operate transversely. This may be clearly shown by following through one cycle of the heating operation.

Consider the reversing damper in position shown in Fig. 6. The air is drawn in through the intake canals, (G) and (H), to the fan. It is then deflected by the damper into the extension of the gallery of the secondary regenerator on the left side of the battery. The air passes back in this gallery and over the top of the hot checker brick work. (In the open part of the secondary regenerator gallery is the only place we find air or burnt gases moving longitudinally.) Now the air passes down through the checker work of the secondary regenerator, transversely to the left through the channels (M) in the base of the dividing wall and up through the checker work of the primary re-

Fig. 6. Plan of Regenerators.

generator. The air, which is now heated to a very high temperature, passes directly up through the slits in the top arch of the primary gallery into the sole-flues (S) under the left half of the ovens. There the air divides and passes up into the vertical heating flues in portions as determined by the sectional area of the opening into each individual flue. At the same time gas is being fed to these flues through a nozzle in the base of each. The burning mixture passes up through the vertical flue into the header (T), moves transversely to the right in the header and passes down through the vertical flues in the right half of the oven wall, down into the corresponding right hand sole-flues and on down through the arch and checker brick work of the primary regenerator, moving transversely to the left through the channels (M) in the base of the dividing wall and up through the checker brick work of the secondary regenerator. Now having given up most of its heat, the spent gases pass longitudinally out through the open spaces of the secondary regenerator galleries and up the stack.

When the heating is reversed, the path followed by the air and gases is unchanged, merely the direction of flow is reversed, the air coming in through the right hand regenerator system, sole-flues and vertical flues and down through the left hand system and out of the stack.

The same mechanism which operates the deflecting damper also opens and stops the supply of gas to the burners on either side of the battery.

Advantages of the Piette Oven System

This system has many advantages derived from the design of oven as well as from the method of operation.

Some of the principal ones are:

(1) This oven uses in its construction fewer special brick than any other type of its class. This means a great saving in first cost and upkeep.

(2) The design combines the advantage in construction, of the longitudinal type of the regenerator, with the operating efficiency of the transverse type of regenerator. Both of these advantages are most generally admitted, due to the strength and freedom from expansion stresses in the construction of the longitudinal type, as well as the lower water gauge required to operate the transverse type, which makes for less leakage as the oven becomes older.

(3) Due to the carefully calculated sections of the openings into the sole-flues as well as at the bottom and top of the vertical flues, dampers are

practically eliminated. Dampers warp and stick in usage, and allow tampering by unauthorized persons.

(4) The chance of the short circuiting of the burning gases in the heating flues is avoided, as the gases are carried up in all the flues in one half of the oven wall and returned down the flues far removed in the other half. Another advantage of this same operation is that the gases more completely give up their heat to the oven wall.

(5) The recovery of heat in the intake canals is considerable, as is shown by the fact that the air in passing through the canals alone is raised to a temperature of from 200° to 280° F. This saving is clearly shown in the tests of these ovens.

(6) The ovens are easily operated and watched. Many loopholes are provided and conveniently placed to permit of inspection all along the route of flame and gases. Loopholes on each vertical flue (see Fig. 5) allows the corresponding nozzle to be inspected through an opening starting at the top of the oven. Loopholes are also provided for each half sole-flue and for each primary regenerator gallery.

(7) There is remarkable stability to the construction. The regenerators are longitudinal to the axis of the battery and therefore perpendicular to the axis of the oven walls and arches of the oven. It is this intersection of the walls of the oven which give to the mass of the battery its maximum stability.

(8) The expansion of the linings and of the arches of the regenerators, as well as of the flues connecting the primary regenerators with the sole-flue, is rendered completely independent of the general sustaining mass of the battery. The result is that the refractory material which constitutes the sole-oven walls and the ovens are built on an absolutely monolithic block which cannot be deformed. This is a worth-while advantage with the high-expansion silica brick used so freely in the United States.

Complete Plants Constructed

The Belgian-American Coke Ovens Corporation is prepared to contract for the building of Piette By-Product Recovery Coke Ovens, with or without recovery of heat, also for plants for the condensation and distillation of tar, production of sulphate of ammonia or concentrated liquor, recovery of benzol and carbolic acid, manufacturing of pure products, volatile alkali, benzene, toluene, xylene, naphthalene, phenol.

USAGES OF BY-PRODUCT COKE

The by-product coke industry has grown rapidly in the United States during the past five years. Much of this may rightly be attributed to contingencies created by the World's War, but it is recognized by all students of conservation methods that the wasteful methods of coking in bee-hive ovens were bound to cease, and that the by-product system was destined to supplant these because of its economies.

By-product coke is suitable for all purposes where a bee-hive coke has been successfully employed, such as for blast furnaces, foundries, smelting, power plants, domestic use, paint and varnish plants, chemical works, construction work, street car heating, bakeries, lime burning, etc.

By-Product Coke for Blast Furnaces

Not many years ago the coke made by the wasteful bee-hive oven was preferred by the average blast furnace man. Now it is generally recognized in American practice that by-product coke gives better results. This has been due, not merely to a change of attitude on the part of the blast furnace man, but also to the marked improvements in the quality of the by-product coke. It is now found to be more uniform in size and harder than bee-hive coke, with a smaller percentage of cell spaces, and therefore about 10 per cent. heavier, bulk for bulk.

Another point worthy of note in favor of the by-product system is that it is possible, as a result of research and experimenting, to increase its quality and thus, in turn, make it possible to attain still further improvement in blast furnace practice. Mixing of coals, variable coking temperatures, design of oven, size of coal charged and the coking time are all subject to change and offer attractive fields for investigation.

New and untried coals may be tested in the by-product oven with a view to making the best possible coke. If they respond favorably to laboratory tests, such coals should be given careful study to determine the conditions best adapted for usage. The results of such investigations are of the utmost importance to the owner and producer of coal, and to the public at large from the standpoint of fuel economy and conservation.

By-Product Coke for Foundry and Smelting Uses

By-product coke is in successful use for copper, lead and nickel smelting and for general foundry purposes, particularly brass and aluminum.

By-Product Coke for Steam Plants

By-product coke for steam generation is not common in American practice, although such plants are in operation and are giving highly satisfactory results. As illustrating the tendency in England,

where fuel conservation is now receiving a great amount of attention, we quote from an article written by E. W. Nicol for the "Colliery Guardian," issue of October 7, 1921:

"During the recent three months coal stoppage, this accumulated experience in firing steam boilers with coke was of very considerable service in maintaining essential public services and industries, and the extent to which coke was used in this connection is probably not fully realized. One of the largest sugar refineries, unable to obtain coke of the size necessary for use with mechanical stokers, accepted supplies of ordinary coke and graded it to the required size by passing it through the sugar crushers; and many express railway locomotives were, to a large extent, fired with coke, thus briefly reverting to the fuel for the use of which the locomotive boiler was originally intended.

"The introduction of coke in the lieu of coal, and of modern coke burning appliances, by the London Coke Committee, has raised many hand-fired steam plants to a relatively high degree of thermal efficiency, and their attendants to a position of comparative comfort and freedom from the unwelcome and often unpractical attention of the smoke inspector. Some 500 sets of this apparatus, each capable of consuming 500 tons of coke per annum, have been made and fixed to hand-fired boiler furnaces, with a view to enable steam users to eliminate entirely the use of crude coal. In the case of a London hospital recently dealt with, the saving effected by using coke in place of coal is at the rate of over \$2,000 per annum.

"The chief difficulty in introducing coke as fuel for steam raising has been in adapting boiler furnaces and automatic stoking appliances primarily designed for use with coal. By supplementing the usually adequate chimney draught with mechanical draught, many of these boilers have readily been adapted to use coke efficiently. A recent invention which facilitates the cleaning of hand-fired furnaces, and prevents loss of fuel and steam pressure during this operation, should tend materially to improve the average efficiency obtained and incidentally to facilitate the use of coke for boiler firing. A very serious disadvantage of the mechanical stoker which did not transpire in the discussion before the Mechanical Engineers, is its inherent limitation to bituminous coal. Steam users whose boilers are so equipped are unable to take full advantage of relatively cheap coke or breeze, however plentiful or cheap, or to realize the bargaining advantage of an alternate fuel.

"Electric power stations almost invariably are equipped with water tube boilers and chain grate stokers. This type of stoker is, like most others, designed on a bituminous coal basis, and is, ordinarily, quite unsuitable for use with coke, or even any considerable admixture of coke with coal. It therefore formed a very serious obstacle to opening up business relations between gas and electric supply undertakings for the supply of coke as fuel. Early in 1913 the author was, however, able to institute experiments at an important power station in Yorkshire, with a view to adapting the chain grate mechanical stoker to use coke and coal slack. Admixtures of coke up to 75 per cent. were used quite satisfactorily with very inferior coal slack. Now known as the "sandwich system," this invention has since been adopted as a permanent institution at some of the largest power stations. It has been the

means of opening up important business relations with public utility undertakings, public authorities, and large power users. Three or four of these undertakings in London, whose boilers are only partially equipped with the "sandwich system," are already consuming over 100,000 tons of coke per annum.

"The introduction of coke as fuel for electric power stations by the London Coke Committee promises to have a far-reaching effect upon the future development of the electric supply industry, and also upon the better utilization and the conservation of the country's coal resources. The invention of the "sandwich system" of firing coke has enabled existing coal burning mechanical stokers in many important electric power stations in London and the provinces to use up to 75 per cent. of coke in conjunction with relatively inferior coal slack. One London power station now uses over 40,000 tons of coke per annum. In this case alone, the gain to the country in by-products recovered from an equivalent quantity of coal is represented by some 800,000 gals. of tar, from which pitch, dyes, drugs, fuel oils, motor spirit, and high explosives are produced; and, in addition, over 800 tons of sulphate of ammonia, which is used by farmers as a fertilizer for the land."

are first broken up and then run over screens that prepare it in convenient forms for domestic use. In the case of by-product coke, it is pushed from the oven mechanically and, after being quenched, is run over screens, the larger pieces being shipped for furnace and foundry uses, and the balance being screened into egg, stove and nut sizes.

A comparative analysis from U. S. government reports on the two fuels is given below:

	Anthracite	By-Product Coke
Moisture	3.30	1.96
Volatile Matter.....	3.80	0.99
Fixed Carbon.....	81.50	90.15
Ash	11.40	6.90
B. t. u.	13,000	13,679
Specific gravity.....	1.66	1.90
Efficiency in burning.	66.30	75.43

As will be noted from the above comparison, anthracite coal has a large percentage of inert

Truckload of Domestic Coke.

By-Product Coke for Domestic Use

Many discussions on the subject of the use of coke as a domestic fuel have appeared of late, and it is quite evident that its use as a substitute for both anthracite and bituminous coal is a matter of growing interest.

In most discussions coke is compared with anthracite coal, which it closely resembles in several respects. Anthracite coal, in the early stages of its formation, had a high volatile content which later was lost by the enormous pressure developed by the folding of the strata. At the same time the coal lost its cellular structure. By-product coke likewise is low in volatile matter, but unlike anthracite coal, the cells are retained.

Anthracite coal comes from the mines in a mixture of large and small pieces. The large pieces

material in the form of ash. The percentage given is, if anything, much lower than what the average anthracite contains today, whereas the percentage of ash in by-product coke, owing to the bountiful supply of low-ash coals, need not go beyond the percentage quoted for many years to come. A practical demonstration on the amount of ash in the burning of 200 pounds of each fuel, made in St. Louis, shows the following results:

	—Ash in 200 Pounds Burned—	
	Pounds	Per Cent. Loss
Anthracite	29½	14¾
Coke	11½	5¾

Taking into consideration the higher cost of anthracite coal, the money loss due to ash was 3¾ times as large as the loss with coke.

In a Bulletin issued by the University of Illinois Experiment Station, the results of tests of different house heating fuels are given and show that by-product coke has an actual heating value $11\frac{1}{2}$ per cent. higher than anthracite.

In comparison with bituminous coal the percentage is much greater. Technical paper No. 242 issued by the Bureau of Mines states that $7\frac{3}{4}$ tons of coke will deliver as much heat as 10 tons of the best soft coal, besides having the great advantage of being clean.

By-product coke in tests made at the Sheffield Scientific School of Yale University, along with both hard and soft coal, showed the highest results for coke, with the highest efficiency ever reported.

Methods of Burning

The furnace size of coke is usually specified for hot air, hot water and steam furnaces; egg and stove sizes for base burners and air-tight heaters; pea and nut sizes for self-feeding furnaces and water heaters.

Successful coke burning depends on proper draft regulation. As all furnaces and flues do not work alike, each user should experiment with his dampers to get the best results. In all cases, however there should be a damper inside of the smoke pipe; when the draft is shut off this damper should be nearly closed and when the draft is turned on it should be opened only part way. As an aid to combustion, some air must be admitted over the top of the fire at all times through the damper in the fire door. Coke being lighter than coal, a correspondingly larger body of fuel should be carried in the furnace.

A coke fire is easy to start. The drafts should not be opened too far and as soon as the fire is well started they should be closed and a uniform, steady heat thus maintained. Instead of shaking the grate bars, run the poker through the fire from the fire door so as to loosen it and let the air through. Coke is no harder on the furnace than any other fuel.

We quote from Technical Paper No. 242, Bureau of Mines:

"When burning coke a furnace requires much less attention than when burning soft coal. The time usually given to poking fires, cleaning the furnace flues and the house, can be spent much more profitably in other ways. The cleanliness of coke will appeal especially to the housewife.

"Coke offers the best means of making our large cities smokeless. Where soft coal is burned for domestic heating about 60% of all the smoke in the atmosphere is made in the residential section, in house heating furnaces. Substituting coke for soft coal will eliminate this 60% of smoke.

"Coke does not make any soot, consequently the cleaning of boilers, smoke pipes and flues is eliminated. Soot is poor conductor of heat; when it is deposited on the heating surfaces of the boiler or furnace, much less heat is

utilized in heating the house, and a large part of the heat passes up the chimney. All formation of soot means a direct loss, because it represents that much unburned coal.

"Soft coal can never be burned in house-heating furnaces with such completeness of combustion as coke. The coal is first reduced to coke by driving off the volatile matter, most of which escapes unburned; then the coke burns in the furnace and heats the house.

"The results obtained thus far show that coke can be burned in house-heating furnaces much more efficiently than soft coal."

Disposal of Coke and By-Products

Our attention has been called to the fact that in a large number of cases where gas producing companies have had under consideration the question of installing by-product coke ovens for their supply of gas, the controlling objections have been:

First. That it was not possible to market the coke produced by the ovens.

Second. That the other principal by-products, namely, tar and ammonia, would soon fall to such a low price by stimulation of production that they could not be considered as stable producers of revenue.

The first objection, as to marketing the coke, may be due partly to the fact that their experience has been confined to the sale of ordinary gas house or retort coke, an entirely different fuel from the coke produced by by-product ovens, and their conclusions may have been reached by not having the territory available for shipment of high grade metallurgical and domestic coke, such as is produced by by-product ovens, thoroughly canvassed by men experienced in marketing this grade of coke.

The results obtained and the methods used in reaching results in Boston, St. Paul, Milwaukee, Chicago, St. Louis, Indianapolis and Terre Haute, and various other cities, would aid largely in removing the wrong impression as to the marketability of this grade of coke.

The second question is raised as to the future of the market for ammonia and tar. Ammonia, being the base of one of our most valuable fertilizers, has become a standard commodity having a world-wide market. Tar can be considered in the same way. While like any other standard commodity, prices may vary with general conditions, the growth of the use of both commodities would naturally increase in the same proportion as the use of coal and steel, and further, it is possible to make contracts for the sale of these commodities before the erection of the plant on a basis that would insure fairly stable conditions of income.

The organization of the Belgian-American Coke Ovens Corporation will be very glad to aid you in the matter of investigations of the possibilities of marketing coke in your territory, as well as the other by-products.

THE GAULEY MOUNTAIN COAL CO.

General Office
ANSTED, WEST VIRGINIA

Sales Office

523-524 American National Bank Building, Richmond, Virginia. E. Vawter, Sales Mgr.

Manufacturers and Shippers of Gauley Mountain Foundry Coke

Ovens Located on the Chesapeake & Ohio Railroad at Ansted, Fayette County, West Virginia.

For use in Foundries, for the manufacture of Water Gas, for Pot Linings and special metallurgical uses requiring a low sulphur, low ash, non-clinkering fuel.

For over a quarter of a century Gauley Mountain Foundry Coke has been used by discriminating foundrymen.

This coke is manufactured in Bee-Hive ovens from finely crushed coal, and is burned 72 and 96 hours. The ovens are hand drawn and the coke carefully forked in loading. It is of hard, dense structure, silver gray in color, carries a high shatter test, and is capable of supporting a heavy burden.

What the Government Says About Coke

From Technical Paper No. 242, Dept. of Interior

"When burning coke a furnace requires much less attention than when burning soft coal. The time usually given to poking fires, cleaning the furnace flues and the house, can be spent much more profitably in some other way. The cleanliness of coke will appeal especially to the housewife.

"Coke offers the best means of making our large cities smokeless. Where soft coal is burned for domestic heating, about 60% of all the smoke in the atmosphere is made in the residential section, in house-heating furnaces. Substituting coke for soft coal will eliminate this 60% of smoke.

"Coke does not make any soot, consequently the cleaning of boilers, smoke pipes and flues is eliminated. Soot is a poor conductor of heat; when it is deposited on the heating surfaces of the boiler or furnace, much less heat is utilized in heating the house, and a large part of the heat passes up the chimney. All formation of soot means a direct loss, because it represents that much unburned coal.

"Soft coal can never be burned in house-heating furnaces with such completeness of combustion as coke. The coal is first reduced to coke by driving off the volatile matter, most of which escapes unburned; then the coke burns in the furnace and heats the house.

"The results obtained thus far show that coke can be burned in house-heating furnaces much more efficiently than soft coal."

Upon request, our nearest office will send a booklet giving further extracts from this paper. These booklets are furnished free to dealers who purchase their coke from us, for distribution to their customers.

The consumer is the judge. Dealers who handle a dependable brand of by-product coke find that THEY COME BACK FOR MORE.

COKE

Many people consider coke simply as something to burn. They do not discriminate. The truth is that there are good and bad cokes. Furthermore, a coke pronounced the "best ever" by one user may be condemned by another in the same line of business. The reasons are many. Cokes, like people, have their individual characteristics.

We offer 29 Brands (Beehive and By-Product) representing practically every producing center, for the following purposes:

Foundry
Domestic Heating
Smelting and Refining
Sugar Refinery
Blast Furnace
Gas Producers
Bakery
Paint and Varnish Plants
Steam Plant (under proper condition)

You know your requirements.

Our salesmen know the characteristics of our brands.

At least one of the 29 brands will exactly meet your needs.

PART I.—THE EXPORT OF COAL

Gradual Development of English and American Export Trade; Review of Exports During 1920 and 1921; Future of American Coal Trade in South America, Europe and Other Countries; England Our Chief Competitor; American Export Coals, Their Origin, Pools and Analyses.

F. R. WADLEIGH*

Historical

The beginnings of the coal export trade, as far as we have record, date back to 1325, when a ship from Pontoise, France, brought a cargo of corn to Newcastle-on-Tyne and returned with a cargo of "charboun de meer," or sea coal. In 1362 the foreign export of coal was prohibited, an exception having been made in 1367 in favor of Calais, which at that time was the only continental port to which British commodities were allowed to be shipped.

In the sixteenth century exportation of coal had attained such importance that the question of its prohibition came up before Parliament as a measure to injure the French manufacturers.

During the reign of Edward III. and Queen Elizabeth a tax on all coal exports was imposed by the Crown, which continued in effect to 1578.

The growing importance of the export coal trade in the seventeenth century was shown by a writer of about 1615: "Besides our own ships (400 in number) thither even to the mines' mouth, come all our neighboring nations with their ships continually. The French sail thither in whole fleets of fifty sail together."

At Liverpool the first record of coal exports shows in 1617, 1,879½ "chaldrons" of coal having been shipped abroad in that year (a chaldron was originally about 2,000 pounds or three one-horse cartloads).

The first record of exports from South Wales seem to be in 1617, when 1,992½ chaldrons were shipped from Swansea and Milford. In 1799, 3,000 vessels were loaded at Swansea, the total amount exported having been 33,228 tons.

At Cardiff as late as 1540 coal was not even used; in 1698 we find records of coal having been brought from Sir Humphrey Mackworth's mines at Neath to the Waterside at Cardiff.

In 1828 records of exports from South Wales ports were:

	Tons
Cardiff	32,109
Newport	422,878
Swansea	339,411
Slavelly	92,144
Milford	18,354
Total	904,896

The steady growth of British coal exports is shown by the following table:

	Tons
1821	260,314
1831	508,697
1841	1,848,294
1851	3,468,545
1861	7,855,115
1871	12,549,874
1881	19,174,753
1891	30,356,328
1901	42,684,752
1911	64,599,266
1913	73,400,118
1918	31,752,904
1920	24,931,853

This table does not include coke or briquettes.

Among the Continental European countries there were doubtless small and unimportant interchanges of coal going on as far back as the eighteenth century, but overseas exports had their beginning in Great Britain, which for several centuries had a monopoly of the trade.

United States

While exports of coal to Canada had been going on for many years, overseas coal export trade from the United States practically started in 1897, although occasional cargoes had been shipped to foreign countries at various times previous to that date. In the year 1897, however, the first real and systematic effort started, looking to the permanent establishment of an overseas market for our coals.

To the firm of Castner & Curran must be given, we think, the credit for this effort and for making known in foreign countries the good qualities of the coal (Pocahontas) which they handled exclusively at that time; for a long time Pocahontas was the only American coal about which anything was known abroad.

In that year and in 1898 several cargoes of Pocahontas coal were shipped to the East coast of South America, two sales managers were sent from this country and a resident agent appointed at Rio de Janeiro. Tests were made on several railroads and at industrial plants, from which gratifying results were obtained, in the face of great difficulties, it being found necessary to send an engineer from this country to look after the tests. This promising attempt to obtain a footing for our coals failed and was a loss financially owing to mistakes and misunderstandings.

*Since writing this article, Mr. Wadleigh has been appointed Chief of Coal Section, Fuel Division, Department of Commerce, Washington, D. C., and Commercial Engineer-Fuels, U. S. Bureau of Mines, Washington, D. C.

Previous to this time a considerable tonnage of United States coals had been shipped to the West Indies, principally for use as steamship fuel at coaling stations, and in 1898 a cargo of Pocahontas coal was shipped to Jamaica, for test by the State Railways, which resulted in the continued use of our coal by the Railways. In 1902 the British miners' strike gave us a monopoly of the West Indies markets and we have held it ever since, a not inconsiderable factor in our overseas coal trade. In 1911 it amounted to 1,812,000 gross tons, which had increased in 1920 to 2,168,000 gross tons.

To the West Coast of South America our coal exports practically began in 1902, when at least three cargoes were shipped to Chile, two to Valparaiso for the State Railways, and one to Antofagasta to the Peruvian Corporation. Of the two cargoes to Valparaiso, one was Pocahontas and the other a high volatile coal from Northern West Virginia. Tests of these coals were made on locomotives against Australia and native coals, but results were not satisfactory for various reasons and costs were not comparable, the United States coals being more expensive, so that no further business was developed at that time. The cargo of Pocahontas coal shipped to Antofagasta gave good results both on locomotives and at the nitrate works; some of it was carried on mule or llama back to the Huanchaca silver mines, then 40 miles from the railway.

About this time (1902-3) efforts were made to secure some business from the Italian State Railways, and one or two trial cargoes were shipped, but no success followed, as the coal was too friable and could not be used successfully on the Italian locomotives owing to their grates and smokebox arrangements not being suitable.

Another attempt on the French market was also made by supplying Pocahontas coal for use on the small canal tugs used in that country. Tests in this use were successful, but the difference in delivered prices as compared with British coals was too great to be overcome.

In 1906 the Italian Navy sent two of its colliers, the S. S. Sterope and the S. S. Bronte, to Hampton Roads for trial cargoes and bunkers of Pocahontas and New River coals. The coals obtained gave excellent results and it is probable that this was the beginning of the use of these coals by the Italian State-owned passenger lines, a use which has continued to this day.

To European countries a few occasional cargoes had been shipped previous to 1905, especially during the 1902 British miners' strike, but no systematic export efforts resulted, although what was done proved sufficient to make British shippers take notice. In 1909 and 1910 more serious efforts were made to enter the overseas export trade; several of the larger coal companies sent men abroad, with the result that in 1911 (fiscal year) our exports to Europe, South America and the West Indies amounted to 670,800 gross tons, and in 1912 (partly owing to the British miners' strike) they had increased to 929,412 tons.

Spasmodic and generally unsuccessful attempts were made to get West Coast business up to the breaking out of the War, since which time we have gradually increased our exports to Chile the only market of any consequence on the West Coast.

Previous to 1902, United States coals, mainly Pocahontas, had been shipped to Colon for use by the Panama Railroad, then a privately owned concern, for use on their locomotives and for supplying bunker coal, both at Panama and Colon. In that year the cargo and passenger ships of the two Pacific Coast lines began to use Pocahontas coal, supplied to them at Panama.

In 1911 the only concerted intelligent systematic effort to obtain a permanent export market for our coals failed, through jealousy, prejudice and ignorance.

Ever since it has been a go-as-you-please race between individual companies, many of them knowing little or nothing about either coal or shipping, but still successful as regards increased tonnage, largely owing to conditions; culminating in the maximum overseas export of 22,296,000 net tons in 1920. (See Table 1.)

TABLE 1. BITUMINOUS EXPORTS FOR THIRTY YEARS

The following table, recently issued by the Geological Survey, shows exports of bituminous coal for the past 30 years, and showing Canada separately. These figures are for net tons:

Year	To Canada	To All Other Countries	Total
Fiscal years—			
1890	613,874	658,522	1,272,396
1891	796,134	855,560	1,651,694
1892	939,772	973,784	1,904,556
1893	1,113,945	872,437	1,986,382
1894	1,615,367	824,352	2,439,719
1895	1,882,148	777,839	2,659,987
1896	1,875,786	640,052	2,515,838
1897	1,947,655	722,502	2,670,157
1898	2,103,958	900,346	3,004,304
1899	2,345,927	1,552,067	3,897,994
1900	4,110,491	1,950,198	6,060,689
1901	3,688,759	2,766,326	6,455,085

*As records for 1920 are not yet complete, many of the figures shown for the year are estimates.

†Fiscal year ended June 30.

‡Production plus imports minus exports, taking into consideration changes in stocks where available.

§In comparing values at mine and of the coal exported, it is essential to remember that the mine value is an average of all coal produced, including mine fuel (often coal otherwise wasted), local sales, and coal coked at the mine, and does not include selling expenses. The export value is the declared value at the port, and supposedly includes selling expenses and transportation charges from mine to port. The two figures are not comparable.

§Geological Survey statistics not yet complete.

Exports Prior to the War

As showing our position, prospects and possibilities at the beginning of the War, the following editorial (by the writer) which appeared in "Coal Age," October 10, 1914, will be of interest and much that is said will apply to today's conditions:

The Export Coal Trade

"Let us say first that any coal company or selling agency, with coal of the necessary quality, that is prepared to give extended credit can get foreign business, but it is doubtful if it will always get its money.

"There is now plenty of good coal available and there are ships to be had, at a price, but the financial end of the business is far from satisfactory. At present our exporters or those who would be exporters, know but little about ocean freights and charters, port charges, unloading conditions, etc., and will only sell coal f. o. b. tidewater, requiring cash against documents before they will allow their coal to be actually shipped. They know that the financial situation, in the countries needing our coal, is generally bad and will take no risks.

"Exporters must realize that the essence of the export coal business is transportation, and that before they can get any large share of the world's foreign coal trade they must learn the devious ways of ocean transportation and provide the required facilities.

"Our competition in the export coal trade, in the past, has been due to opportunities that have come about through outside causes. The British coal strike in 1902 gave us the West Indies markets, which we have never lost, not because we had better coal, but because, in addition to cheaper mining costs, we found iron ore and sugar for return cargoes.

"The British strike of 1912 did us little good, because we failed to take advantage of the oppor-

tunity offered us to increase our exports, getting only such additional business as was offered, but which we failed to retain when British shipping returned to normal conditions.

"Even now, with the chance given by the war, there has been no organized, systematic effort to increase our coal exports; it is all spasmodic, each company for itself after its own plans, usually based on insufficient knowledge of conditions, either of transportation or of finances and credits.

"To capture and retain the foreign coal markets, we must follow the example of Great Britain's exporting companies and understand the basis on which they have worked.

"They have coal of first-grade quality; we also have coals equally as good in heating value.

"They mine and prepare their coal to suit the wishes and needs of the consumer; we prepare our coal as we think best or do not prepare it at all.

"They have the necessary loading facilities that will handle coal with the least possible breakage; we load our coal into ships much more quickly, but with little attention to breakage.

"They build and own their own colliers; we are entirely dependent on other nations for ocean transportation.

"They have established or control their own agencies; we have now but local agents, who often handle British coals and over whom we have no control.

"They build or obtain dock and storage facilities and coaling stations; we have nothing of the kind at foreign ports.

"They have created and maintained banking and financial agencies in foreign countries; we are entirely dependent on foreign banks.

"They meet the consumers' or buyers' views as to sales conditions and credits; we generally refuse to do so and insist on our own conditions, or no sales.

"To sum up, the export coal trade is a business in itself and to succeed in it, it must be studied and learned like any other business; every factor in it (and there are many) must be allowed for and made a part of the whole, otherwise we shall never succeed in obtaining and holding our share of it."

1920 the Banner Export Year

The trend of exports throughout the various Atlantic seaboard ports, while somewhat irregular during the year 1920, was such as to prove very gratifying. During December, 1919, exports had fallen to the low figure of less than 200,000 tons, but from this point there was an increase in each month's shipments, excepting only February and July, until by the month of October a tonnage in excess of 2,400,000 was reached. Succeeding months saw a constant decline up to April, 1921.

The reason for the great increase of our overseas export trade during 1920 lies chiefly in the heavy cut in production in the war-torn countries, due to the physical destruction of the mines, as in France; the drain upon man power, as in Germany; the economic and social disorganization, as in England. The output in France in 1920 (exclusive of the Saar and Alsace-Lorraine regions) was forty-six per cent. less than in 1913, the last year before

the war. Using the same basis for comparison, the decline in Great Britain was twenty per cent.; in Germany (also exclusive of the Saar and Alsace-Lorraine regions) the output of bituminous coal decreased twenty-four per cent. In Central and Western Europe the breakdown was even greater than in Western Europe and the decline in output was proportionately larger.

While practically all non-belligerent countries from Spitzbergen to China helped to fill the void, the largest factor was, of course, the United States. Fortunately the coal production of our country had increased from 38.5 per cent. of the total for the world in 1913 to 45.1 per cent. in 1920, which increase is reflected in our overseas exports amounting to 22,500,000 tons, a quantity five times larger in 1920 than in 1913.

The detailed compilation of exports of bituminous coal from the United States for the calendar year 1920, with comparisons for the year 1919, are shown in the tabular statement. This shows a total of 34,179,559 gross tons of bituminous coal exported as compared with 17,975,090 tons exported in 1919.

Detailed exports by countries for the two years show as follows:

1921 to Date (September)

The curve of coal exports for the first eight months of the year 1921 is irregular and the indications are that the total tonnage shipped overseas for the calendar year will not exceed 10,000,000 tons, or less than half that of the preceding year.

Beginning with April, exports began to increase, due to the British miners' strike, reaching a maximum in June of 1,600,000 tons, most of the increase going to Great Britain. Because of the long duration of shut-down of the British mines—over three months—it was the belief of many that American coals would be plentifully used in the affected countries by manufacturing, railroad and public utility companies, and that our coals would be needed on the Continent because of the stoppage of the Welsh and English supply. While undoubtedly American coals were drawn upon in the emergency, nevertheless great quantities were not required owing to the stagnation in trade and the large supplies of coal on hand previous to the strike. The same paucity of demand existed in France, it having developed that, owing to trade depression, the usual sources of supply were ample for all needs. Additional factors which influenced the lack of orders from foreign countries were financial conditions and the large stocks available as a result of indiscriminate purchases in the previous months.

Future of Our Export Coal Trade

What will be the future of our coal export trade? What must we do to increase it? Do we want an export trade? Where are permanent foreign markets for our coal likely to be found?

First. Should we have an export trade?

The general consensus of opinion is undoubtedly in the affirmative, provided it can be made remunerative and of sufficient volume to be attractive. But there is more to it than the financial side. We are today in many respects the leading nation in the world, and we mean to remain so, but, in order to make our position more commanding we must give up the old idea, still strongly held by some, of being a world to ourselves and of not interfering with or increasing our commercial, political or economic relationship with other countries. Either we must mingle with the world's affairs and take a leading part in them or we must be content to withdraw from them as far as possible.

To many of us, the latter position is unthinkable, a reversion and unmoral; those who take that position must, and no doubt will be, made to see their lack of understanding and perspective.

We do want and need an export coal trade, all that we can get and keep, both to help our position in the world's affairs, to help our general trade and to assist in making our ships and shipping what they should be, besides, perhaps first, improving our relationships with our neighbors and assisting them also to greater development economically; all of which will help us as well as them, from a material standpoint.

Second. What must we do to increase our export trade?

"The export coal trade is a business in itself, and to succeed in it, it must be studied and learned

like any other business; every factor in it (and there are many) must be allowed for and made a part of the whole."

"The essence of the coal export trade is transportation; we must mine and prepare our coals to suit the uses of the consumer."

At home we must have:

1. Coals of the requisite quality; give them the best preparation.
2. We must have railroad freight rates that will enable us to compete.
3. We must have sufficient coal docks or piers and handling facilities.
4. We must have ships of our own and be able to operate them efficiently and at a reasonable cost.

Abroad we must have:

1. Our own local agents.
2. Our own docks and storage facilities.
3. Financial connections.
4. Credit facilities and agencies.
5. The kind and quality of coal the users want, not what we want them to use.
6. Facilities for giving instructions and advice regarding our coals and their use.
7. The investment of United States capital in foreign enterprises and securities and the establishment of branch banks.

Concerted group, not individual, organizations should be established, either—

(1) A national export coal exchange or body, similar to those in other trades, with real classification or grading and inspection at the mines (not at tidewater), or

(2) A group organization of the larger companies, with suitable coals from each field, owning its own ships, foreign sales agencies and docks.

Where are our permanent markets likely to be found?

South America

While the coal imports and consumption of South American countries has often been overestimated (the total imports in 1913 were 8,946,800 tons), great industrial and transportation developments are certain to come in the future. In this direction would appear to be our best chances for a permanent export market.

The introduction of American coals in quantity to the countries on the east coast, such as Argentina, Uruguay and Brazil, may be said to date from March, 1912, when, due to a miners' strike in Britain, exporters were obliged to turn to American coals. While this did not result in permanent business, it served to introduce our fuels and enable comparisons with the Welsh coals. The effect of the Great War on our coal exports to the aforementioned countries is strikingly shown by a comparison of British and American imports which in 1913 bore a ratio of fifteen to one, while in 1920 the ratio had so changed as to stand more than five to one in our favor.

Exports for the first six months of 1921 show favorably for American coals, but since the settlement of the miners' strike British interests have exerted every influence to regain and hold their former supremacy, and in this they are greatly helped by their large investments in all kinds of enterprises in these countries, particularly in the

railroads, which in Argentine, for example, furnish 75 per cent. of the total demand for coal in that country. Another factor in favor of England is that trade exchange is more favorable to them. Argentine and Uruguay have agricultural products to sell, which England needs and the United States does not need, because we also have the same things for sale. Trade exchange with us is more favorable in Brazil owing to the vast amount of coffee and rubber products consumed in the United States.

Since the opening of the Panama Canal, Chile has taken increased quantities of coal from this country, and based on yearly figures it would appear that American coal is quite solidly entrenched there. Peru, like Chile, mines some of their fuel requirements, but not in sufficient quantity to take care of all needs. Until 1914 all imported coal came from England and Australia. A point in favor of American trade there is that return cargoes can consist of sugar and ores.

American Coal Trade in Europe

Our best opportunities for a permanent trade in Europe lie undoubtedly with the Mediterranean countries, especially Italy, which of all overseas countries has been the largest user of American coals over a period of years antedating and following the war. In 1913 Italy imported 10,873,608 tons of coal, nearly all of which was supplied by England. During the year 1920 the imports from England were about 2,900,000 tons, while the United States shipped about 2,300,000 tons. The indications are for a lesser amount of American coal during 1921, due to the depreciation of the Italian lire and the prolonged industrial depression prevailing in Italy.

For geographic reasons, we can scarcely hope to compete with British coals in Norway, Sweden, Denmark and Holland. Previous to the war our exports to these countries were negligible, and while in recent years they have received considerable American coal, trade can be looked for only under exceptional circumstances. Competitive prices will doubtless be a deciding factor in the future coal supply of these countries, and in the face of conditions the matter of price is uncertain.

With a pre-war consumption of 60,000,000 tons and a production of 40,000,000 tons annually, France has long been an importer of coal. Most of this came from Great Britain, the balance being obtained from Belgium and Germany. Exports from the United States began in 1910, a few single cargoes having been shipped as far back as 1904, but from this period up to 1919 yearly shipments had not reached a total of 180,000 tons and averaged much less. During the calendar year 1919 we exported to France 532,222 tons, and during 1920 this was increased to 3,646,359 tons.

Exports of American coals to France for the first six months of the present year (1921) show a decided falling off from the 1920 rate, this being due to lack of activity in industry, to the rapid improvement of her own coal production, to large stocks of coal on hand, to an unfavorable money exchange, and to the fall in British prices and freights. It is only right to state here that another probable cause for the falling off in our French trade is the poor preparation given much

of the American coal shipped them during 1920, the responsibility for which rests largely upon the many inexperienced, and, in some cases, unprincipled concerns which sprang into existence during the exporting heydays. If American exporters will bear in mind that France has been accustomed to receive three-fifths of her imported coal from England, and that the Welsh coals will always be the basis on which the preparation of our coals will be judged, it will help materially in overcoming an unfavorable impression of our fuel.

Nor does it seem that we will have much in the way of a market in France, at least not after the next two to three years, say after 1925.

Spain, Portugal, Greece, North Africa and the Atlantic coaling stations may be classed as possibilities. Turkey appears to offer a growing market for American coal, and such coal as has been tried there has been pronounced satisfactory.

American Coal Trade in Other Countries

Other overseas countries in which American coals have been tried and retained are Egypt and French West Africa. Most of the American coal entering Egypt is used on the railroads, while that shipped to French West Africa is used for bunkers.

Mexico draws largely on the United States for its foreign coal, though, due to her abundant supplies of petroleum, coal is not in such general use as formerly.

With the countries already enumerated and the West Indies markets, which we cannot lose, it would seem that there is sufficient inducement to make strong efforts for a permanent export trade.

England Our Chief Competitor

For economic reasons England has long been an exporter of coal. Never a great country in an agricultural sense, she has nevertheless become one of the greatest manufacturing centers on earth, and in the accomplishment of this has, through a long period of years, made good use of her abundant coal resources. This coal, which is practically the only raw material supplied in abundance by Nature to England, has been used as a basis of trade or exchange with countries scattered in all quarters of the globe. Cargoes of English coal were always readily accepted in exchange for cargoes of fruits, ores and timber by European and African countries, and in exchange for grains by South American countries. Traffic in coal with South American and other countries enabled British vessels to make cheap delivery in England of hides, sugar, etc., and of American corn and raw cotton. In this way England not only provided for her physical wants and comforts, but, in addition, accumulated vast stores of raw materials which were turned into finished products by her mills and factories, and which were, in turn, also subject to export.

Thus it will readily be seen that the influence and might of Great Britain in world's affairs are based primarily on the one article—coal. Since this is the only product which might serve as a medium of exchange, it follows that any destruction or even serious disarrangement to England's coal exports would tend to reduce her prestige to that of a second or third class power.

It may safely be predicted, therefore, that in spite of all handicaps brought about by the war and the arrogant attitude of labor, England means to remain the chief coal exporting nation of the world. In retaining this position she has some undoubted advantages over the United States, one of these being the much shorter haul from the mines to tidewater. British mines shipping coal for export are located within a few miles, 30 to 40 at the outside, from tidewater shipping points; some of their mines are directly at the water's edge, with workings extending out under the sea. Coal from the United States, on the other hand, has to be hauled from 275 to 475 miles, and while freight rates per ton mile are much lower than in England or any other coal exporting country, the greater distance is a decided obstacle in the way of low prices.

An advantage of long standing with England over America lies in her better shipping facilities. Prior to the war the United States had very little in the way of a merchant marine; we were not an exporting nation in the sense as understood in England. This difficulty would appear easy of solution in view of the large number of ships available through the Shipping Board, but it is likely that there must also be some remedial legislation before our shipping can be operated with equal facility as England's.

The British Position Today on American Coal Exports

While England enjoys a considerable advantage as a coal exporting country over the United States, the following extracts from an editorial that appeared in "The Colliery Guardian," the leading British coal trade publication, under date of July 29, 1921, is of considerable interest as showing the British opinion on American competition:

"This discrepancy (between American capacity and demand) is a matter of much moment to the British coal trade, for the natural remedy for over production is to increase external trade. The remedy is so obvious that we should credit American coal operators with little acumen if we refused to believe that they have examined it in all its facets.

"The obstacles, however, are numerous: they may be briefly stated as follows: (a) inexperience in dealing with foreign consumers; (b) disparity in exchange; (c) lack of co-ordinating agencies; (d) absence of a return freight; (e) inadequate transport facilities from mine to tidewater.

"It is clear that the United States cannot hope to build up a great coal export trade if the latter is regarded merely as a stop-gap for the home trade; firm business connections cannot be erected on so unstable a basis.

"Consequently, the validity of an export policy depends upon simultaneous efforts to stabilize the home demand and upon a deliberate and concerted effort to maintain a permanent and constant margin between the output and the home consumption. So powerful are the agencies on the other side of the Atlantic tending toward inflated production that a growth of the American export trade may be regarded as being practically assured, notwithstanding the impediments that have been enumerated.

"The fact that coal operators of the United States have a clear insight into the defects that

harass their own industry should not be ignored by our own coal owners and exporters, who from now henceforth must keep a watchful eye on the American coal trade."

Foreign Trade in Bunker Coal

Foreign bunker trade started at a much earlier period in the United States than cargo shipments. In 1882 over 100 ships were bunkered with New River coal at Newport News, a bunkering agency having been started in that year by Belloni & Company of New York. In 1884 the Norfolk & Western Railroad started to build its first pier at Lamberts Point, Norfolk, although bunkers had been supplied at Norfolk for some time previous, at first with coal brought by barge from Baltimore, and afterwards with Pocahontas coal, the first shipment of the latter coal to tidewater having been made in March, 1883.

Bunker coals from the Pennsylvania and Maryland fields had been shipped at New York, Philadelphia and Baltimore as far back as 1870.

The table below gives shipments of foreign bunker coal in gross tons from 1914 to 1920, inclusive:

TABLE 3. FOREIGN BUNKER COAL, UNITED STATES, GROSS TONS

	New York	Philadelphia	Baltimore	Hampton Roads	Total	Total All Ports in U. S.
1914...	4,129,443	518,482	839,965	1,042,832	6,080,722
1915...	3,273,884	427,671	583,629	1,703,506	5,988,640
1916...	3,405,994	440,098	392,443	2,961,709	7,200,254
1917...	2,529,444	287,687	433,634	1,967,332	5,218,107	6,883,176
1918...	2,258,446	247,036	244,989	1,238,413	4,018,884	5,626,125
1919...	2,912,891	539,042	524,970	1,779,482	7,342,734	7,342,734

American Coals for Export

All of the coal mining districts from which come the United States coals available and suitable for export overseas, are in the Appalachian coal field of the Eastern United States.

For convenience, the districts have been divided into groups, as served by the various coal shipping ports.

At present nearly all of the bituminous coal shipped to tidewater from the Atlantic coast ports shipped to tidewater is handled through the following ports:

New York
Philadelphia } By individual export agencies.
Baltimore }

Hampton Roads } By: Lambert's Point Coal Exchange.
Newport News Coal Exchange, Inc.
Sewalls Point Coal Exchange.

Editor's Note—Since this article was written the Tidewater Coal Exchange, Inc., which handled shipments at the ports of New York, Philadelphia and Baltimore, has been discontinued, all shipments now being made by the individual exporter or exporting agencies. As a matter of record, however, we have thought it well worth while to include information on the various coals which are shipped through these ports, keeping the old pool numbers for the purpose of identification.

GROUP I

Anthracite

Shipping Ports

New York, Philadelphia, Baltimore.
Mined only in Eastern Pennsylvania.

Average Range of Analyses

Comparison Between Welsh and Pennsylvania Anthracites

GROUP II

Pennsylvania Coals

Shipping Ports

New York, Philadelphia, Baltimore.

(a) LOW VOLATILE COALS, 15 to 25 PER CENT.

These coals all come from Central Pennsylvania, Cambria, Clearfield and Somerset counties. They are classed as steam coals.

Considerable variations in quality are found in these coals, as shown by the range of analyses. For Tidewater shipment they are not screened, all being shipped as run-of-mine or "thro" and "thro."

ANALYSES

	Per Cent.
Moisture	1 to 3
Volatile Matter	15 to 25
Fixed Carbon	78 to 81
Ash	6 to 11
Sulphur	0.7 to 2.50
B.t.u., dry	13500 to 14600
Ash Fusing Temp., F..	2200 to 2900

These coals were included in the following pools:

Pool 1—Navy Standard.

Pool 9—High Grade South Fork and Somerset County.

Pool 71—Supplemental Navy Standard.

Pool 10—Superior Steam.

Pool 11—Good Steam.

Pool 18—Fair Steam.

(b) MEDIUM VOLATILE COALS, 25 to 29 PER CENT.

These coals also come from the Central Pennsylvania districts.

Coals of this description are harder than the low volatile coals and are screened, to some extent; they are largely used for making coke and as locomotive fuel, besides being good steam coals.

ANALYSES

	Per Cent.
Moisture	1 to 3.5
Volatile Matter	25 to 29
Fixed Carbon	66 to 75
Ash	7 to 11
Sulphur	0.7 to 1.50
B.t.u., dry	14400 to 13600
Ash Fusing Temp., F..	2720 to 2190

Pool classifications:

Pool 15—Medium Volatile Coals.
 Pool 12—Superior Medium Volatile Coals.
 Pool 14—Medium Volatile Coals.

(c) HIGH VOLATILE COALS, 30 to 37 PER CENT.

These coals come from several counties in Western Pennsylvania, mainly from the Pittsburgh, Youghiogheny and Westmoreland districts, and from the Pittsburgh bed.

Harder and with a cubical fracture, they stand transportation well and are shipped both screened and as run-of-mine.

Among them are some of the best gas coals in the country; they are also good steam-making coals and are very largely used for locomotive fuel as well as for use in both by-product and beehive coke ovens.

From this field come the well-known Westmoreland and Youghiogheny gas coals and the Connellsville coking coal.

ANALYSES	
	Per Cent.
Moisture	1 to 4
Volatile Matter	30 to 37
Fixed Carbon	62 to 57
Ash	6.5 to 10.5
Sulphur	0.7 to 2.00
B.t.u., dry	14400 to 13500
Ash Fusing Temp., ° F..	2100 to 2600

Pool classifications:

Pool 39— $\frac{3}{4}$ " Screened, Greensburg High Volatile Coals.
 Pool 40—Run-of-Mine Greensburg High Volatile Coals.
 Pool 60— $\frac{3}{4}$ " Screened, Westmoreland, Youghiogheny Gas Coals.
 Pool 61—Run-of-Mine, Westmoreland, Youghiogheny Gas Coals.
 Pool 30— $\frac{3}{4}$ " Screened, Low Sulphur Gas Coals, Pittsburgh District.
 Pool 31—Run-of-Mine, Low Sulphur Gas Coals, Pittsburgh District.

Standard Gas and Coking Coals

B.t.u. Gas per cu. ft.	625	615
Coke yield, coal as charged	70.00

GROUP III

Northern West Virginia and Maryland Coals

Shipping Ports

Baltimore and Philadelphia.

The coals in this group show wide variations in both character and quality, comprising both low and high volatile coals.

(a) LOW VOLATILE COALS, 15 to 25 PER CENT.

These coals are practically all shipped for export as run-of-mine; they are used as steam coals, as steamship fuel and for coke-making when low in sulphur.

ANALYSES	
	Per Cent.
Moisture	1 to 3
Volatile Matter	15 to 25
Fixed Carbon	77 to 60
Ash	7 to 12
Sulphur	0.7 to 2.50
B.t.u., dry	13700 to 14600
Ash Fusing Temp., ° F..	2400 to 3100

Pool classifications:

Pool 1—U. S. Navy Standard.
 Pool 9—High Grade Steam.
 Pool 11—Good Low Volatile.
 Pool 18—Fair Low Volatile.

(b) HIGH VOLATILE COALS, 30 TO 38 PER CENT.

Wide variations in character and quality will be found in these coals, from excellent gas and by-product coking coals to inferior steam coals; many of them are also good locomotive fuels. The well-known Fairmont Gas Coal is included in this group.

ANALYSES	
	Per Cent.
Moisture	1.5 to 3.50
Volatile Matter	40.00 to 38.00
Fixed Carbon	48.00 to 56.00

GROUP IV

Southern West Virginia Coals

Shipping Ports

Norfolk, Va.—Lamberts Point, Norfolk & Western Railway; Sewalls Point, Virginian Railway.

Newport News, Va.—Chesapeake & Ohio Railway.

The coals in this group vary widely in both character and analyses; they are suitable for many and varied uses as all-round steam coals, gas and coke making, chemical and metallurgical furnaces, house heating, etc., generally. The group contains the highest grade bituminous coals mined in the United States, including the Pocahontas and New River steam coals and the Kanawha steam, locomotive, gas and by-product coking coals.

(a) LOW VOLATILE COALS, 16 to 25 PER CENT.

ANALYSES	Per Cent.
Moisture	1 to 3
Volatile Matter	16 to 25
Fixed Carbon	79 to 64
Ash	4 to 8

Pool classifications:

- Pool 1—Standard Low Volatile (Mines as Navy List) Run-of-Mine.
 Pool 2—Other High Grade Low Volatile Coals.
 Pool 3—Low Volatile Slack.
 Pool 4—Medium Grade Low Volatile Coals.

(b) MEDIUM VOLATILE COALS, 25 to 30 PER CENT.

The coals in this sub-group are limited in extent and production, but are all of excellent quality for steam making and for use in coke ovens.

ANALYSES	Per Cent.
Moisture	1.00 to 3.50
Volatile Matter	25.50 to 29.00
Fixed Carbon	66.00 to 62.00
Ash	4.00 to 8.00
Sulphur	0.7 to 1.6
B.t.u., dry basis	14400 to 14700
Ash Fusing Temp., ° F..	2360 to 2960
Phosphorus005 to .010

(c) HIGH VOLATILE COALS, 30 to 38 PER CENT.

This sub-group is very large, in point of production, and contains coals suitable for every purpose. Excellent steam coals and the best locomotive coals in the country, if not in the world; especially good by-product coals, etc.

The quality of these coals varies considerably, as does their structure and physical character. The range of analyses given below will show the variation in quality, but there is like variation in structure, from rather soft "Gas" coals, with cubical fracture, to the very hard "Splint" coals, of laminated structure.

It should be noted that the term "Kanawha Gas Coals," as generally used, does not necessarily refer to their suitability for the manufacture of gas, but usually to their physical character and appearance. Many of the so-called "Kanawha Gas Coals," including a number classified by the Tidewater Exchanges in Pool No. 5, are not at all suitable for gas making, but are steam coals.

The Kanawha "Splint" coals, so called from their supposed resemblance to the Scotch Splints, are included in this sub-group. These are not suitable for either gas or coke making, but are excellent steam and locomotive coals and are much used for metallurgical purposes and for domestic heating, as they are very hard and stand screening and transportation with little breakage. Coals for this group are mined from a number of beds covering a large area, principally in Kanawha, Logan, Fayette and Mingo counties, West Virginia. There is also a considerable tonnage actually mined in Pike county, Kentucky, but shipped over the Norfolk & Western Railway to Hampton Roads and included in the pool classifications as Kanawha coal.

	ANALYSES "Gas" Coals	"Splint" Coals
Moisture	1.0 to 3.5	
Volatile Matter.	32 to 36	34 to 38
Fixed Carbon...	57 to 62	56 to 54
Ash	4 to 9	7 to 10
Sulphur	0.6 to 1.60	0.5 to 1.4
B.t.u., dry	13900 to 14600	13700 to 14300
Ash Fusing Temp., ° F...	2200 to 2850	2410 to 3010

Note—The term "Gas" coals refers to character, structure—not to suitability for gas manufacture.

 Pool 6—High Volatile Steam, Run-of-Mine.
 Pool 7—High Volatile By-Product, Run-of-Mine.
 Pool 56—Medium Grade High Volatile Steam, Run-of-Mine.

GROUP V

Southwest Virginia (not West Virginia) and Eastern Kentucky Coals.

Shipping Ports

Norfolk, Va.—Lamberts Point, Norfolk & Western Railway.

Newport News—Chesapeake & Ohio Railway.

Charleston, S. C.

Small tonnages are also shipped from Savannah, Ga., and Jacksonville, Fla.

The coals in this group are all Medium and High Volatile, from 28 to 40 per cent., but differ considerably in structure and character. Among them are found some of the best gas making and by-product coking coals in the world; many of them are excellent steam and locomotive fuels; others are much used as domestic fuels.

Most of these coals are hard and stand handling well. They are shipped as both screened and run-of-mine.

Note—The Pocahontas beds are mined in Southwest Virginia, but the production is comparatively small. The coal is of the same character as in West Virginia.

ANALYSES

GROUP VI

Alabama Coals

Shipping Ports

Mobile, Pensacola, New Orleans, Jacksonville.

Exports of these coals are as yet small and most of the shipments have gone to Cuba, West

Indies, Mexico and small tonnage to South America.

Coals in this group vary from medium to high volatile. There are marked differences in character and structure. Most of the coals exported are rather hard and stand handling and transpor-

tation. The softer coals are generally the medium volatile and are used mainly for coke making, usually requiring washing, but making excellent coke both in beehive and by-product ovens. The high volatile coals are suitable for locomotives and as general steam coals. While used to some extent for gas making they are not as good for this purpose as the West Virginia, Eastern Kentucky and Pennsylvania gas coals.

ANALYSES

PART II.--COAL EXCHANGES AND POOLS

Factors Which Prompted Their Organization; The Function of an Exchange; Where They Operate; Classification of Coals Into Pools; Description of Pools; List of Mines in the Various Pools; Operating Companies; Seams Worked; Railroads and Mining Districts.

Organization of Coal Exchanges

Pooling of coal at Atlantic ports by individual concerns is a practice of long standing. Prior to the war all coal shipped to dumping piers was consigned to the shipper's order at the port, and as it frequently happened that each shipper had several classes of coal, each designated with a classification number, it meant that there were hundreds of different consignments of cars which had to be kept separated by the railroads, and subject to the shipper's order. This required much handling and a great deal of track space. Also it was productive of many delays since each shipper's coal remained at the terminals until ordered to be loaded.

When the war put a special strain on car supply, the Council of National Defense suggested that all coal be pooled as a means of increasing the efficiency of transportation and of effecting a quicker release of equipment. Their plan was to classify every mine into one of the various pools and then to have all coal of each kind shipped to one consignment instead of a hundred or more. This meant the forming of agencies for management at each port, and from this necessity was born in June, 1917, the Tidewater Coal Exchange, a voluntary organization, composed of trans-shippers and railroads handling bituminous coal at the tidewater ports of New York, Philadelphia, Baltimore and Hampton Roads, which took over the handling of all coal at tidewater, classified the mines, inspected the coal and supervised the loading of vessels with coal from the proper pool.

The Exchange started operation on August 1, 1917, and by November 11th of the same year its advantages were so apparent that pooling, under government operation, was made compulsory. This arrangement continued until February 28, 1919, at which time the Exchange again became a voluntary organization and so continued until February 25, 1920, when compulsory pooling was once more required. This remained in effect until April 30, 1920, when the railroads notified the coal trade that they would no longer operate the Exchange.

The visible benefits of pooling were such that it was decided to continue the practice through the organization of Exchanges at the various ports, these to be managed by a co-operative agreement between the shippers and the railroads. In this way was formed the Tidewater Coal Exchange, Incorporated, which looked after the interests of its members at Baltimore, Philadelphia and New York; and the Newport News Coal Exchange, Incorporated, the Lamberts Point Coal Exchange and the Sewalls Point Coal Exchange, all of which operate at Hampton Roads, Norfolk, Va. An Exchange is also being formed at Charleston, S. C., to handle shipments in Virginia, Eastern Kentucky and Tennessee.

The Function of a Coal Exchange

Coal exchanges, when efficiently operated, render a service to the producer of coal, the railroads which carry it to seaboard, and the consumers who burn it. Since the purpose of their organization is to effect the quick release and expeditious handling of rolling stock, and to promote the increased use of railroad facilities, it follows that one of their benefits should be to reduce costs. Pooling of coal is one of the principal functions of an exchange, and, whether this is done by private distributors or by an exchange, it is beneficial for the following reasons: (a) it greatly reduces the time which would be required for a single mine to produce sufficient coal for an entire cargo, (b) it reduces the delays to vessels while waiting for cargoes, (c) it makes it possible to practically wipe out demurrage charges on loaded cars at ports and to similarly affect vessel demurrage, (d) it simplifies car movements at tidewater and greatly reduces the congestion at terminals.

Members of an exchange are credited with shipments to certain pools when the coal leaves the mines and the total daily consignments of all the members provide a working stock of coal at port. This stock of coal enables the members to anticipate the arrival of their individual shipments in loading vessels up to the extent of their credit, withdrawals being replenished by the constant arrival of coal.

Classification of Coal Into Pools

The first classification of mines into pools was made in the summer of 1917 by a group of men thoroughly familiar with the coals shipped to the various Atlantic ports and the mines which produced them. Although the work was done under pressure and no time was available for the collection of extensive data or for examination where data was lacking, the original grouping of the mines was well done. The basis for this first classification was a separation of all mines into low, medium and high volatile groups, with a second classification based on the limits of ash and sulphur, and the heating value of the coal.

Rumors of complaints on the quality of coal shipped abroad during the war have been many, and it is no doubt true that unfit coal was loaded into many cargoes. One of the main difficulties in keeping shipments up to the standards lay in inadequate inspection, a trouble that will be readily appreciated when the number of mines and extent of territory is considered.

The classifications adopted by the various exchanges now in operation are similar to those first used, but the methods of inspections are vastly improved. The effect of this is that at some of the ports the quality of the coal in certain pools can

be forecasted with certainty. Where inspection is lax it may be expected that at some operations the coal will be mined with care and well prepared, while at other mines the reverse will be true. A lack of uniformity in quality is the result, and it is this inconsistency in shipments which the exchange management would avoid. Uniformity may be attained by designating fixed limits to the constituent parts of coal belonging to each pool, and then by means of chemical analyses made on actual shipments, it is possible to group mines in those pools to which they are chemically fitted to belong. Where it is understood that mines are subject to promotion or demotion in accordance with the variation in their analyses, the system serves as a

stimulus for the exercise of constant vigilance on the part of the mine management.

Regions Tributary to Tidewater

All in all about 4,000 mines have outlets to foreign and bunker trade through the various outlets along the Atlantic coast and the Gulf of Mexico. These mines are almost entirely located in the Appalachian region and within 300 to 400 miles of seaport. Figure 1 shows the geographical location of the regions contributing to oversea and bunker trade, with lines indicating the port or ports through which shipments are made. Table 2 gives the distances in nautical miles from American seaport points to the principal coaling ports of the world.

*F. R. Wadleigh in Coal Age, Vol. 7, page 377.

THE THREE NORTHERN PORTS New York, Philadelphia, Baltimore

When the railroads definitely decided to withdraw from the operation of the coal exchanges, conferences on the possibilities of perpetuating the machinery for pooling were held between representatives of the northern coal trade. With the help of the local associations at the three northern ports—New York, Philadelphia and Baltimore—the Tidewater Coal Exchange, Incorporated, was organized and began business on May 1st, 1920.

At the time this is being written, October 1st, 1921, the trade papers report that the Exchange is

to cease functioning. The principal reason, according to rumor, for discontinuing the Exchange is difficulty between the members and the railroads over the question of car demurrage.

It may be remarked here that many large shippers, who under the government requirements were members of the original Exchange, have steadfastly refused to join the voluntary Exchange. Their refusal is based on the belief that the foreign trade prefers to designate a certain brand of coal for shipment, and that membership in the Ex-

Fig. 2. Dumping Piers at Arlington, Staten Island, New York.

change means burying the identity of their fuel.

Because of the likelihood that in the event of reorganization of an exchange, changes would be made in the pool classifications, as announced by the Tidewater Coal Exchange, Incorporated, the lists of mines by pools is omitted in this issue of the Coal Catalog.

Advances in Pier Dumping Equipment

The Curtis Bay pier of the Baltimore & Ohio Railroad, two views of which are shown on the next page, represents recent advances in pier construction and marks a new departure in the adoption of facilities to overcome breakage and to attain speed in loading.

It is built of concrete and steel and is electrically operated. The functions of the pier are interlocked and controlled electrically, with push-buttons located every 20 feet on each conveyor belt runway. By pushing a button all movable parts of the belts, towers and feeders are stopped. It has a capacity of 12,000,000 tons a year, or 4,000 tons per working hour. The original cost to the railroad was \$2,500,000.

The loading tower, shown in Figure 6, is equipped with a cage supporting a shuttle ram. The cage is raised or lowered to suit the height of the vessel being loaded, thus providing further precaution against breakage of the coal. The cage has a variation in height of 27 feet, the minimum

height above the water being 15 feet. The shuttle ram, which can be run out on either side of the pier, has a maximum reach of 45 feet.

In order to maintain the pier's operation in wintry weather, thawing sheds were built to cover the tracks leading to the car dumpers. The sheds

Fig. 6. The belts in use at Curtis Bay are 60 inches in width, with a capacity of 1,500 tons of coal an hour, running at 500 feet per minute. The loading tower shown in center travels along the pier in a horizontal direction and the shuttle ram (with little houses at either end for the operator) working in and out at right angles to the travel of the towers will load a hatch uniformly and reduce trimming to a minimum.

Fig. 7. View of modern dumping pier at Curtis Bay. Car dumpers are shown at left and loading towers on the pier at right. The balancing bin is interposed between the car dumpers and the pier.

have a capacity of 22 cars. A temperature of 180 degrees for 30 minutes thaws the coal sufficiently to allow it to free itself.

This pier has broken all records for fast loading of coal into vessels, having loaded 2,076, 2,548

and 3,670 tons per hour on different occasions. In addition to these records, the pier made a new high mark for a 24-hour period on October 25th, 1920, when it dumped 1,082 cars of coal, exceeding by 6,000 tons the former Curtis Bay record for volume handled in one day.

HAMPTON ROADS

Newport News Lamberts Point Sewalls Point

From the time of the organization of the Tidewater Coal Exchange in June, 1917, up to its disbanding in March, 1920, all coal shipped from the tidewater ports of New York, Philadelphia, Baltimore and Hampton Roads was handled by this single agency. When the Exchange ceased to exist, on account of the cancellation of the compulsory order of the United States Fuel Administration and the discontinuance of Federal control of the rail-

roads, it led to the organization of separate exchanges by the three coal carrying roads with terminals at Hampton Roads. The three exchanges have since been working with great satisfaction to the mine operator, the railways, the shipper and all others concerned.

As will be noted in Figure 8, the Chesapeake & Ohio terminal is located on the Newport News side of Hampton Roads, while the other two terminals are on the Norfolk side. The coal dumped at these piers comes largely from the smokeless and high volatile fields of southern West Virginia, with smaller amounts from Virginia and Eastern Kentucky. The tonnage of coal transshipped is greater at these three ports than at any other locality in the United States. Not all of this coal, however, is for export, as a considerable portion is used for bunkers and for shipments to the New England states.

Fig. 8. Map of Hampton Roads Showing the Three Seaboard Terminals.

Dumping Piers Over Which Coal Consigned to Hampton Roads is Handled

Railroad and Pier	Kind of Coal	Daily Capacity Tons
Norfolk & Western... Lamberts Point...	Bituminous & Semibituminous	40,000
Chesapeake & Ohio Newport News...	Bituminous & Semibituminous	30,000
Virginian Sewalls Point....	Bituminous & Semibituminous	20,000

SOUTHERN PORTS

Charleston Savannah Jacksonville
Pensacola Mobile New Orleans

In comparison with the amount of export and bunker coal loaded at the three northern ports and at Hampton Roads, the quantity of coal which passes through the six Southern points is small. Charleston, however, has possibilities through the use of Virginia and Eastern Kentucky coals for the development of cargo business. It is also quite likely that some of the favorably situated Illinois coals will be shipped in the future through New Orleans. There are no exchanges in operation at any of these ports, all shipments being made by and through individual companies.

FOR EXPORT—BUNKERS—STEAM—DOMESTIC—GAS—BY-PRODUCT

The coal strike and other conditions of the past five years have demonstrated the vast importance to both producer and consumer of proper and efficient means of distributing the country's coal supply. During this period many consumers, and in fact operators, had occasion to learn for the first time that the distribution of coal is a highly specialized business, the improper management of which results disastrously for both consumer and producer, sometimes with a far-reaching effect on the business of the country as a whole.

The highest efficiency in the distribution of coal is attainable only when this important function of the coal business is entrusted to specially trained men comprising an organization suitably financed and equipped to meet all of the demands that are likely to be made upon it.

Castner, Curran & Bullitt, Inc., is an example of such an organization and since this subject has become of such wide-spread interest it is believed that a description of the methods employed and services rendered by this old and successful distributing agency, will be helpful to readers of the Coal Catalog.

Organization

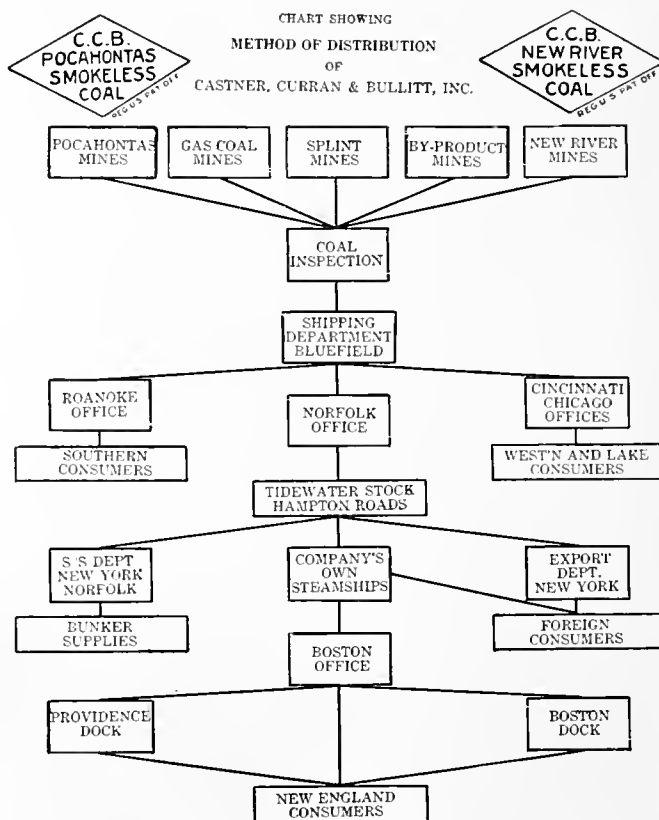

The headquarters of Castner, Curran & Bullitt, Inc. is maintained in New York from which point of vantage the directing head is enabled to keep in intimate touch with the general business situation of the country and the export markets of the world.

In order to visualize the organization of Castner, Curran and Bullitt, Inc., the accompanying chart has been prepared to show the manner in which the coals, customarily handled by the Company, flow through the various departments to the consumer.

As will be seen from the chart, branch offices are located at strategic points in the markets served by the Norfolk and Western, Chesapeake and Ohio, and Virginian Railways, as well as New England where the Company also maintains its own discharging wharves and storage plants for the convenience of its customers.

The Company has always made a special feature of tidewater business embracing Export Bunker Supplies and Coastwise Shipments over the Hampton Roads Piers located at Lambert's Point, Sewall's Point and Newport News, Virginia. It maintains at all times large stocks at Hampton Roads of C. C. B. Pocahontas, C. C. B. New River and other coals. The quality of coal shipped from the mines is backed by its own inspection department as well as the reputation of the Company.

When the world war presaged a shortage of ships, the Company acquired a fleet of its own colliers through the construction of modern steel steamships of 9,000 to 12,000 tons deadweight capacity, many of which were on the ways before

the U. S. Shipping Board had been organized. The Company now owns outright, and has engaged in the foreign and coastwise coal trade, over 50,000 tons carrying capacity of modern steamships.

Policy

This Company has back of it the experience of 37 years gained entirely in the distribution of coal which began with the introduction of Pocahontas coal to the markets of the world by the original firm of Messrs. Castner & Curran and their successors, Castner, Curran & Bullitt, of Philadelphia, and which through all the turmoil and trouble of war strikes and government control has proven of inestimable value in guiding its policies.

A reputation is made by doing the same thing well over and over again, and the prestige which Castner, Curran & Bullitt, Inc. enjoys in the trade has been gained largely from the policy steadfastly adhered to of sticking strictly to the distribution of coal and leaving the operation and ownership of mines to others who have specialized in that branch of the industry.

In fact, this is the cardinal principal inherited from the founders of the Company, on which the whole policy and organization is based as the management of this Company has always worked under the conviction that it could only serve impartially the mine owners whose coal it sells by having no self-interest financially or otherwise in any coal property of its own.

The relations of Castner, Curran & Bullitt, Inc. with the mining companies, whose coal it sells, is generally that of sole agent under a contract entered into for a period of years.

Standard of Quality

The copyrighted trade names "C. C. B. Pocahontas," "C. C. B. New River" or simply "C. C. B. Coal," on which the very valuable goodwill of the Company has been built, have much more than ordinary significance. These trade-marks are only applied to coal from mines which have been added to the C. C. B. list after the strictest investigation and all shipments of which have been loaded by the Company's own inspectors.

When a mining company offers its output to Castner, Curran & Bullitt, Inc., experts are sent to the property to make a careful investigation for the purpose of determining whether the coal is of the proper quality to measure up to the C. C. B. standard. If arrangements are made to take the entire output, an inspector employed by Castner, Curran & Bullitt, Inc., and reporting solely to the

Company's chief inspector, is stationed at the mine and personally loads every ton of coal shipped under the C. C. B. trademark. The inspector works under a set of fixed rules of the Company and besides supervising the preparation of the coal sees that all cars are in suitable condition for loading, tags the cars for shipment and reports daily to the chief inspector and shipping office on the loading and condition of coal.

This system is not only of great assistance to the mine management in the preparation and shipment of coal, but has been found to be the best system for maintaining a high standard of uniform preparation.

Coals Handled

Castner, Curran & Bullitt, Inc. have always made a point of handling only the best coals obtainable for steaming and other purposes, and are constantly on the lookout for new coals and new developments in the coal regions which might prove advantageous both to the producer and to the consumer served by them in a great variety of coal consuming industries here and abroad.

While Castner, Curran & Bullitt, Inc., are known primarily as sole agents for C. C. B. Pocahontas and C. C. B. New River coals, both of which are Navy Standard Quality, and in constant use by the U. S. Navy, they also sell high volatile steam, gas, by-product, domestic, and splint coals of the highest grade.

The quality of the coals handled by this Company is so well known to the consumer in the markets served by C. C. & B., Inc. that it is deemed unnecessary to give here detailed descriptions and analyses of these fuels. Any of the offices of the Company will be pleased to furnish to those interested such information upon request.

EXPORTERS ALL RAIL COAL

BUNKERING CONTRACTORS ALL PORTS IN THE WORLD

The ability of the Cory Mann George Corporation, incorporated under the laws of the State of New York, to supply unlimited quantities of the best grades of coal at the principal ports of the Eastern Hemisphere has placed this company among the recognized leaders in exporting of coals, bunkering of steamships and for all rail delivery.

This company is the American representatives for the British firms of Wm. Cory & Son, Ltd., and Mann, George & Co., Ltd., of London, England. These companies, while separate organizations, together operate, each in their special line, as coal exporters, foreign coaling contractors, coal depot proprietors, fuel oil contractors and steamship brokers. They are contractors to the British Admiralty and other navies and the principal steamship lines.

With these connections Cory Mann George Corporation becomes allied to what is probably the world's largest coal exporting and bunkering organization.

Quotations on export coal and all rail deliveries will be furnished upon request at any of its branch offices.

This company also has facilities for supplying the best grade of coals for bunkering purposes at the current market price at the following ports:

TIDEWATER COAL EXCHANGE, Inc.

Although the above exchange no longer supervises export shipments at the ports of New York, Philadelphia, and Baltimore, it has been thought advisable to preserve the pool numbers and descriptions as a matter of convenience to the trade.

These are as follows:

Pool No. 1

Description: American standard low-volatile run-of-mine coal. Includes all mines on the Navy List. For many years the United States Navy bought their coal on a guaranteed analysis basis, the requirements of which were as follows:

DRY BASIS	Volatile Matter (maximum)	22 per cent
	Fixed Carbon (minimum)	73 per cent
	Ash (maximum)	7 per cent
	Sulphur (maximum)	1 per cent
	B.t.u. (minimum)	14,700

To be placed on this list, and in position to supply the Navy with coal, a mine had to pass an inspection by the Navy Department. This has established what is now known as the Navy Acceptable List.

Seams Mined: "B" or Miller; Fulton; Georges Creek Big Vein.

Pool No. 4

Description: Superior low-volatile (under 24 per cent) run-of-mine coal from mines on the New York Central, Pittsburgh and Susquehanna, and Cambria and Indiana railroads.

Seams Mined: "B", Miller, or Lower Kittanning.

Pool No. 9

Description: Superior low-volatile (under 24 per cent) run-of-mine coal loaded on railroads other than those given under Pool No. 4.

Seams Mined: "C" Prime or Upper Kittanning; "B", Miller, or Lower Kittanning.

Pool No. 10

Description: High-grade low-volatile (under 24 per cent) run-of-mine coal loaded on all railroads.

Seams Mined: "E" or Upper Freeport; "D" or Lower Freeport; "C" or Middle Kittanning; "B" or Lower Kittanning; Clarion.

Pool No. 11

Description: Fair low-volatile (under 24 per cent) run-of-mine coal loaded on all railroads.

Seams Mined: "E" or Upper Freeport; "D" or Lower Freeport; "C" or Middle Kittanning; "B" or Lower Kittanning; Clarion.

Pool No. 14

Description: Medium-grade medium-volatile (between 24 and 31 per cent) run-of-mine coal loaded on all railroads.

Seams Mined: "E" or Upper Freeport; "D" or Lower Freeport; "C" or Middle Kittanning; "B" or Lower Kittanning; Pittsburgh.

Pool No. 15

Description: Other medium-volatile (between 24 and 31 per cent) run-of-mine coal loaded on all railroads.

Seams Mined: "E" or Upper Freeport; "D" or Lower Freeport; "B" or Lower Kittanning; Pittsburgh.

Pool No. 18

Description: Other low-volatile (under 24 per cent) run-of-mine coal loaded on all railroads.

Seams Mined: "E" or Upper Freeport; "D" or Lower Freeport; "C Prime" or Upper Kittanning; "C" or Middle Kittanning; "B" or Lower Kittanning; "A" or Brookville; Bakerstown; Big Vein Georges Creek.

Pool No. 20

Description: Slack coal from low-volatile mines (under 24 per cent) listed in Pools 1-4-9-10-11.

Seams Mined: See seams mentioned in Pools 1-4-9-10-11.

Pool No. 21

Description: High-volatile (over 31 per cent) by-product run-of-mine coal from mines on the Pennsylvania Railroad.

Seam Mined: Pittsburgh.

Pool No. 30

Description: Low-sulphur $\frac{3}{4}$ -inch lump gas coal from the Pittsburgh district. Maximum sulphur $1\frac{1}{4}$ per cent.

Seam Mined: Pittsburgh.

Pool No. 31

Description: Low-sulphur run-of-mine gas coal from the Pittsburgh district. Maximum sulphur $1\frac{1}{4}$ per cent.

Seam Mined: Pittsburgh.

Pool No. 32

Description: Slack coal from Pools 31 and 61. Maximum sulphur $1\frac{1}{4}$ per cent.

Seam Mined: Pittsburgh.

Pool No. 33

Description: High-volatile (over 31 per cent) $\frac{3}{4}$ -inch lump steam coal from the Pittsburgh and Fairmont districts.

Seam Mined: Pittsburgh.

Pool No. 35

Description: Slack coal from Pools 34, 38, 44, 54 and 64.

Seams Mined: All high volatile seams.

Pool No. 37

Description: Marion County (Fairmont) low-sulphur $\frac{3}{4}$ "-lump gas coal.

Seam Mined: Pittsburgh.

Pool No. 38

Description: Marion County (Fairmont) low-sulphur run-of-mine gas coal.

Seam Mined: Pittsburgh.

Pool No. 39

Description: Greensburg basin high-volatile (over 31 per cent) $\frac{3}{4}$ "-lump coal.

Seam Mined: Pittsburgh.

Pool No. 40

Description: Greensburg basin high-volatile (over 31 per cent) run-of-mine coal.

Seam Mined: Pittsburgh.

Pool No. 43

Description: High-volatile (over 31 per cent) $\frac{3}{4}$ "-lump steam coal.

Seams Mined: Upper Kittanning; Lower Kittanning; Upper Freeport; Lower Freeport; Pittsburgh; Sewickley; Waynesburg.

Pool No. 44

Description: High-volatile (over 31 per cent) run-of-mine steam coal.

Seams Mined: Upper Kittanning; Lower Kittanning; Upper Freeport; Lower Freeport; Sewickley and Waynesburg.

Pool No. 53

Description: Superior high-volatile (over 31 per cent) $\frac{3}{4}$ "-lump coal.

Seams Mined: Upper Kittanning; Lower Kittanning; Upper Freeport; Lower Freeport; Sewickley; Waynesburg and Pittsburgh.

Pool No. 54

Description: Superior high-volatile (over 31 per cent) run-of-mine coal.

Seams Mined: Upper Kittanning; Lower Kittanning; Upper Freeport; Lower Freeport; Sewickley, and Pittsburgh.

Pool No. 60

Description: Westmoreland (Irwin basin) and Youghiogheny low-sulphur $\frac{3}{4}$ "-lump gas coal.
Seam Mined: Pittsburgh.

Pool No. 61

Description: Westmoreland (Irwin basin) and Youghiogheny low-sulphur run-of-mine gas coal.
Seam Mined: Pittsburgh.

Pool No. 63

Description: Hard-structure high-volatile (over 31 per cent) $\frac{3}{4}$ "-lump coal. Maximum sulphur 2 per cent.
Seams Mined: Pittsburgh and Redstone.

Pool No. 64

Description: Hard-structure high-volatile (over 31 per cent) run-of-mine coal. Maximum sulphur 2 per cent.
Seams Mined: Pittsburgh and Redstone.

THE NEWPORT NEWS COAL EXCHANGE, INCORPORATED

Organization, Railroads, Dumping Piers, Description of Pools, Seams Mined,
List of Mines by Pools

OFFICERS

W. C. Hull, President, Roanoke, Va.
J. L. Moon, Vice-President, Roanoke, Va.
M. C. Selden, Commissioner, Newport News, Va.
J. F. Shaffer, Asst. Commissioner, Newport News, Va.
F. H. Wilson, Deputy Commissioner, Newport News, Va.
W. S. Bronson, General Counsel, Roanoke, Va.
W. K. Black, Chief Inspector, Newport News, Va.

The Newport News Coal Exchange came into being on May 1, 1920, and was incorporated on July 8, 1920. It is operated entirely by the railroad.

The Exchange maintains an inspection force at Newport News, as well as field inspectors, to insure that the quality and preparation of all coal handled through it comes up to its proper standards. This coal originates in the New River, Kanawha, Coal River and Logan districts of West Virginia and the Princess, Paintsville, Elkhorn and Redwine districts of Kentucky.

Railroads

Inasmuch as all coal reaches Newport News over one railroad, the Chesapeake and Ohio, this information in the pool lists is supplanted with the name of the mining districts. The Chesapeake and Ohio Railroad alone serves the New River, Coal River and Logan districts and is the originating road of most of the Kanawha district coal. The Kanawha and Michigan Railway, a connecting road, also serves the Kanawha district. Most of the coal from the Kentucky districts originates on the Chesapeake and Ohio, the balance being delivered to it

by connecting roads, the Ashland Coal and Iron Railway, Big Sandy and Kentucky Railway, Eastern Kentucky Railway, and the Morehead and North Fork Railroad.

Dumping Piers

Pier No. 9 at Newport News is of all steel construction and has a capacity of 1,000,000 tons monthly. This pier will accommodate six vessels at one time—three on either side. The coal is dumped from the railroad car into a pier car which passes over the scales enroute to the pocket through which the coal is delivered to the vessel, thereby insuring accurate weights.

Pier No. 12 is an auxiliary to Pier No. 9 and is for the accommodation of bunkers and small craft.

Authority For List of Mines

The list of mines here given has been taken from the Newport News Coal Exchange Classification as of date October 15, 1921. Inasmuch as changes in classification may be made at any time, we do not guarantee the lists, nor are we responsible for inaccuracies.

Pool No. 1

Description: Standard New River low-volatile run-of-mine coal.

Volatile Matter (range) 17 to 20 per cent
Fixed Carbon (range) 75 to 79 per cent
Ash (range) 5 to 7.5 per cent
Sulphur 1 per cent and less
B.t.u. (range) 15,000 to 15,500

Seams Mined: Pocahontas No. 3, Pocahontas No. 4, Sewell, Beckley and Fire Creek.

Pool No. 3

Description: Standard and other high-grade New River low-volatile nut and slack coal.

Seams Mined: Pocahontas No. 3, Pocahontas No. 4, Sewell, Beckley and Fire Creek.

WEST VIRGINIA MINES

For list of mines in this Pool, see Pool No. 44, the mines in which are identical with those in Pool No. 3.

Pool No. 5

Description: High-volatile run-of-mine gas coal, fulfilling the following requirements:

Volatile Matter (Range)	32 to 36 per cent
Fixed Carbon (Minimum)	55 per cent
Ash (Maximum)	8 per cent
Sulphur (Range)	1.1 to 1.3 per cent
Coke Yield	60 per cent
Gas Yield	10,500 cu. ft.
B.t.u.	14,200

Seams Mined: No. 2 Gas, Eagle, Chilton, Little Eagle, Cedar Grove, Island Creek, Alma and Elkhorn.

(Continued on Next Page)

Pool No. 6

Description: High-volatile run-of-mine splint steam coal fulfilling the following requirements:

Volatile Matter (Range)	36 to 40 per cent
Fixed Carbon (Range)	54 to 57 per cent
Ash (Maximum)	8.50 per cent
Sulphur (Range)	1.1 to 2.0 per cent
Gas	10,000 cu. ft.
B.t.u.	14,500

Seams Mined: No. 5 Block, Coalburg, Stockton-Lewiston, Winifrede, Island Creek, Eagle, Alma and Elkhorn.

Pool No. 7

Description: Standard high-volatile by-product run-of-mine coal fulfilling the following requirements:

Volatile Matter (Range)	28 to 33 per cent
Fixed Carbon (Minimum)	58 per cent
Ash (Maximum)	7.5 per cent
Sulphur (Maximum)	1 per cent
Coke Yield	68 per cent
Gas Yield	10,300 cu. ft.
B.t.u.	14,200

Seams Mined: No. 2 Gas, Eagle, Chilton, Little Eagle, Cedar Grove, Island Creek, Alma and Elkhorn.

Dumping Pier of Newport News Coal Exchange, Incorporated, Newport News, Va.

LAMBERTS POINT COAL EXCHANGE

OFFICERS

D. E. Spangler, Chairman Executive Committee,
Roanoke, Va.
W. H. Johnson, Manager, Norfolk, Va.
W. P. Bugg, Asst. Manager, Norfolk, Va.
John Stewart, In Charge of Inspection,
Bluefield, W. Va.

EXECUTIVE COMMITTEE

D. E. Spangler, Norfolk & Western Ry.
D. W. Allen, W. C. Atwater & Co.
A. G. Bailey, Castner, Curran & Bullitt.
Kuper Hood, Houston Coal Co.
G. W. St. Clair, Virginia Smokeless Coal Co.
W. H. Johnson, Manager of Exchange.

Lamberts Point, near Norfolk, Virginia, is the seaboard outlet for coal originating on the Norfolk and Western Railway and its connections, including the Carolina, Clinchfield and Ohio, the Interstate, and the Norton and Northern railroads. The Norfolk and Western handles all coal originating in the Pocahontas fields of Virginia and West Virginia and the Tug River, Thacker and Kenova fields of West Virginia. In connection with the other roads above mentioned it provides shipment for coal from the Clinch Valley and Southwestern Virginia coal fields of Virginia and the Elkhorn field of Kentucky.

The Norfolk and Western Railway has a double track, modernly equipped, railroad from the coal fields which it serves to its tidewater terminal. Partly because of its trackage facilities and because of the use of railroad cars having double the capacity of those generally used, it is able to provide quick movement for coal tonnage in great volume. The large trackage at its Norfolk terminals enables it to give extraordinary service in the handling of coal for vessel trans-shipment.

Dumping Piers

The Norfolk and Western Railway has at Lamberts Point three coaling piers, having berthing space for fourteen vessels to receive coal at one time.

Pier No. 4, the largest coal pier, is 90 feet high and 1,200 feet long, and is used primarily for delivering cargo coal, although bunker coal is also delivered when necessary over this pier.

Piers Nos. 2 and 3, each about 800 feet long, are used to deliver principally bunker coal and as a relief to Pier No. 4.

Pier No. 4 is served by scales, dumpers and elevators, all in duplicate and interchangeable, so as to insure uninterrupted delivery of coal. This pier has a rated capacity of 60 cars an hour, or a

total, if handling exclusively the large 100-ton cars, of 6,000 tons of coal in one hour. Actual performance has shown that it can dump and deliver as many as 66 cars an hour, the rate of delivery depending on vessel construction and the proportion of cargo coal and bunker coal taken. Under favorable working conditions the capacity of the pier is 50 cars per hour, and this rate has been maintained for a continuous stretch of eight or ten hours.

Pier No. 4 alone, in one twenty-four hour period delivered 43,287 tons of coal to vessels. In one day of twenty-four hours a total of 47,985 tons of coal was dumped at this terminal and in one month 863,403 tons were dumped.

Lamberts Point Coal Exchange

The management of the Lamberts Point Coal Exchange is vested in an official appointed by the Norfolk and Western Railway, who agree to pay his salary and expenses of his office. Membership in the Exchange is open to all shippers who subscribe to and observe the rules of the organization. The grading of coals and classification in designated pools is under the direction of the Executive Committee. This body is also charged with the duty of protecting the quality of coal shipped into the pool, through the Manager and a system of inspection, and analysis, if necessary in their opinion, and may at any time suspend shipments from any mine when in their judgment the quality or preparation of such coal is below the present standard. The cost of inspection service is borne by the Railway.

Authority for List of Mines

The list of mines here given has been taken from the Lamberts Point Coal Exchange Classification A, as of date November 15th, 1920. Inasmuch as changes in classification may be made at any time, we do not guarantee the list here given, nor are we responsible for inaccuracies.

Pier No. 4 Lamberts Point Has a Record of 47,985 Tons in One Day.

Pool No. 1

Description: American standard low volatile run-of-mine coal. Includes all mines on the Navy Acceptable List. For many years the United States Navy bought their coal on a guaranteed analysis basis, the requirements of which were as follows:

DRY BASIS	Volatile Matter	(maximum)	22 per cent
	Fixed Carbon	(minimum)	73 per cent
	Ash	(maximum)	7 per cent
	Sulphur	(maximum)	1 per cent
	B. t. u.	(minimum)	14,700

To be placed on this list, and in position to supply the Navy with coal, a mine had to pass an inspection by the Navy Department. This has established what is now known as the Navy Acceptable List.

Seams Mined: Pocahontas No. 3; Pocahontas No. 4; Sewell-Davy.

VIRGINIA MINES

NAME OF COMPANY	NAME OF MINE	FIELD
Jewell Ridge Coal Corp.	Jewell Ridge	Clinch Valley Field

Pool No. 3

Description: Low-volatile slack coal from the Pocahontas and Tug River fields.

Seams Mined: Pocahontas No. 3; Pocahontas No. 4; Sewell-Davy; Welch and War Creek.

WEST VIRGINIA AND VIRGINIA FIELDS

For list of mines in this Pool, see Pool No. 2, the mines in which are identical with those in Pool No. 3.

Pool No. 4

Description: Medium-grade, low-volatile, run-of-mine coal from the Pocahontas and Tug River fields.

Seams Mined: Pocahontas No. 4; War Creek.

WEST VIRGINIA MINES

Fleet of Railroad Cars with Export Coal Ready for Dumping at Lamberts Point.

SEWALLS POINT COAL EXCHANGE

INCORPORATED

Organization, Railroad, Method of Classification, Pools and Their Specifications, Standard Analyses, Seams Worked, List of Mines

OFFICERS

G. H. CAPERTON, President, Charleston, W. Va.
 W. P. TAMS, Jr., Vice-President, Tams, W. Va.
 S. T. SNEAD, Secretary-Treasurer and Commissioner, 517 Flatiron Bldg., Norfolk, Va.
 H. H. SMITH, Deputy Commissioner, Norfolk, Va.
 J. S. BURROWS, Consulting Engineer, Norfolk, Va.

The Sewalls Point Coal Exchange was organized in June, 1920, to provide a means for pooling of coal at the Sewalls Point Pier of the Virginian Railway. The Exchange is run entirely by coal operators who ship to this point. From the terminus to the nearest mines, where the Virginian enters the eastern part of the Pocahontas field in Mercer county, West Virginia, is about 400 miles. The Virginian Railway was built primarily as a coal carrying road. It serves the greater portion of the famous New River field, a small portion of the Pocahontas field and a few mines located in the marginal territory of the Kanawha field.

This railroad is unusually well situated, by reason of its down grade to the seaboard and its large capacity coal cars, to handle an immense tonnage in one load. Recently it hauled what is claimed by the management to have been the longest coal train ever handled over the tracks of any railroad, the load consisting of one hundred 120-ton cars of coal, making a train one and one-tenth miles in length.

Method of Classification

The pool to which a mine belongs is fixed by the chemical analysis of its coal. Mines are given a classification based on the results of an analysis made on samples collected at the tippie during loading, in conjunction with data on the method of mining and preparing the coal. There is no assurance, however, that the classification which a mine receives is a permanent one, as its continuance in the pool assigned depends upon the quality of its daily shipments. Mines that do not ship coal within the standard limits are demoted as soon as it is ascertained that their shipments are falling below the standard in quality. On the other hand, mines which by reason of improvement are running ahead of the standard of the pool may be promoted. This system provides an incentive for betterment and likewise a strong reason for watchfully maintaining the quality of coal as fixed in the standardization test.

The method of testing the performance of mines is by means of sampling and analyzing daily shipments. For the purpose of sampling commercial shipments in quantities, the Exchange has provided a specially designed plant, consisting of three units, as follows: The dumper, which is separate from the main dumper of the pier, with its own tracks and connections to the pier; the riffle car of sixty tons capacity, which is self propelled; and the sampling and crusher station.

The operation of the plant is as follows: A car of coal to be sampled is run up into the dumper under which the riffle car is standing. The coal from the railroad car is rolled and mixed in passing through the dumper and falls in a wide stream into the riffle car. The body of the riffle car is arranged like a laboratory riffle and the separate compartments cut out a portion of the stream of fifty to sixty tons of the coal flowing in from the dumper.

When loaded the riffle car is run down to the sampling station and ten thousand pounds of coal is discharged from the compartments through a feeder, crusher and bucket elevator, in which it is finally carried to the top of the station, where an automatic device cuts out a portion of the gross sample, which is further reduced to laboratory size as it passes through the plant. The balance of the sample is all returned to the riffle car, which when the sampling is completed proceeds to the top of the pier, discharges and returns to the dumper for the next sample. All sampling and analysis done for the Exchange is under the supervision of the Bureau of Mines.

Authority For List of Mines

The list of mines here given has been taken from Circular No. 116-E, issued by the Virginian Railway Company as of date June 1, 1921. Inasmuch as changes may be made at any time, we do not guarantee the lists, nor are we responsible for inaccuracies.

Pool No. 1

Description: Standard low-volatile run-of-mine coal.

Specification:

Low-volatile run-of-mine coal from mines which on the average of all tests of the Sewalls Point Coal Exchange for a given mine show more than 15,500 B.t.u. per pound of moisture and ash free coal and which maintain a standard of ash in the dry coal analysis of not more than 7.50 per cent of ash as determined by tests of the Exchange. Coal with respect to size, coarseness and preparation thereof shall not be detrimental to the pool.

Seams Mined: Sewell, Beckley, Fire Creek, Pocahontas No. 3, Pocahontas No. 6.

	Moisture 2.50	Dry Basis
	Volatile Matter	18.50
	Fixed Carbon	75.50
	Ash	6.00
Standard Analysis:	Sulphur	0.75
	B.t.u.	14,700

List of Mines: For reasons already stated, the arrangement of low-volatile mines by pools is subject to constant change. The mines belonging to this pool will be found in the list which follows.

Pool No. 2

Description: Standard low-volatile run-of-mine coal.

Specification:

Low-volatile run-of-mine coal from mines which on the average of all tests of the Sewalls Point Coal Exchange for a given mine show more than 15,500 B.t.u. per pound of moisture and ash free coal and which maintain a standard of ash in the dry coal analysis of not more than 8.50 per cent of ash as determined by tests of the Exchange. Coal with respect to size, coarseness and preparation thereof shall not be detrimental to the pool.

Seams Mined: Sewell, Beckley, Fire Creek, Pocahontas No. 3, Pocahontas No. 6.

	Moisture 2.50	Dry Basis
	Volatile Matter	17.50
	Fixed Carbon	74.50
Standard Analysis:	Ash	8.00
	Sulphur	0.75
	B.t.u.	14,400

List of Mines: The mines belonging to this pool will be found in the list which follows.

Pool No. 3

Description: Low-volatile slack coal.

Specification: None.

Seams Mined: Sewell, Beckley, Fire Creek, Pocahontas No. 3, Pocahontas No. 6.

Standard Analysis: None.

List of Mines: The mines belonging to this pool will be found in the list which follows.

Pool No. 4

Description: Standard low-volatile run-of-mine coal.

Specification:

Low-volatile run-of-mine coal from mines which on the average of all tests of the Sewalls Point Coal Exchange for a given mine show more than 15,500 B.t.u. per pound of moisture and ash free coal and which maintain a standard of ash in the dry coal analysis of more than 8.50 per cent of ash but not more than 12.50 per cent of ash as determined by test of the Exchange. Coal with respect to size, coarseness and preparation thereof shall not be detrimental to the pool.

Seams Mined: Sewell, Beckley, Fire Creek, Pocahontas No. 3, Pocahontas No. 6.

	Moisture 2.50	Dry Basis
	Volatile Matter	17.00
	Fixed Carbon	73.00
Standard Analysis:	Ash	10.00
	Sulphur	0.75
	B.t.u.	14,100

List of Mines: The mines belonging to this pool will be found in the list which follows.

Pool No. 8

Description: Standard medium-volatile run-of-mine coal.

Specification:

Medium-volatile run-of-mine coal from mines which on the average of all tests of the Sewalls Point Coal Exchange for a given mine show not less than 15,400 B.t.u. per pound nor more than 32.50 per cent volatile, both on a moisture and ash free basis, and which maintain a standard of ash in the dry coal analysis of not more than 8.50 per cent of ash as determined by test of the Exchange. Coal with respect to size, coarseness and preparation thereof shall not be detrimental to the pool.

Seam Mined: Eagle.

	Moisture 2.50	Dry Basis
	Volatile Matter	28.75
	Fixed Carbon	63.25
Standard Analysis:	Ash	8.00
	Sulphur	0.90
	B.t.u.	14,300

THE SPECIFIC GRAVITY OF COAL

Two Methods of Determining: Table of Specific Gravities and Weights of Loose Coal for Coals of the United States and Foreign Countries

Specific Gravity—How Found

By the term specific gravity of coal is meant its weight compared with a like volume of water. Thus coal said to have a specific gravity of 1.30 means that it is 1.30 times as heavy as an equal bulk of water. Since the weight of water is usually taken as 62.5 pounds per cubic foot, a like volume of coal would weigh 1.30×62.5 pounds, or 81.25 pounds.

There are various methods of determining specific gravities, but only the two most commonly in use are here described. The first requires the use of a small scale or balance. A clean lump of coal is selected and weighed, preferably by slipping over it a noose of light cord and suspending it from one of the scale pans. The lump is now immersed in water and its apparent weight again noted. The specific gravity is then arrived at by use of the

formula, $\text{Sp. gr.} = \frac{W_a}{W_a - W_w}$, in which W_a = weight

of coal in air; W_w = the apparent weight of coal in water.

The second method involves the use of a stout flask of about 250 cc capacity and having a long and slender neck.* Make a mark by file or etching at the base of neck and carefully determine the capacity of the flask in cubic centimeters up to this mark. This is best done by using a pipette of 100 cc capacity and a burette of similar capacity graduated in 0.2 cc.

Take 100 grams of coal which has been crushed to about 4 mesh, weighing this accurately to .1 of a gram. Place the coal in the flask and add 100 cc of water. Shake the bottle gently in order to disengage all air bubbles entangled in the coal. When air bubbles cease rising, water is run in from the burette. But, before the flask is filled to the mark, 5 c. c. of oil is added from a small pipette. This 5 c. c. of oil must be accurately measured and is, therefore, best added from a 5 c. c. "delivery pipette," or, if desired, a "capacity pipette" may be used. In that case, however, the same pipette should be used in calibrating the flask. After adding the oil, fill the flask to the mark with water. The results may be calculated in accordance with the formula

$\text{Sp. gr.} = \frac{100}{V_o - V_i}$, where 100 equals the weight of

the coal; V_o equals volume of the flask in cc of water to the mark on neck; V_i equals number of cc required to bring water to the mark when coal is in the flask.

As an example, 100 grams of anthracite coal were taken; the volume of the flask, V_o was 262 cc; and the volume of water added to the coal, V_i was 197.

$$\text{Sp. gr.} = \frac{100}{262 - 197} = \frac{100}{65} = 1.54$$

The advantage in using an even 100 units of weight for each test will be apparent as the answer can then be readily read off from a table of reciprocals. Duplicate determinations with the flask method show an accuracy of 0.02 unit of specific gravity.

Practical Value of Information

A knowledge of the specific gravity of coal is important in several ways, one of which is in arriving at the contents of an acre of coal. A difference of merely .01 in the specific gravity makes a difference of 13.6 short tons of solid coal per acre foot, or in the case of a 7½-foot seam this would amount to over 100 tons per acre. In the next place the specific gravity of a coal may help to identify it as coming from a certain seam or locality. Perhaps the most common usage of specific gravities is as an index to its quality, since it bears a definite relation to the ash content of the coal, thus from a given mine coal samples having approximately the same specific gravity will have approximately the same ash content. Fulton† gives the following specific gravities for clean coal and associated impurities:

	Specific Gravity
Water	1.00
Clean coal	1.25 to 1.50
Bone coal	1.45 to 1.80
Slate	2.25 to 2.50
Coal or slate with pyrites...	3.20 to 3.60
Pyrites	5.00 to 5.20

A. G. Blakeley‡ states that for anthracite coal an increase of 1 per cent. in the ash content will correspond to an increase in specific gravity of approximately 0.01. If a coal from a certain mine shows a specific gravity of 1.61, corresponding to 13 per cent. ash content, and a second sample from the same mine shows a specific gravity of 1.80, it may safely be assumed that the second sample will have an ash content of approximately 32 per cent. Averages of hundreds of results on many different coals form the basis on which this statement is made. The specific gravity of a coal, therefore, can be used as a quick means for determining its quality, provided it is known what the average specific gravity of coal from a certain mine or region should be.

In the following table, specific gravities have been given wherever available; in the absence of specific gravity the weight of loose coal is given instead:

*Extracted from a description of the flask method by A. G. Blakeley and E. M. Chance in *Journal of Industrial & Engineering Chemistry*, 1909.

PART TWO

CLASSIFICATION OF COALS

I. ACCORDING TO RANK *

Methods of Classification; Description of Anthracite, Semianthracite, Semibituminous, Bituminous, Cannel, Subbituminous, Lignite, With a List of Seams Producing Each of the Ranks Named; Comparison of Different Ranks.

To serve the purposes of this book coals have been classified in three ways: first, according to rank; second, according to their commercial use; third, according to their trade name or physical structure. The classifications will be treated in the order named.

Methods of Classification

In this book the word "rank" will be used to designate those differences in coal that are due to the progressive change from lignite to anthracite, a change marked by the loss of moisture, of oxygen, and of volatile matter. This change is generally accompanied by an increase of fixed carbon, of sulphur, and probably of ash. When, however, one coal is distinguished from another by the amount of ash or sulphur it contains, this difference is said to be one of grade. Thus "a high-grade coal" means merely one that is relatively pure, whereas "a high-rank coal" means one that is high in the scale of coals, or, in other words, one that has suffered devolatilization and that now contains a smaller percentage of volatile matter, oxygen, and moisture than it contained before the change occurred.

Within the boundaries of the United States there are all ranks of coal, from the coarse, woody lignite of North Dakota and eastern Montana, to the highest rank of anthracite in the fields of eastern Pennsylvania. From the earliest days of coal mining in this country it has been recognized that coals differ greatly, not only in the percentage of ash which they contain, but also in their inherent composition. Although the latter distinction was recognized, little or no attempt was made to determine the reason for the difference or the criteria for fixing the limits of different groups of coals. The first serious attempt in this country to devise a scientific basis for the classification of coals was made by Persifer Frazer, Jr., of the Second Geological Survey of Pennsylvania, under the direction of J. P. Lesley. Frazer† listed most of the commercial coals of the State and then compared the trade distinctions with the "fuel ratio" (the quotient of the fixed carbon divided by the volatile matter of the proximate analysis). He found that there were in use at that time the rank names of anthracite, semianthracite, semibituminous, and bituminous. He found that in practice the fuel ratios of the coals of the different groups overlapped, but he concluded that these ranks might be established with the following limits:

	Fuel ratio.
Anthracite	100 to 12
Semianthracite	12 to 8
Semibituminous	8 to 5
Bituminous	5 to 0

These ranks, with the boundaries fixed provisionally by Frazer, serve very well for Pennsylvania and for the coals of the great Appalachian trough, extending from northern Pennsylvania to central Alabama, but they do not apply to the great mass of western coals, which at that time were of little or no importance. Most of those persons who were instrumental in developing the coal fields of the West originally came from the East, and they carried with them ideas of coal obtained in the eastern fields, which contained high-rank fuel. Not only that, but most of the coals in the Appalachian region and those in the upper Mississippi Valley are of Carboniferous age and hence are very old; but the coals of the West are Cretaceous and even Tertiary in age and hence, when compared with Appalachian coals, are very young indeed. A difference in character was recognized, and as the western coals are generally inferior they were lumped together and called merely "lignite." The term "lignite" is undoubtedly appropriate for many of the low-rank coals of the West, but it is certainly not appropriate for black, shiny coals that show little trace of woody texture and are capable of producing a coke of fairly good quality. Nevertheless such coals are called lignite and relegated to the lowest rank among coals.

Several persons have attempted to devise schemes of classification based upon chemical composition by which a certain coal could be referred to its proper place merely by means of its chemical analysis, but so far no scheme of this kind has been devised that is applicable to all ranks of coal. Some scheme like Frazer's suits admirably one part of the column but cannot be made to fit the other part. Schemes of this kind are so unsatisfactory that the

*The description of coals according to rank has been extracted from Professional Paper 100-A, "The Coal Fields of the United States", by Marius R. Campbell, by permission of the United States Geological Survey, George Otis Smith, Director. (The Survey is not responsible for the list of seams which follow each rank, these being based on information derived from sources other than the Professional Paper referred to.—Editor.)

†Pennsylvania Second Geol. Survey Rept. MM. p. 143, 1879.

United States Geological Survey has finally decided that it is practically impossible to classify all ranks of coal according to their chemical composition, and that it is necessary to supplement chemical by other criteria. Accordingly, Frazer's scheme, with some necessary modification to make it agree more closely with modern trade practices, has been adopted for the higher ranks of coals, and physical characteristics have been used for the lower ranks. Thus, in the West no one questions that there is coal of the rank of lignite, but it is difficult, if not impossible, to specify what a lignite is in terms of its chemical constituents. Similarly in the Rocky Mountain region, where the low-rank coals are abundant, there is no question that there is a difference between brown, woody, or amorphous lignite and shiny, black subbituminous coal, but this difference is one that is not clearly defined by available chemical criteria. There is, however, a marked physical difference, although there is no sharp line of demarcation between them. Thus subbituminous coal is black and shiny, whereas lignite is dull and generally woody in texture; subbituminous coal has a greater heating value and carries less moisture than lignite. Altogether the difference between the two is so marked that they are known by different names in the trade, and for that reason, if for no other, they should be classed differently.

In a like manner the distinction between subbituminous and bituminous is not sharp and does not show in a chemical analysis. Subbituminous

coal generally carries more moisture than bituminous, but there are so many exceptions to this rule that it has very little value as a means of distinction. There is, however, one marked difference by which they can always be separated, and that is the difference in their behavior under weathering, and as this difference has a marked effect upon their commercial value and use it seems to be a legitimate criterion for separating them into the two ranks, subbituminous and bituminous. The difference in the effect of weathering is due primarily to a difference in the percentage of moisture in the coal, but, as stated above, the percentage of moisture is variable. Subbituminous coals, however, in general contain more moisture than bituminous coal, and on weathering lose their moisture readily. This loss of moisture results in shrinkage and the formation of incipient cracks, which do not conform to the few joint faces but tend to run irregularly. On the other hand, the bituminous coals generally contain a smaller percentage of moisture, so that they shrink very little when they are suddenly dried. They may be very highly jointed and may fall to pieces readily when mined and handled, but their breakage is due to the inherent weakness of the coal, and the cracks almost invariably correspond with the joint faces.

By using these criteria (part chemical and part physical) it is possible to classify coals and not only to define the general characters of the different groups but to delimit them with considerable accuracy. The United States Geological Survey recognizes the ranks indicated below.

ANTHRACITE

Anthracite is generally well known and may be defined as a hard coal having a fuel ratio (fixed carbon divided by the volatile matter) of not more than 50 to 60 and not less than 10. Most of it is mined in eastern Pennsylvania, where its peculiar quality is due to regional metamorphism—that is, to the crushing stresses that affected the crust of the earth when the rocks were thrown into the great folds that characterize this region. Small areas of anthracite occur in the West, but generally these coals have been converted to anthracite by the heat of some mass of igneous rock that was thrust into the other rocks while it was in a molten condition. Many such masses take the form of thin sheets, which were forced in between the beds of the other rocks, and consequently for some

distance they may lie parallel with the coal beds. If a coal bed is cut by the igneous rock, it may be burned to ashes, made into coke, or converted to anthracite. The product will depend on the presence of air, the intensity of the heat, and the length of time the coal was subjected to the influence of the heated mass. Anthracite is an almost ideal domestic fuel, but it is not well adapted to steam raising unless an absolutely smokeless coal is needed. Many people believe that anthracite has greater heating value than any of the other ranks, but this is not true, as can be seen by reference to the figure shown farther on under the head of Comparison of Different Ranks. Largely on account of its low heating power anthracite is not an economical fuel for steam raising or for use in general manufacturing.

SEMIANTHRACITE

Semianthracite is also a hard coal, but it is not so hard as true anthracite. It is high in fixed carbon, but not so high as anthracite. It may be defined as a hard coal having a fuel ratio ranging from 6 to 10. The lower limit is uncertain, as it is difficult to say where the line should be drawn to separate "hard" from "soft" coal and at the same time to divide the two ranks according to their fuel ratio. Some hard coals of the anthracite type have a fuel ratio as low as 6.5 or 7, whereas some of the soft coals have a fuel ratio as high as 7 or perhaps more. For this reason it is probable that fuel ratio

alone can not be depended upon to separate these two ranks, but that physical properties also may have to be taken into consideration. The change of ordinary soft coal to semianthracite is due to the same causes that produced anthracite, except that the process has not been carried so far in semianthracite, possibly because the action has not been so intense. There is very little semianthracite in this country, so it is only a small factor in the coal trade. Such semianthracite as is mined reaches the consumer generally under the name "anthracite" and is masquerading under false colors.

SEMIBITUMINOUS

The name "semibituminous" is exceedingly unfortunate, as literally it implies that this coal is half the rank of bituminous, whereas it is applied to a kind of coal that is of higher rank than bituminous—really superbituminous. Semibituminous coal may be defined as coal having a fuel ratio ranging from 3 to 7. Its relatively high percentage of fixed carbon makes it nearly smokeless when it is burned properly, and consequently most of these coals go into the market as "smokeless coals." The best coal of this type has a heating value greater than that of any of the other ranks and is consequently best adapted to raising steam and to general manufacturing that requires a high degree of heat. It is regarded as the best coal for steamship and especially for naval use, as it is nearly smokeless and requires less bunker space per unit of heat

than other coals. The coal is generally minutely jointed and is therefore tender and friable. In fact, it is so friable that in mining a large percentage of fine coal is produced, and in transportation many of the lumps are broken to pieces, so that by the time it reaches the consumer, especially if it has been transshipped, it is generally in small pieces. This fineness is by many regarded as detrimental, because the public is accustomed to lump coal which will stand transportation without crushing, but when this coal is used with mechanical stokers and with a grate adapted to its use the fineness of the coal is not disadvantageous. The great bulk of this kind of coal is in the eastern fields, but some is found in the West, where it has been subjected to a slight amount of regional metamorphism or has been heated by some igneous mass.

BITUMINOUS

The term "bituminous," as generally understood, is applied to a group of coals having a maximum fuel ratio of about 3, and hence it is a kind of coal in which the volatile matter and the fixed carbon are nearly equal; but this criterion can not be used without qualification, for the same statement might be made of subbituminous coal and lignite. As noted before, the distinguishing feature which serves to separate bituminous coal from coals of lower rank is the manner in which it is affected by weathering. Bituminous coal is only slightly affected chemically by weathering unless it is exposed for many years, and then, although it consists of small particles, each particle is a prismatic fragment, whereas coals of lower rank break into thin plates parallel with the bedding.

The definition given above might not indicate that the bituminous rank is a large one, but when it is examined critically it is found to contain a great variety of coals—coals having really little in common with one another. Many attempts have been made to subdivide this great group, but so far no scheme proposed has met with general approval. Many of the better coals of this group will coke or are being coked, but coking coals are not limited to the bituminous rank, for some of the best coke made in the United States is produced from semibituminous coal. Not only is the upper limit of the coking group uncertain, but the lower limit is equally difficult to determine. If the coking property had some definite relation to the chemical composition of the coal as it is at present determined there might be some hope of establishing a class of coking coals by chemical analysis, but no one can say just why a coal will coke, so an actual test in an oven is required to determine whether or not a coal will coke.

Gas coals have been in great demand and such coals must be high in volatile matter, so as to make on distillation a large volume of gas; and as this gas must be relatively free from sulphur the coal from which it is made must contain a very small percentage of that element. In recent years the making of gas for illuminating and heating has undergone a great change, water gas largely taking the place of the gas distilled from coal; and as this gas requires no particular quality of coal, the demand for "gas coals" has been greatly reduced and probably in the near future will disappear.

Cannel coal is very rich in volatile matter, is generally high in hydrogen, and therefore burns with a great heat and a long flame. It is essentially a gas-making coal and in the early days was used extensively for this purpose, as well as for the distillation of oil. As a source of oil it could not compete with petroleum derived from wells, and soon after oil was discovered in the earth in 1859 the business of distilling oil from coal in this country was discontinued. Cannel coal owes its richness to the fact that it is composed almost entirely of the spores, spore cases, seed coats, and resinous or

waxy products of such plants as lived at the time of the existence of the coal swamp. In such swamps, as in those of today, there was doubtless in places open water, into which the spores and seed cases floated and, becoming water-logged, sank to the bottom and in time produced cannel coal. The absence of woody material in such coal gives it a regular texture and grain that are not found in any other coals. As a result, it breaks like glass, with a conchoidal or shell-like fracture, and owing to its richness in inflammable material the best of it will ignite readily when a lighted match is held in contact with a small splinter of it. As the nature of cannel coal is due to the kind of material of which it is composed, it follows that there may be all kinds of cannels, corresponding in a general way with the various ranks of coals. Ashley* has recently proposed the following classification of cannel coal:

1. Subcannel coal:
 - (a) Brown subcannel, of brown coal or lignite rank.
 - (b) Black subcannel, of subbituminous rank.
2. Cannel coal, of bituminous rank:
 - (a) Boghead cannel (fuel ratio less than 0.5).
 - (b) Typical cannel (fuel ratio between 0.5 and 1).
 - (c) Lean cannel or semicannel (fuel ratio more than 1).
3. Canneloid, semibituminous coal, semianthracite, anthracite.

Cannels which are of the rank above bituminous have lost their original richness and therefore do not deserve to be called cannels.

Other kinds of coal, such as "block" and "splint," are recognized in the trade, but the characteristics of these coals are physical and are found in only a small group of coals. Some of the "block" and "splint" coals are very hard, almost as hard as anthracite, but they are generally woody in texture and contain much mineral charcoal. They are valuable coals in the market, but usually their development is so local that they are not of much importance in a general classification of coal.

(The list of cannel seams includes those which are cannel only in part and at irregular intervals. Thus, cannel coal is found only at times in the top portion of the Cedar Grove and Chilton seams in West Virginia. In the eastern part of Kentucky cannel coal sometimes constitutes the entire seam, but is more generally found as a bench or portion of the main seam.—Editor.)

*Ashley, G. H., Cannel coals in the United States: U. S. Geol. Survey Bull.—(In preparation.)

SUBBITUMINOUS

The term "subbituminous" is adopted by the Geological Survey for what has generally been called "black lignite," a term that is objectionable because the coal is not lignitic in the sense of being distinctively woody, and because the use of the term seems to imply that this coal is little better than the brown, woody lignite of North Dakota, whereas many coals of this rank approach in excellence the lowest grade of bituminous coal. Subbituminous coal is generally distinguishable from lignite by its black color and its apparent freedom from distinctly woody texture and structure, and from bituminous coal by its loss of moisture and the consequent breaking down or "slacking" that it undergoes when subjected to alternate wetting and

drying. As the percentage of moisture is an important matter in buying and shipping coal, and as the slacking on exposure to the weather makes it necessary to ship in box cars and to guard carefully against spontaneous ignition, there is a great commercial difference in these two kinds of coal which the Geological Survey has recognized by putting them in different ranks. Despite the many drawbacks in the shipment and use of subbituminous coal it has found a ready market in much of the western country, because it is a very clean domestic fuel and ignites with little difficulty.

Subbituminous coals differ considerably in chemical composition and in physical appearance. Some are banded like much of the bituminous coal,

and some are essentially cannel in physical and chemical make-up. In general, the Cretaceous and younger coals of the West contain a smaller percentage of sulphur than the older coals of the East,

and as some of them are high in volatile matter they would doubtless be excellent coals for making gas, either illuminating gas or producer gas for generating power.

LIGNITES

The term "lignite," as used by the Geological Survey, is restricted to those coals which are distinctly brown and either markedly woody or clay-like in their appearance. They are intermediate in quality and in development between peat and subbituminous coal. As the moisture of lignite as it comes from the mine generally ranges from 30 to 40 per cent, its heating value is low; and the consumer can not afford to pay freight for any great distance on so much water. Also it parts with much of this moisture very readily when exposed to the weather and so falls to pieces or slacks much more readily and completely than subbituminous coal. On this account it is more likely to ignite spontaneously and must be handled even more carefully than subbituminous coal and stored in a place where it will not be exposed to alternate wetting and drying. Lignite is mainly marketed near the mine, as a domestic fuel, but at a few places in North Dakota and Texas it is shipped to near-by towns and used for general manufacturing purposes.

At the Government testing plant at the St. Louis Exposition, North Dakota lignite was found to be an excellent fuel for making producer gas, and probably in the future it will be much more largely used for producing power than it has been in the past. Just how this will be accomplished is difficult to determine, but it is possible that large producer plants may be erected at the mines and the lignite converted into electric energy and delivered by long-distance transmission lines to towns within a radius of 200 miles or to the railroads in this region or in contiguous territory. Lignite has recently been used in powdered form, and it may possibly be better utilized in this way. As some of the Texas and Arkansas lignites are in effect undeveloped cannel coals, it seems possible that when the supply of petroleum is much less than the demand, the lignite may be used for the distillation from it of oil and the various by-products that are now obtained in Scotland from oil shale. Lignite can also be manufactured into hard briquets, which make an excellent fuel, but so far the cost of manufacture has been prohibitive.

COMPARISON OF THE DIFFERENT RANKS

Figure 2 is a graphic representation of the proximate chemical composition of the various ranks of coal and of their heat-producing values. The lower diagram shows the fairly regular increase in fixed carbon from lignite to anthracite, though it must not be supposed that the lines for all coals are as simple as those shown in the diagram. The analysis upon which the diagram is based are, however, actual analyses. No. 1 represents the analysis of a typical North Dakota lignite which as it comes out of the mine has a moisture content of about 40 per cent. It also contains about 5.5 per cent of ash, but as ash varies irregularly without regard to the rank of the coal the analysis has been recalculated to the ash-free basis, thus eliminating ash from consideration. All the other analyses have been similarly recalculated. No. 2 represents a subbituminous coal from Wyoming, having

a moisture content of 23.4 per cent; Nos. 3, 4, and 5 represent various ranks of bituminous coal, the lowest one being from Indiana, the second from Ohio, and the third, or highest, from the Pittsburgh district of Pennsylvania; Nos. 6 and 7 represent semibituminous coal from the Windber district of Pennsylvania; No. 8 represents semianthracite, and No. 9 represents some of the best anthracite of the Pennsylvania region. The diagram shows clearly that the fixed carbon increases very markedly from lignite to anthracite; that the moisture of the higher-rank coals is small and about the same quantity in each, but increases rapidly from medium-rank bituminous coal to lignite; and that the greatest development of volatile matter is not at either end of the series but in the lower ranks of bituminous coal.

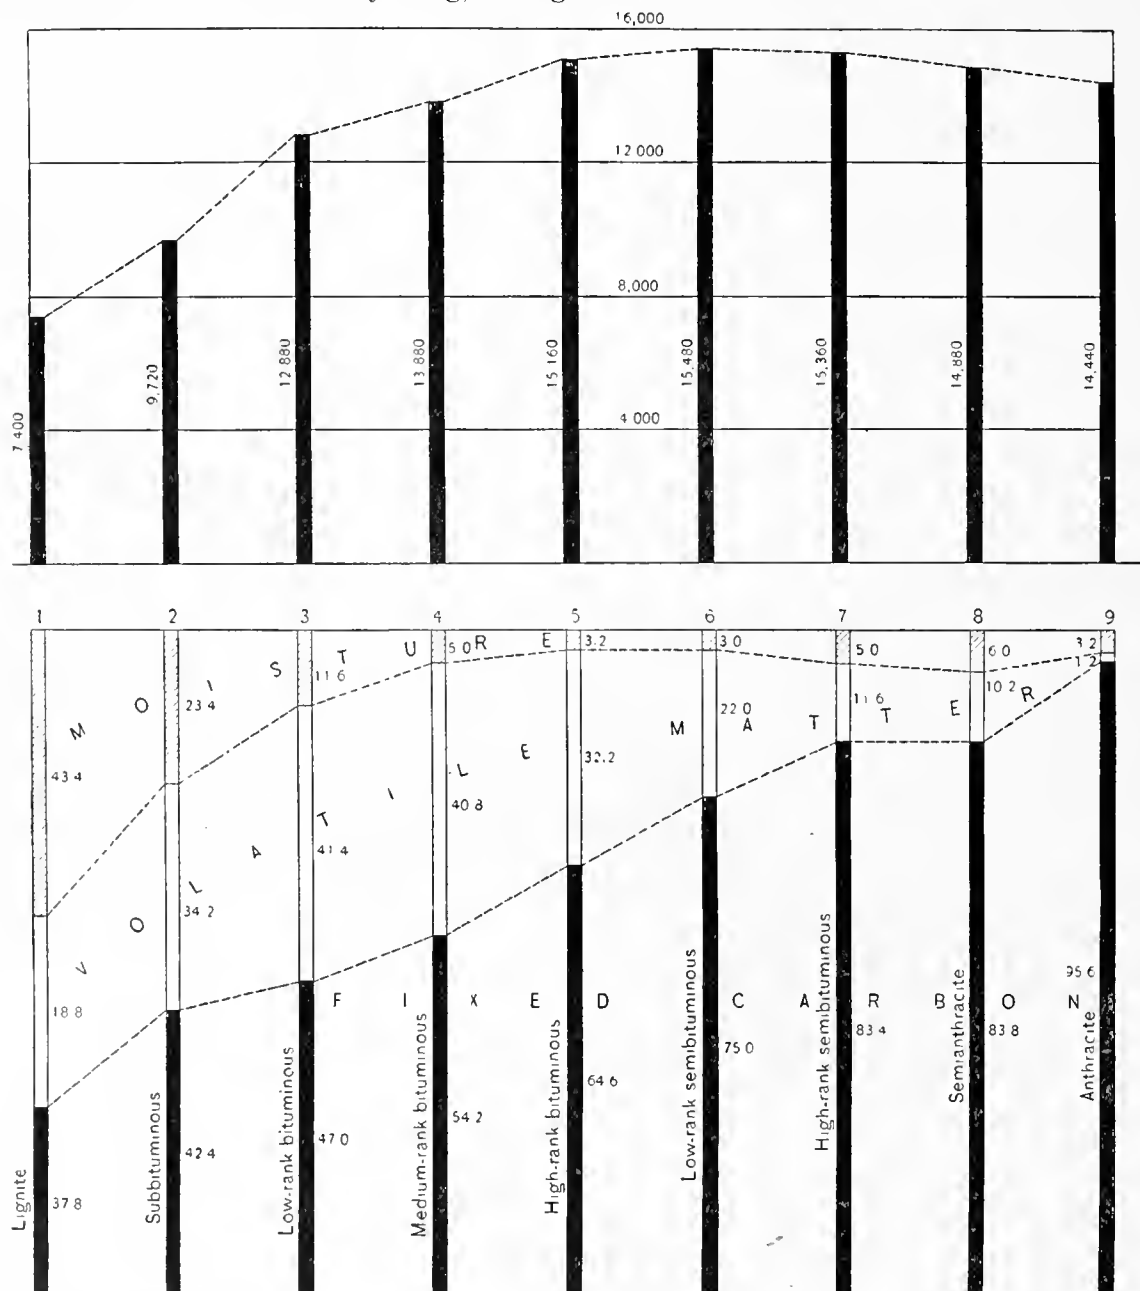

Figure 2—Diagrams showing the chemical composition and heat efficiency of the several ranks of coal. Upper diagram: Comparative heat value of the samples of coal represented in the lower diagram, computed on the ash-free basis. Lower diagram: Variation in the fixed carbon, volatile matter, and moisture of coals of different ranks, from lignite to anthracite, computed on samples as received, on the ash-free basis. Figures on lower diagram represent percentages.

The upper diagram represents the heat value of the same coals on a similar ash-free basis. There is a very general misconception regarding the heat value of anthracite as compared with that of lower-rank coals. Many persons think that because anthracite commands a higher price it must necessarily be a better heating coal than the soft varieties, but this diagram shows conclusively that it is not and that the best coal for heat production is No. 6, or low-rank semibituminous coal. Anthracite commands a higher price than soft coal because of its suitability for domestic use and because of its freedom from smoke, soot and waste.

From the diagram it might be inferred that the heat value of a coal depends directly upon the amount of fixed carbon that it contains, but this can not be true, for the heat value of pure carbon is only 14,580 British thermal units,* whereas coal No. 6 has a heat value of 15,480 British thermal units. Coal derives its heat value mainly from two elements, carbon and hydrogen, the carbon having a heat value of 14,580 British thermal units and the

hydrogen a heat value of 62,000 British thermal units.* The greater heating power of the low-rank coals as compared with anthracite is due to the fact that these coals contain a considerable quantity of available hydrogen,† which when burned produces a much greater heat than the same weight of carbon.

Either diagram well illustrates the slight value of lignite as compared with the higher-rank coals and makes it possible to understand that Pennsylvania and West Virginia coal can be hauled by rail to Lake Erie, shipped by vessel to Duluth or Superior, hauled 400 to 500 miles inland, and then sold in direct competition with lignite mined in the vicinity.

*Richards, J. W., *Metallurgical Calculations*, p. 16, 1906.

†W. S. Parr (*The Composition and Character of Illinois Coals*; Illinois Geol. Survey Bull. 2, p. 37, 1906) defines available hydrogen as follows: "By available hydrogen is meant that part of the hydrogen content which is free to enter into combination with oxygen for the production of heat, as distinct from that hydrogen present which already has *** the necessary equivalent oxygen for the formation of water, and consequently [is] noncombustible."

CLASSIFICATION OF COALS

II. ACCORDING TO USE

Methods of Classification; Qualifications of Coals Which Are Adaptable for Beehive Coking, Bunkering, By-Product Coking, Cement Burning, Domestic, Export, Illuminating Gas, Locomotive Fuel, Melting, Pulverizing, Producer Gas, Smithing, Steam, Tile and Pottery Burning and Water Gas Usages;
List of Seams Producing Coals Fitted for Each Use.

Growth In Usages of Coal

The year 1215 may be safely taken as the time in which coal mining became established in England. In the United States this industry has been in operation about 170 years.

Mining advanced slowly up to the year 1710. There was only one usage to which coal could be put, that of "house" coal, and the shallow workings of those early days easily furnished sufficient fuel to meet all demands. When James Watt, in 1763, began experimenting on steam, and improving the construction of engines, it drew the attention of a number of men, more or less familiar with mechanics, to the steam engine. It is interesting to note that the first application of Watt's invention was for pumping water from a coal mine.

George Stephenson's first locomotive, the "Rocket," made its initial trip from Stockton to Darlington, England, in 1825, while in the United States a short time later, in 1839, the "Tom Thumb", constructed by Peter Cooper, had its first run on the Baltimore and Ohio Railroad. The steam engine was rapidly introduced into all industries and its almost general adoption brought forth cries for coal from all quarters. It was evident that the industry had to expand greatly to meet the demands for steam, domestic and locomotive fuel.

Coal was first coked for blast furnace use in England in 1750. In the United States charcoal was in general use for making iron owing to the abundant timber supplies, so that no sustained attempt was made to carbonize coal until 1850. The first successful steamer was launched by Robert Fulton in 1807, thus providing an outlet for bunker coals and stimulating the possibilities in export trade. Murdock, after years of experimenting with gas distilled from coal, introduced gas lights in an English factory in 1803; street lights burning gas were used in Baltimore as early as 1817.

Thus it happened that increased production of coal, plus the insatiable desire of man to devise new processes or else to perfect old ones, steadily contributed new uses to which the fuel might be put. Some of these are of fairly recent origin. During the early years of the cement industry in this country, oil was employed by spraying it into the lower end of the furnace. The price of oil increased so rapidly that by the year 1900 it had to yield its place to pulverized coal, which has ever since remained the standard fuel for all plants except those located in the rich oil fields of the West. A more recent change still is found in the range

of fuels suitable for the manufacture of water gas. Whereas anthracite coal and coke once held undisputed sway, late years have brought forward some of the medium grade coals as a successful contender for preferment.

Methods of Classification

The classification of coals, According to Use, is based on (1) the requirements as stated under the head of qualifications for each usage; (2) the general and supplementary analyses of each coal; (3) the results of a questionnaire sent to several hundred sales agencies requesting their recommendation on coals for each specific usage; (4) the advertisements and trade literature of producers and sales agencies in which certain coals have been cited as adaptable for certain uses; (5) a search of mining, trade and institutional publications wherein mention is made of coals found acceptable for definite uses.

Considerable weight has been given to the last three mentioned aids, inasmuch as usage is the supremest test of a coal. Where reliable information on usage has not been obtainable dependence has been placed upon the chemical analyses. It must be understood, however, that the mention of a seam under any usage, other than the very general ones, is not meant to imply that the seam in all its localities, is fitted for a particular use. This may or may not be true. The only sure course is to consult the Supplementary Analyses, which follow the states, in each case, by means of which the favorable localities may be selected. Difficulties in classification have been met mostly with the coals of lesser reputation, many of which have never been called upon to meet the specifications for a special purpose, and on such as these no information could be forthcoming.

It is recognized that in any comprehensive classification of coals differences in opinion will arise, in some cases due to a too liberal inclusion of seams unworthy or untried, in others to a too conservative exclusion of some coals worthy of preferment. Special request is made of all users of the COAL CATALOG that they notify the publishers of any error, whether of omission or commission, in the tabulation of coals. Instances of successful or unsuccessful usage should be cited and mention made of the name of the seam, locality at which the coal is mined, the proximate analysis (as received) of the coal and the name and address of the user of the coal.

QUALIFICATIONS OF A COAL FOR BEEHIVE COKING

Coking coals are those which, when placed in the oven and distilled with a limited supply of air, soften, become pasty and swell into a spongy mass. During the process of coking the volatile matter is expelled from the coal, leaving a coherent cellular mass of coke. If the coal is non-coking there is little or no coherence of the particles and there remains in the oven a sandy residue.

The question as to what constitutes a coking coal has been, and still is, much discussed. The original theory that coking depended upon the coal having a goodly percentage of volatile matter has been clearly disproved by such coals as the Pocahontas of West Virginia, which contain about 16 per cent. of volatile matter and produce a celebrated coke, while, on the other hand, coals having as much as 34 per cent. volatile matter have failed to cohere. To further confute this theory it has been found that with two coals of approximately the same analyses, but coming from different seams, one produced a satisfactory coke while the other was sandy, weak bodied and totally unfit for use. The fact is that the proximate analysis of a coal is far from being conclusive proof of its coking or non-coking qualities. It is the experience of years that most of the Appalachian region coals, containing from 17 to 37 per cent. of volatile matter, may be made to yield a satisfactory coke, physically considered.

Investigators, in search for an explanation why some coals coke and others do not, have turned their attention to the ratios existing between carbon and oxygen; oxygen, hydrogen and carbon; hydrogen and oxygen, etc., as revealed by the ultimate analysis of the fuel. Lewes† states, as a generalization, that "coals having an oxygen content above 10 per cent. or below 4 per cent. means bad coke or non-coking."

Broadly speaking, it may be said that most coals of bituminous or semibituminous rank will coke in the oven, but the product of some seams will be found far superior to others. From a physical standpoint it has been demonstrated that coals having in the neighborhood of 32 per cent. volatile matter give the best results, and that with coals of this composition the proportion of gaseous content is about what is needed to maintain the heat of the oven, thus preserving the fixed carbon and showing a high yield of coke to coal used; those having a higher volatile content produce a coke

which is brittle or spongy, lacking strength for metallurgical purposes, and show a low yield of coke to coal used; those having a lower volatile content produce a coke which is porous and weak, and at a reduced yield, owing to some of the fixed carbon of the coal being burned to supply the necessary heat to the oven. It is certain that as coals approach the lignites on the one hand, and anthracite on the other, no tendency to coke is observed.

Since the great portion of coke produced in beehive ovens is used for metallurgical purposes, it follows that the adaptability of a coal for coking depends not alone on the physical structure of the coke produced, but also upon the absence of the two impurities—sulphur and phosphorus, both of which elements are objectionable to the furnace man. Everything else being equal, coals containing the least percentage of these impurities yield the best metallurgical coke. Not all the sulphur in the coal is transferred to the coke, as a certain proportion of that in the form of sulphide is volatilized in the oven. Assuming a coal of about 33 per cent volatile matter, so that there is required about $1\frac{1}{2}$ tons of coal to produce a ton of coke, it will be found that the resulting coke usually contains a slightly reduced percentage of sulphur over that found in the raw coal. The phosphorus in the coal is not affected in the process and remains in the coke.

The ash in coal is, of course, inert, and, based on thermal values, would, along with moisture, be preferably omitted. In using coke for blast furnaces, however, a requirement is that it have sufficient strength, or body, to enable it to bear without crushing the superimposed burden of ore and limestone. To ash is sometimes ascribed the virtue of strength, it being quite probable that much of it is fused to a silicate in the high heat of the oven, and that this gives strength or body to the product. It does not, however, follow that the strength of a coke is in proportion to the quantity of ash present.

In brief, it may be stated that coals best adapted to beehive coking are those in which the—
volatile matter is about 32 per cent.
ash is about 7 per cent.
sulphur is less than $1\frac{1}{2}$ per cent.
phosphorus is less than .02 per cent.

Coals that are high in sulphur and ash may be brought within the limits by such eliminating devices as washers, jigs or breakers, and with the gradual disappearance of the best coking coals recourse to these will need be more general in years to come.

†The Carbonization of Coal, pg. 179.

METHOD OF CLASSIFICATION

The following classification has been based both on analyses and usage. It is probably a safe statement that all coals in the Appalachian region, whether bituminous or semibituminous, will fuse and form coke in the oven. Strictly speaking, therefore, all seams found in this division should be included. The very abundant supply of coking coal, however, has restricted usage to those that meet the requirements chemically, and for this reason seams which must needs be washed to reduce the percentage of sulphur and ash have not been included amongst those of the highly favored fields, unless such washing is presently being done, as in the case of the coked coals of Alabama.

(Continued on Next Page)

In the Eastern Interior field, where the coals are characterized by a high sulphur content, the long haul required for bringing Connellsville coke to the furnaces early encouraged the installation of wash-eries, tables, etc., by means of which the excess impurities in the coal could be eliminated. Thus, by reason of present use, some of the coals of Western Kentucky and Illinois are classified as coking coals, while equally good or superior coals, such as the Sewickley and Redstone seams of the Appalachian region, have been omitted. The classification of coking coals in the Rocky Mountain province is based entirely on present usage and accepted coking tests.

The analysis of a coal is not a convincing proof of its coking quality. Other than its freedom from sulphur and ash, it tells little of its satisfactory quality as a coke, which is dependent largely upon physical characteristics. Barrel tests are likewise not conclusive, inasmuch as the heat supplied to the enclosed sample is derived from a coal different from that being tested. Coal, to be a good coking coal, must supply sufficient heat to store in the crown so as to ignite and coke the succeeding charges.

*Consisting of seams of minor importance

QUALIFICATIONS OF A COAL FOR BUNKER USE

A characteristic of ship service is that the boiler load is quite constant, a feature which is best met by fuels having the property of delivering their heat at a uniform rate. Anthracite coals answer this specification better than all others, and at one time were extensively used by steamship companies, but their high cost turned attention to other high grade fuels.

An important consideration in this service is that the amount of space in the hold of the vessel allowable for coal storage is limited. If a coal running high in ash and moisture—both incombustibles—and low in heat units were selected it would require a greater tonnage of fuel, and therefore more bunker space, than if a high-grade coal were used.

Low volatile, or smokeless, coals running high in thermal value and delivering the heat units at a uniform rate answer all the specifications for a bunker coal, and are preferably used. They run low in ash and sulphur, amply meeting the requirements, which may be stated as approximately under 10 per cent in ash and 2 per cent in sulphur. These smokeless coals are delivered as run-of-mine, in which form they may contain as much as two-thirds small coal. This fine coal is not objected to, as would be the case for locomotive

service, since the draft in vessel service is less than that found in railroad practice, and the fine coal is not blown out of the stack.

In considering fuel for war vessels, where disclosing their presence is to be avoided, the amount of smoke produced is of great importance, and for this additional reason low volatile coals are used.

High volatile coals, which are naturally quick firing and better suited for steam generation where loads are variable, have in late years come into use for bunker service.

METHOD OF CLASSIFICATION.

Coals in this classification are of the low-volatile high-heat type, a requirement best met with coals of semibituminous rank. Pennsylvania, West Virginia, Maryland and Virginia supply the Eastern terminals, while Washington meets some of the demands on the Pacific Coast.

A list of high volatile coals suitable for bunkering use will be found given under the list of seams producing coals suitable for Export.

QUALIFICATIONS OF A COAL FOR BY-PRODUCT COKING

When coal is coked in by-product ovens a true distillation takes place. Unlike the process with the bee-hive oven, there is no access of air to the coking mass and no wasting of the distilled gases. Heat for distillation is generated by burning, in flues surrounding the retort, a mixture of the lean fuel gases, derived as a part of the process, with air which has been pre-heated by passing through regenerators on its way to the ovens. The volatile gases expelled from the coal are collected in mains located over the oven and led to the recovery plant where, by suitable processes, the ammonia, tars and gases are separated as by-products.

The best test of a by-product coal is, of course, usage. The quality and quantity of the by-products enter into consideration, as well as the kind of coal produced. The first requirement obviously is that only coking coals be used. If the plant be located near a city, the intent evidently is to supply gas for domestic lighting and heating, while the coke may be sold for such purposes as domestic use, manufacture of water gas, heating salamanders, etc. The coal selected will be one that produces a high yield of gas and of by-products. If there

is a special demand for toluol, as was the case during the war, this would also result in the use of high-volatile coals, unmixed, in order to increase its yield.

By-product plants located at steel mills place the greatest stress on the quality of coke produced, and not on the by-products. The coke and gases are utilized in various ways about the mill for the production of heat and power, the tars and ammonia being disposed of in bulk. Coals for such uses must, therefore, be low in sulphur and phosphorus, and reasonably low in ash, as explained under the head of Bee-hive Coking. The percentage of volatile matter, according to present day practice, is preferably from 25 to 33 per cent., a range which, strange to say, fits but few of the coking seams of the country. Mixing of coals is, therefore, generally practiced, that is, a low volatile coal is mixed in such proportions with a high volatile coal as to bring the resulting mass to the desired percentage of volatile matter.

One fortunate feature of this mixing has been to make available, as coking coals, seams which, though otherwise well adapted, were either too low

or too high in volatile content to produce a coke of hard body and with a satisfactory yield. At this writing over 60 per cent. of the metallurgical coke used in this country is being produced in by-product ovens, making the value of coals suitable for this purpose readily apparent.

In general, the chemical qualifications of a bitu-

minous coal well adapted for by-product coking may be said to be:

volatile matter 17 to 38 per cent. (this range provides for mixing)
ash 4 to 8 per cent.
sulphur not more than $1\frac{1}{2}$ per cent.
phosphorus not more than .02 per cent.

METHOD OF CLASSIFICATION

The list of coals here given will be found closely parallel to those mentioned in the tabulation for bee-hive coking, for the reason that a coal which cokes in the bee-hive oven will do likewise in the closed retort. In fact it is doubtless true that more coals may, with justice, be classified as by-product coking coals than bee-hive coking coals. The comparative newness of the industry, and its early dependence upon such well known coals as the Pittsburgh seam of Pennsylvania, the Eagle and Pocahontas seams of West Virginia, the Elkhorn seam of Kentucky and the No. 6 seam of Illinois gave these an exclusive and well-deserved preeminence as by-product coals. However, it must appear from a consideration of the remarkably pure coals of Eastern Kentucky that practically all seams in that field will be found excellent for by-product usage, and, although many of these have never undergone an actual test, it is believed safe from the nature of these deposits to include them in the list.

In like manner the same may be said of such coals of West Virginia as are characterized by low sulphur, and if washing be assumed, then the list is subject to further enlargement. No assumption as to washing, however, has been made, as this will hardly be necessary while the industry is so centered that there is an abundance of pure coals at hand to meet all demands. Where washed coals are now being utilized, as is the case in Alabama and Illinois, such seams are included in the tabulation.

QUALIFICATIONS OF A COAL FOR CEMENT BURNING

Since in the burning of cement the ash of the coal becomes a part of the clinker, it is allowable to use coals having a medium ash content, as the impurities of the coal are approximately of the same composition as the cement. Sulphur has not been closely limited, as it does not enter into combination with the cement so long as the proper kiln temperatures are maintained.

Practically all the cement produced in the United States, outside of the natural gas and oil fields, is burned with coal in rotary kilns. The coal

is commonly shipped from the mine in slack sizes, and is reduced to a powder just before usage. This manner of firing is admirably adapted to the securing of high temperatures in long hearths.

The principal requirements of a fuel for this purpose are that it have a high heating value and that it shall be rich in volatile matter, so as to ignite readily and produce a long flame. The best bituminous coals naturally have the preference in the East, but low quality coal is used at places with success. Mills in the West usually buy the most accessible coal.

METHOD OF CLASSIFICATION

Two qualifications necessary for coals in this list are, a percentage of 31 or over in volatile matter and a B. T. U. value of 12,000 or over. Exceptions to this rule have been made in one or two instances of western coals where isolation from the sources of better coals would naturally permit the use of a fuel lower in calorific intensity. From the tabulation it will appear that 20 out of 24 states can furnish a grade of coal satisfactory to the demands of the industry.

*Consisting of seams of minor importance

QUALIFICATIONS OF A COAL FOR DOMESTIC USE

It is difficult to define the requirements of a house coal, since every kind of coal is used for this purpose, depending somewhat upon locality. Where open grates are found a bright cheerful fire is wanted, burning at such a rate as to produce an even amount of heat with a minimum of attention. High volatile coals, because of the long flame and better burning qualities, are preferred although much gas may escape unburned and the effective heat be low. Coals high in sulphur are productive of sulphurous fumes when the draft conditions are bad, and these tarnish picture frames and silverware and also corrode the grate and fuel bowl.

A good house coal should be selected for its free-burning qualities and low ash content. Coals which give off much smoke are objectionable in closely settled communities, and in many cities their use is regulated by ordinances. A coal which readily becomes pasty and spreads into a coked mass, needing a frequent breaking up to promote the passage of air through the fuel bed, is undesirable, especially for self-feeding stoves or base burners. The ash produced in burning should be small in quantity, gray and cindery as compared with the soft white powdery ash characteristic of a good steam coal. A reasonable amount of porous clinker is desirable, as it prevents the fine coal from falling through the grate.

The matter of size is all important in the consideration of a domestic coal. One of the first requirements is that the coal be hard, firm and lumpy. It must be loaded clean and free from slack, in large sizes, as lump, egg or nut, and stand shipping without excessive degradation. Impurities such as slate, bony coal and nodules of iron pyrite are now generally removed on the tippie or breaker by picking. In bituminous regions, the coal on leaving the screens is led to a travelling belt, with boys or men on either side to sort out the waste material. The travelling belt and loading boom may be installed as one unit, the latter serving to lower the large lumps into the car without excessive breakage. Coals prepared in this careful manner are highly regarded as domestic coals. Much fine coal is objected to, as it interferes with the draft and necessitates constant attention.

Anthracite coals are the standard domestic fuels, and as such have held priority for years, commanding a price much in excess of the best bituminous coals. In the Eastern states the domestic sizes are stove and chestnut for ranges and small heaters, and egg for use in furnaces. They are high in calorific value and give off their heat at a uniform rate; do not become pasty in burning; need little attention; lend themselves to easy draft regulation; are smokeless, and produce a small

amount of pulverulent ash, if the coal has been properly prepared.

As a remedy for the smoke nuisance, coke and semi-coked coal are gradually coming into favor. Although gas-coke is admittedly more difficult to burn than bituminous coal, there is no reason why stoves and furnaces should not be constructed so as to overcome the difficulty by providing a good draught. Semi-coked coal retains sufficient volatile matter to make combustion easy, while, at the same time, it produces little smoke owing to the large amount of the volatile gases driven off in the distillation process.

Briquets for Domestic Use

The briquetting of coal has been going on in Europe for over 50 years. It has been developed more rapidly and successfully in Germany than any other country. In the United States the industry has had a slow growth largely because of the abundance of excellent coals throughout the country with which the briquet would need to compete.

Medium hard coals are best adapted to the production of fuel briquets. Gas and coking coals produce briquets that melt in the fire. Hard coals, as a rule, will require more binding material than the softer varieties, hence it is often possible to mix various coals with the object of obtaining a mixture with a low ash content and of such a nature that it will briquet readily without the use of too much binding material. The average ash content of the coal should not exceed 12 per cent. when pitch is used as the binding material, and

when other binding material is used it should be less. Washed coal may be used, but will need be dried before compressing.

Briquets or "boulets", as they are known to the trade, from anthracite culm, Buckwheat No. 4 or dust, and of a size about equal to stove coal, are being made in the anthracite region and shipped to the western states for household purposes. Before mixing with the binder, the moisture in the culm, which, as it comes from the bank, varies from 10 to 16 per cent, is reduced in driers to about 2 per cent. The ash content is relatively high, but 18 per cent. is regarded as the maximum.

A great deal of experimenting has been done for the purpose of finding a satisfactory binder to hold the particles of coal firmly in the briquet. Rosin, pine tar, sulphite liquor, starch, tars, pitches, molasses, slaughter-house refuse, brewers' waste, tanning liquor, naphthalene, asphaltic residuum, emulsion of water, starch and asphaltum, magnesia, magnesia cement, plaster of paris, portland cement, water glass and slag cement have all been used with varying degrees of success.

The requirements of a good briquet for fuel are as follows: (1) it must be strong, hard and tough so as to withstand hard usage in handling and in shipping; (2) it must be able to withstand heat and atmospheric weathering; (3) it must retain its form in burning as reverting to the original fine pieces would obstruct the draft; (4) it must ignite readily and burn without producing smoke or odor.

The advantages of anthracite briquets as a household fuel are said to arise from their rapid and complete combustion, the lack of clinkers in the fire, and the lesser attention needed for the fire.

METHOD OF CLASSIFICATION

All coals on our records have been included in this tabulation for the reason that all coals are used for domestic purposes, though obviously some are better adapted than others. The matter of allegiance to a coal for domestic purposes is based largely on price and propinquity. The New Englander accustomed to the luxury of anthracite would shun a high grade West Virginia bituminous, but the esteem in which anthracite is held in the East is no greater than that accorded to subbituminous coal by the plainsmen of Wyoming or to the moisture-laden lignites by the farmers of North Dakota. Considerable assistance in differentiating good domestic coals from the indifferent or bad may be gained by consulting the Directory Section, where will be found mentioned, for most of the mines, the equipment used in the preparation and sizing of coal.

QUALIFICATIONS OF A COAL FOR EXPORT

Due to causes both economic and political the exporting of American coals to foreign countries has greatly increased during the past six years. Exchanges organized to facilitate shipments at the principal seaboard points and to exercise a supervision over the quality of coals shipped are some of the indications of the zeal with which foreign trade is being sought. However, our successful

invasion of foreign fields does not depend altogether on the high qualities of the coals we ship. So many factors are involved and the matter is of such importance that the subject of Export Coals will be found treated, along with full information on the Tidewater Exchanges with which it is closely linked, in another part of the COAL CATALOG, beginning with page 138.

METHOD OF CLASSIFICATION

Most of the coals exported in ship bottoms is loaded at such points as New York, Philadelphia, Baltimore, Hampton Roads and Charleston. The coals acceptable to foreign trade are those high in heat value and low in both sulphur and ash. High volatile, low volatile and anthracite coals are exported and a list of these is here given. Canada is supplied largely by rail from the mines of Pennsylvania, practically all of the anthracite which is exported being shipped there.

QUALIFICATIONS OF A COAL FOR THE MANUFACTURE OF ILLUMINATING GAS

In the early days of the industry the process of manufacture of illuminating gas was by the distillation of bituminous coal in retorts. Up to the time of the invention of the Welsbach mantle, in 1893, the predominant use of coal gas was for lighting purposes. Open flame burners were used, the union of the gas with air taking place in a thin film, forming the outer surface of the flame. The yellow luminosity of the flame, upon which its success for lighting depended, was due to the incandescence of solid particles of carbon, and possibly also of very dense hydrocarbons. The prime object of the early gas manufacturers was to obtain a gas rich in heavy hydrocarbons, which readily decomposed under the influence of heat and produced carbon. Cannel coal was much used as an enricher because of its large yield of gas of high illuminating power.

When the Welsbach mantle came into use the gas industry gained a new lease of life. This mantle consists of a cotton or other fabric saturated with a mixture of nitrates of thorium and cerium and has the power of emitting light when in a state of incandescence. With this mantle in use the need

of a gas rich in illuminants suddenly disappeared. Another noticeable tendency at this period was the increasing use of gas for domestic purposes. These new conditions call for heating quality in the gas, and is resulting in the gradual displacement of illuminating gas by water gas.

When made in ovens or retorts, the coal gas resulting is the main product, coke being the by-product, and being used for domestic, steam and water gas purposes, gas producers, etc. Distillation is done in fire clay retorts fired with coal, coke, or producer gas.

Two characteristics govern the selection of a coal to be used in the production of illuminating gas, the first being physical quality and the second chemical composition. Under the first caption the gas value will depend upon whether the coal is friable or liable to slack during handling. This is of importance for the reason that the time required for carbonizing depends somewhat upon the size of the coal, small coal needing a longer period than large or lump coal, and showing a lesser yield. Also when large-sized coal is used the gas is evolved

more freely and is of better quality, since it is less subject to decomposition. In its chemical composition the coal should analyze high in volatile matter and low in moisture, ash and sulphur. In England it is generally considered that the nearer the ratio O:H in the coal substance approximates to 2.0 the better the results obtained.* As in the case of coking operations, sulphur is the element which precludes the use of many coals for gas manufacture. A great quantity of coal in the United States would satisfy the requirements, were it not for the high sulphur content. Two per cent. sulphur coals have been used, but it is difficult to purify gas made from high sulphur coals, and consumers rightfully object to the hydrogen sulphide gas produced by the chemical union of sulphur with hydrogen, which is not only ill smelling and dangerous, but readily tarnishes picture frames, silverware, etc. For such reasons some of the largest users of gas coals limit the sulphur to $1\frac{1}{4}$ per cent., and, of course, high volatile coals having a lesser per cent. are the more highly regarded. Frequently the capacity of a plant to purify gas limits the selection of coal. It should be as free as possible from such impurities as iron pyrites and slate. The percentage of ash should be merely such as will produce a coke of commercial value.

The most valuable gas coal is the one that will yield in the form of gas, the greatest proportion of its calorific value. An additional criterion of its value is the length of time required to carbonize the coal, because the longer this period the lesser will be the output and the greater the expense.

Generally speaking, the older coals gasify at the slowest rate and the younger coals most rapidly. The Western Pennsylvania gas coals have been for years the standard gas coals of the country.

The comparative value of coals for the manufacture of illuminating gas can be best determined by actual test in the retorts, since many of the properties are more or less directly dependent upon the temperature of distillation, size of the charge, type of retort and other factors. Chemical analyses, so far as gas manufacture is concerned, affords very little information as to the relative value of coals for this purpose.†

Cannel coal used alone is unsuited to the present-day requirements of gas making. It is rich in resinic bases and frequently analyzes as high as 50 per cent. of volatile matter, but it yields a poor quality of powdery coke which is practically useless for fuel purposes. Cannel coal is much used, however, as an enricher to the ordinary gas coals, with a yield, in exceptional cases, of over 14,000 cubic feet of gas.

A good gas coal should be able to meet the following conditions:

Volatile matter, 32 to 37 per cent.

Ash, 6 to 8 per cent.

Sulphur, not more than $1\frac{1}{4}$ per cent.

Gas yield from 10,000 to 12,000 cubic feet per ton of coal.

Coke yield from 65 to 70 per cent.

*Bone, Coal and Its Scientific Uses, pg. 277.
†S. W. Parr in Bulletin No. 20, U. S. G. S.

METHOD OF CLASSIFICATION

Three essentials stand out prominently in the class of coal for gas making: (1) It must be low in sulphur, (2) high in volatile matter, and (3) must yield coke in the retort. In the following tabulation some of the coals, as for instance those of West Virginia and Kentucky, have been included on the strength of their analyses; Alabama and Washington coals have been limited to such that have been reported successfully used; Pennsylvania coals are limited for the reason that the coals from the Youghiogheny and Irwin districts are predominant as the gas coals of the State. If washing of coals is to be presumed, many additional seams or localities will be able to meet the demand because of the removal of much of the objectionable sulphur.

QUALIFICATIONS OF A COAL FOR LOCOMOTIVE FUEL

Almost all kinds of fuel—liquid and solid—have been, and still are, used by railroads for the generation of steam. To a considerable extent this is due to the practice of transportation companies buying coal from various mining companies along the route of travel, the result being that coal varying in composition and in grades of preparation are made to serve. Factors which determine largely the most efficient type of coal for locomotive service are the type of locomotive, kind of service, design of grate and fire-box, intensity of draft, grades encountered and loads hauled.

Certain types of locomotives will demand certain kinds of fuel; one type, for example, will show greater economy with gas coals, while another type will respond better with splint coals. Many Eastern roads burn anthracite in the smallest grades with a percentage of soft coal intermixed. Where hard coal is used the grate area must be made large owing to the relatively slow rate at which anthracite coal gives off its heat.

Necessarily the fire-box of a locomotive is restricted and small as compared with the capacity of the boiler, therefore the coal burned per square foot of grate area per hour is much larger than is required in ordinary stationary practice. This requires a quick-burning fuel—that is, one in which the gaseous matter is readily evolved from the coal, a characteristic found in those having a high volatile content, which, it has been observed, liberate about one-third of their total heat within two minutes after firing, the remaining coke maintaining a constant temperature by its practically uniform rate of combustion. It is true, of course, that with the use of high volatile coals there is considerable waste in the form of unburnt gases, and that there is less efficiency and more smoke than with anthracite.

Another peculiarity of locomotive service is that the draft is stronger than in ordinary steam practice. To resist the lifting effect of the inrushing air, whereby the fine coal is carried unconsumed through the tubing and on out the boiler stack, entailing the loss of so much fuel, there is required a coal which has sufficient coking quality to coalesce the small coal into a solid mass of sufficient size to stay in place. It is in this respect that semibituminous coals may fail to meet the requirements of heavy locomotive service, although, as is well known, they are unsurpassed for steam

purposes. These coals in mining produce about two-thirds of the slack sizes, and as they are not as strongly coking in the fire-box as the high volatiles, a considerable portion of the fine coal is blown away. Where much smoke is objectionable, as in the case of the well-advertised fast trains, or prohibited by smoke laws, as in city districts, anthracite or the so-called smokeless coals are the ideal fuels.

Ordinarily the use of high volatile coals is accompanied by much smoke, this depending largely upon the manner of firing, the condition of the locomotive, and the size of coal. Three-quarter-inch gas coals in many cases are used with very satisfactory results and almost smokeless combustion. Considerable discussion has ensued on the best sizes of coal. Most authorities agree that the ideal fuel for hand-fired locomotives would be one with lumps of a maximum size of from 3 to 5 inches, which would allow the fireman to shovel without taking his time to break lumps; and of a minimum size of about $\frac{1}{2}$ inch, which would lessen losses through the grates and prevent the draft drawing the fine fuel out of the stack. It is sometimes stated that for best results the size of lump coal should be restricted to a 3-inch cube, the reasons given being, first, that lumps of this smaller size have more surface exposed to the air, weight for weight, than is the case with the larger lumps, and second, the air has a freer passage than with the smaller sizes, and therefore a more rapid combustion takes place, serving to meet rapidly the maximum variation in the demands for steam.

It is not to be understood that slack is objectionable, but there should not be more than 30 per cent fine coal under 1 inch. Coking coals can stand more slack than non-coking coals, as the former fuse together and resist being blown out the tubes. Automatic stokers have been successfully introduced for the burning of lower priced screenings.

From the standpoint of absolute efficiency a number of railroad tests made with run-of-mine versus various sized coals do not show conclusively that it is cheaper to use a closely sized fuel for this work.*

While high ash coal is not especially desirable for locomotive fuel, it can be and is used with very satisfactory results, due to the readiness with which the ashes can be removed from the fire-box

*University of Illinois Bulletin No. 88, Dry Preparation of Illinois Coal at Illinois Mines, E. A. Holbrook.

as well as the increased grate surface with which locomotives of recent design are provided. Bony coal, slate and rash are the usual forms of impurities; the first two are productive of clinkers; the latter fill up the fire-box. For locomotive fuel

sulphur in coal need be given no serious consideration.

In concluding this discussion it may be stated that the ultimate test of fitness for locomotive purposes is a trial under the actual conditions of service.

METHOD OF CLASSIFICATION

Here, as in the case of domestic coal, every coal in the country may be listed, with the proviso, however, that not all coals are satisfactory coals for railroad use. The very nature of railroad operation requires that they depend on local sources for their supply, and due to this contingency all ranks from anthracite to lignite are used. In the case of lignite, however, it is generally mixed with other coals, this practice obtaining, for instance, in Texas.

For Seams Suitable for Locomotive Use, See List Given Under Domestic Coals.

QUALIFICATIONS OF A COAL FOR MELTING (METALLURGICAL FUEL)

Metallurgical operations must necessarily be accompanied by a high heat. This requires that only fuels of high calorific value be used. In the case of the reverberatory furnace, coal is burned on a grate, the flame of the burning gas passing through the furnace and over the hearth on its way to the stack. The resulting heat effects a melting down of the metal.

One essential requirement of a fuel for this purpose is that it be high in volatile matter. When used in the reverberatory furnace for the smelting of iron or for refining copper it should be low in sulphur; for the smelting of copper ores sulphur is not detrimental. (See discussion of Powdered Coal—For Metallurgical Use.)

METHOD OF CLASSIFICATION

All high-grade high-volatile coals are entitled to this classification, and in addition many of the pure coals belonging to subbituminous rank found in the western states. Thus the bituminous coals of Lincoln county, Wyoming, and the subbituminous coals of Montana are used in the smelters at Anaconda and Butte, while the bituminous coals of Carbon and Emery counties, Utah, are used in the smelters of that state.

QUALIFICATIONS OF A COAL FOR USE AS A POWDERED FUEL

Powdered or pulverized coal, as the name suggests, is coal that has been reduced by crushing to the fineness of dust. The purpose in this reduction is to secure better combustion of the fuel by bringing each particle of coal into contact with a sufficient supply of air. It is well understood that a considerable loss of heat energy takes place with the ordinary method of hand firing, due to such causes as the chilling of the furnace while coal is being shovelled on the fire, the checking of the draft through the grate bars by the mass of newly placed coal, and the insufficiency of air to burn completely the large volume of gases released by the destructive distillation of the green coal. If some method of admitting coal to the furnace could be found that is constant rather than intermittent, that does not require opening of doors with its objectionable cooling of flame, that places the coal in regulated quantities instead of en masse, and that keeps each particle of coal surrounded with sufficient air to insure its complete combustion, then a great advance in obtaining effective heating would be made. Combustion would be instantaneous and the smoke nuisance would disappear.

Powdered coal meets all of the requirements just mentioned. First, however, it must be prepared before it is ready for use in the furnace. This requires the use of special apparatus to accomplish what has been found necessary for the use of coal in powdered form, namely, drying, crushing, pulverizing and conveying.

First. Theoretically the less moisture there is in the coal, the better the results. It is therefore often stated that coal should first be dried so that it will not contain over 1 per cent. of moisture. Recent experiments indicate that it is not necessary to dry the coal down to 1 per cent. of moisture in order to get good boiler efficiency and that most of the Eastern coals can be pulverized and burned with good results without drying. Coals which are not low in moisture should be dried by passing through a revolving shell, the temperature of which is maintained at a point high enough to evaporate the moisture in the crushed fuel.

Second. The coal must be pulverized to a high degree of fineness so that the contact surface be-

tween the coal and air may be greatly increased. The underlying principle is well illustrated by assuming a 1-inch solid cube of coal wherewith there is exposed 6 square inches of surface. If this same volume be divided into a thousand cubes of 0.1 inch they will now have an exposed area of 60 square inches, and if the division be carried to one million cubes 0.01 of an inch on a side, the exposed area is increased to 600 square inches. If the million cubes were further reduced to dust spheres 1/200-in. in diameter there would result 216,000,000 grains of dust having a total exposed area of 1152 square feet.

It has been freely stated that in order to get good results the coal should be pulverized to a fineness which will pass at least 95 per cent. through a 100-mesh screen; at least 85 per cent. through a 200-mesh screen and at least 70 per cent. through a 300-mesh screen. Unquestionably the coal must be thoroughly and uniformly pulverized, but recent tests seem to indicate that extreme fineness is not necessary to get good combustion and good efficiency. Complete combustion appears to be more a matter of proper furnace and burner design and the right way of supplying air than of the extreme fineness of the coal.

Third. Where the coal is not used as rapidly as pulverized, or where the supply of fuel is purchased, the reserve supply is stored in bins. Such storage bins should not be placed in a position where they might become heated from furnaces, steam pipes or hot flues owing to the danger from fire. Spontaneous combustion of the coal has taken place under such conditions and will need be guarded against at all times.

Fourth. The coal must be projected into a chamber hot enough to cause instant deflagration. The powdered fuel is conveyed directly to the furnace, either by a system of screw conveyors or by air pressure. It is fed to the burners through a nozzle under light air pressure.

Fifth. It must be supplied with air sufficient to yield the oxygen necessary to burn the carbon of the coal at once to carbon dioxide. The quantity of air supplied is of great importance in the results

attained. This is susceptible to close regulation, being added in proper volume and at the same time mixed with the fuel. If in overabundance, the flame is cooled, smoking ensues and there is a loss of efficiency; if in undersupply, the volatile matter in the dust is burned, while the remainder is coked and unconsumed.

Coals Suitable for Powdering

Because the cement industry, the earliest user of powdered fuel in quantity, required a high volatile coal, the impression grew that such coals only were fitted for pulverizing. In the same way the belief long prevailed that low grade coals could not be utilized in this process. During the past ten years considerable experimenting has revealed that all ranks of coal from peat to anthracite, and all grades of coal may be successfully used in the powdered form. High volatile coals give the best results, and low-moisture, low-ash coals are always to be preferred. Coals running very high in ash may be used, but they frequently cause difficulty, either by the scattering of fine ashes over the surrounding neighborhood or by part of the ash falling into and blocking the back connection. A further difficulty will be experienced if the ash is easily fusible owing to its coating the cold surfaces of the water tubes and the linings of the furnace chamber.

For Steam Plants

An attractive feature of the process for steam purposes is that there can be utilized mine refuse, run-of-mine, screenings or slack grades of coal. The quality of the coal is not of great importance. Inferior coals, as subbituminous, lignite and peat, are applicable. Coals analyzing 25 per cent. ash and 5 per cent. sulphur have caused no trouble in boiler use, while the lignites and subbituminous coals of Washington have proved especially suitable and have shown a much higher evaporative power than when the same coal has been used with stokers.

For Locomotive Use

Inferior coals may also be used for locomotive service. As illustrating the possibilities may be cited the coals of Brazil, which range from 26 to 30 per cent. in ash, and are unusually high in both sulphur and moisture. This coal in a powdered form is being used successfully for locomotive service.

The Swedish government has recently conducted a successful series of experiments in the use of powdered peat as locomotive fuel. Carefully conducted tests between engines of the same class, one burning pulverized coal and the other hand fired, have shown a saving of as much as 23 per cent. in fuel burned when using pulverized coal. But an even greater point in favor of powdered coal is the ability to shut off the fire entirely when standing still, making powdered coal particularly

desirable for switching locomotives. The cost of preparing powderer coal plus that incident to its usage may make the final comparison favorable to hand or stoker firing, but some of the heavy cost items are being gradually overcome.

For Metallurgical Use

Powdered coal for metallurgical use dates back about 90 years. It is now used in practically all branches of the industry where a high heat is required, one company alone having 77 furnaces in operation. C. J. Gadd[†] states the following as the requirements for this work: "Powdered coal used in heating and puddling furnaces should have not less than 30 per cent volatile matter, nor less than 50 per cent fixed carbon. Its moisture should not exceed 1.25 per cent, its ash 9.50 per cent and its sulphur 1 per cent. The requirements for open hearth furnaces are more rigid. The volatile content should be higher and not under 36 per cent. The fixed carbon should be at least 52 per cent. The moisture and sulphur may still be 1.25 and 1 per cent respectively, but the ash must fall below 6 per cent. This is because there is apt to be slagging in the combustion chamber, in the hearth and in the flues. In powdered coal sulphur, when present only in small quantities, has no ill effect in heating and annealing furnaces, but it should be given careful attention when used in the reduction and refining of metals or ores."

Other Uses for Powdered Fuel

One of the very recent developments in powdered fuel is its delivery by trucks in cities for such purposes as heating office buildings, hotels, apartments, etc. It is customary to deliver a day's supply, unless storage is provided for larger quantities. The pulverizing is done at a plant located in the city. One enterprising coal company in the state of Washington has the pulverizing station located at the mine, and makes shipments of the fine coal in specially designed cars to Seattle.

Powdered Coal Ready for Delivery.

(Journal of the Franklin Institute)

METHOD OF CLASSIFICATION

In this classification the use has been limited to metallurgical purposes. For the generation of steam the list given under the head of Domestic Coals may be referred to inasmuch as all coals are applicable. For metallurgical use no seam has been intentionally listed having less than 30 per cent. of volatile combustible and preference has been given to those having a high content of gaseous matter. As in the case of melting, if the coal is wanted for iron or steel metallurgy, it must needs be low in sulphur. If for copper, it may be high in sulphur, but in either case a coal of high heat value and long flame is desirable. The moisture content should preferably be low, though coals may analyze high in moisture, say up to 8 per cent, provided they are dried before using so as not to have over 1 to 2 per cent.

*Consisting of seams of minor importance

THE QUALIFICATIONS OF A COAL FOR THE MANUFACTURE OF PRODUCER GAS

The manufacture of producer gas is carried out in one of the many forms of producers, consisting essentially of a cylindrical furnace lined with fire-brick, with an outer mild steel casing, and usually water sealed at the bottom. The process consists of passing a mixture of air and steam continuously through the fuel which has been charged into the producer, and in such proportions as will maintain its temperature conditions as nearly constant as possible, so that the gas which is continuously generated will be of uniform composition.

Bituminous coal, coke or anthracite may be completely gasified. When a fresh charge of coal is dropped into the producer, it first of all undergoes, in the uppermost layers of the fire, a process of destructive distillation, whereby hydrogen, methane, tarry hydrocarbons, oxides of carbon, together with some steam and also small quantities of ammonia and sulphuretted hydrogen are evolved, probably in much the same proportions as in the high temperature distillation of coal. The coked residue is

rapidly gasified as it descends through the incandescent fuel bed by the upward flowing air-steam blast, yielding chiefly the oxides of carbon and hydrogen, together with small quantities of both methane and ammonia. These gases, in addition to nitrogen, make up the crude producer gas which passes out of the furnace and which contains between 40 and 45 per cent. of combustible constituents.† It is used for metallurgical purposes, production of power, burning of clay products and lime, manufacture of glass, etc.

Any coal whether of high or low grade, or of any rank from peat to anthracite may be used in the producer, although all coals are not used with equal facility. The best gas-producer coals are those which do not cake, or only slightly so, in the furnace. Caking coals tend to obstruct the draft and oftentimes must be broken up by rods operated from the top of the producer. For the same reason coal which has an ash of low fusion point should be

†Excerpts from Bone, Coal and its Utilization.

avoided. Gas produced from anthracite is of a uniformly rich and almost tar-free quality. There is little likelihood of clinkering troubles when anthracite is used. Buckwheat No. 1 appears to be the most suitable size, but a surer method is to specify that not more than 5 per cent. of the coal shall pass through a 1/16-inch mesh screen. Furthermore the coal should not contain more than 2 per cent. of sulphur, nor more than 12 per cent. of ash.

In the case of bituminous coals and lignite, and with special reference to the double flow producer, the percentages of ash and sulphur are the determining factors. The fusibility of the ash should be carefully examined, in fact this quality is often the one factor that will exclude a coal as a producer fuel. The size of the coal is also important. As a general rule, coarse mine run coal does not make the best producer material. The larger pieces work down through the distillation bed and tend to make unequal blow distributions on both the hand poked and mechanical types. Egg and nut, being nearly free of fines, make the most easily handled material. Slack coal can be successfully gasified. Several additional factors must be considered. The producer is capable of utilizing bituminous and lignite fuels of a moisture content of, but not exceeding, 25 per cent. If the moisture content exceeds this amount it becomes difficult to maintain proper temperatures in the upper fuel bed. It is also evident that the fixed carbon content should exceed the volatile content.

If the volatile content exceeds the carbon too much work must be done in the upper fuel bed, and it becomes difficult to maintain proper conditions for gas-making in the lower fuel bed. Caking coals require more labor than non-caking coals. One ton of Pittsburgh coal will produce 150,000 cubic feet of producer gas.

For metallurgical purposes a bituminous high-volatile coal is to be preferred. E. B. Guenther* states the requirements of coals for this purpose as follows: The generation of gas is dependent in a large measure upon the contact of the blast with the combustible of the fuel. Excessive ash prevents this contact, and also renders the fuel bed more or less compact, while the labor of operation is increased.

High sulphur is objectionable. If it exists in combination with other elements it is apt to form clinker formation, which requires labor for its removal. If the sulphur passes off as a gas, sulphur dioxide, it has a corrosive action on all metal parts with which it comes in contact.

The size of coal determines the percentage of voids in the fuel bed. Lumps which are too large allow the blast to pass through the fuel bed too rapidly, whereas coal which is too fine offers too much resistance to the blast, and, in addition, is apt to contain a great amount of impurities. Nut or pea coal gives the best results.

*Proceedings Coal Mining Institute of America, 1912, pg. 321.

METHOD OF CLASSIFICATION

All coals have been included in this classification, though results obtained with each coal may be vastly different. Owing to troubles met with in operation, practice has proved that some coals are used only with difficulty. However, actual tests are needed to demonstrate the true worth of a coal for producer purposes, and in lieu of this, each coal has been accepted as usable until proved otherwise. The prime requirements are that a coal should not coke excessively and should be easily handled. If it shrinks and has a tendency to part from the wall of the producer it allows the blast to rush through the bed and make bad holes, making it necessary to break the fuel against the wall at close intervals. Also it should not clinker excessively, but if it does the clinker should be such as will permit breaking from the top of the producer.

For Seams Suitable for the Manufacture of Producer Gas, See List Given Under Domestic Coals.

QUALIFICATIONS OF A COAL FOR SMITHING USE

While most coals can be used with some degree of success at the forge, it is recognized that some coals are better adapted than others; in fact, a good smithing coal commands a premium. The requirements of a high-grade smithing coal are, first, it should be low in sulphur, not exceeding 1 per cent; second, it should ignite easily; third, it should form a large firm coke arch on the forge sufficient to accommodate the largest work; fourth, it should be high in heat value; fifth, it should be economical in use.

Semibituminous coals, being both high in heat and low in ash, and coking readily, have been the standard smithing coals for years, especially at plants where a considerable quantity of such coal is used. Other coals are, however, in common use,

thus some of the medium volatile coals from Tennessee and West Virginia have supplied markets with smithing coals for many years. In this usage, as in many others, distance from the source of best supply, often dictates the substitution of less adaptable coal.

Blossburg smithing coal was for years the standard for this usage in the East. An average analysis of this coal was as follows:

	Blossburg
Moisture	2.25
Volatile Matter	20.20
Fixed Carbon	71.15
Ash	6.40
Sulphur	0.55

METHOD OF CLASSIFICATION

In this classification semibituminous coals principally has been listed, such coals having by years of usage demonstrated their great adaptability for smithing purposes. The Eagle and Sewanee seams have demonstrated by years of usage their excellent qualities as smithing coals.

QUALIFICATIONS OF A COAL FOR STEAM PURPOSES

The conditions under which coal is used for the generation of steam are many, and practically every rank, grade and size are utilized for this purpose, dependent upon locality, freight rate, etc. It will, therefore, be of interest under this heading to discuss the efficient use of coals, along with the kinds of fuel adaptable.

In general there are two kinds of steam generating installations: (1) stationary heating plants, (2) stationary power plants. A characteristic of the first type is that the load is comparatively steady and the demands made upon the steam capacity do not fluctuate greatly. For such service anthracite coal is well adapted.

With the second type, stationary power plants, the demand may be either steady or variable, depending upon the use for which the power is generated. In the case of power plants furnishing electric power the demands are usually variable and sudden, and this in turn requires a flexible fire. Anthracite coal does not meet this need as well as semibituminous or bituminous coal, which, owing to their higher volatile content, can be burned more rapidly and are therefore to be preferred. Once the gaseous matter is consumed and the additional heat given quickly to the boilers, the remaining fixed carbon of the coal maintains the even supply.

The shortage of fuel throughout the country, due to causes closely connected with the World War, served to drive home the fact that there was an enormous waste in the steam plants of the country, brought about by careless and uneconomical methods of firing. Every stack pouring forth smoke represents so much dissipated energy, but the amount of combustible matter in smoke as it passes from the stack is small, possibly from one to three per cent. of the fuel. The real loss from soot occurs in the boiler settings, due to the deposit on the boiler heating surfaces of soot, which is generally recognized as a most effective agency in preventing the interchange of heat from the furnace to the water in the boiler. As an indication of how serious this loss is, investigations of the U. S. Geological Survey show that it amounts to \$50,000,000 a year in territories where high volatile coals are used.

It is an established fact that high volatile coals are hard to burn economically by the ordinary hand methods of firing. The gaseous matter is evolved freely when the coal is thrown on the fire, and much of it escapes unburnt because of an insufficient supply of air. With some coals the heat value of the volatile matter is greater than that of the fixed carbon, hence the possible loss of energy in the usage of such coals can readily be appreciated.

The employment of stokers, whereby the coal is fed to the furnace at a slow and steady rate, together with the use of forced draft, whereby air in proper proportions can be supplied to the fire, has done much to eliminate smoke and increase the efficiency of the plant. The supply of coal to the fire is evenly regulated, affording sufficient time for the burning of the gases distilled. Furthermore, there is no necessity to open doors and cool the furnace, as is the case with hand firing. Inferior coals, running high in ash or bony coal, can be used with success where ample grate area is provided.

A decision on the fuel to be used is a prerequisite to the selection of boilers. If anthracite coal is used there will need be a larger grate area than with bituminous coals. The conditions of service should also be well understood so that if fluctuations in steam demands are anticipated these contingencies can be successfully met. Constan and Schlapfer are stated by J. S. S. Brame to have investigated the influence of volatile matter on combustion and to have found that coals containing about 20 per cent. (calculated on the combustible) yield the highest temperature and thermal efficiency. With too high volatile matter, the gases escape unburnt and excessive air must be admitted above the grate; and, on the other hand, with low volatile matter, an excessive air supply is requisite for the fuel on the grate. The highest economic efficiency will be attained, therefore, with coals of medium to low volatile content, say from 16 to 23 per cent.

The relative value of coals for steaming purposes depends so largely upon the method of usage, equipment, etc., that full dependence can not be

placed upon chemical composition nor upon records of performance unless all conditions, such as grate area, draft supplied, rate of demand, etc. are well understood. A coal showing by calorimeter tests a high thermal value may prove unsatisfactory in service for reasons utterly unfair to the fuel, while, on the other hand, a coal of lower calorific value may give splendid results at a plant where its use was anticipated and provision made accordingly. With this reservation in mind the following classification by rank according to their steam value is given:*

Relative Value of Steam Coals.	
Semibituminous	100
Semianthracite	93
Anthracite	91
Bituminous (Eastern)	89
Bituminous (Western)	67
Lignite	45

Evaporative Power of Coal

In order to generate steam it is necessary to transfer heat to water, the universally used medium for this transfer being the boiler. The result of the application of heat is to increase the warmth of the water until a temperature of 212 degrees Fahrenheit is reached. Here we find a critical point. However much heat we may apply, the water cannot be heated any hotter, but changes on the addition of heat to steam. In evaporating a pound of water at 212 degrees to steam at 212 degrees, at atmospheric pressure, there are expended 970.4 B. t. u. The heat so utilized is called the **latent heat of evaporation** and is the heat which apparently disappears in causing the substance to pass from a liquid to a gaseous state. This latent heat is not lost, however, but reappears whenever the steam passes through a reverse cycle, from a gaseous to a liquid state. The heat is merely lost to thermometric measurement when the molecular constitution of the water is being changed.

The heat necessary to raise one pound of water from 32 degrees Fahrenheit to the point of ebullition is called the **heat of the liquid**. The sum of the heat of the liquid and the latent heat of evaporation makes the **total heat of the steam**.

*Coal, by J. F. Cosgrove.

The heating power of a coal depends upon its constituent parts, but a pound of coal has a definite heat producing capacity and is capable of evaporating a definite quantity of water under given conditions. It is the function of Steam Tables to give the total quantity of heat which belongs to steam, and the latent heat of evaporation at different pressures, and it will be apparent that if the calorific power in heat units of any coal be divided by the heat units resident in a pound of steam at the pressure in question, the quotient will be the number of pounds of water which will be evaporated, theoretically, by one pound of coal having the given calorific power. Rarely will a fuel be found which will evaporate over 15 pounds of water per pound of coal, and, furthermore, practice with the limitations imposed makes it very unusual to reach 12 pounds of water per pound of coal. Ten pounds is excellent practice, and from ten down to seven is perhaps the most usual experience.

For the purpose of illustration we will assume the following problem: How many pounds of water, fed into the boiler at 60 degrees Fahrenheit, will a pound of coal having a calorific value of 14,200 B. t. u. evaporate into steam at 160 pounds gauge pressure? According to steam tables, steam at 160 pounds steam pressure (equivalent to 174.8 pounds absolute pressure) has a temperature of approximately 371 degrees Fahrenheit. Since the water is fed to the boiler at 60 degrees, each pound must have $371 - 60 = 311$ B. t. u. added to it to increase its temperature to 371 degrees, which increase must take place before the water can be converted into steam.

The amount of heat required, according to steam tables, is in excess of 311 B. t. u. and is stated to be 315.2. This is because slightly more than one B. t. u. is required to raise the temperature of one pound of water one degree at the higher temperatures. Accepting the figure 315.2 B. t. u. as the correct expression for the heat of the liquid, and adding it to 852.7 (taken from steam tables), the latent heat of evaporation, we have a total of 1167.9 B. t. u. as the amount of heat required to raise one pound of water from 60 to 371 degrees and to convert it into steam at 160 pounds steam pressure. Inasmuch as the coal under consideration has a heating value of 14,200 B. t. u. it should be able, theoretically, to evaporate $14,200 \div 1167.9 = 12.2$ pounds of water.

METHOD OF CLASSIFICATION

Since any coal can be used for the generation of steam, all coals may be listed as usable for this purpose. Manufactories, like railroad and domestic users, are often constrained to draw upon the nearest sources for their fuel. An industrial enterprise in Texas would assuredly not use Pittsburgh (Pa.) steam coal, but rather would draw from a source of supply compatible with economic operations. The fact that fuel can be moved only at a high cost for haulage has created industrial centers close to the sources of supply.

For Seams Suitable for Steam Purposes. See List Given Under Head of Domestic Coals.

QUALIFICATIONS OF A COAL FOR TILE AND POTTERY BURNING

In general there are two classes of products from clay burning plants, first, those whose sale would be affected by imperfections in the color and texture of the ware, and second, those which are strictly utilitarian in purpose and do not require a particular color or texture.

Included in this latter class are common brick, which is burned to a temperature of 1,500 to 1,900 deg. F.; drain tile, which is burned to 1,800 deg. F.; hollow tile, which needs a temperature of 1,800 to 2,000 deg. F., and fire brick and other refractories, which are burned to 2,200 to 2,600 deg. F. The

burning of these requires a coal high in volatile matter and producing a flame of long length, so as to penetrate through the kiln and insure uniform burning. Non-coking coals are especially suited for this purpose, although almost any coal sufficiently high in volatile matter and calorific value will suffice, as sulphur and other impurities in the coal are not of great importance, other than the amount of ash and clinker formed.

Included in the finer grade of products may be mentioned pottery, usually burned to a temperature varying from 2,000 to 2,500 deg. F.; terra cotta, burned to 2,300 to 2,400 deg. F.; sewer pipe, fired to a temperature of 2,100 to 2,300 deg. F., and face brick, which is fired to a temperature of 1,800 to 2,100 deg. F. The requirements here are identical to those just given for the burning of common brick, with the exception of the sulphur and ash, since coal for these purposes must be as

free as possible from impurities that tend to mar or discolor the materials. The coal should be high in heat value and low in sulphur, as the sulphurous fumes may form sulphuric acid, which unites with the bases of the soluble salts to make sulphates, causing white spots on the ware, and it may also interfere with the brilliancy of the glaze. Wherever possible plant owners use a 1½ to 3 or 3 to 6 inch size coal. Coal for these purposes should be low in ash, especially if the ash clogs the grates with clinkers, necessitating frequent cleaning, with the consequent danger of the fine ash being carried into the kiln and lodging on the ware. Clinkering coal is especially objectionable where flat grates are used. Coal of this variety will often cake upon the grate to such an extent that shaking is impossible, and removing the clinker is possible only by the use of slice bars and hooks. In dead bottom furnaces a clinkering variety of coal may not be objectionable.

METHOD OF CLASSIFICATION

In this list only such coals as are low in sulphur and ash and high in volatile matter and heat value have been included. The washing of coal has been assumed only where our information shows it being done at the present time. For coals suitable for brick burning the tabulation under the head of Cement Burning should be consulted.

QUALIFICATIONS OF A COAL FOR MANUFACTURE OF WATER GAS

Water gas, which is a mixture of carbon monoxide and hydrogen in nearly equal proportions, is generated on a large scale by passing steam, preferably superheated, through a body or column of fuel maintained at a temperature of 1000 deg. C. or upwards. Unlike the method used in the manufacture of producer gas, the two gasifying agents, the air and the steam, are admitted alternately, each for a definite period, and the products of the action of each are kept separate. The steam is dissociated into hydrogen and oxygen, the latter of which later unites with carbon to form carbon monoxide gas, CO, the hydrogen passing through unattached. The heat required to break up the steam tends to cool the mass—that is, the process is endothermic—and when the heat falls below the point where the desired change will take place, the process must be suspended and the heat of the furnace restored by passing air alone through the bed.

The original fuels used were coke, anthracite coal and charcoal, the first two mentioned still remaining in general use. The use of bituminous coal would permit savings to be made, these being as a general proposition the difference between the cost of coke and coal, with an additional saving of about 10 per cent. in the amount of oil required for enrichment when coal is used for generator fuel instead of coke. The reasons why bituminous coal has not supplanted the use of coke in the water gas generator have been stated as follows:*

1. Bituminous coal on burning yields tar which gums the valves, charging doors, etc., with the result that valves stick and doors leak.
2. Freshly charged fuel can not be raised in temperature rapidly because of its containing moisture and volatile matter.
3. Upon coking the fuel mats together and obstructs the passage of air and steam so that blow-holes form in the fuel bed.
4. Capacity is decreased, chiefly by 2 and 3.
5. The zone of incandescent fuel in the generator is smaller because of the presence of coking coal.
6. The proportion of CO₂ in the gas is increased as the smaller size of the hot zone lessens the time of contact of the steam and hot fuel.
7. More heat (as heat of combustion) enters the blast gas than is required to heat the checker chambers.

8. The difficulty of using waste-heat boilers, wherein the sensible heat of the finished gas is utilized, is increased by the larger production of tar, as flues of the waste-heat boilers rapidly become clogged with tar and carbon.

9. Checker chambers are overheated when the blast gas is all burned within the set.

10. Most bituminous coal is friable, readily breaking into smaller pieces on handling.

11. Much bituminous coal has a higher sulphur content than coke.

During the past few years generators have been designed which overcome some of the difficulties named and it is quite probable that as more experience is had with the use of bituminous coal as fuel, the principal obstacles will be overcome and the use of high volatile coal become general. One company has already placed on the market a generator especially designed for bituminous coal, and they report it in successful use in different parts of the United States.

Usages of Water Gas

Water gas is well adapted for operations requiring intense local heat, as in steel welding. Its principal use, however, is in cities and towns where it is employed for street lighting, and domestic uses, such as in heaters, ranges, water heaters and lighting. For purposes of public supply it is usually mixed with illuminating gas, in proportions of one part of illuminating gas with anything up to five or six parts by volume of water gas. The following figures show the relative proportions of each gas contained in the public supplies of a number of American cities.†

*Technical Paper 246, Bureau of Mines, Water Gas Apparatus and the Use of Central District Coal as Generator Fuel, by W. W. Odell.

†From Bone, Coal and Its Scientific Uses.

METHOD OF CLASSIFICATION

Anthracite coal and coke remain the chief fuels for use in the water gas process, so that no classification beyond these will be attempted. Any of the seams given under the head of Domestic Coals may be considered eligible, though a thorough test should precede final judgment.

CLASSIFICATION OF COALS

III. ACCORDING TO } TRADE NAME PHYSICAL STRUCTURE

Smokeless, Block and Splint Coals. Qualifications of Coals and List of Seams Fulfilling Each Designation.

Methods of Classification

The third classification of coals, that in accordance with its trade name or physical structure, has been formulated in the attempt to designate coals by means of some marked characteristic. The term "smokeless" coal has proved an excellent method for bringing the New River, Pocahontas, Georges Creek, Moshannon and like

coals to the favorable notice of the public. The very word "block" brings to the mind a picture of a mass of large cubical lumps, and there are, in fact, mines in Kentucky and West Virginia producing coal of cubical shape, whose corners, to all appearances, are right angles. The meaning of "splint" coal is not so easily derivable but the word no doubt has come to us from Scotland, and long usage has made it widely known to the trade.

SMOKELESS COALS—A TRADE NAME

The term "smokeless" is a relative one, since all coals give off more or less unconsumed carbon in burning. It is a fixed rule with ordinary hand firing methods that the higher the volatile content of the coal, the freer burning it is and the more smoke it will produce. The use of mechanical appliances in the power house may convert a fuel, which by tendency produces a dense smoke, into one which gives off very little. For instance, a high volatile coal burned as a powdered coal in a

sufficient supply of air will yield little or no smoke, as is also true with the use of stokers on locomotives, stationary power plants, etc., burning high volatile coals. In the same way coals ranking as semibituminous, semianthracite and anthracite are smokeless by comparison with high volatile coals. Amongst the trade, however, the term "smokeless" is restricted to the semibituminous coals because of the little smoke given off during combustion.

BLOCK COALS—PHYSICAL STRUCTURE

The following is extracted from the Twenty-third Annual Report, Department of Geology, Indiana: Bituminous coal is sometimes called "block coal," from its property of commonly breaking up into cubical blocks. These blocks are the result of the existence in the coal of vertical cracks or joints, combined with a tendency of coal to split or break parallel with its bedding. In some coal these joint faces are only a few square inches or even less in area; in others they extend the whole depth of the coal and may have a lateral extent of scores of yards. In the first case the coal is apt to mine in small cubes of from a cubic inch up to a cubic foot or more. In the latter case the coal may be mined in great blocks the full depth of the coal bed, and too heavy to be handled. These joint faces may show no regularity of direction, or they may have nearly fixed directions for a hundred square miles. They would appear to be due to different causes.

Block Coal in an Eastern Kentucky Mine

Such joint faces are very common in other rocks in nature, especially being well developed in very fine grained rocks, as shales or limestones. The finer the grain, as a rule, the more perfect and regular the system of joints. Where well developed these joints have been observed all over the coal area, and are known at other places to extend entirely through beds of shale 100 feet or more thick, so that the bed will look as though some gigantic cleaver had cut it into cubes or blocks of up to thousands of cubic feet capacity.

Where such joints in rocks are very perfectly and regularly developed, it is found that there are two sets of joints, more or less, at right angles to each other. If the rock has a dip or downward slope it is found that one set of joints have the direction of the dip, and are known as the "dip joints," or as the "end" or "butt," while the others are at right angles to the dip, and since they follow

the "strike" of the rock are known as "strike joints" or as the "face," "slyne," "cleat" or "bord." It is found that strike joints and dip joints differ in this that, while the strike joint may be continuous for hundreds of feet, the dip joints commonly

only extend from one strike joint to the next. In the coal of Indiana it is found that over most of the field the coal is broken up by joints of irregular extent so that it mines out in irregular cubes of from a cubic foot or a little over, down.

Over a much smaller area, principally confined to the eastern margin of the coal field, these joints are developed in great perfection and with great regularity. In this State (Indiana) the term "block coal" is commonly restricted to such coal, and coal in which the joints are not regular is locally known as "bituminous."

Block coal may be a coking coal, a non-caking or splint coal, or cannel coal. It is most commonly a splint coal, and the two are sometimes, though erroneously, regarded as synonymous. When struck with a hammer the board-like blocks sound much as when a piece of wood is struck.

SPLINT COALS—PHYSICAL STRUCTURE

This term refers to those coals which break in mining into solid oblong blocks. They are dull black in color, naturally hard and when struck of their block-like nature they are in demand for gas producers, and being high volatile coals, answer well for ordinary steam purposes and as a locomotive fuel. (See also discussion under Pottsville Series—Kanawha Group, Upper Division, West Virginia section.)

Typical West Virginia Splint Coal

emit a metallic sound. Splint coals are highly prized for domestic purposes, as they produce a hot and cheerful fire in the grate and need little attention. Upon heating they tend to splinter. Because

tive fuel. (See also discussion under Pottsville Series—Kanawha Group, Upper Division, West Virginia section.)

ALABAMA*

General Description of the Geology of the State; Treats of the Four Mining Districts, With a Map Showing Their Location; Railroads Entering the Coal Fields; Kinds of Coal Produced, General Analysis, List of Operations, Etc., Etc.

The coal bearing formations of Alabama are all of Carboniferous age. Most, if not all, of the rocks correspond in age with the lowest subdivision of the Pennsylvania section, namely the Pottsville. The thickening of this series is very marked in Alabama, and it appears probable that the five or six thousand feet of coal bearing rocks in the Birmingham district represent the same time interval as the few hundred feet in Western Pennsylvania. The group of rocks consisting of heavy beds of conglomerate or coarse sandstone with more or less cross-bedded sandstone and shale below, is here known as the Millstone Grit. Above this group is a great series of shales, sandstones and occasional conglomerate lenses with numerous beds of coal. Throughout the entire field a rapid diminution in thickness is noticeable in passing from the eastern margin westward. Thus in the Jellico district, Tennessee, the beds of this group decrease in thickness from 3,000 feet at the eastern margin to 1,750 feet within a distance of 50 miles. In the Chattanooga district, Tennessee, the decrease is from 1,200 feet to 300 feet in about the same distance, and in the Birmingham district from 1,700 to 1,300 feet in 25 miles. This westward thinning of the formation suggests that these sediments were derived from land to the eastward, and that the surface on which deposition took place was depressed most rapidly where the material deposited was most abundant—that is, nearest the source of supply.

From the figures given above it will be noted that this upper group of coal bearing rocks is much thicker at either end of the field than in the central portion. Thus on a section along the eastern margin of the field the group decreased from a maximum of nearly 6,000 feet in the Cahaba basin to 1,200 feet in the Walden basin, and then increased to 3,000 feet in the Wartburg basin, Tenn. This extreme variation is due in part, at least, to the fact that only the lower members have been removed by erosion. In addition to this cause, however, there is probably a decided thickening of the formations both north and south, the present greater depth of the basins at the extremes of the field corresponding in part to an original more rapid deposition.

The larger part of the workable coal of the field occurs in this upper group of strata. The more important beds will be enumerated in the descriptions of the several basins. In a general way the coal shows an increase in number and thickness of beds corresponding to the increase in thickness of the inclosing formations. Hence the largest amount of coal to a given area is found along the eastern margin of the field.

The coals of Alabama occur in what is known as the Birmingham district extending from a line connecting the southern point of Lookout Mountain and the great bend of the Tennessee River southwest to the southern limit of the coal field. It includes the Warrior basin, which is the southern portion of the Cumberland Plateau, the Blount Mountain basin, the Cahaba basin, and the Coosa basin. The Blount Mountain basin is a synclinal spur, connected at the north with the Walden syncline, and separated from the Warrior basin on the west by Murfrees Valley. The Cahaba and Coosa basins are long, narrow synclines, entirely isolated from the larger areas of coal-bearing formations to the west by still narrower anticlinal and fault valleys.

The yearly production of coal varies from 16 to 20 million tons, of which from 4 to 6 million tons are used in the manufacturing of coke. The greater portion of the coke thus produced is used in the blast furnaces of the Birmingham district, although a large amount is shipped to the smelters in Mexico. The coal used for coke making comes almost entirely from the Mary Lee and Pratt seams of the Warrior coal field.

The coals of Alabama, although bituminous, are of various kinds and are used for steam, heating, gas and coke making. The greater portion of the output is consumed within the state.

The railroads traversing the coal regions are the Southern; Louisville & Nashville; Central of Georgia; St. Louis & San Francisco; Northern Alabama; Mary Lee; Illinois Central; Mobile & Ohio; Seaboard Air Line; Atlanta, Birmingham and Atlantic; Alabama Central; Birmingham Southern; and Nashville, Chattanooga & St. Louis.

*We are largely indebted to the 22nd Annual Report, Part 3, of the United States Geological Survey for the information here given on the geology of Alabama and descriptions of coal basins.

COOSA BASIN

The Coosa basin is the easternmost of the four which are included in the Birmingham district. It is about 40 miles in length and from 4 to 10 miles in breadth. This basin is cut by separate faults which make acute angles with the axis of the syncline. A short number of faults cross the syncline transversely and separate it into several small basins, the greater portion of the coal bearing rocks upon these cross faults having been eroded. By reason of the folding and faulting which the rocks have undergone, the coal is much disturbed and the workable beds are found in comparatively small isolated areas. Due to these conditions, the development of the coal is attended by unusual uncertainty and expense. The coal is generally somewhat softer than that of the Warrior field and hence it does not bear transportation so well. It

is, however, well adapted for coking, containing small percentages of sulphur and ash and giving a good yield in coke of excellent quality. Although at least 12 coal beds, 36 inches and over in thickness, are reported in this basin, but two of these, namely, the Coal City and Eureka seams, are at present being worked at only one point, namely, Coal City, in St. Clair County.

CAHABA BASIN

The Cahaba basin is a field 68 miles in length with an average width of 5.8 miles and an area of 395 square miles. It is drained by the Cahaba River and its tributaries. This basin lies next west of the Coosa basin, from which it is separated by a long, narrow strip of Devonian and Silurian rocks. It has a structure very similar to that of the Coosa basin; it is a long, narrow syncline, whose eastern edge is sharply upturned and, for the most part, cut off by a fault which brings the Cambrian and Silurian formations in contact with the Coal Measures. About midway of its length the syncline is interrupted by a cross fold which lifts the lower portion of the Coal Measures above drainage level, and from which the greater part of the coal-bearing rocks has been removed by erosion. North-east of this cross fold the syncline is very regular, the beds having a uniform gentle dip toward the southeast nearly to the margin of the basin, where they are sharply upturned and cut off by a fault.

The sandstones and heavy conglomerates which occupy the lower portion of the Coal Measures form a series of parallel ridges throughout the western half of the syncline. The coal beds outcrop in parallel lines between these ridges, and in the lower land occupy the eastern part of the syncline, which is underlain by the upper and softer portions of the coal-bearing formations.

The southern half of the Cahaba basin is much less regular than the northern portion above described. It is broken up into a number of subordinate basins by transverse folds and by a faulted zone which branches from the eastern marginal fault and separates the southern half of the basin into two nearly equal portions. This faulted zone is merely a sharp, broken anticline, and its effect is to duplicate the outcrops of the coal beds, each of which, in the northern half of the basin, reaches the surface only along a single line. According to Squire, the total thickness of the Coal Measures in this basin is about 5,500 feet, which is slightly less than in the Coosa basin, although higher measures are found here, which have been removed by erosion from the basin to the east. The workable coal beds show an increase in number and

thickness for the same reason. The total area of the Cahaba field underlain by workable coal is about 270 square miles, and the aggregate average thickness of workable coal is about 21 feet. The Cahaba field is divided by the transverse fold and the faulted zone above mentioned into three distinct basins, two of which are further subdivided into several subordinate basins by less pronounced transverse folds.

The Henryellen basin embraces the northern half of the Cahaba field.

The Blocton basin, including also the minor Acton and Cahaba basins, occupies the southwestern portion of the field.

The Montevallo basin occupies the southeastern portion of the field. It includes the following minor basins: Helena, Eureka, Dry Creek, Lolley, Montevallo, and Daily creeks.

In all of these basins, except along their eastern margins, the rocks have a rather steep southeasterly dip, averaging about 15 degrees. They are also disturbed by many local folds and faults, and the methods of mining are quite different from those employed in undisturbed horizontal beds. When properly engineered and worked, however, the coal can be mined from these inclined beds with nearly the same facility as from horizontal beds of the same thickness.

The seams mined in this field are known as the Gholson, Helena, Henryellen, Climax, Montevallo, Thompson, Underwood, Harkness, Woodstock, and Youngblood, mined in Bibb, Shelby and St. Clair counties. The coals from the Henryellen basin are fine for coking; those from the southern portion of the Cahaba basin are greatly prized for domestic purposes.

BLOUNT MOUNTAIN BASIN

Blount Mountain is a spur of the Cumberland Plateau extending southwestward between the Coosa Valley on the southeast and Murfrees Valley on the northwest. It has the form of a broad, gentle synclinal trough bounded by Straight Mountain on the northwest and Blount Mountain on the southeast. These are formed by the outcropping edges of the heavy beds of conglomerate near the base of the Coal Measures. This syncline forms a marked contrast to most of the synclines in the Appalachian region in that its steep dips are along the western margin and its gentle dips along the eastern margin. The reverse is generally the case.

According to Gibson 34 coal beds have been discovered in this basin, of which 16 are of workable thickness. Of these the Holt, or Big, seam is reported as having locally a thickness of 12½ feet.

The field contains an area of approximately 100 square miles underlain by workable coal, and the average aggregate thickness of the beds over 2 feet is about 20 feet. It is practically undeveloped, only a few small mines having been operated intermittently for supplying local demands.

The seams mined in this basin are known as the Black Creek, and Underwood, and are found in Etowah and Blount counties. The coal is largely used for steam purposes.

WARRIOR BASIN

This is the most important of the several basins which are included in the Birmingham district. It contains a larger area of workable coal than the other three combined, and by reason of its structure the coal can be mined generally more economically than in the others.

The basin has a somewhat irregularly triangular shape. Its southeastern margin is formed by the sharp Murfrees Valley anticline from which the coal-bearing rocks have been removed by erosion. Its northern margin is formed by a broad transverse uplift which crosses the entire field and on which only the lower portions of the Coal Measures remain, the higher and more productive measures having been removed by erosion. The region occupied by this transverse uplift is not entirely devoid of workable coal, but its beds are so much less important than those higher up in the series that for present purposes they may be entirely neglected.

From this transverse uplift the rocks dip southward, bringing below the erosion surface successively higher beds down to the extreme southern margin of the basin. This northern border is, therefore, very irregular. The lower coals extend farthest north, occupying the highest land between the streams. These gradually pass below drainage southward, while the higher beds come in on the hilltops and in turn pass below drainage toward the south. The highest coals, therefore, are confined to the hilltops in the southern portion of the basin.

The southwestern border is also indefinite. A few small remnants of Tertiary and Cretaceous clays and gravels are found on the hilltops near the center of the basin. These remnants suggest that these formations were at one time continuous, at least this far north, but their outer margins have been deeply dissected and only occasional fragments of the originally continuous beds remain. These patches of gravel and clay become more abundant toward the southwest and finally cover the whole surface except in the river channels. The larger streams remain upon the Coal Measures to the vicinity of Tuscaloosa, beyond which the whole of the surface is formed by these later deposits.

Hence the southwestern margin of the coal basin is occupied by a zone in which the surface is formed partly by the underlying Coal Measures, and partly by the overlying sand and gravel. The proportion of the former increases toward the northeast and the latter toward the southwest.

As already indicated, there is a marked decrease in thickness of the coal-bearing formations observable in passing westward from the Coosa to the Cahaba basin. Although exact correlations have not yet been made between the coal beds of the Cahaba and Warrior basins, the equivalence of various groups of coal beds has been determined with sufficient accuracy to indicate that the thinning is even more rapid between the Cahaba and Warrior basins than farther east. The coal-bearing rocks in the Cahaba basin down to the basal conglomerate have a thickness of something over 4,000 feet. Along the eastern margin of the Warrior basin the same formations have decreased to about 1,500 feet, and from this eastern margin the westward thinning is observable entirely across the basin. Accompanying the decrease in thickness of the coal-bearing formations there is a corresponding decrease in number and thickness of the coal beds themselves.

The seams worked in this field are known as the Pratt, Nickel Plate, Mt. Carmel, Mildale, New-castle, Mary Lee, Carter, Blackwood, Blue Creek, Horse Creek, Black Creek, Morgan, Corona, Harkness, Jagger and Jefferson.

The Pratt seam covers an area of about 1,500 square miles, and varies from 3 to 16 feet in thickness. Ordinarily it is about 4 feet thick and has one slate parting. The coal from this bed is washed and makes an excellent quality of coke.

The Big seam of coal belongs to the same geological horizon as those locally known as the New-castle, Horse Creek, Blue Creek, Mary Lee, Jagger, etc. These seams are extensively mined and used for coking. The Big seam, varying from 6 to 12 feet in thickness, is inclined to be dirty, carrying numerous slate partings as well as irregular lenses of slate and requires washing to make a satisfactory grade of coke.

The Black Creek seam is the most uniform in this field. Commonly, it is without partings but

in places occurs in two benches which are some times separated by 12 to 15 feet of rock interval. The seam varies from 4 to 6 feet in thickness with an average of 5 feet. The Warrior basin, as above defined, comprises parts of the counties of Jefferson, Winston, Marion, Fayette, Blount and Tuscaloosa and all of Walker.

PREPARATION OF COAL

Practically all of the modern devices used in the preparation of coal are found at the mines of Alabama.

Many of the earlier workings have about reached their boundaries and are on the retreat, and at such mines, in many instances, bar screens still prevail; at the newer mines shaker screens, pickling tables and loading booms are being generally installed.

The nature of coal preparation depends considerably upon the characteristics of the seam and the use to which the coal is put. At mines where rash occurs immediately over the coal, or those having a soft shale in the roof so that the impurities mingle with the coal, washing is resorted to, this

being accomplished by jigs. At a number of mines where coal is being coked, washeries are also used to reduce the percentage of ash and sulphur contained in the coke.

Ordinarily, the screens are so arranged as to load either three or four sizes of coal. Where three sizes are shipped, all the coal which goes through 1-inch perforations is designated as nut and slack, and all over 1-inch and under 5-inch is marketed as fancy lump. When four sizes are prepared, all passing through a 4-inch screen and over a 2-inch screen is designated as nut; all passing through the 2-inch screen is known as pea coal, while all that passes over the 4-inch screen is classed as lump.

Operating Thirty-Six Bituminous Mines in Eleven Districts with Annual Capacity of 18,000,000 Tons

COAL MINE MANAGEMENT

Peabody Coal Mine Management is the development of thirty-eight years' experience in the ownership and operation of coal properties. Having first ascertained practical and successful methods of operating our own mines, we have expanded our organization to include the partial or complete management of coal properties for others. Below is a brief summary of the various forms of service rendered, further details of which will be found on pages indicated.

Operating Manager

We operate mines owned by others for their account or for the joint account of the owners and ourselves. We operate mines owned by large consumers of coal, supply them with their requirements and market the remainder of the output, if any, for their account. See Page 333.

Consulting Engineer

We examine undeveloped coal properties, advise as to their commercial value and prepare plans for opening and developing them. We examine active operations and make recommendations for improvements or changes to increase output and lower cost.

We act in an examining and advisory capacity for banks, trust companies and bond houses having interest in coal properties. See Page 394.

Construction Engineer

We sink or open new mines, lay out top works, design and erect mine buildings, tipplers, washers, coke ovens, machinery and power plants, install water works and fire protection systems, etc. See Page 478.

Sales Agent

We undertake the sale of the output of a single mine or a group of mines, with or without an operating arrangement. See Page 741.

Purchasing Agent

We purchase mine supplies, equipment and machinery for clients whose properties we operate. See Page 911.

Auditor and Accountant

We act as Treasurer and Auditor for mines we operate, set up cost sheets, accounting records, pay payrolls and furnish essential data as to daily, weekly and monthly mining costs and results. See Page 911.

Mine No. 19 at West Frankfort, Franklin County, Illinois, owned by the By-Products Coke Corporation and managed by Peabody Coal Company under operating and selling arrangement.

List of Mines By Seams, Including Name of Company, General Office Address,
County, Railroad and Shipping Point

ALABAMA

BLOUNT MOUNTAIN BASIN COALS

Mined in Blount and Etowah Counties. Bituminous rank. Suitable for Steam, Domestic, Railroad,
Cement Burning and Producer Gas purposes.

BLACK CREEK SEAM

ARKANSAS

General Description of the Geology of the Field With the Ranks of Coal Produced
Treats of the Mining Districts, With a Map Showing Their Location, All
Seams Lying Within the Territory, and the Railroads Serving Same;
Description of the Producing Seams Showing Their Geological
Order. Kinds of Coal, General Analysis, Etc

The Arkansas coal field lies in the valley of the Arkansas River, between the western border of the state and Russellville. It is about 33 miles wide and 60 miles long. The area of the region is about 2000 square miles, comprising six counties, viz: Sebastian, Franklin, Johnson, Scott, Logan and Pope. The first three named are the chief producers. It is only in the eastern and western parts of the coal field that the Hartshorne coal is probably thick enough or sufficiently free from partings to be of economic importance.

All of the Arkansas true coal was deposited during the geological period known as the Pennsylvanian. Since the coal was buried, the region has been raised and lowered at different times. During this process, the rock layers, including the coal seams, which were originally practically flat, have been gently folded up into anticlines and down into synclines. As a result they are now seldom level, but have a dip or pitch occasionally as much as 18 degrees from the horizontal, but generally less than 6 to 7 degrees.* One result of the disturbances which this field has undergone is that the coals in many places have become partially devolatilized, thus we find coals ranking as semianthracite, semibituminous and bituminous, all in the same seam, though separated geographically.

Arkansas produces around 2,000,000 tons of coal yearly. This relatively small production is due chiefly to the sharp competition of cheap oil and gas from the great fields of Texas, Oklahoma and Louisiana. The principal market for run of mine, which had always been as a locomotive fuel, is now largely supplied by oil. The railroads, however, continue to be the chief consumers of the output, using practically all of the lump coal produced. There is little industrial development within the state. Some of the harder coal from the thin seams is sold at good prices for domestic use.

The railroads traversing the mining districts are the following: Missouri Pacific; Kansas City Southern; Chicago, Rock Island and Pacific; St. Louis and San Francisco; St. Louis, Iron Mountain and Southern; Arkansas Central; Arkansas Western; Midland Valley; Dardanelle and Russellville.

MINING DISTRICTS OF ARKANSAS

- 1 Bates-Coaldale. Seam mined is the Hartshorne. Coal is used for railroad and steam purposes. Railroad serving is the Kansas City Southern.
- 2 Greenwood-Huntington. Seam mined is the Hartshorne, known locally as the Huntington and Mammoth. The coal is known to the trade as "Arkansas semianthracite", and is used for railroad, steam and domestic purposes. Railroads serving are the St. Louis and San Francisco; Midland Valley; Chicago, Rock Island and Pacific; and Arkansas Central.
- 3 Bonanza-Jenny Lind. Seam mined is the Hartshorne, known here as the Jenny Lind, the output going into railroad and steam uses. Railroads serving are the Missouri Pacific, St. Louis and San Francisco, Kansas City Southern, and St. Louis, Iron Mountain and Southern.
- 4 Denning-Coal Hill. Seam mined is the Hartshorne of semibituminous and semianthracite ranks. Known locally as the Denning. The output is used chiefly for railroad, steam and domestic purposes. Railroads serving are Missouri Pacific and St. Louis, Iron Mountain and Southern.
- 5 Spadra. Seam mined is the Hartshorne, known locally as the Spadra, and producing a semianthracite coal used for railroad, steam, domestic and metallurgical purposes. Coal from this district is known to the trade as "Arkansas anthracite". Railroads serving are the St. Louis, Iron Mountain and Southern, Missouri Pacific, and Dardanelle and Russellville.
- 6 Paris. Seam mined is the Paris of semibituminous rank, the output going into railroad and steam uses. Railroads serving are the Kansas City Southern, Missouri Pacific, and Arkansas Central.

*Coal Mining in Arkansas, by A. A. Steel.

Hartshorne Seam. (Known also as the Mammoth and Huntington in Sebastian county; the Jenny Lind in the Bonanza-Jenny Lind district; the Denning in the Denning-Coal Hill district; the Spadra in the Spadra district; the Shinn Basin in Pope county. Coal from points where the volatile matter is low is known to the trade as "Arkansas anthracite".) (Mined in all districts except the the Paris.)

The Hartshorne is an extension of the Oklahoma seam of the same name, and is the great producing bed of the state. It is of Carboniferous (Allegheny) age. In the Greenwood-Huntington district of Sebastian county the seam is either semibituminous or semianthracite in rank. The coal at most places is soft and friable, and since much of it is shot from the solid, and the Arkansas mining law calls for payment to the miner on a run of mine basis, a great deal of fine coal results, making it difficult to use as a domestic fuel. A great deal of the output is used for engine fuel and much of the slack is sold for stationary steam uses. Very little gas is encountered in the mines.

Sebastian county produces the famous Arkansas smokeless coals which burn with a short sootless flame and make little smoke. They can be stored for months with little depreciation. The mining conditions in the county are good. The coal is overlaid with a hard tough sandstone, making a firm roof. The measures lie in the form of a syncline, the sides having a pitch varying from 10 per cent. on the south to 6 per cent. on the north. The coal is worked on the room and pillar system, openings being made by shafts, slopes, drifts and strippings. The thickness of the seam is 8 feet 6 inches, but this includes two layers of shale 12 and 4 inches thick respectively. Unless care is taken, slate and impurities are likely to become mixed with the coal, making separation difficult without washing. The cleanest product is obtained where mining is done by the three bench method.

From Coronado mine to the southwest for a distance of 10 miles the coal has a good thickness, but carries a dirt band 10 to 12 inches thick. The upper bench averages 3 to 3½ feet; the bottom bench 3½ to 4 feet. The two benches are in close proximity.

The Hartshorne seam in the Bates-Coaldale district is of bituminous rank. In the Bonanza-Jenny Lind district it is semibituminous and thinner than that about Huntington, varying from 2 feet 6 inches to 4 feet, with an average of about 3 feet.

In the Denning-Coal Hill district it is both semianthracite and semibituminous. In the Spadra district, the coal is harder and lower in volatile matter, giving rise to the name "Arkansas anthracite", though in reality it is of the semianthracite rank. The larger sizes are used entirely for domestic purposes. It is free burning, produces a uniform heat and stocks well. The slack is used as a reducing material in the retorts of the zinc smelters.

GENERAL ANALYSIS

	Denning-Coal Hill
Moisture	2.25
Volatile Matter	14.25
Fixed Carbon	74.00
Ash	9.50
Sulphur	1.90
B. T. U.	14,000

Paris Seam. (Mined in the Paris district.)

This seam lies from 1000 to 1400 feet vertically above the Hartshorne horizon and is of considerable importance, although there are but few operations, and these of small size. The seam is of semibituminous rank and ranges from 20 to 30 inches in thickness.

GENERAL ANALYSIS

Moisture	2.75
Volatile Matter	14.70
Fixed Carbon	73.50
Ash	9.05
Sulphur	2.80
B. T. U.	13,775

Lignite Coals. (Mined in Ouachita county.)

The lignites of Arkansas are of Tertiary age. They contain so much water that they are not now commercially valuable for direct burning, although the beds are very thick and used to a slight extent for making gas. The coal slacks quickly and will not stand storage nor transportation.

GENERAL ANALYSIS

Moisture	39.45
Volatile Matter	26.50
Fixed Carbon	24.35
Ash	9.70
Sulphur	0.50
B. T. U.	6,350

PREPARATION OF COAL

The usual manner of preparing Arkansas coal is by passing the run of mine over shaker screens. Four sizes are generally made, the slack passing through a ¾-inch to 5/8-inch screen; the pea through a 1¼-inch screen, and the nut through a

2½-inch screen. At some of the larger mines the slate is separated by mechanical slate pickers. In the Spadra district revolving screens are found at several mines, but as the coal is quite soft and much breakage results, these are being gradually displaced by bar or shaker screens.

ARKANSAS

Alphabetical Directory of Coal Mines, Giving Complete Detailed Information Covering Each Mine

For List of Abbreviations See Page 13.

ACTUS COAL COMPANY

General Office, Huntington, Ark.
PR—C. C. Woodson, Huntington, Ark.
TR—C. R. Holbrook, Huntington, Ark.
GS—C. C. Woodson, Huntington, Ark.

Black Diamond Mine; Slope; Hunting-
ton Seam, 54 in. thick.
PO—Jenny Lind, Ark.; SP—Same; CTY
—Sebastian; RR—Mo. Pac.
MS—Mr. Newberry, Jenny Lind, Ark.
S of H—Mules. Track gage 35½ inches.
S of M—Hand.
PP—1 fire tube boiler, 40 H. P.
EMP—30. Daily tonnage 300.
SIZES SHIPT—Stark, Egg, Lump.
PREP. EQUIPT—Bar Screens.
NOTE—Formerly operated by the Jenny
Lind Smokeless Fuel Co.

ALIX COAL COMPANY

General Office, Alix, Ark.
PR—Dr. J. L. Ross, Altus, Ark.
VP—J. A. Lewis, Alix, Ark.
TR—E. E. Coffey, Alix, Ark.
GM—J. A. Lewis, Alix, Ark.
GS—J. A. Lewis, Alix, Ark.
EM—Lewis & Noel, Fort Smith, Ark.
SA—Midland Coal Co., Kansas City, Mo.

Superior Mine; Slope; Hartshorne Seam,
45 inches thick.
PO—Alix, Ark.; SP—Same; CTY—
Franklin; RR—Mo. Pac.
S of H—Mules and main and tail rope.
Track gage 36 inches.
S of M—Hand.
PP—Power purchased. Transformer 2300-
220 volts A. C., 2 water tube boilers,
150 H. P., 6 pumps.
EMP—125. Daily tonnage 400.
SIZES SHIPT—Run of Mine, Slack,
Lump.
PREP. EQUIPT—Gravity Screens.
NOTE—Successors to Superior Coal Co.

AMERICAN SMOKELESS COAL CO.

General Office, Muskogee, Okla.
PR—J. W. Dougherty, c/o Metals &
Commerce Corp., 120 Broadway,
New York, N. Y.
VP—H. B. Barling, Muskogee, Okla.
TR—Max Breitung, c/o Metals & Com-
merce Corp., 120 Broadway, New
York, N. Y.
GM—H. B. Barling, Muskogee, Okla.
PA—H. B. Barling, Muskogee, Okla.
SA—National Fuel Co., Mutual Bldg.,
Kansas City, Kan.

Fidelity Mine; Slope; Hartshorne Seam,
54-60 in. thick.
PO—Greenwood, Ark.; SP—Same; CTY—
Sebastian; RR—Midland Valley.
MS—Frank Johnson, Greenwood, Ark.
S of H—Mules, steam hoist. Track gage
40 inches.
S of M—Hand.
PP—Power purchased. Transformer 2,300
to 440 volts A. C., 4 fire tube
boilers, 300 H. P., 6 pumps.
EMP—108. Last years tonnage 46,000.
SIZES SHIPT—Run of Mine, Slack,
Lump.
PREP. EQUIPT—Shaker Screens.

ARKOAL SMOKELESS COAL CO.

General Office, Huntington, Ark.
PR—John W. Jasper, Huntington, Ark.
VP—Otto Mitchell, Ft. Smith, Ark.
TR—H. R. Rean, Huntington, Ark.
GM—John W. Jasper, Huntington, Ark.
GS—J. L. Burns, Huntington, Ark.
PA—John W. Jasper, Huntington, Ark.
EM—Dan H. Cadmus, Hackett, Ark.

Jasper Mine; Drift; Lower Vein Seam
in. thick.
PO—Huntington, Ark.; SP—Same; CTY
—Sebastian; RR—Frisco.
S of H—Mules and gasoline locos.
Track gage 36 in.
S of M—Hand.
PP—1 pump.
EMP—10. Last fiscal year output 3,000
tons.
SIZES SHIPT—Run of Mine.
NOTE—Formerly operated by Jasper
Coal Co.

BACKBONE COAL COMPANY

General Office, McAlester, Okla.
PR—J. G. Puterbaugh, McAlester, Okla.
TR—E. P. Joyner, McAlester, Okla.
GM—W. H. McCauley, Greenwood, Ark.
GS—S. K. Smith, McAlester, Okla.
PA—E. P. Joyner, McAlester, Okla.
EM—V. C. Robbins, McAlester, Okla.
SA—McAlester Fuel Co., McAlester,
Okla.

"Jones" Mine; Shaft; Upper Hartshorne
Seam; 34 inches thick.
PO—Greenwood, Ark.; SP—Exp., Green-
wood, Frl., Excelsior, CTY—Sebas-
tian; RR—Midland Valley.
S of H—Mules. Track gage 30 inches.
S of M—Hand.
PP—Power purchased. 2 200 H. P. fire
tube boilers.
EMP—125. Daily output, 11,000 tons.
SIZES SHIPT—Run of Mine, Slack, Nut.
PREP. EQUIPT—Bar Screens, Loading
Booms.

BALDWIN PEACOCK COAL COMPANY.

General Office, Baldwin, Ark.
PR—J. R. Stanberry, Baldwin, Ark.
GM—Geo. Stanberry, Baldwin, Ark.

Baldwin Mine; Drift; Semi-Anthracite
Seam, 14 in. thick.
PO—Baldwin, Ark.; SP—Leith, Ark.;
CTY—Washington; RR—A. T. &
S. F.
S of H—Mules. Track gage, 24 in.
S of M—Hand.
SIZES SHIPT—Slack, Pea, Nut and
Lump.

BATES SMOKELESS COAL CO.

General Office, McAlester, Okla.
PR—J. G. Puterbaugh, McAlester,
Okla.
TR—E. F. Joyner, McAlester, Okla.
GM—W. D. Puterbaugh, McAlester,
Okla.
GS—S. K. Smith, McAlester, Okla.
PA—E. P. Joyner, McAlester, Okla.
EM—V. C. Robbins, McAlester, Okla.
SA—The McAlester Fuel Co., McAlester
Okla.

No. 2 Mine; Slope; Seam, 36 inches
thick.
PO—Bates, Ark.; SP—Same; CTY—
Scott; RR—Arkansas Western.
MS—Ben Evans, Bates, Ark.
S of H—Mules. Track gage 36 inches.
S of M—Hand.
PP—2 pumps.
EMP—70.
SIZES SHIPT—Run of Mine, Slack,
Lump.
PREP. EQUIPT—Shaker Screens.

BLUE HILLS COAL COMPANY

PR—H. C. Parmelee, Coal Hill, Ark.
TR—E. P. Joyner, McAlester, Okla.
GM—H. C. Parmelee, Coal Hill, Ark.
GS—H. C. Parmelee, Coal Hill, Ark.
PA—H. C. Parmelee, Coal Hill, Ark.
CE—H. O. Lewis, Fort Smith, Ark.

Wallis-McKinney Mine; Shaft; Lower
Hartshorne Seam, 44 inches thick.
PO—Coal Hill, Ark.; SP—Denning Yards,
Ark.; CTY—Johnson; RR—Mo. Pac.
S of H—Mules. Track gage 36 inches.
S of M—Hand.
PP—Power purchased, transformer 2,300
to 220 volts A. C., 2 fire tube
boilers, 3 pumps.
EMP—40. Last years tonnage 20,000.
SIZES SHIPT—Run of Mine, Slack,
Lump.
PREP. EQUIPT—Shaker Screens.

BORDER COAL COMPANY.

Now Hackett Coal Co.

CENTRAL COAL & COKE COMPANY

General Office, Kansas City, Mo. Opera-
tions in Arkansas, Kansas, Missouri,
Oklahoma and Wyoming.
PR—C. S. Keith, Kansas City, Mo.
VP—H. M. Taylor, Kansas City, Mo.
TR—E. E. Riley, Kansas City, Mo.
GS—Wm Harkes, Kansas City, Mo.
PA—Thos. Mackie, Kansas City, Mo.
EM—J. S. O'Flaherty, Kansas City, Mo.

No. 2 Mine; Shaft; Hartshorne Seam; 78
inches thick.
PO—Huntington, Ark.; SP—Same; CTY
—Sebastian; RR—St. L. & S. F.
MS—W. H. Risher, Huntington, Ark.
S of H—Rope. Track gage 36 inches.
S of M—Hand.
PP—Power purchased. Transformers 2-
300 to 220 volts A. C., rotary con-
verters, 220 volts D. C., 2 fire tube
boilers, 160 H. P., 5 pumps.
EMP—40. Last years tonnage 31,532.
SIZES SHIPT—Run of Mine, Slack,
Lump.
PREP. EQUIPT—Shaker Screens, Wash-
eries.

No. 3 Mine; Shaft; Hartshorne Seam;
72 inches thick.
PO—Huntington, Ark.; SP—Same; CTY
—Sebastian; RR—St. L. & S. F.
MS—W. H. Risher, Huntington, Ark.
S of H—Mules and rope. Track gage 36
inches.
S of M—Hand.
PP—Power purchased. Transformers 2-
300 to 220 volts A. C., rotary con-
verters, 220 volts A. C., 5 fire tube
boilers, 2 80 H. P., 3 100 H. P.,
8 pumps.
EMP—141. Last years tonnage 126-
055.
SIZES SHIPT—Run of Mine, Slack,
Lump.
PREP. EQUIPT—Shaker Screens, Wash-
eries.

No. 4 Mine; Slope; Hartshorne Seam; 48
inches thick.
PO—Hartford, Ark.; SP—Same; CTY—
Sebastian; RR—C. R. I. & P.
MS—Robert Boyd, Hartford, Ark.
S of H—Mule and rope. Track gage 36
inches.
S of M—10 shortwall marks.
PP—Power purchased. Transformers 2-
300 volts A. C., M. G. set, 300
K. W., 220 volts D. C., 2 100
H. P. fire tube boilers, 6 pumps.
EMP—125. Last years tonnage 35,604.
SIZES SHIPT—Run of Mine, Slack,
Lump.
PREP. EQUIPT—Gravity Screens.

No. 6 Mine; Shaft; Hartshorne Seam, 72
inches thick.
PO—Huntington, Ark.; SP—Same; CTY
—Sebastian; RR—St. L. & S. F.
MS—W. H. Risher, Huntington, Ark.
S of H—Mules and rope, trolley pole type
loco. Track gage 36 inches.
S of M—Hand.
PP—1 100 H. P. and 1 200 H. P.
fire tube boilers, Gen. unit 400 K.
W., 250 volts D. C., 5 pumps.
EMP—350. Last years tonnage 169-
526.
SIZES SHIPT—Run of Mine, Slack,
Lump.
PREP. EQUIPT—Shaker Screens, Picking
Tables, Loading Booms, Washeries.

No. 10 Mine; Slope; Hartshorne Seam;
48 inches thick.
PO—Hartford, Ark.; SP—Same; CTY—
Sebastian; RR—C. R. I. & P.
MS—Robert Boyd, Hartford, Ark.
S of H—Mules and rope. Track gage 36
inches.
S of M—10 shortwall marks.
PP—Power purchased. Transformers 2-
300 to 220 volts A. C., 1 M. G.
set, 100 K. W., 220 volts D. C.,
1 fire tube boiler, 40 H. P., 5
pumps.
EMP—120. Last years tonnage 127-
003.
SIZES SHIPT—Run of Mine, Slack,
Lump.
PREP. EQUIPT—Gravity Screens.

No. 11 Mine; Shaft; Hartshorne Seam;
48 inches thick.
PO—Hartford, Ark.; SP—Same; CTY—
Sebastian; RR—Midland Valley.
MS—J. A. McCurry, Hartford, Ark.
S of H—Rope, storage battery loco. Track
gage 36 inches.
S of M—4 marks.
PP—Power purchased. Transformers 2-
300 to 220 volts A. C., 1 M. G.
set, 35 K. W., gen. unit, 375
K. W., 220 volts A. C., 3 fire tube
boilers, 999 H. P., 5 pumps.
EMP—20. Last years tonnage 114-
742.
SIZES SHIPT—Run of Mine, Slack,
Lump.
PREP. EQUIPT—Shaker Screens, Picking
Tables, Loading Rooms.

No. 15 Mine; Slope; Hartshorne Seam;
48 inches thick.
PO—Hartford, Ark.; SP—Same; CTY—
Sebastian; RR—C. R. I. & P.
MS—Robt. Boyd, Hartford, Ark.
S of H—Rope. Track gage 36 inches.
S of M—5 shortwall marks.
PP—Power purchased. Transformers 2-
300 to 220 volts A. C., 1 M. G.
set, 100 K. W., 220 volts D. C.,
1 fire tube boiler, 40 H. P., 4
pumps.
EMP 206. Last years tonnage 68,470
SIZES SHIPT—Run of Mine, Slack,
Lump.
PREP. EQUIPT—Gravity Screens.

CLARK, McWILLIAMS & CO

General Office, Spadra, Ark.
TR—A. S. Logan, Clarksville, Ark.
GM—T. M. Clark, " "
GS—N. R. Clark, " "
PA—T. M. Clark, Clarksville, Ark.
Sales Agency, Spadra-Clarkville Coal
Clarksville, Ark.

Igo-Deep Shaft Mine; Shaft; Anthracite
Seam, 36 in. thick.
PO—Spadra, Ark.; SP—Same; CTY—
Johnson; RR—Mo. Pacific.
S of H—Mules. Track gage 36 inches.
S of M—Hand.
PP—2 boilers, total 225 H. P., 1 pump.
EMP 175. Last fiscal year output, 57-
542 tons.
SIZES SHIPT—Slack, Pea, Egg, Grate.
PREP. EQUIPT—Shaker Screens.
Old Information.

CLARKVILLE ANTHRACITE COAL CO.

General Office, Clarksville, Ark.
PR—W. N. Cunningham, Clarksville, Ark.
TR—R. G. Johnson, Clarksville, Ark.
GM—W. N. Cunningham, Clarksville, Ark.
GS—R. G. Johnson, Clarksville, Ark.

Clarkville Anthracite Mine; Shaft
Hartshorne Seam; 40 inches thick.
PO—Clarksville, Ark.; SP—Same; CTY—
Johnson; RR—Mo. Pac.
S of H—Mules. Track gage 36 inches.
S of M—Shortwall marks.
PP—Power purchased. Transformer 2,300
to 220 volts A. C.
SIZES SHIPT—Slack, Pea, Nut, Egg,
Lump.
PREP. EQUIPT—Bar and Shaker Screens.

COLLIER DUNLAP COAL COMPANY.

General Office, Clarksville, Ark.
PR—W. F. Collier, Clarksville, Ark.
VP—D. W. Dunlap, Clarksville, Ark.
TR—H. W. Collier, " "
GM—H. W. Collier, " "
GS—H. W. Collier, " "
PA—H. W. Collier, " "
EM—H. O. Lewis, Ft. Smith, Ark.
SCO—Address the Company, Rayer, H. W.
Collier, Clarksville, Ark.
SA—Spadra Clarkville Coal Co., Clark-
ville, Ark.

Collier Dunlap Mine; Shaft; Ark. Anthra-
cite Seam; 36 in. thick.
PO—Clarksville, Ark.; SP—Hartman,
Ark.; CTY—Johnson; RR—Mo. Pa-
cific.
S of H—Mules. Track gage 36 in.
S of M—Shortwall machines.
PP—Purchase power. Transformer 2,300
to 220 volts A. C., 1 fire tube boil-
er, 150 H. P., 6 pumps.
EMP—125. Last years tonnage 35,000.
SIZES SHIPT—Slack, Pea, Nut, Egg,
Grate, Buckwheat.
PREP. EQUIPT—Shaker Screens, Picking
Tables, Washeries.

DENNING SMOKELESS COAL COMPANY.

General Office, Altus, Ark.
PR—W. G. Stiths, Altus, Ark.
VP—D. E. Klein, Altus, Ark.
TR—Ed. Higdon, Altus, Ark.
EE—John Jackson, Altus, Ark.
SA—McAlester Fuel Company, McAlts-
ter, Okla.

Red Devil Mine; Slope; Seam 54 in.
thick.
PO—Altus, Ark.; SP—Same; CTY—
Franklin; RR—Mo. Pac.
MS—W. G. Stiths, Altus, Ark.
S of H—Mules. Track gage 36 in.
PP—Power purchased 2 pumps.
EMP—18. Last fiscal year output
4,125 tons.
SIZES SHIPT—Run of Mine, Slack,
Lump.
PREP. EQUIPT—Gravity Screens.

DENNIS COAL COMPANY

General Office, Paris, Ark.
PR—A. M. Smith, Paris, Ark.
VP—W. A. Tinsley, Paris, Ark.
TR—W. H. Arzo, Paris, Ark.
GM—W. A. Tinsley, Paris, Ark.
GS—J. C. Patton, Paris, Ark.
PA—W. A. Tinsley, Paris, Ark.
LE—O. H. Lewis, Fort Smith, Ark.
SA—Paris Fuel Co., Paris, Ark.

Grand No. 1 and No. 2 Mine; Shaft
and Slope; P. S. A. Seam, 24½ in.
thick.
PO—Paris, Ark.; SP—Same; CTY—
Logan; RR—Arkansas Central.
S of H—Mules and rope. Track gage
28 in.

(Continued on Next Page)

Dennis Coal Co.—Cont.
S of M—3 longwall machs.
PP—Purchase power. Transformer, 2300-220 volts A. C., Gen. units, 4—25 K. W., 12 pumps.
EMP—20. Daily tonnage 150.
SIZES SHIPT—Block

DODSON, GEORGE E. COAL COMPANY.
General Office, Alix, Ark.
OPERATOR—Geo. E. Dodson, Alix, Ark.
EM—H. O. Lewis, Ft. Smith, Ark.
SCO—George E. Dodson, General Merchandise. Buyer, Geo. E. Dodson, Alix, Ark.
SA—Midland Coal Co., Kansas City, Mo.; Southern States Coal Co., Little Rock, Ark.

Dodson No. 1 Mine; Shaft; Denning Semi-Anthracte Seam, 42 to 48 in. thick.
PO—Alix, Ark.; SP—Denning Yard, Ark.; CTY—Franklin; RR—Mo. Pacific.
SM—A. Elser, Alix, Ark.
S of H—Mules, rope and steam locos. Track gage 36 in.
S of M—Hand.
PP—3 water tube boilers, 365 H. P., 5 pumps.
EMP—20. Last years tonnage 1,308.
SIZES SHIPT—Run of Mine, Slack, Lump.
PREP. EQUIPT—Gravity Screens.

Dodson No. 2 Mine; Shaft; Denning Semi-Anthracte Seam, 42 to 48 in. thick.
PO—Alix, Ark.; SP—Denning Yard, Ark.; CTY—Franklin; RR—Mo. Pacific.
SM—A. Elser, Alix, Ark.
S of H—Mules, rope and steam locos. Track gage 36 in.
S of M—Hand.
PP—1 65 H. P. water tube boiler, 4 pumps.
EMP—20. Last years tonnage 4,678.
SIZES SHIPT—Run of Mine, Slack, Lump.
PREP. EQUIPT—Gravity Screens
Old information.

DOUGLAS COAL CO.
General Office, Alix, Ark.
GM—Ben Douglass, Coal Hill, Ark.
GS—Ben Douglass, Coal Hill, Ark.
PA—Ben Douglass, Coal Hill, Ark.
EM—Lewis & Noel, Ft. Smith, Ark.
SA—Sinclair Coal Co., Kansas City, Mo.

Saffire Mine; Shaft; Hartshorne Seam, 45 in. thick.

GENERAL STRATIGRAPHIC SECTION FOR YAMPA COAL FIELD

COAL FIELDS OF COLORADO

COLORADO*

General Description of the Geology of the Coal Fields, With the Ranks of Coal Produced; Treats of the Mining Areas With a Map Showing Their Location; Railroads Serving the Various Districts; Columns of Geological Formations; Kinds of Coal: General Analysis, Etc.

The total area of the coal fields of the State of Colorado has been estimated at 18,100 square miles, of which area 50 per cent is estimated workable. The total yearly production of coal is about 12,000,000 tons, half of which comes from Huerfano and Las Animas counties in the Trinidad field. The yearly production of coke amounts to about 2,000,000 tons, nearly all of which is produced in Las Animas county, with a small quantity from La Plata and Gunnison counties.

The coal fields of Colorado lie on both flanks of the Rocky Mountain Range. The Denver field, the Raton field and the Canyon City field lie along the eastern edge of the mountain ranges. The North Park and South Park fields lie within the great mountain area, and the Yampa, Grand River and Durango-Gallup fields lie on the western flanks of the mountains. The general character of the Cretaceous coals of the Western States is subbituminous, but owing to conditions of mountain building and volcanic action they have been metamorphosed locally into the higher grades of bituminous coal and anthracite. This form of metamorphism is frequently designated "regional" as contrasted with "local." By regional metamorphism is meant those changes in the rocks that are wrought by the forces of heat and pressure accompanying deep burial and mountain-building upheavals. Local metamorphism includes those changes effected by igneous intrusion, which are largely the result of the heat of the molten rock, but also includes the chemical changes brought about by the hot gases and solutions which accompany such processes. As these names indicate, the former is comparatively uniform and far reaching in its effects, while the latter is restricted to the immediate vicinity of the eruptive masses which cause the change. The anthracite coals of Pennsylvania are the product of regional metamorphism of original or normal bituminous coals just as the bituminous coals of the Rocky Mountains are the product of regional metamorphism of original subbituminous coals, but the anthracites of the Rocky Mountains are the product of local metamorphism.

In general it may be said that in close proximity to the mountains the coal of Colorado is changed to bituminous, and at some distance it retains its original subbituminous character. East of the Rocky Mountains the subbituminous coals in general occur in the central and eastern parts of the fields, while bituminous varieties are found along the flanks of the ranges. North and south of the region as a whole a similar change can be noted, from the high-grade coals near the mountain masses to subbituminous in Wyoming and New Mexico. On the west, also, the low-grade coals are found in fields farther removed from the great mountain masses which constitute the core of the Rocky and San Juan mountain ranges.

On account of this metamorphism in the vicinity of the mountain masses, and also on account of its variability from place to place, the State of Colorado contains representatives of almost all grades of coal that are known. Anthracite is found only in limited areas, and at present is mined only at Crested Butte, in Gunnison county.

Bituminous coal is much more common, occurring in the Raton, Durango, Grand River and Yampa fields, in the counties of Archuleta, Delta, Fremont, Garfield, Gunnison, Huerfano, Las Animas, La Plata, Mesa, Moffat, Montezuma, Park, Pitkin, Rio Blanco and Routt counties.

Subbituminous coal occurs in almost all of the fields of the State, though principally in Adams, Boulder, Delta, El Paso, Fremont, Larimer, La Plata, Jefferson, Routt and Weld counties. So far as known at the present time, the Raton, Durango and Grand River fields are the only ones containing good coking coal. From time to time reports are current regarding the discovery of coking coals in other fields, but the quantity has always proved too small to be of commercial value, or the quality such that the product could not be marketed. Las Animas, Gunnison, Pitkin and La Plata counties now produce coal that is utilized for coking, and coal from Garfield county has been coked in the past.

Colorado Anthracite.† Anthracite is, in Colorado, limited to areas that have been invaded by igneous rocks. What regional metamorphism did on a large scale for the coals of the Appalachian region by the mechanical heat of folding and deep burying, and other metamorphic agencies, has been accomplished, and apparently in a much shorter space of time, in Colorado, by the local intrusion and influence of heated or molten igneous rocks. Hence, as the metamorphic agencies and influences were local, rather than widespread or regional, we find Colorado anthracite to be also local, limited and irregular, dependent, as we have said, wholly on the casual intrusion or influence of igneous rocks upon the normal coal, either lignitic or bituminous.

The limited areas of Colorado anthracite are confined to close proximity to volcanic dikes or intrusive sheets of lava, and the anthracitic condition or not of the coal is dependent upon the somewhat erratic behavior of these same igneous bodies. For example, a body of bituminous, or even lignitic coal, may

*The information here presented on Colorado coals has been gathered largely from the following sources: 22nd Annual Report, Part 3, 1901; U. S. G. S. Bulletins Nos. 297, 316, 341, 381 and 471; Monograph U. S. G. S. by R. C. Hills; The Primero Mines, by R. M. Hosea, Mines & Minerals, Vol. 24, pg. 521.

†Colorado Anthracite, by Prof. Arthur Lakes, Mines & Minerals, Vol. 26, pg. 275.

locally, and for a few yards, be changed into anthracite at near contact with an intrusive sheet, but should that erratic sheet leave its plane of horizon in the strata, as it is apt to do, and deviate even but slightly from its original contact or nearness to the coal, the coal in that interval is apt to return to its original unaltered condition.

The favorite local position for a bed of anthracite is on one, or both, sides of an igneous dike, or of a horizontal or gently dipping intrusive sheet of igneous rock, conforming generally to the planes of stratification of the sedimentary beds. The igneous rock may be in close contact, or it may be separated from actual contact with the coal by a few inches, or a foot or two of sedimentary rock. The most favorable position for an igneous rock to produce anthracitism in a coal seam is for it to be a little below the coal, rather than above it, the heat apparently ascending and slowly changing the coal.

Certain varieties of igneous rock appear to be more favorable to produce anthracitism than others, e. g., the light or gray acidic porphyrites, containing a great deal of silica in their quartz and feldspathic elements, are more favorable than the heavy, dark and basic lavas, such as basalt. The latter, if it changes the coal at all, is more likely to burn it and reduce it to a worthless coke, or to an impure graphite. Probably this phenomenon is due to the greater or less conductivity of the varieties of lava rock. In one case the heat may have been radiated more slowly and the process been more gradual than the other.

The anthracite areas in Colorado are, so far as is known, restricted to the Yampa coal field in Routt county, and to scattered occurrences in the Grand River field in Gunnison county. Both fields are remarkable for the igneous activity displayed in them, especially the Grand River field, which is largely occupied by the volcanic ranges of the Elk Mountains, all of which are of laccolitic origin and structure, and from these laccolites a vast number of dikes and intrusive sheets of igneous rocks traverse the coal strata. The Yampa field also has several laccolites, such as Bear Mountain and Hahns Peak, and many of the table lands are capped with lava and traversed by dikes, sending out intrusive sheets into the coal strata, as on the tableland capped by the volcanic mass of Pilot Knob, 20 miles north of Steamboat Springs.

In the Crested Butte district of the Grand River field we have a striking example of the influence of the eruptive rocks in the coal. The structure of the field has been produced by two agencies; first, the mountain-forming movement, and secondly, the Post-Cretaceous eruptive activity. The most prominent eruptions were in the southern half of the field. The character of the coal invariably depends upon the presence or absence, nearness to or distance from, intrusive eruptive rocks, and on their relation to the several coal seams. Thus the coal along the southern border, where volcanic activity was more pronounced, varies from semibituminous to anthracite. The gradation is well shown on Slate River, where the mines of Crested Butte are located upon a zone of coking coal less than one mile wide, grading on one side into semi-coking, and on the other through semianthracite to anthracite.

Railroads. The railroads traversing the coal areas are the Denver & Salt Lake; Colorado & Southern; Denver & Rio Grande; Atchison, Topeka & Santa Fe; Union Pacific; Rio Grande Southern; Chicago, Burlington & Quincy; Chicago, Rock Island & Pacific; Colorado & Midland; Colorado, Wyoming & Eastern; Colorado & Southeastern; Denver, Northwestern & Pacific; Crystal River; and Uintah.

The coals of Colorado will be discussed by fields.

Trinidad Field. (Comprises Huerfano and Las Animas counties.)

The Trinidad field is a part of a large and important area known as the Raton Mountain, or, preferably, the Raton Mesa coal region that lies along the eastern base of the front range in Colorado and New Mexico. This field may be divided into two districts: the Northern, or Walsenburg district, including the mines of Huerfano county; and the Southern, or Trinidad district, located in the southeastern corner of the field and including the mines of Las Animas county.

Walsenburg District. This coal bearing area lies in the northeastern part of the Raton field. The mines are operated on seams lying near the base of the Laramie formation, the lowest seam being within 10 feet of the Trinidad basal sandstone. There are two groups of seams affording workable coal bodies. Both lie well toward the base of the measures, and are separated from each other by a prominent bed of sandstone 30 to 60 feet thick, situated about 100 feet above the Trinidad sandstone.

The productive seams are not of continuous workable size throughout the district, but usually afford areas of "high coal," 4 feet or more thick, at several points along the outcrop. Not only do

the seams vary in thickness from place to place, but the number of seams in a group will vary; that is, small seams present in one section may be absent in another section less than a mile distant. Want of continuity is, therefore, a characteristic of the district, as of the Raton field generally. When one seam expands or thickens, there is generally parallel expansion of one or two other seams, as though there had been a local recurrence of the conditions favorable to coal formation. When the lowest seam is workable, there are commonly overlapping areas of workable coal in other seams.

The Walsenburg-Pictou group is the lower of the two groups of seams recognized. Mines are operated on each of the three workable beds it affords. The lowest, known as the Cameron at Walsenburg, and as the Maitland at Pictou, is 39 inches thick on the Cuchara River. It thickens to the north and in the Pictou mine is 5 feet. In the same locality is a 30-inch seam 14 feet above the Maitland. The Walsen seam at Walsenburg is 35 feet above the Cameron; it includes a lower bench 48 inches thick, separated from an upper bench 36 to 40 inches thick by a 2-inch parting of yellow clay. This seam is called the Lenox in the Pictou workings. There the lower bench is 5 feet thick and is separated by 18 inches of rock from the upper one, which is 20 to 24 inches thick.

The Robinson seam of the Walsenburg mine lies 60 feet above the Walsen, and is $6\frac{1}{2}$ feet thick in the Robinson mine; the same seam at Pictou is $4\frac{1}{2}$ feet thick.

Natural coke is common, adjacent to volcanic dikes. Certain layers in the seam afford purer coal than others, and the quality varies as these layers expand or contract. Explosive gases are rare. Water is sometimes too abundant, and at times may force up the shale floor and inundate the mine, as it did in the old Rouse mine.

The dip of the beds, which is southwesterly, is heaviest near the outcrop, and may be from 8 to 15 degrees. Faults occur, but have no relation to the dikes of the region; the latter appear not to fault the measures in the slightest degree. Displacements by faults range from a few inches to 25 feet.

The coal, which is semicoking or domestic, varies materially in composition at the different mines. The lowest seam generally affords the best quality of coal, but they are all good steam coals. The disappearance of the coking property is really progressive from the Ratón Mountain northward.

Trinidad District. The beds worked in the Trinidad district are confined to the lower series, although in the northern part of the district the upper group contains two workable seams. In the southern part of the district, the producing mines have from 4 to 8 feet of coal. The beds here have a slight inclination which gradually increases toward the north, becoming as high as 15 degrees in places near the northern end of the district.

The excellent coking quality of the coal from the Trinidad district is attributed to the presence of eruptive sheets of lava intruded into the strata of the coal formation. These have sometimes destroyed the coal seams when too near them, or transformed them into natural coke. In other cases, especially if the lava sheet lies below a coal seam and some distance from it, the coking property is highly developed. A peculiarity of the coal about Primero is the almost entire absence of cleavage. The coal seems to have been crushed and reconsolidated by pressure. Generally the coals in this district have the butts and faces very well marked, and mining is facilitated, as the coal breaks out in blocks or cubes when shot.

The principal production of the coke and a portion of the steam coal are consumed by the large lead and iron smelters of Pueblo and Denver.

GENERAL ANALYSIS

Ash	9.20	12.24
Sulphur	0.50	0.69
B. T. U.	13,780	12,227

Durango Field. (Comprises Montezuma, La Plata and Archuleta counties.)

The Durango field is located in the southwestern part of the State and extends thence into New Mexico and Utah. The extent of the field along the southern state line is 85 miles, north of which it extends about 15 miles, giving a superficial area of 1,250 square miles. There are two productive districts, the Durango and the La Plata. The first

is located near the town of that name and the product is entirely coking coal. The La Plata adjoins it on the west. There are two grades of coal in this district; one occurs in the Upper Laramie formation and the other in the Mesaverde formation. The Laramie coals, of which there are several beds, are of medium to low grade and are classed as subbituminous coal, or black lignite. It is dull black in color and softer than the ordinary bituminous coal, and like that breaks at the mines in cubical or block form. When exposed to the weather for a considerable time it gives out and reabsorbs more moisture under varying conditions of the atmosphere than the coals of higher grade and will finally slack, the blocks breaking down into small lumps or particles. It is considerably lighter than the better bituminous coals and when fired in the locomotive a large part of the smaller fragments of coal are driven out in the blast. The Laramie coals in this region contain many partings of shale and bone. This is especially true of the lower and thicker of the workable beds. In mining, these partings cannot be entirely eliminated from the marketable coal. Certain variable and thin bony streaks also are an inseparable part of the coal bed and give it a higher percentage of ash.

The other class of coal in the Durango district occurs in the Mesaverde formation and is known to contain three, and in places, four workable coal beds. The coals in the different beds vary in quality slightly from place to place. The beds that have been mined for a number of years at Porter are the best of those known in the district for carrying a good grade of coking coal, the coke being utilized chiefly for smelting purposes. Coals from this formation are excellent for locomotive use.

GENERAL ANALYSIS

	Laramie Coal	Mesaverde Coal
Moisture	3.45	3.55

Ash	15.75	7.00
Sulphur	0.95	1.95
B. T. U.	11,900	13,200

Canyon City Field. (Comprises the coals of Fremont county.)

The Canyon City coal field is a small syncline of the Laramie formation located in south central Colorado at the foot of Wet Mountain, which is the western range of the Rocky Mountain system in this region. The field comprises an isolated area of 54 square miles, two-thirds of which contain beds of workable thickness. Along the western margin of the field the strata are steeply upturned against the flanks of the mountain, but rapidly flatten out, so that in the body of the field they are nearly horizontal with a slight westward dip as the eastern edge is reached.

Faulting is very rare and there are no dikes or other evidence of eruptive rock within the area. Extensive prospecting with the diamond drill has demonstrated the presence of as many as 16 coal beds 4 inches thick and upward, the lower beds being the most persistent and ranging from 4 to 5 feet in thickness. The coal of the Canyon City field is well known in the west as possessing excellent qualities for domestic purposes. In burning it does not coke, but produces a bright flame and

leaves but a small amount of very light ash. Practical tests have shown that it does not coke. The absence of the coking property makes the coal cleaner to handle and therefore more desirable as domestic fuel, although it would be better for steaming purposes if it had a tendency to coke. In general, the coals of this field may be considered as the transitional type between the lignitic coals of the South Platte field and the more altered coals of the Raton field. The coal is firm and hard and produces comparatively little dust in handling. A very desirable quality of the coal from this field is that it stocks unusually well. This statement applies more particularly to coals from the northern end of the field, it having been observed that the coal is not quite so hard from the south end of the field.

GENERAL ANALYSIS

Moisture	11.70
Volatile Matter	34.70
Fixed Carbon	45.00
Ash	8.60
Sulphur	0.65
B. T. U.	11,000

South Park Field. (Comprises the coals of Park county.)

The South Park coal field is located in the western part of South Park, an intermountain depression in central Colorado. Between 1875 and 1893 several mines near Como were worked on a large scale by the Union Pacific Coal Company, but they were abandoned after the best and most easily available coal had been mined.

There are no commercial shipments made from this region at the present writing and it is probable that extensive operations will not be made for many years, because of the difficulty in finding the coal beneath the cover of gravel and weathered rock and of the apparent absence of thick coal beds.

The coal beds of South Park occur in what is presumably the Laramie formation, consisting of sandstone, with subordinate beds of carbonaceous shale and ranging in thickness from 375 feet down to the vanishing point. The field is about 21 miles long and from 3 to 5 miles wide. Only one-half of this area can be considered available on account of the intrusion of the eruptive mass which limits the workable area on the south. The northern end is badly faulted, which makes the cost of production excessive. The inclination of the beds along the western outcrop ranges from 30 degrees to 50 degrees through the workable area. Three coal beds are present in the Laramie, where the entire formation is present. The lowest coal bed, which is usually the best, is regarded as the basis of the formation and rests directly and conformably on the upper mountain sandstone.

The second coal bed occurs about 180 feet above the lower coal, while the upper coal bed lies about 200 feet above the middle coal.

The coal of the South Park field is bituminous and of an excellent quality for steam purposes. The quantity available is unknown, but such explorations as have been conducted show that very little of the coal is of satisfactory thickness.

The future of the field is problematical and

depends on the discovery of beds of workable thickness. All in all, this comprises one of the least valuable fields of this State.

GENERAL ANALYSIS

Moisture	6.80
Volatile Matter	36.25
Fixed Carbon	53.95
Ash	3.00
Sulphur	0.50

Tongue Mesa Field. (Comprises the coals of Montrose county.)

This field includes a long, narrow, isolated strip of the Laramie Measures occupying the region between the Cimarron and Uncompahgre rivers. The strata which are not steeply inclined, contain two beds of workable thickness. The lower is from 15 to 20 feet thick, the upper, 400 feet above, is 5 feet thick and contains a better grade of coal. The coal is dry, closely resembling the lignitic coals of the eastern slope. The greater part of the output from this field, which is of relatively small importance, is consumed in the town of Montrose on the line of the Denver & Rio Grande Railroad, about 10 miles northeast of the field.

GENERAL ANALYSIS

Moisture	14.00
Volatile Matter	37.65
Fixed Carbon	41.30
Ash	7.05
Sulphur	0.58

North Park Field. (Comprises the coals of Jackson county.)

This field comprises nearly the entire area of the most northern of the interrange parks of the State, extending from its northern end as far south as the divide separating the drainage of this park from that of Middle Park. The measures through the center of the area are covered by post-Laramie beds of considerable thickness. The beds outcropping on the northern edge of the park have a slight dip to the south for a short distance, when they gradually assume a northern dip, owing to the presence of an anticline fold, the beds on each side of which have an inclination of about 15 degrees.

There are in this field apparently three workable coal beds, all remarkably free from shaly impurities, and of considerable size. The largest is from 21 to 32 feet thick, another is 15 feet, and the third from 4 to 5 feet.

The character of this coal is essentially the same as that of the coals in the Denver field, namely, lignitic, but not true lignite.

GENERAL ANALYSIS

Moisture	19.60
Volatile Matter	33.75
Fixed Carbon	39.90
Ash	6.75
Sulphur	0.60
B. T. U.	9,600

Yampa Field. (Comprises the coals of Moffat and Routt counties.)

This field lies altogether on the drainage of the Yampa River. It is but a few miles north of the Grand River field, the two being separated by a small eroded anticlinal valley from the sides of which the strata of the two fields dip in opposite directions, doubtless at one time having been connected. The Yampa field gives great promise of becoming one of the big producing districts of Colorado.

The coal bearing rocks of the Yampa field are found in the Mesaverde formation and in the Laramie. The main basin that composes the field is complicated by a number of cross folds or wrinkles whose axes trend approximately at right angles to that of the major fold. Within the area of the coal bearing rocks the structure of the field is influenced only in a very subordinate way by folds. Local slips or breaks in the strata may be noted at a number of points, but with two or three exceptions these disturbances are not of sufficient magnitude to produce any marked effect on the distribution or general attitude of the strata. Intrusive igneous rocks of several different types cut the sedimentary beds at many points in the Yampa field, and these are the important factors in the anthracization of the coal seams. The heat accompanying the intrusion of molten lava has influenced in varying degrees the character and position of the coal seams that lie adjacent. In general, the effect of this baking process on the coal seams has been to drive off the volatile hydrocarbons more or less completely. In this way all grades of coal ranging from lignite to anthracite have been formed. In general, the lignite is found where the rocks are little disturbed and at a considerable distance from the great mountainous centers of uplift. Bituminous coal usually occurs in those parts of the field that are nearer in position to the mountains, and the anthracite, where some dike, or sill or igneous rock, has cut the coal or come into sufficiently close proximity to drive off its volatile constituents. The bulk of the coal, however, is probably bituminous, having a bright, shiny luster and more or less prismatic structure. It is sufficiently hard to be mined without a heavy percentage of slack and also to stand transportation. It does not weather badly and so is well fitted for domestic use and for the production of steam. The anthracite, although of somewhat limited extent, will doubtless be used largely as a domestic fuel. It is doubtful if any of the coals of the Yampa fields can be classed as coking coal.

GENERAL ANALYSIS

	Bituminous	Anthracite
Moisture	10.30	6.95

B. T. U.	11,900	12,000

South Platte Field—Denver Region. (Comprises the coals of El Paso, Douglas, Elbert, Denver, Arapahoe, Jefferson, Larimer, Adams, Boulder and Weld counties.)

This field consists of a continuous strip of coal bearing rocks beginning a few miles north of Colo-

rado Springs and extending thence nearly to the north line of the State. The western limit is defined by the upturned strata in the foothills of the Front Range along which the field extends, according to Mr. Hills, for a distance of 140 miles. The width of the field averages about 40 miles, these dimensions representing the extent of the Laramie formation containing coal seams of economic value.

The great area east of this line in northeastern Colorado contains, with local exceptions, only coal of an inferior grade. The strata along the western edge of the South Platte field are steeply upturned along the base of the range, but rapidly flatten out toward the east. There are, however, gentle undulations through the body of the field, their axes extending parallel with the axis of the range. Faulting is generally confined to the northern district, in which there are numerous displacements, often of such magnitude as to prevent the extension of mine workings. The occurrence of eruptive rock is limited to the small flow near Golden, on the western edge, and a small patch at Castle Rock, near the center of the field.

So far as known, there are from one to four coal beds in the field, from two to four being found in the southern district and in the southern part of the northern district, and one in the rest of this district. These beds vary from 3 to 16 feet in thickness, the greatest development being in the center of the field.

The character of the coal is essentially lignitic, with local variations, though quite removed from true lignite, since it mines in blocks which show the even fracture of "block" coal. It has a black color and brilliant luster. It slacks rapidly upon exposure to the air and is therefore not adapted for storage or long transportation. The best grade of fuel is produced in that portion of the field in which the strata have been subjected to movement. This is the western edge of the northern district, where the strata are steeply upturned. The poorest coal is produced in the southern district. The coal found in the upper half of the measures contains too many impurities to enter into competition with that from the lower half.

On account of the excessive moisture content of these coals their use is entirely confined to the markets in the immediate vicinity, where they have a large consumption for domestic and steam purposes.

The South Platte field is divided into a northern district, or, as generally known, the Denver basin, and the southern district, or Colorado Springs field.

The Denver Basin. This field includes the mines in and about Boulder, Marshall, Erie, Lafayette and Louisville, where active mining has been carried on for a long time. The coal is shiny and black, is inclined to be massive except as it separates along the planes of bedding. Because of the rapid disintegration on exposure to air, the coal is generally shipped in box cars. Although it is inferior to much of the coal from other fields of Colorado, its nearness to Denver and to a region of intensive farming more than offsets its poor quality.

GENERAL ANALYSIS

Moisture	20.70
Volatile Matter	30.50
Fixed Carbon	43.65
Ash	5.15
Sulphur	0.35
B. T. U.	9,500

Colorado Springs Field. The Colorado Springs field lies in El Paso county. Its northern limit is indeterminate, for the coal bearing rocks pass under cover in that direction and all development or exploration are but little back from the outcrop. There is no marked difference in the character of the coal in different parts of this field. It slacks readily on exposure to the circulating air, breaking into fragments in an irregular network of cracks. Fossil resin is common in the coal.

GENERAL ANALYSIS

Moisture	22.30
Volatile Matter	33.30

Ash	6.15
Sulphur	0.40
B. T. U.	8,625

Grand River Field. (Comprises the coals of Delta, Garfield, Gunnison, Mesa, Rio Blanca and Pitkin counties.)

This is prospectively the most valuable field of the State, both because of its extent and because of the varied character of the coals which it contains. It forms the eastern extension of the Green River Basin, while the Wasatch field of Utah forms the western extension. It extends from the State line eastward to the base of Mount Wheatstone, near Crested Butte, a distance of over 150 miles, and from the drainage of the Yampa River on the north to the Gunnison River on the south, a distance of over 100 miles.

The thickness of the coal bearing Laramie varies from 2,000 feet along the southwestern border to 3,500 feet near the mines at Coal Ridge, on Grand River. The exact limiting beds are very hard to define at all points, and the change from the predominantly shaly beds of the Montana to the sandstones which comprise the greater part of the Laramie is so gradual that an arbitrary dividing line has been established at the massive sandstone immediately

under the lowest of the coal beds. The determination of the summit of the Laramie is equally difficult.

As elsewhere in the Rocky Mountain region, the structure of the field has been produced by two agencies, first, the mountain-forming movement, and, second, the post-Cretaceous eruptive activity. Most of the eruptions occurred in the southern half of the field.

The number of coal beds in this field varies considerably in the different localities. In the eastern, southern, northern and southwestern areas from two to four beds of workable size are known, while through the central tract and along the northwestern border there are from five to seven beds, containing a total of from 22 to 106 feet of clean coal.

The character of the coal invariably depends on the presence or absence of intrusive eruptive rocks and on their relation to the several coal seams. The coal along the northern border of the field is nearly all semibituminous, while that in the southern half varies from semibituminous to anthracite. The graduation is well shown on Slate River, where the mines at Crested Butte are located upon a zone of coking coal less than one mile wide, which grades on one side into semicoking and on the other into anthracite. The coke made from the coals of the Coal Basin district is superior to any other produced in the Rocky Mountain region, being remarkably similar to the Connellsville (Pa.) product, both in chemical composition and in physical structure.

GENERAL ANALYSIS

	Somerset Bituminous	Crested Butte Anthracite	Sunlight	Grand Junction
Moisture	3.70	3.00	6.75	9.75

Sulphur	0.55	0.85	0.90	0.75
B. T. U.	13,000	14,000	12,000	12,200

PREPARATION OF COAL

The large variety of the coals in Colorado, along with the marked differences in the character of seams, necessarily involves the employment of many types of tippie equipment, in preparation and sizing. Because so much of the coal is lignitic and subject to rapid deterioration when exposed to air, a considerable portion of the output is loaded into box cars, usually by a mechanical device known as a box car loader.

The dirty condition of the coal in some regions generally necessitates some sorting before the product is marketable. Most of this work is done in the mines, the miners being required to discard bony coal and impurities. In the Trinidad district, where the greater part of the coal is coked, all that

is so used is first washed. At some places only the slack is made into coke, but where the entire output is coked the lump coal is crushed before washing.

The coal is usually put on the market in four grades—run of mine, lump, nut and slack. The entire product of only a few mines is disposed of as run of mine; generally the coal is sized, both shaking and stationary screens being used. In this region there are no standard sizes for the several grades, and at each mine the practice is different. The most common sizes are as follows: Lump coal is that which passes over openings that vary in size between 1½ and 3 inches, nut coal passes over openings between ¾ inch and 1¼ inches, and slack is that which passes through ½ to 1-inch openings.

List of Mines By Counties, Including Name of Company, General Office Address, Railroad and Shipping Point.

COLORADO

BOULDER COUNTY COALS

Subbituminous rank. Suitable for Domestic, Locomotive Fuel, Producer Gas and Steam uses.

NAME OF COMPANY	GENERAL OFFICE ADDRESS	NAME OF MINE	COUNTY	RAILROAD	SHIPPING POINT
Big Four Coal & Coke Co.	Denver, Colo.	Centennial.	Boulder.	C. & S.	Louisville, Colo.
Cowie Coal Co., The.	Boulder, Colo.	Cowie.	Boulder.	Colorado & Southern.	Marshall, Colo.
Cracker Jack Coal Co.	1800 Bluebell Ave., Boulder, Colo.	Cracker Jack.	Boulder.	C. & S.	Boulder, Colo.
Engineers Leasing Co.	918 Equitable Bldg., Denver, Colo.	Cambria.	Boulder.	C. B. & Q.	Lafayette, Colo.
Fox Coal Mining Co.	Gorham, Colo.	Fox.	Boulder.	Colo. & Southern.	Marshall, Colo.
International Fuel Corp.	328 Gas & Elec. Bldg., Denver, Colo.	Champion.	Boulder.	C. & S. (Louis'v'e Ry.)	Louisville, Colo.
Marshall Coal Company.	311-12 Central Savings Bk. Bldg., Denver, Colo.	Red Ash.	Boulder.	C. & S.	Marshall, Colo.
Marshall Coal Company.	311-12 Central Savings Bk. Bldg., Denver, Colo.	Sunnyside.	Boulder.	C. & S.	Louisville, Colo.
National Fuel Company.	519 Colorado Bldg., Denver, Colo.	Monarch.	Boulder.	C. & S.	Louisville, Colo.
Northwestern Fuel Co.	416 Central Savings Bank Bldg., Denver, Colo.	Nonpareil.	Boulder.	C. & S.	Louisville, Colo.
Rocky Mountain Fuel Co.	Denver, Colo.	Aerne.	Boulder.	C. & S.	Louisville, Colo.
Rocky Mountain Fuel Co.	Denver, Colo.	Simpson.	Boulder.	C. & S., C. B. & Q.	Lafayette, Colo.
Rocky Mountain Fuel Co. (The).	Denver, Colo.	Gorham.	Boulder.	Colo. & Southern.	Marshall, Colo.
Rocky Mountain Fuel Co. (The).	Denver, Colo.	Industrial.	Boulder.	Colo. & Southern.	Superior, Colo.
Rocky Mountain Fuel Co. (The).	Denver, Colo.	Mitchell.	Boulder.	C. B. & Q.	Lafayette, Colo.
Rocky Mountain Fuel Co. (The).	Denver, Colo.	Standard.	Boulder.	C. B. & Q.	Lafayette, Colo.
Rocky Mountain Fuel Co. (The).	Denver, Colo.	Vulcan.	Boulder.	Colo. & Southern.	Lafayette, Colo.

DELTA COUNTY COALS

Bituminous and Subbituminous rank. Suitable for Domestic, Locomotive Fuel, Producer Gas and Steam uses.

NAME OF COMPANY	GENERAL OFFICE ADDRESS	NAME OF MINE	COUNTY	RAILROAD	SHIPPING POINT
Converse Coal Company.	Paonia, Colo.	Converse.	Delta.	D. & R. G.	Paonia, Colo.
Hall, A. W. Son.	Cedaredge, Colo.	Red Mountain.	Delta.	D. & R. G.	Delta, Colo.
Independent Lumber Co.	Hatchkiss, Colo.	Kurtzville Mine.	Delta.	D. & R. G.	Hatchkiss, Colo.
Juanita Coal & Coke Co.	Pueblo, Colo.	King.	Delta.	D. & R. G.	Bowie, Colo.
Red Canon Coal Co.	Cedaredge, Colo.	Red Canon.	Delta.	D. & R. G.	Delta, Colo.
States Coal Co.	Cedaredge, Colo.	States.	Delta.	D. & R. G.	Delta, Colo.
Winton Coal Co.	Cedaredge, Colo.	Winton.	Delta.	D. & R. G.	Delta, Colo.

EL PASO COUNTY COALS

Subbituminous rank. Suitable for Domestic, Locomotive Fuel, Producer Gas and Steam uses.

NAME OF COMPANY	GENERAL OFFICE ADDRESS	NAME OF MINE	COUNTY	RAILROAD	SHIPPING POINT
Colorado Springs Co., The.	Colorado Springs, Colo.	City No. 1 Mine.	El Paso.	A. T. & S. F.	Colorado Springs, Colo.
Corley, W. D.	Colorado Springs, Colo.	Klondike.	El Paso.	A. T. & S. F.	Breed, Colo.
Patterson, Alexander.	2409 W. Feyon, Colorado Springs, Colo.	City No. 2 Mine.	El Paso.	A. T. & S. F.	Santa Fe, Colo.
Pikes Peak Consolidated Fuel Co.	125 E. Pikes Peak Ave., Colorado Springs, Colo.	Keystone.	El Paso.	C. R. I. & P.	Colorado Springs, Colo.
Pikes Peak Consolidated Fuel Co.	Colorado Springs, Colo.	Pikeview.	El Paso.	D. & R. G.	Colorado Springs, Colo.

FREMONT COUNTY COALS

Bituminous and Subbituminous ranks. Suitable for Domestic, Locomotive Fuel, Producer Gas and Steam uses.

NAME OF COMPANY	GENERAL OFFICE ADDRESS	NAME OF MINE	COUNTY	RAILROAD	SHIPPING POINT
Canon Crystal Coal Company.	Box 233, Canon City, Colo.	Bassick.	Fremont.	D. & R. G.	Rockvale, Colo.
Canon-Reliance Coal Co., The.	Canon City, Colo.	"Canon".	Fremont.	A. T. & S. F.	Canon City, Colo.
Colorado Fuel & Iron Co.	Denver, Colo.	Coal Creek.	Fremont.	A. T. & S. F.	Rockvale, Colo.
Colorado Fuel & Iron Co. (The).	Boston Bldg., Denver, Colo.	Emerald.	Fremont.	D. & R. G.	Rockvale, Colo.
Colorado Fuel & Iron Co.	Denver, Colo.	Fremont.	Fremont.	D. & R. G.	Florence, Colo.
Colorado Fuel & Iron Co.	Denver, Colo.	Monae.	Fremont.	A. T. & S. F.	Canon City, Colo.
Colorado Fuel & Iron Co.	Denver, Colo.	Rockvale.	Fremont.	A. T. & S. F.	Rockvale, Colo.
Florence-Canon Coal Co., The.	Florence, Colo.	Florence-Canon Mine.	Fremont.	D. & R. G.	Florence, Colo.
Gibson Lumber & Fuel Co.	Box 75, Canon City, Colo.	Royal Gorge.	Fremont.	A. T. & S. F.	Canon City, Colo.
Harris, Elmer R.	Coal Creek, Colo.	Double Dick.	Fremont.	D. & R. G.	Florence, Colo.
Vezzetti & Moschetti Coal Company.	B. F. D. No. 1, Canon City, Colo.	Brookside.	Fremont.	A. T. & S. F.	Canon City, Colo.
Victor-American Fuel Co.	Denver, Colo.	Chandler.	Fremont.	C. & S.	Chandler, Colo.
Victor-American Fuel Co.	Denver, Colo.	Radiant.	Fremont.	A. T. & S. F.	Florence, Colo.

GARFIELD COUNTY COALS

Bituminous rank. Suitable for Cement Burning, Melting, Tile and Pottery Burning, Powdered, Domestic, Locomotive Fuel, Producer Gas and Steam uses.

NAME OF COMPANY	GENERAL OFFICE ADDRESS	NAME OF MINE	COUNTY	RAILROAD	SHIPPING POINT
Gilson-Asphaltum Co.	Philadelphia, Pa.	Carbonera.	Garfield.	Unita.	Carbonera, Colo.

GUNNISON COUNTY COALS

Anthracite, Semibituminous and Bituminous ranks. Bituminous coals suitable for Cement Burning and Bee-hive Coking; all coals suitable for Domestic, Locomotive Fuel, Producer Gas and Steam uses.

NAME OF COMPANY	GENERAL OFFICE ADDRESS	NAME OF MINE	COUNTY	RAILROAD	SHIPPING POINT
Baldwin Fuel Co.	850 Equitable Bldg., Denver, Colo.	Baldwin Star.	Gunnison	D. & R. G.	Copper Spur, Colo.
Colorado Fuel & Iron Co.	Denver, Colo.	Crested Butte.	Gunnison	D. & R. G.	Crested Butte, Colo.
Colorado Fuel & Iron Co. (The)	Boston Bldg., Denver, Colo.	Elk Mountain.	Gunnison	D. & R. G.	Crested Butte, Colo.
Crested Butte Anthracite Mng Co.	Equitable Bldg., Denver, Colo.	Smith Anthracite.	Gunnison	D. & R. G.	Crested Butte, Colo.
Crested Butte Coal Co. (The)	Equitable Bldg., Denver, Colo.	Bukley.	Gunnison	D. & R. G.	Crested Butte, Colo.
Ohio Creek Coal Co.	Gunnison, Colo.	Ohio Creek.	Gunnison	D. & R. G.	Gunnison, Colo.
Rocky Mountain Fuel Co., The.	Denver, Colo.	Alpine.	Gunnison	D. & R. G.	Crested Butte, Colo.
Ross Coal Co., The.	Crested Butte, Colo.	Lorance.	Gunnison	D. & R. G.	Sumner, Colo.
Utah Fuel Co.	Salt Lake City, Utah.	Sumner.	Gunnison	D. & R. G.	Sumner, Colo.

HUERFANO COUNTY COALS

Bituminous rank. Suitable for Cement Burning, Domestic, Locomotive Fuel, Producer Gas and Steam uses.

NAME OF COMPANY	GENERAL OFFICE ADDRESS	NAME OF MINE	COUNTY	RAILROAD	SHIPPING POINT
Aztec Coal Mining Co.	Denver, Colo.	Toltee No. 1.	Huerfano	C. & S., D. & R. G.	Walsenburg, Colo.
Black Canon Coal & Fuel Co.	Denver, Colo.	Caddell.	Huerfano	D. & R. G., C. & S.	Walsenburg, Colo.
Green Coal Mining Co.	Walsenburg, Colo.	Breen.	Huerfano	C. & S., D. & R. G.	Walsenburg, Colo.
Brennan Coal Mining Co., The.	Walsenburg, Colo.	Brennan.	Huerfano	D. & R. G., C. S.	Walsenburg, Colo.
Caddell & Son.	Lester, Colo.	Heron.	Huerfano	D. & R. G.	Rouse Jct., Colo.
Canon-Reliance Coal Co., The.	Canon City, Colo.	Rivance.	Huerfano	D. & R. G.	LaVeta, Colo.
Castle Coal Company.	Walsenburg, Colo.	Caprock.	Huerfano	D. & R. G., C. & S.	Walsenburg, Colo.
Colorado Fuel & Iron Co.	Denver, Colo.	Camaron.	Huerfano	Colorado & Southern	Farr, Colo.
Colorado Fuel & Iron Co.	Denver, Colo.	Heron.	Huerfano	C. & S.	Lester, Colo.
Colorado Fuel & Iron Co.	Denver, Colo.	Ideal.	Huerfano	Colorado & Southern	Mayne, Colo.
Colorado Fuel & Iron Co. (The)	Boston Bldg., Denver, Colo.	Johal.	Huerfano	D. & R. G.	Walsenburg, Colo.
Colorado Fuel & Iron Co. (The)	Boston Bldg., Denver, Colo.	Kehler No. 1.	Huerfano	D. & R. G.	Tioga, Colo.
Colorado Fuel & Iron Co. (The)	Boston Bldg., Denver, Colo.	Kehler No. 2.	Huerfano	D. & R. G.	Tioga, Colo.
Colorado Fuel & Iron Co.	Denver, Colo.	Lester.	Huerfano	C. & S.	Lester, Colo.
Colorado Fuel & Iron Co.	Denver, Colo.	Pictou.	Huerfano	D. & R. G.	Walsenburg, Colo.
Colorado Fuel & Iron Co.	Denver, Colo.	Rouse.	Huerfano	D. & R. G.	Rouse, Colo.
Colorado Fuel & Iron Co.	Denver, Colo.	Walsen & Robinson.	Huerfano	C. & S., D. & R. G.	Walsenburg, Colo.
Gordon Coal Co.	Walsenburg, Colo.	Gordon.	Huerfano	D. & R. G.	Walsenburg, Colo.
McNally & Thompson.	Maitland, Colo.	Maitland No. 1.	Huerfano	D. & R. G.	Tropic, Colo.
Oakdale Coal Co. (The)	Denver, Colo.	Oakdale Nos. 1 & 2.	Huerfano	D. & R. G.	Strong, Colo.
Sunnyside Coal Mining Co. (The)	1062 Gas & Electric Bldg., Denver, Colo.	Sunnyside.	Huerfano	D. & R. G.	Walsenburg, Colo.
Turner Coal Co.	Walsenburg, Colo.	Turner.	Huerfano	D. & R. G.	Pryor, Colo.
Union Coal & Coke Co.	Denver, Colo.	Pryor.	Huerfano	D. & R. G.	Walsenburg, Colo.
Vesta Mines, Inc.	Cooper Bldg., Denver, Colo.	Vesta.	Huerfano	C. & S.	Ravenwood, Colo.
Victor-American Fuel Co.	Denver, Colo.	Ravenwood.	Huerfano	D. & R. G.	Ravenwood, Colo.
Walsenburg Coal Mining Co.	Denver, Colo.	Solar.	Huerfano	Denver & Rio Grande	Solar, Colo.

JACKSON COUNTY COALS

Lignitic rank. Suitable for Domestic, Locomotive Fuel, Producer Gas and Steam uses.

NAME OF COMPANY	GENERAL OFFICE ADDRESS	NAME OF MINE	COUNTY	RAILROAD	SHIPPING POINT
North Park Coal Co.	Fort Collins, Colo.	North Park	Jackson	C. W. & E.	Coalmont, Colo.

JEFFERSON COUNTY COALS

Subbituminous and Lignite ranks. Suitable for Domestic, Locomotive Fuel, Producer Gas and Steam uses.

NAME OF COMPANY	GENERAL OFFICE ADDRESS	NAME OF MINE	COUNTY	RAILROAD	SHIPPING POINT
Colorado Collieries Co.	911 Foster Bldg., Denver, Colo.	Satanic.	Jefferson	C. & S.	Mt. Morrison, Colo.
Leyden Coal Company, The.	707 Tramway Bldg., Denver, Colo.	Leyden No. 3.	Jefferson	D. & M., D. & S. L., C. & S.	Denver, Colo.

LA PLATA COUNTY COALS

Bituminous and Subbituminous ranks. Bituminous coal suitable for Cement Burning, Bee-hive Coking, Melting, Tile and Pottery Burning and Powdered uses; all coals suitable for Domestic, Locomotive Fuel, Producer Gas and Steam uses.

NAME OF COMPANY	GENERAL OFFICE ADDRESS	NAME OF MINE	COUNTY	RAILROAD	SHIPPING POINT
American Smelting & Refining Co.	120 Broadway, New York, N. Y.	San Juan.	La Plata	D. & R. G.	Durango, Colo.
Calumet Fuel Co. (The)	Judge Bldg., Salt Lake City, Utah.	Perins Peak.	La Plata	Rio Grande, Southern	Durango, Colo.
Hesperus Fuel Co.	Hesperus, Colo.	Hesperus.	La Plata	Rio Grande, Southern	Hesperus, Colo.
Sunshine Coal Co.	Durango, Colo.	Sunshine.	La Plata	D. & R. G.	Durango, Colo.

LAS ANIMAS COUNTY COALS

Bituminous rank. Suitable for Cement Burning, Bee-hive Coking, Melting, Tile and Pottery Burning, Powdered, Domestic, Locomotive Fuel, Producer Gas and Steam uses.

NAME OF COMPANY	GENERAL OFFICE ADDRESS	NAME OF MINE	COUNTY	RAILROAD	SHIPPING POINT
American Smelting & Refining Co.	120 Broadway, New York, N. Y.	Boncarbo.	Las Animas.	D. & R. G.	Cokedale, Colo.
Bear Canon Coal Co. (The)	Trinidad, Colo.	Bear Canon Nos. 1, 3 & 6.	Las Animas.	C. & S.	Berwind, Colo.
Black Hawk Coal Co. (The)	731 Cooper Bldg., Denver, Colo.	Primrose No. 4.	Las Animas.	C. & S., D. & R. G.	Rugby, Colo.
Cedar Hill Coal & Coke Co.	Denver, Colo.	Black Diamond.	Las Animas.	C. & S.	Rugby, Colo.

EE—John Heltefreu, Milner, Colo.
SCO—Stucky-Allen, Milner, Colo.
SA—Carbon Coal & Supply Co., Omaha, Neb.

Elk Creek No. 1 Mine; Drift; Wolf Creek Seam, 168 inches thick.
PO—Milner, Colo.; SP—Same; CTY—Routt; RR—Denver & Salt Lake.
MS—Albert Oliver, Milner, Colo.
S of H—Main and tail rope. Track gage 36 inches.
S of M—1 shortwall mach.
PP—2 125 H. P. fire tube boilers, gen. units, 150 K. W., 250 volts D. C., 3 pumps.
EMP—65. Last years output 40,000.
SIZES SHIPT—Run of Mine; Slack, Nut, Egg, Lump.
PREP. EQUIPT—Shaker Screens.
Note—Formerly operated by Elk Creek Mining Co.

Elk Creek No. 2 Mine; Drift; Wolf Creek Seam, 168 inches thick.
PO—Milner, Colo.; SP—Same; CTY—Routt; RR—Denver & Salt Lake.
MS—Albert Oliver, Milner, Colo.
S of H—Mules. Track gage 36 inches.
S of M—Shortwall machs.
PP—G-erates power, 250 volts D. C.
EMP—10. Last years output 4,000.
SIZES SHIPT—Run of Mine, Slack, Egg, Lump.
PREP. EQUIPT—Shaker Screens.

Yampa Mine; Slope; Madge Seam, 132 inches thick.
PO—Milner, Colo.; SP—Same; CTY—Routt; RR—Denver & Salt Lake.
MS—Paul Talbure, Milner, Colo.
S of H—Mules, main and tail rope. Track gage 36 inches.
PP—2 125 H. P. fire tube boilers, 3 pumps.
EMP—30. Last years tonnage 10,000.
SIZES SHIPT—Run of Mine, Slack, Egg, Lump.
PREP. EQUIPT—Shaker Screens.
Note—Formerly operated by Yampa Coaleries Company.

AMERICAN SMELTING & REFINING CO.

General Office, 120 Broadway, New York, N. Y.
PR—Simon Guggenheim, New York, N. Y.
VP—F. H. Brownell, 120 Broadway, New York, N. Y.
TR—John C. Emison, 120 Broadway, N. Y.
GM—G. P. Bartholomew, 120 Broadway, New York, N. Y.
GS—H. H. Bubb, Cokedale, Colo.
PA—E. R. Reets, 120 Broadway, New York, N. Y.
EE—G. V. Hughes, Cokedale, Colo.
SCO—Gottlieb Merc. Co. Buyer, L. R. Gottlieb, Cokedale, Colo.

Cokedale Plant

Boncarbo Mine; Drift; Boncarbo Seam, 66 in. thick.
PO—Cokedale, Colo.; SP—Frt., Same
EN—Trinidad, Colo. CTY—Las Animas; RR—D. & R. G.
MS—C. R. Garrett, Boncarbo, Colo.
S of H—6 gathering and 1 haulage loco. Track gage 36 in.
S of M—10 shortwall machs.

PP—Power purchased. Transformer 22,000-440 volts A. C., 2—150 K. W., M. G. Sets, 250 volts D. C., 5 pumps.
EMP—225. Last years tonnage 219,641.
Coke Ovens—350 Bee Hive.
SIZES SHIPT—Run of Mine, Lump.
PREP. EQUIPT—Shaker Screens.

San Juan Mine; San Juan Seam, 36 in. thick.
PO—Durango, Colo.; SP—Same; CTY—La Plata; RR—D. & R. G.
MS—R. P. Reynolds, Durango, Colo.
S of H—Mules. Track gage 36 in.
S of M—Hand.
PP—Power purchased, transformer 2300 volts A. C., M. G. Set, 220 volts D. C.
EMP—30. Last years tonnage 26,424.
Coke Ovens 28 Bee Hive.
SIZES SHIPT—Run of Mine, Slack, Lump.

AXIAL BASIN DEVELOPMENT COMPANY

General Office, 631 U. S. National Bank Bldg., Denver, Colo.
PR—H. W. Myers, Kansas City, Mo.
VP—Frank A. Butler, Indianapolis, Ind.
VP—H. J. Paulus, Marion, Ind.
TR—H. W. Swigert, Denver, Colo.
GM—C. M. Thompson, Mt. Streeter, Colo.
GS—C. M. Thompson, Mt. Streeter, Colo.
PA—A. J. Kapple, Mt. Streeter, Colo.
CE—C. M. Thompson, Mt. Streeter, Colo.
SCO—Address the Company, Buyer, A. J. Kapple, Mt. Streeter, Colo.

No. 10 Columbine, Miller and E Mines; Drifts; Mesa Verde Seam; 25-30 ft. thick.
PO—Mt. Streeter, Colo.; SP—Craig, Colo.; CTY—Moffat.
S of H—Mules.
S of M—Hand.
PP—2 pumps.
EMP—10. Daily tonnage 10.
SIZES SHIPT—Run of Mine, Slack, Pea, Lump.
PREP. EQUIPT—Gravety Screens.

AZTEC COAL MINING CO.

General Office, Denver, Colo.
PR—Geo. Fruth, Denver, Colo.
TR—Geo. Fruth, Denver, Colo.
GM—Geo. Fruth, Denver, Colo.
PA—Geo. Fruth, Denver, Colo.
CE—Woolfender, Wood & Webb, 1109 Broadway, Denver, Colo.
SCO—Huerfano Trading Co., Buyer, Jno. Kirkpatrick, Walsenburg, Colo.
SA—G. R. Houghton, Denver, Colo.

Toltec Mine; Slope; Walsen-Cameron Seam, 42-60 in. thick.
PO—Toltec, Colo.; SP—Walsenburg, Colo.; CTY—Huerfano; RR—Colo. & Sou. and D. & R. G.
MS—S. R. Smith, Walsenburg, Colo.
S of H—Mules and rope. Track gage 36 inches.
S of M—2 electric, 2 comp. air punchers and 4 shortwall machs.
PP—Power purchased. Transformer 2,300-440 volts A. C., 2 M. G. Sets 440-250 volts D. C., 4—380 H. P. fire tube boilers, 6 pumps.
EMP—85. Last years tonnage 37,577.
SIZES SHIPT—Slack, Pea, Nut, Lump.
PREP. EQUIPT—Shaker Screens.

THE BALDWIN FUEL CO.

General Office, 850 Equitable Bldg., Denver, Colo.
PR—Frank Bulkley, 850 Equitable Bldg., Denver, Colo.
TR—Joseph Gledartz, Denver, Colo.
GS—Clarence S. Kellenger, Baldwin, Colo.
EM—John Robinson, Gunnison, Colo.
SA—F. C. Ewing, 850 Equitable Bldg., Denver, Colo.

Raldwin Star Mine; Slope; No. 1 Vein Seam; 84 inches thick.
PO—Baldwin, Colo. SP—Copper Spur, Colo.; CTY—Gunnison; RR—D. & R. G.
S of H—Mules. Track gage 36 inches.
S of M—Hand.
PP—1 40 H. P. fire tube boiler, 1 pump.
EMP—10-30. Daily output, 50 tons.
SIZES SHIPT—Run of Mine, Slack, Lump.
PREP. EQUIPT—Gravity Screens.

BEAR CANON COAL COMPANY, THE

General Office, Trinidad, Colo.
PR—John Aiello, Trinidad, Colo.
VP—P. D. Miller, Valloroso, Colo.
TR—W. G. Plested, Trinidad, Colo.
GM—Chas. Beuchat, Trinidad, Colo.
GS—P. D. Miller, Valloroso, Colo.
PA—Chas. Beuchat, Trinidad, Colo.
CE—Douglas, Cory & Fisk, Trinidad, Colo.
EM—C. E. Corey, Trinidad, Colo.
EE—M. D. Enke, Valloroso, Colo.
SCO—Valloroso Mercantile Co., Buyer, W. H. Lincoln, Valloroso, Colo.
SA—J. J. J. Alcerrombie, Trinidad, Colo.

Bear Canon Nos. 1, 3 and 6 Mines; Drift; Bear Canon, McLaughlin and Cass Seams, 48-72 in. thick.
PO—Valloroso, Colo.; SP—Berwind, Colo.; CTY—Las Animas; RR—C. & C. and D. & R. G.
S of H—Mules and storage battery loco. Track gage 42 in.
S of M—2 comp. air punchers and 2 shortwall machs.
PP—Power purchased. Transformers, 2,300-440 volts A. C.
EMP—85. Last years tonnage 50,000.
SIZES SHIPT—Run of Mine.
PREP. EQUIPT—Picking Tables.

BEAR RIVER COAL COMPANY.

General Office, 514 Central Savings Bk. Bldg., Denver, Colo.
PR—John Connell, Denver, Colo.
VP—P. M. Peltier, Denver, Colo.
TR—W. T. Mayfield, Denver, Colo.
GM—John Connell, Denver, Colo.
GS—John Connell, Denver, Colo.
PA—W. T. Mayfield, Denver, Colo.
CE—J. J. Argo, Denver, Colo.
EE—R. R. Smith, Bear River, Colo.
SCO—Bear River Mercantile Co. Buyer, Louis Barberio, Bear River, Colo.
SA—The Big Four Coal Selling Agency, Denver, Colo.

Bear River Mine; Slope; Bear River Seam, 109 to 168 in. thick.
PO—Bear River, Colo.; SP—Same; CTY—Routt; RR—D. & S. L.
MS—R. R. Smith, Bear River, Colo.
S of H—Combination locos. Track gage 36 inches.
S of M—Hand.
PP—2 fire tube and 3 water tube boilers, total 700 H. P., gen. units, 410 volts, A. C.
EMP—73. Last years tonnage 72,481.
SIZES SHIPT—Slack, Nut, Lump, Pea.
PREP. EQUIPT—Revolving and Shaker Screens.

BIG FOUR COAL & COKE CO.

General Office, 512 Central Savings Bk. Bldg., Denver, Colo.
PR—P. M. Peltier, Denver, Colo.
VP—E. Nesbit, Denver, Colo.
TR—E. Nesbit, Denver, Colo.
GM—P. M. Peltier, Denver, Colo.
GS—E. Nesbit, Denver, Colo.
PA—P. M. Peltier, Denver, Colo.
EM—Thomas Knill, Lafayette, Colo.
SA—W. W. Colvin, Denver, Colo.

Centennial Mine; Shaft; Larimer Seam, 72 in. thick.
PO—Louisville, Colo.; SP—Same; CTY—Boulder; RR—Colo. & Southern.
MS—W. Andrews, Louisville, Colo.
S of H—Mules, rope. Track gage 36 in.
S of M—Electric mach. and punchers.
PP—Purchase power, 4 water tube boilers, total 450 H. P., 440 volts A. C., 5 pumps.
Last years tonnage 90,524.
SIZES SHIPT—Run of Mine, Slack, Lump.
PREP. EQUIPT—Shaker Screens.

BIG SIX COAL COMPANY, THE

Now part of Marshall Coal Company.

BLACK CANON COAL & FUEL CO., THE

General Office, 509 Tabor Bldg., Denver, Colo.
PR—Jno. Q. Royce, Wichita, Kan.
VP—S. S. Ott, Topeka, Kan.
TR—T. F. Crane, Denver, Colo.
GM—T. F. Crane, Denver, Colo.
GS—T. F. Crane, Denver, Colo.
PA—T. F. Crane, Denver, Colo.
SA—T. F. Crane, Denver, Colo.

Caddell Mine; Slope; Robinson and Cameron Seams; 36 inches thick.
PO—Walsenburg, Colo.; SP—Same; CTY—Huerfano; RR—D. & R. G. and C. & S.
MS—W. D. Robinson, Walsenburg, Colo.
S of H—Rope. Track gage 36 inches.
S of M—2 shortwall.
PP—Power purchased. Transformer 2,600 to 440 volts, A. C.
EMP—80. Last years tonnage 22,000.
SIZES SHIPT—Slack, Nut, Lump.
PREP. EQUIPT—Shaker Screens.

BLACK HAWK COAL CO., THE.

General Office, 731 Cooper Bldg., Denver, Colo.
PR—J. J. Wolfersperger, 731 Cooper Bldg., Denver, Colo.
VP—David Lewis, Rugby, Colo.
TR—Thos. F. Ahrens, 731 Cooper Bldg., Denver, Colo.
GM—J. J. Wolfersperger, 731 Cooper Bldg., Denver, Colo.
GS—David Lewis, Rugby, Colo.
PA—Thos. F. Ahrens, 731 Cooper Bldg., Denver, Colo.
SCO—Huerfano Trading Co. Buyer, Mr. Stroman, Rugby, Colo.
SA—The Southwestern Coal Co., Amarillo, Tex.

Primrose Mine; Slope; Primrose No. 2 Seam; 46 in. thick.
PO—Rugby, Colo.; SP—Same; CTY—Las Animas; RR—C. & S. and D. & R. C.
S of H—Mules and main rope. Track gage 36 in.
PP—Power purchased. Transformer 23,000 to 440 volts, motor geo. sets, 2 pumps.
EMP—50. Last years tonnage 34,102.
SIZES SHIPT—Run of Mine, Slack, Nut, Lump.
PREP. EQUIPT—Shaker Screens.

BOOK CLIFF R. R. CO., (THE)

LESSEES—Book Cliff Coal Co., Grand Junction, Colo.
GM—Lou Luther, Grand Junction, Colo.
PA—Lou Luther, Grand Junction, Colo.
Book Cliff Mine; Drift; Book Cliff Seam; 72 in. thick.
PO—Grand Junction, Colo.; SP—Same, CTY—Mesa; RR—The Book Cliff
S of H—Mules and 2 steam locos. Track gage 36 in.
S of M—Hand.
EMP—14. Last years tonnage 12,000.
SIZES SHIPT—Slack, Nut, Egg, Lump.
PREP. EQUIPT—Screens.

BOULDER VALLEY COAL COMPANY

General Office, 512 Central Savings Bk. Bldg., Denver, Colo.
PR—P. M. Peltier, Denver, Colo.
GM—P. M. Peltier, Denver, Colo.
GS—E. Nesbit, Denver, Colo.
PA—P. M. Peltier, Denver, Colo.
EM—T. J. Knill, Lafayette, Colo.
SA—Big Four Coal & Coke Co., Denver, Colo.

Boulder Valley Mine; Shaft; Larimer Seam, 114 inches thick.
PO—Erie, Colo.; SP—Same; CTY—Weld; RR—Union Pacific.
MS—J. Weiler, Erie, Colo.
S of H—Mules and storage battery locos. Track gage 36 in.
S of M—Elec. machs. and punchers.
PP—Power purchased, 3 water tube boilers, 360 H. P.; 440 volts A. C., 5 pumps.
EMP—50. Last years tonnage 48,051.
SIZES SHIPT—Run of Mine, Slack, Lump.
PREP. EQUIPT—Shaker Screens.

BRENNAN COAL MINING CO., THE

General Office, Walsenburg, Colo.
PR—Fred O. Roof, Equitable Bldg., Denver, Colo.
VP—James Turner, Walsenburg, Colo.
TR—Ralph Snodgrass, Walsenburg, Colo.
GS—James Turner, Walsenburg, Colo.
SA—Huerfano Agency Co., Walsenburg, Colo.

(Continued on Next Page)

Brennan Coal Mining Co.—Cont.

Brennan Mine; Slope; Robinson Seam; 42 to 48 in. thick.
PO—Camp Shumway, Colo.; SP—Walsenburg, Colo.; CTY—Huerfano; RR—D. & R. G.
MS—James Turner, Walsenburg, Colo.
S of H—Mules and elec. hoist. Track gage 36 in.
S of M—4 shortwall machs.

STRATIGRAPHIC SECTIONS OF ILLINOIS COAL MEASURES

ILLINOIS*

General Description of the Geology of the State With the Ranks of Coal Produced Treats of the Mining Districts, With a Map Showing Their Location, All Seams Lying Within the State, and the Railroads Serving Same; Description of the Producing Seams Showing Their Geological Order; Kinds of Coal; General Analysis; Etc

Illinois is the second largest producer of coal in the United States, being exceeded in production only by Pennsylvania. The annual production is around 85,000,000 tons, or about 15 per cent. of the total annual production of the country.

The coals of Illinois are a part of the Eastern Interior coal field, and are estimated to have an area of 35,000 square miles. All coal bearing rocks of this field belong to the Pennsylvanian or "Coal Measures" division of the Carboniferous. The Pennsylvanian consists of a series of shales and sandstones, and minor amounts of limestone, clay and coal. The series thickens gradually toward the southern part of the state, where it attains a thickness of 2,000 feet. It is underlain by strata varying in age from Upper Mississippian to Ordovician, the youngest rocks belonging to the Chester group of the Mississippian, the oldest to the St. Peter sandstone. Generally overlying the Pennsylvanian rocks are unconsolidated clays, sands, and gravels of glacial or alluvial origin. Exposures of the "Coal Measures" are commonly restricted to the stream valleys and are very rare in the central part of the coal field.

The Illinois "Coal Measures" are divided into three formations. In ascending order these are the Pottsville formation, the Carbondale formation and the McLeansboro formation. The Pottsville includes that part of the Pennsylvania series which lies below coal No. 2. These strata consist of coarse, gray sandstones and some conglomerate in the lower part, and shales or sandy shales predominating in the middle and upper portions. Several coal beds are known in the Pottsville. The most important commercially is the Rock Island coal of Rock Island, Mercer and Fulton counties. The coal lies about 50 feet below No. 2 coal. In southern Gallatin county at least two Pottsville coals are locally mined, the Ice House and Bell coals, the former 250 feet, and the latter 325 feet below No. 2 coal. Locally in southern Williamson county a bed of cannel-like coal is found near the base of the formation. The Carbondale formation is represented by the portion between the base of coal No. 2 and the top of coal No. 6. This is the important coal bearing formation in the state. The McLeansboro formation includes all the "Coal Measures" lying above coal No. 6, the roof shale over this seam being its basal member.

The coals of Illinois are bituminous in rank and are used mainly for steam and domestic purposes. Compared with other coal fields of the country, the quality of Illinois coals occupies an intermediate position. As a general proposition, the coal from the lower seams is superior to that of the upper. The quality improves also from the north to the south, the beds in the southern part of the state being superior to those in the northern part; this is more particularly true of the heating power. The coals of the central field contain from 40 to 55 per cent of solid carbon, from 10 to 25 per cent of combustible gas, from 5 to 15 per cent of water and from 8 to 15 per cent of ash. The average heat value of Illinois coals is about 11,300 British Thermal Units, considerably less than the coals from Pennsylvania, Kentucky and West Virginia, with which the home product is in constant competition. The high quality of these competitive coals, particularly those that make little smoke, has allowed them to set the pace in making prices. Coals of the Illinois type ignite easily and burn freely and quickly, and since the cost of Illinois coal is so much less than that of the other fuels mentioned, it is less expensive to residents of Illinois, if considered solely on a basis of the amount of heat to be obtained for a given expenditure of money.

"Probably all Illinois coals will coke. However, they would as a rule produce considerable breeze, and a coke too high in sulphur for metallurgical uses. Certain low-sulphur coals from Franklin, Williamson, Perry, and Jackson counties are capable, under best conditions, of yielding a metallurgical coke of satisfactory sulphur content, but in present practice such coals are mixed with Eastern coals in the manufacture of by-products coke. Certain low-sulphur varieties are used satisfactorily in gas producers, and during the past two years have come into wide use as a substitute for coke in the manufacture of water-gas."

RAILROADS

The coal mines of the state are afforded transportation facilities by counties by the following railroads: Bond County—Vandalia; Chicago, Burlington & Quincy. Bureau County—Chicago & Northwestern; Chicago, Rock Island & Pacific; Chicago, Milwaukee & St. Paul; Chicago, Burlington & Quincy. Christian County—Wabash; Illinois Central; Chicago & Illinois Midland; Chicago & Eastern Illinois; Cleveland, Cincinnati, Chicago & St. Louis; Baltimore & Ohio Southwestern. Clinton County—Baltimore & Ohio Southwestern; South-

ern. Franklin County—Chicago, Burlington & Quincy; Chicago & Eastern Illinois; Illinois Central; St. Louis, Iron Mountain & Southern. Fulton County—Chicago, Burlington & Quincy; Minneapolis & St. Louis; Toledo, Peoria & Western. Gallatin County—Louisville & Nashville. Grundy County—Elgin, Joliet & Eastern; Atchison, Topeka & Santa

*The information here presented on Illinois seams has been gleaned largely from the various Bulletins of the Illinois Coal Mining Investigations, in particular Bulletin No. 13, "Coal Mining in Illinois," and through the assistance of the Survey.

MCLEANSBORO FORMATION

No. 7 Seam. (Known to the trade as Danville coal.) (Mined in the Danville District.)

This coal is the only seam in the McLeansboro formation that has commercial value, and is mined in the vicinity of Danville and Fairmount in Vermilion county, and until recently has been mined at Streator in La Salle county. Thinner beds, 2 to 3 feet thick, and higher in the formation are mined locally in Shelby, Jefferson, Lawrence and Wabash counties. No. 7 coal has a thickness of 5 feet to 7 feet 6 inches over a large area west of Danville, but thins toward the south. It is exposed all along the river front in the southwest quarter of Danville, but it disappears toward the northeast, having been eroded in the formation of the pre-glacial valley of Vermilion River.

This coal contains a variable quantity of sulphur, occurring as lenses, bands, stringers and plates along bedding planes and cleavage faces. In its massive form it is easily separated and thrown

out. At one mine a large equipment has been installed to separate it from the coal as a valuable by-product. The roof is a black shale of variable thickness, and is generally not good. The seam lies directly upon a 6 to 8-inch bed of clay which heaves badly. This coal is essentially a steam and domestic fuel, although its relatively high ash, moisture and sulphur content renders it less suitable for domestic uses than coal from some of the other districts of the state. It has also a relatively high content of volatile matter which renders it somewhat difficult to burn effectively in many domestic plants.

GENERAL ANALYSIS

Moisture	13.00
Volatile Matter	38.30
Fixed Carbon	38.70
Ash	10.00
Sulphur	2.95
B. T. U.	11,145

CARBONDALE FORMATION

Seam No. 6. (Known to the trade as Franklin-Williamson, Cartersville, Herrin, Belleville, Standard, Mt. Olive, Staunton, Montgomery and Grape Creek coal.) (Mined in Franklin and Williamson counties; Southwestern Illinois; and Danville districts.)

In Jefferson, Franklin and Williamson counties this coal is uniformly thick, varying from about 5 feet near the Saline county line on the east side of the district to a maximum of about 14 feet in the vicinity of Christopher. The thicker and better coal is found in the western part of Franklin county, where there exists a large area of coal having less than 1.50 per cent. sulphur. There is no significant difference in the appearance of No. 6 coal to distinguish it from other coals of the State, all of which are shining black and are commonly banded, due to laminations of bright and dull coal. The No. 6 coal is characteristically interbedded by a dirt band or "blue band" found commonly about 18 inches above the base of the seam. Where the coal is thick the "blue band" is known to lie as much as 52 inches above the floor. Its thickness varies from $\frac{1}{2}$ inch to 4 inches, with an average of about 1 inch. In general, though not in all places, the thickness of the "blue band" increases with the thickness of the coal.

The coal commonly lies in three benches in this district; the upper bench is separated from the middle by a persistent parting, commonly of mother coal, and the middle and lower benches are separated by the "blue band". Each bench varies in thickness as the total thickness of the coal varies. In the eastern part of the district, where the coal is less than 8 feet thick the upper bench is about 12 to 18 inches thick, the lower bench 15 to 18 inches, and the middle bench possibly 4 to 5 feet. Where the coal is thicker each bench is also thicker, the upper bench being in places 3 to 4 feet, the lower 2 to 3 feet, and the middle 6 to 7 feet thick.

Impurities in the coal, in addition to the "blue band", consist of sulphur balls and lenses, these being more common in the eastern than in the western part of the district, where they are relatively rare. Streaks of mother coal are not uncommon. These, however, should not be considered as impurities, except as they tend to make the coal sooty to handle. Streaks of bone and clay are not unknown, but the coal is rather freer of these impurities than the coal from other districts of the State.

The strata overlying the coal vary from the typical dark shale and limestone cap rock within 25 feet of the coal to a large thickness of gray shale, amounting in places to 110 feet. The dark shale and cap rock is the characteristic roof of this coal throughout southern Illinois, but in this district is restricted in distribution practically to the area underlain by coal less than 8 feet thick in the eastern part of Franklin, Williamson and Jefferson counties. Where the coal is thick the roof is gray shale which does not stand well when the coal is removed, and for this reason the upper bench, 18 to 60 inches thick, is commonly left for roof. Some mines in the same region follow the practice of mining only the coal between the "blue band" and the roof, thus removing only the middle bench and gaining a product free from impurities. The clay beneath the coal is hard and generally thin, ranging

from 4 inches to 8 feet. Below it is commonly a limestone. Some rock rolls occur at the top, the larger ones extending down into the coal 2 to 3 feet.

The coal lies nearly level over much of the district or with an average dip toward the northwest of 10 to 20 feet per mile. Along the west side of the district, however, the coal rises for a short distance in the Duquoin anticline, which is more properly called a monocline, at a rate of 300 feet per mile. Also in the 6 miles north of the outcrop of No. 6 coal in Williamson county the coal dips more steeply than it does farther north, so that in this belt the dip averages about 50 feet per mile. A belt of faulting or displacement crosses the southern part of the district extending from Royalton to Johnson City and probably also continuing in the same southeasterly direction across Williamson county and even into the Harrisburg district as far as, and possibly beyond Harrisburg. Displacements of the coal as great as 75 feet are known in mines located in this disturbed belt.

In the Belleville, Standard and Staunton district of southwestern Illinois the coal differs from the coal in Franklin and Williamson counties by having a large content of impurities and by its division into more numerous benches. In considerable areas in this district the coal is missing from the section. It rarely exceeds 8 feet in thickness, and it averages in the areas in which the coal is present about 7 feet.

In part of this district the upper and lower bench of the Franklin and Williamson counties field is present and the middle bench is represented by several small benches. The various benches of this coal are spoken of as the "top" coal, the "nine-inch" coal, "drift" coal, "block" coal, and "bottom" coal. Between successive benches there are generally partings of sulphur or dirt $\frac{1}{4}$ to $\frac{1}{16}$ inch thick. This separation of the middle part of the bed seems to be restricted to St. Clair, Clinton, Washington, Randolph and Perry counties, as it is not characteristic of the coal in the Staunton and Mt. Olive regions in Madison, Montgomery, Macoupin and Bond counties, where only three benches are present.

The roof is commonly dark shale a few inches to a few feet thick, underlying a limestone cap rock averaging 7 feet in thickness. This succession is very persistent in the northern part of the district. In the southern part, however, including Clinton and St. Clair counties and counties to the south, there is greater irregularity. The immediate roof may be a soft draw slate, dark shale, or "slate", an interlaminated mixture of gray shale and black shale or limestone to hold it up, but the draw slate and white top are difficult to hold. In certain areas even the black slate is rendered insecure by the presence of a soft dark-gray or black shale called clod, between it and the limestone cap rock.

In general, mining conditions in the southern part of this district are less satisfactory than in the northern part because of the poorer roof and the greater amount of impurity in the coal.

In the Danville district seam No. 6 averages 6 feet in thickness. Its chief characteristic is the presence of a blue band which divides it into upper and lower benches. This blue band consists of gray shale of varying hardness and in some mines has a

thickness of $7\frac{1}{2}$ inches, the top part lying $1\frac{3}{4}$ to $3\frac{1}{2}$ feet above the floor.

The limestone cap rock characteristically overlying No. 6 coal in other districts is absent in the Danville area except in the immediate vicinity of Danville. The usual roof is a gray sandy shale with so little cohesion that it falls easily. The contact of the roof and coal is extremely irregular. Lenticular masses of shale usually covered by a thin layer of coal extend downward into the coal bed. Such "rolls", as they are called, are extremely difficult to support. In isolated cases there are 3 to 4 inches of black shale between the coal and the gray shale which forms the cap-rock. Wherever this black shale is broken, air and moisture disintegrate the gray shale cap-rock and the roof becomes insupportable.

In all parts of the Danville district the floor is a soft fireclay.

Coal from the No. 6 seam in some localities, notably Franklin and Williamson counties, has produced a satisfactory coke, though always inferior to the Standard Connellsville. It is at the present time being used for by-product coking, after mixing with West Virginia or Pennsylvania coals. This coal is also used at a limited number of places in Illinois and Missouri for the manufacture of illuminating gas. Where the sulphur content is favorable, coal from this bed does satisfactorily. In tests made with high sulphur coal a difficulty in addition to that of sulphur in the gas, lay in the clinkering of the coke when used in the gas producer. The total ash in the seam is not high, therefore it follows that the cleaner portion is low in ash, because a large percentage of it is present in the bands. For this reason a high quality of lump, egg or nut coal is produced.

No. 5 Seam. (Known to the trade as Peoria, Fulton County, Springfield, Harrisburg, Ledford and Eldorado coal.) (Mined in Fulton, Peoria, Sangamon, Saline and Gallatin counties.)

The average thickness of the coal is 4 feet 8 inches, as reported in the Thirty-first Annual Coal Report of Illinois from 240 mines. The seam has a uniform appearance from top to bottom and the coal is hard and massive. It shows fine laminations with knife-edge mother coal partings. In some places there are discontinuous bands of pyrites near the middle of the seam. The seam lacks the blue-band characteristic of No. 6. Udden states that, "In the mines near East Peoria and at Edwards the coal runs out against the drift in several of the entries. Miners recognize that these defects in the coal are due to erosion, and they speak of the drift as 'wash.' The drift generally consists of sand, or silt, which in some places has been found to contain

embedded trunks of trees and other vegetation. Experience has shown that the surface of the bed-rock does not always conform to the present topography of the land, and operators are careful to avoid unprofitable explorations of places where 'wash' has been encountered."

The immediate roof is a black, sheety shale locally called slate. This shale varies in thickness from a few inches to 35 feet and in places contains "niggerheads" of iron pyrites. In many mines between the coal and the shale there is in places a layer of iron pyrites 2 or 3 inches thick. Where this layer is present the shale is protected from the air and stays up; where it is not present the shale falls badly and in places caves to a height of 35 feet.

The cap-rock in most mines is limestone, but in a few is a fine-grained micaceous sandstone. In some places the shale of the immediate roof is absent and the cap-rock comes in contact with the coal. When the limestone is disseminated and mingled with the shale the roof is soft and weathers quickly, owing perhaps to the presence of marcasite. It is then called clod and the "niggerheads" are iron carbonate.

From the viewpoint of the miner the chief characteristic of the district is the great number of clay veins extending through the coal and the roof shale crossing their bedding planes. These clay veins are fissures which have been filled with a hard light-gray clay. Besides clay veins the physical features which affect mining are small faults, slips and rolls. In one mine where the shale of the immediate roof is absent the sandstone has cut out the coal for 150 feet along an entry.

The coal in this district in many places sticks to the roof and is separated from it with difficulty. In one mine about an inch of coal is left up to protect the roof shale from the moisture of the air.

The floor in most places is a dark gray fireclay which heaves badly when wet. At one mine the floor is a blue fireclay containing nodular concretions of iron pyrites.

Seam No. 5 in Saline and Gallatin counties outcrops in a belt extending about east-west from the vicinity of Harrisburg. The strata dip to the north so that in the northern part of these counties the coal is 600 or more feet in depth. At New Haven in White county it lies at a depth of about 770 feet. The seam varies in thickness from 4 to 9 feet, averaging about 5 feet in Saline county and about $4\frac{1}{2}$ feet in Gallatin county.

The roof of No. 5 coal in this district is a shale which is commonly black and which contains the characteristic concretion of iron pyrites or "niggerheads" practically everywhere present in the roof shale of this coal throughout the Eastern Interior Basin of Indiana, Illinois and western Kentucky. The floor is fire clay, which gives trouble only locally and where wet. In general roof and floor conditions are more satisfactory for mining than in other districts of the State with the possible exception of the small field of No. 1 coal in Mercer and Rock Island counties.

The present mining operation in Saline county is in or close to a belt of folding or faulting which crosses Williamson and Saline counties from near Royalton to near Harrisburg. Within and south of the belt the coals are more irregular in position

or "lay" than they are to the north. Within the belt itself the coal is known to be faulted. Faults have been noted in Williamson county between Johnston City and Royalton and a large fault having a throw of about 100 feet is present between two mines about 2 miles northeast of Harrisburg. Adjacent to this belt of faulting the bed contains many hills and rolls, and in one mine continuous grades as high as 75 feet in one-half mile have been encountered. Local grades as high as 15 per cent. are reported in the entries of some mines. Variations in the thickness of the bed apparently bear no relation to the irregularities in the "lay" of the bed.

No. 5 seam is locally absent along a line about 2 miles wide crossing the district from north to south about 2 miles west of Harrisburg. Its absence is apparently due to erosion, its place being occupied by a sandstone which extends from considerable distance above to considerable distance below the horizon of the coal.

A belt of folding or faulting crosses the district from north to south near the central line of Gallatin county. East of this line the coal lies about 475 feet lower than its altitude to the west. There has been no mining and very little exploratory work in this part of the area. Similarly most of the northern part of Saline and Gallatin counties represents an essentially unexplored resource.

The district is characterized by the presence of igneous intrusions in the form of dikes which penetrate the coal in many of the mines in Saline county. These dikes are not known at the surface and in some mines appear to stop at the roof of the coal. No single dike has been traced except across the workings of the mine in which it is found, so actual length of any of them is not known. Rock from a dike near Eldorado was identified by Albert Johansen, formerly of the U. S. Geological Survey, as mica peridotite. One dike is known to have a thickness of as much as 300 feet, but commonly they are thinner. Apparently this system of intrusions is similar and of the same age as that found in the fluorspar region of southern Illinois and western Kentucky. The intrusions commonly have produced a natural coke for a few feet each side of the coal and in places apparently silicified this product. Except for the extra labor necessary to cut through the harder rock of the dike and coke, the intrusions offer no especial difficulty in mining.

No. 5 coal is one of the most continuous seams in the series. Its chemical and physical character, however, varies from district to district so that there is a greater difference between the coal mined from No. 5 seam in Saline county and the coal mined at Springfield-Peoria than exists between No. 5 and No. 6 coal in Saline and Franklin counties. Coal from Saline county stands high in heat value among the coals in the State, being exceeded in this respect only by the No. 2 coal from Jackson county.

GENERAL ANALYSIS

Fixed Carbon	37.60	48.70
Ash	10.50	9.05
Sulphur	3.50	2.90
B. t. u.	10,515	12,275

Seam No. 2. (Known also as Third Vein in the northern part of the State; to the trade as Third Vein, La Salle, or Wilmington in the northern part of the State; as the Colchester coal in the western part of the State; and as Murphysboro coal in the southern part of the State.) (Mined in the Longwall district and in Jackson county.)

Seam No. 2 in the northern part of the State varies in thickness from 2 feet 6 inches to 4 feet, averaging about 3 feet 6 inches in the La Salle field and 3 feet 4 inches in the Wilmington field.

In physical appearance this coal differs little from other coals in the State. There is possibly a slight tendency to break in slabs rather than blocks, and accordingly it is occasionally referred to as a "long-grain" coal. The coal does not possess the persistent dirt or sulphur bands of No. 6 nor the "horsebacks" or "clay slip" of No. 5. For identification of the bed large reliance has been placed upon determination of the fossil plants in the associated roof shales. Lenses and bands of pyrite and bands of mother coal and dirt are distributed throughout the seam without irregularity or persistence, varying in thickness up to 4 inches.

In the La Salle field the usual roof is gray shale called "soapstone" 15 to 18 feet thick, above which is a black laminated shale containing "niggerheads", commonly of large size, and composed mostly of limestone. In places the gray shale is out and the black shale rests directly upon the coal. Mining in this coal is by the longwall method, to which the roof is well adapted.

Near the anticline the immediate roof is in some portions a gray, calcareous shale, called "soapstone"; in others, a black, carbonaceous shale. The black shale is generally laminated and commonly includes "niggerheads" of pyritous material. It is harder than the gray shale.

In the Wilmington field a dark-gray fireclay generally lies directly under the coal and varies in thickness from a few inches to several feet. The clay heaves badly under pressure when wet. In some localities ironstone balls and root remains have been found imbedded in the clay. In the La Salle field the coal is generally underlain by fireclay, but in parts of some mines a hard sandstone lies directly beneath the coal.

Generally bed No. 2 in this district lies nearly flat or is slightly rolling, but on the La Salle anticline it dips as much as 51 degrees.

Bed No. 2 in Jackson county has only a shallow cover, the coal lying at depths varying from 25 to 160 feet. A characteristic feature of the bed is its division into two benches by a gray laminated shale band varying in thickness from $\frac{1}{3}$ inch to 36 feet. Where this parting is thick the lower bench has sometimes been called, erroneously, seam No. 1. The bottom bench varies in thickness from $3\frac{1}{2}$ to 4 feet, averaging $3\frac{3}{4}$ feet. The top bench averages 2 feet.

The bed contains few nodular concretions of iron pyrites, but has a layer of bone 2 to 3 inches thick, generally next to the floor. This floor in most places is sandstone, but in sections is shale or fireclay. The coal shows a pronounced cleavage, northeast to southwest.

Where the parting is thin and the two benches are united, the roof over the coal is a hard gray

shale, but where the parting is thick and only the lower bench is worked the parting becomes the roof. Where this parting is a light gray shale it is easy to support; where it is dark colored it slakes much on exposure to the air.

Numerous small faults occur in all mines, and horses, usually of a hard dark gray micaceous sandstone, are found in the vicinity of the faults.

The presence in places of a quicksand deposit about 30 feet below the surface has a marked effect on surface subsidence after roof-caves.

No. 2 seam in the Wilmington and La Salle field differs considerably from the No. 2 coal in Jackson county. The "Third Vein" coal has a high moisture content which reduces its heating value to the rank of sixth among the coals of the State. Murphys-

boro coal, on the other hand, ranks highest in heating value and lowest in ash and sulphur content. Coal from this bed can be satisfactorily used in the manufacture of coke for metallurgical purposes or of illuminating gas, especially when used with eastern coking and gas coals. The remaining supply of No. 2 coal in Jackson county is small.

POTTSVILLE FORMATION

No. 1 Seam. (Mined in Rock Island and Mercer Counties (No. 3) district.)

Seam No. 1 lies at depths varying from 40 to 213 feet. The topography of the surface in many places is rolling, with hills about 150 feet high near Matherville. The seam averages 4 feet in thickness and is broken in places by small faults, slips, clay veins and rolls. The coal has weak vertical cleavage, dull luster, and banded texture. On cleavage faces thick plates of calcite and iron pyrites are deposited. Near Ellisville sulphur bands 2 to 6 inches thick and in places 50 feet long are found at various horizons. A poorly developed parting divides the bed into two benches, the upper of which is in most places about 2 feet thick.

The immediate roof in the northwestern part of the district is a hard black shale that is easy to support. In the southern part of the district in places a bituminous calcareous shale, 2 to 5 inches thick, lies immediately over the coal. This shale, called clod, is hard when first exposed, but after exposure to the air becomes soft and falls.

Throughout the district the cap-rock is limestone. In limited areas where the shale is missing this limestone is the immediate roof over the coal. Above the cap-rock is a dense, fine-grained non-crystalline limestone locally called "blue rock."

Below seam No. 1 in places there is an irregular band of hard bone, 3 to 6 inches thick. The floor proper is a light gray micaceous fireclay which contains plant stems and roots. This clay heaves badly when wet and in places swells enough to fill the entry. In parts of some mines a carbonaceous shale lies between the fireclay floor and the coal, and in other parts, sandstone. These casual deposits are called "false bottoms."

No. 1 is a clean seam, low in ash.

PREPARATION OF COAL

Illinois was one of the first states to undertake a careful cleaning and sizing of coal, and no mining state can show a greater degree of attention to the production of a grade of coal pleasing to the trade. The following convenient table of sizes is given in Circular No. 4, University of Illinois:

ILLINOIS COAL

NAME	SIZE OF PIECES
Run of Mine	Mixture of all sizes
Lump	Large lumps separated from the finer sizes
Egg or Furnace	Lumps 3"—6"
No. 1 Nut or Small Egg	2"—3"
No. 2 Nut or Stove	1 1/4"—2"
No. 3 Nut or Chestnut	3/4"—1 1/4"
No. 4 Nut or Pea or Buckwheat	1 1/4"—3/4"
No. 5 Nut	Under 1/4"
Screenings	A mixtures of all sizes under 2"

For additional information on uses and analyses of Illinois coals, see descriptive advertisements of coal mines following the Supplementary Analyses.

AMERICAN COAL & SUPPLY CO.

General Office

Suite 618-630—108 S. La Salle Street, CHICAGO, ILL.

MINE AT CAMBRIA, WILLIAMSON COUNTY, ILLINOIS

Served by Illinois Central Railroad

Exclusive Distributors of

"SUNRISE" COAL

(One Carload or Trainload)

Location

Our present holdings in Illinois consist of the Sunrise Coal Mine, located at Cambria, Ill., in the County of Williamson.

"SUNRISE" Coal

The trade name of "SUNRISE" is well known in all the States surrounding Illinois, it having been extensively advertised, and the coal tried out by the most discriminate of industrial consumers.

"SUNRISE" coal is produced from No. 6 Seam and averages six to ten feet in thickness, without a parting.

Nature has seen fit to endow our property with an exceptionally hard roof and floor, thereby making conditions ideal both for the miners and from an operating standpoint.

Production

Our production at this time is 1000 tons per day, consisting entirely of mine run, we specializing in mine run steam business from this operation. Modern equipment has been installed, insuring the loading of clean coal, minimizing the ash content, resulting in an economical fuel and reduced freight accounts.

Analysis

The following recent analysis by the Commercial Testing & Engineering Co., Chicago, Ill., is satisfactory evidence as to "SUNRISE" Purity and Quality:

Moisture	7.10
Volatile Matter	34.09
Fixed Carbon	52.59
Ash	6.22
	<hr/>
	100.00
Sulphur	1.20
B.t.u. (Dry)	13,200

Commercial Usages

Owing to the purity of this coal its uses are many. For Steam it has no equal and is likewise excellently adapted for Tile and Pottery, Cement Burning, Producer, Illuminating Gas and for Coking when mixed with Eastern Coking Coal.

Tell Us Your Fuel Troubles

Having distributed coal for the past quarter of a century, we are prepared to locate and rectify your fuel troubles and give the same high standard of service rendered during our business career.

Contracts solicited and esteemed as a moral obligation.

We have representatives in the States of Illinois, Indiana, Iowa, Michigan, Minnesota, North Dakota, South Dakota and Wisconsin, and all inquiries for further particulars will be handled with promptness and despatch.

"SUNRISE" FOR ECONOMY AND SATISFACTION

OMAHA

MINNEAPOLIS

BIG CREEK COALS, Inc.

Operating Office
PREMIUM COALS
Harrisburg, Ill.

General Offices

Peoples Gas Building, CHICAGO

Operating Office
BIG CREEK COALS
St. David, Ill.

BIG CREEK COALS, Inc., operates seven mines with a daily production in excess of 10,000 tons.

Producing 7,500 tons in Saline county, Southern Illinois, and approximately 2,500 tons in Fulton county.

Properties are equipped with the most modern type machinery, insuring the most careful preparation of Domestic and Steam Coals.

Mines in Saline county are served by the Big Four, Louisville & Nashville, and Illinois Central Railroads, and in Fulton county by the Chicago, Burlington & Quincy Railroad.

Premium Coal

A product of our Saline county mines, is representative of the best production in the state.

Properties are equipped mechanically in such a way as to permit our offering a wide range of sizes.

We prepare for Domestic use:

- 6"—Lump
- 6x3"—Furnace Egg
- 3x2"—Small Egg
- 2x1 $\frac{1}{4}$ "—Stove Nut
- 1 $\frac{1}{4}$ x $\frac{3}{4}$ "—Chestnut

For Steam use:

- $\frac{3}{4}$ x $\frac{3}{8}$ "—Pea
- $\frac{3}{8}$ " and less—Carbon
- 1 $\frac{1}{4}$ x6"—Steam Egg
- 2x6"—Steam Egg

- 1 $\frac{1}{4}$ "—Steam Lump
- 2"—Steam Lump
- 1 $\frac{1}{4}$ " and 2"—Screenings
- 3" and 6"—Run of Mine

The above range of sizes permits our offering coals suitable for any Domestic or Steam plant.

Analyses

Received from the Commercial Testing & Engineering Company, demonstrate the quality of PREMIUM:

6" LUMP

PREMIUM Coal is Mined from Seam No. 5, with an Average Thickness of About 6 Feet, as Shown in the Illustration

Mine No. 2, Ledford, Ill.

PREMIUM—Its Uses

It is desirable for steam purposes in general, due to low ash and sulphur and high heat value, as shown by analyses on opposite page.

Of the various properties operated by this company, one of the most important is Mine No. 5, producing a gas coal that is one of the very best products of its kind. It is adaptable to any type of coke oven on the market, and recent experiments have shown that recoveries are all that could be desired in this type of fuel.

The recovery of residuals is a very important conservation of resources and it forms one of the principal means of revenue to the coal gas producer, the sale of these residuals reducing the cost of gas production in a degree corresponding to the efficiency of the recovery methods adopted and the market value of the product.

Mine No. 3, Harrisburg, Ill.

The coal from Mine No. 5 contains the principal residuals recovered from any other gas coal mined.

The residuals recovered today are tar-naphthalene, cyanogen, ammonia and in the case of coke oven gas, also benzol, by direct recovery method, and benzol is one of the most important of tar constituents.

Service

"BIG CREEK" has become symbolical for Service with the Trade. The advantages derived from the use of PREMIUM go straight back to its excellent mechanical preparation and its inherent basic qualities.

Working Face at No. 3 Mine, Harrisburg, Ill.

BINKLEY COAL COMPANY

11 South La Salle Street, CHICAGO, ILL.

Miners and Shippers of

ILLINOIS AND INDIANA COALS

ILLINOIS COALS

We are the owners and operators of the Thomas-Waters mine, located at Herrin, Illinois, on the Burlington Railroad.

The No. 5 and 6 seams, which are here worked, produce a fine quality of coal, much used for steam, locomotive fuel and domestic purposes.

We are also Sales Agents for two additional Illinois mines, as follows:

MarionI. C., C. & E. I., and Mo. Pac. Railroads

HarrisburgBig Four Railroad

INDIANA MINES

The Binkley Coal Company owns and operates the Pine Ridge mine in the West Clinton District of Indiana on the southeastern division of the Chicago, Milwaukee & St. Paul Railroad. This mine operates in the No. 5 Vein and produces 1,500 tons of coal per day.

Pine Ridge coal ranks as one of Indiana's best fuels. It is an excellent steam coal and is popular with the retail coal trade. It is also much used for railroad fuel.

In addition to the above mine, we are Sales Agents for four additional mines in Indiana, as follows:

Terre HauteVein No. 4.... } Big Four, C. & E. I., and
C. M. & St. P. Railroads

SullivanVein No. 6.....C. & E. I. Railroad

Boonville, Warrick County.....Vein No. 5.....Southern Railroad

Our total production is in excess of 1,500,000 tons.

We specialize in large tonnages for industrial plants and railroads.

We deliver what we sell.

COSGROVE & COMPANY

Producers and Shippers of

"Franco" Coal From Southern Illinois

General Offices
JOHNSTOWN, PA.

Western Sales Offices
Old Colony Bldg., CHICAGO, ILL.

Sales Offices Also Located at
Central National Bank Bldg., ST. LOUIS, MO.
Swank Bldg., JOHNSTOWN, PA.

149 Broadway, NEW YORK CITY
Pennsylvania Bldg., PHILADELPHIA, PA.

Location of Mines

The mines of Cosgrove & Company, FRANCO Nos. 1, 2 and 3, are located in the Williamson-Franklin county district of Southern Illinois. Shipments from these mines are made over five great railroads which serve that district. The coal is of the No. 6 seam, recognized as the most representative of the better grades of Illinois bituminous.

Personnel of Company

Cosgrove & Company is a partnership which owns or controls, operates and sells the output of the three FRANCO mines in Illinois and ten THERMAL mines in Pennsylvania. The members are John C. Cosgrove, one of the outstanding successful coal producers of the present day, and widely known in the East and West as a progressive, constructive organizer; Harry J. Meehan, successful mining engineer and production manager of the firm; Enoch Carver, Jr., general sales manager of the organization; A. Kemerer Cosgrove, a brother of John C. Cosgrove. W. R. Kernohan, of Chicago, is western sales manager and handles the entire output of the FRANCO mines. Homer S. Cotton is in charge of the St. Louis branch.

Character of FRANCO Coals

FRANCO coal is one of the most popular domestic coals by reason of its natural quality and structure and the rigid preparation characteristic of all Cosgrove productions. The sizing is done by the most modern tipple equipment in the field. FRANCO No. 3 mine is frequently visited by dele-

gations interested in the highest developments of American mining equipment.

FRANCO steam sizes are also in demand by reason of the cleanliness of the coal, and its contents, which give a long flame, maintain normal steam loads with a minimum of firing and waste smoke.

Analysis*

The following analysis is a fair representation of FRANCO coals:

Moisture	2.96
Volatile Matter	35.16
Fixed Carbon	56.86
Ash	5.12
	<hr/>
	100.00
Sulphur89
B. t. u. per pound.....	13,520

*Analysis taken from average submitted all sources in 1921.

Tipple Equipment

FRANCO mines are equipped with five-track car-loading facilities and engine-fuel loading device in addition to a most complete system for proper cleaning, inspection and sizing of the coal. Mechanical loading booms are used, avoiding practically all breakage in loading. The capacity at present is approximately 2,500,000 tons per year, with greater development proceeding rapidly, especially at the newer FRANCO No. 3 mine at Paulton. The town of Paulton itself, built by the Cosgroves, is a model mining community with the best of home design and equipment.

Miners of

WILMINGTON
ROYAL THAYER

ORIENT
BENTON
PYROLITE

HICKORY HILL
BLACK BRIER

Location

The nine mines of the Chicago, Wilmington & Franklin Coal Company are located throughout the state of Illinois, Wilmington being in Grundy County (Northern Illinois); Royal and Thayer mines in Sangamon and Macoupin Counties (Central Illinois); Orient, Benton No. 1 and No. 2, Hickory Hill A and B, and Black Brier in Franklin and Williamson Counties (Southern Illinois); each of these mines being supported by extensive coal land areas.

Preparation

The Chicago, Wilmington & Franklin Coal Company is one of the leaders in progressive mining methods in Illinois, and the preparation of its coals has always been a distinctive feature. The preparation plant at each of the mines has been designed with reference to the character and fracture of the coal at each shaft, and planned to give the highest preparation standard possible for each mine. The mines are equipped with shaker screens

and picking tables, also loading booms, which do away with excessive breakage that occurs in other methods of loading.

Capacity

The nine mines have a daily capacity of 25,000 tons, and a yearly capacity of approximately 7,500,000 tons. Orient is the largest single coal mine in the country, and the largest producer, holding the records of 6,777 tons in eight hours, 34,792 tons in one week, and 144,576 tons in one month of 26 working days.

Quality

Not only are the Chicago, Wilmington & Franklin coals exceptionally free from impurities, but the superior preparation insures uniform size, easy draft in burning, and freedom from clinker. The coal burns hot, down to a fine white ash, and can be stored for long periods without material depreciation.

Shippers of

INDUSTRIAL AND POWER PLANT COAL

from

Indiana, Kentucky, ILLINOIS, Missouri, Kansas

The actual merchandising of industrial coal is something which is not often attempted in the development of a coal business. However, nowadays merchandising rather than ordinary selling is necessary. The members of the Great Lakes Coal & Coke Company, one of them an experienced operator, the other two of a good many year's experience in coal sales, have analyzed the market for industrial coal. Their analysis is that the purchaser of industrial coal in quantities must necessarily demand the lowest price that he can obtain. He must be assured of an uninterrupted supply of coal at all times. He must also get a coal that will perform its function economically for him. It is their aim to assist the buyer of industrial coal along each of these lines; thereby becoming merchandisers rather than wholesalers.

Cost

Buying, as this company does, for some of the largest users of industrial coal, and in large quantities always, gives it the opportunity to sell this coal to its customers at a lower cost than is ordinarily possible. This is due in the first place to the fact that mine operators, assured of a steady market for their coal, are inclined to do business on a narrower margin, and this company can also handle the coal on a smaller margin than is usual, on account of the great tonnage involved.

Supply

The same factors, namely the purchase of large quantities of coal and dealing regularly with certain operating companies in each field also make it possible to supply the customers at times when the flow of coal from one or more fields is interrupted. In other words, this company maintains its mining connections in every field of Illinois, Indiana, Kentucky, Missouri and Kansas, either by stock interests in the mining companies or by contracting and controlling the outputs of the mines as sales agents for the mining companies.

It can readily be seen that in the event of car shortages or strikes, or trouble of any kind in any one field, with a knowledge of the client's requirements, a satisfactory coal may be supplied from some other field temporarily.

Proper Selection

Through the knowledge and experience of the personnel of this company, they are able to give expert advice as to the quality and kind of coal that will work to the best advantage in the customer's plant and members of the organization are ready to make a study of the combustion problems presented in an industrial heating or power plant and make expert suggestions as to their handling. In addition to this, being in touch with, and watching closely all of the different fields, they are in a position and ready to give clients a market analysis based on conditions that are not always evident to the buyer, to assist them in buying economically.

In a nut shell, the salient points in the operation of this organization are:

1. It is built around men thoroughly experienced in their profession, whose integrity and financial responsibility is unquestioned.
2. Their ability to serve when needed most.
3. Lower prices through added buying power with minimum profits on exceptionally large tonnages.
4. Strong mining connections in every field of Illinois, Indiana, Kentucky, Missouri and Kansas.
5. Conscientious advice as to when to buy and when not to buy.
6. Merchandising and not selling.
7. A personal knowledge of the power units is taken at the time of the first sale.
8. Not prejudiced by the operation of one or two of their own mines in restricted fields.
9. The ability to supply the customer with his coal requirements at all times.

These are the factors which have brought about the success of the Great Lakes Coal & Coke Company in its chosen field. They are also the factors which must comprise the company's fundamental policy in the future as well.

Owning and Operating

FIVE MINES IN MONTGOMERY COUNTY, ILL.

THREE MINES AT CLINTON, IND.

ONE MINE AT PAXTON, IND.

DAILY CAPACITY 20,000 TONS

THE INDIANA AND ILLINOIS COAL CORPORATION owns approximately 35,000 acres of coal land in Montgomery county, Illinois. It operates in what is known as Seam No. 6; averaging in thickness from seven to eight feet. At the present time it has five producing mines in operation, with a daily average production of 14,500 tons.

The mines are equipped with the most modern machinery, which insures excellent preparation. To the trade the coal is commonly known as "MONTGOMERY COUNTY," and the mines are designated by numbers, viz.: No. 10, No. 11, No. 12, No. 14 and No. 15.

Mine No. 10 is located at Nokomis, Ill.
Average daily production, 3,800 tons.

Mine No. 11 is located at Hillsboro, Ill.
Average daily production, 2,400 tons.

Mine No. 12 is located at Witt, Ill.
Average daily production, 2,400 tons.

Mine No. 14 is located at Witt, Ill.
Average daily production, 3,200 tons.

Mine No. 15 is located at Taylor Springs, Ill.
Average daily production, 2,600 tons.

Preparation and Service

At all times the most particular attention is given to preparation. In addition to modern screens, we employ men on each car to pick out any visible impurities. Our chief aim is reliability of service, and during the past six years, since this

Company has been under its present management, it can point very proudly to the record of having filled its contract obligations 100%.

The following sizes are made at these mines:

6" Lump
1½" Lump
6x3" Egg
6x1½" Egg
3x1½" Nut
1½" Screenings
Mine Run

Quality

The product of the mines owned by the INDIANA AND ILLINOIS COAL CORPORATION is adaptable for both steam and domestic purposes. Approximately 50% of our production is used by railroads centering in Chicago and East; and the other 50% for large industrial plants and domestic purposes.

Although not in the Springfield district proper, we have the same freight rates, which enables our customers to obtain a high grade coal at very low freight cost.

Shipment

The mines of the INDIANA AND ILLINOIS COAL CORPORATION are jointly located on the C. & E. I. and Big Four Railroads, and, having the advantage of drawing our car supply from both roads, we can at all times assure our customers the very best of service.

The Company

The Lumaghi Coal Company is one of those rare institutions among the coal trade that has weathered the business storms of over half a century. The company has grown from a modest beginning until now it is one of the largest operating units in the West—made so by fifty-one years of consecutive service to its customers.

Control of the Lumaghi Coal Company remains in the hands of the original founders. All the present officials have been "born and bred" in the coal business, and consequently are in position to give a quick and definite answer to any coal problem which may arise.

Properties and Output

The Lumaghi Coal Company controls twenty-two thousand acres of coal lands in three different districts of Illinois. It operates four mines, having a daily output of ten thousand tons. All of these mines are working the No. 6 seam, which varies in thickness, in these properties, from 6½ to 9 feet. The Lumaghi mines are fully equipped with the latest improvements for producing a large tonnage, and with the picking table plants and loading booms to give the best possible preparation at low cost.

Cantine Coal

The two Cantine mines operated by The Lumaghi Coal Company are located on the Penn-

sylvania Railroad in Madison County, Illinois. Cantine is a very hard coal. It cleans up like Anthracite and stays clean—a splendid coal for storing.

Florida Coal

The Florida mine is located on the Illinois Central Railroad in the Perry County high grade Southern Illinois district. It serves a large territory North, South and West.

In addition to the usual picking table preparation there are installed at the Florida mine Farrer Slate Picking Machines such as are used on Pennsylvania Anthracite, which remove the impurities

from the smaller sizes. All sizes of Florida Coal are screened twice—are absolutely clean and perfectly sized. Florida is equally excellent either for domestic or specialized steam use. The unique location of this mine, at the point where the high-

grade coal district and the low freight rate district overlap, gives unusual rate advantages to Florida purchasers.

Black Brier Coal

The new Black Brier Mine which has just recently been completed is located at Johnston City, Williamson County, Illinois. It enjoys both Illinois Central and Missouri Pacific rail connections, and serves a wide territory North, South and West—especially the Southwest.

Black Brier is of the highest natural grade coal produced in Illinois, and is generally excellent for both domestic and special steam uses. All Black Brier sizes are screened twice, giving a perfectly clean, pure coal. The screenings from this mine are among the greatest heat producers mined in the West.

Sizes Produced

All of the Lumaghi mines produce the following sizes of coal:

6" Lump, 2" Lump, 1½" Lump, 1¼" Lump, 6" x 3" Egg, 6" x 2" Egg, 6" x 1½" Egg, 3" x 2" No. 1 Egg Nut, 2" x 1¼" No. 2 or Stove, and 1¼" Screenings.

LUMAGHI ANALYSES

The following analyses, made by the Commercial Testing & Engineering Company of Chicago, shows the high natural value of Lumaghi coals:

	Centine	Florida	Black Brier
Moisture	8.41	8.77	4.92
Volatile Matter.....	39.87	39.06	39.01
Fixed Carbon.....	42.40	44.57	49.02
Ash	9.32	7.60	7.05
	100.00	100.00	100.00
Sulphur	3.65	2.80	2.77
B. t. u. (Dry).....	12,722	13,088	13,403
Fusion Temperature of Ash	2050°	2300°	2295°

The Lumaghi Coal Company is able to give the very best service on any of the above standard sizes, whether it be the smallest retail order or the largest railroad contract. Lumaghi quality and service please all customers. Fifty-one years of successful operation and continuous growth guarantees protection to the buyer.

D. E. McMILLAN & BRO.

Old Colony Building, CHICAGO, ILL.

SINCERITY COAL

Exclusive Distributors for the SINCERITY COAL CO., Williamson County, Illinois

Sincerity Mine

The Sincerity mine is located on the C. B. & Q. and the Mo. Pac. railroads. Billing stations are Herrin and Bush, respectively. The No. 6 seam, with an average thickness of ten feet and a blue band which nowhere exceeds one inch, is the coal being worked. This mine has a capacity of 3,000 tons daily, nearly all of which is machine mined.

Sincerity Coal

"Sincerity" coal is low in sulphur and is particularly adaptable for metallurgical and producer gas use. It is highly regarded by industrials, and because of its thorough preparation makes a clean burning coal for domestic use. The following is the average of four analyses made September, 1921, on samples taken at three different sections of the mine:

	Dry Basis	As Received*
Moisture	8.46
Volatile Matter	34.19	31.30
Fixed Carbon	58.21	53.28
Ash	7.60	6.96
Sulphur	1.13	1.04
B. t. u.	13,375	12,245

*Commercial Testing & Eng. Co.

Sincerity Preparation

"Sincerity" coal enjoys the advantages of an unusual preparation. Recently there was completed a five-track steel tippie (shown below) equipped with the balanced "Marcus" screen, which assures a clean and well-sized product. Domestic sizes are shipped as 6-inch lump, 6 x 3-inch egg, 3 x 2-inch No. 1 nut, 2 x 1 $\frac{1}{4}$ -inch domestic stove, and 1 $\frac{1}{4}$ x 2-inch screenings.

SINCERITY COAL—LOW SULPHUR, WELL PREPARED, CLEAN BURNING

All "Sincerity" Coal Passes Over Marcus Screens in This New Five-Track Steel Tippie

NEW KENTUCKY COAL COMPANY

Fisher Building, CHICAGO, ILL

Distributors of Coal

BUCKHORN

NEW KENTUCKY

POCAHONTAS

"Buckhorn" Coal

The location of the mine producing "Buckhorn" coal from the No. 6 seam at Herrin, Illinois, was decided upon only after the entire district had been bored. The tract selected showed a superior analysis and the results since obtained by its users prove "Buckhorn" to be one of the leading coals of Southern Illinois.

Analysis of "Buckhorn" Coal

The following analysis, made at Iowa State College on 6-inch lump coal, is a fair average of its various sizes:

Moisture	7.00
Volatile Matter	33.57
Fixed Carbon	52.17
Ash	7.26
Sulphur	1.06
B. t. u. (commercial)	12,720
B. t. u. (dry coal)	13,660

"Buckhorn" Sizes

6-inch Hand-picked Lump
 6 x 3-inch Egg
 Washed Egg No. 1, 3 x 2-inch
 Washed Stove No. 2, 2 x 1-inch
 Washed Chestnut No. 3, 1 x 3/4-inch
 Washed Pea No. 4, 3/4 x 3/8-inch
 Washed Slack No. 5, 3/8-inch
 1 1/2-inch Screenings
 2" Screenings
 Run-of-Mine
 No. 1 Small Egg Unwashed

The prepared 6" hand-picked Lump, 6" x 3" Egg and No. 1 Washed Egg (3" x 2") are excellent and particularly made for domestic purposes. For steam use, either with hand-fired or stoker-fired boilers, the following sizes are prepared: No. 2 Washed Stove (2" x 1"), No. 3 Washed Nut (1" x 3/4"), No. 4 Washed Pea (3/4" x 3/8"), and No. 5 Washed Slack through a 3/8" screen.

"Buckhorn" Washed Coal

We recommend our washed sizes, because:

1. Less freight and haulage to be paid on waste material.
2. The fuel value of the coal is increased.
3. Washed coal burns freer, with less smoke and with more efficiency.
4. Less ash for removal and disposal.
5. Less clinkers, hence more heat and less labor.

"Buckhorn" Shipments

The two mines in Williamson County have a combined capacity of 5,500 tons daily and during the past ten years have produced over 7,000,000 tons. Shipments can be made on the I. C., C. B. & Q., C. & E. I., and Mo. Pac. railroads.

"New Kentucky" Coal

"New Kentucky" coal is produced at Murphysboro, Illinois. It is a high grade, free-burning coal, low in ash and sulphur. Anyone wanting a fuel above the average will find it in this coal.

"New Kentucky" Analysis

An analysis made on a sample taken from a car of 2 1/2-inch lump gave the following results:

Moisture	7.54
Volatile Matter	34.07
Fixed Carbon	55.23
Ash	3.16

Sulphur	0.81
B. t. u. (commercial)	13,100
B. t. u. (dry)	14,000

As is clearly indicated, this coal is splendidly adapted for gas, clay ware and malleable purposes, in addition to its especial fitness for all-around steam and domestic uses.

"New Kentucky" Sizes

6" Special Lump	2 1/2" Steam Nut
6" x 1 1/2" Egg	1 1/2" Screenings
2 1/2" Standard Lump	Run-of-Mine

"New Kentucky" Shipments

Shipments of "New Kentucky" coal are made on the Illinois Central Railroad and its connections.

Pocahontas Coal

We handle the best grade Third Vein Pocahontas, or as often referred to, Thick Vein Pocahontas.

Seam Worked—Geological Seam No. 5

All the Company's mines work in this same No. 5 Seam, generally known as the "Harrisburg Vein," which ranges in thickness from five to seven feet without a parting, and is found at a depth of from 75 feet at the Southern to 450 feet in the Northern end of the Field. Working conditions are excellent, including a hard slate roof, fire clay floor, not too much water, and very little gas.

The coal has a rich lustre, is of pleasing appearance, hard, rather brittle, with a semi-conchoidal fracture. It is a non-clinkering coal. The ash fuses only at very high temperature and the component parts of the ash contain a minimum of those elements, the combination of which tend to produce a lower fusing point.

Reference to analyses show it to be a high volatile, or gas coal, and while it is not adapted for extensive use for illuminating gas, it makes a splendid producer gas coal in some types of gas producers. The ignition point is at high temperature, so that the best result is secured by light and frequent firing. While the "Harrisburg" coal has not all the properties usually found in a first class coking coal, it does coke, and this makes it a very lasting fuel.

In separating into the various sizes the Run of Mine coal yields about 30% of 1 1/4" round hole Screenings.

"Harrisburg" is a popular Domestic coal with dealers, due to its great heating power, attractive appearance, and careful preparation.

"Harrisburg" is an excellent general purpose industrial fuel, owing to its high percentage of Carbon and low Ash and Moisture.

"Harrisburg" is an unusually efficient Steam coal, and an excellent Railroad locomotive fuel.

Preparation—Equipment

Five of the Company's mines have four loading tracks, so that it is possible to make four different sizes at the same time.

Four of the Company's mines have three loading tracks, so that only three different sizes of coal can be prepared at the same time.

The equipment and machinery for the preparation of the coal into the various sizes required for the many different uses is of the most modern and up-to-date character.

In addition to having the best available Screening machinery, these mines are equipped with picking tables for removing visible impurities and loading booms for lowering coal into the car with minimum breakage, assuring the cleanest, most uniformly sized coal. The screens are of the modern shaker type, being sets of steel plates 18 to 24 feet long and 7 feet wide, perforated with round holes the diameter of which gives names to the various sizes.

By shifting and adjusting these screens the Company is able satisfactorily to turn out in the best of condition practically every size that may be desired for any use to secure best results.

Illinois State Geological Survey Year Book for 1909 Says:

"The Saline County field is the newest, and in respect to quality of product, the most important in Illinois."

Wilson & Co., Packers, Chicago:

"We appreciate the exceptional service you have given us. This only assures and demonstrates that we properly placed our confidence when we awarded our contract to you. We know you have sacrificed considerably by giving your contract customers all their requirements even though you could have sold part of the coal on the open market at a very handsome profit."

Clark Coal Co., Chicago:

"Harrisburg is the best coal coming into this market. It has made good for us in every instance. If we please you as customers as much as your coal and service please us we see no reason why we should not be on your books many years to come."

Jacob E. Decker & Sons, Packers, Mason City, Ia.:

"It gives us much satisfaction to again be able to give you our contract. We know that you can and will give us the required service if anyone can."

OLD BEN COAL CORPORATION

McCormick Building, CHICAGO, ILL.

Operates 12 mines, 305 miles south of Chicago, and owns approximately 61,000 acres of coal land, with agricultural surface. These mines are located in Franklin County, Illinois, which contains the thickest and most desirable body of bituminous coal in the middle west.

The coal which blankets the county is geologically known as No. 6 seam and averages from 9 to 14 feet in thickness that will average .55 to 1.2 per cent. of sulphur content and is rich in by-products, and develops over 13,000 B. t. u. in heat value. Beneath the No. 6 seam and easily workable is another body of desirable coal from 4 to 5 feet in thickness, which can be considered as a reserve for a far-off future.

All the coal on the OLD BEN properties is the very best quality for steam and domestic fuel and commands a steady and ready market always at top prices.

General quality is shown below by one of many analyses made by Robt. W. Hunt & Company, Engineers, Chicago, Ill.

	Small Egg	No. 2	No. 3
Moisture	7.56	7.10	7.60
Volatile Matter.....	32.51	32.20	30.10
Fixed Carbon.....	54.30	54.51	56.10
Ash	5.63	6.19	6.20
	100.00	100.00	100.00
Sulphur	1.18	1.20	1.09
B. t. u., Dry.....	13,618	13,536	13,480
B. t. u., Commercial.	12,588	12,575	12,456

The location of the mines is of the most desirable strategic nature, for distribution to an area

containing 20 prosperous states, cobwebbed with railroads of the best class, and with an easy approach to future export opportunities.

The mines are equipped with every modern mechanical device and are located in or near prosperous and large towns which makes readily available the best sort of mine labor at all times of the year.

The Corporation employs about 7,000 men at the mines, drawn from the best class of mine workers, who are encouraged to build permanent homes by the comforts and advantages that surround them.

In no part of the world is bituminous coal so perfectly prepared, sized and loaded for market as in these plants of Old Ben Coal Corporation, and the product is so superior, and has been so thoroughly advertised through the advanced publicity that has been employed, that it is now the standard fuel of the midwest section of the United States, and is likely to become a real factor in the export market of the world as the development of water transportation, now under active consideration, becomes a fact.

At a fair estimate, the daily capacity of the OLD BEN group of mines is 50,000 tons daily when full working time and adequate transportation conditions are possible. Direct mine connections are made with four great trunk lines: The Chicago, Burlington & Quincy, Chicago & Eastern Illinois, Illinois Central, and Missouri Pacific Railways, with great lakes and tidewater outlets.

With the territory now served by the Corporation properly developed, there are still greater expansions of tonnage and market easily possible.

Coal Mine Management

For General Summary of Peabody Management Service See Page 249

OPERATING MANAGER

Out of the tested, successful operating methods of mines under our active control in most of the important fields, you can secure for your mine the methods which make possible the most efficient, effective and economical operation.

As Operating Manager for your mine, we can employ the fund of data on mining conditions, cost items and improved methods which is daily collected and arranged for comparison for the benefit of each of the mines we manage.

In addition to our own mines, we are operating thirty mines owned by others, located in Kentucky, Illinois, Indiana, Oklahoma and Wyoming. This large scale operation makes possible the employment of a staff of exceptionally well qualified mining experts and field men.

The efficiency of this management was recently shown following an accident at Mine No. 18, West Frankfort, Illinois, owned by the By-Products Coke

Corporation and operated under the Peabody plan. A fire caused by a short circuit in one of the large transformers completely destroyed the power house. The buildings and electrical machinery were wiped out and the hoisting engine partly wrecked. The destroyed electrical machinery consisted of a 550 K. W. A. C. generator, a 400 M. G. generator set and a 300 A. C. generator set complete with switchboards. By bringing in equipment from the company's supply house, which is maintained to minimize delays due to accidents such as this, the buildings were temporarily restored and all damaged machinery replaced so that the mine was operating to its full capacity with an interruption of only three working days.

Operating 36 Mines in 11 Fields on 19 Railroads With Annual Capacity of 18,000,000 Tons

Peabody Service to Coal Buyers

The mining and distributing of coal is full of uncertainties. In no other business are there so many factors utterly beyond the control of the producer. Accidents within the mine which it is impossible to foresee or prevent may at any time completely paralyze a mining operation. Failure in the supply of railroad cars often enforces idleness. Impairment of the working force through strikes and other causes frequently results in stoppage of production.

It is therefore obviously impossible for any coal producing company to maintain 100% service under all conditions. But it is equally obvious that a producing company having a large number of mines with many railroad connections will not be seriously crippled by accidents occurring at one mine and that it is better able to replace production lost through local strikes or failure of car supply on one or two lines. In other words, such a company will be the last to feel impairment of service due to conditions beyond control.

It will be noted that Peabody Coal Company has unusual facilities for supplying coal from the important districts of Illinois, the enormous potential capacity of the mines operated providing a measure of protection against periodical shortages. During the trying times of the past several years, "Peabody Service" has become more than ever recognized by large and small buyers of coal as something more than a matter of good intentions, having back of it physical resources unequalled in the Illinois field.

On the following pages we have set forth essential data concerning our Illinois properties which may be of interest to buyers of coal. The analyses given represent the average of a large number made by The Kawin Co., The Dearborn Chemical Co., The United States Fuel Co., and the University of Illinois.

Peabody Mine No. 3

LOCATION—Marion, Williamson County, Illinois.
RAILROADS—C. B. & Q., I. C., C. & E. L. Mo. Pac.
SHIPPING POINTS—Marion, Bush and Herrin.
SEAM MINED—Illinois No. 6.
CAPACITY—1,350,000 tons per year.
PREPARATION—Round Hole Shaker Screens, Picking Tables and Washer.

Sizes Produced

Mine Run	
6" Lump.....	Over 6" Screen
6" Egg.....	Through 6" over 3" Screen

TAYLOR COAL COMPANY

Northwestern Sales Office
BUI LDERS EXCHANGE BLDG., MINNEAPOLIS, MINN.

Main Office
OLD COLONY BUILDING, CHICAGO

Owning and Operating
Four Mines in Franklin and Williamson Counties, Illinois

Producing **ENERGY** Coal
For Domestic, Steam & By-Product Use

Distributors of High Grade
Central Illinois, Brazil (Ind.), Hocking, Kentucky, West Virginia and Pennsylvania Coals

The Field

The four mines operated by the Taylor Coal Company which produce the coal sold under the trade name of Energy lie close to the center of the Franklin and Williamson County field. The Southern Illinois field, of which this is a part, is considered to be the most important in the state.

The vein of coal mined here is what is known as No. 6. All of the coal mined in Franklin County

Tipple and Washery at Energy Mine No. 2

and most of that in Williamson County comes from this vein. This coal is generally a low moisture and low sulphur coal. The vein averages about nine feet in thickness; one room in Energy Mine No. 5 is working in twelve foot coal. This means economical mining.

Energy Egg from Mine No. 5, Ready for Market

Energy Mines

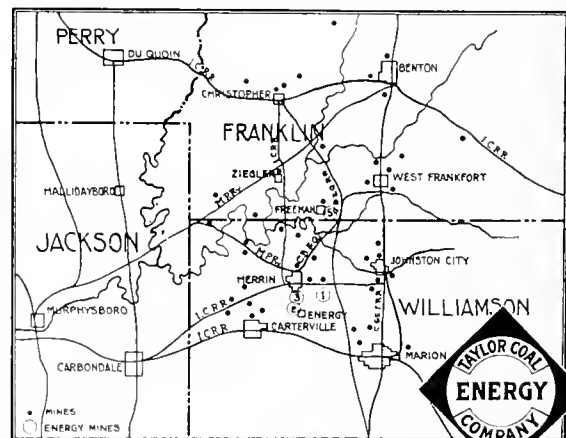

Energy Mines Nos. 1, 2 and 3 lie about five or six miles south of the Franklin-Williamson County line. Mine No. 5 lies just north of the same line. Nos. 1, 2 and 3 ship through Herrin, over the Illinois Central and Missouri Pacific Railroads. The shipping point for No. 5 is Freeman, on the Illinois Central and Chicago, Burlington & Quincy Railroads.

Energy No. 1

In addition to the regular shaker screen equipment this mine has for the purpose of producing a particularly well sized coal for domestic use a re-screening plant which makes the following sizes: 3"x2" small egg, 2"x1 1/4" stove, 1 1/4"x3/4" chestnut, 3/4"x3/8" pea, 3/8"x0" buckwheat, at the same time giving an opportunity for a very close inspection and picking of the coal. Long loading booms insure a minimum of breakage in loading. This mine has a daily capacity of 1,500 tons.

Energy No. 2

Has a daily capacity of 1,800 tons of coal mined and 1,200 tons washed, having beside the regular up-to-date mining equipment a Luhrig coal washer.

Map of Franklin and Williamson County Field

In this as in the other mines the coal is properly mined and the raw coal is given a first grade preparation over shaker screens. The coal to be washed, however, is carried to rotary screens in the top of the washery building. These rotary screens do a double duty. In the first place they will break the coal wherever there is a fracture already started,

and, in that way, to a large extent, eliminate any possible breakage in later handling. In the second place one of the important features of a Luhrig coal washing plant is the fact that the coal must be accurately sized before it is washed.

The washing of the coal occurs in banks of jigs, each bank comprising several jigs, handling a separate size of coal. The jig itself is a tank filled with water divided across the top by a partition, in front of this the coal lies on a perforated plate. Back of the partition a plunger working on a cam gives the proper number of pulsations to the water which forces its way through the coal lying on the perforated plate. The coal, being lighter in weight, rises and is finally washed to the top and over the edge of the tank into a sluice which carries it on. The slate, clay, bone coal and other impurities settle to the bottom and at regular intervals are released through a gate which opens to another sluice leading to refuse disposal machinery.

The coal after leaving the jigs is given a thorough spray with fresh water, which removes any fine coal which may remain from the jig water. From here the washed coal passes through revolving draining screens, which in turn deliver the coal to storage bins.

Energy Coal in the Mine

The coal is washed and delivered in seven sizes: large egg $3\frac{1}{2}'' \times 3''$, small egg $3'' \times 2''$, stove $2'' \times 1\frac{1}{2}''$, chestnut $1\frac{1}{2}'' \times 1''$, No. 3 $1'' \times \frac{7}{8}''$, pea $\frac{7}{8}'' \times \frac{1}{2}''$, buckwheat $\frac{1}{2}'' \times \frac{1}{16}''$.

This coal, according to tests made, carries less moisture content than raw coal and burned properly comes very close to being a smokeless coal. While it kindles very quickly, it also holds fire remarkably well and makes not only a high grade steam coal but a remarkably good and economical coal for domestic use.

Energy No. 3

The coal produced at No. 3 is of a very high grade and is prepared in the following sizes: 6" lump, 6" x 3" furnace, 3" x 2" small egg, and 2" screenings. Each size is very carefully hand-picked.

Energy No. 5

Is the Franklin County mine of the quartet. In this mine the vein reaches a thickness of twelve to thirteen feet in places.

The coal is a remarkable heat producer. It is slightly freer burning than the other coals, but is very easily controlled and has won great popularity both as a steam and domestic coal. It is well prepared and ranks with the finest coals produced in this section of the country. This mine has just been equipped with a Marcus screen and picking table of the very latest design and long loading booms, for each size of coal, delivering to the cars a very fine coal.

Analyses

The analyses which follow were made by one of the most reliable testing companies in the country, the Commercial Testing and Engineering Company, of Chicago, and while only giving the tests on certain sizes, give a very fair indication of what the coal is, as they are the results of tests made on samples taken from consumers' bins.

TAYLOR COAL COMPANY
Producers of ENERGY COAL
Chicago Minneapolis

UNION COLLIERY COMPANY

General Office:
Union Electric Building, St. Louis, Missouri

W. C. SCHROEDER, Sales Manager
500 Old Colony Building, Chicago, Illinois

KATHLEEN MINE

KATHLEEN Mine is located at Dowell, Jackson County, Illinois.

We ship KATHLEEN Coal in 6 inch lump, 6 by 3 inch Egg, and 3 by 2 inch Nut.

KATHLEEN Coal is recommended for Steam and Domestic uses.

All shipments are billed from Dowell, which is on the Illinois Central Railroad.

KATHLEEN Mine is a new installation, electrically driven throughout, including short-wall mining machines, electric haulage, and electric hoists.

In the construction and operation of the KATHLEEN Mine no expense has been spared to insure the maximum character of preparation and quality.

Booms Loading Lump, Egg, and Nut

Located on the main line of the Illinois Central Railroad our production is being distributed throughout the states of Illinois, Wisconsin, Minnesota, Iowa, Nebraska, Kansas and Missouri.

Steel Tipple at Kathleen Mine

Our tipple is equipped with steel picking tables and loading booms, the coal is hand-picked, and delivered into the car with minimum breakage. Our Screenings are made through full 2-inch round openings.

We are desirous of bidding on the requirements of consumers who are appreciative of integrity in the matter of quality and weights, and of dependability of delivery

“QUALITY—DEPENDABILITY—INTEGRITY” OUR MOTTO

UNION FUEL COMPANY

Producers and Distributors of Bituminous Coal

Character of Organization

The Union Fuel Company, with the strategic location of its mines, its excellent transportation facilities, experienced supervision, low operating costs and efficient service to its customers, proposes to continue to merit and to hold the confidence and respect of those with whom it is dealing. The conservative policy of the Company has safeguarded the interests of its customers.

Mines

The Company owns and operates six well-known mines in the Springfield district. At every mine new equipment has been installed, modern buildings erected, and every possible improvement inaugurated to raise the quality of coal produced and lower its cost to the consumer.

Quality and Preparation

The coal is high in heat producing capacity and low in ash content. It is prepared in all sizes and is excellent for steam, railroad and domestic purposes.

Transportation Facilities

The Company's mines are served by six railroads, namely, C. & A., C. & N. W., C. B. & Q., C. P. & St. L., C. I. & W., C. & I. M., and their connecting lines; therefore, our coal is consistently delivered into an extensive territory. And with a potential capacity of 7,000 tons a day from our mines, we are able to make prompt and full shipments even during severe emergencies.

UNION FUEL BUILDING
123 W. Madison St., Chicago

Freight Rates

The coal buyers in the Central and Middle Western States are substantially benefitted by the favorable location of the Union Fuel Company's mines, because the freight rates are decidedly lower than from other coal producing districts.

WASSON COAL COMPANY

Sole Producers of

Wasson's Harrisburg White Ash Coal

"The Best In The Middle West"

Sales Office
1914 Fisher Bldg., CHICAGO

Main Office and Mines
HARRISBURG, ILL.

Location of Mines

The mines of the Wasson Coal Company, two in number, are situated in Saline county, Illinois, one of the three major coal producing fields in the southern part of the state. One mine is immediately north of and the other immediately south of Harrisburg.

Seam Worked and Its Characteristics

The Number Five Seam, from which both mines derive their coal, is everywhere recognized as a superior fuel. Its good reputation is due partly to the fact that the coal mines clean. In Saline county the seam lies under deep cover and has a very hard top and bottom. At the Wasson mines, directly above the seven-foot seam, there is a dense layer of black slate, at some places as much as three feet in thickness. This slate is solid and parts easily from the coal in shooting, so that there is no contamination of the coal with top rock. Neither is it possible to get any bottom dirt mixed with the coal, for the bottom is as hard as flint and can not be cut into by the mining machines. A third natural cause for the production of clean coal from the Wasson mines is that the entire seam between top and bottom is without partings.

In content of volatile matter, Wasson coal ranges somewhere between Hocking and Youghiogheny. It is a coking coal, and, according to A. Bement, is comparable more closely with the Youghiogheny coal of Western Pennsylvania than to any coal found in Illinois.

Its analysis is as follows:

Analysis*

	Dry Basis	As Received
Moisture	0.00	6.65
Volatile Matter	35.80	33.42
Fixed Carbon	54.27	50.66
Ash	9.93	9.27
	100.00	100.00
Sulphur	2.29	2.14
B. t. u. per pound...	13,225	12,346
Fusion Temperature of Ash...	2240° F.	

*Commercial Testing & Engineering Co., Chicago.

Wasson Coal for Steam Purposes

Saline county coal is widely known as a premier steam coal. Forty per cent of the output of the Wasson mines is used under boilers, and gives general satisfaction. This coal predominates at the Chicago Stock Yards where it is burned in stokers.

Likewise, in Chicago and other points along Lake Michigan, it is substituted on tug boats for Eastern coals, which heretofore were supposed to be the only ones that would meet the exacting conditions on board these high-powered lake steamers. Another indication of the unusual qualities of Saline county coal for steam purposes is that in the Chicago market, although in competition with coal from many parts of the United States, the screenings usually sell at a premium of ten to fifteen or even twenty cents a ton over other Illinois offerings.

Method of Firing

As is the case with all high-volatile coals, Wasson-Saline coal will smoke unless carefully handled. For hand firing, the most successful way is to distribute the coals thinly over the glowing bed of coals and thus fire lightly but often. When the coal is fired in this way an almost even surface of coked coal is kept, with the production of very little smoke.

Wasson Coal For Domestic Users

About sixty per cent of the Wasson output goes to the domestic trade. The domestic consumers of this company are as permanent as are the steam customers, and their number is constantly increasing. Wasson coal is free burning and has proved itself a first-class domestic coal wherever it has been used. It sells in Western Indiana in competition with Number Four coal. It is distributed through the central and northwestern parts of Illinois in competition with the best grades of domestic coal. The same is true in the markets of Wisconsin, Iowa, Nebraska and the northwest.

Method of Firing

After firing in a household furnace, the drafts should all be opened wide for fifteen minutes to permit sufficient air to burn off the volatile gases without the formation of dense smoke. The amount of coal fired at one time should be small. After the gases are burned off, the draft should be removed, and if a shovelful of ashes is put on top of the glowing bed of coal it will hold fire over night without any difficulty.

Wasson Coal For Other Usages

Harrisburg coal is being used with success in glass works where a long-flame coal is required. It is also well adapted for cement burning, railroad and cannery use.

Preparation

The equipment at both mines is about the same. After being weighed, the coal passes to shaker screens where it is sized into lump, egg, nut and screenings. Any combination of these sizes can be made. Below the screens there are four loading booms, one to each track, which let the coal down into the cars. Alongside these booms workers are stationed to clean the coal from any impurity which may have found its way into the coal. Having a clean seam to begin with, plus the care taken in preparation, explains why users of Wasson coal find that all shipments consist of real combustible material, rather than an admixture of slate and coal.

Railroads

The mines are served exclusively by the Cairo branch of the New York Central Lines. By means of the originating carrier and its connections, coal

from the Wasson mines can reach any point that can be served by any Illinois railroad.

Selling Zone

In the southern part of Illinois; in the western part of Indiana; in all points reached through Cairo; in St. Louis and all points to the west reached thereby; in Chicago, Peoria and all points reached through these two gateways.

Wasson Coal Company Policy

Satisfactory service for the customer; good preparation for the coal; fair price for ourselves.

This trinity expresses the Wasson creed. We believe the customer's first want is a good, clean coal, one he can burn efficiently. Wasson Service is a lubricant which keeps our relations at all times pleasant with the trade.

A fair price is all we deserve and all we ask.

ILLINOIS

Alphabetical Directory of Coal Mines, Giving Complete Detailed Information Covering Each Mine

For List of Abbreviations See Page 13.

ABBEY COAL CORPORATION

General Office, Collinsville, Ill.
PR—Jesse Long, Collinsville, Ill.
VP—Wm. H. Martin, Collinsville, Ill.
TR—Aug. C. Lohmann, " "
GM—F. H. Rice, " "
PA—F. H. Rice, " "
EM—Hugh W. Flood, Belleville, Ill.

Abbey Mine; Shaft; Belleville No. 6 Seam; 66 to 90 in. thick.

PO—Collinsville, Ill. SP—Same; CTY—Madison, RR—P. C. C. & St. L.
MS—Leon Barber, Collinsville, Ill.
S of H—Mules. Track gauge 19 in.
S of M—3 chain breast mchrs.
PP—2 return tubular boilers, 250 H. P., 1 hoisting engine, 2 pumps.
EMP—73. Last years tonnage 76,741.
SIZES SHIPT—Run of Mine, Slack, Egg, Lump.
PREP. EQUIPT—Bar Revolving, Shaker Screens.

ABEND COAL COMPANY.

General Office, Belleville, Ill.
PR—F. M. Rumbold, Washington, D. C.
VP—Edward Abend, Belleville, Ill.
TR—Edw. Abend, Belleville, Ill.
GM—W. J. Reiss, Belleville, Ill.
GS—W. J. Reiss, Belleville, Ill.
PA—W. J. Reiss, Belleville, Ill.
SA—Kohb Coal Co., St. Louis, Mo.

Abend Mine; Shaft; Seam, 66 inches thick.

PO—Belleville, Ill.; SP—Same; CTY—Saint Clair; RR—L. & N., O'Fallon Br.
MS—John P. Taylor, Belleville, Ill.
S of H—Mules. Storage battery locos. Track gauge 34 inches.
S of M—Hand.
PP—Power purchased, transformer, 220 volts A. C. M. G. Sets, 220 volts D. C., 2 fire tube boilers, 250 H. P., 6 pumps.
EMP—95. Daily tonnage 650.
SIZES SHIPT—Run of Mine, Slack, Lump.
PREP. EQUIPT—Shaker Screens.

ACME COAL COMPANY.

General Office, Streator, Ill.
PR—Thomas Fairbairn, Streator, Ill.
TR—R. J. Fairbairn, Streator, Ill.
GM—Thos. Fairbairn, Streator, Ill.
PA—Thomas Fairbairn, Streator, Ill.
MS—Thomas Fairbairn, Streator, Ill.

Acme Mine; Shaft; No. 7 Seam, 54 in. thick.

PO—Streator, Ill. SP—Same; CTY—La Salle, RR—C. B. & Q.
S of H—Mules. Track gauge 36 in.
S of M—Hand.
PP—Purchase power, 1 return tubular boiler, total 50 H. P., 3 pumps.
EMP—25. Last fiscal year output, 12,000 tons.
SIZES SHIPT—Run of Mine, Slack, Lump.
PREP. EQUIPT—Gravity Screens.

ALADDIN COAL COMPANY

Now Aladdin Coal & Mining Co.

ALADDIN COAL & MINING CO.

Mines operated under lease by the Southern G. M. Coal Corporation.

ALDEN COAL COMPANY.

General Office, Davenport, Ia.
PR—J. W. Gilchrist, Davenport, Ia.
VP—H. W. Gilchrist, Davenport, Ia.
TR—J. W. Gilchrist, " "
GM—H. M. Gilchrist, " "
PA—H. M. Gilchrist, " "
GS—Arch Gilchrist, Davenport, Ia.
CE—H. M. Gilchrist, Davenport, Ia.
EE—Wm. Russell, Farmington, Ill.
SCD—Alden Coal Co., River, Ray Kitzmiller, Norris, Ill.

Sales Agent, C. H. Crowe, Davenport, Ia.

Alden No. 5 Mine; Shaft; No. 5 Seam, 48 in. thick.

PO—Farmington, Ill.; SP—Same; CTY—Fulton; RR—C. B. & Q.
S of H—Mules and rope. Track gauge 28 in.
S of M—Hand.
PP—Power purchased, transformer 2,300 to 110-220 volts A. C., 1 125 H. P. fire tube boiler, 5 pumps.
EMP—151. Last fiscal year output 106,000 tons.
SIZES SHIPT—Run of Mine, Slack, Egg, Lump, Block.
PREP. EQUIPT—Shaker Screen.

Alden No. 6 Mine; Shaft; No. 5 Seam, 48 in. thick.

PO—Norris, Ill.; SP—Same; CTY—Fulton; RR—C. B. & Q.
SM—Ray Kitzmiller, Norris, Ill.
S of H—Mules and trolley type locos. Track gauge, 36 in.
S of M—6 shortwall.

PP—Power purchased, Transformer 2,300 to 110 and 220 volts A. C., 3—450 H. P. fire tube boilers, 2 M. G. Sets, 1—200 K. W. and 1—150 K. W. and 75 K. W. gen. units, 250 volts D. C., 4 pumps.
EMP—180. Last fiscal year output, 151,600 tons.
SIZES SHIPT—Run of Mine, Slack, Egg, Lump, Block.
PREP. EQUIPT—Shaker Screen.

Alden No. 7 Mine; Shaft; No. 1 Seam, 36 to 72 in. thick.

PO—Matherville, Ill.; SP—Same; CTY—Mercer; RR—Rock Island & Southern.
S of H—Mules and trolley pole and storage battery locos. Track gauge, 36 in.
S of M—Hand.

PP—Power purchased, Transformer 2,300 to 110-220 volts A. C., 2 fire tube boilers, 250 H. P., M. G. Sets, 1—100 K. W. and 20 K. W., 250 volts D. C., 8 pumps.
EMP—148. Last fiscal year output, 158,210 tons.
SIZES SHIPT—Run of Mine, Slack, Pea, Egg, Lump, Block.
PREP. EQUIPT—Shaker Screen.

Alden No. 8 Mine; Shaft; No. 5 seam, 48 in. thick.

PO—Farmington, Ill.; SP—Same; CTY—Fulton; RR—M. & St. L.
S of H—Mules and trolley pole type locos. Track gauge, 36 in.
S of M—6 chain breast type and 6 shortwall mchrs.
PP—Power purchased, Transformer 2,300 volts A. C., 1—100 K. W. and 1—200 K. W., M. G. Sets, 250 volts D. C., 2 fire tube boilers, 5 pumps.
EMP—162. Last fiscal year output, 185,084 tons.
SIZES SHIPT—Run of Mine, Slack, Egg, Lump, Block.
PREP. EQUIPT—Shaker Screens and Crusher.

ALUMINUM ORE CO.

General Office, Oliver Bldg., Pittsburgh, Pa.
GM—H. Isler, Belleville, Ill.
PA—N. N. Gould, East St. Louis, Ill.
CE—G. H. Slocum, East St. Louis, Ill.
EE—J. E. Housley, East St. Louis, Ill.

Radium Mine; Shaft; No. 6 Seam, 72 inches thick.

PO—Belleville, Ill.; SP—Same; CTY—St. Clair; RR—Illinois Central & St. L. and Ohio River R. R.
MS—W. C. Wolf, Belleville, Ill.
S of H—Mules and 2 elec. storage battery locos.
PP—Power purchased, 6—75 K. V. A., 400 volts 4—50 K. V. A., 220 volts, M. G. Sets, 220 volts D. C., 3 pumps.
EMP—137. Last years tonnage, 175,069.
SIZES SHIPT—Run of Mine, Slack, Pea, Nut, Egg, Lump.
Note—Successors to Radium Coal Co.

ASSUMPTION COAL & MINING CO THE

General Office, Assumption, Ill.
PR—Silas A. Shafer, Assumption, Ill.
VP—T. P. Myers, Assumption, Ill.
TR—David Lacharite, Assumption, Ill.
GM—Silas A. Shafer, " "
PA—Silas A. Shafer, " "
EE—Albert Palmer, Assumption, Ill.
EM—Wm. Lewis, Assumption, Ill.

No. 1 Mine; Shaft; No. 1 Seam, 42 inches thick.

PO—Assumption, Ill. SP—Same; CTY—Chicago; RR—Illinois Central.
MS—Ira Hinkle, Assumption, Ill.
S of H—Mules and electric locos. Track gauge 29 1/2 inches.
S of M—Hand and 3 longwall mchrs.
PP—4 return tubular boilers, total 600 H. P., 1 125 K. W. gen. units, 250 volts D. C., 3 pumps.

EMP—120. Daily tonnage 250.
SIZES SHIPT—Run of Mine, Slack, Pea, Nut, Egg, Lump, Block.
PREP. EQUIPT—Revolving and Shaker Screens.

ATHENS COAL COMPANY.

Now part of Union Fuel Co.

AUBURN & ALTON COAL CO.

Now part of Union Fuel Co.

B. B. COAL & MINING COMPANY.

General Office, 690 Arcade Bldg., St. Louis, Mo.
PR—Wm. H. Boehmer, St. Louis, Mo.
VP—Mrs. A. Boehmer, St. Louis, Mo.
TR—Wm. H. Boehmer, " "
GM—Wm. H. Boehmer, " "
PA—Wm. H. Boehmer, " "
CE—John J. Guest, Belleville, Ill.
GS—John J. Guest, Belleville, Ill.
EM—John J. Guest, " "
EE—John J. Guest, " "
SCD—Address the Company, Boyer, W. H. Boehmer, St. Louis, Mo.

R. B. Mine; Shaft; 6th Seam, 72 inches thick.

PO—Belleville, Ill. SP—Cooper Sta., Ill. CTY—St. Clair. RR—St. L. & E. and Son.
S of H—Mules.
S of M—Hand.
PP—Power purchased, 440 volts, A. C., 1 pump.
EMP—102. Last years tonnage 47,486.
SIZES SHIPT—Run of Mine, Nut, Egg, Lump.
PREP. EQUIPT—Screen.

BADER, E. G.

Elipsa Mine.
PO—Astoria, Ill.; SP—Same; CTY—Fulton; RR—C. B. & Q.
No report.

BAILEY BROS. COAL CO.

General Office, Duquoin, Ill.
PR—Jos. Bai v. Duquoin, Ill.
TR—Jos. Bailey, Duquoin, Ill.
GM—Jos. Bailey, Duquoin, Ill.
GS—Jos. Bailey, Duquoin, Ill.
PA—Jos. Bailey, Duquoin, Ill.
SCD—Address the company, Boyer, Carl Bailey, Duquoin, Ill.

Diamond Mine; Shaft; No. 6 Seam, 5 and 6 ft. thick.

PO—Duquoin, Ill.; SP—Sunbird, Ill.; CTY—Perry; RR—I. C.
S of H—Mules and 1 storage battery loco. Track gauge 36 in.
S of M—2 shortwall mchrs.
PP—3 fire tube boilers, 200 H. P. 2 pumps.
EMP—60. Last years tonnage 40,000.
SIZES SHIPT—Run of Mine, Slack, Pea, Nut, Egg, Lump.
PREP. EQUIPT—Revolving and Shaker Screens.

BAIRD BROS.

General Office, Colchester, Ill.
PR—Oswald Baird, Colchester, Ill.
GM—J. T. Baird, Colchester, Ill.
PA—J. T. Baird, " "
EM—J. T. Baird, " "

Baird Mine; Shaft; No. 2 Seam, 30 in. thick.

PO—Colchester, Ill. SP—Same; CTY—McDonough; RR—C. B. & Q.
MS—J. T. Baird, Colchester, Ill.
S of H—Mules. Track gauge 36 in.
S of M—Hand.
PP—Power purchased, 220 volts.
EMP—30. Last fiscal year output, 20,000 tons.
SIZES SHIPT—Run of Mine, Egg, Lump, Block.
PREP. EQUIPT—Bar Screens.

BAIRD BROS. & BUCHER

PR R. O. Baird, Astoria, Ill.
GM—E. Bucher, Astoria, Ill.
GS—J. T. Baird, Colchester, Ill.

No. 1 Mine; Shaft; No. 5 Seam, 72 inches thick.

PO—Astoria, Ill.; SP—Same; CTY—Fulton; RR—C. B. & Q.
S of H—Mules. Track gauge 36 inches.
S of M—Hand.
PP—Power purchased, 220 volts A. C., 1 30 H. P. and 1 50 H. P. fire tube boiler, 2 pumps.
SIZES SHIPT—Run of Mine, Slack, Lump.
PREP. EQUIPT—Gravity Screens.
Old Information.

BARTELS COAL COMPANY.

General Office, Carlinville, Ill.
GM—H. W. Bartels, Carlinville, Ill.
GS—H. W. Bartels, Carlinville, Ill.
PA—H. W. Bartels, Carlinville, Ill.

Bartels Mine; Shaft; No. 6 Seam, 78 in. thick.

PO—Carlinville, Ill.; SP—Same; CTY—Macoupin; RR—I. T. S.
S of H—Mules.
S of M—Hand.
EMP—50. Daily tonnage 300.
SIZES SHIPT—Run of Mine, Slack, Lump.
NOTE—Formerly operated by the Carlinville Coal Co.

BAUSER-TRUESDALE

Edward A. Bauser, Lessee, Bunker Hill, Ill.

Bauser-Truesdale Mine; Shaft; No. 1 Seam, 60 in. thick.

PO—Bunker Hill, Ill.; CTY—Macoupin, Ill.; RR—Big Four.
S of H—Mules.
S of M—2 comp. air mchrs.
PP—2 fire tube boilers, total 130 H. P., 1 air compressor, 2 pumps.
EMP—20.
PREP. EQUIPT—Bar Screens.
Note—Formerly operated under name of Edward A. Bauser.

BAXTER, NEIL & SONS.

Now Rawlitt Coal Company.

BEATTY COAL COMPANY

General Office, Mascoutah, Ill.
PR—R. J. Beatty, Mascoutah, Ill.
VP—O. J. Klingenfus, Belleville, Ill.
TR—C. W. Beatty, Mascoutah, Ill.
GM—R. J. Klingenfus, Belleville, Ill.
GS—R. J. Klingenfus, Belleville, Ill.

Beatty Mine; Shaft; No. 6 Seam; 90 in. thick.

PO—Mascoutah, Ill.; SP—Same; CTY—St. Clair; RR—L. & N.
MS—R. J. Beatty, Mascoutah, Ill.
S of H—Mules. Track gauge 19 1/2 in.
S of M—Hand.
PP—1 fire tube boiler, total 120 H. P., 3 pumps.
EMP—6. Last years tonnage 3,904.
SIZES SHIPT—Run of Mine, Slack, Lump.
PREP. EQUIPT—Bar Screens.
Note—Formerly John T. Beatty Operations.
Old Information.

BEESE COAL COMPANY

General Office, 314 E. 11th St., Belleville, Ill.

PR—Charles Stogmeyer, Belleville, Ill.
VP—Edgar McKenzie, Belleville, Ill.
TR—Walter Hoener, Belleville, Ill.
GM—John E. Reese, 314 E. 11th St., Belleville, Ill.
EN—John Reese, Jr., Belleville, Ill.
SA—John Beese, Sr., Belleville, Ill.

Beese Mine; Shaft; No. 6 Seam; 72 inches thick.

PO—Belleville, Ill.; SP—Same; CTY—St. Clair.
S of H—Mules, rope, steam loco. Track gauge 36 inches.
S of M—Hand.
PP—1 fire boiler, 75 H. P., 2 pumps.
EMP—10. Last years tonnage 5,482.
SIZES SHIPT—Run of Mine, Slack, Nut, Lump.
PREP. EQUIPT—Bar Screens.

CELL & ZOLLER MINING CO

General Office, 343 South Dearborn St., Chicago, Ill.

PR—H. E. Zell, 343 South Dearborn St., Chicago, Ill.
VP—R. H. Zell, Chicago, Ill.
TR—W. G. Zell, Chicago, Ill.
GM—R. H. Zell, Chicago, Ill.
GS—J. Y. Zell, Zell, Ill.
PA—J. H. Zell, Chicago, Ill.
EM—Paul Zell, Zell, Ill.
SA—R. H. & Zell, Zell, Ill.

Zell No. 1 Mine; Shaft; No. 1 Seam, 130 in. thick.

PO—Zell, Ill. SP—Same; CTY—Grand River; RR—I. C. & Q. and Mo. Pac.
S of H—27 fire tube boilers, total 1,200 H. P., 2 pumps.
S of M—24 chain breast mchrs.

(Continued on Next Page)

Bell & Zoller Mining Co.—Cont.

PP—6 375 H. P. water tube boilers, 1 500 K. W., 1 300 K. W., 1 100 K. W., gen. units, 250-275 volts D. C., 10 pumps.

EMP—800. Daily output, 5,000 tons. SIZES SHIPT—Run of Mine, Slack, Pea, Nut, Egg, Lump, Special Stove, Chestnut.

PREP. EQUIPT—Shaker Screens, Picking Tables, Loading Booms.

Zelger No. 2 Mine; Shaft; No. 6 Seam, 120 inches thick.

PO—Zeigler, Ill.; SP—Same; CTY—Franklin; RR—L. C.; C. B. & Q., and Mo. Pac.

MS—E. L. Burger, Zeigler, Ill.

S of H—6 trolley pole type locos. Track gage, 42 inches.

S of M—4 chain breast type and 6 short-wall machs.

PP—4 375 H. P. water tube boilers, 1 300 K. W., 1 100 K. W., gen. units, 250-275 volts D. C., 5 pumps.

EMP—1,000. Daily output, 6,000 tons. SIZES SHIPT—Run of Mine, Slack, Pea, Nut, Egg, Lump, Block.

PREP. EQUIPT—Shaker Screens, Picking Tables, Loading Booms.

BENTON BIG MUDDY COAL CO.

Leased to the Fort Dearborn Coal Co.

BENTON COAL COMPANY.

Now a part of Chicago, Wilmington & Franklin Coal Co.

BERRY, B. F. COAL CO.

General Office, Graniteville, Ill.

PR—S. T. Crane, Detroit, Mich.

VP—E. J. Earling, Milwaukee, Wis.

TR—Jas. Phelps, Milwaukee, Wis.

GM—E. J. Earling, Milwaukee, Wis.

ES—John T. Cherry, Standard, Ill.

PA—Chas. H. Sturges, Graniteville, Ill.

SA—Central Coal Co., Plankinton Arcade, Milwaukee, Wis.

Standard No. 1 Mine; Shaft; No. 2 Seam, 37 inches thick.

PO—Standard, Ill.; SP—Same; CTY—Putnam; RR—L. C. & St. P., Chicago, Rochelle & Southern.

S of H—Mules. Track gage 41 in.

S of M—Hand.

PP—6 fire tube boilers, total 900 H. P., 6 pumps.

EMP—250. Last fiscal year output, 196,884 tons.

SIZES SHIPT—Run of Mine, Slack, Egg, Lump.

PBEP EQUIPT—Shaker Screens, Washeries.

BIG CREEK COALS, INC.

General Office, Chicago, Ill.

PR—C. E. Pierce, Chicago, Ill.

VP—(In Charge of Operations) M. S. Coleman, Harrisburg, Ill.

VP—(In Charge of Sales and Accounts) H. E. Stuart, Chicago, Ill.

SECY—W. H. Burnham, Chicago, Ill.

ASST. TR—W. H. Burnham, Chicago, Ill.

PA—D. V. McCarthy, Chicago, Ill.

CHIEF ENGR—J. C. Quade, Harrisburg, Ill.

Additional Information on pages 318, 319.

No. 2 Mine; Shaft; No. 5 Seam, 66 inches thick.

PO—Leford, Ill.; SP—Same; CTY—Sallina; RR—Big Four.

MS—Jno. Wunderlick, Harrisburg, Ill.

S of H—Mules and 3 trolley pole type locos. Track gage 42 inches.

S of M—8 chain breast type and 3 shortwall machs.

PP—Power purchased, transformer 33,000 to 2,300 volts A. C., M. G. Set, 250 volts D. C., 6—150 H. P. fire tube boilers, 12 pumps.

EMP—450. Daily tonnage 2460.

SIZES SHIPT—Run of Mine, Slack, Pea, Nut, Egg, Lump.

PREP. EQUIPT—Shaker Screens, Picking Tables, Loading Booms.

No. 3 Mine; Shaft; No. 5 Seam, 6-72 inches thick.

PO—Harrisburg, Ill.; SP—Same; CTY—Sallina; RR—Big Four.

MS—W. E. Monroe, Harrisburg, Ill.

S of H—Mules and 19 elec. locos. Track gage 42 in.

S of M—20 chain breast type, 7 short-wall and 1 overhead cutter machs.

PP—Power purchased, transformer 33,000 to 2,300 volts A. C., Gen. Units, 1—300 K. W. and 1—200 K. W.

250 volts D. C., 6 fire tube, 1 water tube boilers 1350 H. P., 9 pumps.

EMP—600. Daily tonnage 4,149.

SIZES SHIPT—Run of Mine, Slack, Pea, Nut, Egg, Lump.

PREP. EQUIPT—Shaker Screens, Picking Tables, Loading Booms.

No. 4 Mine; Shaft; No. 5 Seam.

PO—Harrisburg, Ill.; SP—Same; CTY—Sallina; RR—Big Four.

S of H—Mules.

S of M—5 chain breast type machs. Note—Mines No. 2, 3 and 4 formerly operated by Saline County Coal Co.

No. 5 Mine; Shaft; No. 5 Seam, 84 inches thick.

PO—Galatit, Ill.; SP—Same; CTY—Sallina; RR—Big Four.

MS—C. E. Coleman, Galatit, Ill.

S of H—Mules and trolley pole type locos. Track gage 42 inches.

S of M—5 chain breast type machs.

PP—Power purchased, transformer 2300 to 220 volts D. C., M. G. set, 150 K. W. 250 volts D. C., 4—150 H. P. water tube boilers, 7 pumps.

EMP—120. Daily tonnage, 410.

SIZES SHIPT—Run of Mine, Slack, Egg, Lump.

PBEP EQUIPT—Shaker Screens.

Note—Formerly operated by the Galatia Colliery Co.

No. 6 Mine; Shaft; No. 5 Seam, 66 inches thick.

PO—Grayson, Ill.; SP—Same; CTY—Sallina; RR—L. C. & N. and Big Four.

MS—Frank Maynard, Grayson, Ill.

S of H—Mules and trolley pole type loco.

Track gage 40 inches.

S of M—8 shortwall machs.

PP—6—90 H. P. fire tube boilers, 2—100 K. W. and 1—150 K. W. gen. units, 250 volts D. C., 5 pumps.

EMP—230. Daily tonnage 1505.

SIZES SHIPT—Run of Mine, Slack, Nut, Egg, Lump.

PREP. EQUIPT—Shaker Screens, Picking Tables, Loading Booms.

Note—No. 6 Mine formerly operated by the Saline County Coal Co.

BIG MUDDY COAL & IRON CO.

Now part of Consolidated Coal Company of St. Louis.

S of H—1 storage battery and 4 trolley pole type locos. Track gage 36 in.
S of M—6 chain breast machs. 5 short-wall machs.

PP—1 fire tube boilers, 600 H. P. gen. units, 5 pumps.
Last years tonnage 353,237.
SIZES SHIPT—Run of Mine, Slack, Egg, Lump.
PREP. EQUIPT—Loading Booms, Picking Tables, Shaker Screens.

Willis No. 7 Mine; Shaft; No. 6 Seam; 66 in. thick.
PO—Sparta, Ill.; SP—Same; CTY—Randolph; RR—M. & O.
MS—Wm. H. Jeremiah, Sparta, Ill.
S of H—Mules and trolley pole type locos. Track gage 40 inches.
S of M—5 chain breast type machs.
PP—3 fire tube boilers. Purchase power. Transformer 2,300-250 volts, rotary converters, 250 volts, M. G. sets, 100 K. W., 250 volts D. C., 2 pumps.
Last years tonnage 127,213.
SIZES SHIPT—Run of Mine, Slack, Lump.
PREP. EQUIPT—Shaker Screens.

Willis No. 8 Mine; Shaft; No. 6 Seam; 66 inches thick.
PO—Sparta, Ill.; SP—Same; CTY—Perry; RR—M. & O.
MS—Thos. Brown, Willisville, Ill.
S of H—Mules, 2 trolley pole type locos. Track gage 36 inches.
S of M—10 chain breast type machs.
PP—Purchase power. 2 fire tube boilers, 250 H. P., 250 volts D. C., 4 pumps.
Last years tonnage 234,163.
SIZES SHIPT—Run of Mine, Slack, Lump.
PREP. EQUIPT—Shaker Screens.

INDIANA COAL SEAMS

VERTICAL SECTION

INDIANA*

General Description of the Geology of the State With the Rank of Coal
Produced, Treats of the Two Mining Divisions, With a Map
Showing Their Location, All Seams Lying Within the
State, With a Description of the Producing
Beds, Their Geological Order, Kinds of
Coal, General Analysis, Etc.

The coal measures of Indiana lie in the southwestern part of the state, extending from Warren county on the north to the Ohio River on the south and eastward to the northwestern-southeastern line running from Warren county to Perry county. They cover practically all of sixteen counties and parts of nine additional counties. The Indiana coal field is part of the Illinois coal basin, or the Eastern Interior coal region. This region is a true basin shape, being deepest in the center in southeastern Illinois and rising to a rim on all sides. The Indiana field is a part of the eastern or northeastern rim extending in the southwestern corner of the state well into the center of the basin.

The Coal Measures have a total thickness of approximately 2,000 feet, of which about 1,300 feet occurs in Indiana. Of these 1,300 feet there are 600 feet of barren beds at the top, then a 500-foot interval which contains most of the workable coals, followed in descending order by 200 feet or more of rock consisting mainly of sandstone. Recent work of David White indicates that the rock of the upper 600 feet are of post-Allegheny age, those of the next 450 feet of Allegheny age, and the lower rocks of Pottsville age.

The coal occurs at thirty-four different horizons, of which about twenty-five have a fairly wide persistence. Of these beds one is workable everywhere in the state where it outcrops and eight others are workable over large areas. Several of the smaller beds are workable locally. The average thickness of the beds of the state is probably less than two feet, but the workable beds range from three to eight feet. The most important bed in the field probably averages six to eight feet. Many of the other beds average six to eight feet over several hundred square miles, but are thin or absent over adjacent areas. The maximum thickness measured was ten feet two inches, though thickness of eleven to fifteen feet are reported in "swamps."

A few individual coals beds can be traced the whole length of the Indiana coal field. In one case this tracing appears to be thoroughly reliable and in several others it is apparently good, though the possibility of error must be admitted. Still other coal beds can be traced with only a fair degree of probability. On the other hand, beds which maintain a thickness of six or eight feet over large areas thin out within the space of a few miles. In some beds such thinning out is against the edge of its basin, and though the horizon of the coal can be traced for miles, no further indication of coal can be seen within the state. In other beds the coal is very regular over large areas and very irregular over similarly large areas beyond.

In general the upper beds are much more regular than the lower beds. In fact, the lowest beds occur in small, nearly detached basins, usually lying in a west of north and east of south direction and ranging from a few acres to several square miles in extent. In the center of one of these basins the coal may have a thickness of five feet, but between the basins on the ridges the thickness may decrease to as many inches. In these basins it is observed that where the coal has several benches the lowest benches thin out first in approaching the rise, so that the coal going over the divide into the next basin may represent only the upper part of the top bench. Of even more interest is the fact that at two horizons where the coal in the basins has a somewhat distinctive section, the same section is repeated from basin to basin over hundreds of square miles.

All of the coal found in Indiana belongs in the bituminous class, and may be said to occur in three varieties, namely, bituminous, block and cannel. The first two differ but little chemically, but when typically developed show rather marked physical differences. The cannel coal is physically a block coal, but differs chemically from either of the other coals. The so-called "bituminous" coal of Indiana is pitch black, the color remaining black even when powdered; the luster is bright or vitreous. In structure it is banded or bedded, the jointing and cleavage is cubic, i. e., tending to break up into cubes; the fracture is irregular, and the texture dense to laminated. This coal is brittle, soft and rather light. It burns with a long flame, with a bituminous or sulphurous odor, running together on burning, and leaving much white or red ash. Sulphur is usually present.

The block coal of Indiana differs from the bituminous in being distinctly banded when viewed on the edges of the bedding, by splitting readily along the dull bands, which prove to be bands of charcoal, by breaking with difficulty across the bedding; especially by the perfect development of the cleavage, the cleavage planes usually extending vertically nearly or quite the full thickness of the coal, dividing the bed into blocks or cubes, often several feet on a side. This character is reflected in the character of the coal as marketed, where it is noted the blocks are commonly in rather thin, square-edge slabs, being square

*The information on Indiana coals has been gathered largely from "Stratigraphy and Coal Beds of the Indiana Coal Field," by George H. Ashley, Bulletin No. 381, U. S. G. S., and from the 33rd Annual Report, 1908, Indiana Department of Geology.

or quadrilateral, often one to two feet on a side, and six inches thick, with charcoal faces. In burning, the coal does not run together or cake, but remains in distinct blocks, like blocks of wood, and burns to a small white ash. In comparison with early years, but little block coal is now being mined, due to exhaustion of the limited supply.

The cannel coal, of which Indiana has but a small amount, is a block coal as regards being divided by the cleavage into distinct blocks, usually the full thickness of the bed. It differs physically in not having the dull or charcoal bands, or any bedding, being quite massive in structure, in its dull, resinous luster, and in its conchoidal fracture. Under the microscope still other differences are seen which need not be discussed here.

As a whole, it may be said that Indiana coal is characterized by a high moisture, high volatile, medium ash and medium sulphur content and that it does not stand transportation and storage as well as the Appalachian coals. The bituminous coal finds its main use as a steam coal, while the block coals are in demand for household purposes.

The railroads traversing the coal fields of Indiana are: Chicago & Eastern Illinois; Vandalia; Big Four; Southern; Chicago, Terre Haute & South Eastern; Toledo, St. Louis & Western; Baltimore & Ohio Southwestern; Cincinnati, Buffington & Chicago; Evansville & Indianapolis; Chicago, Indianapolis & Louisville; Central Indiana; Evansville, Suburban & Newburg; and Illinois Central.

There are two mining regions, known according to the kind of coal mined, that is whether bituminous or block coal.

DISTRICTS	COAL MINED	
	Geologic Number or Name	Trade Name or Name by Which It Is Known in the Market
Block Coal Field.....	Brazil Block coals, Minshall coal, No. III and No. IV coals.....	"Brazil"
Bituminous Field.....	No. IV, No. V, No. VI, and No. VII coals.....	"Clinton," "Sullivan," "Greene," "Vigo," "Knox" Counties

The coals of Indiana will be discussed in geological order, beginning with the highest seam worked, which is the No. 7. Above this coal, as a rule, only thin coals are found. In a few places these reach a thickness of 3 or 4 feet, but in 9 out of 10 drillings they show a thickness of less than 2 feet, and commonly less than 1 foot. Small coals occur between Seam No. 4 and Seam No. 5, although in some places they reach a thickness of 3 feet. As a rule they are thin and in the presence of much thicker coals above and below they will not be considered of workable character for a long time.

No. 7 Seam. (Mined in Sullivan and Vigo counties.)

About 40 feet above the top of coal VI in Sullivan county comes coal VII, which is practically everywhere a solid coal from 3 to 6 feet in thickness, overlain by shale or sandstone. North of Sullivan county this bed is readily traced past Terre Haute and through the southwest corner of Vermilion county out of the state. West of Terre Haute and to the north it shows a thickness of 4 to 5 feet of good coal, overlain by 1 to 2 feet of bony coal. A few feet below this coal, in all of the northern part of the coal field, is a limestone that is believed to be one of the persistent members of the coal measures. South of Sullivan county this coal bed can be traced through Wheatland, in the hills west of Petersburg, and on to the Ohio River, with a thickness of 4 feet or less, becoming rather thin as the Ohio River is approached.

As stated above, the underlying coal VI is close beneath it from Gibson county southward, and in one place in western Warrick county they are worked together. In general the limestone below coal VII lies between the two coals, and in many places where the two coals are close together the limestone forms the only parting. This condition continues into western Kentucky, where coal VII is known as Kentucky 12 and coal VI as Kentucky 11. Coal V of Indiana corresponds to coal 9 of Kentucky.

No. 6 Seam. (Mined in Clay, Greene, Knox and Sullivan counties.)

About 70 feet above the top of coal V, in Sullivan county, lies coal VI, ranging in that county from 6 to 8 feet in thickness. Practically everywhere it is divisible into four benches—an upper bench of about 2½ feet, a thin bench of 4 to 6 inches, a lower bench of about 2½ feet and a bottom bench of 1 foot. The two main benches range from 2 to 2½ feet or more. Between these benches occur gray-shale partings that are nearly everywhere half an inch thick. When exposed to the atmosphere in the entries of the mines this gray-shale weathers to a white clay, so that in the mines on this coal bed there appear to be two white chalk marks about midway of the wall at every point. Practically no doubt can therefore exist as to the correlation of this coal within that district. The bottom bench of 1 foot is bony and is usually left in the mine. At the north edge of Sullivan county this coal becomes irregular, in places appearing to run out entirely, and north of that point neither

drilling nor mining finds any trace of it in Indiana. It appears to maintain its thickness south of Sullivan county as far as Bicknell and for several miles farther south, though it becomes broken up toward the southwest. From that locality southward it disappears as a regular bed, in many places being entirely absent and in others appearing as a thin bed of 1 or 2 feet. It reaches a workable thickness in a few localities and is commercially worked at two points in Gibson county. Apparently it approaches nearer and nearer to the overlying coal toward the south, until the two range from 20 feet to 6 inches apart, and in at least one place the two coals have been mined together.

No. 5 Seam. (Mined in Clay, Greene, Gibson, Knox, Warwick, Vigo, Vermilion, Pike, Sullivan and Vanderberg counties.)

This is a thick coal with certain peculiarities of roof which render its recognition possible through the whole length of its outcrop in Indiana. It is at almost every point characterized by a roof of black sheety shale, the under surface of which contains pyrite concretions that, as a rule, project downward into the coal. In some mines these concretions are very abundant, the roof being almost botryoidal from their presence. In other mines they are only scattered, possibly one or two to a room, but they are absent in but few of the mines. Some of them project down into the coal as much as 4 or 5 feet. Overlying the black shale is a limestone. Similar black shales overlie other coals and are in turn overlain by limestones, but these coals are almost invariably thin, the accompanying limestone is usually thin, and the presence of the pyrite concretions is not everywhere obvious. There is only one other coal, lying about 300 feet stratigraphically below coal V, whose overlying limestone is thick at many places and which is itself of workable thickness. Its position so far below coal V, however, insures its outcropping well to the east of the outcrop of that coal, so that, although the two have often been confused in the past, there is no danger, with the present knowledge of the coal field, of their being taken for the same coal. Coal V has a thickness of 4 to 10 feet, averaging from 5 to 8 feet over a large part of the area within which it outcrops and maintaining this thickness with considerable uniformity from southwestern Vermilion county, where it enters the state, to Ohio River.

No. 4 Seam. (Mined in Clay, Greene, Vigo, Sullivan and Vermilion counties.)

This seam is extensively worked around Linton, and is from 100 to 130 feet below coal V. It is commonly a solid coal, with a sandy shale or sandstone roof and a sandstone or sandy clay floor. It shows a tendency to split in many districts, the splitting being in places rather extensive, so that the benches are separated by 10 to 15 feet or more. It can be traced northward to Seelyville, where it is the surface bed, ranging from 3 to 6 feet in thickness, and on to the horseshoe bend of Little Vermilion River, being of workable thickness nearly everywhere, except as it may be broken up by one or more large partings. It is a coal of excellent quality. To the south the thickness of this coal is somewhat less, usually not being more than 3½ feet and toward the Ohio River averaging probably less than 2½ feet. In that district it is nearly everywhere a solid coal, with either a shale or sandstone roof.

No. 3 Seam. (Mined in Clay, Perry, Greene, Vigo, Vermilion, Spencer, Fountain, Parke, Owen and Daviess counties.)

About 70 feet below coal IV in Green county is coal III, a bed 6 to 8 feet, almost invariably with one or more regular partings. It maintains this thickness northward through western Clay county and eastern Vigo county, being the large bed worked around Turner and Stanton and the principal bed at Seelyville, Fontanet and Rosedale. It tends to be a strong steam coal, but in many places has a high content of sulphur. In the Rosedale-Fontanet district the sulphur occurs in the form of one or more regular partings and therefore is more easily separated. North of Coxville this bed occurs in scattered patches for a distance of 6 or 8 miles, beyond which it is absent altogether. South of Greene county no bed of this character is found, and it is possible that the coal runs out entirely. In many places one or more thin coals are found about in the position of coal III, and it has been assumed that they may possibly represent this coal. Few of these thin coals south of Greene county, however, are workable, though here and there they increase to 3 feet in thickness. The coal called the Rock Creek coal in the Ditney folio possibly belongs at the horizon of coal III of Greene county.

Minshall Seam. (Mined in Clay, Parke and Vigo counties.)

About 100 feet below coal III in northeastern Vigo county is a coal bed that is being worked around Fontanet, Minshall and Mecca, and at other points. It has been called in the trade the Minshall coal, and this name has been retained for it, as it comes below the bed called coal II, in the general columnar section. It is a coal of variable thickness, lying in basins and ranging from 5 feet to a fraction of an inch. Overlying it in many places is black shale, which is not everywhere sheeted, and above that a heavy limestone. A limestone underlain by a coal that is in some localities of workable thickness occurs at many points through the northern part of the Indiana coal field in Parke, Fountain and Warren counties. It has been assumed to belong at the horizon of the Minshall coal. In the Brazil district of Clay county this bed has been called the Rider Block coal, as it lies only about 30 feet above the Upper Block coal.
