Mines and Minerals

Vol. XXXII—No. 1. SCRANTON, PA.—AUGUST, 1911—DENVER, COLO. Price, 25 Cents

PUBLISHED MONTHLY AT SCRANTON, PA.

ESTABLISHED 1881

WESTERN EDITORIAL OFFICE: 728 Equitable Building, Denver, Colo.
CHICAGO OFFICE: 1006 Michigan Ave.

Entered at the Post Office at Scranton, Pa., as second-class matter.

Address all business communications to MINES AND MINERALS, Scranton, Pa.
CABLE ADDRESS, "RETSOF, SCRANTON"

LONDON OFFICE: INTERNATIONAL BUILDINGS, KINGSWAY, LONDON, W. C.
SOUTH AFRICAN OFFICE: MANSION HOUSE CHAMBERS, ADDERLEY STREET, CAPE TOWN.
NEW ZEALAND OFFICE: 63 DIXON STREET, WELLINGTON.
AUSTRALIAN OFFICE: 83 PITT STREET, SIDNEY.

SUBSCRIPTION RATES

Single Copies .... 25 cents
Yearly Subscriptions, including postage:
To United States, Mexico, Cuba, Porto Rico, Hawaii, and Philippines .$2.00
To Canada 2.50
To all other countries 3.00

The date after your name on the wrapper is that of the month to which your subscription has been paid. If you do not want to continue your subscription after that time, kindly notify us.

Notice to discontinue or change of address should be sent to the Scranton office.

When notifying us of a change of address always give your FORMER as well as your present.

TABLE OF CONTENTS

Foreword

WITH this issue, No. 1 of Vol. XXXII, we inaugurate some improvements in MINES AND MINERALS, which have been in contemplation for some time. The principal changes are in appearance and the more convenient arrangement of the text. Plans have been made to ensure during the coming year the publication of mining literature that will be of even greater interest and value to our readers than the excellent material furnished in the past.

As will be noticed, the journal is divided into two sections of 30 pages each, one being devoted to the mining and preparation of coal and the other to ore mining and metallurgy.

As there is no monopoly of brains and skill in either the coal mining, ore mining, or metallurgical branches of the industry, a mining journal to be of real value must furnish accurate and well illustrated articles depicting the best methods evolved in each, so that its readers may not only learn what their colleagues in their special branches of industry are doing to reduce cost, increase production, or enhance safety, but they may also learn what new labor-saving and safety devices have been worked out by the able men in the other branches.

The editorial policy, as in the past, will be for the best interests of the mining industry regardless of what faction or party it hits. It will always remain a mining journal for mining men.

The Decision on the Cunningham Claims

IN our issue of June, 1910, we treated at length in an editorial on the status of the Cunningham, Alaska coal land claims, and we have seen no reason to modify the views then expressed.

The decision of Commissioner Dennett of the General Land Office, approved by Secretary Fisher declaring the claims illegal may have the preponderance of law in its favor, but law is not always justice nor is it always practicable.

The Cunningham claimants were reputable men who invested their money in the Alaska coal lands and in an open and above-board manner endeavored to secure patents from the Government on lines that were generally followed, and in as close conformity to the then existing laws as possible. A merely tentative proposal made by a few of the claimants to a representative of the Guggenheims, not binding on either party, and in fact not really authorized by the majority of the claimants, and not given much consideration by the Guggenheims, was used to influence public opinion against the claimants. Even if the tentative proposal mentioned had been an actual one on the part of all the claimants, and it had been accepted by the Guggenheims, it would not have resulted in a monopolistic ownership of the Alaska coal lands, as the total acreage involved constituted but a small proportion of the whole. Besides, the Guggenheim interests, while powerful from the standpoint of business accomplishment, were unjustly and unfairly held up as enemies of the people and therefore enemies of the government.

That the claimants joined in the expense of driving a tunnel to determine the mineral value of the land in question was a rational and logical act on the part of men, the most of whom were more or less familiar with mining practice. That they might also later combine their holdings in a partnership in the shape of a corporation would also have been a rational act. Every man familiar with coal mining knows that in many cases a single holding of 160 acres of coal land cannot be profitably worked, but that 5,000 acres can be so developed and worked, through the medium of large plants and the use of appliances and methods that would be prohibitory in smaller areas, and that the coal could not only be profitably worked, but a larger percentage of the coal in the seams could be taken and marketed. This, making the largest percentage of the coal in the ground available for use, to the practical mining man means true conservation. Coal wasted by improper or crude mining methods is just as much wasted as if it was deliberately set on fire and burned without its destruction having served any useful purpose.

If the letter of the law when strictly interpreted and applied prevents any citizen or group of citizens from acquiring sufficient acreage of Government lands, for legitimate mining of coal, to warrant the profitable investment of sufficient capital to conduct mining operations in the safest and most economic manner, the law cannot be too quickly changed; or else some legislation should be quickly enacted whereby sufficiently large acreages of coal land may be leased on reasonable terms to individuals or corporations so as to warrant the expenditure of the required capital to develop and work them. Otherwise, the coal lands of Alaska will lie dormant for many years and the navy department and the citizens of the Pacific Slope will continue to use inferior fuel or pay exceedingly high prices for coal mined in foreign fields or east of the Rockies. Secretary Fisher himself, in commenting on this matter said: "I do not believe the present laws applicable to coal lands in Alaska are wise or practical laws."

JUDGING from C. H. Tarleton's paper on "Mine Explosions From Natural Gas Well," printed in another column, simply leaving a square coal pillar about a gas-well hole will not always prevent natural gas finding its way into coal mines. In one case the well was 2,300 feet distant from where the explosion occurred. In order to prevent the flow of gas into the mines, recourse was had to "bleeding," and it may be probable that this will be found the only sure remedy in other cases; at any rate there is abundant evidence that once the gas sands are penetrated, gas under pressure will follow joints and cracks in strata a long distance.

The Disaster at Sykesville, Pa.

THE press dispatches announce that 21 men were killed at the Cascade Coal and Coke Co.'s mine, at Sykesville, near Dubois, Pa., on Saturday evening, the 15th ult. The early reports state that a comparatively light explosion of gas had evidently occurred, as none of the bodies were mutilated and but few showed burns. The supposition is that the afterdamp, or carbon monoxide, was the cause of the death of the men. The mine was known as a non-gaseous mine, and the fire boss claims that he examined the heading where the explosion occurred an hour before and found no trace of gas.

The term non-gaseous mine is in our opinion directly responsible for numerous fatalities in coal mines, as it gives the employes a false sense of safety and is apt to result in more or less carelessness on the part of the workingmen and subordinate officials. This statement as to carelessness is made in a general way, and may not be applicable in this case, as due care may have been exercised. In our next issue, we will give a statement of the actual causes leading up to the accident as developed by the official inquiry which will be made by competent mining men. Until the results of such inquiry are known it is useless to conjecture, and frequently mischievous as well.

Our Cover Picture

The Lehigh Valley Coal Co.'s Mineral Spring breaker, at Parsons, near Wilkes-Barre, Pa., shown on our front cover is remarkable in the fact that practically all improved methods and appliances in the economical handling and preparation of anthracite coal have been embodied in its construction. Its capacity is 1,500 tons per day, and but 32 men are employed in and about the breaker, as against 72 employed in the old breaker which it replaced. In addition, the new breaker prepares and cleans the coal in a more efficient manner with very much less loss from breakage. All the machinery, chutes, jigs, screens, and conveyers are so arranged as to automatically handle the coal, and each part is so designed as to supply the coal in various stages of preparation to the succeeding stage or final bin, in carefully calculated quantities, and with practically no breakage other than that caused by the rolls. The various bins are arranged so that the lips of the chutes deliver the prepared coal on a belt conveyer, which in turn delivers it to the railroad cars. The delivery of the various sizes to the loading belt is accomplished by one man who controls the flow from any desired bin, by a series of levers. As will be seen in the illustration, the breaker structure is very substantial and compact. Its interior arrangement, as to light, ventilation, and roomy safe passageways and steps, is a model one. While most of the improvements used in this breaker have been in use for some time in other breakers, this is the first instance in which all have been used in one breaker. The entire plant was designed by Mr. Paul Sterling, Mechanical Engineer of the Lehigh Valley Coal Co., assisted by suggestions from Mr. A B. Jessup, Chief Mining Engineer, under the personal supervision of Mr. S. D. Warriner, Vice-President and General Manager.

Book Review

"Good Engineering Literature" is the title of a book by Harwood Frost, formerly editor of the *Engineering Digest*, sales agent, Chicago Book Co., 226 South La Salle Street, Chicago, Ill. The subject of this book is one of growing importance to both the practicing engineer and the student of engineering, and the author has endeavored to bring together information that may serve as a guide for technical men who may have aspirations toward literary success. The book contains 420 pages, is cloth bound, and is 5 in. × 7½ in. The price has been kept at the low figure of $1 in order that its purchase may be no hardship to the beginner of professional life. Every engineer is sooner or later called upon to do some form of literary work, such as the preparation of reports, specifications, and contracts; the writing of descriptive papers for technical societies and periodicals, the discussion of engineering problems with committees, boards of directors, and public gatherings composed of men with little or no technical knowledge. In the course of some professional duties as well as in ordinary correspondence and conversation the engineer will find that the ability to speak and write clearly and forcibly, to express his thoughts and understandings, and to describe his works so that others will understand him, will prove one of the most valuable items in his mental equipment.

The book is divided into 22 chapters and is furnished with an index. Chapter I is on Literary Expression; Chapter II is on Rhetoric and Grammar; Chapter III deals with Orthography and Punctuation; Chapter IV treats on Words and Phrases; Chapter V has Inspiration and Motive in Literary Work as a subject; Chapter VI shows the essentials to success in literature; Chapter VII tells what to write about; Chapter VIII advises on the collection and arrangement of material; Chapter IX is on Exercising the Memory; Chapter X explains the preparation of manuscript; Chapter XI covers the field and policy of technical journals; Chapter XII shows how to write up articles; Chapter XIII is on the rights of an author in his works; Chapter XIV, Copyright; Chapter XV, Relations Between Author and Publisher; Chapter XVI, The Law of Libel; Chapter XVII, Preparation of Illustrations for Reproduction; Chapter XVIII, The Making of a Book; Chapter XIX, Indexing and Filing; Chapter XX, Literary Criticism; Chapter XXI, The Engineer's Library; Chapter XXII, List of Technical Indexes Appearing Serially.

This book will be found good reading, as it contains much information which men are apt to forget after finishing their school days. Very few men are able to dictate a letter satisfactorily, and it is believed that by reviews and writings of this kind, that important branch of business will be strengthened.

The Principles of Scientific Management, by Frederick Winslow Taylor. Published by Harper & Bros., New York and London. It contains 144 pages octavo cloth: price $1.50 net. The search for better and more competent men, from the presidents of our great companies down to household servants, was never more vigorous than it is now, and more than ever before is the demand for competent men in excess of the supply. What we are looking for, however, is the ready-made competent man, the man whom some one else has trained "It is only when we fully realize that our duty as well as our opportunity lies in systematically cooperating to train and make this kind of man instead of hunting for a man whom some one else has trained, that we shall be on the road to national efficiency." In the past the man has been first, in the future the system must be first. This in no sense, however, implies that great men are not needed. On the contrary, the first object of any good system must be that of developing first-class men, and under systematic management the best man rises to the top more certainly and more rapidly than ever before.

Mr. Taylor has written his book, first, to point out through a series of simple illustrations the great loss which the whole country is suffering through inefficiency in almost all of our daily acts. Second, to try to convince the reader that the remedy for this inefficiency lies in systematic management rather than in searching for some unusual or extraordinary man. Third, to prove that the best management is a true science, resting upon clearly defined laws, rules, and principles as a foundation.

The book is divided into two chapters, the first one being Fundamentals of Scientific Management, and the second one being on the Principles of Scientific Management. The whole book is of interest and appeals to employers.

Bureau of Mines, Washington, D. C., Bulletin No. 7, Essential Factors in the Formation of Producer Gas, by J. K. Clement, L. H. Adams, and C. N. Haskins. On page 19 of this bulletin is a discussion of Physical-Chemical Principles, on Application of the Laws of Chemical Equilibrium and Reaction Kinetics. Prof. C. N. Haskins, one of the authors, evidently imagines that a bulletin of the Bureau of Mines is primarily intended for the exhibition of his knowledge of higher mathematics. After wading through several pages of matter that to the average mining man looks as intelligible as a series of Chinese laundry tickets, we find in the summary the following useful information: To obtain a higher percentage of CO, the producer fuel bed should have a temperature of 1,300° C. or over; and that increasing the depth of the hot portion of the bed will increase the percentage of CO generated and consequently the capacity of the producer, at first rapidly and then more and more slowly. Also, to minimize the production of CO in the boiler furnace the fuel bed should be thin. Increasing the velocity of the gas will tend to decrease rather than increase the percentage of CO formed; both of which conclusions are evident to most men without the use of Calculus.

BOOKS RECEIVED

United States Geological Survey Publications, Washington, D. C. Bulletin No. 438, Geology and Mineral Resources of the St. Louis Quadrangle, Missouri-Illinois, by N. M. Fenneman; Bulletin No. 453, Results of Spirit Leveling in Minnesota, 1897 to 1910, Inclusive, by R. B. Marshall, Chief Geographer; Bulletin No. 460, Results of Spirit Leveling in Iowa, 1896 to 1909, Inclusive, by R B. Marshall; Bulletin No. 461, Results of Spirit Leveling in Michigan and Wisconsin, 1897 to 1909, Inclusive, by R. B. Marshall; Bulletin 470-E, Advance Chapter From Contributions to Economic Geology, 1910, Rare Metals, by F. L. Hess; Bulletin No. 470-I, Advance Chapter From Contributions to Economic Geology for 1910, Mineral Paints, by B. L. Miller; Bulletin No. 470-J, Advance Chapter From Contributions to Economic Geology for 1910, Sulphur and Pyrite, by R. W. Richards and J. H. Bridges; Bulletin No. 470-K, Advance Chapter From Contributions to Economic Geology, for 1910, Miscellaneous Non-metallic Products, by J. S. Diller; Charles Butts, A. N. Winchell, N. H. Darton, and E. F. Burchard; The Production of Fuller's Earth in 1910, by Jefferson Middleton; The Production of Quartz and Feldspar in 1910, by Edson S. Bastin; Gold, Silver, Copper, Lead, and Zinc in the Western States and Territories in 1909, by A. H. Brooks, C. N. Gerry, V. C. Heikes, C. W. Henderson, H. D. McCaskey, Chester Naramore, and C. G. Yale; Summary of the Mineral Production of the United States in 1909, by W. T. Thom; Statistics of the Clay-Working Industries in the United States in 1909, by Jefferson Middleton; The Stone Industry and the

Manufacture of Lime in 1909, by Ernest L. Burchard; The Production of Abrasive Materials in 1909, by W. C. Phalen.

Forty-First Annual Report of the Board of Directors of City Trusts of the City of Philadelphia for the Year 1910, Frank M. Highley, Secretary, Stephen Girard Building, 21 S. 12th Street, Philadelphia, Pa. This has to deal with the management of the Girard estate and some invested capital derived from that estate. In the year 1910 the cash receipts from the estate amounted to $1,940,815.11 gross, and $1,342,920.75 net.

Noticia dos Estudos E Obras Contra os Effeitos da Secca, by Antonio Olyntho dos Santos Pires, Rio de Janeiro, Brazil. This book is a government publication relative to water supply in various states of Brazil. It is handsomely illustrated.

Annales des Mines de Belgique for the year 1911, Volume 14. Published by the Bureau of Mines, Brussels, Belgium. The leading article is by Joseph Libert, Inspector General of Mines in the Province of Liege, on the Hygiene of Mines. It also contains a very interesting document giving the list of explosives permitted by the chief engineer and submitted to the Minister of Industrial Affairs, Arm. Hubert. This report gives the materials making up explosives.

Inflammation of Gas Through the Filaments of Electric Lamps, by Emanuel Lemaire. Extracted from the Annales des Mines of Belgium, Volume 16. Published by L. Narcisse, Brussels, Belgium.

Quelques Mots Sur Le Developpement Recent du Procede de Creusement des Puits par Congelation et sur la Securite dans le Foncage des Puits, by Ad. Breyre. Published by L. Narcisse, Brussels, Belgium.

Bureau of Science, Manila, P. I. The Philippine Journal of Science, Physical and Chemical Properties of Portland Cement, Volume 5, No. 6; Eighth Annual Report of the Bureau of Science, by Richard P. Strong; Ninth Annual Report of the Director of the Bureau of Science, by Paul C. Freer.

Mining Laws of the State of Alabama, Secretary of State, Montgomery, Ala.

Biennial Report of the Inspector of Coal Mines of the State of Montana, for the years 1909-10, Joseph B. McDermott, Inspector, Helena, Mont.

Tennessee State Geological Survey, George H. Ashley, State Geologist, Nashville, Tenn., Bulletin No. 13, A Brief Summary of the Resources of Tennessee for the homeseeker, investor, business man, farmer, and others. This bulletin shows Tennessee resources by means of pictures and short articles.

Report of the Mine Inspector for the Territory of New Mexico to the Secretary of the Interior, for the fiscal year ended June 30, 1910. This may be had by application to the Secretary of the Interior, Washington, D. C.

The Relation Between the Tensile Strength and Transverse Strength of Raw Clays, by H. Ries and S. W. Allen, Ithaca, N. Y. This is a reprint from the Transactions of the American Ceramic Society.

Bulletin No. 1, Mineral Resources of Wyoming, Mining Laws of the State and of the United States, by C. E. Jamison, State Geologist, Cheyenne, Wyo.

Volume I, Porcupine Series. The publishers of the *Canadian Mining Journal*, Toronto, Ontario, in view of the fact that the demand for back numbers containing articles on Porcupine cannot be met, are bringing out a book embodying descriptive, geological, and general data relating to Porcupine. This book will also include 13 township maps with all claims recorded up to April 11 and the latest Departmental geological map. The contents are: Introduction; Discovery of Porcupine; five illustrated articles on the district; claim maps of Godfrey, Mount Joy, Tisdale, Whitney, Cody, Ogden, Deloro, Shaw, Carman, Price, Adams, Eldorado, and Langmuir; latest departmental geological map; directory of companies; map of Keekeek District, with article. The price is $2 per volume.

Personals

G. T. Hansen, who has been connected with the Allis-Chalmers Co. for several years in the capacity of metallurgical engineer and has had a varied experience in the mining fields of this country and in Mexico, has been appointed manager of the Salt Lake City office of the Allis-Chalmers Co.

Walter H. Finley, who for the past five years has been in in charge of the active management of the Sterling Coal and Coke Co., of Middlesborough, Ky., has accepted the position of general manager of the Campbell Coal Mining Co., operating mines at Westbourne, Jackson, and Eagan, Tenn., and Coalmont, Ky. He will have his headquarters at Westbourne, Tenn.

W. H. Grady has resigned the position of superintendent of the Seaboard Coal and Coke Co., of Coal City, Ala., to become chief engineer of coal mines of the Tennessee Coal, Iron, and Railroad Co., Birmingham, Ala. His office will be at Rooms 1348–9, Brown-Marx Building, Birmingham, Ala.

Joseph B. Noros, formerly with the Scranton Electric Construction Co., has opened a branch office for the business of the Jeffrey Mfg. Co. at 225–226 Miller Building, 420 Spruce Street, Scranton, Pa.

W. R. Bauder, of Negaunee, Mich., has been appointed general superintendent of the Exploration Syndicate of Ontario, Ltd., Wilbur, Ont.

Baird Halberstadt, F. G. S., of Pottsville, Pa., was the geological expert who established the identity of the B bed of the Lower Productive Coal Measures in the three suits instituted by farmers against Berwind-White Coal Co.

R. G. Mackie, resident engineer of the Geldenhuis Deep, Ltd., Transvaal, S. A., furnishes an interesting account of a new tube mill intended to replace the stamp mill.

John A. Finch, of Spokane, Wash., has been inspecting the zinc-lead properties of his firm at Silverton, B. C.

A. Klockman, President of the Idaho-Continental Mining Co., has returned to Spokane, Wash., after inspecting the company's property in the Kootenai district.

H. W. Woodward, of Lynn, Mass., has secured a 10-year lease on the upper tunnel of the Moonlight property in the Cœur d'Alenes.

Dr. T. X. Schaeffer, Professor of Geology at the University of Vienna, who was invited by the Carnegie Institute to witness the unearthing of the antediluvian monsters in Utah, announces that he will return early in August to make a careful study of the Cœur d'Alene district, also visiting other camps in the inland empire.

W. R. Ingalls, J. Parke Channing, Doctor James Douglas, J. R. Finlay, and John Hays Hammond, have been appointed consulting engineers for the United States Bureau of Mines.

Edward M. Rabb, Jr. has returned to Denver after a six weeks sojourn in the Southwest.

Rescue car No. 5 of the United States Bureau of Mines is in charge of Sumner S. Smith, mining engineer, with headquarters at Rock Springs, Wyoming.

Charles W. Newton, Superintendent of Butte Ballaklava Copper Co., Butte, Mont., has been visiting Detroit and Duluth on business.

W. H. Kemp, who has been in charge of the advertising of The Goulds Mfg. Co. for the past five years, has tendered his resignation. He will be succeeded by C. H. Clark, who will be in charge and give his attention to all matters relating to the advertising of the company.

W. P. Jennings, of Pittston, former district superintendent of the Pennsylvania Coal Co., has been appointed mine inspector for the 8th Anthracite district to succeed P. M. Boyle, recently deceased.

S. J. Phillips has been appointed acting inspector of the 4th Anthracite district to take the place of H. O. Prytherch during the latter's absence.

COAL MINING AND PREPARATION

"Safety the First Consideration"

Methods Employed by the H. C. Frick Coke Co. for the Prevention of Accidents to Employes

*By Stephen L. Goodale**

Since about the 1st of January this legend has appeared on all letterheads, circulars of instruction to officers at the mines, blank forms to be filled out at the mines, and generally on all stationery of the H. C. Frick Coke Co. Up to the present time it has been mostly added in red ink with a rubber stamp, but whenever a new supply of stationery is needed the words are printed in red conspicuously as a part of the form.

For some years this company has conducted, under the able leadership and constant insistence of Mr. Thomas Lynch, president of the company, a strenuous campaign to make the mining of coal and other work about their properties as safe as possible. Four men were sent abroad to study what had been done in Europe and to get all assistance possible from countries which had been reported to have small numbers of accidents. This campaign is still in the course of development, but a very great deal has been already accomplished, and many improvements of the most vital importance have already been made. We can, therefore, describe now only the present state of development of a department that is showing the rapid growth of a healthy infant; but there is now so much to write about, and the subject of safety in the mine is of such great importance, that it cannot receive too much attention from mining men and others who can assist.

WARNING!

EMPLOYES WORKING AROUND ENGINES, MOVING OR REVOLVING MACHINERY, SHAFTING, ETC., ARE WARNED OF THE

DANGER

AND ARE PROHIBITED FROM WEARING TORN CLOTHING, LOOSE OR UNBUTTONED JACKETS, BLOUSES, SHIRTS, LONG NECKTIES AND LOOSE SLEEVES. ALWAYS WEAR THE OVER-ALL JACKETS TUCKED IN THE TROUSERS OR UNDER THE OVER-ALL BIB. NEVER FORGET TO EXAMINE YOUR CLOTHING BEFORE COMMENCING WORK.

H. C. F. C. Co.

Fig. 1

The keynote of all this work is *prevention* of accidents. The means employed are firstly educational, and secondly a number of actual safety appliances and methods of work.

"Safety First" demanded above all a campaign of mutual education. "First we had to educate the steel corporation to the necessity of such work, then they had to educate us how to carry on the work, and now we have to educate our foremen and bosses and miners to carry out the regulations made and how to use the safety appliances provided," as one superintendent put the case—mutual education—a cooperative system among the leaders. That the company has been thoroughly convinced of the great need is proven by the money it has spent and is spending to make its mines and mining and surface works safe places to labor. A live interest and even keen rivalry exists among the superintendents and others at the different mines in furthering the movement for safety first. It took a good while to convince these men that the company was really in earnest, and that the movement was something more than a spasmodic interest, or a temporary spurt for appearances only; but, as one device after another was introduced for safety, and appropriations were made again and again for this purpose, the foremen and superintendents have not only been convinced of the good intentions of the management but have become very zealous assistants in the same cause themselves. These men are studying the problem of safety, both in their everyday work from the practical side and also to make it more effective from the theoretical side as well. Evening meetings and periodical conferences for study and discussion of mine and safety problems are so numerous for many of them that one is reminded of the engineer who said that to keep up with the procession in electrical engineering he had to work all day and study all night.

Of great value in this educational scheme are the signs which are posted everywhere about the properties. The miner who is seeking employment, or as they express it, "trying to catchee a job," is first confronted with the sign in big letters:

"To men seeking employment: Unless you are willing to be careful to avoid injury to yourself and fellow workmen do not ask for employment. We do not want careless men in our employ."

The sign, "Safety First," printed in five languages, is hung or to be hung in the superintendent's office, shop, boiler room, inside and outside engine room, power buildings, mine pump rooms, and all other machinery rooms, at the mine entrance—whether slope or shaft—at the shaft bottom, and everywhere around the plant where they will intrude themselves on the attention of the employes and the public. In addition, a "Safety First" illuminated sign is to be hung at each mine at a point where it will prove most conspicuous to men entering or leaving the mine, probably in the manway. "The sign will be double glass, showing the legend in two directions; it will be illuminated by electric lamps. It is also desired to place an additional illuminated sign on the surface near the entrance to the mine."

*Professor of Mining University of Pittsburg.

The rules and regulations of the company, printed in five to seven different languages and comprising 28 articles, are conspicuously posted at all the mines in several places, and no one can be ignorant thereof who is employed at these mines. They are posted at such places as the lamp house, and the waiting rooms, at top and bottom of the shafts, etc., where they are not only conspicuous, but the men also have the best opportunity in the ordinary course of events to peruse them. These are given herewith in full:

RULES AND REGULATIONS OF THE H. C. FRICK COKE CO.

1. Strict compliance with the Mining Laws of the State of Pennsylvania shall be the first duty of each and every employe, at all times and under all circumstances; and SAFETY must be the first consideration of superintendents, mine foremen, and all others exercising authority or charged with the direction of operations in every department; quality of product second; and, cost of production third.

2. Mines generating explosive gas must have, at the intake, not less than 500 cubic feet of air per minute per person employed in the mine, and so distributed that there will be sufficient volume in circulation in and around working places to give not less than 300 cubic feet per minute, per person employed in each "split." No mine shall have less than 300 cubic feet of air per minute, per person employed, at the intake, with sufficient volume in and around working places to give, at least, 150 cubic feet per minute, per person employed in each "split."

PLACE NO MORE LOAD THAN

9,000 LBS.

ON THIS CAGE.

HANG NO MORE LOAD THAN

15,000 LBS.

ON THE FREE ROPE.

IN EACH CASE, HOIST SLOWLY AND WITHOUT JERK.

$1\frac{3}{8}$ ROPE

Fig. 2

3. Dangerous accumulations of explosive gas must not be permitted in "gobs" or other parts of the mines; if the same cannot be removed with the air-current, release it by means of bore holes from the surface.

4. In all mines where blasting of coal is permitted, all shot firing must be done with the consent, in the presence and under the supervision of the mine foreman, fire boss, or other competent person designated by the mine foreman; and the person designated by the mine foreman to supervise the blasting, or some other person designated by the mine foreman, must visit all the places where shots have been fired as soon as practicable after shots have been fired, to see that the roof is safe and that there is no fire or other danger.

5. Provide and maintain a system of pipes, and a supply of water with sufficient head, and all other necessary appliances, to thoroughly dampen the floor, sides, and roof of all places, in dry mines, where dust is a menace to safety; have the water head sufficiently strong to wash the dust from the roof and sides of these places, if need be, to make them safe, and have regular stated intervals for such watering or washing.

6. Employ steady, reliable, sober men only, in the capacity of mine foreman, fire boss, master mechanic, hoisting engineer, boiler and fan tenders, and stable boss; and the use of intoxicating liquors by any employe while on duty is absolutely forbidden.

7. Air-shafts must be kept open and free, at all times, from ice or other obstructions, and superintendents shall personally examine the air-shafts and stairways therein, and travel either up or down same at least once in each 2 weeks; he shall also see that the cages and safety catches are tested at least once in each 2 weeks, and that the hoisting ropes on cages used for lowering and hoisting men in and out of the mines are taken off as soon as they show any defect or weakness, from wear or other cause, but in no case shall ropes on such cages be kept in service longer than 2 years, even though apparently safe and in good condition.

8. Oils or explosives must not be stored in the mine, and no person shall be allowed to take more than 1 day's supply of oil or explosives into the mine at one time.

9. The best and safest oils that can be procured must be used for illuminating purposes in the mines and mine buildings above ground; and the best and safest explosives that can be procured must be used for blasting in the mines.

10. Engine rooms, pump rooms, power houses, boiler houses, and stables, both in the mine and above ground, must be well ventilated and kept neat and clean at all times. Provide cans in all these buildings for storing oils, oily waste, grease, etc. The use of open lights in any of these buildings, either under or above ground, is strictly prohibited. Hay and straw must be taken into the mines in bales—not loose.

11. All electric wiring, whether used for lighting or power, must be carefully installed in the most approved manner, and thoroughly examined by some competent person at least twice a year.

12. A system for checking men in and out must be maintained at all mines, which will show how many men, and who are in the mines at all times.

13. Fire hose of ample size and length must be maintained near the mine buildings, or some other conveient place at each plant; a sufficient number of ladders of proper length must be kept on the dwelling houses and mine buildings; barrels filled with water and salt, and fire buckets must be maintained on trestles, in tipples, engine and boiler houses, and other buildings where fire is likely to occur—all for use in case of fire only.

14. The use of safety lamps and open lights must not be permitted in the same mine, except only upon the joint recommendation, in writing, of the mine foreman and the company's mine inspectors. Lights must be carried on the front and rear of all trains of cars "or trips" (including trips on slopes) controlled by motors, steam engines, or other mechanical means.

15. Finger boards must be maintained in all mines, which will plainly indicate to persons employed therein, the way out of the mine.

16. Each and every mine must be visited and thoroughly inspected by the company's mine inspector at least once in every sixty (60) days, who shall report condition of same, in writing, to the general superintendent.

17. The superintendent, mine foreman, fire boss, yard boss, master mechanic, hoisting engineer, stable boss, boss driver, boss roadman, and such other employes at each plant as the superintendent or mine foreman may designate, shall meet at least once every week, at the time and place designated by the superintendent, to exchange views, discuss the mine conditions

and operations generally, and especially matters pertaining to the protection of the lives and health of the employes, and the care and safety of the property.

18. Mines in which safety lamps are used must be thoroughly examined by fire boss, or other competent person, on Sundays, holidays, and lay-off days, and all mines which have been idle for two or more consecutive days must be thoroughly examined by some competent person the day before operations are resumed.

19. No one will be permitted to interfere with the religious or political opinions of the workmen, and no superintendent, foreman, boss, or clerk will be allowed to solicit money or make collections from the workmen for any church, society, or association.

20. Any employe wishing to be absent from duty must, before going, apply to and receive permission from his immediate superior.

21. Superintendents and foremen shall see that the "turns" are fairly distributed among the workmen on contract or piece work, and that no more men are employed than are absolutely necessary to perform the required amount of work well and at the proper time.

22. All employes are requested to exercise care and economy in the use of materials and supplies, and any employe who through carelessness or malice wastes materials or destroys the property of this company, or is found stealing or carrying away the property of this company, will be discharged.

23. Any workman offering money, liquor, or valuables of any kind to a foreman, boss, or clerk will be subject to discharge, and any foreman, boss, or clerk accepting money, liquor or valuables of any kind from workmen will be summarily dismissed.

24. Superintendents must pay strict attention to the rights and privileges of all employes; hear and give prompt attention to any reasonable complaint or claim for redress made by any employe, and not allow any discrimination on account of nationality or creed.

25. Every salaried employe of this company is expected to devote his entire service to the work and interests of his employer, and while no restriction is sought to be placed upon employes in the matter of making investments, no salaried employe shall take active part in conducting the business in which an investment is made; nor will such employe be permitted to influence any other employe of this company to buy or in any way assist in the sale of the products of said business.

26. It shall be the duty of superintendents, foremen, bosses, and clerks to strictly comply with and rigidly enforce the above rules.

27. These rules are intended to supplement, not to supplant in any manner or form, any of the requirements or provisions of the mining laws of the state of Pennsylvania, and printed copies of same in the English language, and other languages used by the workmen, must be kept posted in conspicuous places, at all mines, and the attention of all persons must be called to same, when hired, as well as to the printed special and general rules furnished by the State Mine Inspectors.

28. It shall be the duty of all employes to report any violation of the mining laws, or of these rules, to the superintendent of the plant where the offense is committed, and it shall be the duty of the superintendent to immediately report any violation of the mining laws, which may come to his notice, to the State Mine Inspector of the district and to the general superintendent; also, to report any violation of these rules to the general superintendent.

W. H. Clingerman,
General Superintendent

Approved: Thos. Lynch,
President

The sign, Fig. 1, here reproduced in miniature, warning employes of the danger of torn clothing, is one which might well be posted in all machine shops and places where rapidly moving machinery is in use.

In addition, a small sign is used, directing that all machines considered dangerous to oil or wipe while running should be stopped to oil, wipe, or repair. The former sign is to be posted "in all power buildings, such as compressor, or electric stations, not less than two signs, one at each end of the room; in all shop buildings, at least two signs, one at each end of the room." The signs are to be placed also in any additional places which seem to require them. The latter sign is to be applied most conspicuously to all machinery such as "hoisting engines and haulage engines (each side), to electric generators, to high-speed steam engines, to electric motors, to electric pumps, etc. It is not considered necessary to apply them to such slow-moving machinery as direct-acting steam or air-driven pumps." These two signs are made of sheet metal with white letters on a background of blue enamel.

The sign shown in Fig. 2 is placed as a framed placard under glass on the head frame at the ground landing, as instruction to the operatives for any weights that may have to be handled. This would apply to machinery parts, pumps, compressors, etc., or other unusual loads which are handled into the mine. There are many places where this idea might well be copied, such, for instance, as the cranes in industrial works.

A number of other signs will be mentioned in connection with appliances to which they especially refer. It may be well

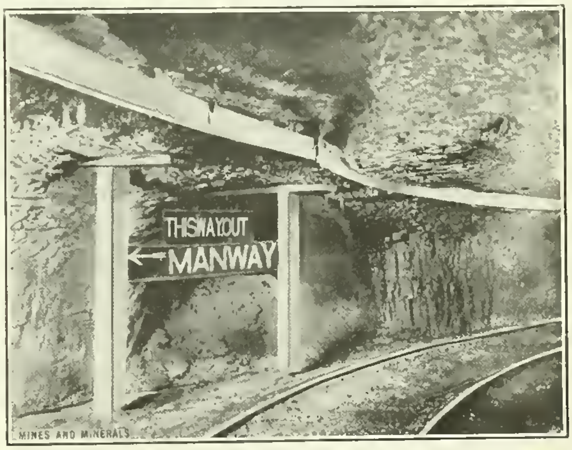

Fig. 3

to add here perhaps a mention of the guide or directional signs such as illustrated in Fig. 3.

These guide signs are placed at a sufficient number of points underground so that even a stranger in the mines could probably find his way out with no great difficulty. Besides this particular sign, dangerous workings are so marked to avoid men going into such dangerous places unnecessarily. The danger signs are white letters on a red background; the directional signs white letters on a black background.

But signs don't do much good unless they are read, understood, heeded, and obeyed. To make them read, they are put up in many prominent places; for understanding, they are translated into from four to six European languages, according to the nationality of the workers, who do not "versthey too much" English. As for attending to these instructions, and obedience on the part of the men, that is where the difficulty comes in. Many a man will take chances of danger to save himself a little inconvenience if he thinks the danger small, or he may even take Hamlet's view "There's such divinity doth hedge a king." You can post a large sign on the main haulage way that no one is allowed to walk there, and in spite of the notice men—and especially those who ought to know better—will often walk that way if they can thereby save a longer walk. If such a man is killed in that kind of place, whom can you punish? He had a right to go by the manway, and was on the haulageway against strict orders. Every breach of discipline must be punished by appropriate means if this kind of thing is to be ended. The man who will not obey the regulations of the coal mines is just as much a menace to the lives of those in the mines as would be the railroad locomotive engineer who disobeyed his orders.

It is not ordinarily the ignorant immigrant fresh from steerage who takes these risks—he is warned by the signs in his native language, and by his older compatriots, and he obeys—he is too much afraid not to obey. Mr. Lynch states that in his own experience he has not known of any casualties to such men who have been less than 2 years in the mines. It is men who know of the dangers, but think—and have not made sure—they have provided for them, and who often go into places to which their duties do not call them; 66 per cent. of all the fatalities last year were to intelligent men who had had long experience in mining.

Perhaps the most important item in securing obedience to the rules and regulations is having the superintendents and foremen personally and vitally interested. And in this safety work Mr. Lynch, the moving spirit for safety, has certainly enlisted the active cooperation of his employes from superintendent down to the actual diggers of coal, the "muleskinners," or even, we may also say, the unemployed miner who is trying to get employment. The willingness, interest, obedience, and cooperation of the employes, which is very marked at all the mines, is, therefore, even a more important factor than the numerous signs and notices of rules and regulations required to make "safety the first consideration."

The end sought in all this work is prevention of accidents. The oxygen helmets, the hospitals, the first-aid training, and all such, are at best but a makeshift. They are like locking the door of the stable after the horse is stolen; but it is rather the constructive making the mines safe, making accidents impossible, toward which Mr. Lynch's efforts are directed. The company has, indeed, three rescue training stations, and has spent much money in training men. It has also hospitals at the various mines, but these are all thought of as of very secondary importance as compared to the prevention of accidents.

Internal-Combustion Engines in Mines

In the Consular and Trade Report of June 28, 1911, is found the following on internal combustion engines in Europe.

The chief inspector of mines of the British home office in an interview stated it to be his belief that there were no gasoline motors used in coal mines in England, though there might be some few exceptions of which he did not know. An Austrian engineering company, which has a branch in England, manufactures a gasoline motor locomotive for special use in mines. While it has succeeded in placing its engine in mines on the Continent, the London manager advises that he has not yet so succeeded in England. The danger from the use of such engines in mines is deemed to be so great that they have not yet found a foothold in England.

Gasoline, benzine, and benzole locomotives are used in the mines of Germany. The motors are usually low speed and are operated principally as locomotives for the transportation of freight and passengers. Stationary motors, however, are sometimes used for driving compressors, blowers, ventilators, etc.

The exact number of explosion motors which are used in the German mines is not known, but one of the largest motor-manufacturing companies of Germany estimates that about 1,000 are being operated at the present time. From information obtained from reliable sources, the use of liquid-fuel motors in the mines of Germany has not increased during the past 2 years, except in Lower Silesia.

Gasoline motors are widely used in Austria for stationary and mine engines. There is one maker of mine locomotives. Coal-mining companies in Austria very generally use explosion motor locomotives. The use thereof in mines is under rigorous inspection and control. The explosion locomotives used in mines are, as a rule, supplied by German manufacturers, though they are beginning to be built in Austria.

As a general rule the extensive subdivision of mining properties and the irregularity of the Belgian coal measures render Belgian coal mines ill adapted for the installation of locomotive transport for subterranean work.

During the last 2 years, however, 12 colliery companies have obtained permission to introduce benzine locomotives into their mines as an experiment. The introduction of these engines is too recent to admit of a definite decision being given as to their use. It is sufficient to mention that many companies, after having introduced these experimental locomotives in one of their mines, have later sought permission to introduce them into other mines. The use of these locomotives is never authorized in mines of the third class, where firedamp is liable to escape suddenly; many, however, are working in mines of the first and second class, where firedamp is present, but they are used exclusively in the principal air galleries. These locomotives have never yet caused any explosion or other accident. The conditions under which permission is accorded for their use are very stringent. It is also to be noted that these permits are only granted temporarily, and on condition that they may be revoked at any time if the inspector of mines considers the use of locomotives undesirable.

Motor locomotives were used for the first time in the Netherlands coal mines in the year 1907, benzine being the only fuel. Since then the number of motor locomotives in use has increased considerably, but the type of benzine locomotives has been adhered to. At present, out of the six mines working, transport in the main galleries in four of them is almost exclusively carried on by means of benzine locomotives. At present in the four Netherlands mines in question there are the following engines: one of 16 horsepower, seven of 12 horsepower, five of 10 horsepower, three of 8 horsepower. The managers of the mines are entirely satisfied with the results of the use of benzine locomotives for transport, and are of the opinion that a considerable saving has been effected thereby. The number of locomotives is therefore shortly to be increased. The number of mining cars containing 500 kilos (1,102 pounds) that these locomotives can draw depends upon the gradients existing in the main galleries; but it amounts in the case of locomotives of 12 horsepower, in a mine where the gradient is small, to 66 cars.

From the point of view of safety of transport with benzine locomotives it must be stated that the section of the galleries in which such traffic takes place should allow sufficient free space. It has sometimes occurred, owing to a car becoming derailed and thus knocking over a wooden prop, that considerable falls, and consequently serious accidents have happened. In cases where it is difficult to increase the section of the galleries, this danger has been successfully avoided by placing iron plates on the wooden props, so that the wagons when derailed glide off them but do not knock them over. Finally, it is important that in the places where benzine locomotives are used, there should be sufficient ventilation, as otherwise combustion products which are dangerous to health may accumulate.

Anthracite Record Broken

The first six months of 1911 exceeds in point of production all previous outputs of coal in the anthracite region. The total number of tons was 35,309,583. The highest previous tonnage was for the six months ending June, 1907, and was 32,884,595 tons. The Lehigh Valley produced 19.55 per cent.; the Reading, 18.27 per cent.; the Lackawanna, 14.59 per cent.; New Jersey Central, 14.10 per cent.; Delaware and Hudson, 9.72 per cent.; the Erie, 12.60 per cent. of the total in 1911. The apparent consumption of anthracite for the first six months is 35,289,000 tons.

Coal Mining in Arkansas

Method Used in Stripping Shallow Seams and in Mining Thin Seams With Partings

*By A. A. Steel, B. S.**

In Arkansas, if the parting of a coal seam is hard and over 16 inches thick, and also if the top or bottom bench of coal is thin or impure, only the thicker or better part of the seam is mined, and one or more of the benches is left. It will be nearly impossible to mine this coal after the mines have fallen in, and it may be considered as permanently lost.

As yet, it is unprofitable to extensively mine both benches of a seam containing a parting unless there are 3.5 feet of bituminous coal or 2.5 feet of semianthracite coal. In this case, the parting must generally be not more than 2 or 3 inches thick. At Russellville, however, one seam is mined that aggregates only 24 to 30 inches of coal and is divided by 16 inches of waste: but this coal is very valuable, the parting is soft, and most of the other conditions favorable.

Clean beds of coal are mined rather extensively even where only 20 to 24 inches thick, provided other conditions are favorable; but usually the minimum thickness for profitable mining is from 28 to 32 inches. As yet no coal has been mined at a depth of more than 480 feet below the surface. The roof is usually good with the exception of a few inches of "draw slate" or a few inches of soft earthy material called "black jack" or "rashing." The floor is generally good. The combined thickness of the coal, its partings and the draw slate over it, determine the height of the place in which most of the miners have to work. Where only one bench of coal is worked, or the seam is clean, this height ranges from 2 feet 10 inches to 4 feet 6 inches, except in rather extreme cases. The least height in the double-bench seams is about 3 feet in some of the semianthracite mines near Clarksville, where the parting is 3 inches thick. The height of the working places is seldom over 8 feet, which is common in the soft-coal districts, where the parting may be as much as 12 or 14 inches thick. In a few places where the partings are soft and easily handled and near the middle of the seam, three benches of a coal seam are worked together. Such seams have from 4 to 6 feet of coal and 12 to 14 inches of waste. In some places where the coal outcrops and the coal bed is fairly flat so that the cover does not soon get too thick, open-cut mining is practiced as in Fig. 1.

Fig. 1. Strip Pit Near Huntington, Ark.

The cover is loosened with plows and removed with scrapers, and as the coal goes deeper under cover and becomes covered with shale, it is first shaken up by blasting before it is plowed. Churn drills having 2-inch bits are used to make a row of holes about 6 feet deep, 12 feet apart, and about 8 feet back from the face. In order to chamber the holes for a large charge of black powder (25 pounds) each hole is sprung by discharging a single stick of dynamite in the bottom of it. This pulverizes the shale near the bottom and throws the dust out through the top of the hole. After the powder is poured into the chamber thus formed, and the fuse inserted, the hole is tamped with earth. Under ordinary conditions, it pays to strip the coal until the shale cover becomes four times as thick as the coal, that is, 1 foot of coal will stand the removal of 4 feet of shale.

If the seam is inclined and the railroad tracks can be conveniently brought to the outcrop, a slope excavation from 8 to 14 feet wide is driven on the dip of the seam from the surface. If the coal bed is thin, some of the slate roof is shot down or "brushed" to make headroom, but even then the height is seldom more than 5 feet, and the miners must generally stoop while walking in the slope. Fig. 2 shows the brushing in an entry. At intervals of about 300 feet "entries" or passageways are driven right and left from the slope in such a direction they are nearly level. If the coal is low, the roof is taken down or "brushed" until there is a height of 4 feet 6 inches above the rails laid in them, so that a mule 14 hands, or 4 feet 8 inches high, can walk between the ties and not strike the roof.* After the entries have gone a short distance from the slope, rooms are turned every 36 feet along the upper side of the entry. The "room necks" or beginning of the rooms are 8 feet wide for a distance of 12 feet and they are then widened to 24 or 30 feet, or whatever has been decided shall be the width of the room. This leaves a pillar of coal from 6 to 12 feet between the rooms as a support for the roof. The rooms are seldom more than 250 feet from the entry to the extreme end or face. There is a switch in the entry track at the neck of each room, as shown in Fig. 3, in order that the mine cars may be pushed to the face of the room where the miner can load one at a time. The miner lays the track in his room as it needs extending, using wooden or light iron rails for the purpose.

In the entries the cars from the rooms are made into trips, generally of three large cars or five small ones. A single mule hauls these trips down the gentle grade to the beginning of the entry where there is a wide place with a short length of double track. This is called the parting. Here the driver leaves the loaded cars on the main track and takes the same number of empty cars from the side track and goes back through the entry to the rooms. If the coal is high enough, he takes the cars one at a time to the face of the rooms with the mule. If the coal is low the miner helps the driver to push the empty car up the room while the mule waits, as the roadway in the room is seldom brushed to a height sufficient to admit a mule. At the entry partings the loaded cars are coupled into rope trips by the drivers. When there are enough cars for the trip the driver waves his light to the rope rider who rides up and down the slope with a train of cars. He lets a train of empty cars down into the parting, fastens the rope to the loaded trip, and signals by electric bell to the hoisting engineer, who winds up the rope and so pulls the loaded cars out into the entry and up the slope.

To get rid of the little gas that is always present and to furnish pure air for the men and mules, a strong current of air must be passed through the mine. For this purpose slope air-courses are driven usually on both sides of the main slope. They are just like the main slope except that they are sometimes wider and are rarely brushed. At the mouth of these

* Fayetteville, Ark.

* This is not high enough or the mule is too high; besides, there should not be holes between the ties.

air-courses is placed a large steam-driven fan. The fan draws a strong current of fresh air down the slope which circulates through the mine and passes up the air-courses. The current from the air-course opposite the fan is carried over the slope in a passage blasted out of the rock above and separated by a tight wooden tunnel through which the cars pass. This is called an overcast.

From the face of each entry the gases and impure air are drawn out to the slope air-courses by another passage just like the entry except that it is seldom brushed. This is along the lower side of the entry opposite the rooms, and a chain pillar usually 12 feet wide is left between them. In Arkansas this passage is generally called the "back entry" and sometimes the "smoke room" or simply "air-course." As the entries are driven forward they are connected at intervals of 30 or 40 feet by cross-cuts or breakthroughs. All but the last of these are carefully closed, generally by tight board stoppings. As soon as a room is widened out it is connected to the adjoining room by a cross-cut through the pillar and the air-current is made to pass through this breakthrough by hanging a curtain of two overlapping strips of canvas across the entry. A mule can pull the cars through this without delay, and even though a little air may blow through it, enough will go to the room face to keep the gas from collecting there. While the slope air-course is being extended, the air current passes down the main slope to the last cross-cut, and through this to the slope air-course and up to the course of the lowest entry. This method is termed coursing. Ordinarily, if a mine is ventilated by coursing, the entire current required for one side of the mine passes down the main slope to the last entry air-course, which it follows to the last entry cross-cut. It returns by the entry to the inside curtain which throws the air into the rooms. The current then passes from breakthrough to breakthrough through the rooms back to the slope air-course, which takes it to the air-course of the entry above. Through this entry the same air is circulated as in the first entry. It then passes out to the air-course again and so on through all the entries in succession.

By coursing, no overcasts are required except the one over the main slope, but there must be a tight door at each end. Fig. 4 shows such a door. The white patches on it are due to a fungus which rapidly destroys mine timbers. After the first room is holed through, the door is usually placed at the inner end of the parting; and to save delay in hauling, a boy is hired to open and close it for the driver. Fortunately, the law requires that these trappers be over 14 years old, and, of course, the work is very light. The trappers all want to be drivers when they are 16, so they often help the driver.

As soon as the first room beyond the parting is holed through, the slope air-course is no longer needed for coursing ventilation, and the stoppings at the entry chain pillars can be removed to give an unobstructed passage up to the first entry. It is therefore used as a traveling way, or manway, by the miners, who thus avoid injury from the rapidly moving trips of cars in the slope. It can also be used as an exit when the main slope is blocked, provided the stoppings at the first entry and the fan house are fitted with small doors.

Whenever the face of a room or entry cuts so far beyond the last cross-cut that a pocket of gas collects in it, the air-current is carried in by a temporary partition reaching from beyond the last cross-cut as far in as necessary. These partitions are called brattices, and are generally made by stretching strips of canvas or brattice cloth along a row of wooden posts wedged against the roof. The cloth is very seldom tight against the roof, so that a good deal of the air leaks through and goes straight across the room. As the brattices are also generally disarranged by blasting, it is customary to make breakthroughs closer and not use brattices, except in cases where another cross-cut cannot be made because the miner in an adjacent room has not driven his room far enough ahead. The brattices are put in by the fire bosses and their helpers, who are the only persons allowed to go into a gassy room. The helpers are called "brattice men." When the entries are just starting and before the partings are complete, they are always ventilated by coursing with curtains in place of doors. Ventilation by coursing has the advantage that when the rooms are holed through from one entry to the air-course above, the fire boss and the mine foreman can pass from entry to entry without each time going out the slope air-course which is often far from the nearest of the rooms in which the miners are working. As it does no harm to continue the

Fig. 2. Beginning an Entry in Low Coal (By courtesy *The American Lumberman*)

rooms until they cut the air-courses above, no surveying is needed to prevent this. In a small mine a surveyor will not be necessary, a manway is more easily provided; no expensive overcasts are required, and there are no regulators to be adjusted. It is therefore easier to keep the places clear of gas by brattices, and the lamp smoke is more promptly blown out of a room. For this reason many of the miners think ventilation by coursing is better than by splitting. The coursing system, however, has

Fig. 3. Side of Room Neck, Showing Props

the disadvantage of requiring many doors with trappers to see that they are kept closed, and the wages of a trapper for three or four months will equal the cost of an overcast. By coursing, all of the air-current has to go through the entire mine. It therefore travels much farther than if divided into splits each passing through only one entry. Also, if the same amount of fresh air is forced through a single passage instead of several combined, its velocity must be several times greater. Therefore the resistance of the air is much greater, so more power is needed to drive it, and the pressure is greater, which increases the loss by leakage through the stoppings. With straight overcast ventilation there are no unlocked doors to be left open. With coursing, on the other hand, there is danger that all the air will be cut off from the entries below if any door is left open, unless pairs of doors are used, which is not done in Arkansas.

The great disadvantage of coursing lies in the fact that the air supplied to the last entry has previously passed through all other parts of the mine, so the miners working there get the lamp smoke and impurities from all the other miners. Then if the amount of gas in the mines suddenly increases there may be enough to cause an explosion by the time the air-current reaches the light of the last miner. In case such an explosion does occur it may travel through the entire mine and not merely through the gassy split. It is for this reason that the Arkansas law requires that there be a separate split of air for each party of miners.

Kanite Explosives

According to Charles P. Peistle, chemist of the Bureau of Safe Transportation of Explosives and Other Dangerous Articles, kanite C is in the form of a finely divided dry powder of buff color. The powder is packed in paraffined paper cartridges $1\frac{1}{2}$ in. $\times$ 8 in., and the material examined contained organic matter so modified by oxidation, vulcanizing, or similar treatment as to be insoluble in the ordinary solvents.

The explosive was not ignited or exploded by shooting into it with a 30-caliber military rifle, but was completely detonated by a double-strength electric cap. The temperature of ignition was found to be 205° C. and the powder burned slowly and quietly when placed on a hot wood fire. It is not readily ignited, is classed as a high explosive, and is considered safe for transportation.

According to the same authority, kanite A and B ignites at 210° C. The ease of detonation was tested by placing cartridges on sand, end to end. With kanite A detonation extended from one cartridge to the next when 1 inch space intervened, but not at 2 inches. With kanite B detonation communicated $\frac{1}{2}$ inch, but not 1 inch. Neither explosive ignites or explodes on shooting into it with a 30-caliber military rifle. Both are detonated with a double-strength electric exploder. Both explosives ignite with difficulty and burn slowly and quietly when placed on a hot wood fire. These explosives are considered safe for transportation.

Kanite A is said to have passed the highest test made by the Bureau of Mines Pittsburg Testing Station for establishing permissible explosives, and to be fumeless, flameless, and smokeless, safe to handle, and not to freeze or deteriorate. It contains no nitroglycerine, chlorate of potash, gun cotton, or acids. It is insensible to concussion, friction, or ignition.

One of the advantage claimed by the manufacturer of kanite is that when dynamite is used quite a little time must elapse before the fumes clear away, and this time, taken on the total blasts fired daily, amounts to considerable in lost labor. As there are said to be no poisonous fumes with kanite explosives, the men could return to work immediately and thus the time that is usually lost while waiting for the smoke to be dispersed, often under some circumstances amounting to from 25 to 30 per cent. of the working time, would be saved.

Fig. 4. Mine Door

Sixty-five citizens of Newport recently visited Portsmouth, R. I., where they inspected the machinery, breaker, and briquet plant, of the Rhode Island Coal Co. Superintendent Johnson said that the present output was from 200 to 300 tons a day, but he expected by the use of mechanical pickers and different arrangements underground to increase this 1,500 tons a day. He also stated that he expects before fall to bring the coal into the Newport market.

Coal Geology of West Virginia

An Attempt to Correlate the Different Coal Beds With Those of Pennsylvania

The Carboniferous period, known geologically as the age of acrogens and amphibians, belongs in the Paleozoic or ancient life era. So far as the coal beds are concerned this period is best developed in what is termed the Eastern or Appalachian coal district. That includes Pennsylvania, West Virginia, Eastern Tennessee, Kentucky, Ohio, and Alabama.

Below the Carboniferous is the Devonian period of the Paleozic era, known also as the age of fishes, while above is the Triassic period of the Mesozoic, or middle life, era.

For convenience, geologists have divided the Carboniferous period into three rock systems known as the Subcarboniferous, Coal Measures, and Permian.

The Subcarboniferous system includes all rocks from the Devonian to the Pottsville conglomerate, which in the anthracite fields are Mauch Chunk red shales, and in the bituminous fields the Subcarboniferous or Mississippian limestones.

The Coal Measures are divided from the Subcarboniferous upwards into Pottsville, Lower Productive, Lower Barren, Upper Productive, and Upper Barren or Permian series.

It is usual in descriptive geology to work from the oldest rocks upward, in this case from the Pottsville series which more aptly could, from structural reasons and from the methods adopted by geologists, be called Millstone-grit series outside of the anthracite fields of Pennsylvania. The Pottsville series, which is also known as Rogers No. XII, is divided into three members, upper, middle, and lower.

There seems to be no way of correlating the so-called Pottsville series of West Virginia with those of Pennsylvania, on account of the difference in the composition of the coals and the thickness of the strata. In Pennsylvania there is an approximate correlation, but not absolute, owing to the conditions mentioned varying in different parts of the state. In eastern Pennsylvania the Mauch Chunk red shale is the Subcarboniferous and is topped by a coarse water-rounded pebble rock called Pottsville conglomerate. To the west the Mauch Chunk red shale is replaced by the Subcarboniferous limestone, known also as Mississippian, and above this, corresponding to Pottsville conglomerate, is a hard gray coarse sandstone, known as "Millstone grit."

The Pottsville series, which is known as Rogers XII in Pennsylvania, where it has been thoroughly studied, is divided as follows:

Homewood sandstone.
Mt. Savage fireclay.
Mt. Savage coal.
Lower Mercer coal.
Upper Connoquenessing sandstone.
Quakertown coal.
Lower Connoquenessing sandstone.
Sharon coal.
Sharon conglomerate.

The coal seams, like other geological formations, are named from localities where they are typically developed, consequently in new locations they receive local names at first, which are afterwards changed to the oldest geological name applied to it in print. The local name is not changed, however, until the correlation has been definitely established. It is for this reason, and in order to avoid geological confusion and economic complications, that the West Virginia Geological Surveyors are apparently moving slowly in their correlation, while as a matter of fact they are concentrating data yearly that must soon establish the exact positions of the coal beds relative to those of Pennsylvania. The coal beds assigned to the Pottsville series in West Virginia are:

Pocahontas 1, 2, 3, 4, 5, 6, 7, 8, 9.
Fire Creek or Quinnimont.
Beckley.
War Creek.
Welsh Coal.
Sewell or Nuttall.
Jaeger, Hughes Ferry Coals.

The Pocahontas beds, Nos. 3 and 4, of McDowell County, and the Sewell bed, of the New River series, are the most important coal beds.

Average analyses of these coals are as follows:

	Pocahontas		Sewell	
	Coal	Coke	Coal	Coke
Moisture	.2300	.0900	.690	.0140
Volatile matter	17.4300	.9800	23.950	1.0600
Fixed carbon	77.7100	90.9900	72.040	91.2600
Ash	4.6300	7.9400	3.320	7.5400
Sulphur	.6200	.5800	.740	.7500
Phosphorus	.0057	.0061	.008	.0095

One of the earliest coals to be mined in the New River district was the Quinnimont seam. It is not yet known definitely which of the Pocahontas coal beds the Quinnimont seam represents, because the country between New and Tug rivers has not been developed sufficiently for geologists to trace the connection. Stuart M. Buck stated some years ago that he believed the Quinnimont and No. 3 Pocahontas beds to be the same.

An average analysis of the Quinnimont coal and coke is as follows:

	Coal	Coke
Moisture	.600	.130
Volatile matter	19.930	.980
Fixed carbon	75.200	91.710
Ash	4.270	7.180
Sulphur	.670	.640
Phosphorus	.035	.062

The Lower Productive coal measures are known in Pennsylvania as Rogers XIII or Allegheny River series; above the Nuttall sandstone, which forms great cliffs along New River. From Kanawha Falls to Sewell, there is a series of rocks which contain coal beds and have been assumed in a general way to represent Rogers XIII, but at the present time are termed the Kanawha series. The West Virginia Geological Survey, Vol. IIA, has divided the coals of this series into a higher and lower group. The lower group are softer than the higher group, and are higher in volatile matter than the New River coals, thus making them excellent gas, coking, and general fuel coals. The most important coal bed of the Kanawha series is the "No. 2 Gas," which is considered a split from the Campbell's Creek bed, according to I. C. White, state geologist. An average composition of the coal is given in the following analysis:

Moisture, 1.18; volatile matter, 33.52; fixed carbon, 59.78; ash, 5.52; sulphur, 1.29; phosphorus, .01.

Seventy-two-hour coke, made from No. 2 Gas coal, gave the following analysis:

Moisture, .19; volatile matter, 1.35; fixed carbon, 87.21; ash, 11.25; sulphur, .96; and phosphorus, .023.

In the following table the Allegheny series as they occur in Pennsylvania are given in the first column; the second and third columns are the writer's attempt at correlation. One difficulty in connection with the correlation of the lower productive coal beds in the Kanawha district is that the beds seem to split or divide, thus intercalating coal beds not known in other coal fields, even in the same state. This makes it fairly certain that some beds commercially valuable in one county are not so in another, owing to the thinning and thickening process undergone.

Allegheny Series	Tug River	Kanawha Series
Upper Freeport coal	Stockton, Lewiston	Stockton-Lewiston-Belmont
Upper Freeport limestone		
Bolivar fireclay		
Upper Freeport sandstone		
Lower Freeport coal	Buffalo Creek	Coalburg
Lower Freeport limestone		
Lower Freeport sandstone		
Upper Kittanning coal	Thacker	Winefrede
Middle Kittanning coal	Alma	Cedar Grove
Lower Kittanning coal	Warfield	Campbell's Creek, or No. 2 Gas, or Peerless upper division of Campbell's Creek
Lower Kittanning clay		
Lower Kittanning sandstone		
Vanport limestone		
Clarion sandstone		
Clarion coal	War Eagle	Eagle
Clarion clay		Lower War Eagle + 660 above Sewell

The Middle Coal Measures.—These measures, while composed of the same kinds of sandstone, shale, and clay slates, as the Kanawha coal series, contain few workable coal beds and have been termed the "Barren Coal Measures," "Rogers XII," and "Conemaugh series." The important coals in this rock series are Bakerstown and Elk Lick beds, although the Brush Creek bed below the Bakerstown, and the Harlem coal bed above, have a wide distribution and in places reach a thickness where they are workable.

The Bakerstown coal is mined in Mineral County, in the North Potomac basin, and has received attention in Preston County for local consumption. It extends southwestward through Barbour, Randolph, Upshur, Lewis, and Braxton counties. The following analysis of the coal in Mineral and Preston counties show it to be high in sulphur and quite different in calorific value.

	Mineral County	Preston County
Moisture	.70	.8900
Volatile matter	15.05	29.0100
Fixed carbon	73.83	63.0300
Ash	10.42	7.0700
Sulphur	2.23	2.4600
Phosphorus	.10	.0095
B. T. U. calculated	13,698	15,050

The great difference in volatile matter and ash would indicate that the coal came from different places if not different beds.

Immediately below the Ames limestone is the Harlem or Crinoidal coal bed. It is at its best (2½ feet) in Preston, Harrison, and Wirt counties, where it is mined to some extent for local use. This coal is generally high in ash as the following analysis shows:

Moisture, .80; volatile matter, 27.78; fixed carbon, 54.54; ash, 16.88. There is 1.77 per cent. sulphur and .005 per cent. phosphorus.

The Elk Lick coal bed is found from 50 to 75 feet above the Harlem coal and is named from a locality in Somerset County, Pa., where it was long ago opened. It is generally present in Preston, Barbour, Upshire, Lewis, and as far south as Lincoln and Wayne counties. Elk Lick coal is mined in a commercial way to some extent, and while high in ash and sulphur, breaks into hard blocks that women use for bombarding "hawgs" and for other domestic purposes. An analysis of the coal from Lewis County is as follows: Moisture, 1.10; volatile matter, 37.40; fixed carbon, 46.46; ash, 15.04; sulphur, 2.49; phosphorus, .106.

The Little Clarksburg coal bed is about 100 feet above the Elk Lick coal. In the Fourth Potomac basin of Maryland and West Virginia it contains many impurities so it has been named the "Dirty 9-Foot." A section of this coal in the George's Creek basin 1 mile northwest of Franklin is: Coal, 2 inches; shale, 1 inch; coal, 10 inches; shale, 2 feet 3 inches; coal, 2 feet 9 inches. Total 6 feet 1 inch.

About 65 feet above the Little Clarksburg is the Little Pittsburg coal seam. Neither of these beds is worked at present in West Virginia, and as an analysis would approximate 50 per cent. ash unless the coal was cleaned, none have been reported.

The thickness of the Conemaugh series varies from 495 to 595 feet between the Upper Freeport of the Allegheny series and the Pittsburg bed of the Monongahela series. Sedimentary rocks are found about 35 feet below the Ames limestone, termed Pittsburg red shale. These red beds of the Conemaugh, I. C. White says, were deposited as red muds, and are not the oxidized rocks found in places in the coal measures. No other red beds are to be found in the coal measures, in fact where red shales of the Mauch Chunk formation, or red shales of the Permian formation are found, coal is wanting. Le Conte states in his geology that when iron ore is diffused as a coloring matter in earths there has been no organic matter to leach and accumulate it as an ore deposit. A section of the Lower Barren measures with the nomenclature of Pennsylvania, Maryland, and West Virginia with the approximate distance between the beds in feet follows:

Lower Pittsburg sandstone, Pennsvlvania and West Virginia, below the Pittsburg bed and about the Upper Freeport bed.

Pittsburg limestone, Pennsylvania.

Little Pittsburg coal, 80 feet below the Pittsburg bed and 515 feet above the Upper Freeport.

Connellsville sandstone, Pennsylvania.

Little Clarksburg coal, Pennsylvania and West Virginia; Franklin and Dirty 9-Foot, Maryland; 150 feet below the Pittsburg bed and 445 feet above the Upper Freeport.

Clarksburg limestone, Pennsylvania and West Virginia.

Morgantown sandstone, West Virginia.

Elk Lick, Crinoidal or Barton, Pennsylvania and West Virginia; 250 feet below the Pittsburg bed and 345 above the Upper Freeport.

Elk Lick limestone, Pennsylvania.

Birmingham shale, Pennsylvania.

Ames limestone, Pennsylvania and West Virginia; about midway of the Lower Barren measures, 292 feet between Pittsburg and Freeport coal beds, and about 100 feet above the Pittsburg red shale.

Harlem coal, West Virginia and Pennsylvania; not generally more than fireclay, 280 feet above the Freeport and next above the Pittsburg red shale. Not recognized in Maryland although the Maynadier slate seam is in its horizon.

Pittsburg red shale, Pennsylvania, West Virginia, and Maryland; about 100 feet below the Ames limestone and about 192 feet above the Upper Freeport.

Saltsburg sandstone, Pennsylvania.

Barkerstown coal, West Virginia and Pennsylvania; synonymous with "Three or Four Foot," "Honeycomb," and Barton of Maryland. About 180 feet above the Upper Freeport coal.

Pine Creek limestone.

Buffalo sandstone, about 8 feet below Barkerstown coal and from 80 to 98 feet thick.

Brush Creek limestone.

Brush Creek coal, about 67 feet above the Upper Freeport and the lowest coal bed in the Barren measures.

Upper Mahoning sandstone.

Mahoning coal, Pennsylvania. Not recognized in Maryland and West Virginia.

Lower Mahoning sandstone.

The Upper Productive Coal Measures.—These measures, known as Rogers XV and Monongahela River series, have as the lowest member the celebrated Pittsburg coal. West Virginia. is supposed to possess an area of 1,100,000 acres of this valuable coal, averaging more than 8 feet in thickness. Pittsburg coal has a specific gravity of about 1.275, thus making an acre of coal 1 inch thick weigh 144 tons, or 1 foot thick weigh 1,728 tons. An average of 95 analyses of this coal in West Virginia is as follows: Moisture, .89; volatile matter, 38.52; fixed carbon, 53.55; ash, 7.04; sulphur, 2.48; phosphorus, .012.

This Pittsburg coal is much higher in sulphur than the same bed in Maryland and Pennsylvania.*

At approximately 40 feet above the Pittsburg coal is the Redstone coal, which appears to have a wide distribution in Lewis and Gilmour counties. The Redstone coal so closely approximates the composition of the Pittsburg bed, it has sometimes been taken for it. From 60 to 80 feet above the Redstone coal is the Sewickley coal bed. This coal is separated by thin partings of mother coal or mineral charcoal into two benches. For domestic use it is preferred to Pittsburg coal, because even although it is higher in sulphur the ash is less fusible and produces less clinkers. The coal covers a wide area in West Virginia, as it is found in Monongalia, Marion, Mineral, Ohio, Brooke, Hancock, Marshall, and Wetzel counties.

About 180 feet above the Sewickley coal is the Uniontown coal bed, which is mined for local use by farmers in Gilmer, Lewis, Calhoun, and Roane counties.

The Waynesburg coal bed is at the top of the Upper Productive series at about 330 feet above the Pittsburg bed. This coal has economic value in Marshall, Monongalia, Ohio, and Wetzel counties. An average analysis of the coal is as follows: Moisture, 2.10; volatile matter, 32.4; fixed carbon, 51.24; ash, 14.26; sulphur, 2.7.

The Waynesburg coal varies considerably in composition and thickness according to the locality from which it comes. It is also separated by a band of fireclay, therefore taken as a mining proposition at the present time it belongs to the coals suited to conservation.

The following is a section of the Upper Productive coal measures:

Waynesburg coal, thickness from 6½ to 9½ feet with fireclay parting. Known in Pennsylvania, Maryland, and West Virginia by same name, 330 feet above Pittsburg bed.

Little Waynesburg coal 6 inches to 12 inches.

Waynesburg limestone.

Gilboy sandstone.

Uniontown sandstone.

Uniontown coal, 3 feet to 4 feet 6 inches; 180 feet above Pittsburg bed, Pennsylvania and West Virginia.

Uniontown limestone.

Fulton green shale.

Benwood limestone.

Sewickley sandstone.

Upper Sewickley coal, 2 foot 8 inches, Pennsylvania and West Virginia; known as Tyson and Gas in George's Creek, Maryland, 110 feet above Pittsburg bed.

Lower Sewickley coal, 3 feet 4 inches, Pennsylvania and West Virginia; known as Tyson and Gas in George's Creek, Maryland, 110 feet above Pittsburg bed.

Sewickley limestone.

Redstone coal, about 5 feet thick; name the same in Pennsylvania, Maryland, and West Virginia, about 40 feet above the Pittsburg bed.

Upper Pittsburg sandstone.

Pittsburg coal, 8 feet 8 inches, West Virginia and Pennsylvania; synonymous with Big Vein of 14-foot bed; Elk Garden bed, Maryland.

The Upper Barren, Permian, Rogers XVI, or Dunkard Creek series, of Pennsylvania, contain but one coal bed of moment, and that is the Washington. This varies from 13.13 per cent. to 25.6 per cent. in ash, from 1.64 to 9.75 in sulphur, and is not much in demand. The remaining coal beds in the Dunkard Creek series vary from 12 to 18 inches in thickness and are therefore adapted to conservation. According to the names first adopted by Professor Lesley, of the Pennsylvania Second Geological Survey, the Washington County group, from the Waynesburg coal bed to the Jollytown coal bed, was numbered XVI, and the Green County group, from the Jollytown to the Proctor sandstone, was numbered XVII. The total thickness of the Barren measures XVI and XVII is about 1,200 feet. A vertical section of Rogers XVI taken by I. C. White in Greene County, Pa., is appended.

Coal for Spain

A company was in process of formation in the United States some months ago, says U. S. Consular Report, for exporting American coal to Spain, France, and Italy, the idea being that it could undersell English coal in these markets provided the fleet of ships, which it was proposed to build for this purpose, could be assured of return cargos. Agents were sent to Spain for the purpose of ascertaining the possibility of making contracts with the iron miners of the country to supply a sufficient quantity of iron ore for return freight to the United States, and it was understood that the ore could be furnished in any quantity, but up to the present it is not known if the company in question has taken any steps to put its enterprise in operation.

The consumption of coal in Spain in 1908 amounted to 6,336,921 tons, of which 4,118,276 tons were Spanish coal and 2,218,645 tons imported. The amount of pit coal used for coking purposes in 1908 was 644,727 tons, from which 477,059 tons of coke were produced.

Prices of Cardiff steam coal in cargoes, c. i. f. Barcelona, are as follows per ton: Large, $5.71; small, $3.54. The price of Asturian coal, f. o. b. Barcelona, is as follows per ton: Large, $6.56; middle-sized, $6.17; siftings, mixed with crushed coal, $4.82.

Mine Explosions From Natural Gas Well

Description of Two Explosions that Were Caused by Gas Escaping From a Well into Mines

*By C. H. Tarleton**

On December 19, 1910, the officials of the Consolidation Coal Co. were called upon to face a disaster resulting from a gas well, and, as is usually the case, the trouble came from an unexpected source. About 6:50 A. M., an explosion occurred in Consolidation No. 47 mine, which caused the death of three men, and completely wrecked one section of the mine. On the same date, about 4:50 A. M., Consolidation No. 49 mine was badly wrecked and set on fire by an explosion, but fortunately no lives were lost. Eventually both explosions were found to have been caused by natural gas escaping into the mines through the pavement or bottom, from a gas well located over and drilled through a pillar of coal in mine No. 47.

Mine No. 47 is located about 8 miles south of Fairmont, W. Va. The opening to mine No. 49 is about 4 miles by railroad from No. 47, but the workings are adjacent to each other. Both mines are drift openings and are operating the Pittsburg seam. Mine No. 47 was opened in 1899, and previous to December 19, 1910, there had never been a trace of explosive gas detected in it. Mine No. 49 commenced operation in 1897, and with the exception of some slight traces in clay veins in the farthest advanced workings, no explosive gas had ever been detected in it. In the last year or two, numerous oil and gas wells have been drilled through or near the mine workings.

These wells were always located so they would pass through solid coal and where it would be possible to leave a block of coal of what would be considered ample dimensions to protect the mine and the well. It was generally thought that there would be no particular danger from these wells until the time arrived for extracting the coal around them. For this reason no one was expecting the occurrence on the morning of December 19.

On the date mentioned, the miners at mine No. 47 started to their work as usual. Some of them had already reached their places, while others were on the main heading, when an explosion occurred that threw them down and rolled them quite a distance along the heading, but aside from being slightly bruised and badly scared, those on the main heading were uninjured, and were able to make their way to the outside. The fan was running as a blower, but was immediately reversed and a rescue party organized and started in the mine. It was soon discovered that the explosion had occurred on the first south face, and had not extended beyond this immediate section. The men beyond this section were able to leave the mine through an opening on the No. 3 south face and through an opening to mine No. 36, thus avoiding the afterdamp.

While the necessary arrangements were being made to restore the ventilation on first south face, a census was taken and all men accounted for, except five. By this time the rescue party was able to advance and explore the first south face. A body was found at the neck of No. 2 room, second butt, and two more at the junction of the third butt. All were badly burned and a statement of one of the doctors who made a post-mortem examination of one of them was to the effect that death was caused by inhalation of flame. After the exploration of the second and third butts, and the discovery of the three bodies, it was thought that the other two were on first butt. This heading was longer than the others and the men were supposed to be a considerable distance from the bottom; it seemed a certainty that they would be dead. For this reason and from the fact that there had been considerable gas and some smoldering fire on the other headings, it was not thought advisable to act hastily in restoring the ventilation on this heading. The company's oxygen apparatus had been sent for, and was expected any minute. With its arrival, it was the intention to explore the heading before any air was permitted to enter. While these arrangements were being made, a very happy incident occurred which, however, illustrates one of the great dangers to which a rescue party is subjected while exploring a mine. A start had not yet been made to enter the heading when two lights were noticed near the top. It was quickly ascertained that the lights were on the heads of the two men that were being sought and that the men were coming out. A stopping had been blown from a cross-cut through the barrier pillar, enabling them to pass to the main heading, thus unconsciously avoiding the gas, preventing a second explosion that probably would have killed all present. These men, who were foreigners, stated that when the explosion occurred, they supposed it was a heavy shot in the adjoining room. When the afterdamp reached them, they left their working place and passed up the heading to where there was a door that had not been wrecked. Finding the air fresh on the other side of this door, they remained there until they got tired waiting for the driver, when they started out to find why he did not come.

When an entrance was gained to the first south face section, large bodies of standing gas were encountered at second and third left butts, and on the sixth right butt. This gas was being liberated through the pavement and could be heard boiling and seething through the water for a long distance, a near approach made it possible to detect the gas with the lamp. Later on it was found that these blowers occurred in almost a straight line from a gas well located in the barrier pillar between first south face heading and room No. 1 off second left butt, the line extending in a southwesterly direction, parallel to the contour lines of the Pittsburg coal seam, to a point in mine No. 49 about 2,300 feet distant from the well. On account of the very pronounced odor of the gas, it was surmised that it was coming from a gas well, and the well mentioned above, being the nearest one to the affected area, was naturally suspected as being responsible. As soon as the necessary arrangements could be made, or about 9 P. M., on December 19, the valves on this well were opened, and immediately thereafter the gas blowers in both mines began to recede.

The explosion in mine No. 47 was evidently caused by the miners on first south face coming into contact with the gas with their open lights. It could not be definitely determined which one of the men fired the gas, but in all probability it was one of those found at the entrance to third left butt. These men had passed the point where the gas was being liberated and, it seemed, had been in the act of shifting their car to their working place, where there undoubtedly was a body of standing gas. The explosion in this mine was not violent, and from the indications, extended but a short distance from the point of origin, due in all probability to the fact that there was not sufficient air at that point to dilute the entire amount of gas to an explosive mixture. This belief is substantiated to some extent by the fact that a large amount of standing gas was found in that section of the mine by the first men reaching the scene soon after the explosion.

It has been proved that the circulation of large volumes of air through a mine in cold weather will carry out the moisture, thus creating a dangerous condition from dust. For this reason, and mine No. 47 being a non-gaseous mine, the fan was run only when the mine was in operation. Although the fan had been idle for a period of 36 hours, and to within about 1 hour previous to the accident, it is not thought that this fact had any immediate significance in connection with the explosion. From calculations, it was estimated that the time necessary for air entering at the fan to travel the entire distance of the split which passed the affected area and return to the outside, was about 38 minutes. Assuming that these calculations were approximately correct, the air, after the fan was started on the

* Superintendent of Mining, West Virginia Division, The Consolidation Coal Co., Fairmont, W. Va. Paper read before West Virginia Mining Institute.

morning of December 19, would have had almost enough time to make two complete circuits around the split, in which event it is reasonable to assume that it had sufficient time to carry away any gas directly in its path. No provision had been made, however, for circulating the full volume of air to the working faces, it not being required or considered necessary in a non-gaseous mine, consequently the air-current would not have removed any gas that might have collected in tight ends or places where the ventilation was light. With the gas blowers in this mine located in just such places as described, one of them being in a tight end, and several others in places where the ventilation would be light, without special arrangement being employed to conduct the air into them, it is not unreasonable to believe that conditions would have been practically the same had the fan been running continuously.

The above statement can be strengthened somewhat by the following: It has already been said that the fan was operating as a blower; as a result, the miners entering the mine traveled against the air, even as far as the end of first south face, where the explosion occurred. The two men, found at the entrance to third left butt, who have been mentioned as probably firing the gas, passed by some of the heaviest blowers in the mine to a point 100 feet or more beyond where they were found, in the direct path of the current of air supplying this section of the mine. The inference to be drawn from this fact, is that the gas directly in the path of the air-current was being swept away, and that the amount was not sufficient to render the air-current explosive; but as soon as the men left the main volume of air, and reached a point where the ventilation was lighter, they came in contact with an explosive mixture which was fired from their open lights. This being true, it is reasonable to assume that the same conditions could have existed, as has been stated, with the fan running continuously.

The explosion in mine No. 49 was set off by the night pumper, who was the only man in the mine at the time. He was not seriously injured. According to reliable information, he entered the mine on the evening of December 18, and sometime near 8 P. M., came in contact with some gas blowers in rooms Nos. 10 and 11, on third right butt off main south face, the blowers being ignited from his open light. After considerable trouble, he was able to extinguish the flames with his coat, after which he continued at his work, not thinking it important to report the matter to the officials at once, but deciding to wait until morning; this, of course, was a bad mistake and one that might have caused a more serious disaster, but was due to his lack of previous experience with gas in that mine. He attended the pumps in the same section of the mine until nearly 5 o'clock in the morning of the 19th, at which time he started into third face heading to throw an electric switch which was located a short distance from the main heading and beyond an overcast at the intersection of first butt off third face. When directly under the overcast, and before he had reached the switch, he came in contact with a body of gas that must have extended throughout that section. The gas was ignited from his open light, causing an explosion with apparently little violence at the point of ignition, but from indications, accumulating tremendous force farther in the mine. The gas evidently burned rather than exploded for some distance, when the flames probably encountered a mixture of gas and air more nearly the correct proportion, where a violent explosion took place.

On account of there being little force at the initial point of the explosion, the pumper was not seriously injured, beyond being slightly burned, and about the only other damage done at that point was a partial wrecking of the overcast; the latter no doubt saved the pumper's life, since the damaging of the overcast caused a short-circuit of the air at that point, the ventilating system from there to the pit mouth and fan having been little disturbed. This allowed a supply of fresh air to reach him, which of course kept the gases away. As soon as the afterdamp was cleared sufficiently from the main heading, parties from the outside entered the mine, found the pumper, and took him out.

The fan at mine No. 49 as at No. 47, was operating as a blower. The only difference in connection with the operation of the two fans was that with the exception of about five hours on the 17th, the fan at No. 49 had been running continuously. This was thought to be another good reason for assuming that the explosion at mine No. 47 would have happened just the same if the fan there had been running continuously. The fan at mine No. 49 was reversed before any extensive exploration was arranged for. When arrangements were completed, a party of mine officials and others, properly equipped with the necessary tools and material for restoring the ventilation, entered the mine. When they had made their way into the third face, gas blowers were found coming through the pavement in several different places, and a fierce fire was burning in room No. 5 on first left butt. It was the general opinion that some of the gas blowers were fired by the flames and continued to burn, thus firing the coal.

The fire in room No. 5 extended from the first to the second cross-cuts and was burning fiercely when it was first reached. It was soon realized that it would be useless to undertake to fight this fire with the means at hand. Work was commenced at once to seal it off and prevent it spreading to other sections of the mine. To do this necessitated the building of eight stoppings. Work was commenced at the first cross-cut on the intake of the air, and continued without any serious trouble around until the last one was reached, which of course was the most difficult one to close. The stoppings were first built with canvas, quickly reinforced with wood and plaster, and at the same time a force of men was started to build substantial concrete stoppings against the wood. By this means the fire was confined to four rooms on the heading mentioned, the rooms being Nos. 5, 6, 7, and 8.

In sealing off the fire, it was necessary to enclose with it at least one large gas blower, and in all probability there were several others within the enclosed area. At first it appeared that it would be dangerous to enclose this gas with the fire, but since there were no effective means at hand with which to fight it, and nothing being known of conditions beyond to where it was rapidly spreading, there was no choice but to take chances and seal it off as quickly as possible. Immediately after sealing off the fire, it began to die and become quiet. The action within the enclosed area was noted by means of a piece of 2-inch pipe inserted in one of the stoppings on the end of which pipe was a valve to permit its being opened and closed.

From the initial point described, the explosion seemed to travel in a general course toward and to an air-shaft located along the main face heading, about 300 feet beyond on third left butt. The greatest damage to the mine was done on second left butt off third face, and third and fourth right butts off the main heading. All of the places mentioned were in the direct path of the explosion from its point of origin to the air shaft. Nearly all stoppings and overcasts along the main heading were of brick or concrete construction, and were all destroyed in the section covered by the explosion. Electric wires were twisted and coiled into nearly every conceivable shape, mine cars were wrecked, some of them being blown from their positions in the rooms up on to high piles of coal and roof falls, but little damage was done to any of the mine beyond the fourth left butt and the air-shaft. Had it not been for this air-shaft and the excellent condition of the mine relative to humidity, the dust being well saturated, the explosion would no doubt have traversed the entire main heading to the back end of the mine, and the rebound or backlash from that point would have continued in all probability to the pit mouth, branching out on its way into the headings to the right and left, and wrecking the entire mine.

In both mines careful attention had been given to the prevention of accumulation of dust. This was accomplished by the introduction of moisture in the mine air by means of steam, and in addition to that, the careful and systematic spraying with water of any part of the mine showing the least tendency to become dry. Had it not been for the good conditions resulting from such precautions, or had the mines not been wet or damp, it is believed the statement will not admit of doubt that the explosion of gas would have been propagated and reinforced by dust, with the result that both mines would have been completely wrecked as well as the mines connected with them.

It was said in the beginning that the cause of the explosions described was a gas well located over and drilled through a barrier pillar in mine No. 47. The reasons for that conclusion are briefly as follows: First, both of the explosions were undoubtedly caused by gas; second, previous to December 19, 1910, no explosive gas had ever been detected in mine No. 47, even by chemical analysis of the air, during its entire history, and with the exception of the blower reported to have been ignited by the pumper on December 18, only a slight trace was ever detected in mine No. 49, this being liberated from clay veins at the face of the main heading, which is in a different seciton of the mine from where the explosion occurred, and which was not affected by it; third, the gas discovered had an odor resembling gasoline, benzine, or naptha,, which odor is not peculiar to marsh gas or methane as commonly met with in coal mines, but which odor is present in the case of gas produced from a gas well; fourth, samples of gas from the well, and also samples from the blowers in both mines, were analyzed, the analyses of the different samples having an uniformity and bearing a close relation to each other; also the analyses of the samples taken from the blowers in the mines showed them to contain a percentage of ethane, a gas which is rarely, if ever found in coal mines from natural causes; fifth, after the well had been opened up, and given free vent to the outside, the gas blowers in both mines began to diminish until the greater number of them entirely disappeared.

The analyses of the samples mentioned are as follows:

Analyses by West Virginia Geological Survey

	From Sturm Well Dec. 23, 1910 Per Cent.	From Mine No. 49 Dec. 20, 1910 Per Cent.	From Mine No. 49 Dec. 22,1910 Per Cent.
Carbon dioxide		.35	.70
Oxygen		.70	5.90
Methane	86.90	88 60	68.40
Ethane	12.70	7.30	2.76
Nitrogen	.40	3.05	22.24

Analyses by Pittsburg Testing Laboratory

	From Sturm Well March 15, 1911 Per Cent.	From Mine No. 47 March 15, 1911 Per Cent.	From Mine No. 49 March 15, 1911 Per Cent.
Carbon dioxide	.30	5.70	1.60
Oxygen	.20	.90	1.10
Illuminants	.20	.10	.10
Methane	86 05	78.84	74.97
Ethane	12.35	9.00	12.07
Nitrogen	.90	9.46	10.16

The manner in which the well was closed, it is believed, was responsible for the gas escaping into the two mines. At its completion, 2-inch tubing, Fig. 1, was inserted in the well with a wall packer *g* placed above the Bayard sand; another packer *e* was also placed around and near the bottom of the $5\frac{3}{16}$-inch casing *f* above the 50-foot sand. A Braden head *b* was used on the well, which was attached to the $8\frac{1}{4}$-inch or outside string of casing, thus closing off any vent to the outside, and making impossible the escape of any leakage of gas outside of the inner strings of casing. Fig. 1 shows about the manner in which the well was closed. Should anything have happened to the packer on the 2-inch tubing, or to the tubing itself, causing it to give way or leak, the gas would have escaped up around the outside of this tubing to the top of the hole or to the Braden head, when it would pass over the top of the $5\frac{3}{16}$-inch and $6\frac{5}{8}$-inch casing *d* and down along the inside of the $8\frac{1}{4}$-inch or outside casing, to the bottom of the same, below which point the entire pressure of the well would be directed against the bare walls of the hole, and where there undoubtedly was an opening or crevice of some kind that allowed the gas to escape into the mines. On February 8, 1911, the 2-inch tubing and the packer were removed from the well. No defects were found in the tubing, but the packer was entirely stripped of its rubber. As to whether the rubber was taken off in pulling the packer from the hole or not could not be determined.

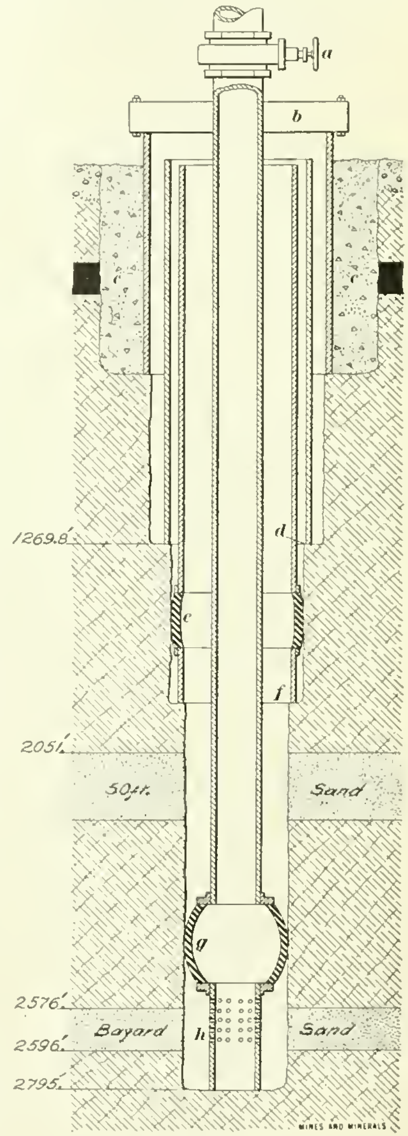

Fig. 1

An injury to either the packer or tubing might result from any one of many possible causes. It might be due to the natural and constant rock pressure of the well, or to the settling of the block of coal around the well. Such settling could be caused by the disintegration of the fireclay beneath the coal on account of open entries and rooms surrounding the block, thus permitting the action of the air and water on the fireclay strata mentioned. It is not impossible or improbable that the mining of pillars in proximity to the block of coal would cause a settling or a disturbance of the same, although the block itself, which was 380 ft. × 135 ft. in dimension, had not been touched since the well was drilled, which was March and April, 1910. The covering over the coal at this point is 176 feet, with a strong sand rock immediately above the roof slate. On account of this heavy sand rock, roof breaks are sometimes difficult to make and the effects from mining may be seen a considerable distance away from where any coal is being removed. In this connection, it may be stated that a fresh break occurred in the surface near the well, at or near the time of the explosion. The break was over territory where the pillars had been drawn for some time, indicating that the strata over the coal were probably throwing an extra amount of weight on that particular block of coal before the break occurred.

After the explosions, all of the 2-inch tubing and the 5-inch casing was pulled from the well and inspected. The well was then recased in the same manner as described above, new packers being used, but the Braden head was placed on the 5-inch casing, leaving an open vent for all gas that might escape around the 5-inch casing between the 5-inch packer and the top of the hole. The valves on both the 2-inch tubing and the 5-inch casing were closed on March 21, 1911, but no perceptible increase was found in the blowers inside the mines.

The writer has attempted to give the principal facts in connection with the explosions described, and sufficient evidence to prove beyond any reasonable doubt that the cause was the gas well mentioned. If this paper tends to impress more forcibly upon mine operators, managers, and engineers the importance of accurate location of all oil and gas wells, of protecting them by the best methods to be devised, and of employing the proper method in closing such wells, he will feel that he has contributed, at least in a small way, something toward the welfare of the men who toil underground.

Tennessee Coal Production

The following table shows coal product and values of Tennessee coal mines in 1910 by counties, also disposition of product and average value per ton obtained:

Coal product and values, disposition of product, and average value per ton obtained in 1910.

	Coal Product (Short Tons)					Coal Values	
County	Loaded for Shipment	Used for Fuel and Steam	Sold Local Trade and Employes	Coked	Total Product	Total Value	Average Value Per Ton
Anderson	783,630	13,889	4,555		802,074	$ 834,149	$1.04
Bledsoe	27,500	200	300		28,000	30,800	1.10
Campbell	1,655,257	33,015	19,397	8,896	1,716,565	2,016,181	1.17
Claiborne	1,502,499	18,385	2,532		1,523,614	1,527,729	1.00
Cumberland	48,643	1,135	202		49,980	56,375	1.13
Fentress	96,114	2,734	189		99,037	106,857	1.09
Grundy	320,868	1,571	1,776	32,995	357,210	393,212	1.10
Hamilton	193,853	7,707	7,706	68,853	278,119	320,975	1.15
Marion	492,156	9,663	4,797	41,300	547,916	692,421	1.26
Morgan	385,216	11,218	2,627	105,985*	505,046*	482,180	.96
Overton	77,156	914	265		783,35	77,791	1.00
Rhea		3,811	9,120	153,965	148,896	208,976	1.40
Roane	5,481	10,654	3,000	175,264	194,399	234,035	1.20
Scott	128,020	2,200	2,457		132,677	158,986	1.20
Sequatchie	35,134	2,133	852	46,067	84,186	93,445	1.11
White	344,965	15,428	2,439		362,832	392,728	1.08
Total	6,096,492	134,657	62,214	615,325	6,908,688	$7,626,840	$1.10

* The product of the State operations of Brushy Mountain mines, at Petros, amounted to 333,693 short tons, valued at $307,564 or 96 cents per ton. The product of Morgan County excluding the operation of the State mines amounted to 171,407 short tons, valued at $174,616 or $1.02 per ton.

Obituary

FRANCIS M. OSBORNE

Mr. Francis M. Osborne, of Cleveland, Ohio, one of the leading coal-mine operators in the Middle West, and prominent in a wide range of business ventures, died on the 16th ult., at a Toledo, Ohio, hospital, where he had been taken after having collapsed on a Lake Shore train while en route from Cleveland to Chicago.

E. W. MARPLE

E. W. Marple, who has been paymaster of the Lehigh and Wilkes-Barre Coal Co. practically since its organization, died in Wilkes-Barre, July 9. Mr. Marple was a veteran of the Civil War and took an active interest in local affairs.

Appointment of Ohio Mine Inspectors

Since first elected governor, the attitude of Governor Harmon toward the mining interests of the state and his determination to make the Mining Department non-partisan and free the inspectors from any undue political influence, has given the very strongest evidence of his broadmindedness, as well as his keen interest in seeing that the best possible service is secured from state appointees whose duty it is to see that the lives and property of its citizens are properly cared for by a judicious application and enforcement of its laws.

In accordance with the law and with the approval of Governor Harmon, George Harrison, chief inspector of mines, made the following appointments in the Department of Mines:

Second District.—Composed of the counties of Hocking, Meigs, and a portion of Athens and Gallia, Edward Kennedy, Carbon Hill, Hocking County, Ohio, for a term commencing July 1, 1911, and ending June 30, 1914.

Third District.—Composed of the county of Athens, John L. McDonald, Glouster, Athens County, Ohio, for a term commencing July 1, 1911, and ending June 30, 1914.

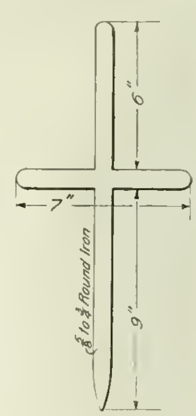
Sixth District.—Composed of the counties of Coshocton and Tuscarawas, Alex Smith, New Philadelphia, Tuscarawas County, Ohio, for a term of three years, commencing July 1, 1911, and ending June 30, 1914.

Seventh District.—Composed of the counties of Holmes, Medina, Ottawa, Portage, Stark, Summit, Trumbull, and Wayne, W. H. Miller, Massillon, Stark County, Ohio, for a term commencing July 1, 1911, and ending June 30, 1914.

Eighth District.—Composed of a portion of both Belmont and Jefferson counties, Lot Jenkins, Martins Ferry, Belmont County, Ohio, for a term commencing July 1, 1911, and ending June 30, 1914.

Iron Sprag at Radiant Mine

An effective sprag used on the tipple at the Radiant mine of the Victor American Fuel Co., near Florence, Colo., is shown in the accompanying sketch. The dimensions may be altered to suit the ideas of the maker. It is made of ordinary round iron, the diameter of which will naturally depend upon the size of the car and its consequent loaded weight. Aside from the fact that these sprags never wear out, they possess a great advantage in the ease with which they may be released. This latter is an important point where cars are being spragged into a dump. When properly used the wear upon the car appears to be little, if any, more than with wooden sprags. J. Q. McNatt is the originator of this sprag.



The water gauge or pressure produced by a fan varies directly as the square of the speed. If a fan is running 80 revolutions per minute and produces 1-inch water gauge, what pressure will it produce at 160 revolutions per minute? Stating the proportion thus: $(80)^2 : (160)^2 : : 1$ inch $: x$, we have $x = 4$-inch water gauge.

Lessons To Be Learned From Mine Fires

The Important Influence of Powerful Ventilating Currents in Spreading Fires in Mines

At a recent session of the Mine Inspectors' Institute, the following paper was read by John Verner, Mine Inspector, of Chariton, Iowa:

The value of a lesson of a mine disaster to be of practical use as a guide for devising means of prevention of a possible occurrence of similar nature does not depend on painting the calamity in vivid colors or in giving in harrowing detail all the suffering and horrors caused by it or in heaping blame, deserved or otherwise, on state and mine officials, but rather on a careful, fair, and full inquiry by competent men, including miners, into all the causes of the disaster, and a well-considered presentation of the influence of each.

After the Cherry fire nearly all these things were done, but there was evidently one mistake made that, in my judgment, impaired the future value of the disaster's lesson materially. While the presence of the torch with its burning drops of oil falling on the hay was given a prominent place as the main cause of the fire and was denounced as a great menace and blunder, although the use of such torches at shaft bottoms was fairly general in the mines of this country, the fact that the great draft playing on the incipient blaze was really the most powerful and determining cause in this great disaster was almost entirely ignored. Had this feature of the Cherry lesson, showing the influence of a great draft passing through the shafts and entries as through a large blowpipe, forcing the rapid development of a small initial flame and producing the most intense concentration of heat, been given the prominence and emphasis it deserved, so its import could have been correctly appreciated and understood by mine managers and mine employes, it is probable that, had the knowledge so gained been put to proper use in the Delagua and Pancoast mines, the great loss of life in them would not have occurred. Miners and men in charge of mines generally see only the beneficial effects of a strong air-current sweeping through the underground passages and workings, and they do not realize as they should, that while ordinarily a large air volume is highly desirable and necessary as a health and safety promoting agency, in conjunction with even a very insignificant blaze, it becomes the most potential force in the destruction of life.

The Delagua mine fire, that first killed 33 men by smoke and then caused a dust explosion killing 46 more, was evidently started by a piece of smoldering lamp cotton or by burning tobacco thrown away by one of the number of drivers who had been eating their dinner in the return end of a cross-cut closed by an unused door. A large volume of air was passing along the intake and its pressure on the door was considerable, with the result that jets of air were driven with great force through the cracks under and around the door from the intake into the return and the smoldering fire. Under the forceful impinging of the air the fire gained rapidly, and as soon as it had partially destroyed the door the air was short-circuited, the cross-cut and vicinity became a roaring furnace, the air rushing into it with such great force as to violently stir up the coal dust and carry it to the fire in such quantities as to cause the subsequent explosion. This disaster would not have occurred if the driver, who passed the cross-cut after the men had left it and who noticed some smoke there, had stopped and put out the yet insignificant fire. No doubt this driver had read or heard all about the sensational features of the Cherry calamity, but his reprehensible and culpable neglect to investigate and promptly extinguish the fire showed that he knew nothing of the instructive features of the Cherry lesson. It is possibly unjust to condemn this man too severely, and a large share of the moral responsibility for the accident must be assumed by the mine management, if it can be shown that the management, with a great lesson before it, neglected to profit by it and failed to make such preventive plans and arrangements as the lesson may suggest.

The fire in the Price-Pancoast colliery started in an underground engine room while the engineer was temporarily absent, and its exact cause has not been established. A brisk air-current was passing through the engine room. The management of the mine evidently recognized the possible danger from fire, for pipe lines were laid to different parts of the workings to provide a ready water supply in case of need and a tap was placed in the engine room. The arrangement, however, while commendable in a general way, proved not as effective for checking the fire as it should have been. A tap with hose attached located at the center or on the return end of a mine stable where the air flow is always in the same direction, with the air entering at one end and going out at the other, would be useless in fighting a fire that had started near the intake of the stable, and so it was a mistake to locate the tap in the interior of the engine room in the Pancoast mine where it could not be reached when most needed, on account of the fire and smoke. The logical location for the tap, if intended for available fire protection of the engine room, would have been at its intake opening near the sheave wheel. From the report I have regarding the fire, it appears that in this case, as in the Cherry and Delagua cases, the combustible material present and burned was only a factor of secondary importance, and that the most powerful and dangerous factor in spreading the fire so quickly was the strong draft passing through the engine room. The danger of this draft could have been greatly decreased by the erection of a door in the cross-heading (the air outlet) connecting the engine room with the turn out. The engineer, whenever required to leave the room for a few minutes, could then have closed this door and there would have been no excessive draft available to start a dangerous conflagration during his short absence, and, if on his return he found the engine room on fire, the tap at its entrance would have provided a ready water supply for instant and effective use.

The recent legislation in Illinois and Pennsylvania covering the fireproofing of shaft bottoms, underground stables, engine rooms, etc., is commendable, but at best it can only affect very small parts of any mine, parts, too, that by reason of location and through the advantage of having almost constant supervision, already have a greater measure of protection against fire than the less frequented interior mine workings and passages. The use of more or less timber and wood in mines cannot practically be dispensed with, and an air-current of high velocity must often traverse some parts of the mine in order to render other parts healthful and safe, and under such conditions there will still be danger that specific legislation like the above cannot be depended on to remove. Coal mines, the natural storage places of a vast fuel supply, cannot be made fireproof, but that does not mean, notwithstanding the occurrence of three disastrous mine fires in less than 2 years, that they are fire-traps, for I believe I am justified in saying that there is less danger to life from fire in the ordinary mine having fair care, than in many factory buildings and manufacturing establishments on the surface that have been examined and pronounced reasonably safe.

The most impressive and valuable feature of the combined lesson of the three mine fires is the fact brought out that forethought, preparedness, and timely action on the part of man constitute the best and most reliable safeguard against the occurrence of disastrous mine fires in the future, and the lesson also shows plainly the necessity and advantage of instruction and training of the mine worker to make him a dependable factor, and to accomplish this I suggest the enactment of a general law that, in addition to requiring the providing of certain safeguards of known merit, will direct that mandatory frequent instruction be given the mine employes regarding the causes of mine fires, their danger, their prevention, the manner of dealing with them promptly and effectively, and the arrangement for notification and withdrawal of the mine workers in case of danger.

The Waterfall Chute

*By Paul Sterling**

Introduction.—Among the various conveniences which have been introduced in the preparation of anthracite in recent years is the vertical step chute, known locally as the waterfall chute, or vertical telegraph. Paul Stirling, M. E., has described it so well under the heading "Chutes,"* and has interjected so much other good material on chutes, that it is reprinted from his paper on the "Preparation of Anthracite." The valuable features in connection with this kind of chute are the almost entire elimination of breakage, the saving in floor space, and decrease in complications that frequently necessitate the changing of machinery from place to place to make conditions that will aid chutes in carrying coal properly.—Editor.

Coal chutes are used to convey material from a higher to a lower point by gravity. If badly constructed, they cause a loss by degradation of size, which exceeds the combined losses

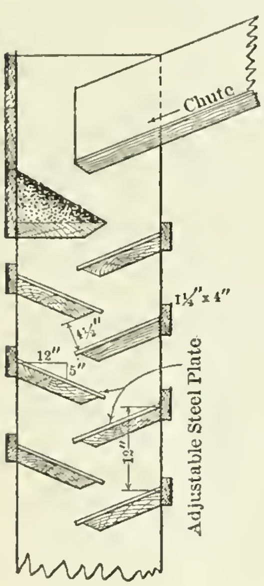


Fig. 1

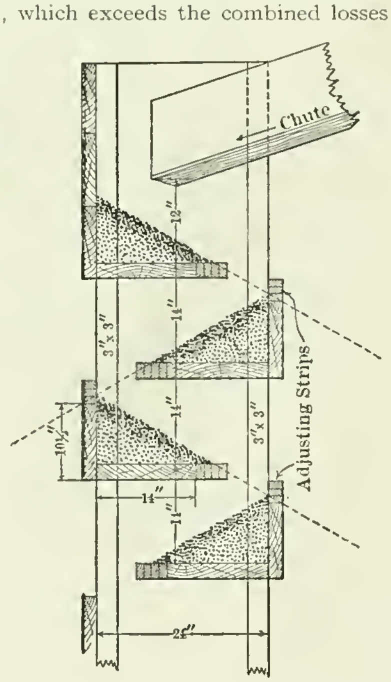

Fig. 2

from all other sources. The quality of coal varying, the pitch on which it will slide must be changed to suit local conditions. Clean coal will run on less pitch than the mud-screen mixture of coal and slate of the same size; hence, each particular chute must be built to accommodate the coal which it is to handle. The breakage of coal in gravity chutes may be attributed to the following sources: irregularities in the bottom of the chute; the striking of one piece of coal against another; drops at any point, especially at right-angle turns; and the blow which the coal receives at such turns when it runs against the side of the chute, or when one piece of coal strikes another. An ideal chute should eliminate the above features, thus reducing the breakage and increasing the mine-car yield.

Chutes may be divided into two classes, inclined chutes, and vertical telegraphs. The former are used to convey coal from a higher to a lower point not directly beneath the starting point, and the latter are used to lower coal vertically.

A proper chute is generally rectangular in cross-section, and of a pitch which will just allow the coal to start running after it has been stopped or held back. The corners or turns are banked or raised so that pieces will slide around without striking the sides and without drop. When the chute makes a 180-degree turn, a back switch is recommended, so that the coal may be brought practically to rest and the velocity reduced before starting down the pitch again. The following table gives the size of coal, the pitch in inches per foot of a chute for that size, and the width of the chute usually adopted. The lining of the chute is sheet steel for all sizes below broken. The lump, steamboat, and broken will slide on smooth cast-iron plates, inclined on the pitches shown.

Pitch and Width of Anthracite Chutes

	Pitch	Width
	Inches Per Foot	Inches
Lump	2.25 to 2.5	36
Steamboat	2.25 to 2.5	36
Broken	2.5 to 3	30
Egg	2.625 to 3.25	24
Stove	2.75 to 3.5	24
Nut	3 to 4	18
Pea	4 to 5	12
Buckwheat	4.5 to 6	12
Rice	5.5 to 6.5	12
Barley	7 to 8	12
Dirt	8 and over	12

After steel-lined chutes have been installed in a breaker, it is sometimes found that the coal blocks at certain places by reason of lack of pitch. When it is not practical to change the pitch of the chutes, the steel lining may be replaced with bronze, or sometimes with glass, on which the coal will run at a much lower pitch. A test made in a bronze-lined chute 18 inches wide showed that, for the passage of 2 tons per minute the following pitches were required: For egg, 2.75 inches; for nut, 3.75 inches; and for barley, 4.2 inches.

The vertical telegraph consists of a wooden box-shaped pipe, shown in Figs. 1 and 2, with openings on two sides, and a series of shelves inside. The telegraph shown in Fig. 1 is used for lowering coal alone, and for that reason has shelves inclined toward the center. Each shelf is covered with a steel plate so arranged that the opening inside between shelves may be contracted or enlarged by adjustment of the plate. The openings on the side permit of observation and if so desired the breaker boss can examine the quality of coal passing through the chute, which in this case is open at both ends.

The second type of vertical telegraph shown in Fig. 2 has the same outside construction, but has shelves at right angles to each other and larger openings on two sides. This arrangement of shelves and openings permits the use of this telegraph for filling coal pockets, since as the apex of the coal in a pocket increases it blocks one lower hole in the side and causes the flow of coal to take place from the next higher hole in the chute. The coal forming on these shelves forms a slope down which the following pieces of coal roll with the smoothness of water. Tests show that when anthracite rolls down on a pile of similar coal, the velocity is uniform and the breakage practically nil; and this telegraph was designed upon that principle. The shelves are so spaced that a line tangent to the angle of repose of the coal on any shelf will be tangent to the back of the opposite shelf, so that the coal will roll down the telegraph until the filling of the pocket blocks the bottom opening, when the coal will roll down on the tangent line and discharge through a side opening.

Tests of this style of telegraph show very little loss—generally under 1 per cent. when properly constructed. They are used for all sizes up to and including egg coal. They may be of any height. The writer has designed one of large capacity (300 tons per hour) 65 feet high. The capacity for a 24-inch square telegraph is about 150 tons per hour; for a 48-inch square, about 300 tons per hour. The capacity is directly proportional to the width.

British Rescue and Aid Order

Text of Proposed Order Concerning the Establishment of Rescue Stations at British Mines

A draft of an order which the Secretary of State of Great Britain is proposing to make under the Mine Accidents (Rescue and Aid) Act, 1910, is as follows: The draft order gives effect, with some drafting alterations, to the unanimous recommendations of a departmental committee (including representatives of mine owners and miners) which was appointed to frame proposals for an order under that act, and whose report was recently presented to Parliament (Cd. 5550). In accordance with the requirement of the act, the order is issued in the first instance as a draft. If within 40 days from this date a general objection is made to the order, that is, an objection made either by or on behalf of owners of mines employing not less than one-third of the total number of men employed at the mines affected by the order, or by or on behalf of not less than one-third of the total number of men so employed, the objection will, under the statute, be referred to a referee agreed upon by the Secretary of State and the objectors, or, in default of agreement, appointed by the Lord Chief Justice of England.

In pursuance of Section 2 of the act, the Secretary of State gives the following notice:

That he proposes to make an order requiring provision to be made at all mines to which the Coal Mines Regulation Act applies and in which coal is worked, in regard to the supply and maintenance of appliances for use in rescue work, and the formation and training of rescue brigades, in accordance with the enclosed draft, copies of which may be obtained on application to the Home Office; and that any objection with respect to the draft order by or on behalf of any person affected thereby must be sent to the Secretary of State within 40 days from this date. Every such objection must be in writing, and must state:

(*a*) The specific grounds of objection; and

(*b*) The omissions, additions, or modifications asked for.

In pursuance of Section 1 of the Mines Accidents (Rescue and Aid) Act, 1910, I hereby make the following order:

1. This order shall apply to all mines in which coal is worked; provided, however, that the Secretary of State may, if he thinks fit, exempt from the order any mine at which the total number of underground employes is less than 100 if the mine is so situated that in the opinion of the Secretary of State the organization of a central rescue station from which it could be served is impracticable.

2. No person, unless authorized by the manager or official appointed by the manager for the purpose, or, in the absence of the manager or such official, by the principal official present at the surface, shall be allowed to enter a mine after an explosion of firedamp or coal dust, or after the occurrence of a fire, for the purpose of engaging in rescue work.

3. (*a*) There shall be organized and maintained at every mine, as soon as is reasonably practicable, competent rescue brigades on the following scale:

Where the number of underground employes is less than 250, one brigade.

Where the number of underground employes is more than 250 and less than 500, two brigades.

Where the number of underground employes is more than 500 and less than 800, three brigades.

Where the number of underground employes is more than 800, four brigades.

But the owner, agent, or manager of a mine, at which the total number of underground employes is less than 100, shall bé deemed to have complied with this provision if he has acquired the privilege of calling for a brigade from a central rescue station.

(*b*) A rescue brigade shall consist of not less than five persons employed at the mine, carefully selected on account of their knowledge of underground work, coolness and powers of endurance, and certified to be medically fit, a majority of whom shall be trained in first aid and shall hold a certificate of the St. John's Ambulance Association, or of the St. Andrew's Association.

(*c*) There shall be selected from the ranks of each rescue brigade one person or leader who shall act as captain of the brigade.

(*d*) A brigade shall not be deemed competent unless (1) it undergoes a course of training approved by the Secretary of State; (2) after the preliminary course of training it undergoes in every quarter at least 1 day's practice at the mine with breathing apparatus; (3) the members of the brigade shall have received instruction in the reading of mine plans, in the use and construction of breathing apparatus, in the properties and detection of poisonous or inflammable gases, and in the various appliances used in connection with mine rescue and recovery work.

(*e*) Arrangements shall be made at every mine for summoning members of rescue brigades immediately when their services are required.

(4) If it can be clearly proved that the necessary number of persons employed underground at a mine will not consent to form a brigade or brigades, or having offered their services fail to be trained or maintain their training, the owner, agent, or manager of the mine shall not be liable to any penalty, provided first, that he has endeavored to the best of his ability to constitute the requisite brigade or brigades, and has afforded every opportunity to the persons employed at the mine to undergo the necessary training; and secondly, that he has made a bona fide attempt to arrange for the supply from a central rescue station of such rescue brigades as he is unable to provide at his mine.

5. (*a*) There shall be provided and maintained at every mine sets of portable breathing apparatus in the proportion of two sets to each brigade required by Section 3 (*a*). The apparatus must be capable of enabling the wearer to remain for a least 1 hour in an irrespirable atmosphere, and must be kept ready for immediate use. The apparatus must be housed in suitable receptacles in a dry and cool room.

The owner, agent, or manager of a mine shall be deemed to have complied with this requirement if he has acquired the privilege of calling for such of these appliances as he may not possess from a central rescue station, always provided that the central rescue station is situated not more than 10 miles by road from the mine and is in telephonic communication with the mine.

If it can be shown that it is not possible, at the date of this order, to procure the aforesaid breathing appliances, owing to lack of supply, the owner, agent, or manager shall be deemed to have complied with this order, if he procures such appliances as soon as is reasonably practicable.

(*b*) There shall be kept at every mine tracings of the workings of the mine up to a date not more than 3 months previously, showing the ventilation and all doors, stoppings, and air crossing and regulators, and distinguishing the intake air by a different color from the return air, which tracings shall be in a suitable form for use by the brigades.

(*c*) There shall also be provided and maintained at every mine which maintains a rescue brigade or brigades:

1. Two or more small birds or mice for testing for carbon monoxide.

2. Two electric hand lamps for each brigade, ready for immediate use and capable of giving light for at least 4 hours.

3. One oxygen reviving apparatus.

4. A safety lamp for each member of the rescue brigade for testing for firedamp.

5. An ambulance box provided by the St. John's Ambulance Association, or similar box, together with antiseptic solution and fresh drinking water.

6. There shall be kept and maintained in every central rescue station not less than 15 complete sets of breathing apparatus, with means of supplying sufficient oxygen or liquid air to enable such apparatus to be constantly used for 2 days, and of charging such apparatus; and 20 electric hand lamps; four oxygen reviving apparatus; an ambulance box or boxes, provided by the St. John's Ambulance Association, or similar boxes, together with antiseptic solution and fresh drinking water; cages of birds and mice; a motor car shall be kept in constant readiness.

7. Every central rescue station shall be placed under the immediate control of a competent person conversant with the use of the appliances.

8. There shall be adopted at every mine such rules for the conduct and guidance of persons employed in rescue work in or about the mine as may appear best calculated for the carrying out of rescue operations, and the rescue brigade or brigades, if any, maintained at the mine shall be thoroughly instructed in such rules.

9. "Central rescue station" means a station established to serve several collieries.

Trade Notices

The Union Iron Works Co., of San Francisco, Cal., has purchased the business and good will of the Risdon Iron Works. They will continue to manufacture the line of dredging, mining, milling, and power machinery for which the Risdon Iron Works was well known and will give especial attention to the manufacture of water-tube boilers, hydraulic machinery, gold dredges, oil-well drilling tools, etc. The Union Iron Works is prepared to furnish spare parts and repairs for all Risdon machinery in service and is equipped for handling any kind of heavy machinery work.

An Electric Forge Blower.—The Sirocco electric forge blower is made in three sizes, the largest one being capable of caring for five fires. Because of the high mechanical efficiency of the new Sirocco turbine type wheel the electric current consumption for the smaller size, suitable for single light fire, is less than half the current consumed by an ordinary electric lamp. The larger sizes are relatively of equal efficiency. There are no belts or pulleys, and the Sirocco patented wheel being set-screwed to the motor shaft, there are only two bearings on the entire machine. They have high mechanical efficiency, hence small current consumption, are quiet running, and give a large volume of air at ample pressure to overcome resistance of tuyere and fire, and are smooth in operation, due to extremely small diameter of runner. They are manufactured by the American Blower Co., of Detroit, Mich.

Coal Washing Plants.—The Roberts & Schaefer Co., engineers and contractors, of Chicago, have closed a contract with the Nicola Valley Coal and Coke Co., of Vancouver, B. C., for the designing and building, complete in operation, of a 500-ton Stewart coal-washing plant for installation at their mine at Merritt, B. C., at an approximate contract price of $40,000. They will also install a large coal-washing plant at Rathburn, Tenn., for the newly reorganized Durham Coal and Iron Co. The approximate contract price will be $75,000.

The Oklahoma State School of Mines Laboratory.—The contract for the equipment for the new Oklahoma State School of Mines, to be located at Wilberton, has been awarded to the Allis-Chalmers Co. The plant covers a complete equipment for an ore-dressing laboratory consisting of Blake, Dodge, and Gates type of crushers, a Bridgman automatic sampler and sample grinder, a tube mill, steam drying pans and ore-bin fixtures, three elevators and a set of three screens with feeders, a feeder and two sets of rolls; a concentration section consisting of five-compartment, three-compartment, and two-compartment jig, two-spigot Richards hindered settling classifier, a Callow pulp-thickening tank, two small size concentrating tables and a Frue vanner, together with necessary pumps; a gravity stamp section consisting of feeder and gate, five 500-pound stamps, copper table, amalgam trap, and pumps; 3½-foot Huntington mill with feeder and gate, copper table and amalgam trap; 30-inch amalgamating pan, dewatering cone, clean-up pans, pumps, etc.; a chlorination plant consisting of precipitating, storage, and settling tanks, lead-lined chlorination barrel and fixtures; a cyanide plant consisting of solution tanks, leaching tanks (one with mechanical agitator), gold tanks, sump tanks, filter boxes, pump and fixtures; a magnetic separating plant consisting of Dings magnetic separator and detail equipment. The total cost of this plant erected will be approximately $25,000 and will represent one of the most complete laboratory equipments in that section of the country.

Safety Lamps and Apparatus.—To operate successfully a large mine entirely by locked safety lamps requires system, care, and a considerable labor. In England, many mines are so operated, and much attention has been given there to the equipment of them with dependable safety lamps and machinery for cleaning, filling, locking, and relighting with special relighters or in safety stations underground. A catalog recently issued by Ackroyd & Best, Ltd., Morley, near Leeds, England, describes different styles of safety lamps, with magnetic and other unlocking apparatus, Hailwood's underground relighters, lamp racks, and oil tanks, as well as lamp cabins equipped complete with lamps and labor-saving machinery suited to the care of the lamp equipments of the largest mines. Messrs. Ackroyd & Best have an American office at No. 2 Arrott Power Building, Barker Place, Pittsburg, Pa.

The Metallic Flexible Tubing Co. announce that all their patent rights, stock, machinery and fixtures are transferred to Mulconroy Co., Inc., 722 Arch Street, Philadelphia, manufacturers of flexible metallic hose and tubing. The name and registered brands will be continued. The Mulconroy Company has improved and additional machinery to manufacture all kinds of flexible metallic hose and hose coverings, and a centrally located factory.

Christy Box-Car Loaders.—A number of mining companies have recently installed Christy box-car loaders at their mines. Among these are the Lilly Coal Co., of Altoona, Pa., for their Lilly mine. The Consolidated Fuel Co. have purchased two improved loaders for their Hiawatha, Utah, mine. These two will load two grades of coal simultaneously on different tracks. The St. Louis and O'Fallon Coal Co., of East St. Louis, have installed a semiportable loader at their No. 2 mine. An order has also been received for a large portable dock loader to be used on the new dock at Manitowoc, Wis. This dock is operated by the C. Reiss Coal Co., of Sheboygan, and this is the second Christy loader used by that company.

Steam and Air Specialties.—A catalog describing gauge-cocks, water gauges, pressure regulating valves, and other steam specialties has been issued by the Ohio Brass Co., Mansfield, Ohio. It is sent free on request.

Copper Wire, for trolley lines and the transmission of electrical currents, manufactured by the Hazard Mfg. Co., of Wilkes-Barre, Pa., has won a high reputation on account of trueness to gauge and its high conductivity. Unless otherwise specified it is thoroughly annealed. When insulated wires and cables are desired for any purpose, and especially for mine use, the insulation is such as to maintain the high standard of excellence which has won for Hazard products an enviable reputation.

Removal.—The C. S. Card Iron Works Co., of Denver, have moved to their new shops on Alcott Street, where they now have a most complete and modern works devoted exclusively to the manufacture of coal-mine equipment. The shops include foundry, forge, sheet iron, machine, and car shops, all provided with cranes and industrial railways for the economical handling of material. These improvements enable them to take care of all requirements promptly and in a careful manner.

Coal Dust and Zone Systems

A Criticism of the Report of the Commission on British Coal Dust Experiments

By E. O. Simock

In the Transactions of the Institution of Mining Engineers, E. O. Simock publishes a paper on the "Prevention of Coal Dust by the Zone Systems," of which the following is an abstract:

Among the means of staying the inflammable propagation set up during a coal-dust explosion, zone systems are now taking a prominent place; and these remarks question whether there are sufficient facts available to enable a sound opinion to be expressed as to their practical utility.

The precise conditions and requirements for inflammable propagation are not exactly known, but an hypothesis may be deduced from the observations of many careful investigators who, during recent years, have given much attention to the subject.

Most of the theories advanced assume an instantaneous action throughout the mine, but this is untenable, for there is absolutely no evidence that natural coal dust *per se* is explosive. It must be mixed with an oxygen derivative, and in this case, the oxygen derived from the atmosphere. That the dust must be mixed intimately with the atmosphere after the explosion has commenced is shown by the fact that during normal working conditions there is insufficient dust floating in the air to support this inflammable propagation, and the theory of the pioneering action of the air stirring up the dust, gives a good general explanation as to the second essential to the continuous action.

The first essentials are the reactionary materials, in this case there must be a large amount of intimately mixed fine coal dust in suspension in the air. This intimate mixing of air and coal dust must be part of the general phenomenon pertaining to this propagation of combustion. Under these circumstances, it may be taken as an axiom that, after the initiation, the flame or heat does not advance first, but follows the stirring up action. But there would be no pioneer air movement without a difference of pressure being set up and maintained by the heat generated during the reaction. These two actions are mutually dependent and the cessation of one will stop the other.

The question is, will zones, wet or dry, dustless or treated with inert dust, stop the pioneering air wave; or, alternatively; will they stop the reaction of combustion?

Mr. Hodges champions the dry, dustless zone; Mr. Henshaw argues the case for the wet zone, and strongly supports the opinion as to the action of inert dust. Both have made extensive observations of the after results of explosions, and base their arguments upon what they have respectively observed.

In the instance given by Mr. Hodges† of a dustless zone stopping the propagation of the Blackwell explosion on October 11, 1895, the evidence upon which this assumption is based requires careful reconsideration, for the conclusion does not seem to be warranted. The fact of there being no dust in this length of roadway may have conduced to the prevention of propagation in that particular direction; but if other factors had not been present, it is doubtful whether this alone would have prevented the explosion from extending beyond the downcast shaft.

The incident under review occurred in a road in Blackwell colliery of which Fig. 1 is an approximate plan. The arched road is not in line with the road whence the explosion traveled, and the deviation commenced at a place that formed the junction of four roads. Owing to this bend in the road, the force would largely expend itself in attempting to maintain a straight line. There would be a rebound, and this rebounding wave would materially conduce to the stoppage of the explosion in that direction. Coupling this with the fact that there were two other roads open for the explosive force or wave to take, the assumed value of the dustless arch is considerably weakened.

What effect a rebounding action has in stopping an explosion is well shown by what occurred in the breakthrough connecting the intake with the main return. In this breakthrough three doors were blown down, but the propagating wave traveled no further in that direction. This was attributed to the non-inflammable nature of the dust; but it has been shown that dust containing 80 per cent. of inert material will support propagation, so that this conclusion cannot, without further evidence, be sustained.* The force required to break down these doors would have to be transmitted through the air. This compressed air would receive a check when it came in contact with the doors, and this would cause a backward moving wave which would be strong enough to stop or "blow out" the inflammable wave.

Corroboration of this action is found in the Denny explosion,† where the propagating wave was stopped by the rebound set up at a door. Further confirmation is shown in the case of the Talk-o'-th'-Hill colliery explosion of May 27, 1901. At a point *a*, Fig. 2, close to where a sample of dust was taken, there was a pair of doors, and at or about this point the propagation ceased. In this case the rebounding action may have been enhanced by the fact that the workings, which are pillar-and-stall, did not extend very far beyond this point, which would materially help quick compression.

That this rebounding action is a great deterrent of propagation can be gathered from the fact that the lives of men working

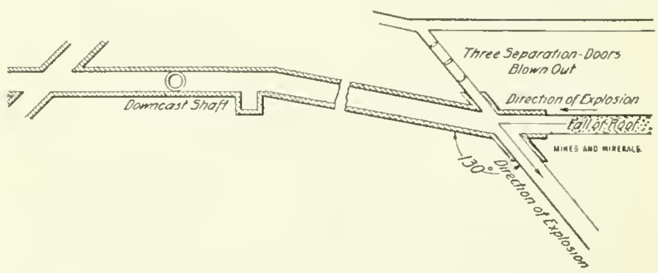

Fig. 1. Part of Workings at Blackwell Colliery

at the face in blind headings have been saved, although the explosive wave had entered the heading; but had been unable to reach the face; owing to the backward action of the compressed air.‡

Applying this fact to the various actions which occurred in the case of the Blackwell explosion at the junction of roads, as illustrated in Fig. 1, it will be seen that what happened can be reasonably explained without reference to the dustless condition of the arched length of road. A rebounding action would be set up both at the commencement of the bend in the arched road and at the doors in the breakthrough at the moment of impact, and this rebound, plus the remaining energy in the explosive wave, would find a vent by passing into the southwest road. The southwest road is about the natural line that a force would take as the result of the three mentioned; so that to this dustless arch is given credit which does not belong to it.

A. M. Henshaw's opinion§ is that 100 yards of wet roadway will stop an explosion, and in his opinion, explosions have been stopped by wet roadways of less length. On the other hand, W. W. Hood, in his evidence,|| states that at Clydach Vale colliery the explosion on March 10, 1905, traveled along 700 yards of well-watered, closely timbered roadway, and that

† Report of the Royal Commission on Mines, 1908 [Cd. 3,873], Vol. II, page 62.

* See discussion later.

† Report of the Royal Commission on Mines, 1908 [Cd. 3,873], Vol. II, page 228.

‡ Editor's Note.—See "Primero Explosion," Mines and Minerals, March, 1910; "Delagua Explosion," Ibid., 1911.

§ Report of the Royal Commission on Mines, 1908 [Cd. 3,873], Vol. II, page 14.

|| Ibid., page 100.

10 days after the explosion the timber in this road was still found to be wet. It has been contended that along this length of roadway the explosion was fed by gas and dust, blown from over the timber. Such an argument lacks corroboration, for there seems to be no record of gas having been found above this timber, either before or after the explosion. Then, as regards dust, if there were any present, the fact that it was not in the path of the current would tend to preserve it from disturbances by the pioneer air wave, and if disturbed by the disruptive effect of the main reaction, it would then only serve as a palliative. W. Armstrong, the manager of Wingate Grange colliery at the time of the explosion on October 14, 1906, records in his evidence* that the explosion, which was one of dust initiated by explosives, traveled over 200 yards on a damp and dustless roadway.

If a wet, well-timbered length of road of these proportions will not stop an explosion, it is doubtful whether an arched zone—wet or dry—will be more effective, for, in this case, there would be less resistance to the dust-laden air, as the smooth cemented sides and roof will help the dust traveling in the

Fig. 2. Part of Workings of Talk-o'-th'-Hill Colliery

pioneering air-current to pass quickly along the zone, thereby setting up conditions favorable to the propagation of combustion in the zone itself.

The system of zones, advocated by A. M. Henshaw in his evidence before the Royal Commission, is the best system promulgated, but, having regard to the possible long intervals between the zones, it is doubtful whether such a system would have a great deterrent effect. The distance between the zones is about 400 yards; and, presuming this length to be dry and dusty, it is probable that the pioneering action will be so developed that its velocity will be sufficient to force a mixture of air and dry dust into and through these zones.

In the Blackwell case the explosion traveled about 400 yards before reaching an arched dust-free zone, where two other roadways met. Consequently, owing to the largely increased sectional area which the initial pressure had to cover, the pressure per unit of area would drop, and as a result, notwithstanding this drop there was sufficient power and heat left to take the propagating action round the very sharp bend into the southwest road beyond the arching therein, and to start the dust-and-air reaction there. If there had been no great variation in the area, and only the one road for the explosion to take, there is no reason to suppose that the pioneering action was not carrying forward sufficient dust to allow the explosion to travel to the shaft or beyond.

The disaster at the Marianna Mine of the Pittsburg-Buffalo Coal Co., Washington County, Pa., on November 28, 1908, showed what occurs during an explosion when the roads are of equal section and there are no other differentiating circumstances. This colliery was only being developed, and all the roads were in the fast coal, so that a large accumulation of dust is improbable. An efficient water supply was laid throughout the mine, and all conceivable precautions were taken. The mine inspector had completed a careful inspection of the mine but half an hour prior to the explosion, and was satisfied with all that he saw. Yet, notwithstanding the wet roads and no noticeable evidence of a dangerous accumulation of dust, the mine was devastated. Had there been a stoppage of the explosion following on a drop in pressure, owing to a sudden enlargement of the sectional area, it is presumed that the water treatment to which these roads had been subjected, would have received the credit; but, as a matter of fact, the roadway from face to shaft was practically one wet zone, which failed to stop the inflammable propagation. Therefore, in the writer's opinion, further evidence of the practical value of wet zones is required before such methods are adopted.*

There remains the hypothesis as to the stone-dust or inert-material zones, which are now being advocated as a result of the coal dust experiments at various stations. Zones of this description were suggested by Conrad Gautsch, of Munich, in 1896. He later took out letters patent in this and several other countries for such zones, proposing to use boracic acid as a deadening substance, but he did not confine himself to the use of any one substance. The present exponents of this hypothesis base its claim upon observations after explosions, where such explosions have apparently been stopped, owing to the augmented dirt or ash contents of the coal dust. Although the experiments at some of these experimental stations seem to show† conclusively the hypothesis to be an actual fact, yet, when the evidence is carefully examined, it will be seen that there is little upon which a claim for practical utility can be based. The advocates of the theory have a fair number of disciples. Several have expressed the opinion that inert material, in lieu of water, would be efficacious, and such opinions have been expressed and recorded by others many years ago, but simple assertions without evidence in support on such a question are not convincing arguments.

It is almost a universal opinion that the distillation and combustion of the volatile matter of the coal dust is the cause of propagation. The merits or demerits of this opinion the writer does not wish to enter upon, but it is mentioned here to show that the inert-dust theory and this theory are at variance.

Assuming that the volatile matter is the cause of propagation, then, if the dust with the least percentage of volatile matter that has allowed propagation to proceed is taken as a standard of comparison, it will be seen that there must be a reconsideration of one theory or the other. Taking the dust of the Albion colliery, which was the cause of one of the most disastrous mine explosions in this country, and comparing the percentage of volatiles with any of the percentages of volatiles given in the two sets of analyses, it will be found that, with two exceptions, their volatiles are much higher. The volatiles in the dust of the Albion colliery were only 14.1 per cent., yet in the case of the Courrieres explosion a dust containing 22.25 per cent. of volatiles is said to have arrested the explosion; and in the case of the Talk-o'-th'-Hill explosion, the dust at *b*, Fig. 2, containing 21.37 per cent. of volatiles is said to have stopped it. There seems to be something anomalous here, and either one or the other theory is wrong, or possibly both. The two exceptions mentioned are in the list of the Talk-o'-th'-Hill dust analyses, and are as follows:

* Report of Royal Commission on Mines, 1908 [Cd. 3,873]. Vol. II, p. 100.

*Editor's Note.—See United States Bulletin 425, also Record of First Series British Coal Dust Experiments.

† See "Shale Dust and Coal Dust Tests at Broxburn," by Robert McLaren and William Clark, Tran. Inst. M. E., 1909, Vol. XXXVIII, page 362.

No. 3. Coked dust, 8 feet level, from the flanges of a girder in the roof, outby side: Carbon, 36.05; volatiles, 9; ash, 54.95.

No. 4. Coked dust from the same girder, inby side: Carbon, 24.90; volatiles, 13.95; ash, 61.15.

The coked condition of the dust is taken as evidence that the inflammable wave passed that way, and had this condition not been in evidence, presumably it would have been assumed that the action had ceased there, owing to the dirt contents of the dust. Prof. W. Galloway, however, mentions a case, in his lectures on mining,* in which the inflammable wave passed along a road without leaving any evidence of its passage in the shape of coked dust, and he attributes this want of coherence to the shale dust and other impurities present. The writer believes that somewhat similar observations were made at West Stanley colliery. In some experiments with dust which would coke in mass, the writer observed that if it were traveling at a fair velocity, it did not cohere, although it was subject to temperatures ranging from 390° to 1,650° F. (200° to 900° C.). This dust was not impure, but it was rather dry, and it may be that the difference of moisture contents and the fact of its not being quiescent will account for the difference in coking ability. Impurities, of course, unless fluxible, will largely prevent coking or coherence. The presence and condition of the dust on the girder is negative evidence, both of high velocity and of high temperature, and direct evidence that it contained moisture.

A covering note to the table of analyses of the Talk-o'-th'-Hill dust says:

"The figures show that roads which contained dust with ash up to 31.75 per cent. were traversed by flame. The explosion was stopped where the dust contained 44.73 per cent. of ash, as at *b* Fig. 2, and possibly by 39 per cent. of ash, as at *c*."†

The two last-named dusts, however, contained respectively 21.37 and 24.15 per cent. of volatiles, as compared with 14.1 per cent. of volatiles contained in the dust of the Albion colliery, which allowed propagation to proceed. It is also interesting to compare the ash contents of samples taken at *b* and *c* with those of Nos. 3 and 4. It is impossible to reconcile the apparent fact that in one case 39 per cent. of ash stopped combustion, and in another, combustion proceeded with over 60 per cent. of ash.

By a reference to Fig. 2 it will be seen that the explosion stopped some distance outby from the place where sample *b* was taken—at a point where there was a pair of doors. Beyond this point inby, the workings were of small extent, and practically a cul-de-sac. These facts, combined with that of the resistance set up at the doors, would be sufficient to explain why the explosion ceased at that point, although the dust contained sufficient volatiles to allow propagation. They do not, however, explain why the explosion did not travel far up Shaw's Dip, which was on the outby side of the doors. It will be seen that Shaw's Dip represents one side of a rhomboid, the four sides of which are the main level, Bodge's Dip, Paskin's Level, and Shaw's Dip. The explosion stopped a short distance along Paskin's Level. The explosion entered at the junction *d* and the propagating action continued along the main level and started up Shaw's Dip, in addition to continuing along the main level to the doors near *a* which stopped in that direction. The wave going up Bodge's Dip divided at the junction with Paskin's Level, the one part continuing up the dip and spreading to workings beyond, and the other entering the level and stopping at about the same distance in the level as in Shaw's Dip. These two points are about equidistant from where the pioneering action entered the rhomboid, and the two wave forces, which would be of about equal magnitude, were opposed to each other. Therefore, the axiom, that when two forces of equal magnitude are opposed they will neutralize each other, is well illustrated, for the explosion ceased in both directions. Of the four routes taken by the explosion in this part of the mine, in three it met with opposition sufficient to stop the action; but in the fourth route, meeting with no check, it spread to the workings beyond. There is nothing therefore in the observations in connection with the Talk-o'-th'-Hill explosion which will substantiate the inert-dust hypothesis.

W. E. Garforth based the inert-dust theory upon observations after the Altofts colliery explosion, which occurred in 1886. He does not record any dust analyses, but assumes that, as the explosion did not in any case reach the coal face, it must of necessity have ceased through the non-inflammable nature of dust. A glance at any of the published plans of the workings of the Altofts colliery affected by the explosion will show that the coal face is practically the circumference of a circle, connected to the shafts inside that circle by radial roads. The explosion passed up these roads toward the face or circumference, and, as there was no outlet, each line of force tended to meet and oppose the others. Thus, each force traveled onward inby until met by an equal, or stronger, opposing force, and so was stopped.

Here, then, are similar explanations—without reference to lengths of roadway containing inert dust—of the stoppage of the two types of explosions upon which the modern theory of the inert-dust remedy is based, and any argument showing that these explanations are incidental and the similarity coincidental will be awaited with interest.

It has been remarked that the theory of the propagation of combustion due to distillation of the volatiles contained in the coal dust, or the theory of inert material, or both, are anomalous. It has also been observed, from a comparison of coal dust responsible for an explosion with dust collected after an explosion, that the first contained less volatiles than remained in the second.

This evidence seems to point to the carbon constituent of the coal as being the principal cause of the propagation of combustion. Assuming the truth of this, if it could be shown that a mixture of inert material, carbonaceous matter, and free oxygen or air would not burn, or allow the propagation of combustion to proceed, then it might be said that zone systems, based upon this inert-material theory, have a substantially practical basis. There are, however, many every-day examples which are evidence to the contrary, and one of these may serve to demonstrate the futility of the application of inert material.

In the North Staffordshire and other mining districts, there are heaps of burning pit debris. It is doubtful whether any of these contain more than 10 per cent. of inflammable material —in the writer's opinion, 5 per cent. would be more accurate— yet combustion proceeds. The difference between the inflammable material in the heap and that found on the roadways of a mine is one of degree of fineness only. Therefore if such material be reduced to the requisite fineness, and floated in the air in sufficient quantities, it is doubtful whether it can be proved that this would not burn with sufficient rapidity in a semi-enclosed place, such as a mine roadway, to produce explosive violence.

The recorded experiments of Captain Desborough,* showing that dusts containing 80 per cent. of inert material are capable of supporting the propagation of combustion, even in a tube of small diameter, must be taken into consideration; and this fact, taken in conjunction with the practical impossibility of totally eliminating coal dust from any given length of haulage road, makes it evident that any zone system so far suggested is unreliable.

The discussion on this important paper which brings out some interesting points will be printed in an early issue of Mines and Minerals.

Oils for Lubrication

The Action of An Oil in Preventing Friction. Qualities Necessary and Methods of Testing

*By C. E. Ward**

All are aware that the metal bearing can absorb a great amount of frictional heat but cannot free itself of it as fast as generated; therefore, a lubricant with a fire test far above the normal temperature of the bearing is applied so it can absorb and carry away the frictional heat, and thus keep the bearing in normal conditions.

If the oil or lubricant be of low fire-test the result is a hot journal. A high fire-test oil does not mean a cylinder oil of 600° F. to 650° F., as this class of lubricant on a rapidly moving journal would cause as much trouble as a low fire-test lubricant, for, it being heavy and viscous, it could not readily flow over the rapidly moving parts, and if a square inch of the surface, or even a very much smaller area were not covered, friction would immediately increase the temperature of the bearing, and if not carefully attended to would result in a hot bearing.

Have any of you given it a thought while you were riding in a railroad train that you were riding on oil? As a simple illustration of how friction and how lubrication act, rub the hands while in a dry state rapidly together, and feel the heat generated; next soap them or drop some oil on them and one hand will glide over the other and become cool almost immediately, thus overcoming the friction. If water should be applied the hands would become cool, but would not move on each other readily. Should any pressure be applied they grit on each other, showing conclusively that while water is an excellent cooler it is not a lubricant.

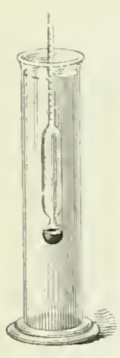

Fig. 1. Baumé Hydrometer

As everything depends upon the successful turning of the wheels around a mine, mill, railroad, steamboat, and in fact every mechanical device, it is necessary to overcome friction with the proper lubricant or operation would be at a standstill.

The greatest expense around coal mines is the lubrication of the mine cars, still this lubrication is often left to boys, who think all they have to do is squirt the oil at the wheel on the sides of cars and use it up as fast as possible or the boss won't think they are doing their work. Evidence of this is seen along the track where oiling is done; four or five times more oil is used than is necessary to run the cars successfully if the oil is properly applied.

The wheels used are also factors in poor lubrication. The method of carrying the oil in a receptacle between the spokes is objectionable in my opinion, for when a wheel revolves at the rate of 2 miles per hour with a thin limpid oil the centrifugal motion throws the oil away from the axle, and while the wheel is in motion it gets no lubricant. If some one would get up a practical wheel that could be lubricated with grease in the winter months as well as summer, and a device that would feed the grease gradually to a journal without generating any heat to liquify it, it would solve the question of the greatest expense of lubrication around the coal mines. The cost of pit-car oil to one company is as high as $1\frac{9}{10}$ mills per ton, while all other lubricants average $\frac{6}{10}$ of a mill per ton of coal mined.

Very often oil is condemned unjustly, not that the oil company is infallible, but in many cases good oil is condemned. For example, take wheels with 2-inch axles under a car which weighs loaded 4,000 pounds. Each axle sustains a weight of 1,000 pounds on an area on its under side of $\frac{1}{8}$ in. × 6 in. long, or, carrying on $\frac{3}{4}$ of a square inch 1,000 pounds. The best authorities state that oil will not pass between two surfaces under pressure of more than 800 pounds per square inch, unless forced there. Many operators have increased the capacity of the car bodies, never giving the axle or the weight of the wheel any thought; as a sequence, the axles are flattened on the under side owing to the excessive weight and the two metals coming in contact tear particles from each other, thus reaming out the wheel and further injuring the axle. Then a new wheel is put on the flat axle and in a very short time this wheel is reamed out and the oil is blamed. Bent axles are placed frequently under heavy loads, and a bent axle will ream out a wheel in a very short time, and the oil is the cause again to the uninitiated. In many cases where the oil is unsatisfactory, it will be found due to some mechanical defect when one sifts the complaint down. There are cases where the oil is at fault, but in every instance thus far that has come under my observation, where the oil was at fault a mistake was either made in the shipment or it was improperly used. In several instances where they were having trouble lubricating the cylinders of a hoisting engine, investigation showed that pit-car oil was being used, and this, being low in fire test and having no admixture of animal or vegetable oils, did not emulsify and coat the walls as would a properly compounded oil.

To ascertain whether an oil is suitable for the purpose it is to be put to it is subjected to tests.

Viscosity is the degree of fluidity of an oil or the ability to adhere to: viscos; sticky. By comparing the viscosity of one oil with another which has been giving good results in practice, a test is made with a viscosimeter, a number of which are on the market; but as one cannot always have these instruments in the engine room, a simple method to test the viscosity of one oil with another; i. e. (this will only apply to engine oils), is to take a medium piece of glass, place on an incline, then place a drop of each kind of oil side by side on the glass at top. The oil that reaches the bottom first is the less viscous.

Viscosity is the first thing to be considered, as the most fluid oil that will do the work and stay in place is the best engine oil. The viscosity is generally taken at 70° F. to 100° F., which compares with the temperature of the average bearing, while the cylinder oils are tested at 212° F., or boiling point of water.

The writer, in testing cylinder oils, heats the oil to 338° F., which is the temperature of the steam at 100 pounds pressure. In making a number of tests it was found that cylinder oils from a petroleum with an asphalt base will stand up in viscosity with the best of Pennsylvania cylinder oil at 212° F., but go all to pieces at 338° F., hence the reason of testing at 338° F., or the temperature at which it is used.

The standard of specific gravity is water and the specific gravity of oil is the weight of the oil compared with water. It is readily obtained by the use of the Baumé hydrometer, Fig. 1. The temperature is taken at the time, in case it is not 60° F., and for every 10° F. subtract 1° B. from the hydrometer, if it be above, and add 1° B. for every 10° F., below 60° F.

The formula for ascertaining the specific gravity is $\frac{140}{130 + B°}$. The hydrometer is first placed in water and sinks say to 10; it is next placed in the oil to be tested and sinks to 30; then by use of the formula $\frac{140}{130+20} = .933$, as the specific gravity.

The flash test of an oil is the temperature to which the oil is heated to give off vapors, which, when mixed with air, produce an explosive mixture. The flash point of an oil is considered important, as an oil with low flash point, in mills, especially the cotton mills, that would give off gaseous vapors at low temperatures would be dangerous.

The fire test of an oil is obtained by continuing to run the temperature of the oil up after the flash test, until the vapors that are given off will ignite and burn continuously. The size of the cup, the quantity of oil, and the size of the test flame are noted in this test.

*Oil Inspector, Pittsburg Coal Co. Paper read before Coal Mining Institute of America

The cold test of an oil is the temperature at which the oil will just flow.

Compounded oils are used to a great extent, in fact it is difficult to get an oil that is not compounded. It is the writer's opinion if an oil is properly compounded with petroleum products of proper physical test, good results will be obtained; but, if it be compounded with semidrying oils, such as corn oil, rape seed, castor oil, or any of the blown oils (the latter is sometimes used to increase the viscosity of lubricating oil), the results will not be as satisfactory.

It is also the opinion of a number that a mistake is made in using a light-colored oil; for to obtain this oil it is treated with sulphuric acid, and the acid is neutralized with caustic soda. In a number of cases when a well-known oil, treated as described, came in contact with the water from cylinders, it became milky and emulsified and made the oiling system inoperative by clogging. One point should always be kept in mind, that is, one does not lubricate with color.

It has been found that the best universal results are obtained by using a non-treated engine oil having the proper physical test that has been filtered once through bone charcoal to eliminate any burnt carbon or suspended matter. It has never turned milky or emulsified, although this class of oil has been in service for 6 years undergoing all kinds of conditions. The compounder is the same in relation to mechanical movements as the doctor is to his patient in prescribing for the different ailments and troubles to be overcome. Compounding is a science

In a paper of this kind one cannot lay down with any degree of accuracy the grade of oil one should use or how it should be used any more than one could tell you how you should raise your children. Personally, I believe the only practical method of reducing the cost of oil and keeping it down to the minimum is to have one conversant with oils and lubrication in general to pass all requisitions, to visit mines, and keep in touch and familiarize himself with all the machinery and their requirements.

Coal Mining Notes

Berwind-White vs. Farmers—Trespass.—A rather serious or what might, because of prejudice, have become a serious case, was brought by a number of farmers against the Berwind-White Coal Mining Co. for trespass, and over $2,000,000 damages were demanded.

The problem involved the identity of the coal bed being mined by the defendant company. The integrity of nomenclature of the Lower Productive Coal Measures was attacked, it being claimed that bed *C'* and not the *B*, or Lower Kittanning, was being mined upon the land of the plaintiff. The case was not merely of a local nature but was most decidedly general, as an attempt was made to discredit the nomenclature of the entire first bituminous basin of Pennsylvania. The case involved a search of the records for 70 odd years, an examination of sections and the bed itself over an area of upwards of 100 miles. By the aid of geologists it was possible to establish the identity of the bed beyond question and the farmers' attorney requested Judge Kooser to instruct the jury to render a verdict for the Berwind-White Co.

Death Due to Detonating Caps.—In an explosion of detonating caps and dynamite at North Mahanoy mine of the Philadelphia and Reading Coal and Iron Co., one man was killed outright and three injured, one having his eyes blown out and his hands blown off. The men were carrying explosives into the mine. Had the advice on handling powder and caps so frequently given in MINES AND MINERALS been observed this accident would not have occurred.

Powder Strike.—Because they were prohibited from using black powder by State Mine Inspector Williams, of Johnstown, the 230 employes of the No. 2 plant of the Argyle Coal Co., at South Fork, Pa., quit work. The inspector, on a visit, discovered an unusual quantity of gas in the mine, and as a precautionary measure, ordered the black powder cut out. The men objected, alleging, the permissible explosive recommended by the inspector was not as effective as black powder and their earnings would be proportionately reduced. They were out three days, when permission was given them to resume the use of the powder. Some years ago a somewhat similar strike occurred in Nova Scotia that was not so readily settled.

Enforcement of Mine Laws.—The superintendent of the Price Hill Colliery Co.'s mine on New River has been found guilty of permitting men to enter the mine before an examination had been made of the mine for dangerous gases. No accident followed, but the superintendent, who stands high among the officials of the New River Co. and subsidiaries, was assessed a fine of $50, the commission issued him by the state department was revoked and his removal as superintendent demanded. In the circular letter being sent out, the district inspectors are ordered to prefer charges against mine officials for every violation of the law. "If mine officials persist in violating the law we will have some of them in the penitentiary," said Chief Laing in an interview at Charleston recently.

Pittsburg-Buffalo Inspection Committee.—An investigating committee composed of A. C. Beeson, chief engineer; W. J. Holsing, general superintendent; and Sim Reynolds, so well known to the readers of MINES AND MINERALS, has been appointed by the Pittsburg-Buffalo Co. to visit the different mines of the company at stated intervals and make a thorough inspection with the view of improvements along the line of safety and economy. Report of this inspection is to be made in detail to the general manager of the company and instructions issued to the management of each mine in accordance with the recommendations of the investigating committee.

University of Illinois School of Mines.—The University of Illinois will receive for its support for two years, following July 1, the sum of $3,500,000. One-half million dollars is for buildings. The College of Engineering obtains $192,000 for maintenance and for a building $200,000. The Department of Mining Engineering, in addition to this, has an appropriation of $35,000 for maintenance and $25,000 for equipment. The legislature in providing for the future support of the University has authorized a 1-mill tax upon the assessed value of the state. This it is expected will furnish over $2,000,000 per annum to the university.

Lake Superior Mining Institute

A. J. Yungbluth, secretary of the Lake Superior Mining Institute, states that the local committee on the Menominee Range have selected Tuesday, Wednesday, and Thursday, August 22, 23, and 24, as the dates for holding the sixteenth annual meeting, and the council has voted in favor of the same. Arrangements are now under way for the entertainment of the members and further circulars will be issued containing the itinerary of the trip together with list of papers to be read, also any excursion features which may be decided upon.

Kentucky College of Mines and Metallurgy

The board of trustees of the State University of Kentucky has changed the name of the School of Mining Engineering to that of the College of Mines and Metallurgy, which composes the School of Mining Engineering, the School of Metallurgy, and the School of Extension. The School of Mining Engineering will offer three courses as follows: A four-year course leading to the degree of mining engineer, a two-year course leading to a certificate of proficiency in the work covered, and a 10-week course for practical miners. The School of Metallurgy will offer a four-year course leading to the degree of Metallurgical Engineer. The School of Extension will take instruction to the miners in the field, lectures being given at various points in the state.

Coal Mining Institute of America

*Presidential Address of S. A. Taylor**

"How Can the Bituminous Coal Industry be Placed on a More Stable Basis?" was the subject which President S. A. Taylor, of the Coal Mining Institute of America, took for his address at a recent meeting of the Institute at Indiana, Pa., of which the following is an abstract:

He assumed that the bituminous coal industry was in an unsatisfactory state and that there was something radically wrong with the business. If there was any doubt about this, he said all that was necessary was to consult the operators on one hand and the miners on the other. In discussing the elements that entered into the cost of coal to the consumer he stated that in the home market where there was plenty of coal, in some sections of the East there was also plenty of wood, gas, and oil, which competed with coal. All that the operator desired was that the price of coal should be fair to the consumer, fair to the operator, and fair to the mine labor, but this could not be accomplished easily under existing conditions, as the location of coal and the cost of transportation vary according to the locality of the consumer and whether there is competition at his place.

Continuing, he said: There are a number of things which enter into the cost of production of coal and these either add or subtract from its price to the consumer. A strike in some district of the country may induce people to enter the coal business in the district from which coal must come to supply that suspended temporarily by the strike. In a number of places coal mines can be opened and worked cheaply by people with small means, and after they are once started it seems compulsory for them to continue so long as they can keep business going. This results often in unfair treatment to their men and customers. With such conditions there can be little or no control of the output of the mines.

There is another factor which recently has become quite an item of cost to the consumer, that is, the requirements of some of the specifications that coal should be purchased only on the basis of heat units and compelling forfeits to be paid by the producer if the coal he ships falls below the heat units guaranteed. The United States Government is one of the large consumers that purchase coal on this basis, and is therefore placing a premium on the waste of coal in the mines from which they purchase, for the reason that only the highest grade of coal can meet the requirements of the specifications, and for this loss and extra cost of production the operator must be paid if he in turn can pay the miners and others employed in connection with the production of coal. This is levying a toll upon the future population of our country which cannot be abolished until the national government shall act in a fair and intelligent manner in the matter. This may seem at first thought an unwarranted interference on the part of the government, but as I will attempt to show, I believe that not only would it be well for the coal industry to have the government so interfere but it is a duty the government owes to the industry as well as posterity to so interfere.

The coal operator holds a position as middleman between the consumer on one hand and the mine laborer on the other. The consumer demands low prices, while the mine laborer demands high wages. In addition to being ground between two millstones, the operator is usually the recipient of unjust newspaper criticisms. The press has much to do with the opinion in which the public holds the coal operator. He is called "coal baron" and other terms that deride and tend to belittle him before the public. Without any knowledge of facts and without any truthfulness, sensational writers state that the operators make a great amount of money out of their property at the sacrifice of everything that is manly, including the killing of their employes and charging the consumer exorbitant rates for coal. The operators are not in a position to contradict this, for what they would say would not be believed, and any statements which they might make could not be put in such vigorous language. Recently a number of yellow journals published articles in connection with the coal-mining industries that are gross fabrications and misstatements of facts. The general reading public, however, absorbs its impressions from the columns of these journals, and they tend to create a feeling of animosity against those who have probably much more than their share of the burden to bear.

The operator is often forced to sell his coal at prices that mean no profit to him. When this occurs it is only a question of time until some person suffers. The operator in dealing with the labor around the mine is oftentimes forced by reason of circumstances, public opinion, or other considerations beyond his control, to pay wages which are not warranted by the price received for his coal.

Another matter which is a serious one to the operator is the position which our government is advocating and which posterity also demands, namely, the conservation of fuel. As conditions exist today, taking for example the Pittsburg district, from 40 per cent. to 60 per cent. of the Pittsburg seam of coal, including as the seam, roof coal and all, is lost in mining, for the reason that the operator could not sell his coal for a price that would be equal to that of the cost of production, and yet the demand is upon him just the same to mine this coal, in order to protect the fuel supply for future generations. Under existing methods of operation, a greater percentage of the recovery of coal cannot be expected or accomplished. It therefore becomes a matter of importance that the government should in some way assist in solving this problem and not place the entire blame and burden on the operator.

A serious problem that confronts the operator is that if he should attempt to join with a fellow operator and form a combination by which the industry could be put on an equitable basis relative to coal production, wages paid, and the price to consumer, he would be haled into court as attempting a combination in restraint of trade. There is no part of the business of producing coal that receives more publicity than the conditions which surround the mine laborer at the mines. There is one condition, however, in which the mine workers have an advantage over the operator, or the consumer, namely, that they are permitted to combine in the form of labor unions and demand a great many favors that the individual worker could not secure. I will not undertake to defend the position that this combination has always been used to the advantage of the worker, but I do say that the fact that they are able to combine in forming unions without any governmental interference is growing stronger in their favor in making and securing demands, which others not being permitted to so combine are not in a position to withstand, but I am of the opinion that if some such combinations were permitted to exist among the operators and the consumers as well, with the additional condition that the government shall be a party to all of these combinations, that the entire industry would then be placed on a much better basis.

I think there are several positions which the government can consistently and with good effect take. I believe the government should take a position in connection with the industry somewhat analogous to the German government in connection with their coal industry. I believe that the government should go further to the extent that they should also permit or demand that the price at which coal should be sold should also be fair and equitable. This can be done by having a commission something similar to the Interstate Commission to review all conditions and controversies and have power to regulate the same through their decision, taking into consideration the cost of production in the various districts and permitting the fixing of a price above this cost that will guarantee to the capital invested a fair return, or they could permit combinations of the operators in the various districts, also a com-

* Pittsburg, Pa.

bination of all large consumers who could meet together and take into consideration all the conditions necessary to carry out the requirements made by the government and then fixing their price accordingly. Also granting the commission above mentioned the right to review these prices and if they should be considered exorbitant, or in any way unfair, to have power to reduce them to such an amount as to render them fair and equitable to all concerned

In conclusion I believe that before the coal industry can be placed on a permanent and equitable basis the present methods of handling the business must be revised. All parties interested therein must deal with this matter in a fair and business-like manner.

West Virginia Mining Institute

The following is the address of President Frank Haas, delivered before the summer Meeting of the West Virginia Coal Mining Institute, at White Sulphur Springs, West Virginia, June 19 and 20, 1911.

Fellow Members:—Were one to chronicle the events of the past half year in the coal industry of West Virginia, he would put forth as the predominating feature the demoralized condition of the coal trade. The severity and continued period of this depression has been remarked by some of our older operators to be the worst they have experienced. The causes of any of these commercial depressions are evidently so entangled in multitudinous conditions that our wisest economists have not yet been able to dissect them.

The present controversy in our National Congress over Canadian reciprocity can have but little effect, and that indirectly, on the West Virginia coal industry. One of our Senators has offered an amendment to the reciprocity bill, the effect of which will be to place Canadian soft coal on the free list whenever the President shall have sufficient evidence that the Canadian duty on American coal is removed. It would be an interesting subject indeed to investigate, free from all political features and localism whether as a whole, this country would be benefited by free coal with Canada. True, some districts would be materially benefited, while some others might suffer. It is stated that statistics show that American coal is imported into Canada largely in excess of Canadian coal imported into this country, the proportion being about 17 to 3. We trust, whatever the legislation, that the most good will come to the greatest number of people.

The recent decision of the Supreme Court on the famous trust cases, particularly that of the Standard Oil Co., and others pending almost as important, seem to have had a reassuring effect on the larger industrial interests of the country. We are told that business conducted with no unreasonable restraint of trade is legitimate, whatever that may mean. The layman can be forgiven, however, if he does not understand a subject or decision about which our wisest counsel cannot agree. The country at large has faith in our courts and we trust that their action will relieve the apparent strain to which this matter has subjected the business interests of the country.

A question of particular interest to West Virginia coal operators, is now in hearing before the Interstate Commerce Commission. This is the demand from the so-called Pittsburg operators for a reduction of freight rates from the Pittsburg district to the lakes. The point really at issue is a further differential against West Virginia coals. The argument is advanced that the cost of operation in the Pittsburg region is greater than that of the West Virginia fields, that their coals cannot be sold in competitive regions at a profit for this reason. I believe that a careful analysis would reveal that their excess of cost is due, not to natural conditions, labor, or materials, but to high fixed charges which they carry on their coal lands. The coal-land speculators of the Pittsburg field have boasted that the value of coal lands has risen from $50 an acre to as high as $3,000 per acre. Evidently some one is confused as to the relative definition as to value and price. Would it be unreasonable to suppose that such profit to which the Pittsburg region operators are justly entitled has been long anticipated and discounted by these speculators in coal lands and has long since been carefully tucked away in their pockets? Should the Interstate Commerce Commission be convinced that a readjustment of freight rates is reasonable or just, the first indication of prosperity for Pittsburg operators will be the glad news that Pittsburg coal lands have again increased in value.

Coal dust is still in the lead of subjects of technical discussion not only in this country but in nearly all foreign countries in which coal mining is an important industry. Some time ago the question of permissible explosives was considered of greatest importance, but for some reason the interest in this has begun to lag. The theory then was that the most important feature in the prevention of coal-dust explosions was to prevent an initial explosion. I should be sorry, indeed, to learn that this is no longer considered as the most important feature. We, and I mean Americans, especially, have yet much to learn about permissible explosives, and, among many others, I am not yet moved to the spirit of implicit faith in the permissible explosives now offered us commercially. The trend of endeavor now seems to be to prevent the propagation of an explosion if once started. Watering, once so universally urged, has apparently been temporarily abandoned and in its place stone dust is highly recommended. It must be borne in mind that most of these rapidly succeeding conclusions emanate mostly from foreign countries, and it is highly essential that we keep before us the relative conditions under which coal is mined in the various countries. For instance, in most European countries the main haulways are in rock tunnels, while ours are in coal, and they do not have the loose end-gate mine cars which are used almost exclusively in this country.

Belgium still pins its faith to permissible explosives and allows no watering; Germany is extravagant in its watering systems, while England and France tend toward the stone dust as a preventative of propagation. Where there is still such a lack of agreement as to the proper remedy I would advise you to keep your mines wet, when you have to shoot, shoot with care, and do not fail to practice eternal vigilance, the lack of which has caused more disasters than all others.

It is gratifying to note that our National Bureau of Mines is still working with the enthusiasm that characterized its beginning. It has had several opportunities within the past year to lend itself to practical rescue work. It is reported that the experimental mine at Bruceton will soon be ready for practical experiments. I do not hesitate to state that this method of taking an actual mine for experimental purposes will prove a great success, not only for verifying some of the conclusions which have been tentatively reached with less accurate methods, but also in the discovery of new things which nothing but the actual combinations of conditions as found in a coal mine can illustrate.

Only a few days ago my attention was called to the fact that a mine explosion had occurred in a mine near Clarksburg, in which there was no open light and the shot which was set off, and coincident in time with the explosion, was discharged by battery from the outside, and the powder used was one of the permissible type passed by the Pittsburg Testing Station. True, the mine contained firedamp, which was well known at the time, but every known precaution had been taken to avoid accident. One man evidently had faith and stood partly in front of the mine opening and was badly burned and had his face shot full of coal. Another incident not quite so recent has come to my notice, where a permissible powder set the mine on fire, possibly in the presence of a small gas feeder.

It is such cases as these that need special investigation, to find out just what the peculiar conditions were which made them possible. In the first case mentioned the mine was small and no one was in it when the explosion occurred. In the latter case men were present and extinguished the flame before it had time to spread.

West Virginia had but one dust explosion to record during the past year. The unfortunate accident at the Ott mine, on April 24, which cost the lives of some 23 men, was caused, in the opinion of our Chief Mine Inspector, by a shot fired in the solid and that the explosion was propagated through the mine by the presence of dry dust. Whether black powder or Monobel was used was not definitely determined, but Mr. Laing is of the opinion that it was black powder. The fact that there was a battery and wire leading from this shot would indicate a rather unusual method of shot firing if black powder was used.

The former meetings of the institute have been held in the vicinity of the various coal fields in West Virginia, and the change to the White Sulphur Springs was an innovation greatly appreciated by the members. During the business sessions it rained, while during the social sessions the sun shone and then each member sought diversion in his favorite pastime. The meeting was well attended, quite a number bringing their wives and daughters, which added to the gayety. The papers read were discussed intelligently, although it is to be regretted that they could not have been mailed to the members two weeks previous to the meeting. Among those present, the following were recognized: T. H. Huddy, Boomer; A. J. Sting, Guy A. Willey, F. H. Palmer, Chas. Connor, C. L. Hibner, W. H. Daffern, A. B. Cherry, W. L. Alston, C. E. Krebs, I. D. Shaw, A. F. Beck, C. K. West, A. W. Pruitt, J. S. Cunningham, Jas. Martin, of Charleston; D. Howard, Frank E. Parsons, of Clarkesburg; W. B. Crawford, Coalwood; L. W. Snyder, C. Ewart James, Carbon; L. Blankinsopp, Branchland; D. M. Petersen, W. J. Jinks, W. T. Williams, A. Mitchell, Wm. Nicholson, Bluefield; Thos. Pethoski, Eccles; Morris Watts, Eckman; A. E. Reppert, H. W. Hesse, Frostburg; F. Haas, J. C. Evans, R. E. Rightmire, John Thompson, C. H. Tarleton, Fairmont; F. G. Wood, Sullivan; Charlton Dixon, Low Moor, Va.; F. C. Brown, J. J. Echols, Lewisburg; Ernest Chilton, Raleigh; C. M. Fenton, Marting, W. Va.; F. K. Holmisted, Quinnimont; R. D. Leach, Hotcove; Louis Nahodil, W. E. Smith, E. W. Riley, John McMillan, Layland; G. H. Balen, Ethel; E. P. Connell, G. B. Lee, J. W. Herron, P. A. Grady, Jas. Clark, D. R. Phillips, J. C. Miller, W. M. Shaul, Huntington; R. S. Ord, Maybeury; J. C. White, Morgantown; M. Hanford, Powellton; Wm. Laing, D. B. Evendall, McCalpin; E. B. Day, R. G. Johnson, W. L. Walker, Ed. Kerchner, G. W. Mingus, Creighton Dilworth, D. Hunter, Jr., H. C. Owen, W. B. Spellmire, B. G. Fernald, G. R. Wood, F. C. Albrecht, W. A. Thomas, J. W. Paul, Clarence Hall, Pittsburg, Pa.; H. W. Black, J. A. Lay, Thurmond; J. C. C. Mayo, Paintsville, Ky.; G. L. Hart, W. W. Coy, Roanoke, Va.; E. W. Parker, Washington, D. C.; F. W. Parsons, New York City; E. B. Wilson, Scranton, Pa.

Mine Inspectors' Annual Meeting

The following is the address of Geo. Harrison, President of the Mine Inspectors' Institute of the United States of America, at their Third Annual Meeting, held at Charleston, W. Va., June 13, 1911.

Fellow Members:—Since our last gathering the usual number of lives have been sacrificed in the mines of this country, and, in consequence, the customary number of wives, children, and dependents have been called on to mourn the untimely end of their breadwinners.

A year ago we prided ourselves on the establishment of a Federal Bureau of Mines, and the enactment of more adequate mining laws in various mining states, and many of us were buoyant with hope that the fatalities in mines would be materially reduced in consequence of added safeguards.

The number of lives lost from gas and dust explosions and other causes classed as mine calamities may not have been so great, but the number of individual fatalities seems to have more than kept pace with the ever increasing production of coal, and we are still confronted with the unsolved and important problem of how to accomplish the prime object which prompted the establishment of our Institute.

A careful investigation of the causes leading to fatalities in the mines in Ohio shows that over 80 per cent. of all fatalities are avoidable, and would not occur if employes and the management of mines were more obedient to the requirements of laws and more disposed to a strict performance of duty. Lack of discipline is, to a great extent, the secret of the high death rate in our mines, compared with that of older mining countries where greater responsibility is imposed on the management of mines, and where inside foremen have sufficient help to insure not less than two visits each day to every miner under his jurisdiction. During these visits time is taken to see that working places are properly timbered, dangerous roof secured at the proper time, and miners not permitted to work under it. The orders of the mine foreman or superintendent, in regard to the safety of working places and general security, are as binding as statutory law, and quick punishment for violations always follows. There is no disposition to aid each other in dangerous violation of law and orders given by the management, and, in consequence, prompt prosecution of offenders has a very beneficial effect in the way of lessening the number of fatalities.

One of the objects of our institute was to exercise our influence to make the Mining Departments in the various mining states institutions of efficiency, relieving the inspectors of any political obligation that would embarrass them in the enforcement of laws and protection of life and property in the mines. Judging from the many changes of mine inspectors that have recently taken place in a number of State Mining Departments, there has not been much progress made in eliminating politics. The State Mining Department, the miners and mine operators, of Ohio are all deeply indebted to Governor Harmon for his insistence that where so many lives are at stake political influence must have no consideration in the ability and faithful performance of duties of inspectors.

I call attention to the fact that we are not deriving the benefit that most of us expected, in an educational way, from our annual meetings. Much of our time is consumed in ways other than in discussions of important subjects pertaining to every-day occurrences in mines, which unnecessarily fill our cemeteries and graveyards and leave women and children helpless and dependent upon others.

It is true that many intelligent and well-prepared papers on subjects of first importance are either hurriedly read to the institute or submitted to the secretary without reading, and we have no opportunity even to read them until another shower of annual subjects crowds them out of our memory; the greatest benefits to be derived from these papers read at our meetings is the logical, practical discussion of their merits and demerits; a frank, free but friendly criticism of their strong and weak points that will not only benefit our own membership, but that we can support and maintain against all illogical opposition.

In conclusion I desire to say to the practical mine inspectors, especially those who are still on the sunny side of life, "Don't think you know it all, learn all you can about mining matters, but let me implore you, remember that upon you and those connected with the management of mines under your jurisdiction and the judicial but rigid manner in which you enforce the law, depend the lives and health of those underground."

Answers to Examination Questions

Selected Questions of the Pennsylvania Anthracite Mine Inspectors' Examination, at Scranton, Pa., May 25, 26, 1911

By J. T. Beard

Note.—The following questions, selected from the examination, are here numbered consecutively.

Ques. 1.—What principle or rule should be followed in interpreting or construing the law in reference to mining?

Ans.—All law should be interpreted or construed in harmony with itself, and in accordance with the plain and evident intention of the statute whether expressed or implied. In case of ambiguity or reasonable doubt, the matter should be referred to the attorney-general for his interpretation, as the legal advisor of the state.

Ques. 2.—What are the duties of the mine inspector?

Ans.—It is the duty of the mine inspector to enter and carefully inspect, as often as required, each working mine in his district, and see that it is being operated in compliance with the law, and that all machinery and appliances in use are safe, and the airways, roads, passageways, and working places maintained in a safe and healthful condition with respect to ventilation, drainage, timbering, mining of coal, etc. It is his duty to make any inquiry that is designed to acquaint him with the true condition of the mine and its entire equipment, with respect to the health and safety of all persons employed in or about such mine. The inspector must keep a correct record of all visits made to the mines in his district, showing the condition of the mine, quantity of air in circulation, dangers found, changes suggested, etc. He must carefully investigate all fatal mine accidents, and attend inquests, examine witnesses, and record the facts as he finds them.

Ques. 3.—What are the duties of workmen in general employed in and about mines, in relation to any threatened danger?

Ans.—Any person, immediately on discovering any threatened danger in or about a mine, should promptly give the alarm and notify the mine officials.

Ques. 4.—How are the coal mines of Wayne, Susquehanna, and Sullivan counties rated, in respect to their being fiery mines or not?

Ans.—They are generally non-gaseous mines.

Ques. 5.—What are the principal dangers to which mine employes are exposed in these counties?

Ans.—Falls of roof and coal, movement of cars, machinery in breakers, explosion of powder, contact with live wires, mine fires, mules, etc.

Ques. 6.—Name the different systems of mining coal.

Ans.—Stripping or open-cut mining, room-and-pillar system, panel system, buggy system, single and double chutes, rock chutes, cross-tunnels, and long-wall system.

Ques. 7.—What is the greatest number of veins of coal in any locality in Wayne, Susquehanna, and Sullivan counties?

Ans.—The greatest number in the counties named probably occurs at Forest City, Susquehanna County, where borings by the Hillside Coal and Iron Co. showed a total of 12 coal seams, only five of which, however, were of workable thickness, varying from 2 feet 2 inches to 5 feet 2 inches thick.

Ques. 8.—After the headings have been driven beyond the shaft pillars, what method should be adopted to work the coal?

Ans.—This will depend wholly upon conditions. A large output and available funds, or a gaseous seam, may make advisable the employment of the triple-entry system. The character of roof, floor, and coal, thickness and depth of seam, and quantity of waste material to be handled will generally determine the size of entries and the width of chambers and pillars.

Ques. 9.—What gases are found in coal mines?

Ans.—The common mine gases are marsh gas, or methane (CH_4), carbon dioxide (CO_2), carbon monoxide (CO), hydrogen sulphide (H_2S), and olefiant gas (C_2H_4).

Ques. 10.—What quantity of pure air is required in coal mines for men, mules, lamps, and the deflagration of powder?

Ans.—A sufficient quantity to make all working places and passageways safe and healthful for men to work in them. This, however, will vary widely in different mines, depending on the quantity and kind of gas generated, the thickness of the seam as determining the size of openings; quantity and kind of powder burned, quality of oil used in lamps, and other like conditions affecting the mine atmosphere. It is common practice to allow 200 cubic feet of air per minute per man in all mines in the anthracite regions of Pennsylvania. A mule generally requires from five to six times the quantity of air allowed for a man.

Ques. 11.—(*a*) What is the maximum velocity of air allowed by law, in mines generating large quantities of explosive gas? (*b*) What is the reason for this maximum being so fixed?

Ans.—(*a*) The anthracite mine law forbids a greater velocity of the air-current than 450 feet per minute. (*b*) The reason for this limitation is that the unbonneted Clanny lamp, so much used in these mines, is unsafe in a current velocity exceeding 480 feet per minute.

Ques. 12.—What are the symbols and specific gravities of hydrogen, nitrogen, oxygen, and carbon?

Ans.—Hydrogen, symbol H, specific gravity referred to air of the same temperature and pressure, .06926; nitrogen N, .9713; oxygen O, 1.1056; carbon C. Carbon occurs in a number of allotropic forms, as diamond, graphite, coal, charcoal, lamp black, etc., all of which have different specific gravities, varying from 3.5 to .24. By experiments on the burning of diamonds in oxygen the combining weight of carbon, or its density referred to hydrogen as unity, has been determined as 12.

Ques. 13.—What is the symbol and specific gravity of carbonic acid gas, and how may its density be calculated?

Ans.—Carbonic acid gas (carbon dioxide), symbol CO_2; specific gravity, referred to air of same temperature and pressure, 1.529. The density of any gas referred to hydrogen as unity is always one-half its molecular weight. For carbon dioxide (CO_2), the molecular weight is $C=12$, $O=16$; hence, $CO_2=12+2\times16=44$. The density of this gas is therefore $44\div2=22$.

Ques. 14.—What is the symbol, combining weight, and density of light carbureted hydrogen gas?

Ans.—Light carbureted hydrogen (methane or marsh gas), symbol CH_4. The molecular weight is, $C=12$, $H=1$; hence, $CH_4=12+4\times1=16$. The density of this gas is then $16\div2=8$. We cannot speak of the combining weight of a compound, but only of elements. The molecular weight of any compound is always equal to the sum of the combining weights of its constituent atoms.

Ques. 15.—What is the symbol, combining weight, and density of carbonic oxide gas?

Ans.—Carbonic oxide (carbon monoxide), CO; molecular weight, $C=12$, $O=16$; hence, $CO=12+16=28$. The density of this gas is therefore $28\div2=14$.

Ques. 16.—What can you say of the affinities of oxygen and nitrogen, respectively, for other elements or matter in nature?

Ans.—Oxygen has a very strong affinity for most of the known elements, combining with them at all temperatures to form oxides; while nitrogen, on the other hand, is exceedingly inert, combining directly with but few of the elements.

Ques. 17.—(*a*) What proportion of air mixed with marsh gas (CH_4) will render the mixture explosive? (*b*) Describe the effect of mixing air with gas in different proportions.

Ans.—(*a*) When air is mixed with marsh gas the mixture first becomes explosive when the proportion of gas and air is in the ratio of 1 to 5. (*b*) The effect of adding air to marsh gas is as follows: The mixture first becomes inflammable when the proportion is one volume of gas to 2.39 volumes of air. At first the mixture burns quietly, but as more air is added the gas snaps and crackles and finally reaches the explosive point when the proportion is one volume of gas to five volumes of air. As more air still is added the violence of the explosion increases and reaches a maximum when the proportion is one volume of gas to 9.57 volumes of air. The further addition of air beyond this point diminishes the violence of the explosion, which ceases altogether when the proportion is one volume of gas to 13 volumes of air. The mixture, however, is still inflammable and remains so till the proportion reaches one volume of gas to 17 volumes of air, when the flame dies out.

QUES. 18.—What is the least percentage of gas in a firedamp mixture that will explode?

ANS.—The proportion of gas and air at this point is 1:13. The percentage of gas in this mixture is $\frac{1}{1+13} \times 100 = 7.14$ per cent.

QUES. 19.—What is the percentage of gas in a firedamp mixture at its most explosive point?

ANS.—The proportion of gas and air is then 1:9.57; and the percentage of gas is $\frac{1}{1+9.57} \times 100 = 9.46$ per cent.

QUES. 20.—What is the percentage of gas in a firedamp mixture, at the point where the addition of more air renders the mixture inexplosive?

ANS.—The proportion of gas and air is then 1:13; and the percentage of gas 7.14 per cent., as given in reply to Ques. 18.

QUES. 21.—What are the mixtures of air and gases immediately before and immediately after an explosion called?

ANS.—The mixture of air and gases before explosion is very variable in composition; it is called firedamp. The mixture of gases remaining after an explosion has taken place is likewise very variable; it is called afterdamp.

QUES. 22.—In case of explosion how would you proceed to rescue any workmen who might still be alive in the mine?

ANS.—Everything would depend on the extent and violence of the explosion, and the damage done to the ventilating and hoisting machinery and the mine openings. Necessary repairs must be made as quickly as possible in order to reestablish a reliable ventilating current. While this is being done volunteers must be chosen of the most experienced men, and these must be equipped with lamps and tools. The mine must be entered by following the intake current. Only safety lamps must be used, and the condition of the mine air must be constantly observed by examining the flame of the lamps, and by noting the effect produced on caged mice and birds, which should be kept on hand at all mines ready for such use. Airstoppings and doors must be repaired and temporary brattices built sufficient to conduct the air forward and enable the rescuers to proceed.

QUES. 23.—What process should be adopted for the resuscitation of persons suffering from asphyxia or the effects of afterdamp?

ANS.—Asphyxia describes the condition that results from a cessation of respiration by which air is taken into and again expelled from the lungs. This may be caused by an obstruction of the windpipe, or the inhaling of some gas that will not support life and which, by filling the lungs, excludes the necessary oxygen on which life depends. In addition to such suffocating gases as carbon dioxide and nitrogen, mine afterdamp may contain poisonous gases, carbon monoxide being most frequent. To overcome these effects, remove the person promptly to an atmosphere of good air; loosen any tight clothing, and proceed to produce artificial respiration as follows: Place patient on his back with a bundle of clothes under his shoulders to elevate and expand the chest. Kneel at the patient's head and bending forward grasp his forearms firmly below the elbows, and draw them outward and upward as far as they will go above the head; hold them there for a second, giving time for the lungs to expand and draw in some air under this action; then bring them down and press the arms against the sides and chest in such a manner as to compress the lungs and drive out the air inhaled. Hold them in this position for a second; and continue to repeat this operation for an hour, or until the patient begins to breathe. The rate of inhalation and exhalation should be about 15 times a minute. In the meantime keep patient warm with blanket; apply ammonia to handkerchief and hold under his nose. When breathing is restored rub the limbs toward the heart to assist the flow of venous blood back thereto. Give rest and keep warm with hot-water bottles, and allow plenty of fresh air by open windows after patient has been put to bed.

QUES. 24.—Name the instruments used in connection with the working of coal mines.

ANS.—Anemometer, water gauge, barometer, thermometer, hygrometer, safety lamp and indicator for measuring gas, miners' compass, and measuring tape.

QUES. 25.—How many kinds of thermometer scales are there, and which of these is commonly used in this country?

ANS.—Three, the Fahrenheit, Centigrade, and Reaumur. The Fahrenheit scale is in common use here.

QUES. 26.—Describe the Fahrenheit thermometer.

ANS.—The thermometer is a glass tube with capillary bore, closed at one end, and having at the other end a glass bulb filled with mercury. Any rise or fall of temperature causes an expansion or contraction of the mercury, which rises and falls in the tube in a corresponding manner. A graduated scale attached to the tube measures the height of the mercury, and is calibrated to mark the temperature in degrees. All thermometer scales are calibrated by reference to two fixed points, namely, the temperature of melting ice and that of boiling water, at sea level. In the Fahrenheit scale the temperature of melting ice is marked 32 degrees, while that of boiling water, at sea level, is 212 degrees; giving, therefore, 180 degrees between these two points in this scale.

QUES. 27.—Describe the Centigrade thermometer and its graduation.

ANS.—The general description of the thermometer is the same as that given in answer to Ques. 26; but in the Centigrade scale the temperature of melting ice is marked 0 degrees, while that of boiling water is 100 degrees; thus giving 100 degrees between the same two fixed points in the Centigrade scale.

QUES. 28.—Describe the graduation of the Reaumur thermometer.

ANS.—In the Reaumur scale the temperature of melting ice is marked 0 degrees, as in the Centigrade; but the temperature of boiling water is made 80 degrees, thus giving only 80 degrees between these fixed points in this scale.

QUES. 29.—What are the readings on the Centigrade and the Reaumur thermometers corresponding to 100 degrees on the Fahrenheit scale?

ANS.—Centigrade $= \frac{5}{9}(100-32) = 37\frac{7}{9}°$.

Reaumur $= \frac{4}{9}(100-32) = 30\frac{2}{9}°$.

QUES. 30.—What is the atmosphere and what are its principal ingredients?

ANS.—The atmosphere is the aerial envelope that surrounds the earth. Its chief ingredients are oxygen and nitrogen, with small quantities of carbon dioxide, ammonia, argon, and water vapor.

QUES. 31.—Is the composition of the air always the same on the surface and in the mines?

ANS.—The composition of free air, on the surface, is practically always the same. Mine air generally contains a trifle less oxygen and somewhat more carbon dioxide than atmospheric air, besides often other mine gases in varying quantities.

Correspondence

Rolling Friction

Editor Mines and Minerals:

Sir:—In the June number W. C. A. says: "Some people maintain that the resistance due to rolling friction of mine cars is greater in summer than in winter." In a catalog of a large concern is this sentence: "The resistance is greater in winter." Your correspondent asked which statement is correct and the reasons.

Both statements are correct if the term "rolling friction" is used in its proper sense. The first statement refers then to rolling friction, while the second refers to the combined friction of the entire locomotive.

Rolling friction is the resistance that a rolling body meets from the surface on which it rolls, as, for instance, the resistance offered a car wheel that is rolling on a rail. The rolling frictional resistance offered to the movement of a car along a track is greater in summer than in winter, but not directly on account of the difference in temperature. In the winter the ground is frozen and the rail, consequently, is held more rigid. In summer there is a greater movement to the ties, and consequently to the rails, as the car moves over them. This all tends to increase the force necessary to keep the car moving along the rail, and is applicable to surface roads in cold countries. On the other hand, the temperature of a mine does not vary greatly in winter and summer, so the effect would not be very marked so far as rolling friction is concerned.

It is possible, however, that your correspondent referred to the journal friction, which is a sliding friction and is dependent on the lubricant used. If the query refers to the resistance due to the journal turning in the box, that is a different matter and will come under journal friction.

The second statement that "the resistance is greater in winter" refers to journal friction and is true until the bearings become heated up to the normal working temperature. If the car has been standing in cold weather long enough for the journals to cool to the weather temperature, the frictional resistance offered to the movement of the car will be increased. The car will move stiffly and it will be harder to get up to speed. Once a trip of such cars has been running sufficiently long to heat all the bearings to the normal, the bearing friction will reduce to about normal. However, bearings that do not have sufficient movement to cause them to heat up to summer temperature will exert considerably more friction in winter than in summer.

To compensate this it is usual to lubricate with oils suitable for summer and winter, known as summer and winter oils. Such oils have the same viscosity; that is, the same power for adjacent layers to adhere together, but vary in their "body." It is the body of the oil that regulates the thickness of the layer intervening between the journal and its bearings, and the body of an oil changes with the temperature, becoming thickened with cold and thinned with heat.

The object of using a lubricant on a journal is to reduce the amount of friction by floating the journal bearing on a film of the lubricant interposed between it and the journal. The function of the lubricant is to prevent the bearing from coming into metallic contact with the journal. If the oil has not sufficient viscosity, it will be squeezed out, and therefore cannot keep the surfaces of the journal and the box apart. This will greatly increase the journal friction. If the lubricant has not sufficient body, the film of lubricant interposed between the journal and the bearing will be so thin that the journal will not be completely separated from the bearing at all points. The friction in this case will be due partly to fluid friction and partly to metallic friction, due to the metal of the journal coming into contact with that of the bearing at points.

The journal has a certain normal working temperature in the winter, and the body of the oil must be sufficient to give a film of oil of a thickness that will completely separate the journal and its bearing. The normal temperature of a journal in the summer time is higher than in the winter, but if the lubricant has the proper body it will give the same thickness of film in the summer as in the winter; however, the tendency in the summer is for the increase in temperature to reduce the body of the lubricant, and, therefore, the thickness of the film that it will interpose between the journal and its bearing. The tendency in the winter due to the temperature lowering is to increase the body, and, therefore, the thickness of the film.

Any mistake made in the quality of the oil will show up worse in the summer than in the winter, because the increased temperature tends to magnify the trouble. From this it will be seen that the journal friction in summer is very apt to be more and to cause greater trouble than in winter if the proper oil is not used. It is possible that your correspondent meant this when he referred to rolling friction.

J. F. Cosgrove

Filter Presses

Editor Mines and Minerals:

Sir:—My attention has just been called to Mr. Broadwater's communication in your June issue, in which he rather takes to heart my reference to filter-press practice in my article in your May issue, and, I think, almost misses my point.

Mr. Broadwater is in the filter-press business and naturally is sensitive on the subject, but the fact remains that the use of the vacuum filter has so far outstripped the filter press for recovering the pregnant solution from the cyanided slime that filter pressing is now hardly a competitor of the vacuum type of filter.

We admit the excellent work of the Homestake filter-press plant, the remarkably low costs, and the unusually high efficiency of operation, but the Homestake is really no criterion, because it, next to the Alaska-Treadwell, is the lowest grade gold ore in the world to be treated profitably, and is an unusual case.

Mr. Broadwater advises me to go to Blair to see the Silver-Peak mill, where three filter presses treat 480 tons per day. I have seen the mill. Just over the Montezuma range from Silver Peak are Goldfield and Tonopah, where the Goldfield Consolidated, Goldfield Florence, Tonopah Extension, Montana-Tonopah, and Belmont are all using vacuum filters with a combined capacity of about 2,500 tons per day.

To quote from his communication: "If anything further were needed to show that Mr. Barbour's statement is misleading, it will be found in the following list of orders for filter presses placed with this company in the last year." Now the fact that the orders for filter presses in the past year have a total capacity of 2,100 tons per day seems to me to prove the correctness of my statements. The total capacity of vacuum filters ordered during the past year would make this 2,100 tons look small and insipid.

I have before me a letter from Mr. G. C. Patterson, vice-president of the Butters Patent Vacuum Filter Co., in which he states that in a little over a year he, himself, has sold nine filter plants with a total of 1,946 leaves, and a total capacity of about 6,000 tons per day. The various other vacuum-filter companies are busy adding to these figures. The more we go into the matter the narrower looks the filter press field and the broader looks the vacuum filter field. Therefore, I cannot admit that my statement was misleading.

Percy E. Barbour,
Tecoma, Nev. Mining and Metallurgical Engineer

Manganese ore is being mined in South Africa, near Cape Town, and several hundred thousand tons have been shipped to Antwerp. Most of the ore is higher in phosphorus than is used in the United States.

An Outline of Mining

Suggestions for the Arrangement of a Course Covering Mining Appliances and Mining

*By Will H. Coghill**

The accompanying outline is intended to cover the subject of mining appliances and mining. It is submitted for publication with the thought that it may be of some assistance to the young instructor who has to arrange lecture courses in mining and aid the young mining engineer who wishes to institute a card indexing system on a small scale and capable of development. The outline is the result of an investigation of the subjects treated in all the available textbooks on mining, bulletins of the United States Geological Survey, and Bureau of Mines, and articles in the mining journals and machinery catalogs.

Outline of Mining

- A. Hoisting.
  - 1. Hoists.
    - (a) Man power.
      - Windlass.
      - Crab or hand winch.
    - (b) Horsepower.
      - Whip.
      - Whim.
    - (c) Steam power (air, electric).
      - Geared.
        - Friction.
        - Spur and pinion.
      - First motion.
        - Single rope.
        - Counter balanced.
          - Reels.
          - Drums.
            - Conical.
            - Cylindrical.
          - Koepe and Whiting systems.
    - (d) Pneumatic hoisting.
    - (e) Man engine.
  - 2. Ropes.
    - (a) Vegetable fiber.
    - (b) Steel.
      - Parallel wires.
      - Twisted wires.
        - Round (cylindrical and conical).
          - Ordinary lay.
          - "Lang" lay.
        - Flat.
  - 3. Sheaves.
  - 4. Carriers.
    - (a) Bucket or tub.
    - (b) Skip.
      - Inclined.
      - Vertical.
    - (c) Cage.
  - 5. Head-frame.
- B. Haulage.
  - 1. Hand trucking.
    - (a) On track.
    - (b) Mono-rail.
  - 2. Animal power.
  - 3. Motors.
    - (a) Stationary.
      - Inclined plane.
      - Endless-rope system.
      - Tail-rope system.
    - (b) Traction.
      - Air.
        - Single expansion.
        - Two-stage.
      - Electric.
  - 4. Aerial tramway.
    - (a) Single rope system.
    - (b) Two-rope system.
- C. Drainage.
  - 1. Motive power at surface.
    - (a) Air lift.
    - (b) Lift pump.
      - Cook steam head.
      - Balance bob.
    - (c) Force or Cornish pump.
    - (d) Bailing tanks.
    - (e) Pulsometer.
    - (f) Hydraulic ram.
  - 2. Motive power underground.
    - (a) Reciprocating pump.
      - Piston or inside packed pump.
      - Plunger or outside packed pump.
    - (b) Rotary pumps.
    - (c) Centrifugal pumps.
- D. Ventilation.
  - 1. Mine gases.
  - 2. Breathing apparatus.
    - (a) Stationary type.
    - (b) Portable type.
      - Oxygen-regenerative apparatus.
        - Solid regenerators.
          - Helmet type.
            - Draeger.
            - Fleuss-Siebe-Gorman.
            - Weg.
          - Mouthpiece type.
            - Westphalia.
        - Liquid regenerator.
          - Tissot apparatus.
      - Aerolith (liquid air).
      - Pneumatogen.
  - 3. Ventilating Systems.
    - (a) Natural.
    - (b) Artificial.
      - Furnace.
      - Fans.
      - Blowers.
      - Turbo blowers.
- E. Illumination.
  - 1. Stationary illuminators.
    - (a) Reflected daylight.
    - (b) Electric.
    - (c) Gas.
  - 2. Portable illuminators.
    - (a) Candles.
    - (b) Torches.
    - (c) Lamps.
      - Electric.
      - Safety.
      - Acetylene.
- F. Preservation of mine timbers.
  - 1. Brush treatment.
    - (a) Creosote.
    - (b) Carbolineum.
  - 2. Open-tank treatment.
    - (a) Creosote.
    - (b) Zinc chloride.
    - (c) Sodium and magnesium chloride.
  - 3. Closed-cylinder treatment.
    - (a) Creosote.
    - (b) Zinc chloride.
- G. Boiler water and treatment.
  - 1. Precipitation in boiler.
    - (a) Aluminum plates.
    - (b) Chemicals.
  - 2. Purification by softening.
    - (a) Continuous treating and filtering.
    - (b) Intermittent treating and settling.
- H. Acquiring mining land.
  - 1. Government subdivision.
  - 2. Lode claim.
  - 3. Placer claim.
  - 4. Tunnel site.
  - 5. Mill site.
- I. Exploration.
  - 1. Trenching.
  - 2. Test pit.
  - 3. Dipping needle.
  - 4. Magnetometer.
  - 5. Swedish mining compass.
  - 6. Boring.
    - (a) Percussion.
      - Churn drill.
      - Percussion core drill.
    - (b) Hydraulic.
      - Hydraulic rotary drill.
      - Jetting method.
    - (c) Abrasive core drill.
      - Diamond drill.
      - Calyx drill.
      - Chilled shot.
  - 7. Surveying bore holes.
- J. Exploitation.
  - 1. Open work.
    - (a) Placer mining.
    - (b) Excavating by water.
      - Water as solvent.
      - Salt mining.
      - Sulphur mining.
      - Water as loosener—hydraulic mining.
    - (c) Excavation under water.
      - Suction dredge.
      - Bucket.
      - Dipper.
    - (d) Open-cut mining.
      - Hand work.
      - Scraper.
      - Steam shovel.
      - Milling method.
  - 2. Underground work.
    - (a) Tunneling.
    - (b) Shaft sinking.
      - Vertical.
        - Boring.
        - Drilling and blasting.
        - Freezing.
        - Drop-shaft.
      - Inclined.
    - (c) Coal mining.
      - Longwall.
        - Retreating.
        - Advancing.
      - Pillar-and-room.
    - (d) Metal mining.
      - In thin veins.
        - Underhand stoping.
        - Overhand stoping.
      - In thick veins and masses.
        - Pillar-and-room.
        - Square-set.
        - Filling system.
        - Caving system.
- K. Breaking ground.
  - 1. Air compressors.
    - (a) Hydraulic.
    - (b) Mechanical.
      - Reciprocating.
        - Straight line.
          - Simple steam, single-stage air.
          - Simple steam, compound air.
          - Compound steam, compound air.
        - Duplex type.
          - Belt driven.
            - Duplex air.
            - Compound air.
          - Direct driven.
            - Duplex steam, duplex air.

ORE MINING AND METALLURGY

A Twentieth Century Cyanide Plant

Process and Machinery for Treatment of 400 Tons of Silver-Bearing Ores in 24 Hours

By Chas. E. Christensen, M. E.

In discussing a modern cyanide plant it is assumed that the ore carries silver and that the pulp requires about 36 hours to be leached from silver. It will further be assumed that electric current can be secured, transformed to the proper voltage, and distributed from the main switchboard to the motors, which will be so arranged as to give unit drives to the different sections of the plant. A separate crushing plant of double the capacity required will be installed so that it need run during the daytime only. The cyanide plant is assumed to treat about 400 tons of ore per day of 24 hours.

The process and the machinery required would then be as follows: The ore is taken from the mine in steel cars and dumped into large ore bins in the crusher building. From here the ore is drawn through an ore-bin gate into a large Gates breaker set to crush all the ore to pass a 3-inch ring. The product is discharged to two continuous bucket elevators which elevate and deliver the ore into two large iron-frame revolving screens having 2-inch perforations. These revolving screens have no shafts, spiders, or any other obstruction to wear out or impede the free passage of the material to the discharge openings. They run on rollers and are driven through a bevel wheel attached to the periphery of the discharge end of the screen. This meshes with a bevel gear on a counter shaft. The product passing through the 2-inch perforations is delivered directly to two belt conveyers and conveyed to the mill building. The rejections from the screens, or material which will not pass the 2-inch perforations, is spouted into two smaller Gates breakers. These breakers reduce the rejections to 1½-inch size and finer, and discharge the product to the same conveyers that receive the material from the screens. These conveyers have carrying belts 14 inches wide and, if necessary, could be designed to travel up an incline of about 20 feet per 100 feet of length.

At the entrance to the mill building these belt conveyers discharge the ore to two other conveyers of the same type and size, but operating in a horizontal plane right and left. These conveyers are provided with automatic trippers or distributors which travel the whole length of the ore bins and deliver the ore automatically into the bins which are located behind the stamp batteries.

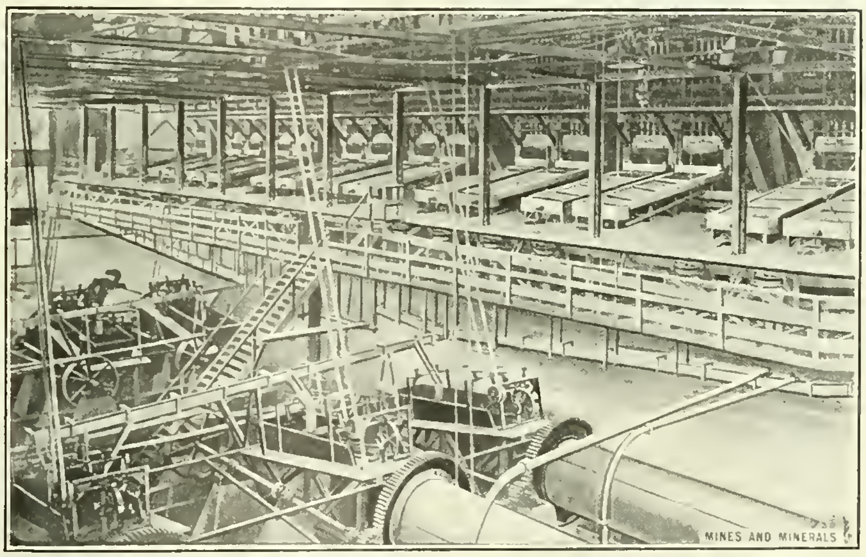

FIG. 1. BATTERY AND TUBE-MILL FLOOR OF CONCENTRATING MILL

At the point where the crusher building conveyers discharge into the mill building conveyers, a Cole automatic sampling device is placed to take samples of the crushed ore. The arrangement of this ingenious sampler is such that a sample scoop is made to pass through the ore stream and take a sample across the full width of the belt during its passage. By properly adjusting the driving mechanism the frequency of sampling can be regulated.

The crushed ore is drawn from the battery bins into automatic feeders, Fig. 2, which are of the suspended or hanging type arranged to be moved back from the mortars when necessary, thus giving a large working space for making repairs. There is one ore-bin gate for each five-stamp battery. Forty stamps are needed, each weighing 1,050 pounds. They are arranged in eight batteries of five stamps each, driven by belts with tighteners from the line shaft. The batteries are made right and left hand and set in three-post frames. The mortars, one for each five stamps, are of the Allis-Chalmers narrow, rapid-crushing, quick-discharge type, provided with four-mesh screens. The principal battery parts are made of steel to insure maximum wearing life. The pulp from each five-stamp battery is delivered to a cone classifier, which makes two products. The spigot or coarse product of each is spouted to a concentrating table and the overflow from each cone is delivered to a classifier. The tailings from the eight table concentrators are also elevated to the classifiers by belt and bucket elevators one for each five stamps.

On the classifiers the sand and the slime are mechanically separated. The classifiers separate that part of the pulp crushed to 150-mesh size and it is then delivered to the thickening cones for concentration on vanners.

The coarse sand product from the classifiers is discharged into four trunnion-style, wet-grinding, spur-gear driven tube mills. These mills may be arranged with silex flint brick linings, 4 inches thick, or with El Oro linings. The initial charge of pebble stones for each mill is 10 tons.

The sand is ground to 150 mesh or finer in these mills, each discharging its product into a classifying cone for the purpose of separating from the product any sand which may have passed through the mills without being ground fine enough, and this sand is returned to the classifiers to be fed again to the tube mills. The finished product is delivered to spiral sand pumps by which it is elevated to four large pulp thickening or settling cones, where any excess of water is removed and forwarded to the cyanide plant. The thickened pulp from the bottom discharge is conveyed to Frue vanners. This type of concentrator has an endless rubber belt with turned up flanges on the edges so as to form a plane inclined rubber surface. The belt travels up the incline and around a lower drum, which dips into a water tank in which the mineral is washed off and collected. In addition to the travel the belt receives a side shake from a crank-shaft along one side, the shake being at right angles to the travel of the belt. The pulp is fed on the belt about 3 feet from the head and flows down the incline subjected to the steady shaking motion which deposits the mineral on the belt. At the head of the belt is placed a row of water jets which wash back the lighter sand, allowing only the heavy mineral to pass and become deposited in the water tank below as already mentioned. The concentrated product is collected and dried, after which it is shipped to the smelters.

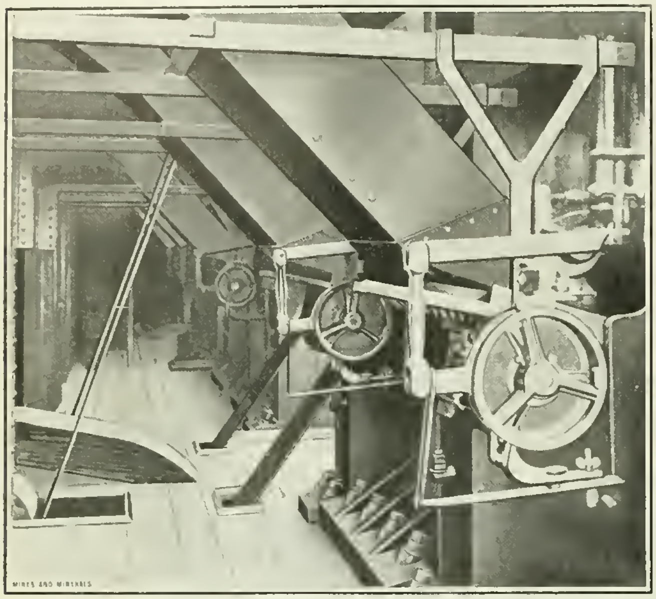

Fig. 2. Automatic Feeders

The tailings from the vanner and the overflow from the settling cones are delivered to any one of six dewatering tanks in the cyanide plant. These tanks are provided with filters through which the water is drawn off and from which it flows to a final settling box to collect any slime carried in suspension. It is then delivered to two sump tanks to be pumped back to the mill and used over again.

The thickened and dewatered pulp from the settling tanks is drawn off from the bottom discharge through a pipe line connected to the suction of a centrifugal pump. This pipe line is arranged so that the contents of any tank can be drawn off. A cyanide solution pipe is connected to each tank to introduce solution if desired. The pulp is discharged by the pump into the agitator tanks, which are of the tall, cylindrical, conical-bottom type of 100 tons capacity each, and designed for rapid extraction of gold and silver by means of air agitation in a weak solution containing a small percentage of cyanide.

It was assumed that silver was the predominating metal in the ore that required about 36 hours to be brought into solution. After the required agitation the pulp is drawn from the agitator tanks by two centrifugal pumps and delivered into the pulp storage tanks, where it is kept in gentle agitation and prevented from settling by a stirring gear. From the storage tanks the slime is drawn into the filter tanks as required.

For removing the solution from the pulp the vacuum filter system is used. A charge of pulp is delivered to the filter box, and, after removing the solution by a vacuum applied to the filter leaves and following it up with the necessary washings, it is finally discharged through the bottom of the tanks and is sluiced out. The solution is collected in a small storage tank and from there is pumped through a clarifying filter press into any one of the six precipitation tanks.

By means of zinc dust introduced in the form of an emulsion and with agitation by compressed air, precipitation is effected. The contents of the precipitation tanks are pumped to the refining plant and the precipitates are collected in the filter presses through which the material passes. The solution is delivered to the storage tanks for restandardizing before using again. The precipitates are dried and shipped to the refineries for reduction to bullion. The loss of cyanide of potassium is about 4½ pounds per ton of ore treated.

All elevators and pumps for handling water solution and slime for such a plant as described should be installed in duplicate to insure against stopping the plant in case of a break-down.

In a cyanide plant for treating gold ores the number of tanks and agitators will be reduced according to the time required for bringing the gold into solution, and loss of cyanide of potassium in pounds per ton of ore treated will be proportionally lower.

The cyanide process is developing rapidly and in some of the most modern cyanide mills, both amalgamation and concentration are eliminated, except in cases where the ore contains material that is detrimental to the action of cyanide, or where the ore contains sufficient lead to warrant the additional expense of concentration. The general tendency of up-to-date metallurgists is to simplify the mill as much as possible.

Mention should be made of the modern practice of crushing in a weak cyanide solution and not using water at all. This practice is adopted even where concentration is necessary. The reason for crushing and concentrating in cyanide solution is that it prevents dilution of the cyanide solution by the water in the tailings where water is used for crushing, and also hastens the process by immediately acting on the gold or silver.

Converting Basic Slag Into Fertilizer

According to a United States Consular Report a new industry for Sydney, Nova Scotia, is a plant for converting basic slag, at present a waste product of the local steel works, into a fertilizer. The Dominion Iron and Steel Co. has contracted with a company providing for the use of the steel-slag waste from their Bessemer plant as material for the manufacture of a fertilizer. At present, the slag from the steel works, amounting to about 30,000 tons per year, is dumped into a creek.

Fig. 3. Vanner Room

Driving the Loetschberg Tunnel

Methods and Machinery by Which Rapid Work Has Been Accomplished Under Difficult Circumstances

The following is an abstract from an article entitled "Tunnel Driving in the Alps," by W. L. Saunders, which was published in the Transactions of American Institute of Mining Engineers.

The Loetschberg tunnel, driven through the Bernese Alps, in Switzerland, is the last link of a railroad system connecting the city of Berne directly with the village of Brigue, which is situated at the north portal of the Simplon tunnel. With its completion, and the lately finished 12,000-foot Weisenstein railroad tunnel located about 30 miles north of Berne, it forms the shortest route between London, Paris, Brussels, or Hamburg, and Genoa, via Berne, Thun, Brigue, and Milan.

The question of connecting the Bernese Oberland with the Rhone valley had its origin as far back as the year 1866, and the present location of the tunnel was proposed in 1899.

Estimates were prepared, and the cost of the new proposed tunnel was calculated to be:

Tunnel excavation and lining	$ 8,660,000
Tracks, installations, etc.	1,400,000
Total	$10,060 000

or a total cost of $211 per linear foot.

The new road begins at Frutigen, in the Bernese Oberland, about 32.5 miles from the north portal; 50.5 per cent. of this length is on horizontal curves, and 90 per cent. is on grade. There are 12 tunnels, aggregating 16,000 feet, one of which is a spiral tunnel 5,460 feet long, with a 985-foot radius. The maximum grade is 2.7 per cent., and the difference in elevation between Frutigen and the north portal of the Loetschberg tunnel is 1,370 feet.

The main tunnel is 47,678 feet long, and was first planned to be on a tangent. After the cave-in of July 23, 1908, it was found necessary to insert a curve of 3,600 foot radius in the tunnel in order to drive through solid rock. The elevation of the north portal is 3,940 feet; of the south portal is 4,000 feet., and the maximum elevation of the tunnel is 14,081 feet above sea level. The maximum grade in the tunnel is 7 per cent. The distance from the south portal to the end of the line, at Brigue, is 15.75 miles. Of this length 28 per cent., or 23,200 feet, consists of 21 tunnels, the longest being 4,450 feet. Of this stretch 54 per cent. is on curves, and 90 per cent. on grade. The difference in elevation between the south portal and Brigue is 1,110 feet, and the maximum grade is 2.7 per cent.

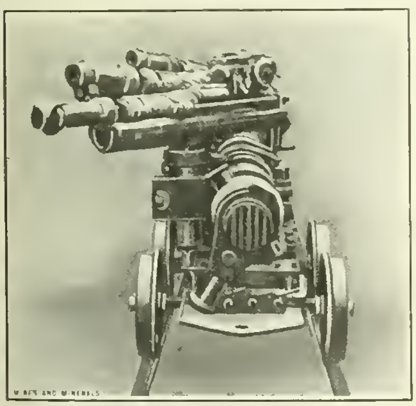

Fig. 1. Carriage with Drills

Summarizing, the total length of the road is 45.8 miles, of which 36 per cent., or 86,900 feet, is tunnels. Let it be added that, for construction purposes, a narrow-gauge railway had first to be built to reach both portals. On the south side of the tunnel the construction railway necessitated 38 tunnels, aggregating 18,000 feet. Of the 38 tunnels, 11 only will be part of the permanent road.

Beginning at the north portal, the materials penetrated have been calcareous for a distance of about 13,100 feet; while on the south side, crystalline schist has been found on about 13,000 feet, and granite, forming the central part of the mountain has been penetrated by both headings.

On July 24, 1908, when the main heading had reached a point 1.6 miles from the portal, it struck a cleft filled with sand, gravel, and water. There was a sudden and violent inburst of these materials, which in a few moments filled up the tunnel for a length of 5,900 feet, burying 25 workmen and all the drills and other installations beyond hope of recovery. It is estimated that about 8,000 cubic yards of sand and gravel entered the tunnel.

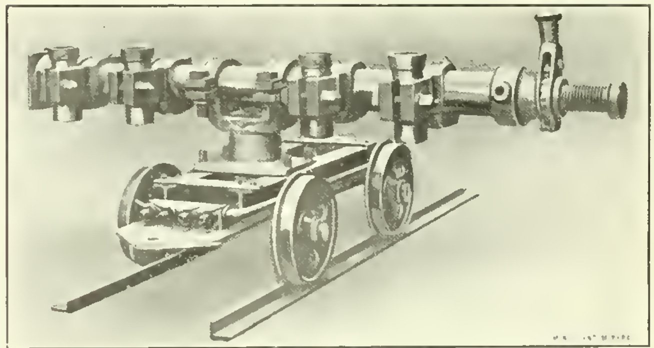

Fig. 2. Carriage for Four Drills

To avoid any further irruption of the materials, the tunnel was walled up by a 33-foot wall at a point 4,675 feet from the portal.

A commission of engineers was convened to decide upon a course to be adopted. Three methods were considered: (1) To force the tunnel through on the original line; this was considered impracticable, due to the great pressure from the 590-foot depth of water, sand, and gravel, over the tunnel. (2) To use the freezing process; this also was considered impracticable. (3) To deviate the line and cross the Gastern valley further up stream. The last plan was adopted. The new line leaves the original location at a point .75 mile from the north portal. No further serious difficulty was experienced in tunneling through the diversion

Driving of the headings was begun on October 1, 1906, for a single-track tunnel, and continued until October 1, 1907, when it was decided to drive a double-track tunnel; 86 per cent. of the tunnel had been driven by October 31, 1910, and it is expected that, unless unforseen delays or accidents occur, the headings will meet in 1911. On October 31, 1910, the 4,000 feet of heading, which had been abandoned after the cave-in of 1908, had been regained.

The power plant for the south heading, situated at Goppenstein, is driven by electric power. The current is brought at 15,000 volts, and stepped down to 500 volts for power purposes.

Compressed air for the drills is furnished by three two-stage Ingersoll-Rand compressors, each having a capacity of 1,950 cubic feet of free air per minute, and a compression of 145 pounds per square inch. They are driven by 400-horsepower electric motors. Compressed air for the locomotives is furnished by two four-stage Ingersoll-Rand compressors, having a capacity of 460 cubic feet of free air per minute, and a compression of 1,760 pounds per square inch. They are driven by 250-horsepower electric motors.

The power plant for the north heading is situated in Kandersteg. Electric power, used throughout the works, is brought from Spiez at 15,000 volts, and stepped down to 500 volts for power purposes in the tunnel as well as in the shops.

Compressed air for the drills is furnished by two two-stage Meyer air compressors, each having a capacity of 1,770 cubic feet of free air per minute, and a pressure of 117 pounds per square inch. They are belt-driven by 450-horsepower electric motors.

Compressed air for the locomotives is furnished by two five-stage Meyer high-pressure compressors, with a capacity of 565 cubic feet of free air per minute, and a pressure of 1,760 pound per square inch. They are belt driven by a 250-horsepower electric motor.

All trains in the tunnel are operated on a regular time schedule, changed from time to time according to the progress of driving.

Steam locomotives are used outside, while compressed-air locomotives are run inside of the tunnel. A few mules are still in use in the south bottom heading.

Four types of cars are used for the service inside and outside of the tunnel: (1) Passenger cars having a capacity of 24 men each, and run only when shifts are leaving or entering the tunnel. (2) Cars having a capacity of 35 cubic feet, used for mucking. (3) Cars of 70-cubic-foot capacity, used chiefly for transporting masonry materials. (4) Flat cars, used for timber, rails, etc.

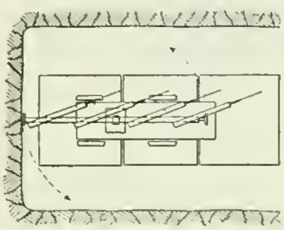

Fig. 3

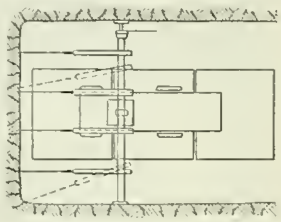

Fig. 5

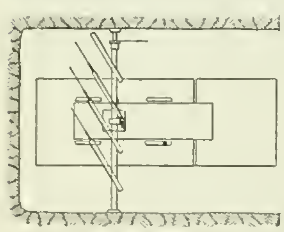

Fig. 4

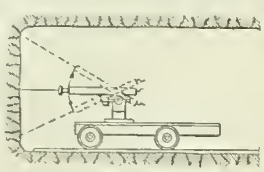

Fig. 6

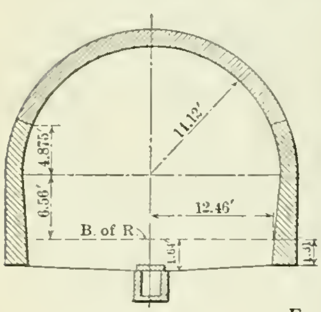

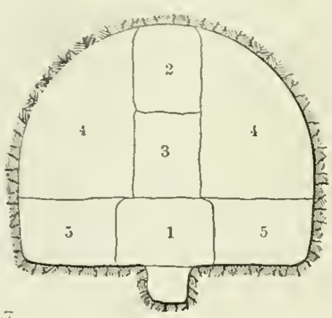

Fig. 7

The gauge for all tracks laid in the tunnel is 30 inches; the rails, of from 30 to 40 pounds per yard, being laid on wooden stringers, except in the last 100 feet of the bottom heading, where portable rails with pressed-steel tires are used. Trains are run in the tunnel at a speed of from 8 to 10 miles per hour.

Electric light is used only in that part of the tunnel already lined with masonry and partly completed. Portable acetylene lamps are used throughout the tunnel with a few exceptions.

Drainage on the north side of the tunnel is provided by means of a ditch 2 feet 8 inches wide, and 2 feet deep, placed between the two tracks. It has the same slope as the tunnel. The flow of all springs encountered on this side of the tunnel amounts to about 105 gallons per second, most of the water coming from that part of the tunnel where the cave-in occurred in 1908. The flow on the south side of the tunnel amounting to only 20 gallons per second, the section of the drainage ditch is but half the size of the one on the north.

The records made in driving the headings are due to the excellent organization, and to the methods of setting up and taking down the drills.

Fig. 1 shows a carriage with drills mounted in position to be taken from the heading after a blast, and Fig. 2, the carriage carrying four drills. In this type the beam and counterweight are omitted, the bar, on which 4, 5, or 6 drills are mounted, being placed directly on the truck. The width of the tunnel in which these cars can operate varies from 6 to 13 feet.

A drill carriage of simple but efficient design was devised by the contractors. Each carriage carries four or five drills, Fig. 3 shows the carriage, together with the drilling machines, when brought forward just after mucking in the heading. Fig. 4 shows the horizontal shaft swung into position ready for being jacked, and the drills ready to be swung into the position shown in Fig. 5. It can be seen from Fig. 5 that the drills can be swung through an arc of a circle or moved sideways, while in Fig. 6 the different positions which the drills can be given by being swung in a vertical plane are shown.

The time required to change the machine from the position shown in Fig. 3 to that shown in Fig. 5 and to commence drilling is usually from 6 to 8 minutes. This shows the superiority of carrying the drills for such work over any other method used up to the present time.

Three kinds of explosives are used. Dynamite, with about 85 per cent. nitroglycerine, is mostly used in the headings. Westphalite and cheddite, being more safely handled, are used for enlarging and for small blasts.

Great stress is laid on the fact that a high-grade explosive breaks the rock into small pieces, not larger than an orange, which enables mucking to be done with shovels.

Firing is done with ordinary fuses. The dynamite cartridges are wrapped with red paper in order to be easily detected in case of a misfire; and dynamite carriers and handlers are provided with red lanterns.

Italian labor is used throughout the works with the exception of some Macedonians lately imported. Mostly Italians from the northern provinces of Italy are employed.

A bonus system of payment is used throughout the different kinds of operations. The following wages are paid:

Drill foreman, $2.60; drill runners, $1.70; muckers, $1.30; nippers, $1; tracklayers, 95 cents; masons, $1.40.

There are three 8-hour shifts per day.

As shown on Fig. 7, the width of the finished tunnel section is 28 feet at the arch springing and 25 feet at the base of the rail. The arch is semicircular, the crown being 20.7 feet above the base of rail.

The sequence of excavation is illustrated by Figs. 7 and 8. A bottom heading 6.5 ft.×10 ft. is first driven several hundred feet in advance of the enlargement. Upraises are then driven from 500 to 600 feet apart, and a top heading started back and forth. The top heading is then enlarged as shown by the sections in Fig. 8.

In the bottom heading the mining operations proceed as follows: The drill carriage is run forward from its siding close to the face of the heading, passing over 5'×5'×⅜" steel plates laid on the floor of the heading for a length of about 30 feet. Each plate is provided with 1-inch holes at the corners for ease in handling with a pick.

The water and air pipes laid on one side of the heading to about 40 feet from its face are connected with the drill carriage, and the drilling begins with the top holes. Water sprinkling is frequently done, especially in starting the holes, in order to lay the dust.

Without interfering with drilling, mucking is going on just behind the drill carriage, and the loaded muck cars are run back to a siding, where trains of from 20 to 30 cars are formed and hauled out by air locomotives.

Drilling being completed in the heading, the drill carriage is run back to its siding, and the steel plates laid on the floor are covered with a layer of muck about 4 inches thick to prevent deterioration.

The drill holes are then loaded and carefully tamped, and the last man to leave the heading, after firing the fuses, opens the air-pipe valve, the escaping air thus creating a cushion of fresh air from the face of the heading back to a certain distance, so that, after blasting, the muckers are able to go to work without delay.

A high-grade explosive only is used in the heading, which breaks the rock in small pieces and renders mucking with

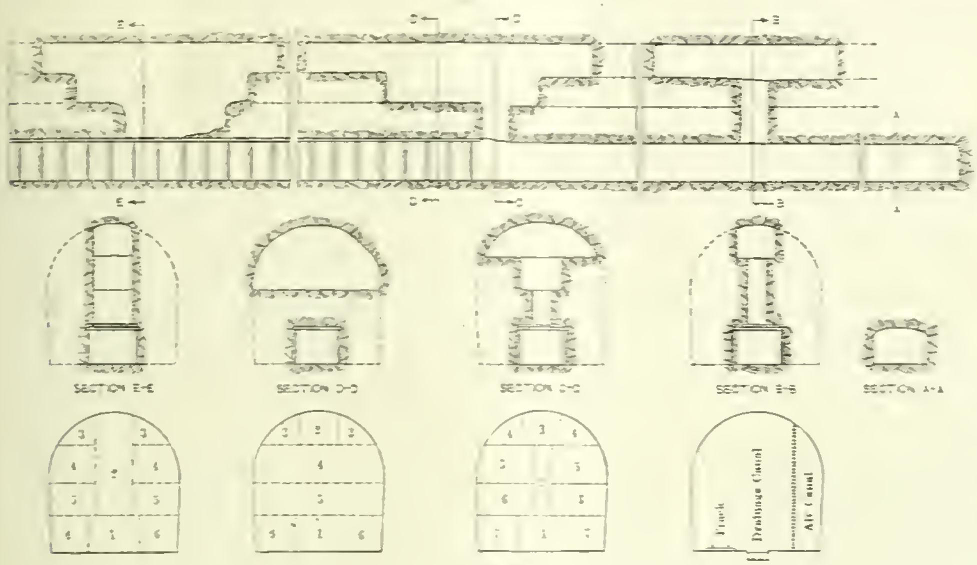

FIG. 8

shovels easy. The drill holes, having an average depth of about 4 feet, are started with a 3-inch bit and finished with a 2-inch bit. On account of giving better results, firing is done with fuses, about 4 feet long, the center holes being fired first.

Mucking operations proceed as follows: Two empty cars are run to the heading, the first one being immediately loaded by two or three men shoveling without interruption until the car is fully loaded. This operation is performed in 3 or 4 minutes, which means that 1 cubic yard is loaded in from 2.5 to 3 minutes.

Owing to the manner of drilling and blasting and to the shallow holes, the muck, instead of piling up in front of the face of the heading, is thrown back, and forms a layer over the floor, which enables the track to be cleared rapidly.

At Loetschberg a cubic-meter car (35.5 cubic feet) is filled in 5 minutes, and it takes only 1 minute to get this car away and bring an empty car to the heading. In order to do this, small entries or chambers are excavated at intervals in the lateral wall of the main heading, which enables an empty car to be thrown from the track on the side, thus clearing the track and allowing the filled car to pass, whereupon the empty car is turned up on its wheels and rolled into the heading. An illustration of an improvised siding in a narrow heading, by means of which one car may pass another, is shown in Fig. 9, the operation being as follows:

When the car, *A*, is filled, it is taken away on the track, *B*. and immediately after it has passed the point, *C*, the empty car, *D*, which had been turned on its side, is righted on the track, and brought to the advancement in the space of 1 minute. As soon as the car, *D*, has been brought to the advancement, another empty car, *E*, is brought to the same point, *C*, turned on its side, until car, *D*, is filled and taken away. In one instance, 14 carloads, each of 1 cubic meter volume, were taken away in 1.5 hours, which cleared the heading completely and allowed the drill wagon to be brought in. Eight men remove the debris, two men go to the face *F*, and search the debris for any dynamite cartridges which might not have exploded. Of the eight men, four fill the car, as shown at *M*, which takes 5 minutes; then they rest for 5 minutes, while the second gang of four men fill the second car, etc.

Drilling is started not more than 5 minutes after the removal of the last carload. This result, which at first sight seems impossible, is only obtained by absolute discipline.

The man who knows that his only work at this moment is to connect the air main to the drill carriage does not do anything else; the men whose duty it is to screw the carriage tightly to the wall immediately jump to the right place.

The system has been adopted of low and wide gallery in the proportion of 1 : 2; that is, the gallery is 6 feet high by 12 feet wide.

The rate of drilling is 15 to 16 holes in from 1.1 to 1.15 hours.

Drilling in the top heading is accomplished by means of two or three drills carried on tripods or on a horizontal bar, while hammer hand drills are used generally for the enlargement.

Mucking operations in the top heading are very simple, since all blasted material is dumped directly through the upraises into cars running on a siding in the bottom heading.

The operations of blasting, mucking, timbering, and hauling are performed without interruption and without interference with each other, and a special force of engineers is required in order to obtain such a result.

All employes and workmen are insured against accident or death, by the contracting company, and great care is therefore exercised in handling explosives and in operating the trains. Data pertaining to the driving of the bottom heading are given in Tables 1 and 2, and the rate of progress in the bottom heading is given in Table 3.

Ventilation in the tunnel is obtained from two fans 11.5 feet in diameter, having a capacity of 53,000 cubic feet of air per minute at 5.5-ounce pressure. Each fan is belt driven by a 175-horsepower electric motor, housed in a building at each portal, forming part of the permanent ventilation system.

Air is taken in that part of the tunnel already completed through a canal of 68 square feet area, made of hollow tiles,

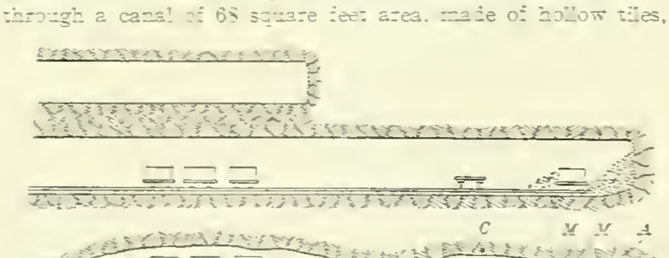

FIG. 9

shown in Fig. 8, then through steel pipes to electric-driven blowers running in series, and having a capacity of 6,300 cubic feet of air per minute at 14-ounce pressure. These two blowers are mounted on carriages, and are moved along as the work advances.

Openings are provided at intervals in the above-described air canal so as to allow part of the air to escape in the tunnel.

TABLE 1. DATA OF DRIVING 430 FEET OF BOTTOM HEADING (NORTH SIDE)

Number of drills	5
Number of rounds	112
Number of linear feet driven per round	3.84
Number of hours per round for drilling	1.39
Number of hours per round for blasting and mucking	4.58
Number of rounds per 24 hours	5
Total length of bore-holes per round, feet,	55.40
Number of holes per round	12
Average depth of bore holes, feet	4.43
Length of holes per cubic yard, feet	6 25
Dynamite used per cubic yard, pounds	5.80
Number of steel bits used per cubic yard	1.45

TABLE 2. DATA OF DRIVING 1,751 FEET OF BOTTOM HEADING (SOUTH SIDE)

Number of rounds	510
Number of linear feet driven per round	3 44
Number of hours per round for drilling	1 25
Number of hours per round for blasting and mucking	2.91
Number of rounds per 24 hours	5
Number of bore holes per round	11.70
Total length of holes per round, feet	40.70
Average length of holes	3.54
Length of holes per cubic yard, feet	5
Dynamite per cubic yards, pounds	5.95
Number of steel bits per cubic yard	2.85

TABLE 3. RATE OF PROGRESS PER MONTH IN BOTTOM HEADING JUNE, JULY, AUGUST, AND SEPTEMBER, 1909

	North Side *	South Side †
Progress, feet	959.30	526.60
Number of drills	4	5
Average daily progress	34 30	17.50
Temp. rock F. degrees	59.75	83.77

* Material in north heading, limestone.
† Material in south heading, crystalline schist.

In comparing conditions on the north and south ends of the Loetschberg tunnel, it is well to bear in mind that at the south end the rock is generally harder and the temperature higher. At the north end the temperature varies from 75° to 80° F., while at the south end it has reached a maximum of 110° F. It is also claimed that a remarkable organization of the working force exists on the north end. The settlement at south end was built by the Loetschberg company. The winter there is extremely severe and dangerous. Three years ago, by an avalanche, seven men were killed, among them an American engineer named Merwarth, who was at the time installing the compressed-air machinery. Conditions of this kind do not favor the contractor in getting the best kind of labor. Kandersteg, at the north end, is practically a summer-and-winter resort, full of good hotels, easy to reach, and a more favorable labor market.

At one time, when the north heading was making a daily progress in excess of the south heading, the contractors sent some of the drills from the north heading over to the south, thinking that perhaps the difference in progress was due to the drill, but the results were not changed. It seems plain that were it a question of machinery only, the machinery making the greater progress would be used throughout, but the difference appears to be one of natural conditions and of organization.

Ore Mining Notes

The Hartford Mine Fire.—In the Hartford iron mine, near Negaunee, Mich., seven men were smothered by the timbering catching fire. Taken in the aggregate, the loss of life in metal mines due to mine fires will approach closely that in coal mines.

Metal Mine Fire.—Rock high in sulphur is on fire in the Youngs mine of the Breitung estate on the Menominee Range. The company working this property brought a winze through to the surface and capped it with a smokestack, up which the fumes from the burning mass are being safely conveyed from the mine.

Careless Blasting.—An explosion in the Czar shaft of the Copper Queen mine, Bisbee, Ariz., took place some time ago, in which one man was killed and seven others were injured. The men were going down into the mine on a cage when the blast was set off. The cage was down about 250 feet when the explosion occurred, and every man of the eight on the cage was injured, but not seriously, except the one that was killed. It is not absolutely known whether the explosion hurled a boulder into the passing cage, or whether the shock of the explosion jarred a section of rock from the side of the shaft.

Unwatering Giroux Mines.—When the pumps were started on the 1,200-foot level of the Giroux Consolidated Mines, Kimberly, Nev., the water in the Alpha workings subsided at the rate of 3 feet a day. It is presumed that the water zone will be passed through at this depth, and miners are now engaged in finishing the station at the bottom of the shaft where a permanent pumping plant will be installed.

Canadian Blast Furnace.—The largest blast furnace in Canada has been lighted with appropriate ceremonies by Miss Ruth McDonald, in connection with the Lake Superior Corporation. It has a capacity of 500 tons, and there is work awaiting it sufficient to keep it going 5 years.

Cochrane, Ontario, Chimney Gold.—According to the Cobalt *Nugget*, Cochrane, Ontario, has the gold fever. A few days ago a plumber was taking down a chimney of one of the houses burned in the fire at Cochrane. He found a speck of gleaming metal in the cement, and with the gold fever in the air went to an old miner with it. It is alleged that the latter said it was gold and then the excitement began. The rush was to discover where the sand came from that was used in the chimney. That discovered, the plumber and his friends got a miner's license from Matheson and hiked out to stake out the sand pit. Others on the suspicion that the plumber might have made a mistake in the location of his sand staked out the only other sand deposit in the neighborhood. If this excitement continues the Gold Dust Twins will be staked out.

Cananea Consolidated Copper Co.—The new construction work at the Cananea Consolidated Copper Co.'s plant, at Cananea, Mex., is completed, with the exception of the dust chamber for the converters. Six new McDougal furnaces have been installed, bringing the total to 10. The spreading bed for handling the calcined ore from the roasters is in operation, and the ore dryers are installed. Since the 1st of April the Miami concentrates have been sent to Cananea from the Globe, Ariz., district, at the rate of about 50 tons daily.

A 10,000-Dollar Grub Stake.—In the mining industry of Colorado several thousand dollars have been subscribed to a fund to grub stake prospectors. The word has gone forth that Colorado needs another camp like Cripple Creek or Leadville, and it is presumed that its discovery will be heralded to the world before the snow flies.

Reopening the Henrietta Mine.—The Greene-Cananea Copper Co. has reopened the Henrietta mine after a shut-down of about 10 months. An electric hoist has been installed and the force of men increased considerably over the number at first placed at work. It is reported that the Puertocitos mine will be reopened eventually. The first trains from Naco brought a large amount of concentrates which were waiting the resumption of railroad operations. They were shipped by the Miami company. The first day the road was opened three freight trains were run into Cananea, carrying supplies and concentrates. The first trains out of Cananea contained many cars of bullion that had accumulated during the tie-up.

Alaskan Gold.—When the steamer Schwatka sailed for Fort Gibbon a few days ago from Fairbanks, she carried more than a ton of gold bricks. The shipment is valued at $500,000. Another shipment, the value of which was not made public, was made by the American Bank. The clean-up is progressing on all creeks and gold-dust shipments are coming into town daily from the mines. So far there has been plenty of water for washing.

A New Nye County, Nev., Silver Mine.—William Lloyd and E. A. Hodges have located ground along a ledge of rocks about 125 miles southwest of Pioche, and about 25 miles north of the San Pedros main line. The white men were guided to the spot by two Indians. The rock forwarded to Salt Lake City is tinted delicately with yellow and green and is fairly loaded with silver and lead.

The Pittsburg Mine of California.—The Pittsburg mine, which is located near Nevada City, Nevada County, Cal., has been developed to the 1,300-foot level, where a good body of ore has been found. The 20-stamp mill of the property is running at full capacity on an excellent quality of quartz.

The Black Oak Mine—In the Black Oak mine, near Soulsbyville, Tuolumne County, Cal., the vein which was lost several months ago has been recovered. It was found on the 15th level with about 5 feet of ore in evidence. The vein was lost about 2 years ago after yielding more than $1,000,000 of gold, and its recovery beyond the fault is expected to add new life to the entire district, as it demonstrates the persistent nature of the veins in no uncertain manner. The Black Oak property is equipped with a 40-stamp mill, canvas concentrator, and cyanide plant. R. C. Knox is manager.

The Montana Smelters.—The ore output of the original group of the Anaconda properties in Montana is sent to the Washoe smelter at Anaconda, and the ore taken from the mines formerly owned by the Boston & Montana Co. is nearly all sent to the smelter at Great Falls, Mont. Under normal conditions about 10,000 tons of ore are hoisted to the surface and sent to the Washoe smelter in steel cars weighing 18 tons each and carrying about 50 tons of ore. Taking into consideration the custom ore and the supplies other than coal and coke, a combined tonnage of 14,000 tons is brought to the Anaconda smelter every day in the year. To treat the 10,000 tons of ore from the mines, 2,000 tons of crushed lime rock and about 1,000 tons of the coal and coke are required daily.

Green River, Utah, Oil Field.—According to advices, oil in large quantities has been found in the Cook-Lebi well near Green River, Utah. The oil is found in the second sand, or less than 500 feet in depth, and it is estimated that from 125 to 200 barrels a day are flowing. The oil is said to analyze 60 per cent. gasoline and 35 per cent. gravity.

Steamboat Camp, British Columbia.—It is reported that a discovery of a 75-foot vein of copper ore has been made in the new Steamboat Camp in British Columbia. The value of the ore has not been made public.

Progress in the Ketchikan District, Alaska.—The Alaska Industrial Co.'s property near Sulzer, on the west coast of Prince of Wales Island, is being steadily developed. Shipments of ore have been made monthly since 1906, the output for 1910 being over 20,000 tons of a good grade of copper (chalcopyrite) carrying from $1.50 to $2 in gold per ton. Under the management of Chas. A. Sulzer, the expense of operating, as well as that of building a tram road, of installing machinery, and of acquiring some 100 claims, has been largely paid for from the proceeds of the ore. The greater part of the force of 50 men are now working in ore of which an ample supply seems assured, a diamond-drill hole sunk last summer still being in mineral at a depth of 123 feet.

Tungsten Mining.—The principal tungsten properties in the Randsburg, Kern County, Cal., district, with the exception of the Atolis Mining Co. properites, are owned by the following individuals: J. S. Deacon, W. A. Wiskard, B. M. Atkinson, F. W. Atkinson, and Samuel H. Dolbear. The deposits are very irregular and cannot be developed by ordinary working methods without the expenditure of considerable capital. It is doubtful if even the Atolis company has at any time had a year's reserve of ore developed.

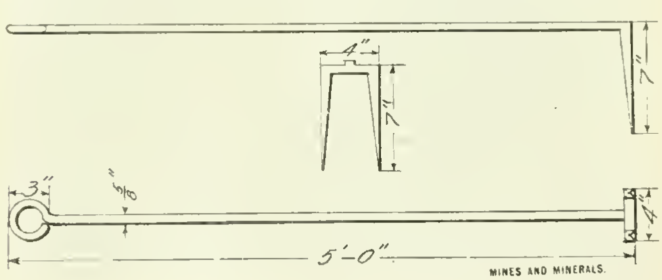
Snake Bite.—It will be of interest to total abstainers to learn that whiskey as an antidote to snake bite is tabooed. For hydrophobia, skunk bite, rattlesnake or copperhead bite, for scorpion and tarantula stings, use permanganate of potassium, $KMnO_4$, in solution. Tie a tourniquet above the wound, then cut it deep with a knife, and if there is no one to suck the wound previously, apply the solution or rub in the permanganate in crystal form the same as a barber applies alum to a cut. Permanganate of potassium dissolves in 20 parts of water, forming a purple-red solution, which turns yellowish-green when brought in contact with a substance having affinity for oxgyen. It is a caustic and an oxidizer.

The 700-ton smelter of the Clara Consolidated Gold and Copper Mining Co., at Swansea, Ariz., was blown in on June 19. The company is still doing considerable construction work in the way of improving facilities for handling and treating ores. A spur track from the Arizona and Swansea Railroad is being continued by means of a switchback to a point above the reduction works, which, when completed, will allow customs ores, coke, and fuel to be handled by gravity direct to the points of consumption at a minimum cost. A No. 11 Roots blower is being installed which will give additional blast to the furnace and considerably increase its capacity. A 44-foot structural steel extension to the converter building has recently been completed. The sampling plant for handling customs ores has been finished and is now in operation. This will give the small producers of that section an opportunity of disposing of their ores to advantage and will, no doubt, greatly increase mining activity in the vicinity. Development of ore bodies in the company's mines at Swansea is being pushed, particularly on the 400- and 500-foot levels. Considerable exploration work with churn drills is also being conducted with gratifying results.

Electric Power Plant of the Santa Rosa Mining Co.—The Santa Rosa Mining Co., located in the State of Zacatecas, Mex., near Concepcion del Oro, is erecting most of the machinery that will enter into the equipment of its mills. Electric power is supplied to the property from a gas-producer plant. The gas engine will be connected by a belt to a 150-kilowatt Westinghouse alternating-current generator. Switchboards, transformers, etc., and 20 motors have been installed. The tube mill is driven by a 60-horsepower motor; there are 7 motor-driven direct-connected pumps for supplying water to the cyanide plant, and nine other motors located at various places around the plant. A transmission line about 2 miles long supplies the current to three motor-driven pumps, which control the water supply.

Chute Hook at Radiant Mine

We are indebted to Mr. J. Q. McNatt, mining engineer, of Florence, Colo., for the sketch of a hook used to clean the mine-run screens at the Radiant mine of the Victor American Fuel Co., near that city. It will be noted that the rake shape of the points makes this more effective in removing pieces of coal



Plan and Section of Chute Hook

wedged between the bars of a screen than the single point of a pick. This hook is particularly useful to the car trimmer as the double points enable him to easily draw forward a lump of coal which may need to be broken to remove a layer of slate or bone. It would seem, for use by the car trimmer, that the handle had better be made elliptical in shape, similar to that employed on coke scrapers, than circular as in the sketch. The points of the hook being sharpened, the use of a pick is dispensed with.

The Cranberry Iron Ore Mine

Large Deposit of High-Grade Magnetite. Methods of Mining and Electric Concentrating

*By J. M. Cameron, M. E.**

In 1887, W. C. Kerr and G. B. Hanna of the Geological Survey of North Carolina, wrote a book entitled "The Ores of North Carolina." In this a short description of the Cranberry ore bank will be found. In the May, 1911, issue of *Mine and Quarry* there is a descriptive article on the Cranberry mine by B. C. Hodgson, from which much of this article has been abstracted.

The Cranberry iron ore deposit is formed by an aggregation of magnetite crystals cemented together so as to form an almost pure mineral mass. Magnetite, Fe_3O_4, when chemically pure, contains 72.4 per cent. iron and 27.6 per cent. oxygen; as found in magnetic form, however, the iron analysis is not likely to exceed 70 per cent. Of the two analyses given, No. 1 was made by the late Professor Genth, of Philadelphia, and No. 2 by the late Professor Chandler, of New York City. From the analyses furnished, the writer is inclined to the belief that they were made from picked samples and not run-of-mine or shipping ore.

Cranberry ore bank, which is on the western slope of Iron Mountain, in the northeastern part of Mitchell County, N. C., receives its name from Cranberry Creek, which flows at the foot of the steep hills on which it outcrops. It is owned by the Cranberry Iron and Coal Co., who mine and ship it to their furnaces at Johnson City, which is 34 miles distant.

Fig. 1. Cranberry Iron Mine

The ore deposit is in the form of a large lense whose length and depth are not fully known. The gangue minerals are pyroxene, epidote, quartz, feldspar, and garnet, with occasionally other minerals of a common kind. It is now the generally accepted belief that the magnetite deposits of the Appalachian Mountains crystallized from the magmas of which they formed a part. The isometric crystals, when small, formed a hard compact mass, but when large the mass had less cohesion, and on account of the diamond-shaped crystal faces it presents, it is locally termed "rattlesnake ore." The magnetite is associated with epidote and feldspar, which form horses in the deposit and decrease its purity; usually, however, it is in lenticular masses whose greatest lengths are along the strike, and these are the chief sources of ore. The thickness of the ore lenses varies from a few inches to 70 feet.

Analyses of Cranberry Ores

	No. 1	No. 2
Magnetite Fe_3O_4	94.37	91.83
Magnesia MgO	.36	.23
Alumina Al_2O_3	.42	1.03
Lime CaO	.43	1.06
Manganese oxide MnO_2	.26	.32
Water		1.15
Silica SiO_2	4 16	4.02
Sulphur S		.25
Phosphoric acid P_2O_5		

*Johnson City, Tenn.

The country rock is gneiss in contact with syenite; the ore zone, however, is confined within the gneiss. The normal strike of ore beds in the Appalachian Mountains is northeast and southwest, and as the Cranberry bed strikes northwest and southeast it would indicate that it had been subjected to faulting, and this probably accounts for the deposit being cut out by rock in a southeasterly and narrowed in a northwesterly direction. A general idea of conditions prevailing at the Cranberry mine can be had from Fig. 1. At the outcrops on the top of the hill the deposit is approximately 400 feet wide between the foot-wall and hanging wall, and has an average dip of 34 degrees. The top 80 feet of the deposit was worked as an open-cut mine until drift and stope mining was substituted to avoid handling horses of rock. In order to reach the ore at the level of the valley a tunnel was driven about 450 feet in length. On reaching the ore the drift was continued to the right in a northerly direction 350 feet to the foot-wall. The drift was made large, and from it stopes were worked up to the open cut above, thus allowing daylight to shine into the lower or main level. A good idea of the height of one of these stopes can be obtained from the pillars, shown in Fig. 2, and the hole in the upper right-hand corner through which daylight shines. On the main level there are several parallel tracks which serve the rooms on this level and the three slopes put down from this to a level below. Underhand stoping is practiced, and as the rooms are formed care is taken to secure such shape to the roof that when once finished it will remain safe indefinitely. After each blast a force of men termed "scalers" work from the top of the stope, pull down or break if necessary any pieces of ore likely to come loose in time, and thus make the roof safe. As the drills are always advancing the stope room, the roof is usually left in safe condition. Occasionally, however, in some part the roof of one of the large rooms will need attention, and it is reached then by specially constructed ladders, or other means are devised by the scalers.

The three slopes sunk from the main level to the lower level are inclined at 30 degrees and have a length of about 400 feet. From these slopes, levels are driven right and left on the strike of the ore at intervals, and after any one of the levels has been advanced a sufficient distance a room is turned and by underhand stoping driven to the level above. Between adjacent rooms a pillar of ore shaped like an hour glass, as in Fig. 2, is left standing to support the cover, and as that is not heavy, a small pillar of strong ore is sufficient.

The open-cut level shown in Fig. 3 is approximately 100 feet higher than the main level. In the face of ore left after open-cut work was abandoned, levels have been driven, as shown, and rooms opened as on the other levels. In Fig. 3 an opening resulting from working upwards from the main level is seen, and this is now used as a chute for ore from the upper to the main level. The floor of the open cut, which has been stated as having been 400 feet from foot-wall to hanging wall, is also shown. During the time open-cut mining was followed the ore was loaded into cars and dumped into the chute shown in Fig. 1, and thus lowered to the ore bins.

Entirely separate from and 200 feet above the floor of the open-cut mine is another outcrop of magnetite. This deposit is separated from the other by a horse of rock which does not pass through, although it enters the ore, for which reason the upper deposit is presumed to be part of the lower. Three slopes having a pitch of 38 degrees have been sunk on the upper deposit to a depth of 150 feet, only one of them, No. 2, will be continued, the other having been sunk to quickly open working places. At present the ore is hauled up these slopes by separate

Fig. 2. Pillars in Cranberry Mine

hoisting engines in end-dump cars having a capacity of 3,000 pounds. The cars are then run to the gravity plane shown in Fig. 1, but better shown in Fig. 4, and lowered to the open-cut level. Here the ore is dumped into a chute 80 feet long through which it slides into bins on the main level. The inclined plane from the upper deposit to the open-cut level is 275 feet long and has a perpendicular height of 145 feet, or a ratio of $\frac{1}{1.89}$. At the top level, which is almost to the outcrop, the ore is 20 feet thick, but at a depth of 400 feet measured along the dip the diamond drill core shows it attains a thickness of 70 feet. The main, or No. 2 slope, of the top or outcrop level is being sunk on the true dip of the ore, and another starting from the main, or tunnel, level in the northwest corner of the old mine, is being sunk in the ore, with a view of eventually intersecting the No. 2 slope when the latter has reached a length of 1,800 feet.

About 30 standard piston rock drills of 3⅛ and 3¼-inch cylinder diameter are employed for breaking ground. These drills are mounted on tripods, or mining columns, and are driven by compressed air at 90 pounds receiver pressure. The ample size of the pipe lines and their careful arrangement and maintenance render pressure losses very small. Air reheaters, burning coal, insure dry air at the drills, and further minimize transmission losses. Both the rock and the ore itself are very hard, rendering the drilling slow and throwing a heavy burden on the drills. In recent diamond-drill prospecting, the average progress was 10 feet per 10-hour shift, but for much of the work only 2 feet per shift could be drilled. This will give an idea of the severity of the drilling conditions.

Drill Maintenance.—The cost of drill maintenance resulting from this difficult ground induced the mine officials to conduct very thorough tests on different kinds of drills. This investigation resulted in the adoption of the Sullivan 3¼-inch tappet valve drills, which gave the best results in drilling speed and in repair costs per foot. Since these drills were put in, nearly 2 years ago, there has been a noteworthy reduction in maintenance charges, and an increase in the amount of ground broken per drill. The average drilling speed in this mine is about 6 feet per hour, or 30 to 40 feet per 10-hour day, including setting up, tearing down, and moving the drills. The ore is removed in benches, from 15 to 70 feet high, and the average depth of holes drilled is 8 feet.

The writer, when general superintendent of the company, designed an automatic lubricator which is used on all the drills at this mine and has maintained their efficiency at a high level. The oil chamber is so arranged that the oil is under air pressure, the pressure above the surface of the oil being about 15 pounds in excess of that at the discharge opening. This results in injecting a small quantity of oil into the cylinder at every stroke, and thus keeps the drill properly and positively lubricated at all times.

Ventilation and Drainage.—No artificial ventilation is required. The mine makes but little water in any of its workings, and is kept dry by a pump of 200 gallons capacity, running less than half time. These conditions render labor conditions much more agreeable than usual in a mine of this size and character.

About 25 years ago there was a small charcoal iron furnace in operation at Cranberry. The ore for this furnace was taken almost entirely from the surface outcroppings. Only the choice lump ore was used. The ore at or near the surface, being "weathered," crumbled easily into small particles. Practically all of the fine ore was thrown out with the waste rock and clay. As this went on for a number of years, there accumulated thousands of tons of dump material containing large quantities of ore in fine particles. About a year ago an investigation was made of the quality of these old dumps, with the result that they are now being worked. About 150 tons of this old dump material is being sent daily direct to the furnace, and about 75 tons of it is sent daily to the concentrating plant, making a total of about 225 tons of ore per day taken out of the dumps that but a few years ago were considered as having no value. The ore taken from these dumps and sent direct to the furnace averages about 40 per cent. in iron, has practically no sulphur, and less than .01 of 1 per cent. phosphorus.

The ore is transferred from the mines to the concentrating plant in trips of five cars, each car carrying 3,000 pounds of crude ore. Cars, as they reach the first crusher, are run into a cylindrical cage that, rolling sideways on a track, turns the mine car bottom up, dumping the contents into the crusher hopper. The crusher is a No. 5 Gates gyratory and discharges directly into a $32'' \times 16'$ revolving screen, in which the ore first passes over holes 1½ inches in diameter; the coarse ore then passes over holes 3½ inches in diameter; the 1½-inch size goes

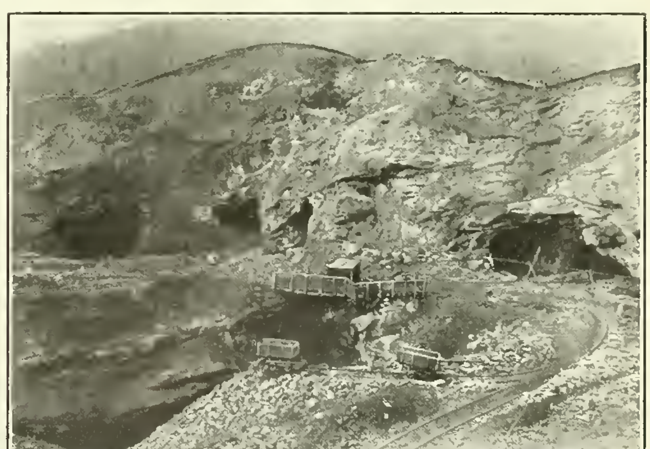


Fig. 3. Open-Cut Level

from the screen to the washers; the 3½-inch size goes from the screen to "cobbing magnets." From these magnets the heads go direct to the loading bin, and the tails go to a smaller crusher. A feature in use at the cobbing magnets is worthy of note: the speed of these magnets is such that dead stock is thrown off by centrifugal force, and many tons of rock are in this way disposed of that would otherwise have to pass through the smaller crusher. After leaving the washers the material is screened into four sizes; first, that which will not pass through a 1¼-inch hole; second, that which, having passed through a 1¼-inch hole, will not pass through a ⅝-inch hole; third, that which, having passed through a ⅝-inch hole, will not pass through a $\frac{3}{16}'' \times \frac{1}{2}''$ hole; and fourth, that which passes through the $\frac{3}{16}'' \times \frac{1}{2}''$ hole. These several sizes are known, respectively, as "coarse concentrate," "fine concentrate," "⅝-inch concentrate," and "dust concentrate." On leaving the screens, the coarse and fine concentrates pass over a series of revolving magnets, while the fine and dust concentrates are carried with a stream of water to magnets that revolve in a water-tight box and pick the ore up out of the water.

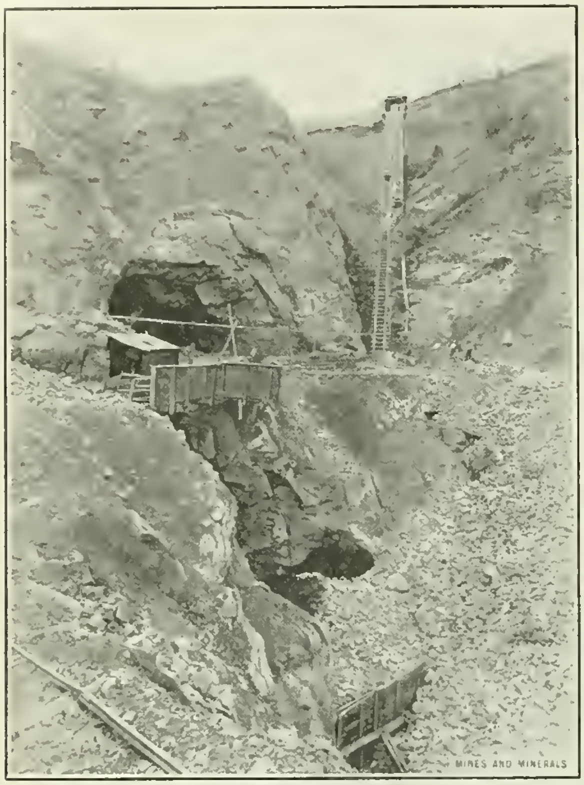

Fig. 4. Incline from Upper Deposit

The magnets in use at the Cranberry concentrating plant are of the revolving cylindrical type. Each magnet has four poles, and carries about 10,000 feet of No. 11 copper wire. The voltage used is 125. Each magnet has attached a suitable rheostat, and the current varies from 4 to 10 amperes per magnet. In operation the current passing through the several magnets is closely watched and readings are taken twice in each 10 hours. When the crude ore coming from the mines carries an excess of phosphorus, the current on magnets is weakened, and there is a greater or less loss in consequence of the tails being richer. When the phosphorus in the crude ore is low, the strength of the magnets is increased; the tails are then proportionately leaner. While the Cranberry iron ore is noted for its small percentage of phosphorus, yet the uniformity and excellence of the product from these mines is largely due to the equipment at the concentrating plant and the care taken in the work of concentration.

The electromagnets in use at this plant are extremely simple, and when properly wired and insulated, run for years without any repairs whatever. The tailing leaving the final magnets averages about 16 per cent. iron. Of this about 8 per cent. is insoluble. When it is remembered that there is no fine crushing of the ore, no rolls being used in this plant, it will be seen that the results obtained are exceptionally good.

The machinery of the concentrating plant is at such an elevation that the magnets discharge directly on to railroad cars beneath the plant. The cars for the "heads" being on one track and the cars for the "tails" being on another track. This arrangement is not entirely satisfactory, as there is difficulty at times, particularly in cold or stormy weather, in getting the cars to follow each other in such order as will not delay the work of the plant. On the whole, however, this concentrating plant gives good results, both as to the quality of product and economy in operation.

Diagonal-Plane Concentrating Table

A Description of a New Form of a Wet Reciprocating Concentrating Table

*By S. Arthur Krom, Plainfield, N. J.**

Recent experiments indicate that the usual type of concentrating table is not only poorly adapted to produce the desired results, but also is based upon an incorrect principle, namely, the use of riffles to perform the work of stratifying the various minerals.

We have heard a great deal about riffles for concentrating tables; exhaustive experiments have been made to discover the proper form of riffle, or to prove the superiority of this or that form; disputes and patent litigation have arisen over the matter of riffles, and thus many have been led to believe that the riffle is the saving device upon which the process of concentration depends.

In the present paper it is proposed to show that the riffle is greatly overrated as to the part it performs in the concentration of minerals, and that, in the near future, it may possibly be eliminated entirely.

The experiments in question have shown that the troublesome riffle can be considered of secondary importance at the most, and should be so classed in the construction of a concentrating table built upon the right lines.

The action of any form of riffle on a concentrating table is such as to upset and retard the process of settling and stratifying the various minerals on the table deck.

From the deck of a riffle table no concentrates can be delivered until the deck is "bedded," that is, until a sufficient amount of material has been fed to and spread over a large portion of the deck, to form a substratum of the heavier minerals. This substratum must be maintained by the feed within narrow limits, and must be directly proportional to the rate of discharge from the table, in order that the bed shall not be lost. On the other hand, the riffles having a very small carrying capacity, considerable care is needed to prevent overfeeding; otherwise, the table will proceed, in mill parlance,

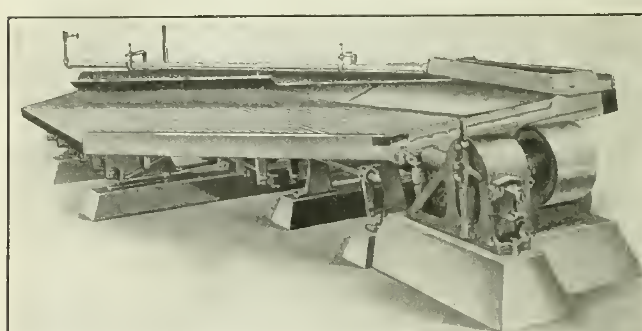

Fig. 1. Diagonal-Plane Concentrating Table

* Wilkes-Barre Meeting, A. I. M. E., June, 1911.

to rob itself. As soon as the space between the riffles becomes filled to and above the riffle tops, the mineral passes off the table with the tailing or lighter material before it can be delivered by the table motion to the proper discharge point.

To regulate a feed that will keep a riffled table between the points of not sufficiently bedded and overbedded (which are not very far apart), is no easy performance, and it is rendered doubly difficult by the varying metallic content of the pulp fed.

It is not often that favorable conditions for feeding a riffled

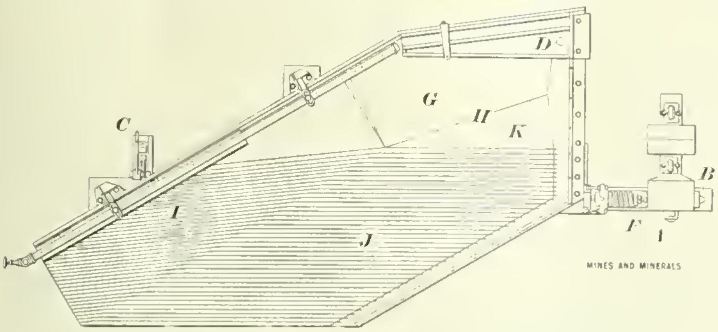

FIG. 2. PLAN OF DIAGONAL-PLANE TABLE DECK

table deck can be secured in practice; and when they are, the riffle proceeds to upset the whole business in hand. As the pulp reaches the first riffle it is forced over it by its own momentum; and this process is repeated at each succeeding riffle. In passing over each, the entire mass of the pulp is disrupted and shaken up. Whatever settlement and stratification of heavy particles has taken place between the riffles, is to a large extent destroyed. Each time the pulp is forced over a riffle it is an even chance whether the lighter or the heavier particles reach the deck first. They may drop from the top of the riffle and reach the table together, in which case the lighter particles become mixed and imbedded with the heavier, and are unable to stratify according to their specific gravities before they again meet an obstacle to their proper settlement in the form of another riffle. In other words, the work of settling and stratifying the various minerals in the ore is upset and retarded as many times as there are riffles on the deck of the table.

Another defect in the construction of some concentrating tables is that the line of motion of the table is parallel to the riffles upon the deck of the table, hence there is no action to counteract the downward flow of the heavier minerals and aid in their separation from the gangue by the dressing water.

A series of experiments extending over a period of 6 years was conducted to obtain the best means of concentrating minerals by the use of a wet reciprocating table. They culminated in a table differing radically in construction from the riffled table with parallel motion. A view of the table is given in Fig. 1.

The deck of the table is composed of a plain, non-riffled surface, and what might be termed a slightly riffled surface. The plain, non-riffled portion of the table is formed by two planes of different inclinations to each other, meeting in a line diagonal to the line of motion of the table, and for this reason has been named the diagonal-plane table deck. The planes in question form a basin in which the minerals of the greatest specific gravities are stratified previous to their discharge upon the riffled portion of the deck.

Referring to Fig. 2, which is a plan of the table deck, A and B are the stroke adjustments, and C is the tilting lever. The pulp, which enters the launder through pipe D is fed along the upper edge of one plane and on a line parallel to the table motion. During the travel of the pulp down the gentle incline of this plane G, which may be called the receiving and settling plane, the heavier minerals in the pulp settle and slide gently on the surface of the plane, to the line of intersection, H, of the planes forming the basin. Along this line the most important action of the whole operation takes place; namely the stoppage of the heavy portion of the pulp flow by the rising plane K forming the lower section of the basin, and the carrying onward of the lighter or tailing portion of the pulp by the wash water. All these actions take place simultaneously with the discharge of the concentrate from the settling basin by the motion of the table.

The degree of inclination of the settling planes to each other, and the angle of their intersection to the line of the table motion, is of importance in securing the above results.

The practice of settling and stratifying by means of a settling basin provides for the disposition of a very wide range in quantity of metallic contents. There are no confining limits other than the limits of the basin itself. The basin does not require "bedding" and is very difficult to overfeed. It settles and discharges whatever quantity of metallic particles the ore may furnish.

The riffled surface of the deck is divided into two sections, one for the reception of the concentrate, I, Fig. 2, and the other, J, for the tailing. The riffles on the concentrate section are very thin, being but $\frac{1}{32}$ inch high. As the concentrate is discharged from the settling basin on this portion of the deck, the low riffles allow it to spread and enable any gangue in it to form a thin upper stratum, which is easily washed away by the dressing water. As the metallic mineral emerges from the settling basin upon the thinly riffled section of the deck, it is, by reason of the line of table motion being diagonal to its line of settlement, driven not only forward but upward against the inclination of the deck, thus counteracting the tendency of the dressing water to wash the concentrate into the tailing section.

The tailing from the settling basin does not come in contact with the riffles until it has been washed entirely free of mineral. These riffles act simply as retarders to prevent the too rapid discharge of the tailing and the washwater from the non-riffled section. They have nothing to do with the stratification of the minerals. That the table motion may be adapted to a variety of pulps, the eccentric actuating the table is mounted upon an adjustable pin, and may be placed more or less off center.

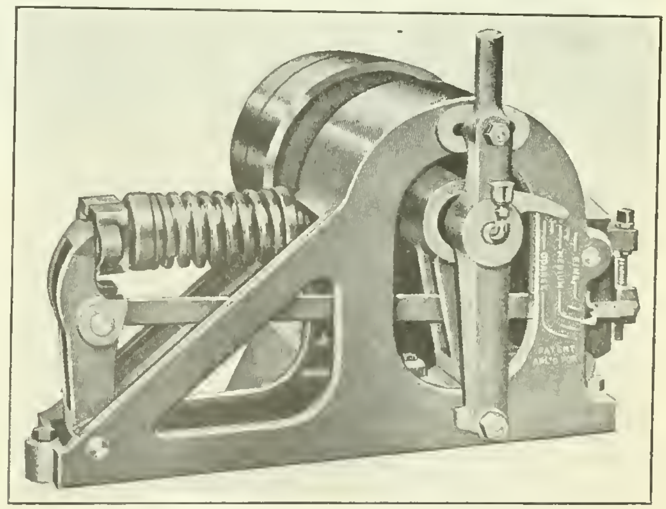

FIG. 3. HEAD MOTION OF DIAGONAL-PLANE TABLE

This adjustment, combined with the stroke adjustment, provides for more than 200 different movements, ranging from a very mild kick and long stroke to a very sharp kick and short stroke, or any combination of movements between these extremes. As a guide to the unskilled operator there is an index plate, shown in Fig. 3, based upon the size of the material, which is of great assistance in selecting a movement with which to start.

Magnetic Separation of Ores

A Description of the Process as Used in Mills at Joplin, Mo., and Galena, Illinois

*By Lucius L. Wittich**

Electric magnets of varying power are employed successfully in separating iron from zinc ores in the Missouri-Kansas-Oklahoma district, and in the zinc districts of Wisconsin and Illinois.

The Joplin Separating Co., operated by W. P. Cleveland and W. S. Picher, of Joplin, Mo., is running two plants, one at Joplin, the flow sheet of which is shown in Fig. 3, and another of larger capacity at Galena, Ill., shown in Fig. 3.

Due to the comparatively small production of zinc ores containing a heavy percentage of iron sulphide in the Missouri-Kansas-Oklahoma district, the Joplin plant sometimes is forced to close for lack of material on which to work, but as a rule enough low-grade ore can be obtained to keep the plant in operation.

The new camp of Miami, Okla., shown in Fig. 1, is a heavy producer of zinc ore running high in iron, and from this camp much of the ore treated by the Joplin Separating Co. is secured. Galena, Kans., also produces a comparatively heavy tonnage of ores running high in iron. In the early days of the Galena camp, before a market existed for the heavy iron ores, hundreds of tons of blende were discarded; and even at this late day, when many of the old-time dump piles have been reworked, it is possible to find enormous heaps of boulders rich in zinc ore, but so heavily impregnated with pyrite that the early-day operators found it inadvisable to attempt the concentration of the product. Iron in zinc concentrate is penalized at the rate of $1 per unit; one unit of iron, however, being permitted without making a deduction in the price. For example, zinc ore is purchased on a basis of 60 per cent. metallic zinc. If the basis price is $40 a ton, ore of 60 per cent. zinc and 1 per cent. or less of iron would bring $40 a ton; but ore carrying 10 per cent. iron would be penalized $9 a ton, leaving the price paid $31.

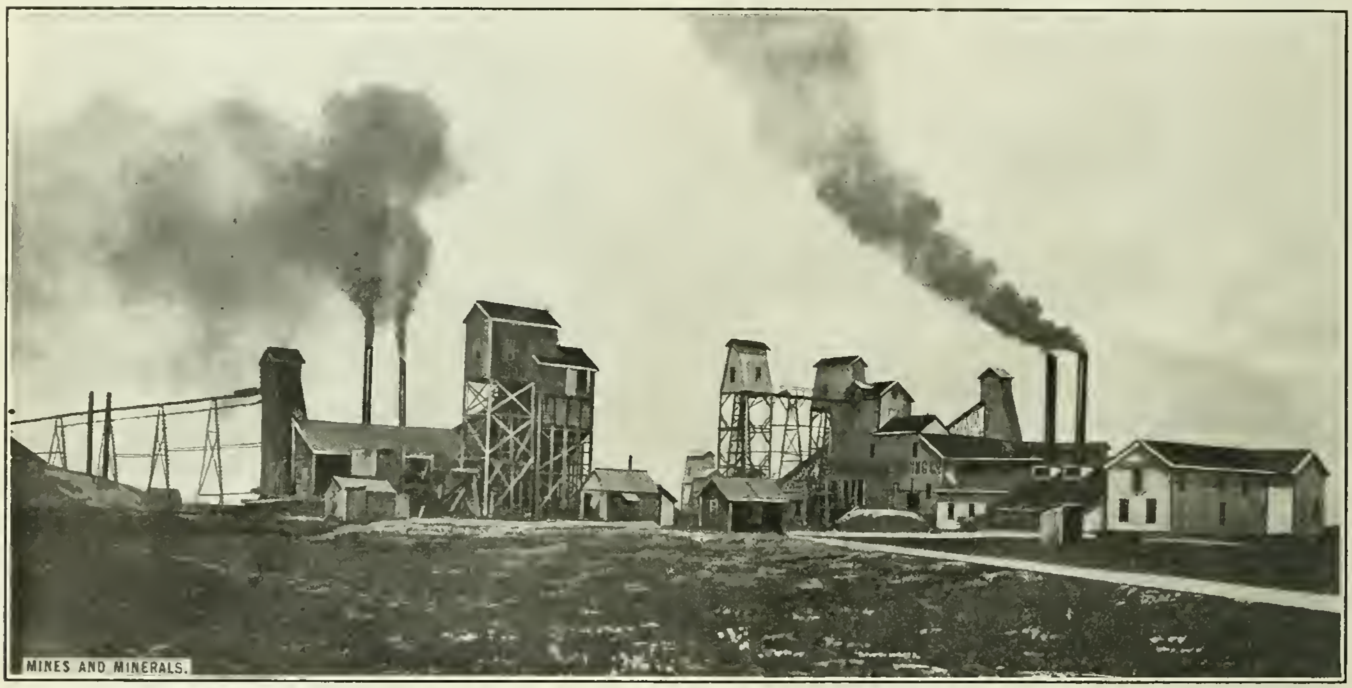

Fig. 1. Miami, Okla. Separating Plant

It is therefore evident that the presence of iron not only reduces the market price of the ore, but it reduces the demand for the ore. Where the percentage of iron is high, 20 or 25 per cent. for example, it is possible that when a certain smelter wishes this grade of ore, the actual basis price may be higher than that for good ore, although the price paid for the ore will be low, the deduction of $1 a unit for the iron bringing the market value down to where there can be comparatively little profit for the producer.

On the contract system of selling zinc ores the penalties are not so high, but as comparatively little ore is yet being sold on this system it is not making a material difference in the methods that have been in vogue since the district began producing.

Through the use of magnetic separators, the Joplin Separating Co. is enabled to purchase iron-zinc ores, and, by a system of roasting and separating, produce high-grade zinc concentrates which sometimes command a premium over the prevailing basis price, as the smelters, to counterbalance their system of penalizing, pay $1 per ton above the basis price for each unit of metallic zinc above 60 per cent.

When roasted, the sulphide of iron in the zinc ore becomes magnetic and responds to the attraction of the saturated magnets, beneath which it passes on belt conveyers.

Referring to Fig. 3, it will be observed that the plant is equipped with ordinary jigs and tables, such as are found in the concentrating plants of the district. As low-grade ores contain sand, chatts, and galena, in addition to pyrite, and as the presence of these substances also is penalized by the buyers, it is important that the jigging process be employed to free the ore from these impurities before it is sent to the roaster. Where the ore has already been cleaned of sand, chatts, galena, etc., the rejigging process at the plant of the Separating company is not necessary, and in such cases the ore goes direct to the roasting ovens *3* instead of to the sizing screen *1* and the jigs *2*.

The roasting ovens, of which there are two, consist of one firebox and three eyes each. In the first eye, nearest the furnace, three charges of 1,500 pounds each may be roasted in 12 hours; in the second eye from the furnace, two charges of 1,500 pounds each may be roasted in 12 hours; in the third eye from the furnace, one charge of 1,500 pounds may be

*Joplin, Mo.

roasted in 12 hours. Thus the capacity of the plant is 18,000 pounds of ore from the roasters in 12 hours.

The eyes in which the ore is roasted are floored with brick. The fireboxes are at the outside ends of the kilns, the flames being drawn toward the flue stationed in the center of the two kilns. In this manner the fire sweeps over the ore that has been distributed evenly over the floors of the eyes. In a comparatively short time the ore in the eye nearest the fire will become a glowing red; while a longer period will be required to heat the ore in the eyes farthest from the source of the flames. At first the ore will throw off a flickering bluish flame, intermingled with the glaring red of the heated mass. The sulphur in the product is responsible for the bluish glare. As the time approaches for the removal of the ore the blue flames will disappear.

From the eyes the roasted ore is wheeled in barrows to the cooling floors *4*, and when cooled is ready for the separator, first being wheeled to the receiving hopper *5*, from whence it is elevated by a cup elevator *6* to a revolving screen *7*. The upper half of the screen is equipped with wire mesh with openings ⅛ inch square. The ore that passes through this feeds into a large hopper *8*, which is divided into two parts by a partition running crosswise through the center. At the lower end of the revolving screen is a perforated iron mesh, the holes being ⅙ inch in diameter. Ore passing through this also falls into the other part of the hopper. The object of the different

Fig. 2. Galena, Illinois, Separating Plant

sized mesh is to secure different sizes of ore for the two separators with which the plant is equipped. The oversize from the screen *7* passes to the rolls *17* via the launder *16* and thence back to the elevator *6* after it has been ground. In this manner the ore continues to circulate until it will pass through one or the other sections of the screen.

From the hopper the ore descends by gravity through launders to the distributing hoppers *9* at the upper ends of the belt conveyers *10*. At the base of the distributing hoppers are spreaders on to which the ore falls and is conveyed in an even layer to the slow-moving belt conveyer beneath the magnets *11* and *12*. One of these belt conveyers is 12 inches wide; the other 18 inches. They operate over wooden pulleys about 8 feet apart, and are prevented from sagging in the passage beneath the magnets by wooden rollers.

The magnets consist of cylindrical soft-iron shells which cover helices of copper wire. The shells are 20 inches in diameter, but differ in height, the first magnets beneath which the roasted ore passes being 10 inches high, while the second magnets—the more powerful ones—are 20 inches high. The magnets revolve slowly and the iron oxide which is attracted to their surface is scraped off into launders by means of brass knives, which cause it to fall vertically.

As it is imperative that the recovery of blende be thorough and yet contain as little iron as possible, a careful regulation of the electrical current is required. The iron oxide scraped from the first magnets *11*, beneath which the belt conveyer passes, goes direct to the waste pile and is of no further value save to be used in road making, sidewalk building, etc., and even for such purposes it is in little demand owing to its unattractive color. These weaker magnets range in power from 2 to 5 amperes, the variation being due to the different kinds

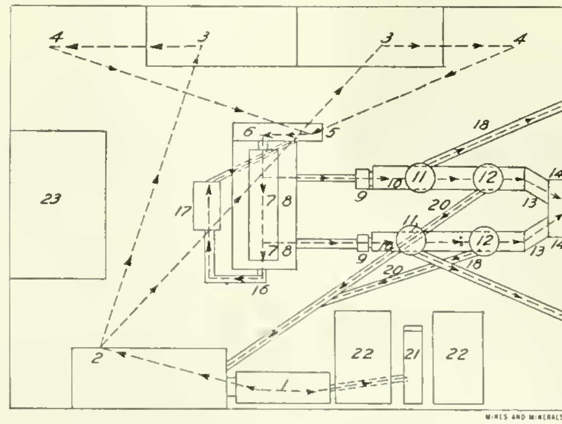

Fig. 3. Flow Sheet

of ores treated. Some ores will respond to a slight magnetism while others require a more powerful force.

The object of the weaker magnets therefore is to attract only the iron particles that are virtually free from zinc ore, although a small percentage of ore is bound to escape with the waste through the launders *18* to the tailing piles *19*.

As the belt conveyer passes beneath the revolving magnets its surface is about ¾ to 1 inch beneath the surface of the magnet, and across this space the iron particles rise to the magnetized zone of the apparatus. This zone is ⅝ inch wide, is near the extreme outer edge of the round face of the magnet, extends entirely around the magnet, and represents the gap between the positive and the negative poles, this narrow strip being the one point of the entire surface to which the iron particles are attracted. As the magnet swings around, bringing the clinging particles of ore against the brass knife, the product is scraped loose.

Passing on beyond the first magnet, the belt goes beneath the second magnet which ranges in power from 9 to 12 amperes and attracts a heavy volume of particles that contain some zinc. A pin point of iron attached to a piece of zinc 50 times heavier than the iron, will respond to the magnetic force and jump upward to the magnetized zone. The ore that succeeds in getting beyond the second magnet and reaching the trough *14*

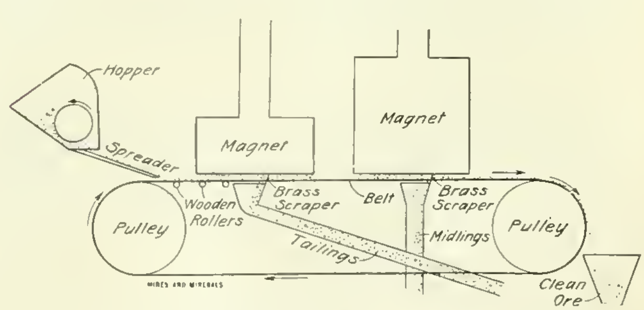

Fig. 4. Section Through Magnetic Concentrator

at the end of the belt conveyer is therefore as free from iron particles as it is possible to get it. The cleaned ore passes to an elevator *14* and is lifted to the clean ore bin *15*. It is in demand, as it is equal to the ores produced from the high-grade mines of the district.

To discard in the waste pile the particles that adhere to the powerful magnets *12* would cause a loss of zinc, therefore, the scrapings, instead of going to the tailing pile, fall into launders *20*. The product is sized, *1* and *21*, that passing through a mesh of 3 millimeters going to the jigs, while that passing through a 1-millimeter and a ¾-millimeter mesh goes to the tables. The oversize goes to rolls *17*, where it is reground and returned to the magnetic separators.

That the rehandling of the middlings from the magnets *12* results in a great saving of zinc is the belief of the operators of the plant. Whether the small iron particles are broken loose from the zinc during the process of jigging and are washed away with the tailings, or whether the separation is effected on the tables or at the magnetic separator, has not been determined.

While the company operates its plant with electricity obtained from a local power company, it operates its own dynamo, stationed in a room designated as *23*, in Fig. 1, and the magnets are charged with electricity from this dynamo.

Visitors to the plant are warned to leave their watches outside, as the magnetic influence permeates the air for a great distance from the magnet. A watch brought within the electric zone will become saturated with magnetism and will be useless as a timepiece until it is demagnetized, which process will cost the owner from $2 to $3. A magnetized watch may run 2 hours fast in the forenoon and 2 hours slow in the afternoon.

The plant at Galena, Ill., is equipped with five separators instead of two, as is the plant at Joplin. At the Illinois plant automatic roasters and cooling devices are employed and other equipment used which tends to expedite the process of separation. The Illinois plant is within 6 miles of many zinc mines whose ore carries usually high iron.

Swinging Rock Dump at Cokedale

Under any circumstances the handling of the waste rock at a coal mine is a constant source of annoyance and expense. If stowed underground the services of a driver and mule in addition to those of the rock gang are necessary. These men are taken from their regular duties, and the haulage of coal is not infrequently seriously interfered with. If brought to the surface, anywhere from two to six men may be needed on the dump, men who work frequently but half time or less, yet who must constantly be on hand to take care of the rock cars as they come out. Again, if the cars are dumped from the end of a

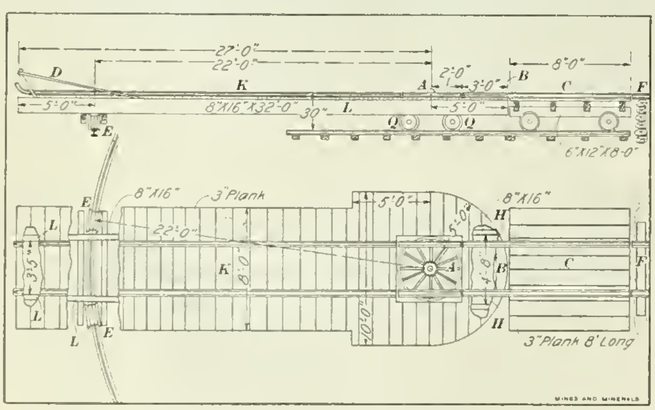

Fig. 1. Swinging Rock Dump

trestle, as is almost invariably the case, this has to be constantly moved forward if there be any large amount of rock.

To save labor and this constant moving, the revolving rock dump, used at the Cokedale mine of the Carbon Coal and Coke Co., near Trinidad, Colo., may prove of interest. It consists essentially of a swinging truck, *K*, composed of two pieces of 8″×16″ Oregon pine, *L*, 32 feet long, upon which is laid a platform of 3-inch planks, and upon which in turn are laid the rails. The rear end is supported by a four-wheeled truck, upon which the platform is pivoted at *A*. The outer end is supported upon wheels, *E*, which travel upon rails bent to a radius of 22 feet. As there is an overhang of 5 feet at the outboard end, the total radius of action is 27 feet. The total width of the dump made by this device is thus 54 feet, and, consequently, the dump needs to be moved forward much less frequently than is the case in the old fixed dump where the width of the embankment rarely exceeds eight feet. There is, of course, a great saving in the amount of trestle required. The arrangement of timbers at the outboard end, *D*, is for the support of the chain which opens the latches in the end gate of the car.

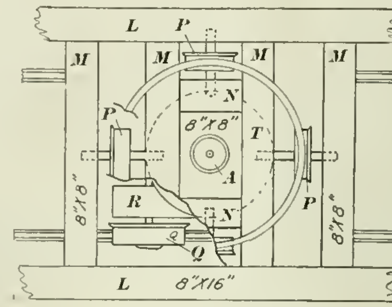

Fig. 2. Turntable

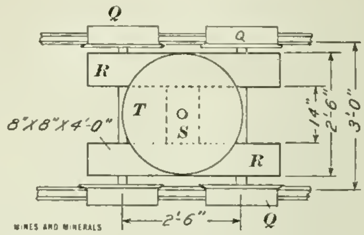

Fig. 3. Truck

The construction is very simple; one that any mine carpenter or blacksmith can duplicate. The forward wheels, *E*, are double and are made of two mine car wheels set face to face. The rear truck is supported upon four wheels *Q*, and *T*, Fig. 2, is a plate of ½-inch steel upon which the platform turns.

As the cars approach the dump wrong end first, a turn table is necessary that the end gate may be brought to face the dump. This turn table is shown in detail in Fig. 2. It consists of a heavy wheel taken from a wagon and mounted upon the same spindle, *A*, as that upon which the rear truck of the platform turns. The outer rim of the wheel bears upon four mine car wheels, *P*, set in a frame. This frame in Fig. 2, rests immediately upon the truck frame shown in Fig. 3. Upon the upper side of this wheel are bolted short lengths of mine rails, thus forming a perfect turn table. The cap shown at *A*, Fig. 1, is intended to engage the axle of the car to prevent its overrunning the table. The timbers, *M*, *M*, etc., where they engage the main floor beams, *L*, *L*, are supported by stirrups of bar iron and the same is the case where the shorter pieces, *N*, *N*, engage those marked *M*, *M*, etc. Stirrups are also used to support the center block, *S*, which carries the spindle, and also on both ends of the axles of the four wheels, *P*, *P*, etc.

The rear truck, *C*, carries the rails from the cribbing, *F*, to the swinging truck. These rails on *C* are loose at the outboard end, so that the swing truck may turn under them. This truck is not absolutely necessary, as these loose rails may be laid upon the cribbing at *F*, but it saves some time in moving the machine forward.

Two men are able to handle 100 cars of rock per day, where formerly six were required. This is very good work, as the cars have to be moved from and returned to the tipple by hand, a distance of about 100 feet, besides being turned twice on the table *A*.

We are indebted to Mr. Jacob Spahr, outside superintendent, for the description of this interesting device.

One of the most widely known of the rarer metals is tungsten. The production of this metal in the United States, however, is not large, as a little of it goes a long way for some of its most important uses. The principal uses are in electric lamps and as an alloy for special steels.

Making Gasoline from Oil Well Gas

Methods by Which a Valuable Product Is Recovered from What Has Been an Absolute Waste

By F. W. Brady, M. E.

A striking example of waste has always been found in the great oil and gas fields of Ohio, West Virginia, and Pennsylvania. This does not mean that the oil has been wasted deliberately, for the supply is cared for remarkably well, but the direct loss has been through accident and carelessness, while the indirect loss has been from the light vapors passing off from the storage tanks, and the immense quantities of gas escaping from the wells. A visitor to the oil fields has always been impressed with the loss of gas, and "Why don't you do something with it?" has always been the commonplace inquiry. On the other hand, the habitues of the oil fields had lapsed into a state of indifference, having for the most part become resigned to a loss that they believed could not be prevented. Any one with a technical instinct who visits the eastern oil fields today will experience a feeling of relief, for the newest of the new things in oil production is the perfection of a process for manufacturing gasoline from the gas from oil wells. These plants are located here and there on the farms wherever a group of wells can be worked to the best advantage. The gasoline is shipped in 50-gallon iron barrels which are hauled by wagon to the nearest railroad station, while the by-product gas is turned into the pipe lines that for years have distributed the high-pressure natural gas supply.

It is stated briefly for the benefit of the reader that oil development is going on continually. Each season sees some new field or oil excitement where production is booming. For examples of this kind, see notes on the Brooke County oil fields in Mines and Minerals, November, 1907; also the Follansbee field, in December, 1908, and the Steubenville field in October, 1909. At the beginning, most of the wells are self-flowing and some of them are real "gushers," producing five or six hundred barrels, or more, the first 24 hours; most of them, however, make less than one hundred barrels; but the decrease of production is rapid and soon all the wells become

Fig. 1. Gasoline Plant

"pumpers." At first the pumping is daily, then about twice a week, and finally a settled system of pumping once a week, or once in 10 days or so, is kept up for several years with those wells that continue to produce oil, the quantity in many cases averaging much less than 1 barrel per day. All this time, however, from the first strike of oil, and for long after the well is abandoned as an oil producer, there is a flow of gas from the well. In some cases the first strike was a "gaser," which afterwards turned to an oil producer. Generally, though, the reverse is the case, and practically all the oil wells close their careers as gasers.

Now it is this gas from the oil-bearing sands that has made the bulk of the waste. Especially has this waste been too bad where an oil well has been abandoned and the gas has been burned on the spot from the open pipe, or has escaped freely in the air. Millions upon millions of cubic feet of nature's best fuel have thus been disposed of. The final choking up of many abandoned oil wells by salt that encrusts in the casing

Fig. 2. Gas Cooler, Accumulator, and Loading House

will really be a boon to posterity. Not only has there been a direct waste of this kind of gas, but also there has been an indirect waste in the use of the gas piped from the oil wells. In the long pipe lines it has been a common occurrence for gasoline to collect wherever a down bend or pipe would trap it. Then the reevaporation of the gasoline will produce a freezing effect that will clog the pipes with ice where water has collected. This reevaporation may take place where the gasoline flows from a leak in the pipe and probably within the pipe also. The freezing of the gas pipes from this cause has been annoying, and it was due to this trouble that the apparatus for manufacturing gasoline from the gas was developed.

The process depends upon the condensation and liquefaction of gases—the direct processes being dependent on the laws governing the compression and refrigeration of the gas. The present plants are equipped with a refinement of the various apparatuses that have been perfected after a considerable experimentation with one thing and another.

The general arrangement of a gasoline plant in a deep hollow on Titts Run, near Wellsburg, W. Va., are shown in Figs. 1, 2, and 3, and a plan view of the arrangement of the apparatus in Fig. 5. This plant has a capacity for treating 150,000 cubic feet of gas in 24 hours, and produces from 500 to 800 gallons of gasoline having a gravity of 92° Baumé.

The power plant is housed in a one-story galvanized-iron building, 30 ft. × 40 ft., with the floor and foundations of concrete. Two direct 35-horsepower gas-engine-driven air compressors, made by the Bessemer Gas Engine Co., compress the gas. The first engine, which may have a piston varying from 6 to 12 inches, draws the gas from the piping system connecting all the available wells in the neighborhood. From a partial vacuum of 15 inches the gas is compressed to 20 or 30 pounds. It then passes through a water cooler to the second engine, which has a 4½-inch piston, and which compresses to 150 pounds or over. The final pressure must be determined by trial, as the process depends considerably upon the quality of the gas and the refrigeration treatment. Thus in this plant 150 pounds compression was found to produce more gasoline than did 250 pounds compression.

The gas at 150-pounds pressure passes through an 80-foot water cooler, and then through a double 80-foot gas cooler, the latter using the by-product gas for cooling. The collecting and separating tank is of heavy boiler plate construction and resembles a 40-horsepower vertical boiler. The saturated refrigerated gas under a pressure of 150 pounds or over, enters the side of the accumulator tank at a point about two-thirds its height, measured from the bottom. A baffle plate riveted in the tank deflects the flow and precipitates the gasoline. The accumulation of gasoline is shown by a gauge glass, and periodically the attendant blows it into a storage tank of 120-barrels capacity. A similar storage tank, located below the first one, is shown in the foreground of Fig. 3. The storage

Fig. 3. Storage Tank, Loading House, and Magneto Building

supply stands at about 20 pounds pressure. These tanks, of heavy boiler-plate construction, are erected in a horizontal position. From the stock tanks the gasoline is loaded into iron barrels of about 50 gallons each. The loading, however, is made by weight. The barrels weigh 75 pounds, and 270 pounds of gasoline is put in, making a total shipping weight of 345 pounds.

The iron barrel is placed on a platform scale and balanced. A piece of $\frac{3}{4}$-inch hose is attached to a valve plug on top of the dome of the storage tank and the other end inserted in the bung hole of the barrel. A pipe leads from the valve plug to near the bottom of the tank, so that the gasoline is forced by the gas pressure into the barrel. As a cleanser, it is par excellence and at the works is as plenty as water. The gasoline is cool, and to bathe one's hands in it on a hot day gives a delightful feeling. The storage tanks have safety valves, and the blow-off gas is turned into the gas supply mains.

The loaded barrels are hauled by wagon, eight barrels to the load, 2 miles to the freight station at Wellsburg. The wholesale price of the gasoline f. o. b. cars at Wellsburg ranges from 9 to 12 cents per gallon. Most of the product is handled by the Petroleum Products Sales Co., Cleveland, Ohio.

The gas engines are of the tandem type and supplied with two flywheels. The gas-engine cylinder is at the head end and the gas compressor cylinder next to the crank end. Both the engine and compressor cylinders are water-jacketed. The crank case on some of these engines is closed and has a vent pipe leading above the building; thus, any gas leaking from the cylinders will be carried out of the building and the danger from fire or explosions lessened. The make-and-break spark system is used for ignition, and a friction-driven magneto for each engine is located in a small building some 100 feet distant. A small gas engine operates these magnetos and also the generator for lighting the plant. An air starting outfit, consisting of one air pump compressing to 150 pounds, air receiver, starting valves, pressure gauges, etc., makes the starting of these large gas engines an easy and a safe operation. About 2 pounds gas pressure is used for the gas-engine service. A regulator placed outside the building is necessary to deliver the fuel at a uniform pressure.

Cooling System.—All the engine and compressor cylinders are water cooled. The gas as it comes from the wells is probably at 60° F. The heated gas from the first compression goes to a water cooler consisting of a concrete vat 20 ft. × 4 ft. × 4 ft. A continuous flow of cool water passes through this tank in which a 10-inch pipe is laid lengthwise along the middle and to which the 3-inch delivery pipe from the first compressor is attached at one end, while to the other end an inlet pipe to the second compressor is attached.

The high-pressure gas from compressor No. 2 passes first through an automatic separator that removes any lubricant that may be carried over from the compressor. It also catches any gasoline that may drain back from the second cooler.

The second cooler is 80 feet long and consists of a concrete tank like the intermediate cooler. A 10-inch pipe is placed lengthwise of the tank. The arrangement of the piping system for the second cooler and also that for cooler No. 3 is shown in Fig. 5. The 2-inch delivery pipe enters a special fitting at the rear end of the 10-inch pipe, and the water-cooled gas passes out a 3-inch pipe 80 feet distant. This 3-inch pipe enters the end of an 80-foot length of 6-inch pipe, and returns through a second 80-foot length of 6-inch pipe and thence to the accumulator tank. From the gas space in the top of the accumulator tank a pipe leads to a gasoline trap which collects any gasoline that may be carried over from the accumulator and returns it to the stock tank. This trap is also fitted with a pop safety valve that relieves the accumulator from any over pressure and delivers the gas that may be blown off to the fuel-supply gas mains. Above the gasoline trap the by-product gas passes through a reducing valve of Lunkenheimer make and enters at low pressure the lower 80-foot branch of the 6-inch gas cooler. This No. 3 cooler is made up of a loop of 6-inch pipe laid in a box packed with sawdust. The peculiar design of the cooling system makes it necessary to use some specially designed pipe fittings. The cooling effect of the expanded by-product gas is considerable, as it flows 160 feet through the 6-inch pipe that encloses the 160 feet of 3-inch pipe carrying the compressed gas to the accumulator. From the 6-inch gas cooler, the expanded gas goes to the 80-foot water cooler and passes through a 3-inch pipe laid lengthwise through the center of the 10-inch pipe. From cooler No. 2 the by-product gas goes through a 2-inch pipe to the gas engine feed-line. The by-product gas not used by the plant goes into the natural gas mains and is sold. The overflow water from

Fig. 4. Hand Rigged Pumping Head
A, Connecting rod; *B*, Pump box; *C*, Pump rod; *D*, Lifting arm; *E*, Gin pole.

the concrete tanks flows by gravity to the water-jackets of the engines and compressors. The by-product gas is a blue-flame gas that is more desirable for fuel and lighting than the raw gas, as it does not deposit any soot or blacken at all the furnaces, gas mantels, cooking utensils, etc. By-product gas is sold to the Tri-State Gas Co., which has pipe lines connecting the oil and gas territory. The price paid is 4 cents per 1,000 cubic feet. The retail price of the gas for household use is 25 cents per 1,000, and for factory use a discount is given from the 25-cent rate.

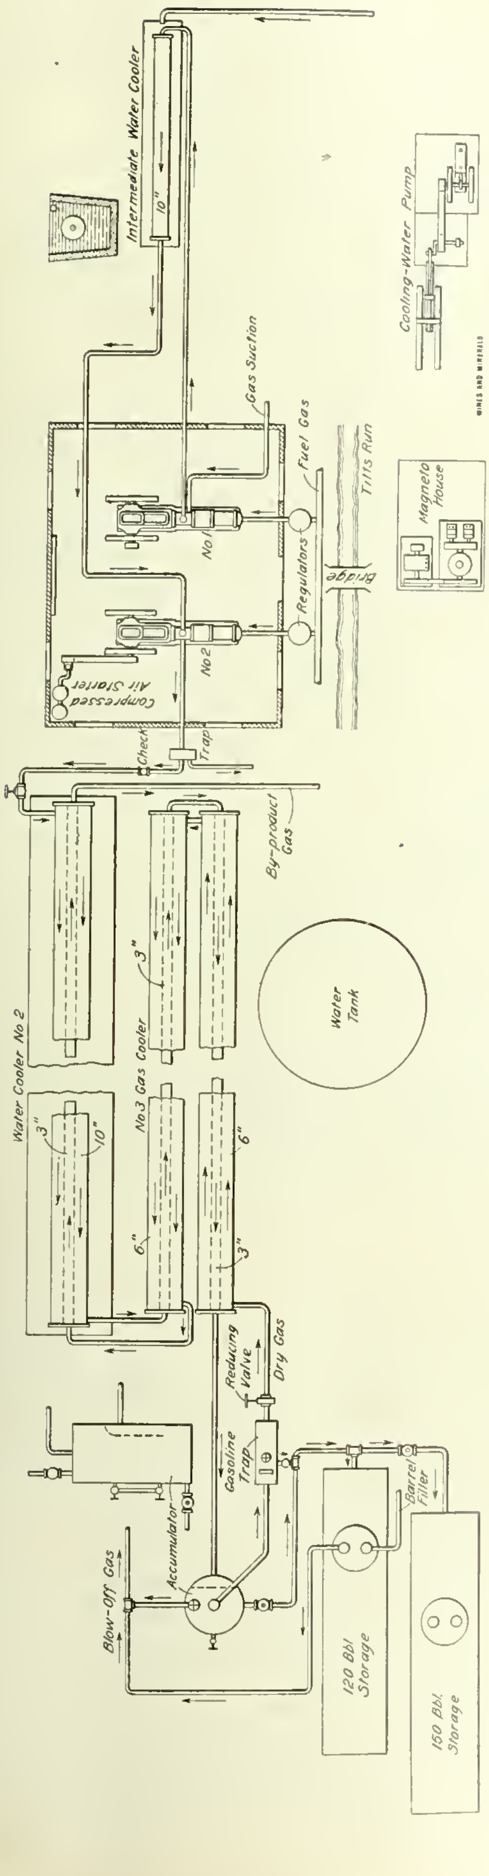

Fig. 5. Plan of Gasoline Plant

The partial vacuum produced by the first compressor as it draws its gas supply from the wells aids both the oil and the gas production; in fact, in some cases the gas is given to the gasoline plants, as the increase of oil due to the vacuum is quite an item to the well owner. At the same time, however, the owner draws back all the by-product gas he needs for pumping the oil.

The vacuum in the field lines is one of first importance in gasoline production. So great is this feature that in some gasoline plants a special independent low-stage vacuum pump and gas compressor has been installed so as to regulate the field pressure and increase the production. This machine can be operated at any desired speed necessary to keep the pressure conditions constant. With this low-pressure compressor 24 inches or more of vacuum can be held on the wells, and at the same time the efficiency of the regular compressor units not lowered. The advantages observed from the use of the vacuum system have led to the reopening of abandoned oil fields, not for the oil but for the gas from which to make gasoline.

The cooling water is taken from Titts Run, which flows by the plant, and it is also pumped from a nearby abandoned oil well. The pumping-head rig is shown in Fig. 4. A 3-horsepower gas engine housed at the right of the rig does the pumping. The engine is belted to a jack-shaft carrying tight and loose pulleys. A crank on this jack-shaft gives motion to the horizontal connecting-rod of the pump rig. This rig is made from discarded timbers from oil-well derricks. Sixty feet of well rods are used, and the stroke is about 30 inches, at 15 strokes per minute.

The business of making gasoline from natural gas is necessarily a hazardous one. It is a new business, and this, coupled with the usual combinations of ignorance and carelessness, makes a list of accidents that one would naturally expect. Even the empty barrels have exploded when standing exposed to the hot sun and with the vent plugs set tight. On one occasion an empty went up when standing on the freight station platform. The heavy iron head was bulged like a scoop from a grocer's scales and knocked a section from the body of an express wagon as it flew into the freight yard. The heavy iron ring under the crimp over the barrel head was pulled apart and thrown some distance over the tracks. A special design of sockets and double incandescent globes are used for lighting the plant. The loading house and storage tanks are erected at a considerable distance below the compressor house. Those old in oil-well service have become accustomed to handling nitroglycerine, and while they respect it, they treat it with a feeling of contempt. On the other hand, gasoline of from 92° to 100° Baumé is a new thing to them, and they have got "burned" as a consequence. Therefore, to hear an operator about a gasoline plant remark that he would rather carry "nitro" than gasoline is evidence of the fear in which it is held.

Gasoline can not be produced from all natural gases, at least not in paying quantities. As a general thing, the paying proposition is in connection with oil wells. In some cases the profits have been very great, and in the present state of the art it is not believed that the highest efficiency is yet attained. Any one can see that the process is one of conservation of the very best order, and fetches to the owner "a smile that won't come off." Though the process has been eagerly awaited, it is proper in most cases to test the gas. This can be done with considerable exactness and the amount of gasoline per 1,000 cubic feet of gas determined. Not only is the test necessary, but individual study must be given each prospect if the maximum efficiency of production is expected. The reason for this is that the gases in the different fields differ widely in their compositions; hence, the necessity of making both a physical examination and a chemical analysis to insure that the venture will not be a gamble. From the sample analyses already made, anything from zero to 9 or 10 gallons of gasoline per 1,000 cubic feet of gas could be expected. From 4 to 6 gallons is a good average proposition. The plant will cost anywhere from $1,500 to $6,000.

The gas sample is collected in a ½-gallon bottle, or two 1-quart bottles, by filling the bottle full of water and inverting it in a pan of water. Attach 3 or 4 feet of rubber tubing to the gas cock and let the gas flow freely for 2 or 3 minutes so as to insure that it is dry. Then insert the open end of the tube under the mouth of the bottle. The gas will fill the bottle, driving out the water ahead of it. After the bottle is entirely full of gas, insert a tightly-fitted cork while the mouth is still under water in the pan or pail. Now remove the bottle, wipe dry and dip the corked mouth in a cup of melted paraffin. Finally, tie a piece of linen cloth over the cork and redip in the paraffin. Label the sample, carefully giving the name and address of the sender, and something of the character of the well; such as its depth, age, amount of oil it produces, name of the sand, amount of gas available, etc. Pack the sample bottle in excelsior or hay and ship via express to the chemical laboratory, which in the case of wells in the territory mentioned in the beginning of this article, would be the Bessemer Gas Engine Co., Grove City, Pa.

The name gasoline is a very broad term as commonly used. The name may apply to any oil from the heaviest kerosene to the lightest volatile production of over 100° Baumé made from natural gas. For gas engine use, the oil having a gravity of from 64° to 68° Baumé is most in demand at present Heretofore the demand was for 72- to 76-degree oil, but there has been a diminishing of the supply. The lightest qualities ranging from 90° to over 100° Baumé, and which are made from natural gas, are of great purity and are perfect solvents for the heavier oils produced by the fractional distillation process from petroleum. Hence, perfect and homogeneous mixtures can be made easily so as to increase the weight of the high degree oils and thus produce any desired grade. Herein lies another great boon from the newly perfected process. Otherwise the use for the high-degree oil would be chiefly for lighting and in the arts. Also as these very light oils are difficult to store and most dangerous to handle, the mixtures with heavier oils serves greatly to save the supply.

Nova Scotia Oil Fields

The Maritimes Oilfields Co., Ltd., continued during 1910 developing the oil and gas territory in Albert County, New Brunswick. It is stated in the United States Consular Report that the company has drilled 11 wells, but owing to the pressure of natural gas only three wells have been "shot," which produce an average of 35 barrels of oil per day. The gas flowing from these wells is estimated at 40,000,000 feet daily. A pipe line will be laid to Moncton, to supply the city with gas for heating and lighting purposes.

Prior to the discovery of petroleum in Pennsylvania, the oil shale of New Brunswick, known as Albertite, was largely shipped to the United States, where it was used in the production of illuminating gas. The discovery of petroleum decreased the demand, and this, with the loss of valuable machinery, caused the operators to abandon the industry. A United States Consular Report states that recently a company with a capital of $1,000,000 was incorporated to develop the oil-shale territory and it is said $3,000,000 will be spent in its operations.

Equipment of the Poverty Gulch Mine

Specifications, Calculations of Capacity and Costs of Machinery and Buildings Required

*By Chas. W. Henderson**

According to the assumption it is necessary to design a surface plant that will hoist 200 tons of ore daily from a depth of 1,000 feet.

The following is a well-known rule used in selecting electric hoists: L = pull on rope at drum with load at bottom of shaft in pounds = weight of ore + rope + skip; R = rope speed of hoisting in feet per minute; H. P. = $\frac{L \times R}{28,000}$.

Lupton, Parr, and Perkins, on electric hoisting for haulage on inclines add 5 per cent. for friction.

In this case, L = skip, 1,300 pounds; ore, 1 ton, 2,000 pounds; 1,000 feet of $\frac{3}{4}$-inch rope, 880 pounds; total, 4,180 pounds.

L on 22° 42′ slope = 4,180 × .385 = 1,610 pounds + friction, 161 pounds; total, L = 1,771 pounds.

With the proper motor, this hoist can be run at a speed of 600 feet per minute, and with a load of 1,771 pounds, the horsepower in either case being nearly the same, the advantage being that the hoist is 6.6 horsepower more powerful than necessary.

Cost, f. o. b. Denver, $500; freight to Cripple Creek, at carload rate ($.55), $48.15; total cost of hoist, $548.15.

In hauling on an incline, the motor should be in excess of the maximum pull required by 45 per cent. to overcome a 20 per cent. friction of gearing and 25 per cent. for starting. The horsepower of the motor for this hoist should be 37 × 1.45 = 53.7 horsepower.

Cost f. o. b. Denver, $384.90; freight to Cripple Creek, 3,260 pounds at 55 cents, $17.95; total cost of motor, $402.85.

For haulage, use the six strands of seven wires, Lang lay rope, as haulage rope has to take more wear and does not need to be so flexible. Lang lay ropes stretch less and are smoother.

Strength of rope required is as follows: Weight of skip, 1,300 pounds; weight of ore, 2,000 pounds; total, 3,300 pounds Resolved on incline, 3,300 pounds × .385 = 1,270.5, and doubling this for shock = 2,541 pounds; friction, 10 per cent., 127 pounds; weight of rope, 880 pounds; total, 3,548 pounds. Total possible stress, 4.39 tons.

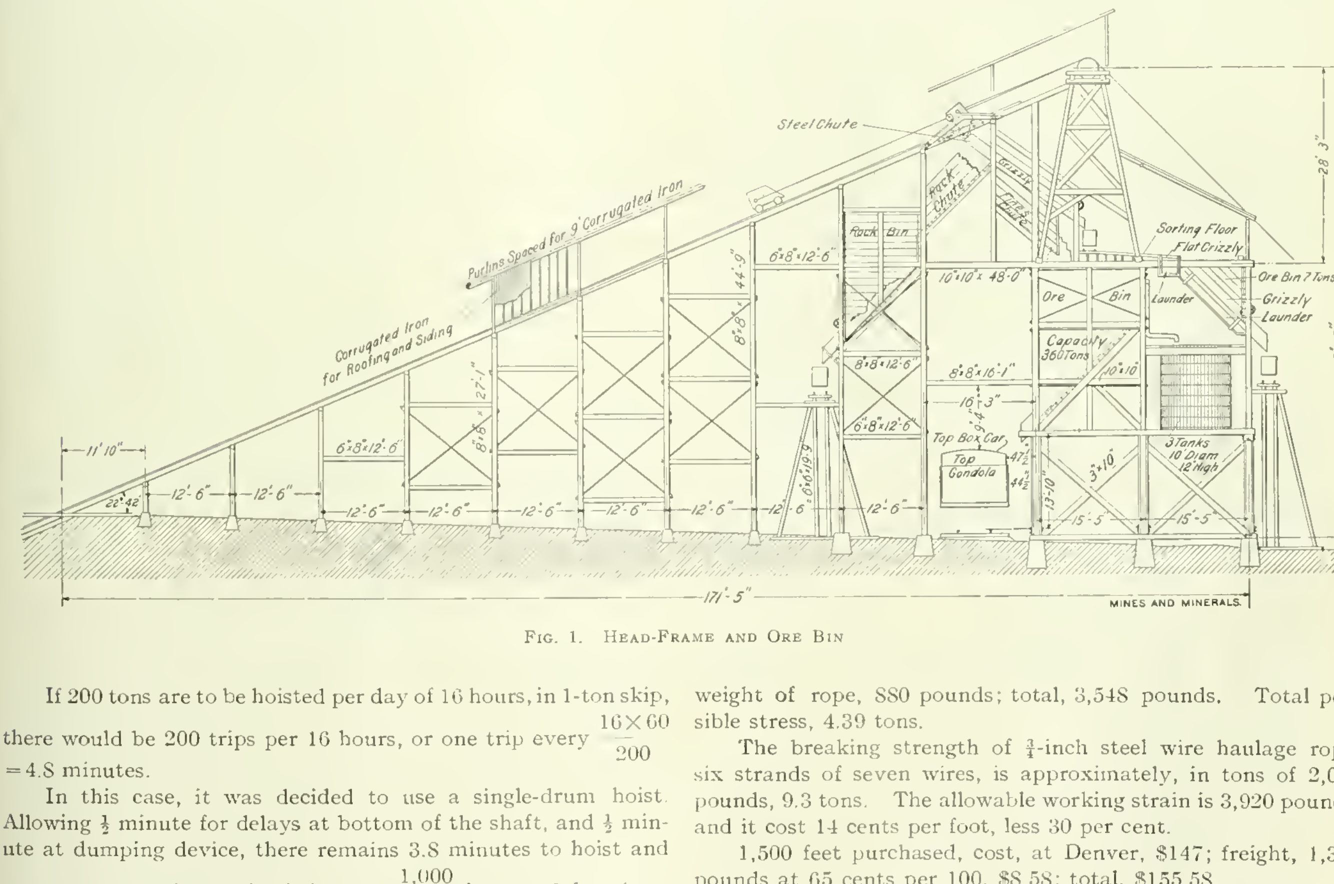

Fig. 1. Head-Frame and Ore Bin

If 200 tons are to be hoisted per day of 16 hours, in 1-ton skip, there would be 200 trips per 16 hours, or one trip every $\frac{16 \times 60}{200}$ = 4.8 minutes.

In this case, it was decided to use a single-drum hoist. Allowing $\frac{1}{2}$ minute for delays at bottom of the shaft, and $\frac{1}{2}$ minute at dumping device, there remains 3.8 minutes to hoist and return, or 1.9 minutes for hoisting. $\frac{1,000}{1.9}$ feet = 526 feet (say, 600 feet) per minute = R.

The electrical horsepower necessary for this speed is

$$\frac{L \times R}{28,000} = \frac{1,771 \times 600}{28,000} = 37 \text{ H. P.}$$

The specifications for the hoist would be 37 horsepower, 2,710 pounds load; 450 feet per minute rope speed; 36-inch diameter drum; 17-inch drum face; capacity of drum, 2,800 feet of $\frac{3}{4}$-inch rope; weight with single drum, 8,750 pounds.

These specifications give $\frac{2,710 \times 450}{28,000}$ = 43.6 horsepower.

This hoist can be used by getting the proper motor for the hoist, the change in speed depending on the build of the motor, not on the build of the hoist.

* Part of Mr. Henderson's thesis.

The breaking strength of $\frac{3}{4}$-inch steel wire haulage rope, six strands of seven wires, is approximately, in tons of 2,000 pounds, 9.3 tons. The allowable working strain is 3,920 pounds, and it cost 14 cents per foot, less 30 per cent.

1,500 feet purchased, cost, at Denver, $147; freight, 1,320 pounds at 65 cents per 100, $8.58; total, $155.58.

The minimum size sheave is 48 in. × $\frac{3}{4}$ in. (rope) = 36 inches diameter. Price with shaft and ball-and-socket boxes, $45. Total weight, 430 pounds. Extra heavy, split, wood filled, cost plus freight (430 pounds at 65 cents, $2.80), $47,80.

The head-frame (four posts) is designed to be placed on top of the ore bin.

Though the skip and weight of ore is to be regularly sustained by the head-frame, it is designed to withstand the stress of a 2-ton skip and contents.

The calculations are as follows:

Live load stresses (2-ton skip): Skip (2-ton capacity), 2,000 pounds; ore, 4,000 pounds; total, 6,000 pounds. Resolved 22° 42′ incline, 6,000 × .385 = 2,310 pounds.

2,310 × 2 (for shock) = 4,620 pounds; rope, 880 pounds; friction, 231 pounds; total, 5,731 pounds.

This force of 5,731 pounds pulling equally on rope to skip (22° 42′) and on drum of hoist (at 45°) gives a resultant of 6,410. $2.5R-4.33x=0$. $x=\frac{2.5\times 6{,}410}{4.33}=3{,}700$ pounds, and $R-x=2{,}710$ pounds. These stresses divided over two sides of head-frame, $\frac{x}{2}=1{,}850$ pounds; $\frac{R-x}{2}=1{,}355$ pounds.

Dead load stresses include: Weight of sheave + bearings, 430 pounds; platform and sheave supports on top of head-frame, 1,040 pounds; weight of roof and galvanized iron siding, 1,016 pounds; dead load = 2,486 pounds. This dead load divided by 4 gives 621 pounds as the load supported on each post of head-frame.

In making allowance for wind pressure, wind loads are figured at 30 pounds pressure per square foot, which is equal to a wind velocity of nearly 80 miles per hour, and represents a hurricane.

The main timbers of the head-frame are 8 in. × 8 in., and are braced by 6 in. × 8 in. stuff. The details of the head-frame ore bins, and ore house are shown in Fig. 1.

The ore bin proper is designed for a capacity of 360 tons, and also designed to withstand the weight of the head-frame and the stresses of hoisting. The capacity is figured on a basis of 200 tons hoisted per day, of which 57 per cent. is to be shipped (114 tons), in 40-ton cars, or 120 tons daily, and the capacity foi 3 days reserve is 360 tons.

The ore bin proper is 15 feet 5 inches wide by 50 feet long, the main supports being 10″ × 10″ timbers. There are three ore chutes designed to load at one time a car and a half at their quarter points. The chutes are designed also to load into box cars or gondolas.

The ore house includes the ore bin, head-frame, sorting tables, tripper (belt conveyer), grizzlies, tanks for settling washed fines, and also may include the trestle or approach from the shaft to the ore bin, with dumping device, and grizzlies for fines.

SPECIFICATIONS AND COST OF ORE HOUSE

Timber, 99,117 board feet, at $20 a thousand	$1,982.34
Wrought iron, 2,636.53 pounds, at 3¼ cents per pound	85.69
Steel, 1,699.79 pounds, at $2.90 per 112 pounds	44.00
Bolts, 522.83 pounds, at 9 cents, 55 per cent. off	21.17
Washers (malleable iron), 24 1 inch, $9 per 100 pieces	2.16
Washers (malleable iron), 22 1¼ inch, $20 per 100	4.40
Washers (malleable iron), 378 ½ inch, $2 per 100	7.56
Washers (malleable iron), 214 ¾ inch, $4.50 per 100	9.63
Washers (wrought) 112 ½ inch, at .092 cent. per pound	.36
Washers (angle), 268 ¾ inch, at $4.50 per 100 pieces	12.06
Cement, 50 barrels, at $2, 14 cubic yards sand, at 75 cents, 28 cubic yards broken stone, at $1	138.50
Lagscrews, 36 ⅝ in. × 4 in., at $4 per 100	1.44
Lagscrews, 144 ⅝ in. × 3 in., at $3.48 per 100	5.01
Iron wood screws, 148 2½ inches long, at 1.3 cents	1.90
Pulleys (hollow steel) six 3 inches long, at 95 cents	5.70
Chain, 3/16 inch (weight per 100 feet, 50 pounds), 52.5 pounds, at 8 cents	4.20
Gates, ten rack and pinion, 24 in. × 36 in., at $24	240.00
Grizzlies, 458.75 square feet ¾-inch screen opening, size ¾ in. × ⅝ in × 2 in., at $2.30 per square foot	1,055.16
Sheave and bearings	47.80
Three tanks, each 12 feet high by 10 feet diameter, capacity, 205 barrels; weight, 2,180 pounds, at $85.40	256.20
Pipe, 100 feet standard water pipe, 6 inches diameter; weight, 18.76 pounds per foot price $1.88 per foot	188.00
Four valves, straightway, 6-inch diameter, at $30	120.00
Corrugated iron, No. 28, 8.104 square feet (8.104 + 10 per cent.), 8,904 square feet weight per 100 square feet, 69 pounds, 8,151 pounds, at 17 cents per pound	1,045.67
Freight, about 40,000 pounds at carload rate, 55 cents per 100 pounds	220.00
Total	$5,498.94

The skip is designed to hold 1 ton, or 21.5 cubic feet of Cripple Creek ore. It is made of ¼-inch steel and is 2.5 feet wide, 2.5 feet high, and average of 4 feet long (3 and 5), capacity 25 cubic feet, the additional capacity being for safe loading. The track gauge is 33⅓ inches, wheels 12 inches diameter, front wheels 3 inches, and back wheels 6-inch tread. The axles are bolted to the bottom of the skip, which is of the type generally used on long inclines.

A 1911 catalog gives skip No. 1, capacity, 25 cubic feet; thickness of steel in box, ¼ inch; weight, approximate, 1,300 pounds This is quoted at $125, with $15 extra for water valve. It is built of Swedish iron and steel plate, and the wheels are of best chilled iron. Cost of the two skips purchased is $298.20, of which $18.20 is freight.

Information from a manager in Cripple Creek gives the fact that one stoping drill will break down 8 tons of ore. This is also checked by the report of the Portland company, showing 29 machines stoping, and an average for the year of 230 tons a day. Based on this practice, 200 tons of ore will need 25 machines, and a good safe margin is 12 additional machines on development. This is more than necessary during preliminary development work. It is estimated that 25 air-hammer drills take 25 cubic feet of air each at sea level. The multiplication factor for 25 drills at 10,000 feet altitude is 23.7; hence, $23.7\times 25=592.5$ cubic feet per minute. Twelve 2¾-inch piston drills at air pressure of 90 pounds at drill take 80 per cent. of catalog figures, or 67.2 cubic feet each. Multiplication factor for 10,000 feet elevation is 12.1, which gives 813 cubic feet air per minute, or for both hammer and piston drills a total of 1,405.5 cubic feet air per minute. Allowing 5 per cent. for leakage brings the requirements to 1,480 cubic feet per minute. Assuming efficiency of 80 per cent., and the requirements amount to 1,850 cubic feet per air minute.

The size of a two-stage belt-driven compressor, weighing 50,000 pounds, for altitudes of 10,000 feet will be found by consulting catalogs to have about the following dimensions:

Size		Revolutions Per Minute	Piston Displacement Cubic Feet Per Revolution	Horsepower Required 100 Pounds Air
Air Cylinder Inches	Stroke Inches			
28 × 17	24	125	17.2	380

This gives an excess of 16.2 per cent. in capacity and the revolutions per minute can be increased to 150, giving an additional capacity above requirements of 39.5 per cent., a total reserve for future of 55.7 per cent. Cost f. o. b. Cripple Creek, $5,620.

Assuming that 20 horsepower is required for 100 cubic feet of free air per minute, $20\times 18.5=370$ horsepower.

For this compressor a 380-horsepower motor, weighing 45,000 pounds, completely boxed, is advised. This, f. o. b. Cripple Creek would cost $3,477.50. The motor is to be three phase, 60 cycle, 440 volts, at 720 revolutions per minute.

As a service main, 1,660 feet of 4-inch air pipe, weighing 88 pounds per 100 feet and costing $182.34, was decided upon, bringing the cost of air installation to the following: Compressor, $5,620; motor, $3,477.50; pipe, $182.34; total, $9,279.84.

All buildings, except powder house, which has brick walls and corrugated iron roof, are of ordinary balloon frame with corrugated-iron siding and roofing. The cost of surface buildings summed up is as follows:

COST OF SURFACE BUILDINGS

1.	Ore house	$5,498.94		
	Cost of construction at $8.50 per thousand board feet	842.00	$6,340.94	
2.	40 ft. × 15 ft., 600 cu. ft. erected, at 15 cents per cu. ft.		90.00	
3.	20 ft. × 20 ft., 400 cu. ft., at 10 cents		40.00	
4.	17 ft. × 50 ft., 850 cu. ft., total cost, erected at 15 cents per cu. ft.	$ 127.50		
	Shafts, pulleys, and equipment of machine shop	$1,000.00		
	One Bradford engine lathe, 14,500 pounds	800.00		
	Machine tools	500.00		
	One power driven forge	100.00		
	One 10 H. P. Westinghouse induction motor	150.00		
	One Leyner drill sharpener, weight 1,494 pounds	1,000.00		
	One complete blacksmith outfit, weight 500 lb.	40.00		
	One extra anvil, 100 lbs., solid wrought, at 15 cts.	15.00	$3,605.00	$ 3,732.50
5.	Timber shed 115 × 10, 1,150 cu. ft. at 4 cents per cubic foot		46.00	
	One D. E. W. timber framing machine, shipping weight, 6,500 pounds		1,500.00	
	15 horsepower induction motor		225.00	$ 1,771.00

6.	Main office and superintendent's office, 80×15, 1,500 cu. ft., at 15 cents...	225.00	
	Assay office, 20×15 materials.......	2,000.00	
	Furniture, office....................	500.00	$ 2,725.00
7.	Store house, 60×10, 600 cu. ft., at 15 cents.....		90.00
8.	Powderhouse, 10 ft.×10 ft., brick, erected......		100.00
9.	Two water tanks, each holding 10,544 gallons, weight, each 3,000 pounds, each $195..........................	$ 390.00	
	1,500 feet of 4-inch supply pipe from city reservoir, weight 10.60 per foot (15,900 pounds), at $1.08 per foot..	1,620.00	$ 2,010.00
	Freight on all materials bought in Denver, about 80,000 pounds, at 55 cents..................		440.00
	Total..		$17,339.44

ELECTRIC INSTALLATION—SURFACE

One 53-horsepower induction motor for hoist; one 80-horsepower induction motor for development compressor; one 380-horsepower induction motor for compressor for final work; one 10-horsepower induction motor for machine shop; one 15-horsepower induction motor for timber mill.

INCANDESCENT LIGHTS

One 16-candlepower for every 100 square feet in all buildings, except offices. In offices, two 16 candlepower for every 100 square feet and localized near desks.

Hoist house, 6 and 6 localized..........................	12	
Blacksmith and machine shop, 8 and 6 localized.........	14	
Electric station house.................................	2	
Timber yard and shed, 12 and 6 localized...............	18	
Offices, 30 and 10 localized...........................	40	
Store house, 6...	6	
Powder house...	1	
Sorting house..	10	103

UNDERGROUND

One 150-horsepower induction motor for large pump.

INCANDESCENT LIGHTS

At ore chutes..	24	
For two stations.......................................	4	
In cross-cuts..	12	
For two loading stations...............................	4	
For shaft..	60	
For pump stations......................................	4	108
Total incandescent lights..............................		211

Allowing 55 watts power for each 16-candlepower lamp energy consumed, 11.6 kilowatts; 1,100 feet No. 0 B. & S. three-conductor cable to carry current to pump, 477 pounds; 1,500 No. 0000 B. & S. three-conductor cable for lights, 900 pounds.

A Cast-Iron Water-Jacket

*By E. C. Reeder, E. M.**

In smelting copper ores to matte in a water-jacketed blast furnace, there is always more or less trouble with the jackets burning. When making high-grade matter of 40 to 50 per cent. copper, usually the jackets most likely to give out are the tap-hole jackets or plates on the settler, which in most plants are made of cast iron with a cooling coil cast in them.

The Canadian Copper Co., Copper Cliff, Ontario, Can., smelts copper-nickel ores to a copper-nickel matte containing from 28 to 35 per cent. in combined *Cu* and *Ni*, the *Cu* and *Ni* being in the ratio of 3 to 5. This is without doubt the hottest and most corrosive matte made in a water-jacket blast furnace anywhere.

The furnaces at Copper Cliff measure 50 in. × 204 in. at the tuyeres and have a height of about 20 feet from tapping floor to charge floor. The smelting column ordinarily is about 10 feet deep and the furnaces are usually blown with about 30,000 cubic feet of free air per minute at a pressure of 50 ounces. The average capacity of each furnace under normal conditions is from 450 to 500 tons of charge per day. The ores in the charge average between 5 and 6 per cent. combined copper and nickel, and the result is a very heavy matte fall accompanied by large quantities of heavy irony slag, all very hot. About 8 per cent. coke is used on the charge.

* Chicago, Ill.

Some 6 years ago, when smelting first began at Copper Cliff, the furnaces were constructed with the steel-plate water-jackets and water-jacketed spouts. When the first furnace was blown in, as soon as the starting bar was pulled out of the breast jacket, there was an explosion when the hot matte touched the steel spout, and a series of explosions followed, lifting the spout from its place and hurling it 50 feet or more. Other spouts were tried, but until the scheme of building the spout of chrome brick was tried there was little success. The spouts are therefore now built of standard chrome brick, cooled with cast-iron plates containing pipe coils. The channel in these spouts lasts about a month, when the furnace is shut down for a few hours until the brick can be replaced. But spout troubles were as nothing compared with the time lost and trouble caused by holes burning in the furnace jackets. The hot matte would burn a hole through a ⅜-inch jacket sheet like a small boy pushing his thumb through a warm pat of butter. Of course when the matte struck the cooling water of the jacket, the inevitable happened, with the result that the jacket, or may be several of them, would be found on the floor. It sometimes happened that a furnace would run for a month without losing a jacket, and often it might not be in blast more than an hour or so after replacing a jacket before it would be necessary to make a fresh start. The repair gang often was on duty 3 days at a stretch, as one furnace after another would go out. Under such conditions a large stock of spare jackets of all descriptions was required in order to keep two furnaces out of three in blast continuously. The difficulty was overcome by using cast-iron jackets for the lower tier containing the tuyeres instead of the plate jackets. The upper tier of jackets, which did not come in contact with the molten charge, continued to be of the ordinary plate construction.

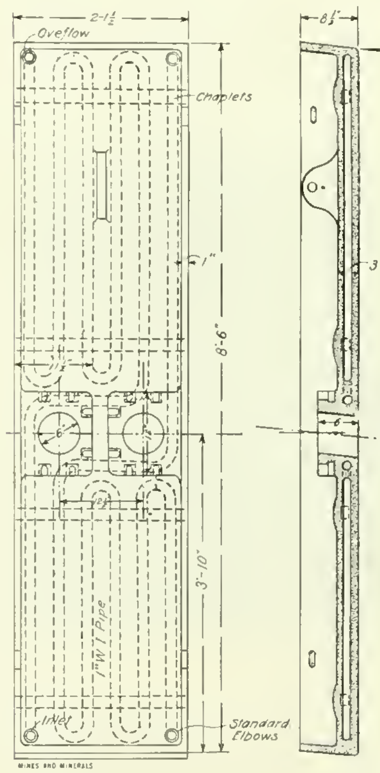

FIG. 1. WATER JACKET

The design of this cast-iron jacket with its cooling pipes is shown in Fig. 1. They are made in the company's foundry and it took a good deal of effort and care before a really first-class jacket was obtained. When in use, these jackets last indefinitely, as the matte seems to have no effect upon them, and when failure does take place, it is by cracking along the line of the chaplets which hold the pipes in place in the mold while casting. These chill the iron and make a weak spot. Some of the jackets have been in service for 9 months and were in good condition at the end of that time. The cooling pipes are blown out every day with compressed air to remove accumulations of sediment. No machine work is necessary on these castings outside of facing off the seats for the tuyere elbows.

When the jackets are scrapped they can be broken, remelted, and recast.

This style jacket, which has been applied to all the furnaces at the Copper Cliff plant, has now been in use over 3 years.

International Smelter at Tooele, Utah

Method of Sampling, Handling Ore by Conveyers, and the Process of Roasting and Converting

By Leroy A. Palmer

The Tooele* smelter, the first plant built by the International Smelting and Refining Co., has been in successful operation since the late summer of 1910. From the start, operation has been attended by little difficulty; and the business of copper smelting being well under way, the company has announced its intention of building a lead smelter; and ground is being broken for this plant adjacent to the other. The site is 7 miles from Tooele Station on the San Pedro, Los Angeles & Salt Lake Railroad, which is 34 miles west of Salt Lake City. The plant and the railroad are connected by the Tooele Valley Railroad, operated by a subsidiary corporation of the smelting company.

The smelter site proper embraces 300 acres, but in order to preclude litigation over fume damage, options were secured on all the cultivated land within a radius of 4 miles. To secure an adequate water supply a number of these options were exercised so that the company owns outright about 2,000 acres of land. $150,000 was spent in securing the land and options.

Fig. 1. Tooele Smelter

The plant is exceptionally well designed and favorably located, the ground having a slope such that gravity assists to a large degree in the handling of the product of one department to another. It embraces the usual equipment of a copper smelter designed to convert ore or concentrate into blister copper, with the exception of blast furnaces. A space has been reserved for these and it is the intention to equip the plant with them later.

Sampling Mill.—The plant is provided with spacious railroad yards, about 10 miles of track being included in the entire industrial system, with a double standard-gauge track running over the steel trestle to the ore bins. A 50-ton electric car handles the ore from the Utah Consolidated tramway bins, and the Tooele Valley Railroad delivers that which comes in by rail. The bins, which have a capacity of 10,000 tons, are built double and in two sections, the conveyer belts which feed the sampling mill running laterally between them. The rails of the tracks are supported on 15-inch I beams and the bins rest on 30-inch I's with 18-inch uprights on 10-foot centers tied across the top with 24-inch I's. The bottoms are sloping and lined with ½-inch iron. One set of bins is used for the storage of coal, ore that has been custom sampled, fine ore that is to be split shoveled, etc. These discharge through air-operated gates to cars run on the industrial system. The other set of double bins is used for the ore which is to be run through the sampling mill.

* Pronounced Too-il-la.

These bins discharge through hand-operated rack-and-pinion gates to a mechanical feeder, shown in Fig. 2, which runs on a 48-inch track over a 30-inch horizontal belt conveyer. The feeder consists of a hopper with a capacity of ½ cubic yard above a belt of 20 iron panels, each 9 in.×24 in.×3 in. A 10-horsepower Westinghouse direct-current motor drives the panel belt which delivers a uniform feed to the conveyer which runs at the rate of 160 feet per minute. If desired, the feeder motor can be clutched into a gear and the feeder moved back and forth along the track to whichever bin it is desired to sample. The conveyer belt is controlled by a clutch whose lever is connected to the second floor of the mill by a wire rope so that the feed can be regulated at the crusher.

The horizontal conveyer discharges to one of the same width which runs at an angle of 11½ degrees at a speed of 170 feet per minute and delivers to the second floor. The sampling mill is in two units throughout, each being driven by a 175-horsepower, 2,000-volt, Westinghouse induction motor. The building which occupies ground space of 40 ft.×84 ft. has a steel frame with corrugated iron sheathing and reinforced concrete floors. On the second floor the inclined conveyer discharges to a hopper which feeds over a shaking screen with 2-inch punched holes to a 12″×24″ Blake crusher making 198 revolutions per minute and set to break to 2 inches. The screen undersize drops to a short inclined 20-inch conveyer and discharges with the crusher product to a steel-housed elevator. This elevator is gear-driven with a speed of 350 feet per minute, having a 20-inch belt with cups 10 in.×10 in.×18 in., spaced at intervals of 2 feet. It discharges at the top of the mill where a sample is cut out and chuted to a shaking feeder which discharges to a 20″×10″ Blake crusher set to 1 inch and making 192 revolutions per minute. Passing this a second cut is made and sent to a set of 48″×12″ Anaconda rolls set to ¼ inch, making 80 revolutions per minute, passing which a third cut is made and sent to a set of 26″×15″ rolls, after which the final cut is made and sent to the sample safe. The sample is split shoveled and finished in a laboratory crusher and a Braun pulverizer. Brunton samplers are used and a $\frac{1}{5}$ cut made after each crushing so that the final sample represents $\frac{1}{625}$ of the whole.

As the equipment of the plant does not include blast furnaces, it is necessary that all ore shall be crushed to such size as will enable the reverberatories to smelt it readily, and a portion of the sampling mill is given up to the crushing apparatus. The reject of the first sample goes to a 4′×14′ trommel, with a frame of heavy angle irons and a covering of three ½-inch manganese steel plates, which makes 16 revolutions per minute. The first two plates have ⅜-inch punched holes and the third 1¼-inch holes. The oversize of this trommel goes by a divided chute to two 15″×9″ Blake crushers set to 1 inch and making 310 revolutions per minute. The crusher product, with the undersize from both screens of the trommel, goes to a similar trommel with ⅜-inch openings. The oversize of this trommel goes to two sets of 48″×12″ Anaconda rolls making 84 revolutions per minute which discharge with the undersize to a short 20-inch conveyer to the boot of an elevator which dumps to the fine ore conveyor. The rejects of the different samples after the first, are chuted into this system at the point necessary to give them the proper crushing. When the blast furnaces are installed this crushing will not be necessary, and the coarse will be chuted to a belt running parallel to the fine ore conveyer, and that which is rejected at a point in the system too low to run to this belt by gravity will go to a third elevator beside the second and be elevated to it. The second and third elevators are uniform with the first in equipment and speed. Rolls, trommels, and elevators are steel housed to prevent the escape of dust. A belt elevator is provided to convey the men from one floor to another.

Conveying System.—The coarse and fine ore conveyers run parallel and discharge to two 20-inch rubber belts, also parallel but running in opposite directions. The coarse ore goes to the blast furnace bins which are of steel construction and have a capacity of 3,500 tons. The bin is double, discharging on either side through air-operated gates to cars on the industrial system. The fine ore bins are double, 180 feet long, with a capacity of 5,700 tons. The fine ore conveyer, 300 feet long, moves at a speed of 375 feet per minute, and discharges by means of a tripper to any desired point on either side of the bin, over a 1-inch grizzly carried on the discharge hopper.

On either side of the roaster bin the ore is fed mechanically to a 20-inch horizontal conveyer that discharges to a third conveyer that runs at right angles. The first conveyer has a 10-horsepower motor, and the third, which is much shorter, a 5-horsepower. The latter conveyer is about 6 feet below the surface of the ground, and above it is a hopper in one of the tracks of the industrial system. By means of this hopper the ore that has not been run through the sampling mill is conveyed to the roasters. The third conveyer discharges to a fourth which runs at right angles to it but inclined at an angle of 14 degrees. This fourth conveyer, which is 280 feet long and has a speed of 340 feet per minute, carries the ore to the top floor of the roaster building, passing on its way over a Blake-Dennison continuous weighing machine by which the feed is automatically weighed and the weight recorded. The inclined conveyer is provided with a tripper by which it dumps to any of the four belts running over the roasters on each of which is a tripper to discharge the feed to the particular roaster it is desired to supply. Each of these belts and the inclined belt have a 10-horsepower motor. It will be noted that from the time the ore leaves the bins at the sampler until it is dumped into the roasters it is handled entirely by belts, with the exception of the elevators in the mill. There being no loading into cars with the attendant switching, manual labor is reduced to a minimum, a continuous feed is secured, and only 35 horsepower is required to run the conveying system.

The roasting plant contains thirty-two 16-foot MacDougall roasters arranged in four rows in two steel-frame buildings, each 64 ft. × 162 ft. Each roaster has six hearths and the arm makes a complete revolution in 55 seconds, this speed requiring about 2 hours to work the charge through the roaster. The capacity of a single roaster is about 45 tons per day. The ore of the Utah Consolidated, the largest individual shipper to the plant, carries from 26 to 30 per cent. sulphur, and this is given a roast which eliminates about 80 per cent., bringing the calcine down to 5–7 per cent. sulphur. Silicious ores received from the Tintic district are discharged to a spout alongside the roaster and conveyed by it to the fifth hearth where they mix with the calcine. The mixture is in the proportion of 70 tons of silicious ore to 400–500 tons of base, so that the resultant calcine contains about 5 per cent. sulphur. In those roasters treating the Utah Consolidated ore, water is used on the third, fifth, and sixth arms, but in those treating the fine concentrates of the South Utah, which run 24 per cent. sulphur, no water is used at all. The introduction of the silicious ore on the fifth hearth tends to cool the lower portion of the furnace, so that on the furnaces used for this purpose a brick firebox has been built on each side of the third hearth and these are fired with coal to bring the heat to the proper point. One roaster is used to drive off moisture from the silicious ore that is used for converter linings. Each unit of 16 roasters is driven by a 30-horsepower motor. The hot water that has been through the roaster arm is piped to the cooling tower and the cool water is pumped to the circulating tank in the top of the roaster building by a centrifugal pump belted to a 30-horsepower motor.

The roaster buildings are provided with brick dust chambers 162 ft. × 14 ft. × 12 ft., which receive the fumes from each roaster through two 36-inch elbows. These smaller dust chambers discharge to the main dust chamber, which is 120 ft. × 140 ft. × 40 ft., terminating in a flue 255 ft. × 16 ft. × 16 ft., which enters one side of the stack. The smaller dust chambers are provided with 14′ × 2′ steel hoppers, 8 feet apart, and the larger with 6-foot steel hoppers running across, with 12-inch gates. The hoppers are above tracks on the industrial system by means of which the dust cars are brought directly beneath. An analysis of calcine from Utah Consolidated ore shows: *Cu*, 2.30 per cent., SiO_2, 26.7 per cent., *FeO*, 49 per cent., *CaO*, 3.6 per cent.

Each MacDougall furnace discharges to two hoppers beneath, from which the calcine cars, holding 7,300 pounds, are loaded and hauled to the reverberatory charge building, which is 66 ft. × 280 ft. The furnace building proper, is 82 ft. × 326 ft., adjoining which is the boiler house, 36 ft. × 326 ft. At one end of this building space has been reserved for two blast furnaces. The reverberatory furnaces are of the Anaconda type, five in number, each 19 ft. × 102 ft., with a minimum rating of 300 tons per day. Each side of the furnace is provided with eight doors and the space between them is braced with 6-inch I-beam buckstaves on 12-inch centers. The tops are tied both crosswise and lengthwise with heavy steel rods so as to give a strong structure. Calcine is charged through two hoppers, one with two and the other with three discharge openings, and coal through a single hopper with five openings. The coal is brought in from the stock pile by the electric cars or can be run in in the large railway cars from the Tooele Valley tracks. As the ashes are raked out they fall into ash cars which are hauled to the dump. So far no attempt has been made to recover the coal in the ash. Back of four of the furnaces are 750-horsepower Stirling water-tube boilers utilizing the heat that would otherwise be wasted in the flue. Each of these boilers generates 600 horsepower in steam at 150 pounds pressure and is set with a brick by-pass, so that when it is necessary to clean a boiler it can be cut out and the gases discharged into the flue.

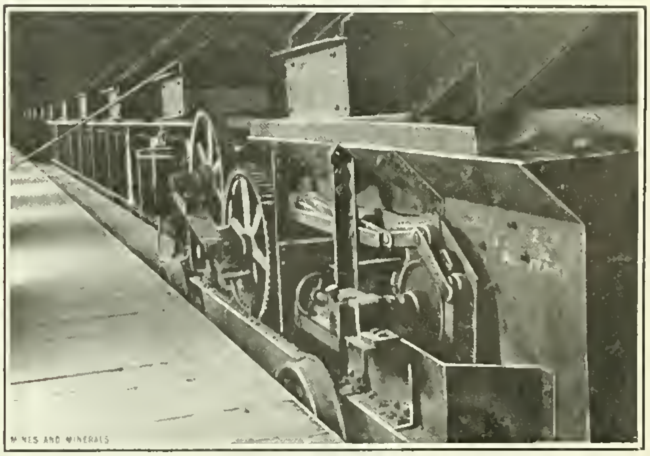

Fig. 2. Mechanical Feeder at Sample Bins

Twelve tons of calcine are dumped to a charge, and twice a shift. When the slag rises three or four inches above the skimming plate in the furnace it is skimmed through a steel launder to slag cars in the slag tunnel in which is a standard gauge track on steel ties. These cars have a volume of 225 cubic feet and a capacity of 20 tons of slag, and each is provided with a motor with rack-and-pinion gearing, so that the car may be dumped from the cab of the locomotive. The cars are hauled to the dump by a Baldwin-Westinghouse locomotive fitted with two 60-horsepower motors, automatic couplings and air brakes. An average reverberatory slag will analyze: *Cu*, .35 per cent.; SiO_2, 42 to 45 per cent.; *FeO*, 42 to 45 per cent.; *CaO*, 4.5 per cent.

The matte produced in the furnace is tapped through a copper tap-hole plate to steel launders in which it runs to the converter plant. The launder discharges to a steel spout on ball bearings, so that the matte can be run direct to a converter or to a ladle and be transferred to some other converter in the line. The launders from each side of adjacent furnaces cross each other running to different converters, so that one side of a furnace can be tapped to either of two converters without using a ladle. An average matte assays: *Cu*, 28 to 31 per cent.; *Fe*, 40 per cent.; *S*, 25 per cent.

The flue that serves the reverberatories is 20 ft. × 18 ft. × 1,360 ft. terminating at the stack on the side opposite to that at which the reverberatory flue enters. It is provided with clean-out doors and both flues have heavy counterweighted steel dampers. The stack is 350 feet high with an inside diameter at the base of 36½ feet and the top of 25 feet; 1,750,000 brick were used in its construction. Natural draft alone is used and averages 1.8 inch.

The converter building, Fig. 4, is 65 ft. × 408 ft., adjoins the reverberatory building, and next to it is the casting shed, 52 ft. × 255 ft. The size of the converter building affords ample room for the handling of ladles and converters and does not present the crowded appearance so often found in this branch of the operations. There are five stands for Power and Mining Machinery Co. Leghorn converters, 96 in. × 150 in. in size, with sixteen 1-inch tuyeres. Each converter is controlled by a 40-horsepower motor. The slag is poured to ladles that are picked up by a crane and set on a platform convenient to a smaller cross-travel crane which carries them to the reverberatory building. Between two pairs of the furnaces are pouring stands with launders running each way to a side door in the furnace. When converter slag is to be poured a spout is attached to the launder, so that the slag discharges well within the furnace where the heat is high, so it does not have a chance to chill and solidify around the doors. The slag assays: SiO_2, 29 per cent.; *FeO*, 58 per cent.

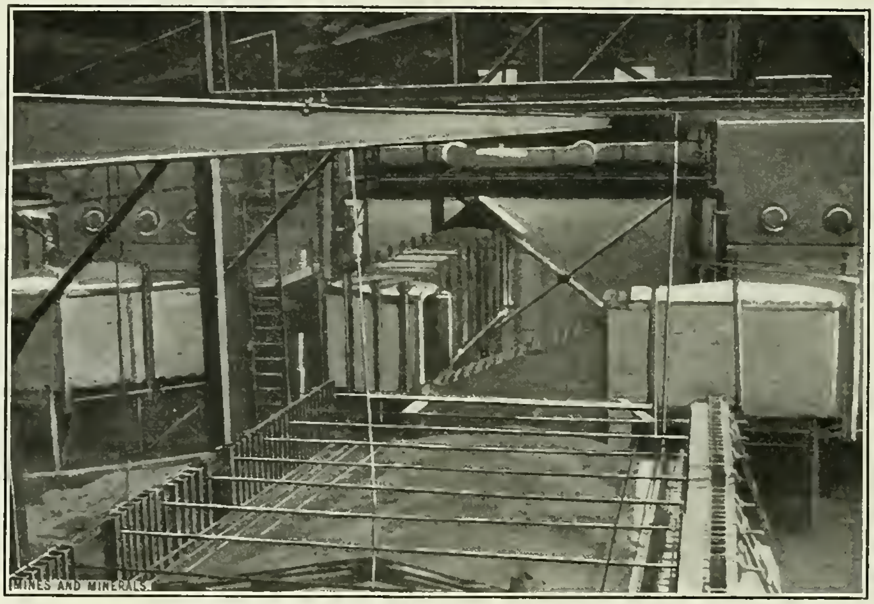

Fig. 3. Top of Reverberatory, Showing Bracing, Waste Heat Boiler, and By-Pass

The ladles to which the blister is poured are set convenient to a crane by which they are picked up and carried to the casting floor. Here the blister copper containing 98–99 per cent. copper, is cast into ingots weighing 250 pounds, and these are shipped to the United Metals Refining Co., at Raritan, N. J., for refining. At present the converters are operated only one shift. When one is closed down it is sealed, so as to retain as much of the heat as possible, and by this means it is found that no inconvenience results from the interrupted operation.

The converter hoods are raised and lowered by small motors. The fumes go to a steel hopper-bottomed flue, 248 feet long, 8 feet wide, and 12 feet deep, with hoppers terminating in 12-inch discharge pipes 4 feet apart. This discharges to a flue 181 feet long with a cross-sectional area of 132 feet, which connects with the flue which serves the reverberatory furnaces. The converter plant is equipped with five Morgan-Gardner electric cranes, one 60-ton for handling converters, one 30-ton for handling ladles on the converter floor, one 30-ton for handling ladles on the casting floor, and two 12½-ton for handling slag.

The power house is built of brick over a steel frame, 52 ft. × 240 ft., widening at the middle by a bay on each side to 112 feet. Steam is carried in two 12-inch lines from the waste-heat boilers and from one 250-horsepower hand-fired boiler. There are three of these hand-fired boilers, but only one is kept under steam, the others being held for an emergency. They discharge into the main flue, but are so connected that they can discharge through a steel stack, 15 ft. × 40 ft., and when this is used they are supplied with induced draft from a 12-foot Sturtevant fan direct-connected to a vertical 8″ × 13″ piston valve engine. In the basement of the power house the feed-water is filtered through coke and heated in an open heater by using the exhaust from the pumps and the discharge from the steam traps. It is forced into the boilers by a Knowles twin-tandem plunger pump, 8 in. × 12 in. × 6½ in. × 10 in., with a capacity of 332 gallons per minute. A Worthington, outside, center-packed duplex, 12 in. × 7 in. × 10 in., with a capacity of 346 gallons per minute, is installed as an auxiliary. For fire protection, a Worthington duplex plunger pump, 16 in. × 9 in. × 12 in., with a capacity of 750 gallons per minute, forces water to two 44,000-gallon tanks placed at a height that gives good pressure at any part of the works.

The following engine equipment has been installed:

One Nordberg tandem-compound Corliss engine, 16 in. × 30 in. × 36 in., 350 horsepower, making 120 revolutions per minute, direct-connected to a 250-kilowatt Westinghouse direct-current generator, generating at 550 volts, 455 amperes.

One Nordberg tandem-compound Corliss engine, 16 in. × 32 in. × 36 in., 350-horsepower, making 120 revolutions per minute, direct-connected to a generator the duplicate of the above. These generators furnish the direct-current used on the industrial system.

Two Union Iron Works triple-expansion marine engines, 18 in. × 26 in. × 40 in. × 24 in., 1,000 horsepower, 180 revolutions per minute, direct-connected to 750 kilowatt Westinghouse alternating-current generators generating at 2,200 volts, 455 amperes, three phase, 60 cycles. These generators supply current for the various induction motors used around the plant.

One Nordberg cross-compound Corliss engine, 15 in. × 30 in. × 42 in., 350 horsepower, making 85 revolutions per minute, tandem connected to 36-inch duplex air cylinders with a capacity of 9,800 cubic feet of free air per minute.

One Rarig cross-compound Corliss engine, 26 in. × 52 in. × 48 in., 600 horsepower, making 40 revolutions per minute, connected to 52-inch duplex air cylinders with a capacity of 8,700 cubic feet of free air per minute. These blowing engines work to 15 pounds of air for the converters.

One Laidlaw-Dunn-Gordon cross-compound Corliss engine, 13½ in. × 26 in. × 36 in., tandem-connected to two-stage air compressor, 26 in. × 15 in., making 50 revolutions per minute, with a capacity of 1,550 cubic feet of free air. This compressor works to 90 pounds, supplying air for the forges, sampling mill, etc.

One Ingersoll-Rand two-stage compressor, 26¼ in. × 15¼ in.

$\times$ 8 in., with a capacity of 2,000 cubic feet of free air, belted to a 175-horsepower, 2,080-volt Westinghouse induction motor. This is held as an auxiliary to the steam-driven compressor. The air leaves the high-pressure cylinders at a temperature of about 140° F. and, as the mill and blacksmith shop are some distance away, the entrained moisture caused some trouble by precipitating along the lines. To obviate this the high air is passed through an intercooler before leaving the power house and subjected to a cooling that removes a sufficient amount of the moisture, without lowering the pressure to a point that makes an appreciable decrease in the efficiency.

One Westinghouse generator set, consisting of a 290 horsepower, 2,200-volt induction motor direct-connected to a 200-kilowatt, 550-volt direct-current generator. With the present smelting equipment one of the marine engines alone generates an excess of alternating current, so this generator set is used to supply part of the current for the industrial system, and one of the steam generator units is not operated.

Two exciter sets. One of these consists of a 12″$\times$12″ Skinner slide-valve engine making 300 revolutions, direct-connected to a 50-kilowatt direct-current generator and the other of a 75-horsepower 2,200-volt Westinghouse induction motor direct-connected to a similar generator.

All the engines are run condensing. The marine engines each have their own condensers connected to 12″$\times$18″ circulating

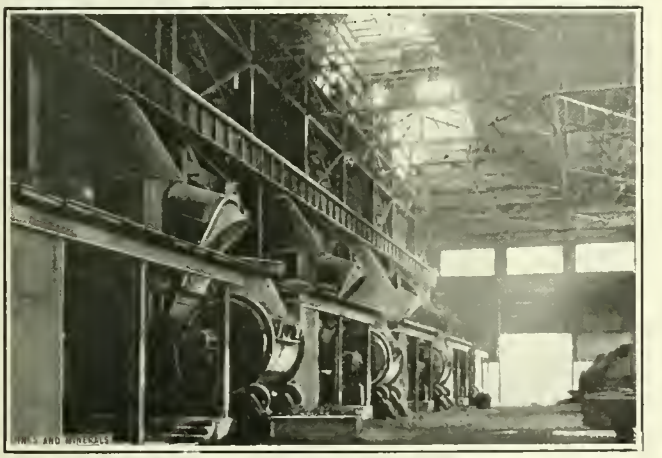

Fig. 4. Converter Building

and air pumps. The latter give a vacuum of 18 inches in an altitude where 22 inches is absolute. The engines on the generator units are connected to a Deane condenser with 16″$\times$24″ steam cylinder and 24-inch water cylinder, giving a vacuum of 20 inches. The blowing engines and steam-driven compressor are connected to a Westinghouse-LeBlanc condenser, driven by a 95-horsepower induction motor. All of the condensers pump to a natural draft cooling tower, 140 feet long, 20 feet wide, and 49 feet high. The power-house is equipped with a 15-ton electric crane.

The alternating current which is generated at 2,200 volts is transmitted at this voltage and stepped down by small transformers placed on the line at various points where it is desired to use the lower voltage. It is intended later to supply current to the Utah Consolidated mine and tram, and for this purpose three 200 kva. transformers stepping up from 2,200 to 11,500 volts have been installed but are not yet in use.

In the construction of the smelter a great deal of material from the Highland Boy smelter, formerly the property of the Utah Consolidated, was used. The greater portion of the power-house equipment came from this plant and from Anaconda, Mont. The Highland Boy furnished 3,000 of the 9,900 tons of structural steel and 20 of the 32 MacDougall roasters. The old steel stack was also cut up and used. In the construction, 26,000 yards of plain and reinforced concrete and 200,000 yards of excavation, most of it by steam shovel, was required.

It will be noted from the description that manual labor has been reduced to a minimum, especially in the handling of products. The operative force is less than 300 men. From the start, operation has been attended by no difficulty due to design. The various foremen have been permitted to try such minor changes in operative methods as seemed advisable to them, and a system excellent in detail has been worked out. The chief handicap has been a shortage of ore. The contract with the Utah Consolidated called for a maximum daily tonnage of 1,200 tons and it was expected that an amount approximating this would be shipped and that, with ores from other sources, the five reverberatories would be working to full capacity from the start. The amount from this source has fallen below this, so that for a considerable portion of the time only three of the furnaces are in operation. Not working the full complement of furnaces for which the flues and stack were designed has tended to decrease the draft and the ratio of coal to ore, 1 to 2½, is not as low as was expected. As more contracts for ore are being made, it is hoped to overcome this difficulty.

The water supply is from Pine Creek. It is brought to the plant from a dam in the cañon, a distance of 5,000 feet, in a 12-inch pipe line, and distributed from a 50,000-gallon standpipe. A good supply of lime rock for fluxing purposes can be obtained from this cañon. For the reasons given in the first part of this article, no trouble is expected with the surrounding ranchers, but as a matter of precaution the stock and vegetation of the surrounding country was examined, before operations were commenced, by veterinarians and botanists, and careful notes, which, if necessary, can be used later for comparison, were collected. A hospital is in operation at Tooele City and at the plant is an emergency hospital under charge of a competent trained nurse who is always on duty. A gasoline car is held at the disposal of this department for quick transportation to the general hospital of any cases requiring immediate surgical attention. The plant has about the same haul from most of the camps as the Garfield smelter, with which it comes in competition, but with the Utah Metal Tunnel in operation will be about 17 miles nearer Bingham.

The writer is indebted to the many employes of the smelter from whom he sought information and to E. P. Mathewson, General Manager, H. N. Thomson, Superintendent, and W. G. Walton, Chief Engineer of the power plant.

Society Meetings

The Lake Superior Mining Institute will hold its sixteenth annual meeting, August 22, 23, and 24, on the Menominee Range. At the meeting, held last year, a committee was appointed to prepare papers on the subject of Mining Methods on the Menominee Range. There will be papers on Efficiency, Uniform Mining Laws, and Safety Appliances.

The American Mining Congress will hold its fourteenth annual session in Chicago during the week beginning September 25. President Taft and the Secretary of the Interior, Walter L. Fisher, have promised to attend this convention.

The Nanticoke District Mining Institute of Pennsylvania, which was organized October 18, 1910, with John T. Thomas, president; William H. Morgan, vice-president; John D. Evans, treasurer; D. M. Hopkins, secretary; and F. H. Kohlbraker, John Kelly, David Samuel, J. N. Turner, Joseph J. Walsh, John E. Thomas, George Hopper, Frank Kettle, William T. Jones, Samuel Saville, C. K. Gloman, and C. L. Fay, directors, held its first regular meeting November, 5, 1910. The first annual dinner of the Institute was recently held in the Broadway Hall, at Nanticoke. It was an enjoyable affair in which coal company officials mingled with the members of the Institute.

Gold Dredging in Foreign Countries

Difficult Conditions Met With in Africa. Methods Used in New Zealand

When a river flows over land the top soil is washed away, leaving the gold-bearing gravel as river bed. It is from this residue that gold is obtained in South and West Africa by floating dredges. The gold coast of West Africa is a typical tropical dredging country. From the coast inward, stretches a swampy belt of dense forest. Most of the sluggish rivers which flow through this country to the sea owe their origin to the highlands of the hinterland, and are fed by the periodical heavy rains that make life a burden all along the coast. These rivers must at various points have cut through or alongside of the gold-bearing reefs of Ashanti, and in their beds are to be found large quantities of alluvial gold. During the dry season many of them are but small, shallow streams, but the Offin River has been known to rise as much as 15 feet in a single night when the wet season begins. The banks of these rivers are covered with the densest forest (bush), and from their surface arises the miasma, probably microbes, which has had the effect of bringing West Africa into such ill repute as a fever-stricken country. Except in the case of the big navigable rivers, the waterways of West Africa are used solely by native fishermen. No good roads exist, and as a result, jungle tracks have to be cut and maintained by the mining companies. Running as they do through swampy country, these roads are for six months of the year almost impassable, and all the time require constant cutting.

Conditions existing in a much cooler country like New Zealand are, of course, very different. There the country is open and the roads are, taken as a whole, good. Coal is used for fuel, as much as 100,000 tons in a year, while in West Africa there is enough lumber along the banks of most of the rivers to keep the dredges going for 50 years.

It may be said that steam launches or tugs will do the transport work satisfactorily in West Africa, but however

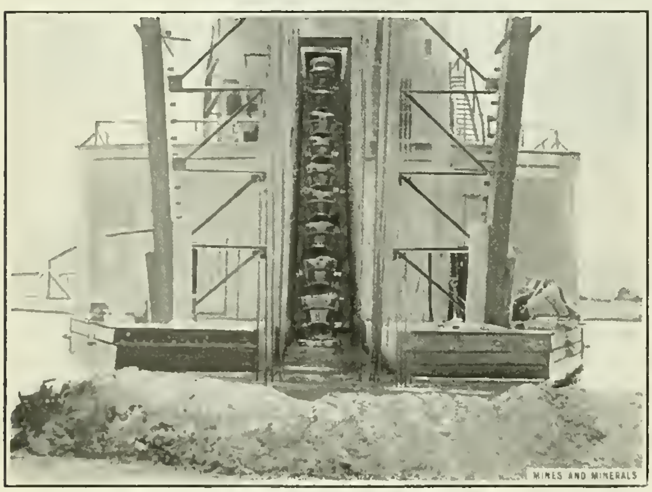

Fig. 1. Bucket Dredge

careful the dredgemaster may be in the disposition of tailings, the scattered heaps of worked gravel left behind by a dredge make navigation very hard in the dry season, while in the wet season it is almost impossible to steam against the swift currents.

In appearance, West African gold dredges are very much like the dredges which work in harbors and on river bars, with the difference that gold-saving appliances in the form of sluice tables, revolving screens and other apparatuses are built into their after end. They do not propel themselves, but are moved and steered by means of steel head, side, and stern lines. Each dredge is fitted with a steam winch, with the aid of which and the lines, these latter being tied to big trees, it can haul itself forward or move from side to side. A string of buckets (dippers), each of from 4 to 7 cubic feet capacity, is driven by a main engine, and can dig to a depth of as much as 40 feet, while the pumps suck from the river and throw a constant stream of

Fig. 2. Dredging Ground and Dredge

water on to the gold-saving tables, into which are emptied the contents of the buckets as they come up. These tables are about 60 feet long, and are laid at a suitable angle. They are paved with steel riffles and cocoanut matting, like those used in our own country, the gold being interrupted by the former while it is in transit, and held by the latter. In ordinary circumstances these riffles and mats are taken up and washed about once a week. Some dredges are fitted with revolving perforated screens, into which the gravel is tipped and broken up, the gold falling through the perforations on to the tables, which in this case are placed immediately below the screen.

This short account of the process of gold getting is, of course, incomplete, and does not attempt to describe the problems with which the mining engineer is confronted in such matters as slope of tables and quantity of water required.

Mention has already been made of New Zealand as a dredging ground, and there is little doubt that that country has pioneered the industry. In the sixties the now out-of-date spoon dredges were at work there, and since then the apparatus has steadily improved, although it is not yet on a par with the most modern American machinery. The "Earnscleugh" No. 3, now working in New Zealand, has buckets each with a capacity of 7 cubic feet. The pontoons are 130 feet in length, and the width is 30 feet. The dredge draws 7 feet of water, dredges to a depth of over 50 feet, and by means of an elevator, with which nearly all modern dredges in New Zealand are fitted, stacks the tailings to a height of over 70 feet. In New Zealand about 250 dredges are working at the present time, and about 2,000 men are directly employed in the business of dredging for gold, to say nothing of such supernumerary dependants, as coal carriers, dredge builders and repairers. When it is mentioned that a modern dredge costs (in New Zealand) from $40,000 to $75,000, an idea will be given of the importance of this branch of gold-mining.

Before a dredging claim is definitely taken up, there are many things to be done, and considerable expense to be incurred in foreign countries, much the same as at home. When the existence of paying gold has been determined, a systematic prospect should be made. By means of such devices as the percussive drill, a series of bore holes is usually sunk in the adjoining river bank. By these bore holes are discovered the depth of "overburden," as the top soil is called, the depth of gravel below the overburden, its richness—ascertained by panning the earth thrown up by a drill—and the average depth at which bed rock is met. Rich patches or flats have probably formed along the bank which will give good results, yet alluvial gold is such an elusive quantity that a dredge which shaves the bank in order to prospect it while working a river bed will often miss the rich streak that exists only a few feet inland. In tropical countries there is also a considerable amount of clearing to be done, as the jungle grows in great profusion right down to and overlapping the water's edge.

While actually working, the difficulties that are met with are sometimes enough to take all the ambition out of a conscientious dredgemaster. He has always to be on the lookout for hidden trunks of trees, huge logs, boulders, and other obstructions which, if dredged carelessly, would break his bucket ladder and probably put his dredge out of commission for some time. Again, there is always a great strain upon machinery which works a stable object, but which has not itself got a stable foundation. Bucket links are liable to give way, and drop out; steel bushes wear with extraordinary rapidity, and the engines themselves are always being subjected to sudden jerks and strains.

In New Zealand, a crew of eight white men can work a dredge, and the ratio of accidents is small; but in a country like West Africa, where costs of working are high and the white crew as a rule consists of only four men—a dredgemaster and three winchmen—natives have to be relied upon as greasers and firemen, with the result that, where the white man is unable to supervise everything, the bearings often become heated, the boilers have either too much or too little steam in them, and expensive accidents are not uncommon.

One of the greatest problems with which the dredging industry has up to now been confronted in New Zealand is involved in the dredging of agricultural land. In our own country this problem does not trouble us at all, and is not likely to do so for the next half century or more. Some authorities consider that it is practically impossible to redeposit top soil on top of dredged gravel in sufficient thickness to make the land available for agricultural purposes almost immediately. At present all tested methods seem impracticable. Nature forms, inscrutably and slowly, and by means of many contributory conditions a combination of soils which we call "fertile," and if we violently upset and destroy that combination, nature's ideals cannot be attained again in a few weeks or months. A New Zealand firm, named George, of Naikaka, has used a contrivance by which the top soil is separated from the gravel and, after passing through a long extra chute, is redeposited on top of the gravel. This plan has its advantages, but some time must, nevertheless, elapse before the land regains anything like its original value; and although in our country the mineral wealth may be much greater than the agricultural value of the land in which gold is found, in New Zealand the permanent wealth, represented by fertile agricultural land, will always be greater and more important than the value of any mineral which may be extracted from it.

Cobalt Silver Veins

Why should the calcite veins of the Cobalt, Ontario, silver district continue with depth is a question which has been asked by more than one person. The answer involves a comparison with known ore deposits in similar rocks, and simple deductive reasoning. The veins are in Huronian rocks, which were formed at a time when organic matter was very scarce, if there was any at all; and when veins occur in such rocks they are nearly perpendicular, because of the rocks being hard, and naturally the earth movements that caused such fissures must have originated at great depths. It is evident, from the lakes and other known geological signs, that the present rocks were covered by rocks of a later period, which in all probability were Cambrian limestones. It is evident that the diabase eruptions occurred while the Cambrian rocks were in place. This would also indicate that the fissures originated at great depth and that the rocks must have hardened previous to the fissuring, otherwise there is no way of accounting for the calcite in these veins, because it must have been deposited prior to the glacial erosion which followed long after the diabase was erupted. The diabase in the immediate vicinity of the Cobalt silver-calcite veins is a deep-seated aqueo-igneous magma which, when ejected, undoubtedly was accompanied by magmatic solutions that in all probability carried silver. Bearing in mind that this rock material carries no carbonates, it seems plausible to assume that the ejection of the diabase occurred after the Cambrian rocks had formed and prior to their erosion. If this hypothetical reasoning is correct then the ascending waters carried the metallic solutions and the descending waters the carbonated solutions, which, on meeting, caused the precipitation of silver and calcium carbonate, or calcite. There is, of course, no method of determining to what extent the present Cobalt veins have been shortened by erosion, but it would appear from their age that they should go to considerable depth.

Attention is directed to the fact that where metals are found carbon in some form is also found. Gold is found in the metallic state that is practically free from impurities in only those positions where carbon in solutions, either in place or descending from the surface, has been able to reach it; copper is another example, so also may be included silver.

National First-Aid Field Day

The Federal Bureau of Mines has decided to hold a first-aid meet at Pittsburg, Pa., in the Fall. First-aid teams will be sent to participate in the events by the various mining companies in the North, East, South, and West. While there will be no competitive events between the different teams, there will be exhibitions of their skill in bringing injured from the mines and furnishing first aid to the injured. The Bureau of Mines will have the cooperation of the Northwestern Improvement Co., Colorado Fuel and Iron Co., Tennessee Coal and Iron Co., the large anthracite mining companies, the Pittsburg Coal Operators' Association, and the American Red Cross. It is expected that between 20,000 and 30,000 miners will attend, and that there will be a parade, as the United Mine Workers are interested in the event and have signified their willingness to assist. The members of each team taking part in the events will be awarded a medal and each miner in the parade will be given a badge as a memento of the occasion. President Taft and Secretary of the Interior Fisher have promised to be present.

In addition to the first-aid teams, the miners will witness gas and coal-dust explosions in miniature, which will be staged in the great explosive gallery of the Bureau of Mines. In Arsenal Park there will also be a temporary gallery that will resemble a coal mine. This will be placed at the bottom of a natural amphitheater, giving a clear view to thousands. There will be a gas explosion in this play mine, miners will be entombed, and some of the Government Rescue Corps in oxygen helmets and rescue apparatus will enter and save them.

A number of spectacular events illustrating the danger from roof falls, blown-out shots, misfires, accidents due to cars and electric currents, carrying the injured after first-aid treatment over roof falls, over loaded cars in a narrow passage and placing them in an ambulance. At this writing it has not been definitely decided whether the exercises will be held in the Pittsburg base-ball grounds or in the Arsenal grounds. The former would seem preferable if it could be obtained as it offers better observation facilities.

The Ely Mining District, Nevada

Location and Railroads. Company Combinations. Method of Mining and Handling the Ores

*By Percy E. Barbour**

Ely is located in White Pine County about 140 miles south of the main line of the Southern Pacific Railroad and about 30 miles east of the Nevada-Utah state line. Connecting Ely with Cobre on the Southern Pacific, is the Nevada Northern Railroad running in almost a straight line through Steptoe Valley, which is broad and flat and bordered on both sides by parallel mountain ranges. A standard Pullman sleeper on the regular daily train each way affords comfortable and convenient traveling. The trip from Ely to Salt Lake City requires about 11 hours. The Nevada Northern Railroad is owned exclusively by the Nevada Consolidated Copper Co.

Ely and its suburban towns of various names cause much confusion to one who has never visited the district. En route from Cobre over the Nevada Northern, the town of McGill, where is located the concentrator and smelter, is passed on the opposite side of the valley, about 14 miles from Ely. At a small station, McGill Junction, a couple of miles farther on, connection is made with a spur running to McGill. At the Junction is a settlement called Smelterville which contains some of the overflow population from McGill. Just before Ely is reached is the town of East Ely, a more recent growth than Ely, with more space to grow and more pretentious buildings and streets and the location of the main offices of the Nevada Northern Railroad. Ely is situated in a slight hollow at the very mouth of Robinson cañon, and is the business center of the whole district, and has ample and very satisfactory hotel accommodations. The streets are wide and graded, the sidewalks are cement and there are costly buildings, some having cost from $80,000 to $100,000.

The population of the entire Ely district is between 8,000 and 10,000. The monthly pay roll of the district amounts to about $300,000. Ely has two national banks, the usual quota of saloons, a red-light district shut off from the town by a high board fence, and some unusually good retail stores.

Ely, as a mining camp, has been known for over 40 years. In the early 60's there was a silver excitement in Hamilton, some 50 miles away. Many prospectors drifted from there into Robinson cañon in search of gold and silver. Considerable low-grade gold ore was found and cyaniding was subsequently applied to the treatment of them but with poor success owing to the considerable amounts of copper contained. As late as 1902 the Chainman mine erected a cyanide mill and added another failure to those of the past 30 years. Up to that time Ely was considered a gold camp. The low-grade copper ores were discovered in the meantime, although of course their enormous extent was not realized until within the last 10 years. Bradley, Requa, and McKenzie, developed the properties which were finally combined into the Nevada Consolidated. They put up an experimental mill and demonstrated the commercial feasibility of concentrating this very low-grade sulphide ore. So carefully were their experiments carried out that the 8,000-ton concentrator at McGill now uses practically the same flow sheet. In 1904, J. Parke Channing made his classic report on these properties and their capabilities. The Guggenheims then bought a stock control and the active development of this now famous low-grade porphyry copper camp was begun.

The present mining activity is up Robinson cañon, about 7 miles from the town of Ely. Frequent passenger trains from Ely to Veteran give very good accommodations for all interests. Up the cañon about 3 miles is Lane City with two old mills, both now idle. Just beyond Lane is the relic of the old Keystone smelter with its old-style rotary drier and elephant boiler and hot-blast water-jacket furnace, mute evidence of earlier struggles. Farther along is Junction City, a name rather than a community, but Star Pointer, the next station, is the location of the Star Pointer shaft, with its fine steel head-frame, which is to be the main outlet for the ores of the Ruth mine and the deep mining of the Nevada Consolidated on the eastern portion of its estate. A mile to the north is Copper Flat, the scene of the Nevada Consolidated steam-shovel operations, and the center of the present greatest activity in the camp. Beyond in the broad flat is Rieptown, a quiet sunny residence town for miners, removed from the dirt and bustle of the work. A short distance farther west is Kimberly, the town of the Giroux company with its old smelter and mill, and a mile farther at the terminus of this railroad is the town of Veteran and the Veteran shaft of the Cumberland-Ely mine.

Since early in the fall of 1909 the Ely district has witnessed increasing activity and increasingly important developments. In August, 1909, the Cumberland-Ely mine was forced to suspend operations due to a miners' strike. Four hundred idle miners were thrown upon the district but were almost immediately absorbed by the other operating properties and no trouble ensued. The Cumberland-Ely owned a two-fifths interest in the concentrator and smelter at McGill. This shutdown allowed the Nevada Consolidated, the coowners of the plant, to greatly increase its output and shortly thereafter it absorbed the Cumberland-Ely property by an exchange of shares on the basis of 3¼ shares of the latter for one of the former. Under the new ownership the Cumberland-Ely has never been reopened. Some underground development work has been continued but the large tonnage already blocked out will await additional reduction facilities at the McGill plants. The Veteran shaft is 1,700 feet deep and is well equipped.

The Ruth mine, the mine that made the district, is developed quite extensively and has a large tonnage of ore ready for caving which is the system to be employed in mining. A new shaft, the Star Pointer, was sunk and connected with the old Ruth workings and will be the main outlet for the mine when shipments from it begin. The shaft is more conveniently located on the railroad and is well equipped to handle 2,000 tons of ore per day. A drift from this shaft has been run under the old Ruth dump, which contains a large tonnage of commercial ore, to which an upraise has been driven and this ore by these workings will be transferred to and raised through the Star Pointer shaft.

The present total tonnage produced by the Nevada Consolidated amounts to between 7,000 and 8,000 tons per day and comes almost wholly from the steam-shovel pits which now cover about 35 acres and have a maximum depth of 185 feet. Five steam shovels are working here stripping overburden and mining ore. Three of these machines have 5-yard dippers, one has a 3½-yard dipper and one has a 3-yard dipper. The first four are 95-ton and the last a 70-ton shovel.*

Churn drills are used for both prospecting and blasting holes. The cost of churn drilling here varies greatly at different holes, but at one mine averaged $1.87 per foot. Depending upon conditions, 25 to 120 feet are drilled per 24 hours. When prospecting the ore, drill holes are put down at the corners of 100-feet squares and samples of the bore are taken every 5 feet.

The overburden removed by the steam shovels is loaded into Oliver contractor-type dump cars of 12-cubic-yards capacity, which weigh empty 28,000 pounds each. These are hauled in trains to other portions of the property whose surface is used for a dumping ground.

The ore is hauled to the reduction works 20 miles up the valley in trains of 20 cars each. The latest ore car is of the Inglesby type, which with a load limit of 120,000 pounds, weighs only 37,800 pounds. Five of these cars are loaded in 12 minutes by the steam shovels. although the total average time consumed is very much greater owing to the unavoidable lost time

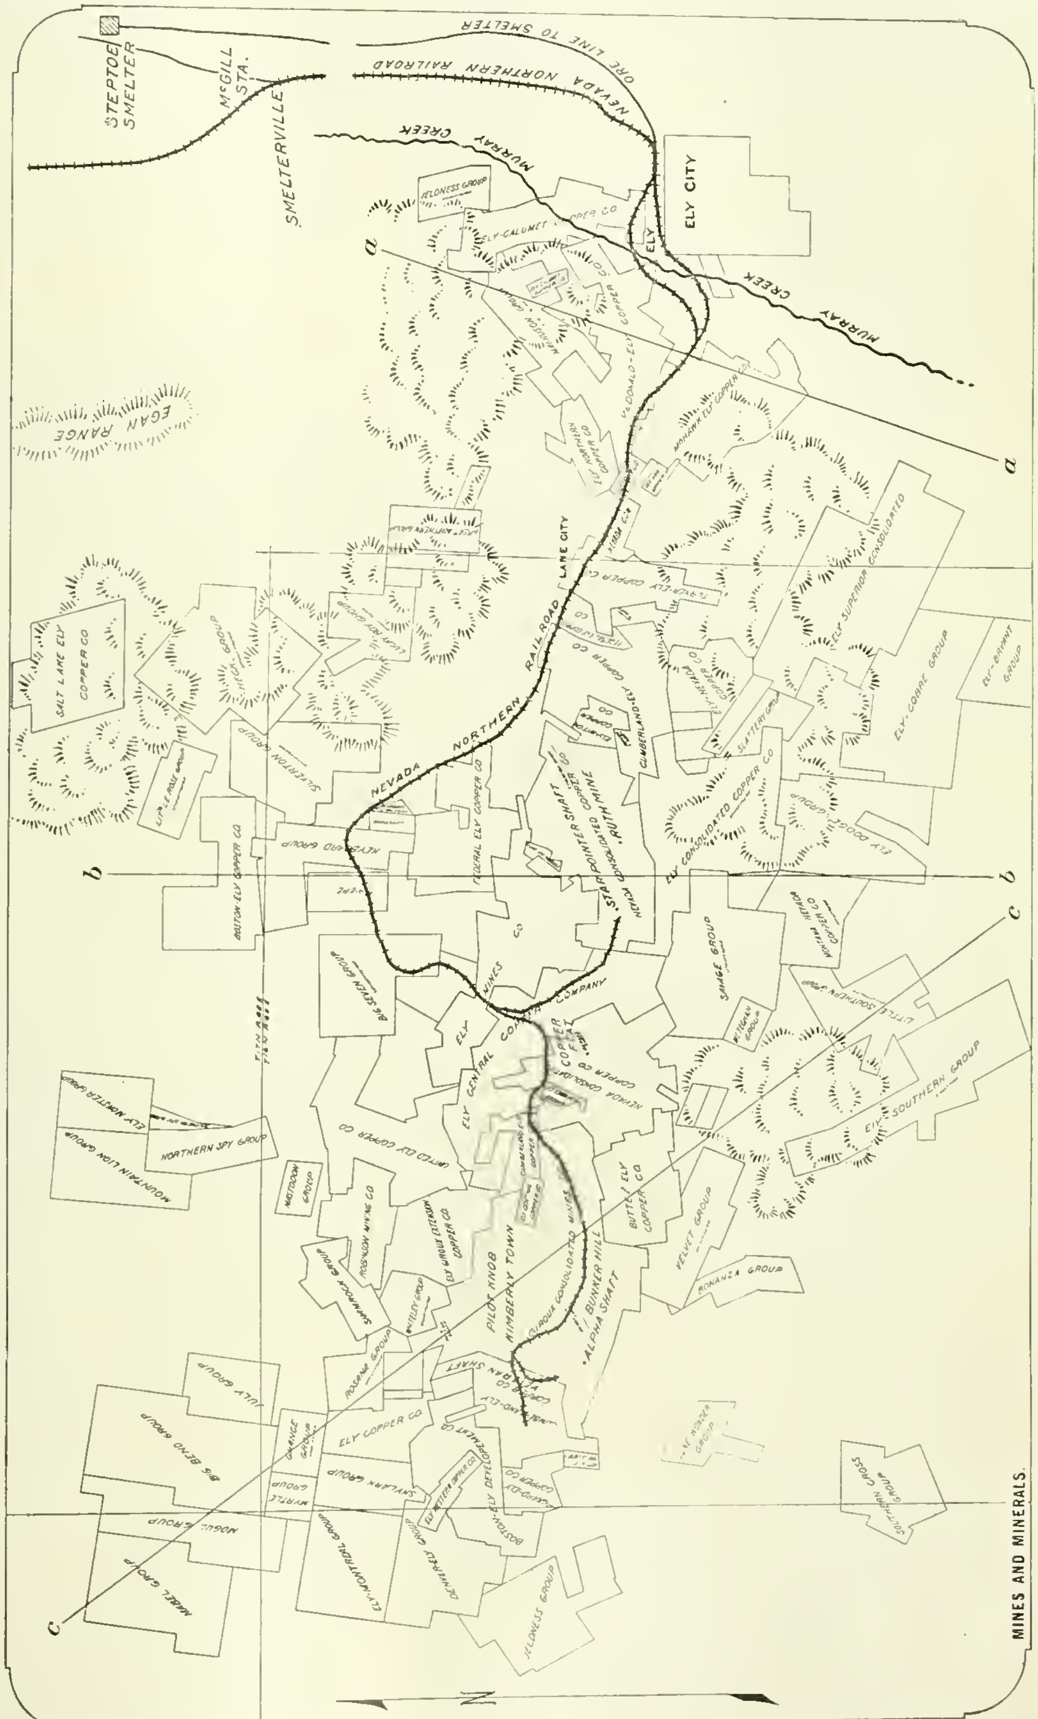
* Consulting Mining Engineer, Tecoma, Nev.

* Since this was written two more steam shovels have been added, making seven in all. Four are removing overburden, two are mining ore and the seventh is held in reserve.

required in switching and handling the empties and the loads. The grade of the ore road averages about 1.4 per cent. with a maximum of 3 per cent. but only empties are hauled against the grade. From the mine to the smelter the locomotives use no steam.

For the company's fiscal year ending September 30, 1910, the Nevada Consolidated mined and treated 2,236,434 tons of ore which averaged 2.06 per cent. copper. The Utah Copper, at Bingham, mined and treated 4,340,245 tons of an average grade of 1.54 per cent. The overburden stripped and disposed of amounted to 1,163,069 cubic yards, plus 329,346 cubic yards removed for approach work, making a total of 1,492,415 cubic yards. The total stripping cost was 40.6 cents per yard, equivalent to 15 cents per ton of ore. The mining costs were 15.4 cents per ton. The total cost of mining including every expense, stripping, taxes, eastern office expense, etc., amounted to 30.4 cents per ton of ore. The Nevada Consolidated has now blocked out 40,360,000 tons of ore which averages 1.7 per cent. copper, besides proven ore reserves of 18,000,000 tons averaging 1.25 per cent. copper. The initial dividend was paid late in 1909 and dividends at the rate of $3,000,000 or $4,000,000 per year are assured for years to come.

Although the Nevada Consolidated is now the only large producer in Ely, the Giroux is expected to be soon a large factor in the output of the camp. The Giroux is controlled by the Cole-Ryan interests. This mine though extensively developed has never been a producer except on a sufficient scale to furnish ore for its experimental mill at Kimberly. A small smelter was also erected here but the building burned down before the single blast furnace was blown in and it is now wholly unsuited in size, in type, and in location for present needs. A 2,000-ton concentrator and smelter are in contemplation. Water for this experimental plant was obtained from the 1,000-foot level of the company's Alpha shaft, and was ample for the purpose. Underground development and churn



Map of Ely and Vicinity

drilling from the surface have been carried on aggressively with continuously satisfactory results. In the Alpha shaft, where the remarkable feat was accomplished of rescuing alive two entombed miners after 45 days burial, water was encountered below the 1,000-foot level, which increased at the 1,200-foot level beyond the capacity of the pumps, and the workings below the 1,000 were drowned. A westerly drift about 1,000 feet long was run to a point chosen for a new shaft, the Giroux, and sinking and raising were carried on until the connection was made. This shaft, 12 ft. × 19 ft. 6 in. with five compartments, was then timbered with regular shaft sets to replace the temporary timbering used in driving. The timber purchased for this shaft amounted to about 750,000 board feet. Two 600-gallon steam-driven mine pumps handle the water through extra heavy steel pipe columns with solid steel forged flanges. The Giroux has a total development of 9,620,000 tons which average 1.9 per cent. copper.

The Butte-Ely group had been acquired by the Giroux before the advent of the Cole-Ryan interests.

The Ely-Amalgamated, owning property which adjoins the McGill smelter site on the east and extending over the mountain ridge into what has always been referred to as Duck Creek district, has been acquired by Salt Lake interests, including Keith and Kearns of the Silver-King and Jesse Knight of Provo, and extensive work on the lead-silver deposits has been done.

The Boston-Ely has a deep shaft driven in the limestone to cut the Ely porphyry below. The shaft is about 1,500 feet deep.

A considerable amount of leasing has been going on in the camp for a long time. Now there are nearly 200 men thus engaged, principally on lead-silver ores. The Elijah lease has been operated off and on for 30 years.

The reduction works at McGill, including both the concentrator and the smelter, are known as the Steptoe Valley plants and are owned by the Steptoe Valley Smelting and Mining Co. This company is now owned in toto by the Nevada Consolidated. The concentrator was originally designed for less than 6,000 tons per day but recent additions of various improvements have largely increased its capacity until now it is treating over 8,000 tons per day. The ore is crushed by rolls and Chilean mills and is concentrated on Wilfley tables and Frue vanners. The concentrates are dewatered in steel tanks and are then loaded into trains of cars, running underneath the tanks, by means of Blaisdell excavators. Milling costs 55 cents per ton of ore. The ratio of concentration is 10.6 and the recovery is 69.5 per cent. There are employed in and about the mill about 300 men, millmen and laborers. Millmen receive $3 and laborers $2 per 8-hour shift.

The smelter has five reverberatory furnaces 112 ft. × 19 ft., each of which has two 400-horsepower waste-heat boilers in parallel at the front or skim end. The reverberatory ash is used in the power-house boiler plant, being fed to the furnaces of the water-tube boilers by automatic stokers and burned by means of mechanically induced draft. There is one water-jacket blast furnace for smelting ladle skulls, etc. The roaster plant consists of 16 McDougall furnaces. The converter plant has four stands of converters and three casting machines admirably arranged for the work in hand. The matte regularly converted is about 40 per cent.

During the last fiscal year the Steptoe plants produced 60,513,009 pounds of refined copper. For the last quarter of the year the total cost of producing copper was 6.8 cents per pound and for the whole year the cost averaged 7.05 cents.

Ely is to be served by more railroads. About 20 miles south of Cobre and 120 miles north of Ely the Western Pacific crosses the Nevada Northern at Shafter. While this road does not go into Ely, it gives the camp another outlet and makes it independent of the Southern Pacific, on which it was formerly wholly dependent. The Ely-Goldfield road will connect Ely through the Tonopah and Goldfield and the Tonopah and Tidewater roads with the Santa Fe, and thus afford it an outlet to Los Angeles and give it the advantage of the water rates to the coast. This road will cross the Giroux property between the Alpha and Giroux shafts. A new road east from Ely running through the Deep Creek country on the western border of Utah to Tooele, Utah, is now being rather aggressively boosted. This road would serve the double purpose of opening up the Deep Creek country, which of itself has never been able to gather momentum enough to get the road, though it has a very large-tonnage of ore in sight, and of affording an outlet for the Ely ores, especially the Giroux, to the International smelter at Tooele. Ely is therefore in a very comfortable position regarding transportation facilities whereas only five years ago the stage and the ubiquitous burro were the only means of transport.

The Post Office After Mine Frauds

Walter P. Edris, postmaster of Spokane, has received a fraud order issued by the Post-Office Department, effective at once, against C. E. Mitchell, a promoter, convicted in the federal court there last May on the charge of using the United States mails in furthering certain worthless mining properties. It also is specified that money orders received prior to June 12 must not be cashed but taken up, if presented for collection, and the money r funded to the senders. The order 's against the following: C. E. Mitchell, Spokane, Wash.; The C. E. Mitchell Co., Box 2234, Spokane; Blue Bell Belcher Mining Co., successor to the Coeur d'Alene Eagle Mining Co., Spokane; Snowstorm Deep Mines, Ltd., successor to the East Snowstorm Mining Co., Spokane; Coeur d'Alene Reliance Mining Co., Spokane; Lee-Jumbo Mining Co., Spokane; Montana Mining Co., Spokane; Montana Mammoth Mining Co., Thompson, Mont.; C. E. Mitchell, president Montana Mammoth Mining Co., Thompson, Mont.; J. R. Kemp, agent Mitchell Mining Operations of Spokane, E. 11 Lexington Street, Box 3, Baltimore, Md. All offices and agents of any of these companies, wherever located.

Mitchell was convicted following a sensational trial on an indictment returned by a federal grand jury, charging him with fraudulent use of the mails in promoting worthless mining enterprises. The trial consumed 10 days and was expedited by agreement of counsel whereby an innumerable mass of correspondence was not read to the jury, but was sent with the jury to its room.

United States Attorney Oscar Cain, who handled the case, announces that the conviction was secured at an expense to the government of about $15,000. Thousands of letters written by Mitchell to prospective customers had been gathered and from this mass of correspondence and more than 50 witnesses from various parts of the United States, the district attorney was enabled to make out a convincing case.

The dramatic moment of the trial came at the conclusion of the government's case, when a letter from Mitchell to one of his agents was read, in which Mitchell said: "For years I have been known as the king-pin grafter of the Spokane country." A conviction was secured in less than two hours.

Valuable deposits of gypsum, in Nova Scotia, are mentioned in a recent United States Consular Report. The exposures are said to show beds of from a few feet to hundreds of feet in thickness, ranging in color from gray to snow white and frequently of the best quality. Some of the deposits have been operated for nearly a century, but during all that time only two mills have been established for the manufacture of gypsum products, one at Windsor, in 1901, and the other at Cheticamp, Cape Breton, in 1908. In 1908, about 300,000 tons of gypsum were produced in Nova Scotia, while in 1910 the production amounted to 322,974 tons. Practically all this was shipped to foreign countries, $290,949 worth being sent to the United States and there manufactured into different products.

Mines and Minerals

Vol. XXXII—No. 2. SCRANTON, PA.—SEPTEMBER, 1911—DENVER, COLO. Price, 25 Cents

PUBLISHED MONTHLY AT SCRANTON, PA.

ESTABLISHED 1881

WESTERN EDITORIAL OFFICE: 728 Equitable Building, Denver, Colo.

Single Copies....................25 cents
Yearly Subscriptions, including postage:
To United States, Mexico, Cuba, Porto Rico, Hawaii, and Philippines. $2.00
To Canada.................... 2.50
To all other countries.................... 3.00

The date after your name on the wrapper is that of the month to which your subscription has been paid. If you do not want to continue your subscription after that time, kindly notify us.

Notice to discontinue or change of address should be sent to the Scranton office.

When notifying us of a change of address always give your FORMER as well as your present.

TABLE OF CONTENTS

Electric Mine Lamps

THAT progressive American mine managers are alive to the advantages of better and safer lights for miners is evidenced by the fact that in this issue we publish two illustrated articles on the development of electric mine lamps, one being based on the experiments and developments worked out by the Philadelphia & Reading Coal and Iron Co. in Pennsylvania, and the other by the officials of the Cedar Hill Coal and Coke Co., of Colorado.

In neither instance did the men who produced the practical lamps described in the articles know what the others were doing, and the descriptive articles were written by different authors who had no knowledge that they were preparing articles on similar lines.

In addition, the Buffalo and Pittsburg Coal Co. are giving the Pilley electric mine lamp a thorough test under actual working conditions at the Marianna mine in Western Pennsylvania.

Revival of Gold Mining

INDICATIONS all point to a healthy revival of gold mining; not that there has been a cessation of work at the prominent producers, but because so many old mines are starting up throughout the West.

At this writing there is not so great need of cautioning investors against the wiles of fake promoters, owing to several states exposing and the Federal Government prosecuting them, nevertheless there are a number of important matters which investors in gold mines should understand. There are a few gold deposits discovered at long intervals which make poor men rich, and when they are found the owners do not ask outside assistance. The majority of deposits are low grade and require large sums of money in order to work them successfully, because large mills must be erected to concentrate or treat the ore. Since there must be a large tonnage worked to make such mines pay, the proposition is unsuited to companies of small real cash investments. The Homestake, the Alaska-Treadwell, and the South African gold mines belong to this class.

Those gold mines which are a mean between the small bonanza and the large low-grade deposits usually contain partly high grade and partly milling ore, such as some of the Goldfields and Tonopah, Nev., mines are working to advantage. Nearly every patriot and some who are not patriots take a dip in gold mining during their career, mostly, however, in a speculative way after consulting the man with the big diamond in his tie, who whets their cupidity with tales of Blue Birds, Independences, Goldfield Consolidateds, etc.

No one should invest in a stranger's mine without verifying the tale by an engineer who is either personally known, or vouched for by another well-known mining engineer.

During the early days of mining in this country many good gold and silver properties were located where $100 and $200 ore could not be made to pay. Many other good prospects became failures through insufficient capital and lack of knowledge regarding the recovery of gold and silver. These properties are being picked up and worked in an intelligent manner; and, owing to better transportation facilities and modern metallurgical methods, are paying. The investor should also understand that gold veins and coal beds are as dissimilar in formation as the two minerals themselves, and therefore if he cannot invest in prospects on the vein it is policy not to invest at all in that particular district. Before a man can apply for a claim he must uncover a vein, if he does not and tries to raise money to work the claim, he is a fraud.

An Historic Mine

On page 89 of this issue we present one of the most important contributions of recent years to the history of American coal mining.

In this article the date of the first watering of coal dust in mines of the United States is set five years earlier than the date given by Mr. George S. Rice of the U. S. Bureau of Mines. In Bulletin No. 425 of the U. S. Geological Survey Mr. Rice says, "in the United States the system of watering by hose and nozzle has been employed in the coal mines of Utah since the Scofield disaster of May 1, 1900," and he gives that date as being the time of the first use of water in laying the dust in American mines.

To Mr. Joseph Watson, then superintendent of Como No. 5 mine, at Como, Park County, Colo., and now general superintendent of the National Fuel Co., at Louisville, Colo., must be given the credit of having adopted this system 5 years earlier than the date set by Mr. Rice; viz., in May, 1895. It also seems probable that to Mr. Watson is due the further credit of having first employed shot firers in the mines of our country.

If any of our readers are advised of an earlier date than May, 1895, on which watering of dust was practiced or shot firers were employed in American mines we shall be glad to hear from them.

In the August issue of Mines and Minerals there was an article on "Coal Mining in Arkansas," by A. A. Steel, Professor of Mining in the University of Arkansas. This was selected from a description of "Arkansas Coal-Mining Methods," published by the Arkansas Geological Survey for the information of persons unfamiliar with coal mining and as an introduction to a technical report. Considerable interest is being manifested in Arkansas coal, since outside of Pennsylvania and possibly Colorado the state contains the largest deposit of semi-anthracite so far discovered in the United States. While the bed is not thick it is favorably situated for transportation and there is no appreciable loss of fine coal, the culm finding a ready market at the Kansas-Missouri zinc smelters. The Arkansas coal fields stand in a class by themselves, and the description of them, which will be furnished later, will be of interest to coal men generally.

Our Cover Picture

The largest mining enterprise in Mexico is that of the Green–Cananea Copper Co., part of which is shown on our front cover. In the foreground to the left is the sampling mill; to the rear of this is the large reverberatory smelter 100 feet long by 19 feet wide, which uses oil for fuel and raises steam with the waste heat. In the center-right foreground is the ore-bedding and mixing plant; to the right rear of this is shown part of the fume chamber. In the left background is shown the power house covering the blowing apparatus, and in the right background are the furnaces.

The promoter in chief of this enterprise, Col. W. C. Green, died recently from injuries received in a runaway.

Electric Machinery for Mining

W. A. Thomas, engineer for the Westinghouse Electric Co., writes as follows:

In the matter of power there is a notable tendency to the development of central energy plants at mining operations, instances being the plant of the Consolidation Coal Co. at Van Lear, Ky., with turbogenerators, condensers, and substation equipment; the Clinchfield Coal Corporation at Dante, Va., with the development of a 2,000-kilowatt plant and four substations. These show that coal-mine officials appreciate that the value of fuel is what it can be marketed for.

The Homestake Mining Co., at Lead, S. Dak., is just completing a 6,000-kilowatt hydroelectric installation by diverting the Spearfish River through 25,000 feet of rock tunnels to a cañon, thus securing about 400 feet head for the development of waterpower to generate electricity that will be transmitted approximately 15 miles to gold-mining operations.

The application of electricity to pumping has made remarkable advances in mining operations, installations of importance being that of the Ward Shaft Association in the old Comstock mines at Virginia City, Nev., consisting of four 250-horsepower completely enclosed motors with forced ventilation by driving air first through cooling coils, then through the motors and again through the cooling coils, the water pumped being at a temperature of approximately 175° F. 2,500 feet below the surface of the ground, and the water for the cooling coils being taken from the surface at approximately 80° F.

An important improvement of the past year has been that of small, self-starting, direct-current motors for isolated pumping in and around coal mines. These motors are made with especially strong commutating facilities, so that they can be connected directly across the line without injury, the advantage being that starting devices are unnecessary and the pumps can be allowed to run constantly. In the event of the circuit being opened, no injury will develop when the power is again connected to the line with the motor on the circuit.

The past year has witnessed a number of installations of steel-frame mine locomotives. This construction reduces frame breakage, makes stronger locomotives and permits greater horsepower of electrical equipment on a given weight of engine.

COAL MINING AND PREPARATION

The Coaldale Head-House

A Plant for Separating Large Amounts of Rock and Preparing Anthracite for Market

The Lehigh Coal and Navigation Co. is the oldest of the anthracite companies and the first company to ship coal from Northeastern Pennsylvania. Its product in the market is known as Old Company's Lehigh. In the early days this company constructed the famous Mauch Chunk switchback which hauled the empty coal cars to the top of Mt. Pisgah over an incline and allowed them when loaded to run by gravity and to deal with unusual mining conditions in an unusual manner.

The Mammoth coal bed in this vicinity varies in thickness from 50 to 80 feet and is split by a bed of rock, which must be removed with the coal. To add to the difficulty of separation the bed is steep pitching, making it necessary to remove all material from the rooms, there being no place to stow gob, which probably averages 25 per cent. of the material hoisted to the dump. To avoid sending this rock through the breaker machinery, it was decided to eliminate the greater part of it as it came from the mine, and to this end an innovation in anthracite breaker practice was planned and a head-house erected. The head-house head-frame, and the pan conveyer run-

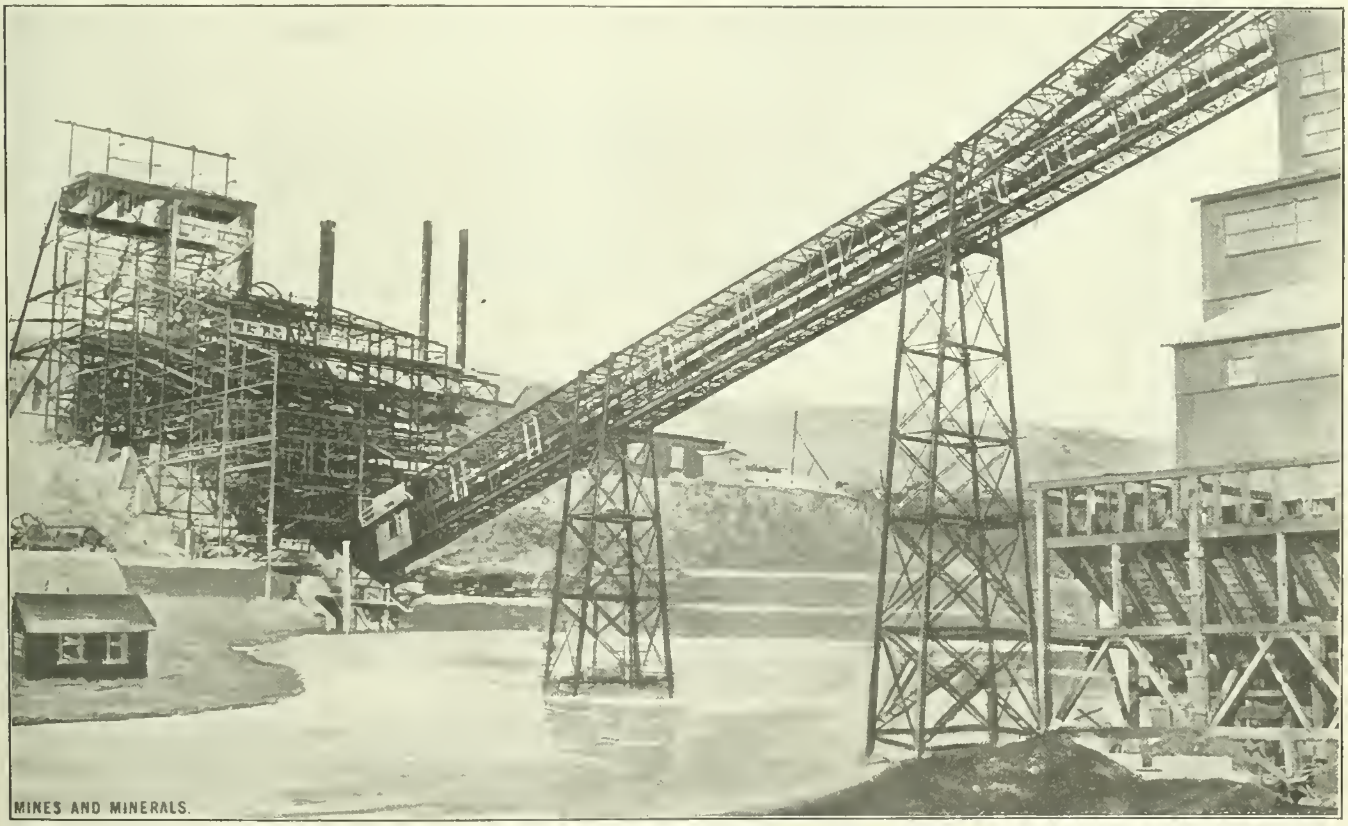

FIG. 1. HEAD-HOUSE, HEAD-FRAME AND CONVEYER AT COALDALE

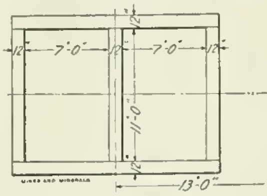
from Summit Hill to the Lehigh Canal. Afterwards they constructed a railroad. This, however, they leased to the Central Railroad of New Jersey and then shipped their coal over it. At the present time they are constructing another road over which they intend to ship their product to New England.

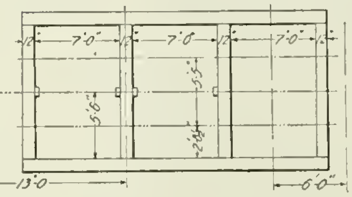
Because it is the oldest anthracite coal company, it does not follow that its management from the president down are in any way unprogressive; in fact being coal mining engineers of long experience they are able to see and take advantage of any improvement that will lessen the cost of operation. The headquarters of the operating department are at Lansford in Panther Creek Valley, and possibly three-quarters of a mile away are the Coaldale head-house and breaker, the subjects of this article. These are two separate structures planned to meet the requirements of the mine openings relative to the railroad, way shown in Fig. 1, was designed and erected by the Jeffrey Mfg. Co., of Columbus, Ohio. It is served by two shafts, No. 8 and No. 9, shown in Fig. 2 and is built so as to be in line with them. The No. 8 shaft has three compartments, two for hoisting coal and one for hoisting water in tanks, a system which has been adopted as more economical than pumping in the Schuylkill region where the depth is more than 500 feet.

On top of each water bucket there is a circular compartment which will hold five men and this is made use of by those who desire to enter or leave the mine during working hours, at the same time it leaves the cages free to hoist coal.

The two-compartment shaft known as No. 9 receives coal from three different directions from the deep workings, from the drift workings and from an opening across the valley. To accommodate the cars from the latter mines the two tunnels shown are directly under the shaft house. When cars are being hoisted from the mine others accumulate on the drift level which makes it necessary to hoist for a given time from each level. The change in rope length is made so quickly, that the only loss in time is that necessary to hoist the empty cages from the bottom to the tunnel landing.



Plan No. 9 Shaft



Plan No. 8 Shaft

All four cages are of the self-dumping type, known as the Jeffrey automatic drop-rail cages, the cars dumping their loads as they reach the top of the head-house without leaving the cages. The hoisting engines for the coal compartments are at right angles to those for the water compartment, and the drainage tunnel is below the drift level in shaft No. 8.

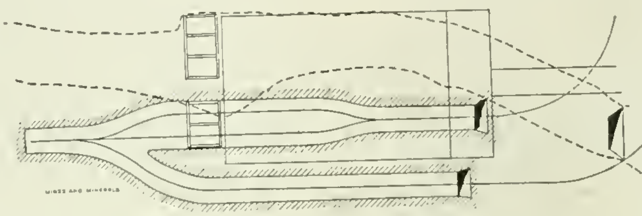


Fig. 2. Plan of Coaldale Plant

In Fig. 4 a plan of the head-house flow sheet is given. The cars discharge the coal on an inclined chute, having as its lower end a rotary feeder *a* which in revolving permits only a measured quantity to go on the platform screens *b*, thereby avoiding a rush with the attendant difficulties of flooding and poor rock picking. Just enough coal is measured out by the rotary feeders to allow a uniform quantity to pass on the shaking platform screen where it is riddled through 6-inch diameter round holes. That coal which passes through, not having been separated from refuse, is designated as dirty coal; that material which passes over is in large pieces, and after the rock is picked from it on the moving table it is termed clean coal. The dirty coal goes by gravity to the dirty-coal shaking screens *c* where anything above 3 inches in diameter is called steamboat coal and what passes through goes direct to the dirty-coal carrier *d* and by this is raised to the top of the breaker. The material that passes over the dirty-coal steamboat shakers is hand picked on the table *e* and then being comparatively clean coal is sent to the steamboat rolls *f*, where it is broken and sent down a chute to the clean-coal carrier *g*, which raises it from the bottom of the head-house to the top of the breaker 256 feet distant. The coal and rock which passes over the platform screen *b* in large pieces falls to the lump-coal picking table *h*, which is an endless belt that travels so slowly that men on each side of it have time to pull off the clean rock on one side, and the rock with coal frozen to it on the other side. The latter are separated by a pick and sent to their proper destination through holes in the floor. The rock chutes from the platform terminate at a point where a traveling belt running at right angles receives the rock and removes it to the rock bin. From this bin it goes by

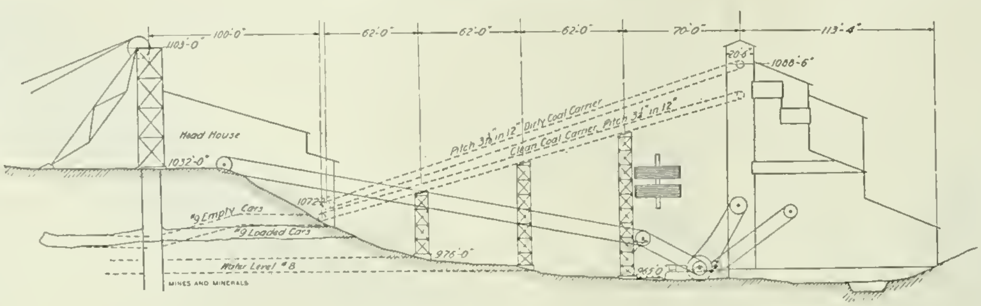

Fig. 3. Profile of Coaldale Plant

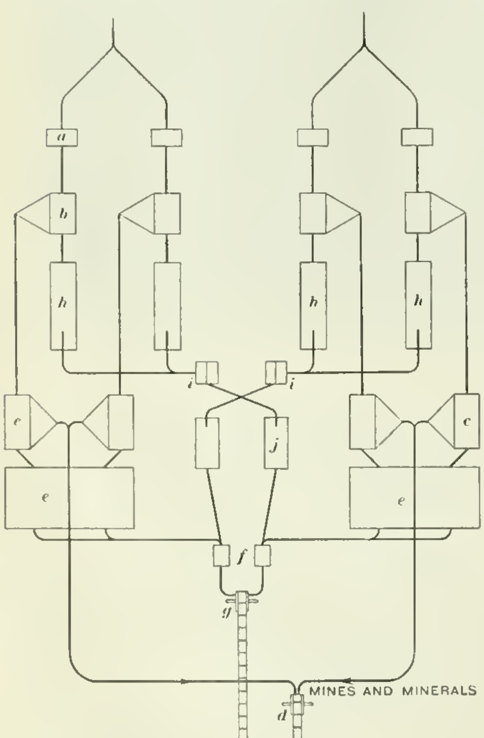

Fig. 4

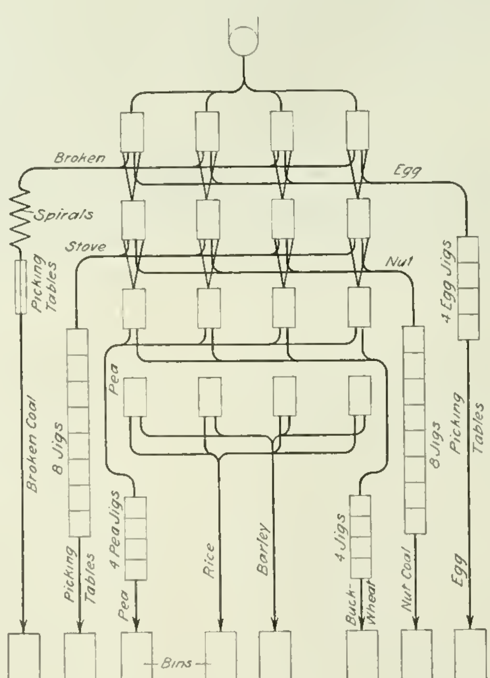

Fig. 5

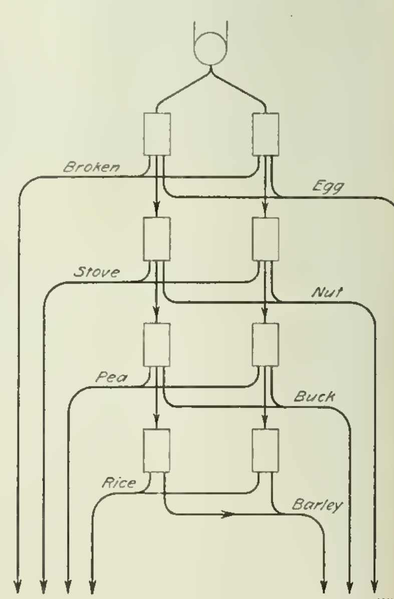

Fig. 6

car to the rock pile and is wasted. The quantity of rock thus handled soon makes an enormous pile, but, unlike many rock dumps in the anthracite fields, it is free from coal. The lump coal from the picking table goes to coarse rolls *i* where it is broken and passed on to the clean-coal steamboat shakers *j*. The clean coal passing through these screens goes direct to the clean-coal carrier *g*, while the coal going over the shakers goes to the steamboat rolls *f* and then to the clean-coal carrier *g*.

The saving in machinery and time by the use of this preliminary preparation is such that the Coaldale plant holds the record for coal treated in a single breaker in the Southern Coal Field, it amounting to 777,714 tons of market coal in 1910, the first year of its operation. The conveyer lines, which have been called carriers, raise the coal approximately 81 feet, or about 122 feet above the loading tracks at the breaker. The horizontal distance between sprocket wheel centers of the dirty-coal carrier is 256 feet, the pitch being $3\frac{3}{16}$ inches in 12 inches. The material delivered is sized into broken and egg coal, stove and nut coal, pea and buckwheat coal; and rice and barley coal by the wet process. The broken coal passes through spiral pickers which separate most of the impurities, then to picking tables and from them to the broken-coal bin. The egg coal passes over a screen having 2-inch meshes and through a $2\frac{3}{4}$-inch mesh and is jigged to separate it from impurities. After jigging it is hand picked before passing to its bin. The stove coal is treated in the same manner. The nut, pea, and buckwheat are jigged and passed to their respective bins, the wet separation being sufficient. Rice and barley sizes are not jigged. The flow sheet of the dirty-coal side of the breaker is shown in Fig. 5, and the clean-coal flow sheet in Fig. 6. It will be noticed in the latter instance that no other machinery but that necessary for sizing is needed, the coal having been thoroughly prepared in the head-house.

In Fig. 1 is shown the steel framework of the head-frame head-house and conveyer runway at the time of its completion. The head-house and runway were afterwards covered with corrugated metal siding, thus making the structures practically fireproof. In the runway there are steps the entire length of the pan and two sets of conveyers from the foot of the head-house to the top of the breaker. The dirty-coal conveyer is constructed with flat bottom pans 24 in.×36 in.; the clean-coal conveyer has similar pans 24 in.×24 in., both being open-top overlapping with sides extended. The dirty-coal conveyer has a capacity of 300 tons per hour; the clean-coal conveyer a capacity of 150 tons per hour when traveling at a speed of 90 feet per minute.

Those who attended the Glen Summit meeting of the American Institute of Mining Engineers were shown this plant, and were immediately interested in what appeared to be two breakers 250 feet apart connected by an inclined conveyer. Many of them, however, who were not versed in the peculiar conditions that suggested this method of treatment, failed to fully comprehend that the preparation of anthracite for market is a coarse concentration process which produces a product that compares with the best ore milling practice.

As an illustration of the progressiveness of this company it is stated that it was the first to erect a briquet plant for anthracite. The readers of Mines and Minerals are indebted to Manager Baird Snyder, Jr., Mechanical Superintendent C. A. Straw, and their assistants for the information incorporated in this paper.

Coal Industry of Nova Scotia

The value of the output of coal from the 16 mines operating in Nova Scotia in 1910 is given by United States Consul at Halifax as $15,675,000, against $14,200,000 in 1909. In these mines 14,000 persons were employed, not including those on the railways and steamships engaged in transporting the output.

The fleet regularly employed for the carriage of coal, ore, and limestone consists of 26 steamers, of a total of 135,000 tons, in addition to two seagoing tugs and a number of barges and lighters.

The total annual disbursement for wages at Sydney and vicinity is $15,000,000. Coal to the value of $368,146 was shipped to the United States during 1910.

National Mine Safety Demonstration

Arrangements have been definitely perfected for the first National Mine Safety Demonstration, to be held in Forbes Field, Pittsburg, Pa., October 27. This will be conducted under the auspices of the Bureau of Mines and the Pittsburg Coal Operators' Association, with the cooperation of the American Red Cross. There will be souvenir programs, souvenir buttons, a military band, and public speakers, including President Taft, Secretary of the Interior Fisher, and Governor Tener, of Pennsylvania.

Trained first-aid teams from many of the important coal-mining centers in the United States have been invited to participate and a large attendance is anticipated.

In view of the fact that this is not a competition for prizes, but an exhibition in skill in administering first aid to persons injured in mines, and with a view to creating interest in instruction of this nature, it is hoped that the plan will appeal to all mine operators and that they will endeavor to interest as many mine workers as possible in this worthy movement.

The following are the program and rules:

1. Non-competitive exhibition of skill in first aid to the injured in mines, to be held in Forbes Field, Pittsburg, Pa., October 27, 9 a. m. to 1 p. m.

2. Not more than one team of five men to represent any one coal mine, or the United States Bureau of Mines, or state mine departments, provided that coal mining companies operating more than one mine may enter additional teams representative of groups of miners, helpers, trapper boys, or other mine workers.

3. All persons entering to submit certificates showing that they are, or have been, bonafide mine workers.

4. All entries to close 1 month prior to date finally selected for the meet.

5. Coal companies entering teams to be invited to present, not later than 1 month in advance of meet, a list of five events as their choice, these to be submitted to the managers, who will select five for adoption from the various events suggested, each entering team to exhibit in those events suggested by them, and such others of the five as they may elect. All teams to exhibit in unison.

6. Should any unusual or valuable events be suggested, the managers may increase the program by one or two such special stunts.

7. In addition to the five first-aid events there will be a representation of a coal-dust explosion, with rescue by helmet-men and first-aid treatment.

8. Exhibition of skill in adjusting and use of rescue apparatus by teams of four with a captain; entries to be as above for first-aid teams.

9. Exhibition in use of fire extinguishers upon a fire by members of the rescue crews.

10. Souvenir badges of the American Red Cross, souvenir buttons of the United States Bureau of Mines, and souvenir programs to be presented to individual entrants; a souvenir first-aid box to be presented to each team entering; a souvenir pennant with the name of the company sending entrant, and to be used on the field as a marker, to be presented to the company represented.

11. There will be introductory remarks by the Director of the Bureau of Mines and a member of the Executive Committee of the American Red Cross.

12. Presentation of souvenirs will be made at the close of the exercises in brief addresses by speakers of national repute.

Panel System of Longwall Mining

C. E. Krebs*

The mining methods generally used in West Virginia in mining coal have been the room-and-pillar system, which was probably adopted on account of its first low cost of development, and possibly also it was not expected to extract all the coal from the seam. This method has played havoc with many mines, and millions of tons of coal have been lost that can never be recovered because of its use, or rather misuse. Then, too, it is true that thick seams of coal were the first mined where this method of mining was peculiarly fitted, but the thickest seams are being worked out very rapidly, and thin seams of coal will have to be worked and at a minimum cost, so as to meet the competitive price of coal in the market.

To meet these demands the writer will briefly discuss a method of longwall mining, which he believes, if adopted, will add materially to the solution of the question of first cost, maximum recovery of the coal, and minimum loss of life and property and with greater safety to those so employed in its use.

We are told by mining men coming from Europe, that longwall mining has long been successfully used in the mines of those countries and that it is now successfully employed there, but it appears the system used by them was the retreating system of mining and not the advancing.

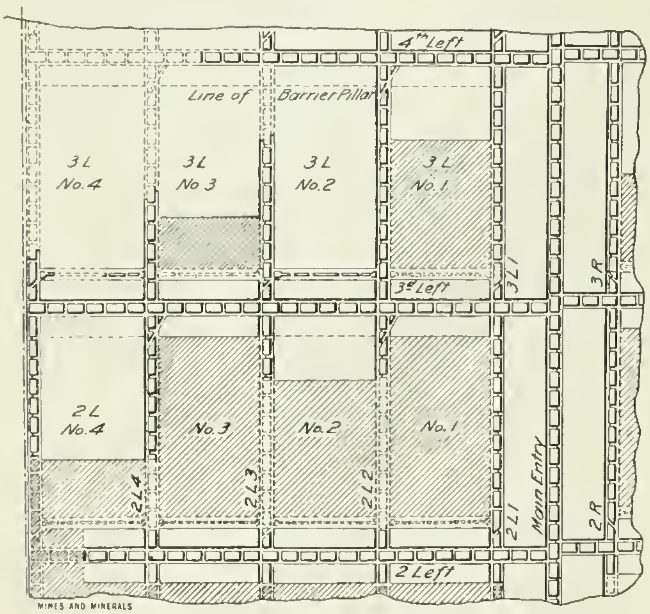

Fig. 1. Longwall Mining Worked Advancing

In order to use the retreating longwall system as it is generally done, it will be necessary first to drive the main entries to the boundary lines of the leasehold before any results can be obtained. This operation is very expensive and can only be done by the strongest and wealthiest companies. It also takes years of a small output to do this work, as only the entry coal is mined. This would naturally make very costly coal during the development.

The system as proposed to be used by the writer is a plan which has been designed by the firm of Clark & Krebs, civil and mining engineers, of Charleston, W. Va., about 2 years ago and a description of which, as given in Fig. 1, is as follows:

The mine can be laid off in a general way similar to that of an ordinary room-and-pillar working; that is, a two or three or even four main-entry system can be adopted, with cross-entries to the right and left, having overcasts for the splitting of the air, and directing the current into these right and left cross-entries.

These main entries can have from 20 to 50 feet of a pillar between them, and then be protected by a barrier pillar on each side of them of a width of 200 to 250 feet. The plan shown in Fig. 1 has a two-entry system with 50-foot pillars between the two entries, and a barrier pillar of 210 feet on each side of them. The cross entries are driven at intervals of 1,100 feet on the right and left.

The panel of coal to be mined will be a block of coal 480 ft. × 850 ft. These panels are worked alternately; that is, No. 1 block on second left is being worked by starting two rooms off *2 L 1* entry and connecting with two rooms of the *2 L 2* entry. When this connection is made between these entries the panel is then ready to begin longwall mining. While *2 L Block* No. 1 is being worked *2 L* Block No. 2 is not worked, but as soon as the *2 Left* entries are far enough then *2 L Block* No. 3 is worked. Thus, No. 2 Block is retained as a barrier pillar until Nos. 1 and 3 are worked out.

This system can be pursued along this course until the property line is reached.

When the No. 1 and No. 3 Block has been worked to the barrier pillar line then No. 2 Block can be worked. This block will have to be worked retreating, that is to say, the coal will have to be taken from the third left entry and hauled to the main entry.

The system can be worked on each side of the main entry, that is on the right and the left of same, as shown in Fig. 1.

Fig. 1 gives a general plan, but the measurement will have to be revised, and plan made to suit each individual seam as local conditions will govern to a certain extent.

When the longwall system is being actually worked, the face of the coal will have to be undercut to a depth of from 5 to 6 feet by a longwall mining machine, and this cut is cleaned out while the cutting proceeds. In order to keep the coal from falling down in a solid block, stays can be inserted from 5 to 10 feet apart. These stays can be made from timber from 4 inches to 6 inches thick and must be removed before the coal is shot down.

The track is laid along the face of the coal and about 8 feet from it. This will give ample room for the cutting of the coal, and when the cutting is done and before the blasting begins this track can be moved near the face of the coal. This track is connected on both ends to the track in the entries, and curved rails are so attached that it can be easily moved, having also short rails from 4 to 10 feet at each end so as to connect quickly.

Another important feature to be observed is the proper posting of the roof before blasting down the coal. At least three or more tiers of posts should be constantly kept set, but these will have to be regulated in different mines in accordance to the roof that is encountered. The main object is to hold the roof until the coal has been worked out enough in advance, and then to take out the posts behind so that the roof will be allowed to fall, and relieve the excessive weight. However, at least three rows of posts should be left set at one time.

The coal can be hauled with gathering motors, having drums with cables for attachment to trolley wires on the cross-entry or trolley wires can be placed on the roof and moved from time to time as the track is mined.

The system as proposed has the following prominent points in its favor:

It is an ideal one for ventilation, and is well adapted to carry out the state mining laws to the letter. It is beyond question that good pure air is necesssary for health and safety of a miner. By this system a current of pure air can be supplied along each working face, and the currents so split that only one panel need be supplied by the same current. It further complies with the mining laws, that less than 60 persons are on one split or current of air.

Each panel is worked independently of the others, and in case of accident it need not disturb the other workings.

* Assistant Geologist, Charleston, W. Va. Paper read before West Virginia Mining Institute.

Also each panel will be under the direct supervision of a competent and experienced mining man, possibly an assistant foreman, who remains in the working place during the working hours and thereby lessens the chance for dangerous practices among the miners. It will also be much safer in blasting down the coal since there will not be much danger of any blown-out shots. Furthermore, the blasting can be done at night if necessary, when the men are out of the mine.

This system concentrates the men, and tends to bring the cost price for day laborers, as track men, drivers, etc., to a minimum. This cost in some mines is enormous, while by this system it will be comparatively small. It also makes supervision easier, and in every way tends to lessen the work of the mine superintendent. It also lessens the cost of track material, such as ties and rails.

By this system the greatest production can be attained, since it is possible to get the greatest efficiency from the men, machinery, and material.

If this system is correctly operated, it will be possible to obtain more than 95 per cent. of the coal from the seam, and thus eliminate the great loss of coal that can never be recovered.

Mr. Chas. A. Cabell, manager of the Carbon Coal Co., of Carbon, Kanawha County, W. Va., has secured a patent, dated January 3, 1911, from the United States Patent Office of a block system of retreating longwall. His system has a great many points similar to the one proposed by the writer.

He is now installing his system in one of his mines, and the writer sees no reason why it will not work successfully. Mr. Cabell has every assurance that the system will be the one to work low seams of coal.

Lehigh Valley Fire-Fighting Car

When fires occur in the steep pitching breasts of anthracite mines they are difficult to reach, particularly when the fire-fighters are loaded down with the heavy breathing apparatus which is used generally to protect the men from the coal gas evolved. Under such conditions the men practically become exhausted in 15 minutes and are relieved by another force of men who work 15 minutes. If the fires have not gained too much headway they may be extinguished without great difficulty provided they can be reached with water. Several large operations have installed fire-fighting apparatuses that have been described from time to time, but none hitherto so far as known, have made use of electricity for the purpose of throwing water on the fire.

Fig. 1. Electric Fire-Fighting Car (Right-Hand Side)

The following description of the fire-fighting car in use at Packer No. 5 and Centralia collieries of the Mahanoy and Schuylkill Division of the Lehigh Valley Coal Co. has kindly been furnished by Division Superintendent J. M. Humphries, Superintendent of that division

On several occasions considerable difficulty was experienced in fighting breast fires at Packer No. 5 colliery, in a vein that has considerable gas, and in one fire in particular the gas became ignited beneath the coal in the breast, the pitch of the vein being about 60 degrees, consequently the breast was worked full. Carrying water to the face in powder kegs up a 60-degree manway is not only very laborious but very inefficient. It is with difficulty that the powder keg is kept full to the top of the breast.

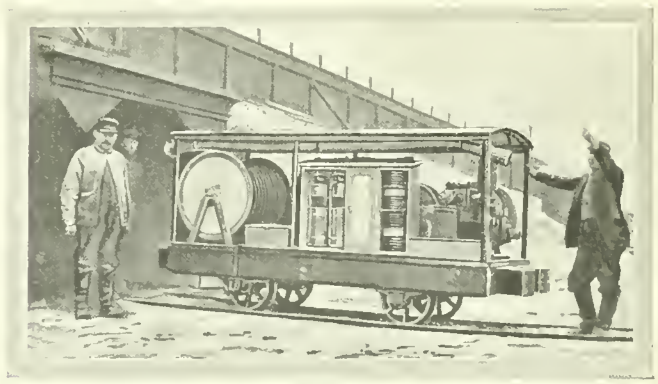

Fig. 2. Electric Fire-Fighting Car (Left-Hand Side)

The thought occurred that some easily portable pump that could be placed upon a mine-car body to pump water from the mine ditch, would not only be much more effective, but it would be very much easier to extinguish such fires. With this idea in mind a truck was designed, the essential parts of which are shown in Figs. 1 and 2. It consists of a 4″ × 5″ horizontal triplex electric pump with a capacity of 80 gallons of water per minute. The truck is also equipped with the following: 2,000 feet of No. 6 insulated wire; 1 controlling box for the operation of the motor; two 3-gallon fire extinguishers with 16 charges for same; 1 half hatchet; 1 single-bit axe; 1 cross-cut saw; 400 feet of 1-inch rubber hose in 50-foot sections; 50 feet of 3-inch tail-pipe in 10-foot sections, including one 10-foot section 3-inch wire-lined rubber hose with strainer; fittings for connecting 2-inch pipe; 1,000 feet of 2-inch pipe is carried on hand at the colliery solely for fire purposes and the necessary reducers for connecting 2½-inch fire hose, of which there is carried at this colliery, 1,200 feet.

There is also a chest containing all the necessary hospital supplies for giving first aid to any injured persons.

The truck is so designed that it can go to any point in the mines where a mine car can go, and we have two reels of wire that can be extended in the gangway beyond the electric haulage for over 1,000 feet.

The truck is kept on the surface in a fireproof building, on a track and it can be lowered to any lift of the mines within 3 minutes after an alarm of fire has been given.

Several tests have been made with this truck and it has been found very efficient although there has not yet been occasion to use it at an actual fire.

First-aid work is attracting attention in all parts of the world. A recent United States Consular Report mentions a demonstration recently given by the Singapore Volunteer Corps of a method devised for the utilization of jinrikisha wheels and axles in connection with stretchers. The body of the jinrikisha was dismounted and a cross-bar placed above the springs, from which projected two upright wings fitted into iron slots attached to the wooden arms of the stretcher. A waterproof awning was placed over all. Army medical men expressed themselves as pleased with the simplicity and ingenuity of the device.

Calorific Value of Anthracite

An Adaptation of the Usual Method of Testing with the Atwater Calorimeter

The following is an abstract from a paper by A. G. Blakeley and E. M. Chance, chemists of the Philadelphia & Reading Coal and Iron Co., Pottsville, Pa., presented before the American Chemical Society, on "The Accurate Technical Estimation of the Calorific Value of Anthracite":

Though much has been published on fuel calorimetry in general, but little has been written on that phase of this subject dealing with anthracite. Moreover, that which has been published is in a large measure discounted, because the coals tested were not examples of the usual merchant sizes. Thus, in the paper published by Parr & Wheeler (J. I. & E. C., Vol. 1, page 673), the two anthracites described contained but 11 per cent. and 13 per cent. of ash, respectively. Palmenburg published the results of an examination of a series of representative coals in Vol. 2, page 404, which range from 9 per cent. to 27 per cent. ash, and which may be considered as covering practically the whole range of the merchant coals. It is frequently stated in the literature of this subject that with high ash anthracite it is necessary to apply a correction for unburned carbon. Under the conditions which usually obtain, this statement is undoubtedly true, and while it is known that an error is ever present, the methods suggested for its correction are of but doubtful value. Such methods include the weighing by difference of the unburned carbon, and the mixing of the coal to be burned with a smaller quantity of a substance of relatively high calorific value. This well-known method has recently been brought forward by Palmenburg as an original solution of this troublesome question. While this method will doubtless give accurate and concordant results, it is only with the greatest care and skill on the part of the operator that such a desirable issue can be expected. The writers have found that with this method the bituminous coal underlying the anthracite is rapidly raised to a high temperature, and that the large volume of gases thus produced are likely to project small particles of the anthracite out of the nickel capsule and thus permit them to escape combustion. Thus, after combustion it is no uncommon thing to find small particles of unburned coal upon the floor of the bomb.

Another source of error worthy of attention is that a greater error is incurred in weighing a small quantity of a coal of high heating value than in weighing a large quantity of coal of low heating value, and that this whole error in weighing is calculated as error in the heating value of the anthracite. Thus the errors in weighing and sampling in both the coal and its kindler are concentrated as error in the heating value of the anthracite. Moreover this error is multiplied 1¼ times as .8 gram of anthracite is taken instead of 1 gram. It is to be understood that these errors are generally small but they are avoidable.

Table 1 shows a few determinations by the method of the addition of a kindler compared with a determination by our routine method.

Table 1

Number	Per Cent. Soft Coal	British Thermal Units	Asbestos Method British Thermal Units
C-2241	30.31	10,440*	
C-2241	31.02	10,690*	10,740
C-2241	32.68	10,720*	10,770
C-3022	31.37	9,860*	10,010
C-3022	30.20	9,920*	10,040
C-2300*			14,800
C-2300†			14,850

* Poor burn.
† Soft coal used as kindler.

A total of approximately 1 gram of the anthracite and kindler was used for each determination.

When first the Atwater calorimeter was applied to the determination of the calorific value of anthracite in this locality the usual difficulties were encountered. Upon observation it was noted that while the upper or exposed surface of a high ash anthracite might be completely burned to ash, the lower stratum or that part in immediate contact with the nickel capsule would in the vast majority of cases be completely unconsumed. Thus it would seem that the real cause of the incomplete combustion was the chilling of the coal by the rapid conduction of heat through the nickel capsule and heavy platinum wire.

The thermal insulation of the coal from the nickel capsule was then tried with most satisfactory results. This insulation was brought about by lightly tamping into the bottom of the capsule a layer about 3 millimeters thick of soft previously ignited asbestos. By this slight modification it is possible to burn completely and without difficulty coals containing as much as 40 per cent. of ash. The coal after burning leaves the ash either as a porous mass or vitreous globule. In either case the residue is free from unburned carbon as is proved by its failure to lose weight when dried and ignited. Briefly the procedure is as follows:

A nickel capsule 15 millimeters in height by 25 millimeters in width is chosen and a fair sized pinch of soft thoroughly ignited asbestos is placed in it. This asbestos is then slightly tamped in place with some blunt instrument such as the butt end of a fountain pen. This mat of asbestos may be readily formed with a pin so as to form a concave depression, with the center, perhaps 2 millimeters lower than the edges. The mat at its thinnest point, its center, should not be less than 2 millimeters thick. The coal, which should at least pass a screen of 80 meshes to the linear inch, after weighing in counterpoised scoop or bottle is then poured into the capsule, which is placed in the bomb, and the usual routine of combustion followed, except that a pressure of oxygen of 25 atmospheres is used.

It will be seen at once how slight is this divergence from the usual routine. The increased accuracy to be gained is not so obvious. To test the accuracy of the determinations by this method we calculated from the determined calorific value of the coal, the heating value per pound unit of coal by the formula of Parr & Wheeler.

This scheme has been found admirably adapted to such a purpose, for though the heating value per pound unit coal of anthracite from different localities may vary widely, that from the product of the same breaker will adhere more closely to a mean, an exception being an occasional intermixture of badly weathered coals with the usual freshly mined material. A few of these results, given in Tables 2 and 3, may not be out of place as illustrative of these statements. It should be noted that these results are taken from the daily routine and are in no case the result of work performed with a view to future publication.

Table 2

As these coals were fired wet, the samples were preserved in air-tight containers, the moisture being determined prior to grinding. When reviewing Tables 2 and 3 it is understood that the formula by which the values were obtained is but an approximation having no absolute accuracy, and that the errors of the proximate analyses as well as those of the actual calorimetric determination are reflected in the heating value per pound unit of coal.

Table 3

Size of Coal	Per Cent. Moisture	Per Cent. Volatile Matter	Per Cent. Fixed Carbon	Per Cent. Ash	Per Cent. Sulphur	Heating Value Per Pound Dry Coal in British Thermal Units	Heating Value Per Pound Unit Coal in British Thermal Units (Parr & Wheeler)

Barley	2.44	6.90	69.80	20.86	.50	12,120	15,780
Broken	2.95	5.57	80.75	10.73	.55	13,660	15,530

It may be well to note that the above results were obtained with the Atwater calorimeter, the water equivalent of which was determined by burning samples of naphthalene and hippuric acid as recommended by Atwater in his original article. (Journal American Chemical Society, Vol. 25, page 659.)

Although having no direct bearing on the method, it may be of interest to state here, that this particular Atwater calorimeter has been slightly modified by us for convenience in manipulation. The screw cap, socketed for a spanner on the original apparatus, has been replaced by a screw cap bearing a hexagon head. Thus, by substituting a box wrench for the original spanner the annoying tendency to slip has been removed. The stirring motor together with an upright some 42 centimeters high, has been mounted upon a piece of oak board, free to move upon the calorimeter table. This upright supports a walking beam, one end of which is connected by a driving rod direct to the crank of the motor; while the other end of the beam may be thrust into the ring of the stirrer, thus giving the stirrer a positive movement much to be preferred to the more or less uncertain motion imparted to it by the usual string and pulley device.

Calcium Chloride as Dust Preventative

Referring to the use of calcium chloride for laying dust in coal mines, Mr. Caldwell Harper says that calcium chloride has already been tried for a similar purpose, and failed. In 1875, Doctor Dammer, of Berlin, recommended it for freeing roads from dust, but the roads treated with it remained as dusty as ever. The reason it is expected to lay dust is that it is hygroscopic, but because it is hygroscopic it readily becomes a solution, and when in solution it is easily decomposed. Ferrous sulphate soon decomposes it, so do dilute sulphuric acid, magnesium sulphate, copper sulphate, sodium carbonate, potassium oxalate, sodium phosphate, ferric aluminate, and many others. Mr. Belger, of Newcastle-on-Tyne, in the course of his researches on the ankylostoma, found that a 25-per-cent. solution of $CaCl_2$, poured on a sample of crushed rock from the bottoms of three different mines at 25° C., lost 85 per cent. of its $CaCl_2$ in 48 hours. Even while it remains undecomposed and hygroscopic, it may do more harm than good. For when only a little moisture is present, the $CaCl_2$ may absorb it all and leave none to lay the dust. Indeed, it is to produce dryness that laboratory chemists put it inside the cases of their balances. It is also stated that calcium chloride harms iron and steel only a third as much as plain water does. This is doubtful. Water gives iron a coating of oxide which serves as a partial protection against further oxidation. Calcium chloride forms iron chloride, which does not accumulate in this visible way, but weakens the iron quite as much. The effect of the chlorides is illustrated by the fact that iron disappears as fast on a sea beach as on a river side. It is also doubtful if calcium chloride would be harmless to miners. It has a drying and irritating effect on the skin, especially the perspiring skin, and it would hurt the blisters which mine ponies often have above the heel. It might, however, be useful underground for another purpose—that of making wood less inflammable.

Chocks for Chain Hauls

On hook-chain hauls there is danger of the hooks giving way through either the link or the hook breaking. On single hook chains this is more apt to occur than on double hook chains, and when it does, if there be no chocks, the car runs back, breaking off the other hooks or causing a wreck. In case the pitch is not steep and no wreck occurs from the car running back and striking another car coming up, there are nevertheless grave chances of the car axle at the hook being bent, or the hook injured. To avoid this, the Philadelphia & Reading Coal and Iron Co. introduced the chock block shown in Fig. 2, which, in a modified form, has been adopted on scenic railways in amusement parks. The wooden chock a is constructed of such length it may be pivoted to one tie and overlap the rail when in position. To the chock is fastened a 2-inch diameter hickory hoop pole b of such length it will reach over two ties and form a spring pole. As the cars go up the incline the chocks, placed at suitable intervals to correspond with the wheel base,

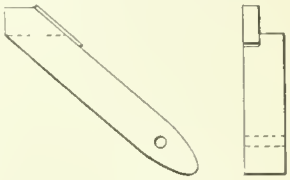

Fig. 1

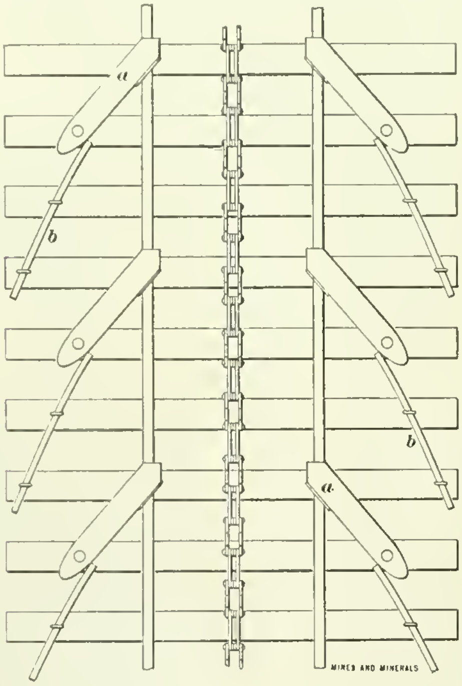

Fig. 2

are pushed to one side by the wheel tread. As soon as the wheel has passed, owing to the spring pole, the chock flies back over the rail; consequently, in case of a hook breaking, the car would not run back more than the length of the wheel base before all four wheels were chocked. While the arrangement is crude it is just as effective and more economical than metal springs. The method of constructing the chocks is shown in Fig. 1. The portion which is hit and pushed off the rail by the wheels, is covered with iron to preserve the wood from wear.

Appliances for Preventing Accidents

Guards and Automatic Devices to Render Impossible Many of the Common Accidents

*By Stephen L. Goodale**

A number of signs and notices posted at various parts of the properties of the H. C. Frick Coke Co., to provide for the safety of their employes and others, were described in the August issue of Mines and Minerals. This article is descriptive of a considerable number of devices and appliances adopted and in use at these plants to prevent accident. "An ounce of prevention is worth a pound of cure," might be written for this case "A pound of prevention is better than a ton of cure." Many of these devices for the promotion of safety have been developed at the various Frick mines. A number also are mentioned which are not peculiar to this company, but are more or less generally in use; such, for instance, as railings about open shafts, guard cases over exposed gearing, and others. The purpose of this paper is to present, as nearly as may be, all the safety devices now in use by this company, so that in general no mention is made as to where the different items were first developed and introduced, or which are peculiar to these mines. It is hoped that the enumeration and description presented will promote the cause of industrial safety and lead some concerns, whose works are not now as safe as they might be made with a little effort and money, to "ante up," to use a phrase which will be understood.

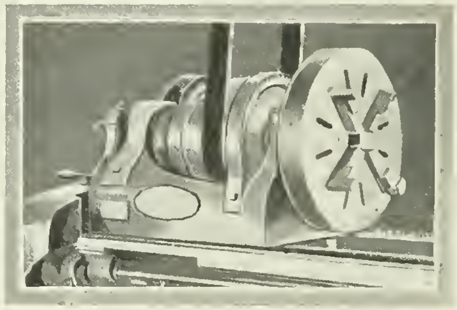

Fig. 1. Gear Guard

Machinery Guards.—In the machine shop and other places where men must work about gear-wheels and where there seems to be danger of clothing being caught by the teeth, such gear-wheels are covered by heavy sheet-metal cases; for instance, on the turret-head toothed pinions of the lathes in the shops, Fig. 1; over the reduction gears from the motor to the conveyer in the coke-drawing machine; over all gears (a single large case) of the pipe-threading machine. These guards are all made substantial and strong, so that they offer ample protection in case of a man falling or stumbling heavily against one. The emery wheels, Fig. 2, are covered over nearly the whole top of each wheel with a heavy cylindrical sheet-metal case, so that if one should break, which happens occasionally because of the high speed, the pieces of emery could not fly.

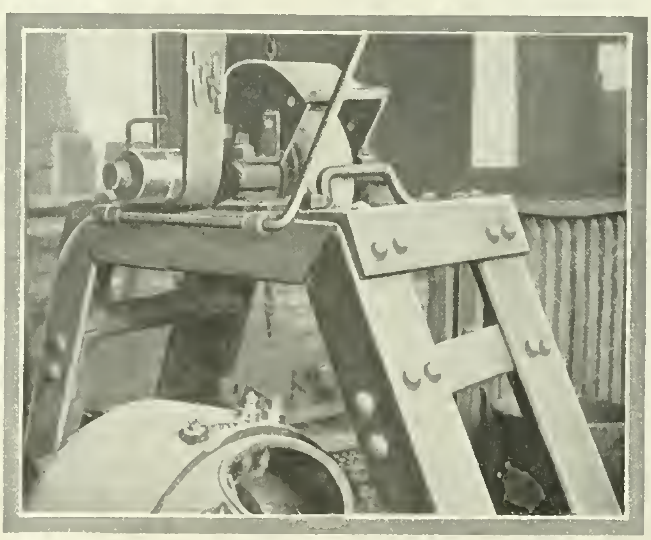

Fig. 2. Emery Wheel Guard

Over the top of the circular saw, Fig. 4, is a narrow guard held up by an iron bar the thickness of the saw, and in line with it projecting from the table behind the saw. This can be raised or lowered according to the size of saw being used and the thickness of piece being sawn. The band saw, Fig. 3, is entirely enclosed, top and bottom, and except only that short piece where the work is being done. This case is made of light matched stuff, and together with the guard over the circular saw constitute two of the most important shop safety devices. A danger sign also is sometimes tacked on the band-saw case to draw attention to the danger of a saw breaking and its pieces being thrown across the shop.

High-speed belts are cased in when they are so located that there is danger of a person being caught by them. It may not be amiss to call attention to the regulation that machinists are required to wear whole and not ragged clothing, and that long neckties are not permitted. In certain cases of rapidly turning spoked wheels, practically the whole wheel is encased; open pulleys are sometimes the cause of serious accidents.

A railing is placed about high-speed machinery, and also at places about other machinery which is dangerous, as hoisting drums, and so on.

The Nicholson engine stop is employed at practically all of the Frick company's shaft mines to prevent any accident from overwinding in hoisting. Its application to a hoist is shown in Fig. 5. Without going into the detail of its construction the following may be quoted from a letter of Mr. R. H. Nicholson. The principle of the device is to operate "every hoist, cutting off the steam supply at the main or slide-valves gradually, when approaching the landing or dump, thus weakening the power of the engine and the slow application of the steam brake acting in unison. It does not depend upon speed requirements, but acts at any speed, no matter how fast or how slow, as the movement of the drum in either direction actuates the stop mechanism at a prearranged time suitable to the hoisting conditions."

At many of the hoists a matched-board partition is set up between the hoisting drum and the engineer with a strip of canvas stretched from its upper edge to the rafters of the hoisting building. Small particles of dust lodge on the hoisting rope and are thrown off when hoisting, and this narrow partition is to prevent such dust from getting in the eyes of the engineer.

A gate is set at the end of any switchboard carrying high potential lines so that persons cannot conveniently get to the uncovered conductors at the rear of the board; this gate is kept locked. Rubber mats are stretched along the front side of the switchboards. The transformer station, at mines like the York Run where electric haulage is used, is enclosed by a strong fence, and the transformers are set on a platform above the ground so that the danger of any accidental contact with high-tension wires is eliminated for employes or others about the plant.

Any electric switch may be locked, either by means of a wooden block that can be locked on the knife edge, absolutely preventing the switch from being thrown in; or the switch may be placed in a heavy sheet-metal box; the key in either case being carried only by the electrician or whoever is working on the line so that such a man will be safeguarded against any inadvertent closing of the switch. As this switch lock might well be applied in electric work very generally, drawings for the device are shown in Fig. 6. At the coking plants making

* Professor of Mining, University of Pittsburg.

use of the waste heat from the ovens for steam-raising purposes, the long waste-heat flue conducting the very hot gases to the boilers has been a source of great trouble. A very high temperature is developed, and instead of the smokiness of the ovens that discharge directly into the atmosphere the gases in the flue are clear and transparent, showing complete combustion, and resulting in a temperature high enough to require silica brick for the lining. These brick sometimes work loose and leave a dangerously thin place in the flue; and a wire fence is placed alongside the flue with large danger signs to warn people from walking along the flue. Directly over the flue are also built at intervals low brick pillars to interrupt walking and also help in keeping people off. This is shown in Fig. 7, as well as the contrast between the smoky ovens beyond discharging into the air and the near row of ovens free of smoke.

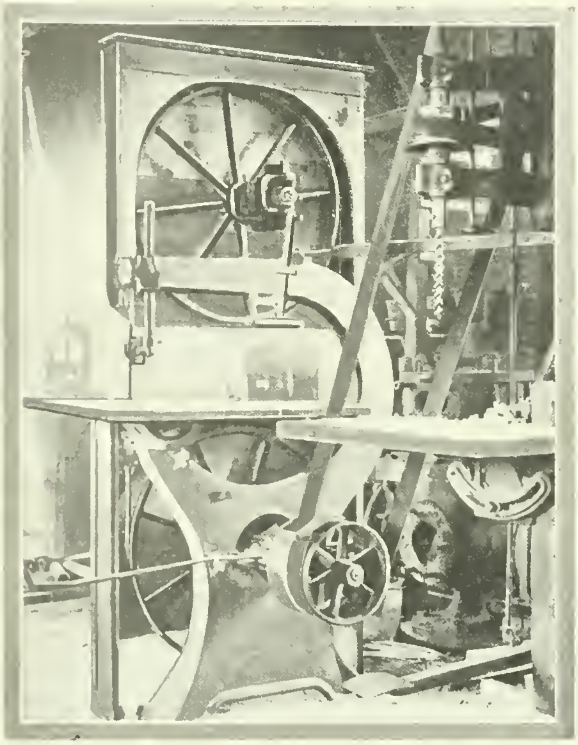

Fig. 3. Band Saw Guard

When a boiler is to be taken out of service, so that men may work in or about it, a suitable blank flange is inserted in the steam connection, in the blow-off connection, and in the feed-connection, so that in the event of leakage or breakage of a valve the workmen are still safeguarded. These blank flanges are an additional safeguard to the locking device for hand wheels on valves, shown in Fig. 8. It consists of a sheet-steel case of a size to fit over the hand wheel and effectually prevent its being turned. Each boiler steam valve carries the same number that the boiler carries, punched in No. 20 steel and fastened to the valve by suitable clips, so that no mistake can be made in opening steam valves. Whenever a man is working in any boiler a large sign is hung on a tripod in front of the boiler "Man in Boiler." Each water gauge is provided with a semi-cylindrical full-length cover, and when a new glass is inserted this is used to protect the workman from danger of breakage of the glass in heating when the steam is turned on, and when the glass is hot the guard is simply swung around out of the way. The boilers blow off into a large underground cistern covered with a heavy cast-iron grated lid, sometimes a number of boilers through one line into such a cistern, in which case the flanges and cases above described are used on the blow-off as well as steam and feed lines, and sometimes each boiler blows through a separate blow-off line from the boiler. There is a continuous pathway over the tops of the boilers from one end of the bank of boilers to the other with continuous hand rails along the sides for the whole distance, so that in any case of escaping steam a man, even without being able to see, can guide himself safely along the pathway. This has been of actual service in a number of instances of minor blow-out or leakages.

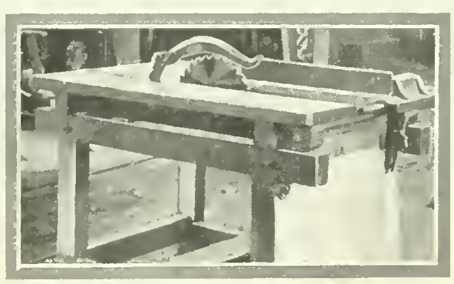

Fig. 4. Saw Guard

Four-stage compressors are used to supply air at 800 pounds for the mine air locomotives. The presence of oil in the high-pressure cylinder sometimes causes an explosion if the temperature runs too high, due to the compression of air. A safety device, consisting simply of a fusible plug set in a small valve inside the discharge pipe from the high pressure prevents this by melting before the dangerously high temperature is reached, and the engineer is called by the whistling of the escaping air.

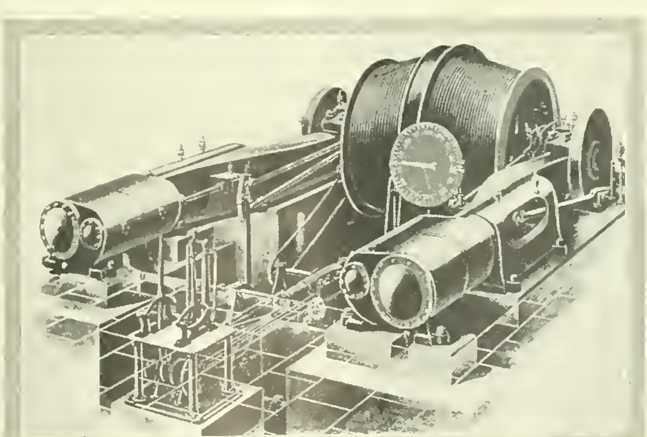

Fig. 5. Engine Stop

With the shaft-gate locking device shown in Fig. 9 it is impossible to open the gate in the railing about the top of the shaft unless the cage is there. The latch can be raised only by a system of levers operated by a handle extending through the fence just beside the gate; and it is only when the cage is in position at the surface that the proper bearing is afforded to the levers so that the latch can be lifted. On the shaft framing at the ground level is fastened a horizontal plate—an L-shaped lever turns about a pin in this plate. The lever arm is ordinarily back from the shaft out of the way of the cage, but when the cage is present one arm may be turned so as to bear against the side of the cage; the other arm being connected by a straight rigid link to the lower end of an upright lever, to the upper end of which is fastened the rod and handle to operate the gate latch, and which ordinarily when the cage is not present turns about a pin held by a heavy weight about 10 inches from the lower end. If now the upright lever is pulled with the cage away the L-shaped arm is simply turned forward and one arm extends out over the shaft; but if the cage is present the L arm can turn only until it hits the side of the cage when the lower end of the upright lever is prevented from further movement by the rigid link and the weight is lifted by any further pull. The gate latch is connected by a simple system of levers to this weight, holding the gate locked except when this weight is moved by the lever.

Only When the Cage is Present.—It is proposed to connect this device also to operate a car stop so that it will not

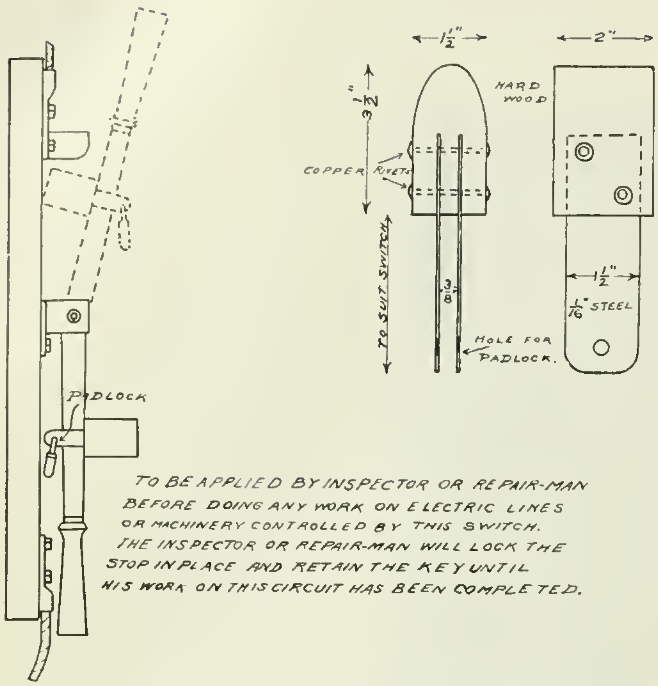

Fig. 6. Lock for Electric Switch

be possible for a car to run to the shaft except when the gate is open, the cage in position and ready for it. Thus, the gate itself is protected against having a heavy car run against it.

An additional light hand railing set just outside of the fence beside the gate, so as to leave a pathway toward the gate, is used at some of the mines to regulate the number of men getting on a cage and prevent crowding, the miners being obliged to go through this passageway single file to reach the gate.

At the rear edge of the shaft a bright light is set on a timber reflected toward the shaft by a parabolic reflector. This illuminates the exact edges of the shaft very distinctly, especially at night, thus calling attention to the shaft, and minimizing the danger of any one walking into the shaft.

Fig. 7. Protection for Waste-Heat Flue

The larry driver's ordinary position is standing on a narrow step at one end of the larry. There have been accidental collisions in which the driver was knocked off this step on to the track, and now a guard or fence is used to make this impossible, as shown in Fig. 10, and in a number of cases since the addition of the railing it has been the means of preventing serious accident. The driver does not have a very clear view from his larry, and at times it is not possible to see clearly along the track because of smoke from the ovens. On this account a large gong similar to those used on street cars, only operated by a foot-button, is put under the driver's step so that he can give warning of his approach when necessary. A sloping roof is provided over the driver so that he shall not be struck by falling pieces of coal when near the tipple.

Such railings are not, of course, peculiar to the Frick mines, but as they are important in the prevention of accidents, they are here mentioned. Railings are also used to shut off approach to dangerous places in general, such as the air-shaft at the fan house, about inclined mine entrances, on stairways, landings, etc.

For fire protection at the surface, at all the mines bountiful high-pressure water supply is provided with numerous fire-plugs and hose houses, so that water can be played on any part of any building at short notice. A plan of the town is exhibited in the hoist house, showing the location of each fire-plug, and indicating the whistle signal referring to each plug; every plug being numbered and having its individual signal. In this way a fire-alarm can be very quickly given.

The water pressure per square inch carried varies at the different mines, often running to 150 pounds or more.

In the mine tipples and in many buildings about the mines, steel construction has replaced wood to a very large extent, and thus the fire-risk has been lessened. In the case of a wooden tipple, a heavy steel door is provided at the shaft top which can be immediately thrown over the shaft, thus preventing the spread of a fire through the shaft. In the machine shops, hoist rooms, and power plants, metal cans are provided for the reception of dirty greasy waste, and no accumulation of greasy material is permitted. The tops of cupboards in the shops are sloped so that waste, etc., cannot rest there, even should it be thrown up by a careless workman.

At the Leisenring mine the hoist signals are a whistle from the shaft bottom and a bell from the tipple, so that there is no possibility of any mistake being made as to where the signals come from. The whistle is blown by a cylinder whose piston is forced up by hand quickly to give the blow.

Wherever a ladder is frequently required to reach a valve on an elevated pipe line, permanent ladders are set, the top being fastened securely in place, as for instance by being bent around such a pipe line. When it is to reach a higher floor or platform, the sides of the ladder, either one or both, are extended above the platform and bent over to act as hand rails. These ladders are built at each mine, the sides being 2" × ½" iron and the rungs being ½-inch round iron with two nuts threaded on at each end to hold the sides securely.

At most of the shaft mines there is in the track where it approaches the shaft on the ground, either a derailing break in the track or a block held in place on the rail to stop a car from running to the shaft when not desired. In many instances at frogs in the track, the space between the rails is filled in to floor it up even with the rails, so no man can catch his foot in the frog.

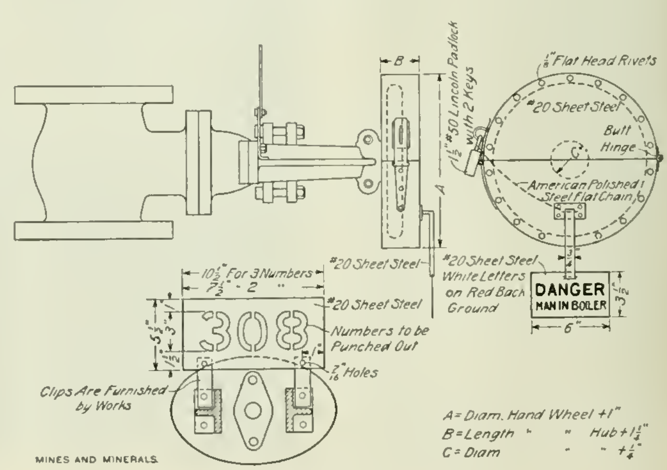

Fig. 8. Locking Device for Valves

Fig. 9. Shaft Gate Locking Device

The mine superintendent is required to look over reports and initial them daily, thus signifying that he has examined the reports made and entered by mine and fire bosses in the regular books. This insures that the superintendent shall keep constantly posted on the reports made by those under his authority.

Fig. 10. Guard for Larry Driver

Every month a list is made up showing all accidents which have been reported from all mines belonging to the company. These lists are classified and arranged under various headings and copies sent to all superintendents to bring to their attention the causes of accidents so that by exercising foresight and care they may be able to avoid similar accidents in the future.

The habitations provided for the employes are large comfortable double houses for two families, and when possible sufficient space is provided with each house for a small garden. At some mines the employes are encouraged by the offer of prizes to keep the place in a fine condition and to have the best garden possible, so that as a rule the towns are neat and attractive.

No Sunday work is done if the work necessary can be done on any other day or at night. On Sunday only the firemen on the boilers, pumpmen in the mine, hoisting engineer day and night, and night watchman do work.

The provisions of the United States Steel Corporation and Carnegie Pension Fund apply to employes of the H. C. Frick Coke Co.

At each mine there is either a small building or a room, warmed and lighted and provided with hot and cold running water, and equipped to give the first attention to those who may be injured accidentally. The equipment includes a Johnson's first-aid cabinet, an army stretcher, an operating table, towels, rubber blankets, linseed oil, bandages, and so on. The stretchers are covered with canvas and differ from an ordinary one only in being provided with short legs made of a loop of $\frac{1}{4}'' \times 1''$ iron so as to hold the stretcher about 6 inches above the ground and provide runners on which the stretcher can be dragged along while carrying a man if necessary. Ambulances are provided with covered tops and have stretchers hung from springs attached to the sides in much the same way as in the mine cars shown in Fig. 11. The hospital equipment is duplicated underground.

All the mines have either a number of men trained in first-aid to the injured, or else a number of squads now receiving the training; for instance, the Continental No. 1 has seven such squads undergoing training. They practice each Tuesday night under competent instruction, and every second week the company physician gives special lectures on first-aid work. The men take great pride in doing this work nicely, and many of their bandages would do credit to a trained surgeon.

A small library containing books on mining and allied subjects is usually available and is appreciated by some of the more ambitious men.

Oil and Coal in Honduras

About four years ago, writes Consul Arminius T. Haeberle, of Tegucigalpa, while search was being made for silver in the Guare Mountains in the district of Rosario, Department of Comayagua, indications of petroleum were discovered about 21 miles from the town of Comayagua. A gulch in the mountains exposes a stratum of rock about 2 miles long, samples of which were examined and stated to be bituminous limestone containing oil, either with petroleum or asphalt base; this has not been definitely ascertained. The land was denounced some time ago, but only recently a company was formed and a concession granted by the government to carry on the work of searching for the exact location of the oil.

Indications of coal are said by the United States Consul to exist in many parts of Honduras, in the Departments of Tegucigalpa, Yoro, Choluteca, Comayagua, and Valle. Until now no investigation has been made as to quantity, nor has the quality been carefully examined. There is an outcrop in the Department of Choluteca, samples of which, taken from a vein about 45 feet wide, are said to be good. Also in the Department of Paraiso, coal has been found which is said to contain about 70 to 75 per cent. of carbon.

Fig. 11. Hangers for Stretcher in Mine Car

Coal-Dust Explosions

Conditions Necessary to Sustain a Dust Explosion. The Method by Which Air Is Supplied

*By John Verner**

In a letter published in the July issue of Mines and Minerals, Mr. C. M. Young, Associate Professor of Mining Engineering, University of Kansas, expressed the belief that certain errors of fact were contained in the article on "Coal-Dust Explosions" which appeared in the May number of Mines and Minerals, errors which he thinks should not be allowed to go without some correction.

Mr. Young believes it to be an error to accept the conclusion that the manner and amount of the air supply constitute the paramount factor in a dust explosion. He also considers as insufficient the data submitted to sustain the conclusion that the dust is injected into the flame by a strong air draft directed toward the advancing explosion, and he states what he assumes to be the facts as follows: "I wish to emphasize the statement that the conditions necessary for an explosion are, first, an explosive dust; second, the suspension of a sufficient quantity of it in the air. The error in the author's conclusion that explosiveness depends largely upon the quantity of air present, lies in the fact that in most cases there is too little dust present to be explosive. In other words the air is greatly in excess of the required amount. The dust present does not furnish sufficient heat for sustained combustion; therefore there is no explosion. It is only when considerable quantities of dust are suspended in the air and when this dust is of readily combustible character that an explosion occurs. I wish to take issue with the conclusion that the quantity of air rather than the quantity of the dust is really the measure of the magnitude of an explosion."

Professor Young's criticism is welcome because it directs attention to that phase of dust explosions which so far has had but little attention and that must be cleared up before the final solution of the problem can be reached. Mr. Young objects to Haas' conclusion, quoted by me, that "the quantity of air rather than the quantity of dust or coal is really the measure of the magnitude of an explosion." The conclusion is based upon the fact, as stated by Haas, that air is a necessary element for an explosion and that coal and coal dust are always in excess and the amount of gas that could be given off is incalculable. The following examples will tend to show the correctness of the conclusion. There were no better ventilated mines anywhere than the Monongah mines at the time of the explosion; they were provided with a rather unusual number of openings connecting them with the surface and in consequence draft facilities in these mines to promote and sustain combustion were of a very high order, yet Professor Payne in giving the results of his investigations of this explosion stated that while under the extremely favorable conditions named the explosion was one of the most violent on record, it would have been more destructive "had there been sufficient air to support combustion, in which case the almost incredible pressure of 21,600 pounds per square foot would have been reached with a temperature of 4,683° F."

Peckham and Peck in their experiments with inflammable dust found that the making of holes in the testing box, through which the air could enter, in all cases increased the force of the explosion in the box.

To show the opposite effect, I refer to the Illinois Mine Inspectors' Report regarding the dust explosion several years ago in Mine 18 of the Dering Coal Co. After the main explosion, secondary explosions occurred at intervals of about 2 hours, but they ceased as soon as the fresh air supply and draft was prevented from reaching the fire by the sealing of the shafts.

If Mr. Young's emphatic conclusion is correct that the only conditions necessary for an explosion are, first, an explosive dust; second, the suspension of a sufficient quantity of it in the air, the danger from dust explosions should increase with a mine's extent, for it may be reasonably assumed that the longer a mine is worked and the more extensive it becomes, the greater the total dust accumulation in it and the better the chances for its suspension in large quantities, but the Kansas mine inspector's reports show that the older and more extensive mines in that state were fairly immune from dust explosions, although such explosions may have occurred in them while they were new, and the reports further show that these explosions have been confined almost entirely to new mines. Kansas is not the only coal-mining state where this was found to be the case. It is a fact of general application. In Iowa, for instance, the record of the last 35 years shows that in all the mines, in which explosions occurred while they were new, the danger from their reoccurrence decreased with the increase of the distance from the mine openings to the working faces and with no perceptible material change in other conditions. How is this fact to be reasonably explained if not by the logical conclusion that the greater and more readily available air supply and the better draft facilities in the new mines promoted and sustained combustion with explosive results, while in the older and more extensive mines with longer air-courses, perhaps more or less obstructed by falls or otherwise, the amount of air supply and the draft facilities were insufficient for that purpose?

Dust explosions have originated in the interior of extensive mines, but in every instance where this occurred, it was found that the mine afflicted was provided with an exceptionally large air supply and with superior draft promoting facilities.

As Mr. Young questions the sufficiency of the data given in the article tending to prove that the dust is injected into the flame, by an air draft of greater or less force traveling opposite to an explosion's advance, I shall submit supplementary evidence that may be more convincing. There can be no better evidence regarding this matter than the testimony of men who were caught in explosions, observed what occurred and escaped to give their experience. It will be noted, that although these men were in mines far apart, unlike in conditions, their evidence regarding air and heat movements is exactly the same. In the article reviewing the second Lick Branch explosion, I mentioned the testimony of Mine Foreman Bowers relative to an inrush of cold air of great force followed immediately by an outrush of flame and hot gases from the inside. After the Cokedale explosion "the two survivors testified that they first felt a rush of cool air in the face which blew out their lights and which was instantly followed by a hot blast from inside which knocked them down." Last February a small explosion occurred in an Iowa mine. The shot firer, a cool headed and experienced man, felt the initial shock and threw himself on the floor. He saw the flame, confined to the upper part of the entry, coming toward him and at the same time felt an inrush of air behind him that was strong enough to pick him up bodily from the floor and hurl him some distance toward the advancing flame. He was severely burned but made his escape.

The testimony of these men shows, first, the probable method of air supply to sustain combustion during an explosion's progress, second, the possible intensity of draft directed toward the advancing explosion, and third, the probable manner in which the dust is conveyed to and injected into the flame.

Professor Young admits the necessity of extremely rapid combustion of the dust to produce explosive results, but he rejects the natural process by which this can be accomplished, for he expresses his emphatic belief that the rate of combustion is not determined by the amount of air and draft supplied and that therefore the laws governing combustion have no application in a dust explosion. Until the proof of this is furnished it may be well to still continue to accept as true Haas' conclusion that "the quantity of air rather than the quantity of dust or coal is really the measure of the magnitude of an explosion."

* State Mine Inspector, Chariton, Iowa.

Victor Electric Safety Lamp

Methods of Charging Batteries and Handling Lamps. Increased Output from Better Light

*By Mark O. Danford**

An interesting test of electric safety lamps was made at the Toller mine, of the Cedar Hill Coal and Coke Co., at Tollerburg, Colo., the past year. The lack of efficiency of the company men, on account of using the flame safety lamp, led the management to investigate the electric safety lamp, as the mine is gaseous and safety lamps are a necessity.

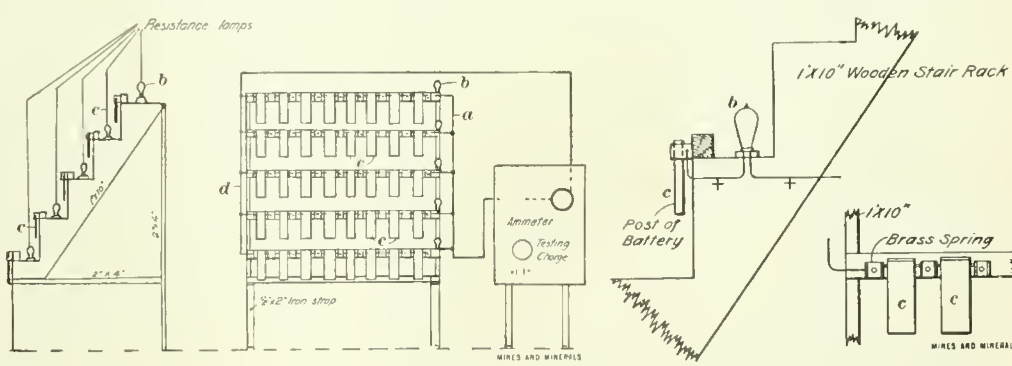
FIG. 1. VICTOR ELECTRIC LAMP

After experimenting for several months, Mr. Victor Patton, electrician at the plant, designed a lamp and battery which he calls the Victor electric safety lamp, which has been patented. This lamp has been adopted by the Cedar Hill Co. and furnished to all underground men at the Toller mine.

The first trial was made about a year ago, when five lamps were issued to the drivers, and the first day that they were used, with the same number of men, drivers and mules, the production was increased 125 tons. All other conditions were equal, the mine working every day, and no stored loads were in the mine the day the test was made. In fact it had been a problem to gather the coal, and considerable dissatisfaction was felt by the miners on this account. Thus the efficiency of each driver was increased 25 tons, with greater safety in handling his trips, spragging cars, etc.

Next the lamps were issued to the tracklayers and it was found that the work could be done with one man that had formerly required two. With the flame safety it requires one man to hold the lamp while the tracklayer works and even then the light is insufficient. The electric safety lamp is at all times on the cap and the light is sufficiently strong to make the work as advantageous as with an open light. The same condition was found applicable to the timberman, and one man could do the work of two in this line.

As fast as the lamps could be manufactured they were issued to the miners and now all are equipped with electric lamps. By this installation the efficiency of each miner was increased from 5¼ tons per day per man to 6½ tons per day per man. It is well known how hard it is to interest an old and experienced miner in any new device that he is not thoroughly acquainted with, yet it is gratifying to see how quickly they adapted themselves to the new electric safety, and the best boosters for the lamp are the miners themselves.



Detail of Spring Brass Connection

FIG. 2. CHARGING RACK

Aside from the increased efficiency and financial benefit to the miner the best feature of the lamp is its possibility to test the roof conditions. The miner does not now have to depend altogether on sound in testing the roof, but the slips and cracks are at all times visible, whether the roof be 1 foot or 6 feet above his head. This added degree of safety is probably the most appealing feature of the lamp.

The lamp is so made that all connections are accessible to repairs. The back part of the lamp is fitted with a lug on each side that fits into a slot in the front or reflector part of the lamp. By a simple turn the two parts are separated and the connections are exposed and ready for repairs should any be necessary. The globe is protected by a glass crystal fastened into the outer casing with a spring ring. The reflector is of nickled tin and acts as a circuit-breaker in case a fall should crush the outer casing, for the instant the outer casing touches any part of the reflector the circuit is broken and the lamp goes out, eliminating any spark in case the globe should be broken. The lamp has a hook at the back that fits any style of pit cap. Insulated lamp cord connects the battery to the lamp. One-half candle power tungsten globes are used and by the aid of the reflector cast a strong light. The miners usually carry the battery in a leather pouch swung from straps so as to hang under the arm, as shown in Fig. 1. This is the most satisfactory way to carry the battery, yet many have made a simple leather pouch with a slot cut in the back through which is passed the belt. The battery then hangs similar to a cadger of oil. One dollar per month is charged each man for upkeep of lamp and recharging of battery. This is the same as was charged for the flame safety and is less than it would cost per man to furnish open light.

As the success of the lamps depends greatly upon the recharging of the batteries several experiments were made before a suitable charging rack to handle a large number of batteries was evolved. This rack shown in Fig. 2 is made of 1 in. × 10 in. uprights with a run of 7 inches and rise of 10 inches. A 2 in. × 2 in. piece connects the uprights. Pieces of spring brass 1½ inches wide and about 4 inches long shaped like an "U" are screwed to the 2 in. × 2 in. with scant distance between to receive the battery. The poles of the battery rest in small grooves in the spring brass. The current is taken in at the right side, through the wire *a*, passed through the resistance lamp *b* to the first brass connection, then through the battery *c* to the next brass, and so on across the row of batteries to the left side of the rack where connection is made to the negative wire *d*. This rack can be made any size and to hold any number of batteries, the current being regulated to the number of batteries being charged at one time. The best results at Toller are obtained by charging at the rate of 1 ampere per hour for 9 hours. It requires direct current to charge batteries and as the power at Toller is alternating current, a small generator was made in the shop and is driven by an inner belt on the shop motor. The battery casing is made of hard rubber and when completed and charged ready for use weighs 1 pound, 6 ounces. The life of the elements of the battery should be about 2 years, depending upon the care used. The battery should never be set aside without charge, as the acid without the charge sets up chemical action that destroys the positive plate. When the batteries are fully charged they are tested

* Danford & Sanderson, Mining Engineers, Trinidad, Colo.

at the switchboard and they should read from 50 to 60 amperes, 2.9 volts, and when so charged and using ½ candlepower globe, burn from 16 to 24 hours. One candlepower globe will burn just half as long.

A rack of lockers has been constructed in the lamp shanty equipped with padlocks. The lockers are numbered on the front and back to correspond to the check numbers of the men. The lamp and battery are placed in the lockers from the rear which is left open, as shown in Fig. 3. The miner is furnished

Fig. 3. Lamp Lockers

with key to his locker and takes lamp and battery out in the morning, returning it at finish of shift. The lamp tender takes the batteries from the lockers, fills them with solution and hangs them on the charging rack. While the batteries are being charged he goes over all lamps, making any repairs necessary. After the battery has been charged they are drained of the remaining solution on to a board constructed for that purpose, tested at the switchboard, and replaced in the locker with the lamps, ready for the next shift. Each lamp is numbered with a corresponding number on the locker. In this way it acts as a check system for the men in the mine, and the tender can at all times account for all men in the mine in case of an accident. One man can easily take care of 500 lamps.

The cost of upkeep for 500 lamps is as follows:

Bulbs should burn 650 hours or for 500 lamps, say 3 bulbs per day at cost of 33 cents each	$ .99
Lamp cord renewal for 500 lamps, one per day	.30
Broken lens	.10
Cost of charging batteries is 3 watts each = 1,500 watts for 500 batteries, say 3 horsepower per hour, at 1¾ cents per horsepower hour = 5¼ cents per hour for 9 hours	.47¼
One lamp tender	2.75
Three quarts of solution	.10
Total per day for 500 lamps	$4.71¼

This shows a trifle less than one cent per day per lamp.

The lamp has been tested in all mixtures of firedamp, and no flame can be produced. It is well to remember that it will not test gas, and flame safeties will have to be used for that purpose by the fire bosses and inspectors.

Miners in Arkansas

Prof. A. H. Purdue in a report to the Governor and the members of the Geological Commission of Arkansas, says: In Arkansas 79.4 per cent. of the miners are English speaking, 66 per cent. are American born, and 2 per cent. are negroes. American born white make up about two-thirds of the mine crews. Of these 20 per cent. to 25 per cent. are natives of Arkansas. The other Americans are generally experienced coal diggers from other states, chiefly Alabama, Pennsylvania, Indiana, Tennessee, and Kentucky.

The natives of Arkansas are men used to mines, and those underground are generally young; but of the top laborers three-fourths or more are Arkansas men.

A considerable number of English-speaking miners have studied more or less with the correspondence schools, and the majority of the fire bosses and pit bosses have finished such courses. Through these men the technical knowledge of all the miners is increased. Many of the men are generally interested in geology, ventilation, and general mining problems, and ask intelligent questions whenever the opportunity offers.

Coal Mining Notes

Anthracite Miners' Demands.—The following is a list of the resolutions presented at the Anthracite Miners' Convention, at Wilkes-Barre: Recognition of the union and check-off; weighing of the coal and payment by the ton; standard price for powder; general increase in wages, averaging from 10 to 20 per cent.; legislative committee; 10 additional mine inspectors; mine bosses to be eligible to the position of mine inspector; mine inspectors directed to enforce the engineers' 8-hour law; that non-English speaking laborers be not permitted to enter the mine; that the chief mine inspector be forbidden to interfere with the present engineers' 8-hour law; the constitution to be amended; that tellers count the ballots 4 days before the convention, and to be in a position to report at the first session.

New Concrete Breaker.—The Lehigh Valley Coal Co., who has in course of erection a mammoth new concrete breaker, between Buck Mountain and Vulcan, are now engaged in the erection of residences in close proximity to the breaker. It is said that the company intends to erect homes for at least 50 families, among which will be those for colliery officials. Work on the breaker and houses will be pushed rapidly, and it is expected that by early fall a thriving village will be placed upon the map where once existed nothing but brush and trees. The site is considered a beauty spot for a mining hamlet, pure air, pure water, and lots of room being among the guarantees of home comfort for those who may call the place home.

The Elkhorn, Ky., Coal Field.—The Consolidation Coal Co., which recently purchased 100,000 acres of coal land in the Elkhorn field, Ky., will be tapped by the Baltimore & Ohio on the eastern end, and the Louisville & Nashville on the other end. To build and equip the railroad branches into the property will, it is estimated, cost the railroads $30,000,000. The Consolidation Coal Co. is also spending considerable money in developing the property in order to be ready for shipments so soon as the railroads are ready to handle the coal.

Washing Coal for Coke.—Of the 2,069,266 short tons of coal used for coke making in Colorado and Utah in 1910, 1,387,070 tons were cleaned by washing before being charged into the ovens. The washed coal included 836,067 short tons of mine-run and 551,003 tons of slack. In addition to the washed slack, 429,728 tons of unwashed slack and 252,468 tons of run-of-mine coal were used unwashed.

Opening 2,000-Acre Tract.—The Standard Kanawha Coal Mining Co., Quick, W. Va., will develop 2,000 acres of coal, and plans a daily output of 1,200 tons. Pennsylvania capitalists incorporated this company recently with $200,000 capital.

Pennsylvania Coke in the West.—Frank M. Sylvester, of Spokane, assistant general manager of the Granby Consolidated Mining, Smelting and Power Co., states that if the two trains of coke obtained from Pennsylvania prove that the cost of operating with eastern coke is not much greater than with Crows Nest coke, it will be used in the future.

International Coal and Coke Co., a Spokane corporation, operating at Coleman, Alta., paid its regular quarterly dividend of $45,000 on August 1, making $135,000 so far this year and $796,000 to date. The property is closed on account of the miners' strike in the Crows Nest Pass district.

Underwood Colliery.—The Pennsylvania Coal Co. is arranging to develop a piece of property in Throop Borough, Lackawanna County, Pa., which is underlaid by six seams containing, it is estimated, 18,000,000 tons of available coal. These seams are the Big (or Grassy Island), the New County (or Marcy), the Clark, and the three Dunmore (red ash) seams. Three shafts will be sunk; two for taking out coal and one for hoisting men and supplies. The two main shafts will be driven to the lowest, or Third Dunmore seam, with tunnels running across the measures to the seams above. Electricity will be used for haulage and lighting, and it is also planned to use electric mining machines. Electric power will be used to some extent in connection with the pumping. The new colliery will be named Underwood, after the president of the Erie Railroad.

Lessons to be Learned from Recent Disasters

*By John Verner, Chariton, Iowa**

While each mine disaster teaches a valuable lesson it may prove a serious mistake to form final conclusions from any one disaster and prescribe them as remedies for the future prevention of calamities of similar nature; and the possibility of wrong conclusions based upon the investigation limited to one particular case, the necessity and advantage of a comparative study of mine disasters of similar kinds, so the combined lessons of all may be used to bring into harmony apparently discrepant results, can be readily established, as the following will show.

Looking over the report of one of the recent explosions, I found that it ceased on reaching an extended wet area in the mine, and it was assumed that the presence of moisture was the reason why it stopped in that particular place. Turning to the report of another explosion it was shown that the application of moisture and the damp condition of the dust did neither prevent the occurrence of the explosion nor stop it after it had started. Again, looking up another report, I found that the explosion ceased to advance in the presence of an abundant supply of dry coal dust.

The Elk Garden explosion may be taken as an example of the first case. As an example of the second case, I will quote from Miners Circular 3, recently issued by the Bureau of Mines: "In a recent mine disaster in this country, the explosion traveled 1,500 feet along a slope that had been washed down with hose just before the explosion, and even had a wet floor after the explosion. The explosion burst forth from the slope mouth in a great flame and deposited much coked dust on the timbers of the trestle."

To present an occurrence covering the third case I will give the essential part of the report of the mine inspector of New Mexico, relating to an explosion that occurred in the Weaver mine on March 6, 1910: "At the place where the blown-out shot initiated the explosion, apart from the combustion of the crushed coal and dust from the blown-out shot, all conditions were such as to prevent or retard a dust explosion. The explosion traveled outward to the parting on No. 3½ seam, about 500 feet distance. About 15 feet inside of the parting a driver was severely burned, and the two mules he was driving were so badly burned as to cause their death. Indications of the explosion were trivial beyond this point, although conditions were far more favorable for a violent dust explosion than in the locality where the explosive condition was maintained. Where the explosion ceased, at the parting where empty mine cars are delivered from the surface and loaded cars put on the rope to be transported to the surface, the roadways were covered with coal dust and were quite dry. The area was large, air comparatively fresh, and conditions favorable to the extension of the explosion, but it ceased at this point."

Now, if the first case is considered by itself, it may permit the conclusion that the presence of moisture stops an explosion; if the second case is taken as the sole criterion for basing judgment, there is very strong evidence that the presence of moisture does not stop an explosion; while the consideration of the third case alone might bring the conclusion that the presence of dry coal dust is not a dangerous factor. But when the matter is investigated on a broader scope and a careful comparison of all conditions surrounding recent explosions is made, it appears that the larger lessons so presented show fairly conclusively that the presence of dry dust is a dangerous factor, although not the dominant factor in determining either an explosion's extent or the degree of destructiveness produced by it, and the lesson further justifies the definite conclusion that the moistening of the coal dust as a preventive of explosions is of uncertain value of itself and unreliable to produce the expected results. It is granted that, other conditions being identical, a sprinkled, sprayed, or otherwise moistened mine may be considered less dangerous than a dry and dusty mine, but the margin of possible safety is too narrow and too uncertain to justify the claim, in view of the proofs to the contrary, that a mine can be rendered immune from explosions under any conditions by the application of moisture.

I said at the beginning that it may prove a serious mistake to attempt to prescribe remedies for the prevention of explosions suggested by conclusions based upon narrow and superficial investigations of the subject; and the possible injurious consequences of such mistake become all the more threatening, when men with good intentions, but evidently knowing little of the principles governing explosions, and therefore incompetent to give good advice, can prevail on the members of a state legislature to make mandatory by law the use of an alleged remedy that cannot possibly provide even a small measure of the safety the proposers and makers of the law expected to secure. For instance, in Indiana the law provides that roadways and entries (rooms, cross-cuts, etc., apparently exempt) in any mine shall be regularly and thoroughly sprinkled when they are so dry that the air becomes charged with dust. The law also permits the use of 6 pounds of blasting powder to the shot as a presumably safe charge. A dust explosion occurred in a mine in Indiana, causing loss of life. Suit was brought against the company and the Supreme Court of that state found that "the failure to sprinkle may be charged as the proximate and direct cause of the explosion." I have no fault to find with the decision under the circumstances, but it shows the futility and possible injustice of an extremely faulty law that, in a manner, compels the court to fix the cause of an explosion according to its letter rather than according to the true facts in the case. Such law should be repealed at the earliest opportunity, for it is really a legal obstruction to the promotion of safety, and its possibilities for future harm are great.

From the nature of the experiments recently made in England and France to discover a reliable preventive of dust explosions, it appears that the use of water is not considered adequate or satisfactory in these countries. The men engaged in making these experiments are evidently of the opinion that the use of stone dust in dry mines can subdue an explosion more effectively and quickly than the application of water, but even should the superior effectiveness of stone dust be established beyond a doubt, the present Indiana law would prevent the coal operators of that state from using the proved safeguard, and thus providing an increased measure of protection for the men in the mines, because the effectiveness of the stone dust would be destroyed by the compulsory use of water.

*A paper presented at the Charleston meeting of the Mine Inspectors' Institute of America.

3—2—4

There is no law for compulsory watering of mines in Belgium, yet the Belgian mines, with their great depth, their dryness, and the presence of gas, show a remarkable and pleasing record of freedom from explosions. There should be hesitation about hastily enacting laws in the mining states of this country for the compulsory application of water, because it is not only of doubtful value, but it carries with it a promise of safety that may not be redeemed when the test comes. Case after case could be cited to prove this, and it is only hindering the final solution of the explosion problem to present excuses why the application of water failed to produce the desired effects in this or that explosion, instead of fairly facing the fact that they were not prevented by the method in use, although the method as employed, for instance, in the slope mentioned in Miners Circular 3 of the Bureau of Mines and in the Banner mine in Alabama was as near perfect as man could reasonably be expected to make it.

Method of Testing Miners' Oil

For purchasing miners' oil, the Consolidation Oil Co.'s (Fairmont, W. Va.) specifications are: The sample, having a density of 24° B. scale or under, is placed in a glass cylinder 1½ inches in diameter and brought to a temperature of 60° F., as prescribed in the State Mining Law, and a hydrometer, standard Baume, with thermometer combined, is placed in the oil, and after stirring and mixing the oil thoroughly the last line of the scale appearing below the surface of the oil is read.

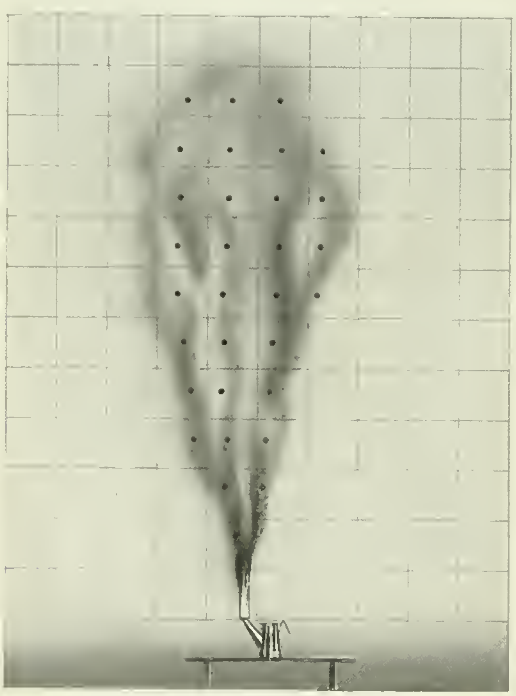


Fig. 1. Testing Oil for Smoke

The flash point is not to exceed 425° F. or to be under 300° F. The sample to be tested is placed in the inner can of a small double bucket, and a thermometer suspended so that the mercury bulb extends just below the surface of the oil. The temperature of the oil is raised by means of a Bunsen burner lighted and placed directly under the bucket. As the temperature rises a lighted match tells when the oil will flash.

To test the congealing point, which should be less than 24° F. or under, fill a medium-sized test tube one-third full of the oil to be tested, and place it in a 500-cubic-centimeter beaker. Pack fine ice and salt around the tube. Place a thermometer in the oil and remove after stirring the oil. When the oil will no longer drop off the end of the bulb, read the thermometer for congealing temperature.

To find the grams of oil burned per minute, which is not to exceed .5 gram per minute, a No. 2 Star miner's lamp is supplied with an 8-inch wick of lamp cotton weighing 2.5 ounces per ball, running 7 threads to a strand made by using four strands. The wick projects ⅜ of an inch beyond the end of the lamp spout. The lamp is filled with the sample, lighted and placed on balances, and allowed to burn 10 minutes. The loss in weight is calculated to grams per minute.

The flame height is measured while the lamp is on the balances, the end of the first, fifth, and tenth minutes; the average of the three readings is taken as the height of flame, which should be between 3.5 and 5 inches.

The apparatus used to make the smoke test consists of an electric arc spot light (such as used in a theater), and a curtain of tracing cloth 4 ft.×5 ft., ruled off in 4-inch squares, and stretched tight on a vertical frame. The spot light is placed 15 feet from the curtain and so focused as to cast a white light or spot over the entire curtain or chart.

The lamp used is a standard No. 2 Star miner's lamp, and the lamp cotton weighs 2.5 ounces per ball and runs 7 threads to a strand. The wick is made of 4 strands and is 8 inches long. It projects ⅜ of an inch above the top of the lamp spout when the lamp is lighted, and during the burning period it is not disturbed. The lamp is filled with the oil to be tested and lighted and placed 5 inches from the curtain, between the curtain and spot light, so the shadow of the smoke will be cast directly on the curtain, as shown in Fig. 1.

In the illustration the squares dotted are the ones counted as being covered with the smoke shadow. There being 31 squares, this is the figure representing the oil under test.

After lighting, the oil is allowed to burn for 3 minutes before a reading is taken. At the end of 3 minutes the number of 4-inch squares covered by the smoke shadow are counted. The burning continues for a period of 30 minutes, a reading being taken every 3 minutes. The average of the 10 readings is taken as representative of the smoke of the oil being tested. The figure "30" is the figure for pure cottonseed oil (used as a standard of comparison), and the figure "35," which is the number of squares covered by the smoke shadow, is the limit established, and if the smoke shadow exceeds this number of squares, it is considered objectionable for use by this company.

Book Review

A Study of the Blast Furnace, by Harbison-Walker Refractories Co., Pittsburg, Pa. This book has been prepared by the publisher for the benefit of the members of its organization. It is considered a digest of the subject in a simple and brief form; nevertheless, the reviewer considers it about as terse and useful a little book as was ever published on the subject of pig-iron manufacture. It supplements the company's "Study of the Open Hearth," and should be in the hands of every practical furnace man who has ambition for advancement. It is divided as follows: Description of Plant, with illustrations of Calder, Foote, McClure, McKee, Roberts, Julian Kennedy, White & Kernan hot-blast stoves; Ores and Their Treatment; Fluxes and Fuels; Burdening the Furnace, and Calculation of Charges; Operating the Furnace; Furnace Reactions, including a discussion on the dry-air blast. The illustrations are excellent, and the book is bound in red leather. In a pocket is a map in colors showing iron blast-furnace districts and iron-ore deposits of the United States. No price is set for this book, and although it has cost considerable to manufacture, it is possible that it may be obtained gratis by those interested in iron blast-furnace practice.

Annual Report of the Division of Mineral Resources and Statistics on the Mineral Production of Canada, During the Calendar Year 1909, by John McLeish, B. A., Department of Mines, Mines Branch, Ottawa, Canada.

Profit and Loss Account

Necessity of Considering Relation Between Capitalization and Annual Output of Mines

The importance of proper accounting, both as regards costs and capital account, was treated upon by Neil Robinson, of Charleston, W. Va,, at the December, 1910, meeting of the West Virginia Mining Institute, in a paper entitled "Profit and Loss Account," as follows:

The mine managers of the country, as a rule, are men of ability who have accomplished results under difficulties, and who are entitled to honor and profit for the faithful performance of services to the world.

Upon strict analysis it will be found that the majority of our mine managers exercise skill, good judgment, and economy in handling the labor and physical conditions connected with their plants, and deliver coal on board at the tipples at a low and reasonable cost per ton. In all things over which he has supreme control, the manager of today is achieving success and doing his part in the struggle for a satisfactory profit and loss account.

Although the requisite qualifications are possessed and employed by scores of men in the more important districts of West Virginia, the business as a whole may fail to show substantial profit at the close of the year. In this common event, stockholders, particularly those who are non-resident, are disposed to class coal mining as a financial hazard and attribute responsibility for the condition to the mine management.

In a majority of instances this is absolutely unfair and results in withholding from competent officials the credit that is due to them.

Coal mining is a legitimate business that is conducted in response to a public demand, and is entitled to the stability in returns that accompanies the operation of water, light, railway, and other public utilities.

When there is failure to realize profits commensurate with the natural inevitable risks in mining, it is essential that the cause or causes responsible therefor be sought in order that a remedy may be effectively applied.

The unit of measurement for a mine under full development is the average annual production that may reasonably be expected under normal trade conditions. To this tonnage unit all other features should be coordinated, inasmuch as a lack of perfect harmony in the adjustment of capitalization, area, and equipment to production will inevitably lead to financial losses for the company and discredit for the management.

There are elemental laws in mining that cannot be violated without the payment of a penalty.

The prudent manager, who is to be responsible for operations and profits will, at the inception of the organization, submit to his stockholders a concrete plan, based upon his own experience and that of others, that will give the greatest measure of protection to the capital invested during the full life of the plant.

Capital is not well protected if the number of dollars invested, outside of the free land, is largely in excess of the number of tons of coal produced per annum. For instance, an ordinary mine with 150,000 tons production may protect a sinking fund and pay 6 per cent. (9 cents per ton) on stock and bond accounts aggregating $225,000, but if we double this capitalization and make an investment account of $450,000 ($3 per ton) there is a capital charge of 18 cents resting against every ton of coal production—which is more than many of our mines can stand. If, by reason of extra construction costs for deep shafts, long railroad connections, or unfavorable topography, the investment is to be materially increased above the normal ratio to the ton of production, the prudent manager will advise against the undertaking.

A manager who will persistently add to his production cost sheets an allowance for interest on capital invested, will put a stop to many of the ruinously low quotations made by the sales departments.

Many companies are capitalized upon the tonnage they hope to attain, and meet with disappointment through failure to secure the anticipated output. In this connection, it is interesting to study the performance of the mines in West Virginia for the year ending June 30, 1909, as compiled from the records of the mining department.

Production		Per Cent.
Total number of producing mines	709	
Number producing over 100,000 tons	129	18.2
Total production June 30, 1909	41,693,766	
Production from 129 large mines	22,248,264	54 4
Total number men (excluding coke)	58,582	
Number of men in 129 mines	26,377	45
Average production 709 mines	58,806	
Average production 580 mines	33,527	
Average production 129 mines	172,624	

Mines Producing Over 100,000 Tons Per Year

Thickness Seam	Number Mines	Tons Production	Average Per Mine Tons	Number Men Exc. Coke	Number Tons Coal Produced Per Employe
3′ 5″ to 4′ 0″	8	1,167,277	145,910	1,531	762
4′ 4″ to 5′ 0″	24	3,675,086	153,128	4,772	770
5′ 2″ to 6′ 0″	34	5,623,093	165,385	6,843	822
6′ 2″ to 7′ 0″	26	4,502,712	173,181	4,730	952
7′ 3″ to 8′ 0″	28	5,239,507	187,125	6,591	795
8′ 4″ to 9′ 0″	6	1,457,113	242,852	1,222	1,192
Over 9′ 0″	3	583,476	194,492	688	848
	129	22,248,264	172,624	26,377	843

From the foregoing table it appears that an average mine in coal running from 4 feet 4 inches to 5 feet, inclusive, producing 153,128 tons per year, will need 198 employes. In an isolated district, tenements, outside of boarding houses, may be provided on the basis, approximately, of 70 houses per 100 employes, but there can never be an arbitrary rule, and each company will find a profit in studying its own conditions and building upon some well defined system. Too many houses are a drain upon capital, and a shortage may hold a mine below its productive capacity.

The profits of a company are derived from the labor performed by its employes, and any impairment in the energy of the individuals engaged in the work will lessen the ultimate income from the business.

Villages located a mile or more from the mine, involving travel through snow and rain, heat and cold; a mountain path badly graded, surfaced, and drained; slovenly, uncomfortable travelways underground—each of these conditions, if allowed, will cause a waste of energy that must be paid for by the company, whether the labor is producing coal under contract or handling it for a day wage. The wise manager will place his men at their working stations in the freshest condition possible for humanitarian as well as economic reasons.

The manager who, to avoid solving a problem, adopts the motto, "The future will take care of itself," concedes that those who are to come after him will have an ability greater than his own. There are very few mining conditions, aside from concealed troubles existing underground, that cannot be provided for at the opening of a mine.

To begin with, there is the question of acreage to be mined from one plant. We must hold that there are certain economical limits in haulage distances beyond which a mine cannot go without undue cost. It is, therefore, a waste of money if acreage beyond the haulage limit is added to a lease and the company must pay a minimum royalty per acre.

When the lease lines are definitely fixed, a careful estimate should be made to show approximately the number of tons of coal to be won. Divide this estimate by 25—a fair number of years for a mine—and the answer will be the number of tons per year for which equipment should be provided. In some cases, however, there may be reasons for exhausting the coal in less than 25 years. When this condition is presented, economize in construction work and use material that will answer for the life of the mine only. There will be no profit in stone power houses, slate-roof tenements, high concrete foundations, etc., in connection with a mine that is to have a short life. In other words, harmonize every item of construction with the length of time it is to serve—temporary, if the work is to be temporary; permanent, if the service must run many years. But, under any and all circumstances, the best qualities to be obtained cannot be too good for roadways, motive power, and cars.

The purpose of this short paper is to quicken the interest of our mine managers and superintendents in matters that are frequently left to the decision of others. You are given mines to operate that may be so handicapped by over-capitalization, under equipment, excessive royalty guarantees, etc., that dividends to stockholders can never be realized and losses must surely accrue. It is not necessary to enter into details as to the manner in which these propositions shall be handled, but let me urge each manager who is here today to seek for a true balance between the capital invested and the tonnage to be produced. You are entitled to protection for your reputation, and stockholders are entitled to protection for their investments. You will both suffer when a mine, designed by nature for a small tonnage, is given an expensive equipment, or a mine that has great natural advantages is unduly restricted in its outfitting. Strive for harmony between capital account and betterments on one hand, and your actual output on the other, and the profit and loss account at the end of each year will be closed on the right side of the books.

Sykesville, Pa., Explosion

Mention was made in the August issue of Mines and Minerals that an explosion in which 21 lives were lost occurred Saturday, July 15, at Sykesville, Pa. Judging from the conclusions drawn, the statement made concerning non-gaseous mines giving a sense of false security seems not to have been overdrawn in this case.

Sykesville is a small mining town on the Buffalo & Susquehanna Railroad, in Winslow Township, Jefferson County, Pa. At this place there is a shaft 180 feet deep that taps the lower Freeport or D seam. The mine belongs to the Cascade Coal and Coke Co., of Buffalo, N. Y., and is not a commercial mine, the product mostly being converted into coke in 200 beehive ovens and shipped to the company's furnaces at Buffalo. Considering that the mine was opened in 1904, the area covered by the workings is quite extensive, the main haulage road being 9,000 feet long. The mine is worked double entry, room-and-pillar system, and the rapid advancement of the main entries is due to the fact that no pillars have been removed. Approximately 200 men are employed on night and day shifts in the mine, and on the night of the explosion there were 29 men inside, eight of whom, including the fire boss, escaped. The fan, under normal conditions, at 80 revolutions and water gauge of $\frac{9}{10}$ inch, produced 74,400 cubic feet of air per minute. The ventilation was conducted in three splits and returned into a third shaft. The relief doors of the fan were blown open by the force of the explosion, remaining open 15 minutes, as indicated by the pressure gauge. The fan was otherwise uninjured and continued running. All the bodies were recovered within 24 hours after the explosion, and some of them being slightly burned it is presumed that the remainder died from afterdamp inhalation.

On July 18 and 19, Inspectors Thomas D. Williams, Elias Phillips, Joseph Knapper, Chas. P. Byrne, and Chas. P. McGregor, appointed by Jas. E. Roderick, Chief of the Department of Mines, of Pennsylvania, made an official investigation. From the inspectors' report to their chief the following is gleaned: "There was no indication of an explosion at the bottom of the shaft, nor until 4,000 feet had been traveled along the main entries. Near the sixth right entry a door was blown out toward the face. For a distance of 1,200 feet up this entry to a point near the fourth butt entry evidences of an explosion were plainly visible. From the fifth butt to the fifth right entry, and from the sixth butt to the seventh right entry and along these entries, there was no evidence of an explosion, until, 800 feet from the south main entries on the seventh cross-entries, stoppings were found partly destroyed. Along the left eighth main haulage road there were electric wires down and stoppings on the left were blown down in the direction of the airway. In the second butt left, explosive gas was found, and a 6-inch air line broken by the force of the explosion in the back heading second butt, eighth left, or air-course opposite right. The third butt was in a normal state, although some gas was generating. In the fourth right butt some explosive gas was found and compressed air blowing from pipe. Going along the left main entry to the third right butt, a large fall of coal was found and evidence of an explosion that had spent itself with a considerable division of inward and outward force. Farther in the third right butt, fine coal was found adhering to the ribs, and the cars had been charred with flame. There was considerable heat here and evidence of force. A large cavity in the roof, made in the course of mining, was filled with explosive gas and the atmosphere was charged with so much marsh gas that difficulty was experienced in reaching the face. The air-course to the third right butt was partly closed by the explosion knocking out timber and allowing the roof to fall. At this point along the eighth left main back to second left butt, 14 cars were badly wrecked and thrown across the entry. The flame originating in the third butt right traveled 1,200 feet from point of ignition. In the ninth left entry there were some falls, the cars were wrecked, tracks torn up, and stoppings blown out. In the ninth left and back entry explosive gas was generating. Open lights were exclusively used in these mines. The stoppings used for guiding and directing the ventilation were built of bony coal and refuse from the mine, with the exception of the shaft bottom, where they were built of masonry."

The conclusions of the inspectors were as follows:

"1. That explosive gas having accumulated in dangerous quantities in the third right and parallel entries, we are of opinion that a door on the eighth left used in conducting or directing ventilation into said third right was left open.

"2. That the gas was ignited by the flame of an open lamp or the flame of a blast fired in the coal at the face of the parallel entry to said third right.

"Owing to the fact that there was considerable explosive gas generating in the advance workings on the eighth and ninth left entries, rendering the mine unsafe, we recommend, in order to prevent the recurrence of another such accident, the following precautions:

"1. That all stoppings between inlet and return airways be constructed of concrete, brick, or stone.

"2. That permissible explosive that has passed the test of the Government Testing Station be exclusively used hereafter for blasting.

"3. That all shot holes be tamped with incombustible material and all shots fired by electric batteries in the hands of competent shot firers.

"4. That electric wires, where installed, be kept on intake airways where locked safety lamps are used.

"5. That all the workings at face of south main headings and all workings to left of south mains be worked exclusively with locked safety lamps."

Coal Dust and Zone Systems

Discussion on E. O. Simcock's Paper Printed in August Issue Mines and Minerals

The following is an abstract of the discussion of the paper by E. O. Simcock*, which appeared in the August number of Mines and Minerals, and which was printed complete in the Transaction of the Institution of Mining Engineers, Vol. XL, Part 1, page 37.

In the discussion A. M. Henshaw understood that Mr. Simcock had taken the opinions and evidence on record of a number of people, and had attempted to show that the conclusions they drew, and even the facts upon which they based their conclusions and arguments, were, if not absolutely wrong, open to grave question. In the paper and illustrations which they had before them, Mr. Simcock had embodied a good many facts that Mr. Henshaw thought had been sufficiently proved, and figures that, so far, had never been disputed.

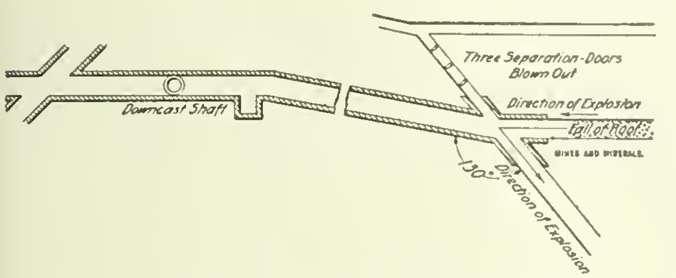

Fig. 1. Part of Workings at Blackwell Colliery

Fig. 2 related to the Talk-o'-th'-Hill explosion, and Fig. 1 was taken from Isaac Hodges' evidence. Mr. Simcock went so far as to contend that no matter whether the zone were dustless, wet, or a zone containing inert and incombustible material, it was incapable of stopping an explosion. All three contentions had been already proved, not only by the advancement of theories based upon experience, but by actual explosions underground. In the case of the Talk-o'-th'-Hill explosion, there was sufficient evidence to show that inert material actually did stop an explosion, and if Mr. Simcock would go further in his investigation he would find other cases where stone dust or inert material did actually stop the explosion, and where wet roads had also stopped it. That was also proved at Courrieres, and the figures that were given of the analyses of dust in the paper on the Courrieres explosion†, by Mr. Atkinson and himself, were not disapproved nor their value discounted, by anything that Mr. Simcock had told them. Dealing with Fig. 1, that was Mr. Hodges' explanation of the arresting of an explosion at the Blackwell Colliery. Mr. Simcock, however, advanced the theory that when the explosion, coming out of the level road to the right, reached the corner by the three cross-roads, it met with an obstruction because the road was not straight, and that that obstruction caused a rebound, the rebound preventing the explosion from advancing in the direction of the shaft. If that part of his argument were of any value, how was it that an explosion traveled through a pit at all? Why did it not rebound and stop the advancing wave, or the pioneering wave, at almost every considerable bend in the road? He, however, did not entirely base his argument upon that, but also on the reduction of pressure of the pioneering wave, when it met with the cross-roads and had to be diverted in different directions. At that point it was diverted in three directions. Mr. Hodges said that the roadway from that point to the pit bottom was free from dust, and that was sufficient reason why the explosion did not advance to the shaft. His recollection, was that Mr. Hodges stated that the roadway to the right, in which there were three doors, was comparatively free from combustible dust. He believed that it was the airway, and, in the ordinary course, there would be very little coal dust in it. That the absence of dust stopped the explosion was sufficient for Mr. Hodges to base his argument upon. Where the explosion continued, namely, down the slant to the left, there was sufficient dust to carry it, and that was why the explosion followed that direction. If there was anything in Mr. Simcock's argument of the reduction of pressure when the explosion was diverted in different directions, then he asked: Why did it go in any direction at all? Why did it follow the downward road? It could only have followed that because there was something to propagate it, and that was the dust in that road.

Mr. Simcock went on to say that the explosive wave met with the obstruction of the doors, and that the rebound helped to stop the explosion. Mr. Henshaw believed that if there was an explosive wave going along a road, there was no ordinary door that would stop it. It would go through many miles of roadway and hundreds of doors, and in many places it seemed as though the more obstruction it received, the greater was the pressure and the more violent the explosion.

Mr. Simcock's argument was that the explosion met with some obstruction, Fig. 2, which acted as a back lash, and prevented the explosion from going in that direction, although there was sufficient dust to take it there. He was sorry that he could not agree with that explanation, and he would go further and say that he believed that if an explosion was advancing along a sufficiently dusty roadway and creating compression therein, the compression of air was more likely to assist in carrying on the explosion than if there was no compression, which was quite contrary to the opinion that Mr. Simcock expressed.

Referring to the roads, which were mainly "strait" roads, Mr. Simcock had said that as the explosion advanced toward the extreme ends of the workings, the compression there and the consequent rebound would prevent the explosion from going to the face. Mr. Henshaw contended again that compression was more likely to cause the flame to advance to the face than

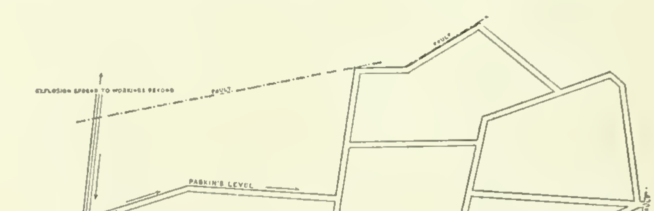

Fig. 2. Part of Workings of Talk-o'-th'-Hill Colliery

if there were no compression at all—that was, assuming that there was anything to carry the flame to the face. Mr. Simcock had raised the question of the volatile matter in coal dust being the necessary ingredient for propagating the flame. He did not think that Mr. Simcock would find anything that he had said or written which supported that statement. His view on the point was this: it was not the volatile matter in dust alone, or the carbon alone, that propagated flame, but the two together.

*Through a typographical error Mr. Simcock's name was spelled Simock in the August number.

†"The Courrieres Explosion," by W. N. Atkinson and A. M. Henshaw Trans Inst. M. E., 1906, Vol. XXXII, page 439.

They must consider coal dust in two parts, the combustible and non-combustible, the combustible being the carbon plus the volatile matter, and the non-combustible being the ashy ingredient. He contended that any dust, anywhere, in any pit, which contained 50 per cent. of ash, was incombustible matter that would not carry forward the flame of an explosion. Mr. Simcock mentioned Captain Desborough's experiments, showing that dusts containing 80 per cent. of inert material were capable of supporting propagation. He did not know anything about those figures; he had never come across them.

Mr. Simcock asked Mr. Henshaw to refer to his own figures —Nos. 3 and 4 of the coal-dust analyses quoted in the Appendix to his (Mr. Simcock's) paper.* No. 3 contained 54.95 and No. 4, 61.15 per cent ash.

Mr. Henshaw said that those were not analyses of coal dust, but analyses of the coke resulting from the burning of the dust. Some of the analyses were of dust; others were of coke. When, after an explosion, they took a sample of the coke, that is, burnt dust, they would find little or no volatile matter. They would find some remains of carbon which was unburnt, but the bulk would be ash, because it was cinder.

Mr. Simcock said that he could not see the difference; he could not understand why they were going to have combustion in one case and not in another.

Mr. Henshaw said that if it had been possible to take some of the dust before the flame passed over it, they would not have found 61 per cent. of ash in it. The 61 per cent. of ash was there after the flame had burnt it.

Mr. Simcock said that he quite saw Mr. Henshaw's point, but Mr. Henshaw did not see his. What he wanted to say was this: in one case Mr. Henshaw said that dust would not burn if it contained only 44 per cent. of ash. Then why should this not cease at 44 per cent.? Why should it go on burning until there was 60 per cent. of ash?

Mr. Henshaw, in reply, said let them take, first of all, a sample of dust which contained by analysis, say, 44 per cent. of ash and 20 per cent. of volatile matter, the remainder being carbon. That might represent the condition of the dust before the explosion. Now, if that dust were passed through a flame, what resulted was this: most of the carbon was burnt, almost all the volatile matter was burnt, and a larger proportion of ash was left. That accounted for the 61 per cent. of ash to which Mr. Simcock was referring.

Mr. Simcock said that he quite followed Mr. Henshaw's argument, but in one case he had said that the dust would not burn with 44 per cent. of ash, and in another case that combustion would go on until there was over 60 per cent. of ash. If the presence of 44 or 50 per cent. of ash would stay combustion, then it would be impossible for combustion to proceed until the ash contents were increased to over 60 per cent.

Mr. Henshaw said that they might take as an illustration the fire in the meeting room. If they had analyzed the coal of which the fire was made that morning, they would have found that it contained about 65 per cent. of carbon and 5 per cent. of ash, the remainder being volatile matter. If they were to take the cinders, the remains of that coal at that moment, and analyze them, they would find little volatile matter, very little carbon, and 70 or 80 per cent. of ash.

Mr. Henshaw said that the zones were in the intakes only, and not in any of the returns, because they could scarcely find a record of an explosion that followed the returns to any extent. The faces generally did not contain enough fine dust to propagate a flame, and the return airways in a mine very rarely had combustible dust in them. Therefore, they only found the flame passing along the main intake roads, along which the coal was carried and pounded into dust by the men and horses traveling along them. If the zones, wet, dustless, or containing inert material, were properly set out so as to divide the workings of the colliery into small districts, so placed as to isolate one part from another, it would be sufficient for them to be in the main intake and haulage roads.

The clearest evidence as to the stoppage of an explosion by a wet road was seen at Courrieres. The end of one of the south branch roads for 200 feet was so wet that it had been necessary to bore a hole in the floor, so as to let the water off into some old workings. The explosion traveled throughout several pits, passing along nearly 30 miles of underground roadway, but at that particular place it was stopped dead. There was no evidence of explosion, of force, of damage, or of flame beyond that wet place, and 21 days after the explosion 13 men walked out from beyond the place in question. They were the only people saved in that part of the mine, and they owed their lives to the existence of the wet zone. Mr. Simcock said in reply to a question: "There was first, a pioneering air-current, which must be able to raise the dust. He did not know of any reason why this current should not be governed by the usual physical laws relating to air-currents in mines, and, therefore, he considered that this current would be amenable to them. The source of power causing the current was the combustion reaction. In the case under review there were two currents meeting, and, after the combustion reaction, they divided at the junction of the main level and Bodge's Dip, Fig. 2, two sources of power tending to meet at the junction formed by the Shaw's Dip and Paskin's Level. The only vent for these two currents was through the upper end of Shaw's Dip. For these combined currents to pass out through this part of the road quickly enough to relieve congestion, the velocity would have to be doubled, and to double the velocity, the power would have to be increased eight times. But, as the source of power was the combustion reaction, it would be inherently impossible to increase it. The propagating action being unable to create power to relieve itself, there was compression there, which, owing to the resilience of the air, reasserted itself against the propagating action, and tended to stop it. The initiation of the explosion was remote from that section of the mine, and the rise in pressure would, comparatively speaking, be gradual, and have little or no effect in raising dust in the two roads. Therefore, the essential factor of the propagation of dust in suspension in the air would be missing, and hence the inability for the propagation of combustion through this mass of compressed air. It was necessary to discriminate between compression with dust in suspension and dust not in suspension."

Mr. Henshaw said that some further facts had been brought to mind: Bodge's Dip was a very dusty drawing road in the Seven-foot Banbury Seam. It was an old and big dip, and had a gradient of 45 degrees. It was, therefore, a very important haulage road. Shaw's Dip was a road with a much lower gradient, in which there were three or four jigs. There were a dozen faults in the dip itself, and there were probably as many men beating up the floor night after night as were employed at the face. Paskin's Level had not been used for a year or two, except as an old airway. It served simply as a means of communication between one road and another, and was only a crawl road. Paskin's Level was a dirt road; Shaw's Dip was a dirt road, because of the beating up; and then there was the dust in the main level and Bodge's Dip. That was why the explosion went up those roads, and failed to go up Shaw's Dip and along Paskin's Level.

Mr. Simcock said he would like to hear an expression of opinion as to the minimum amount of carbon and volatile matter which must be present in coal dust to prevent an explosion. How much or how little carbon must the dust contain before there was an explosion?

Mr. Henshaw said that the main thing was: How much ash or inert material was required to prevent an explosion?

Mr. Simcock said that, with regards to the zone system mentioned, there was a space of 400 yards between the zones, and he could see no reason why the explosion should not gather sufficient dust in the intervals between the zones to pass through

*Trans. Inst. M. E., 1910, Vol. XL, page 49.

them. Mr. Henshaw's contention that if combustion reaction met with dust containing 44 per cent. combustion proceeded no further, was quite incompatible with his remark that the cinder in the grate would on analysis show 70 or 80 per cent. of ash; and this latter remark certainly supported the opinion that the application of inert dust would not be efficacious in staying combustion reaction.

J. R. L. Allott agreed with Mr. Henshaw's theory that the force of the explosion would pass up Bodge's Dip, being a large and dusty one, and would be unable to pass up Paskin's Level and Shaw's Dip owing to their contracted size and the absence of dust.

The lines on which Mr. Simcock was carrying out his research made it imperative that he should accept the facts recorded by observers, but there was a great difference between matters of fact and matters of opinion. For instance, W. W. Hood had made an explicit statement, based upon direct observation of plain facts, that: "The explosion at Clydach Vale Colliery went through 700 yards of wet roadway. This roadway, which was artificially watered, was found to be wet 10 days after the explosion."*

Had Mr. Henshaw said that the propagation of combustion went no farther along the south branch at Courrieres than to the commencement of the wet length, it would have been a plain statement of fact which, coming from a man of Mr. Henshaw's experience, could not have been called in question. But when Mr. Henshaw claimed that the propagation was stopped by the wet length, that was an expression of opinion which, in the face of Mr. Hood's clear statement of facts, required much more material evidence in its support before it could be considered incontrovertible.

It was the fear of unconscious bias that caused Mr. Simcock to take up the research on lines of pure deduction, based upon the recorded facts of other observers, and, from the results attained, he was satisfied that that course was the right one to pursue.

Certainly, such a method of research would not cause him to say that he did not believe in the recorded results of an unbiased experimenter, and he believed that he was able to discriminate between fact and opinion. Even if it could be proved that the wet length of 70 yards in the south branch at Courrieres, or in the Old South return at Talk-o'-th'-Hill did stop the propagating action in those particular cases, so long as Mr. Hood's record of 700 yards of wet roadway having failed to stay propagation stood, no security could be assured by the existence of wet zones.

Mr. Henshaw had variously stated that, in his opinion, 39, 45, and 50 per cent. of inert material would stay combustion. These seemed to be mere expressions of opinion on the ascending scale. However, as concrete quantities had been mentioned, it ought not to be impossible to calculate fairly concrete results from them. Taking a cubic foot as a unit of volume upon which to base such results, in conjunction with the higher percentage of inert material given, then, a cubic foot of air weighed approximately 560 grains, and, without reference to the minute quantities of argon, watery vapor, etc., would be made up of 432 grains of nitrogen and 128 grains of oxygen. As the density of air in reference to the solids which entered into the action was, at least, as 1 is to 1,000, and the quantity of solids introduced was only about 500 grains, the loss in weight due to mechanical displacement of air by them was negligible.

The density of carbon as a gas was 12, and oxygen, 16; therefore the 128 grains of oxygen would require 96 grains of carbon for its reduction to carbon monoxide, and in this reaction would give an excess of about 32 British thermal units of heat. If the dust of the Banbury coal were taken, 147 grains would be required to give this amount of carbon, without reference to the carbon contained in the volatile constituents. Taking the round number of 150 grains, the cubic foot of mixture would contain the following:

	Grains
Nitrogen	432.00
Oxygen	128.00
Carbon	97.95
Volatiles (as methane)	49.80
Ash	2.25
Inert material	150.00
Total weight	860.00

The specific heat of this mixture would be about .25, taking water as 1. The theoretical surplus quantity of heat which a cubic foot of this mixture would give by chemical reaction to carbon monoxide was about 32 units; therefore, its temperature under equal pressure would be 1,042° F. (561° C.). This temperature was below that of the ignition of the volatiles taken as methane, so that the volatiles—at least, at this stage—did not enter into the reaction. Proof, therefore, must be forthcoming that the other combustible material would ignite below that temperature. Sir Henry Hall had recorded the ability to ignite coal at a temperature of 752° F. (400° C.)*, and Dr. P. P. Bedson was able to ignite coal dust with a current of heated air at a temperature of only 291° F.† These were experimental facts, and as the temperatures mentioned were considerably below the temperature of the ignition of the volatiles, it was reasonable to infer that it must be the other combustible constituent of the coal dust that entered into the reaction of combustion. The writer could adduce further proof of this, but he felt that the foregoing was sufficient evidence for the present.

If a smaller quantity, down to 50 per cent. of the carbon mentioned, entered into combination with the oxygen given, there would be a considerably larger quantity of heat liberated, and, consequently the temperature would be higher. So that, by further increasing the inert material to 75 per cent., there seemed to be a better chance of more complete combustion. Fine division and complete mixing with the air would still further ensure this. The temperature also might be raised to above the ignition point of methane; hence, there was still a reserve of material to combine with any stray oxygen or to allow for further adulteration with inert material. The inert material would take up, but not retain, the excess heat, and as it would deliver it up quite as freely as it had taken it in, the presence of such material merely served as a regenerator receptacle. It might be remarked, as would be observed in the foregoing calculation, that the oxygen was the only combustible quantity which could be relied upon as being fairly constant.

From the foregoing remarks it might be gathered how little reliance could be placed upon the inert-material treatment, either complete or in zones. But to discuss the possibilities of this proposed treatment was, in the writer's opinion, as useless as beating the air, for as there was comparable authoritative evidence upon record of the insidious indirect results of inert-material dusts, even if it were incontravertibly proved that the application of such would prevent colliery explosions, the disastrous and fatal results following their use would be out of all reasonable proportion to the disease which they proposed to cure; and it was doubtful whether any one fully comprehending those results would have the temerity to recommend their use.

The theoretical water gauge of a fan is computed from the following formula:

$$\frac{V^2 \times .078}{32.2 \times 5.2}$$

Where V = peripheral speed of fan in feet per second;

32.2 = g. acceleration due to gravity;

.078 = weight of cubic foot of air;

5.2 = pressure per square foot for 1-inch water gauge.

If a fan is running at $80\frac{1}{3}$ feet peripheral speed per second we have

$$\frac{(80\frac{1}{3})^2 \times .078}{32.2 \times 5.2} = 3 \text{ inches theoretical gauge.}$$

Coal Production in Japan

Locations of the Different Coal Fields, their Extent, Output, and Development

*By T. Haga**

It is not long since Japan awakened from her centuries of slumber. In fact, since the usage of coal became feasible, scarcely 30 years have elapsed. Although the output in 1880 was 880,000 tons only, in 1890 it was 2,620,000 tons; in 1900, it had increased to 7,470,000 tons; and in 1910 it reached the enormous quantity of 15,540,000 tons, and 55,500,000 yen† in value (Manchurian output excepted). Coal occupies the foremost position of all minerals in Japan, representing 54 per cent. of the total mineral production. Also in exportation it leads the others, standing at 2,820,000 tons, having a value of 16,300,000 yen ($8,117,400).

The different coal fields are as follows: (1) Kyushu coal fields; (2) Hokkaido coal fields; (3) Northeastern coal fields; (4) Formosan coal fields; (5) Korean coal fields; (6) Saghalien coal fields; (7) Manchurian coal fields.

What is called Kyushu coal fields, in the southern part of Japan, produces 80 per cent. of the total coal output, or 12,420,000 tons. There are in all 1,495 properties, covering an area of 270,000,000 tsubo.‡ The principal operation is the Miike mine, situated on the frontier between Chikugo and Higo provinces, Fukuoka Prefecture, facing the Omuda port. This is owned by Mitsui magnate. The coal in this property is extensive and of good quality. Though there are a number of coal beds, only two are at present operated, one of which averages 8 feet thick, but measures in some places 200 feet thick; the other is from 6 feet to 10 feet beneath the former and is about 6 feet thick. According to last year's statistics, this mine produced 1,768,000 tons. The coaling ports in Japan are all imperfect, and accordingly require an enormous expense for coaling. The Mitsui magnate started the construction work for improving the Omuda port November, 1902. This cost 4,000,000 yen, and was completed in 6 years. It is now called Miike port, and is able to moor three vessels of 8,000 tons capacity. Coal is now loaded into vessels at the rate of 20,000 tons in 24 hours by the means of two machines, making a saving of 800,000 yen per annum. Besides this mine, those which produce over 100,000 tons number 28 in these districts. The greatest number of mines are in Fukuoka Prefecture and these produce over 90 per cent. of the total production in Kyushu, or 10,380,000 tons per annum. One property south of Wakamatsu port produces 70 per cent. of the total per annum in these districts, or 7,300,000 tons. This is 8 to 13 miles long by 4 to 9 miles broad, and is known widely as the Chikubu mine. It produces 50 per cent. of the total output in Japan. All the coal is hauled to Moji and Wakamatsu ports, thence is distributed to various ports.

The Kyushu coal fields are at present the most prosperous, furnishing the greater part of the export coal; nevertheless, as this prosperity has reached a climax, there is every indication that these mines are disposed to be declining. After a decade, the leading mines of the Kyushu coal fields will reduce their production. An engineer declares that, according to his estimates, the total coal hereafter to be excavated in the Kyushu coal fields is 500,000,000 tons. At present, every capitalist is planning the establishment of coal operations for the purpose of increasing the coal production.

Next to the Kyushu coal fields, come the Hokkaido coal fields. The leading mines in quantity and quality are in the Yubari, Sorachi, and Horonai districts, east of Sapporo. These cover an area of about 21 miles north to south, by about 5 miles west to east, and have facilities for transportation. The coal in the Yubari mine is estimated to be 300,000,000 tons. The beds are said to be 1,000 feet deep by 4 feet thick. In addition, the other beds that may be operated bring up the total to over 500,000,000 tons. The mines at present in operation have coal beds from 3 to 5 feet thick; in some cases over 25 feet thick. The coal mining in Hokkaido has developed in the past few years. The production of last year was 10 per cent. of the total output in Japan, but the field shows evidences of increasing year by year. Most of the mines are owned by the Hokkaido Colliery and Steamship Co., of which the most remarkable one is the Yubari mine, which produces 480,000 tons per annum. Those mines which produce over 100,000 tons in Hokkaido number at present six, because it is only a few years since coal mining commenced in this part of Japan, but every mine promises to make a remarkable development in the near future. The claims in these districts number 140 and have an area of 80,000,000 tsubo.

Northeastern coal fields contain those in Fukushima and Ibaraki prefectures, in the northeastern part of the Japan mainland. These are ranged on the Pacific coast for a length of 21 miles. They are popularly called Joban coal fields. The annual output in these districts is 1,530,000 tons. Every prefecture in the northeastern part of the mainland abounds in gold mines, but coal is worthy of note in the two prefectures mentioned. The quality of coal stands third and the quantity cannot be said to be abundant. For all that, as these districts are near Tokyo, the consumption is comparatively large.

Formosan coal fields are not worthy of note. These mines have an area of 10,000,000 tsubo, producing roughly 140,000 tons per annum. They are mostly situated in the part of Kylung.

Korean coal fields abound in places in the peninsula. Among the best is the mine 6 miles in length along the Daidoko from Heijo. It is known as Heijo coal, and is used for the Imperial navy.

The Saghalien coal fields are also promising. The area of coal at present known is estimated at 235,670,000 tsubo. The area will, no doubt, be increased by an elaborate investigation going on. The various beds range from 3 feet to over 10 feet in thickness. On the whole, as it is not long since this land was taken by Japan, so it lacks facilities of communication and traffic, by reason of which there are very few who invest in Korea, but the government plans to work the profitable minerals as government enterprises, capitalizing at an enormous sum. The government is encouraging capitalists and engineers to explore these districts for coal.

In the Manchurian coal fields, the mine which is especially noteworthy is the Fushan, under the control of the South Manchurian Railway Co.

Fushan is situated 10 miles east of Mukden. The claim is 1 ri* north-south by 5 ri west-east along the canal traversing this district east-west. This district is reached by a branch line of the South Manchurian Railway, which branches off at the Sokaton station and terminates at the opposite side of a canal beyond Fushan Castle, through Senkiusai, Yohakuho, and Rokatai.

The Fushan mine is divided into two parts, eastern and western. In the western part there is the Rokatai mine, also the Raisan mine near Senkiusai, and Togo mine near Yohakuho, where shafts are in course of construction and will be completed next year.

The coal is of the bituminous variety and has a glassy black color. The coal beds extend 4 miles and in thickness they are rarely exceeded. They measure 174 feet thick in Senkiusai, 120 feet thick in Yohakuho, and 144 feet thick in Rokatai mines. This great field was operated by Chinese hundreds of years ago, when these settled in the capital at Mukden, but on account of the customary superstition, the exploration was strictly pro-

*39 Sakanamachi, Ushigome Tokyo.

†Yen = $.498. Value per ton $1.78.

‡Tsubo = 6 square feet, according to Standard Dictionary.

* Ri = 2.43 miles.

hibited. In 1901, Mr. Oshogo and other Chinese applied for permission to operate the Fushan mine. This was granted, because Mr. Soki, then Viceroy, memorialized their application to the Throne, explaining the absurdity of the hitherto observed superstition. Mr. Oshogo got possession of Senkiusai mine and Mr. Ozu and Mr. Choshisu got the Yohakuho and Rokatai mines. Mr. Oshogo cooperated in this enterprise with Messrs. Ei, Shiyoku, and others, and operations were making progress by degrees, but at that juncture there took place a difference between him and the other three, who brought action before the Mukden Viceroy, but this case did not attract the viceroy's attention. Therefore, he exerted himself to monopolize this mine and by the support of the Russians in Mukden won the case. As some of the expenses of this proceeding were assumed by the Russians, he was obliged to accede one-half of the rights of the mine. On the other hand, Messrs. Ozu and Choshishu also acceded part of their rights to interpreter Mr. Kihotai, who afterwards acceded his rights to the Russians. Thus, at last, half of the western mines and part of the eastern were owned by Russians. In 1902 the Russians planned to develop the coal, and excavated various pits and had the construction work under way, including a branch line of railway, east of Sokaton, when the Russo-Japanese war broke out. Japan occupied Fushan Castle and the whole of the above coal mines March 9, 1905. In April, 1907, the South Manchurian Railway Co. was organized, and at the same time these mines came under the control of the company. As soon as Doctor Matsuda was engaged as superintending engineer he made radical reforms. Moreover, Taisan and Togo mines have been exploited, land purchased for a new town, and many houses built, with waterworks, hospitals, and schools, etc. In 3 years all these improvements have made great progress.

According to the table of output, at the end of last year Senkiusai, Yohakuho, Rokotai, Taisan, and Togo mines produced 722 tons, 949 tons, 32 tons, 62 tons, and 342 tons, respectively, per diem, totalling 3,113 tons in all; of which 139 tons per diem was consumed for the productive use. The remainder, 2,860 tons, was exported. When Taisan and Togo mines are completed, they will produce 4,000 tons. Therefore, in 2 years or so the Fushan mines will produce 7,000 tons per diem.

The principal coal mines and their output are as follows:

Name of Mine	Place	Owner	Output Tons per Annum

The oil fields of Lambton County, Ontario, have been in operation a long time, and are unique because of the small individual production of the wells, which is only a few gallons a day, and of the economy with which they are operated. Being shallow, many wells may be worked by one engine on the "jerker" system, and so give a profit which, if not large, is constant.

Como Mine No. 5

The Method of Working the First Mine in the United States to Adopt Shot Firers and Sprinkling of Dust

*By Joseph Watson**

Como mine, No. 5, which was worked out and abandoned October 1, 1896, was situated near the town of that name on the interior plateau of the Rocky Mountains, in Park County, Colo. Opened at an elevation of 9,500 feet above sea level, making it at that time one of the highest coal mines in the world, its location gave it a distinct market advantage over mines at a lower altitude in saving a vertical haul of nearly 4,000 feet. For this reason, as well as because of the excellent steaming qualities of the coal, practically the entire output was used by the South Park Division of the Colorado & Southern Railroad, with headquarters at Como.

The coal seams in and around Como are "pockety" in character, the one on which No. 5 was opened having an extent

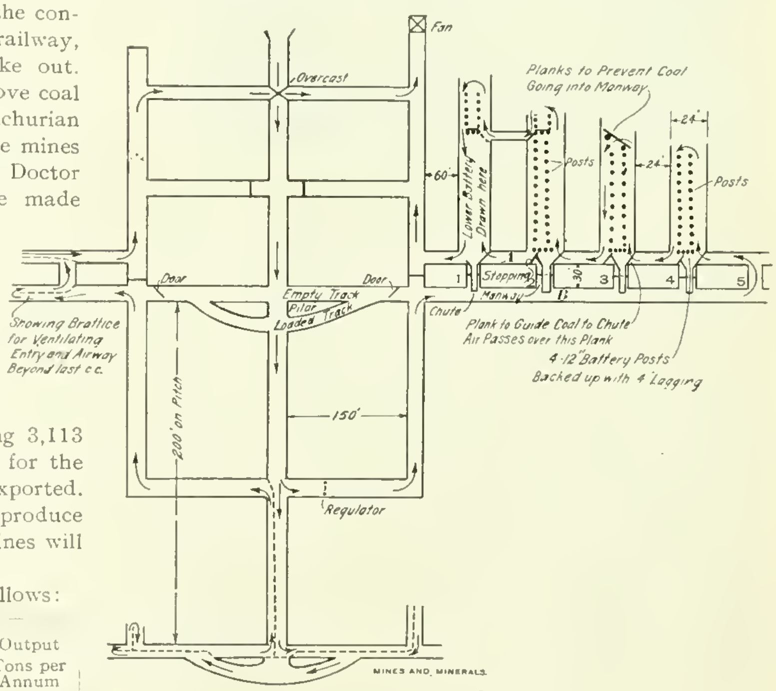

FIG. 1. PLAN OF COMO MINE

of about 1,800 ft. × 3,600 ft. with an average dip to the east of 45° 36'. While the coal averaged 6 feet 6 inches in thickness, it was decidedly irregular, frequently being as thin as 4 feet and rarely expanding to 14 feet.

As the seam made a large amount of gas, and as the coal produced large amounts of highly explosive dust through the attrition of its particles in dropping through the chutes from the face of the room to the entry, or loading level, more than ordinary precautions were necessary to prevent a repetition of the dust explosion of the fall of 1892 in which 26 men lost their lives.

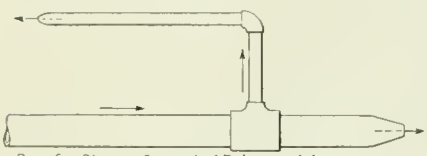
Fig. 1 shows the method of laying out and ventilating the mine. It may be said to consist in general of a three-entry slope driven directly to the dip, from which a single-room entry or level was turned and from which latter the rooms were driven up the pitch. In sinking, the middle of the three slope entries was first advanced 100 feet. At this point cross-cuts were turned both left and right. At 150 feet from the central slope, airways were turned up hill to the fan, the slope being continued downward to the next cross-cut from which, as before, the two airways were driven on the rise to intersect those first

* General Superintendent National Fuel Co., Louisville, Colo.

driven from the upper cross-cut. Each half of the mine was ventilated independently by its own split and the air-current was carried by brattices to the face of each heading and of each of the three slopes.

On the levels, or cross-entries, owing to the pitch of the coal, there was a triangular-shaped space over the cap timbers in which large amounts of gas accumulated. In order to dislodge this, air with a compressor pressure of 80 pounds to the square inch was conveyed to the face in pipes, and a portion of it discharged into this space by means of the connection shown in Fig. 2. It will be noted that another portion of the air was thrown against the face of the entry.

At the slope the loaded track was driven in the rock hanging wall, the empty track only being in coal Connection to the slope tracks was had by means of a hinged door on which the switches were laid, its upper end resting on the slope rails. The air passed around this door and down the slope through holes on either side. When hauling from a lower level the upper end of the door was raised by means of a rope passing to a windlass, thus allowing the cars to pass under it.



Pipe for Blowing Gas out of Entry and Airways

MINES AND MINERALS

Fig. 2

Rooms were 24 feet wide with a pillar of the same size, and were driven from the haulage entry A, with a neck width of 9 feet. After being driven narrow for 30 feet the rooms were connected by cross-cuts which served for a back entry or air-course. The rooms were given the full width on the upper side of this first cross-cut.

Two rows of posts 4 feet apart in the direction of the dip and 10 to 12 feet apart on the strike were led up the room. The inside of these posts was planked with 2-inch slabs, forming a storage chute for the coal. The bottom of the chute or battery was made of four 12-inch posts lagged with 4-inch poles. The sides of the chute were continued to the roof in order to force the air up to the face. On the left side of the chute was a 4-foot wide manway, and on the right side an air-course 8 to 10 feet wide. The chute in the neck of the room, or loading chute, was about 4 feet wide with sides 2 feet high and an end gate which could be raised to let the coal into the mine cars on the entry. At the entry the manway was bratticed shut and provided with a door, and a curtain was hung over the chute to prevent leakage of air. After a room was holed through to the next place on the left, the lower chute was taken up and a new battery built just above the cross-cut. The details of the room work are shown in the illustration.

The coal was undercut as far as possible, say to a depth of 2 feet, and was broken down by shot firers after all but the night-entry shift had left the mine.

Considerable water had to be pumped from the bottom of the main slope against a head of 900 feet. In May, 1895, 1½-inch water lines were laid from the discharge pipe of the pump through the various levels and were provided with hose connections at the mouth of each room, and with an ample quantity and pressure of water, every place in the mine was thoroughly washed down every other day.

According to the United States Consular Report, the mining industry of Spain is undergoing a great change. The miners have become united by large unions, whose influence upon wages and hours of work has been marked. This increased cost of production has caused the installation of modern labor-saving machinery and means of transporting the ore. The daily wages in the different mines range from 32 to 86 cents, and the working hours from 7 to 12. England and Germany are the principal purchasers of Spain's mineral products, though large shipments of iron ore are sent to the United States.

Correspondence

Rolling Friction

Editor Mines and Minerals:

Sir:—In reply to inquiry of W. C. A., June number, regarding rolling friction, if there is any difference at all it would be due to oil freezing in the car boxes, and to overcome this they use an oil in winter termed zero oil, which will not freeze readily, while in summer they use a thick oil which will not melt too freely Decrease of temperature causes an increase of journal friction, but tends to decrease rolling friction on rails, owing to a firmer unyielding roadbed. The reference in the locomotive works catalog might refer to the decrease in steaming capacity of locomotives in winter, which lessens the tractive power. In case of mine cars I would say there is little difference, because mine temperature is nearly constant summer and winter.

J. T. Beard

Editor Mines and Minerals:

Sir:—Replying to your correspondent W. C. A. regarding the friction of mine cars, I am of the opinion that the two frictional resistances mentioned do not refer to the same thing. The first probably refers to the rolling friction, and the second to the journal friction. Undoubtedly, the journal friction would be greater in winter than in summer, as the lower temperature would tend to solidify the lubricants and also to cause some contraction of the parts, thus causing a closer running fit. On the other hand, the rolling friction would undoubtedly be slightly greater in summer than in winter.

To illustrate, assume a dray being drawn over an asphalt pavement in winter when the pavement is hard. The rolling friction under these conditions is comparatively small. During the summer when the asphalt is soft and the wheel depresses it somewhat in passing over it, the rolling friction is much greater. The same would be true in a measure of a wheel rolling upon a rail. The summer temperature might well be 100 degrees or more higher than the winter temperature, and the higher temperature would undoubtedly cause the wheel to depress the rail somewhat more than it would at the low temperature, thus increasing slightly the rolling friction. However, in the case of a wheel rolling upon a rail, working under ordinary conditions, this increase of friction would, it seems to me, be so slight as to be inappreciable; yet there is no doubt but that the rolling friction would thus be very slightly increased.

A. B. Clemens

Double Explosions from Powder

A correspondent writes: "There were three holes drilled 5½ feet each, in which three sticks of powder were used in each hole. These were tamped with clay and fired with a detonating cap. The three shots exploded six times with the three detonators. What caused the three extra reports?"

It is rather difficult for one to account for this phenomenon, but as a general theoretical explanation to explain the double reports it might be stated that the formula under which the powder was manufactured was not balanced properly in its supply of oxygen, and since the lack of oxygen was subsequently supplied from the air, secondary explosions resulted.

Questions of this kind have been received several times since the use of quick explosives has become common in coal mines.

Correction

In our last number, in a foot note accompanying an article on the Waterfall Chute, Mr. Paul Sterling, M.E., was mentioned as Mechanical Engineer of the Lehigh and Wilkes-Barre Coal Co., instead of Lehigh Valley Coal Co.

Electric Mine Lamps

Description of a Practical Storage Battery Lamp Especially Designed for Use of All Classes of Mine Employes

*By J. T. Jennings**

During 1908 the management of the Philadelphia & Reading Coal and Iron Co., awake to the dangers and disadvantages of the open-flame miners' lamp, and considering the benefits in safety, efficiency, and cleanliness an electric lamp would have over the ordinary open-flame oil lamp in the hands of a miner, arranged a systematic plan to investigate the possibilities of the development of a practical electric storage-battery lamp. A canvass of the United States showed that no electric miners' lamp existed at that time, and that practically no serious thought had been given the matter.

It was therefore evident to Mr. W. J. Richards, vice-president and general manager, that to secure the desired lamp it would be necessary for the electrical department of the company to devise and develop one that would meet the requirements. Naturally, the first requirement was a storage battery that would be light in weight, small in size, and reliable in action. The first experiments conducted were with various cells of the alkaline type, and lead type, with the result that the pasted cell was selected. It was soon demonstrated that a liquid cell was not practical because the electrolyte could not be prevented from spilling and destroying the miner's clothing, also that the vertical type cell could not be constructed to satisfactorily retain the active material, and prevent short circuits.

Subsequent experiments proved that the "Hirsch" type of cell met the conditions better than other types. This battery consists of two electrodes arranged on a horizontal instead of a vertical plane, the plates being separated by a combination of wood fiber and perforated hard rubber substance.

To prevent the spilling of electrolyte, tests were conducted with the view of finding some method of solidifying it. A material was found, which, when treated with acid, forms gelatinous silicic acid, which sets to a congealed jelly-like substance in about 30 minutes after charging. Some difficulty was experienced in getting the proper mixture, which would at the same time form a congealed mass without causing too much internal resistance in the cell.

The dimensions of the batteries in most of the equipments are 2 in. × 3 in. × 4.5 in., but the size of those manufactured now is 2 in. × 3 in. × 4 in. It is provided with a belt support, weighs but 2 pounds, and is capable of supplying electricity for a 3-candlepower lamp, at 2 volts, for 12 to 14 hours.

FIG. 1. LAMP OUTFIT COMPLETE

While the battery, as described above, is giving good results, the electricians and engineers of the company are now conducting experiments on various substances as an absorbent for the electrolyte, by means of which they desire and hope to accomplish three purposes; viz.: To effectively prevent acid leakage; to positively hold all active material in place; and to reduce the internal resistance of the cell to a minimum. The results now being secured are very gratifying.

* Electrical Engineer, Philadelphia & Reading Coal and Iron Co., Pottsville, Pa.

Next to the battery, the important features of the outfit are the cord, reflector, and lamp. The outfit was in use but a short time when serious cord troubles appeared, caused by the various positions of the miner when working, and by perspiration saturating the cord and destroying its insulating properties. Specially constructed cords have practically eliminated all troubles from this source.

FIG. 2. ELECTRIC LAMP OUTFIT AS WORN

To obtain the greatest efficiency in light from the 2-volt cell, a special high-efficiency Mazda lamp is used in connection with a strong parabolic reflector producing a clear light with no shadows. The lamp is protected from injury and dirt by a heavy clear glass front. A view of the entire outfit is shown in Fig. 1.

The manner in which the miner wears the outfit is shown in Fig. 2. The battery, weighing, approximately, the same as a driver's oil can (2 pounds) is supported on the hip by the belt usually worn by the miner, though some of the men prefer the support suspended over the shoulders. The circuit from the battery to the lamp is completed by a special flexible cord worn under the clothing, thus protecting it from damage. The lamp, reflector, and cord are detachable from the cap and the battery.

In the earlier outfits the current was turned on and off by a switch on the outside of the battery, but that has been eliminated, as the mere insertion of the small pins, or plugs on the ends of the cord into the proper sockets on the battery turns on the light, and the pulling out of one breaks the circuit and extinguishes the light.

One small feature that also proved a good one was the provision of a short tape fastened to the cord directly above where it branched to run to the two poles of the battery, and made a trifle shorter than the divided cord. This tape is provided with a flat hook on its loose end which slips into a receptacle on the outside of the battery, and its function is to prevent the connections with the batteries being broken. That the lamp is a practical one is evidenced by the fact that it not only furnishes a better light than the ordinary lamp, but all things considered it is more convenient. By means of the reflector used the rays of light are thrown further, and the miners soon become accustomed to bend the head so as to throw a comparatively strong light on any point they desire. Or, as the lamp is easily detached from the cap, it can be taken in the hand and the rays can then be thrown wherever desired. When attached to the body by either a belt or by a shoulder support the battery is out of the way, does not interfere with free motion of the body in any direction, and its weight is not felt. The cord does not interfere in any way with free motion. A man wearing the outfit can put himself quickly in any position without restraint. He can use a pick, drill, or shovel, set timbers, lay rails, pick up and lay down materials, or do any work desired with as much or more freedom than when wearing an ordinary miner's lamp, and in addition, he does not experience the nuisance of smoke, dropping oil, or the usual mess incident to the oil lamp. At this writing there are about 1,000 of these lamps in use at the Philadelphia & Reading Coal and Iron Co.'s collieries.

The recharging of batteries and the care and maintenance of the lamps is usually done at a station located in the safety-lamp house. The man in charge of the safety lamps also charges the batteries, except at mines where a large number of the electric lamps are in use. In the latter case a battery man is employed.

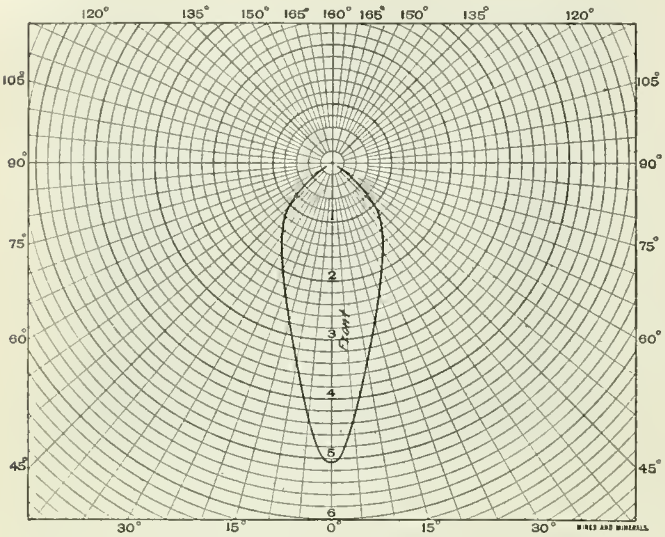


Fig. 3. Light Distribution

Fig. 4 shows the interior of one of the charging stations. The charging apparatus consists of a series of racks for supporting the cells arranged so that the batteries are always placed in the same position where the wire connections are easily made in such manner as to prevent any reversals. Direct current from the ordinary mine-haulage circuit is used for recharging. An ammeter indicates the proper charging current, a voltmeter the conditions of charge, and a rheostat or bank of lamps controls the charge, the rate of charge being 2 amperes for 8 hours, followed by 1 ampere for 1 hour. This permits as many as a hundred batteries in series being charged from a 250-volt circuit. A system of numbering the batteries is arranged for record purposes, each miner retaining the same battery, receiving it from, and returning it to the lamp man, who inspects, cleans, recharges it, and makes any necessary repairs.

Fig. 3 is a graphical chart showing the candlepower distribution of the lamp due to the reflector. As shown, the 2-candlepower Mazda lamp, in practice, yields as much light as a 5-candlepower lamp without a reflector.

It is not the intention of the officials of the Philadelphia & Reading Coal and Iron Co. to replace safety lamps with the new electric lamp. They realize that the safety lamp has a field of its own which cannot be encroached on, although the electric lamp has been thoroughly tried out under gaseous conditions and proved absolutely safe because of its low voltage, and also because no air can get to the incandescent filament. Most satisfactory results are being obtained with the Hirsch lamp by all classes of mine employes, and its use around stables and other buildings where inflammable materials are necessarily stored is particularly recommended. In dry portions of the mine where considerable timber is used, and for the use of repairmen employed in timbering on slopes and in main headings, it is especially valuable, as all danger of fire is eliminated. Fire bosses equipped with the electric lamp, in addition to the safety lamp, are enabled to make more thorough and extensive inspections of working places, and to do their work in a safer and more expeditious manner.

The Two-Million-Dollar Trespass Suits

The much heralded suits involving upwards of $2,000,000 damages brought by Mrs. Annie E. Ott *et al.* against the Berwind White Coal Mining Co. were, after numerous postponements, decided in favor of the defendant company, at the June term of the Somerset County, Pa., Court.

The large amount of damages claimed, the attack on the integrity of the established nomenclature of the coal measures, and the prominence of the witnesses summoned, made the case one of the most celebrated ever tried in the courts of Western Pennsylvania.

The contentions of the plaintiff, Mrs. Annie Ott, were (1) that the Berwind-White Coal Mining Co. was mining the C′, or Upper Kittanning, seam of coal beneath her farm, which the Berwind-White Co. did not own, and therefore had no right to mine; (2) that the defendant was not mining the B, Miller, or Lower Kittanning seam, the mineral right of which was owned by the company; (3) that through reckless methods of mining, the defendant had irreparably ruined the surface of the plaintiff's farm and destroyed the springs upon the property, for all of which the plaintiff prayed that remuneration to the amount of $1,071,914 be awarded. This amount, together with the claims of the other plaintiffs, amounted to $2,160,000.

The principal point at issue was the identification of the coal bed being mined at the No. 30 colliery of the Berwind company. Although for nearly 9 years, more or less trouble was experienced from the owners of some of the farms, it was not until 1906 that suit was brought and then suddenly withdrawn by the plaintiff. Two years later, the suit recently decided was brought by the same party, but, in addition to the damages asked for the coal removed, a second claim for damage to the surface was included. Between the bringing of the first and second suits, a large number of diamond-drill holes had been sunk by the plaintiff and her associates to bolster up their claim that the bed being mined is the C′, or Upper Kittanning, seam.

To offset or verify the records reported, the company sunk several holes in practically the same territory. In both holes sunk by the plaintiff, the horizon of the Upper Freeport seam

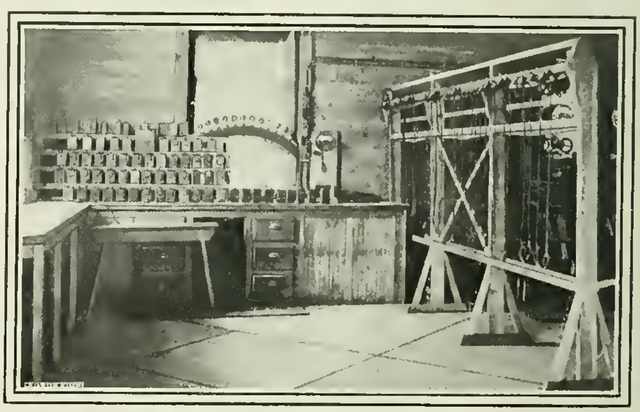

Fig. 4. Charging Station

was represented by a small bed of coal in one, and slate and fireclay in the other, and in both these holes, the Upper Freeport limestone, which occurs some 12 feet below the coal bed, was replaced by sandstone, while above it the usual slates and shales had been likewise replaced by sandstone. Notwithstanding the fact that all the other beds in the series were present at the usual intervals, the geologists of the plaintiff were led into incorrectly correlating them by beginning to letter from the lowest bed; hence the entire set of seams received letter designations entirely different from those by which they had been known for nearly 40 years. All the regular beds of the series were represented by coal or their horizons by slate, shale, or fireclay. Since two coal beds had been introduced into the section of the Lower Productive series, in addition to the seven seams usually present in this series, it became necessary, in order to account for this newly proposed nomenclature, to designate one regular member as an "unnamed bed," and to do absolute violence to the section by placing the Upper Freeport coal in the Conemaugh series.

The three limestones of the series, the Upper Freeport, Lower Freeport, and Johnstown Cement limestone were found in many of the drill holes and in all of the open cuts on the hillsides on the farms adjoining the Ott property.

The Upper Freeport coal in the No. 7 drill hole was represented by a seam of coal 1 foot 3 inches thick enclosed between shales 4 inches and 6 inches thick, while in the No. 10 hole, a soft fireclay and fossiliferous shale 2 feet 6 inches thick indicated its horizon. In both these holes, the Upper Freeport limestone had been replaced by sandstone, the bottom stratum containing pebbles about the size of a pea or less. This replacement of the limestone and the absence of the shales and slates usually found between the bottom of the Mahoning sandstone and top of the Upper Freeport coal deceived the plaintiff's geologists and led them to believe that the highest coal cut was the Mahoning seam.

As this limestone and the coal were always found in other drill holes and shafts in the immediate vicinity, it was apparent that the conditions on the Ott farm were abnormal.

With such weak evidence as this, the plaintiff's geologists attempted to attack the well-established and long-accepted nomenclature of the Lower Productive series, but fortunately failed signally.

In the section in controversy, some of the best sections of this series have been developed, for not only are the Mahoning and Homewood sandstones forming the upper and lower lines of demarkation between the Conemaugh and Pottsville series present and visible, but all of the seven coal beds and the three limestones.

The resemblance of the C′, or Upper Kittanning, and the B, Miller, or Lower Kittanning, seams in the territory, to the same beds in other localities where no question as to their identity had ever been raised was remarkably striking. It is hard therefore to see how even an ordinary geologist could be led into drawing such erroneous conclusions, and advise clients to spend thousands of dollars in bringing a suit where there was not the slightest possibility of winning before an unprejudiced jury.

The trial lasted for 6 days, but at any time after the testimony of the plaintiff's witnesses had been given, the trial judge would have been entirely justified in ordering a non-suit. The Berwind-White Co.'s attorneys would not make such a request, preferring to have the jury pass upon the case.

At the opening of court on Monday, June 5, the plaintiff, through one of her attorneys, requested Judge Kooser to instruct the jury to find for the defense and to enter non-suits in the other cases, which was done. Thus ended a case which should never have been brought, for there was nothing upon which to base it.

Society Meetings

The council of the Institution of Mining and Metallurgy has, on behalf of the institution, accepted an invitation from the Canadian Mining Institute to hold a joint meeting in Ottawa or Montreal about the first week in March, 1912. The exact date and other information in regard to the meeting will be issued in due time, but it may now be stated that it is proposed to arrange a visit to one or two important mining camps to follow the meeting.

The executive committee of the American Mining Congress, J. F. Callbreath, secretary, has given notice of the annual meeting of the members of the American Mining Congress, which is to meet at the La Salle Hotel, Chicago, Ill., on Tuesday, September 26, 1911, at 7:30 o'clock p. m., for the purpose of electing one director to hold office for 1 year, one director to hold office for 2 years, five directors to hold office for 3 years, to succeed John Dern, B. F. Bush, S. A. Taylor, James Douglas, and Carl Scholz, whose terms of office expire, and Geo. W. E. Dorsey, deceased; and for the transaction of such other business as may be properly brought before said meeting.

The Disposal of Ashes at Mine Boiler Plants

The Philadelphia & Reading Coal and Iron Co. has adopted a method of disposing of ashes at their large boiler plants, located on hillsides, that is worthy the attention of mine managers generally, on account of its simplicity, efficiency, and economy.

In front of each line of boilers there is a trench of sufficient depth to accomodate a flume lined with semicircular steel plates 16 inches in diameter, set at a grade of about ½ of an inch to the foot. Where the grade is ⅛ inch to the foot satisfactory results are secured, but the slightly heavier grade is preferred. In front of each ash-pit door this trench containing the flume is provided with removable covers *a* which can be readily taken off or put on. The construction of the flume is shown in plan and section in Fig. 1.

This steel-lined flume is extended from the boiler house to an ash dump by a similar but open flume, lined with terra cotta of the same diameter and set at the same grade. The ash dump is situated on lower ground at any desired distance from the boiler plant. In cases where the hill slope is comparatively steep the flume from the boiler house is carried through a short culvert to the face of the hill, whence it emerges and is extended to the dump.

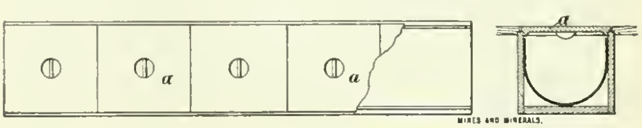

Fig. 1

To supply water to move the ashes, the mine drainage is delivered by the mine pumps to a reservoir or tank placed at a convenient elevation above the boiler house. From the reservoir or tank a 3- or 4-inch pipe runs to the end of the boiler house and is then given a vertical drop of 10 or 12 feet, ending with a curved end so as to deliver water into the head of the flume. A convenient valve, actuated by a lever, is attached to the vertical pipe.

When the time arrives for cleaning ashes from the ash pit, the fireman uncovers the flume immediately in front of the ash-pit door, opens the valve in the vertical pipe, and scrapes the ashes into the flume. The running water extinguishes any live coals and carries all the ashes rapidly along the flume to the place of deposit. In some instances the ashes are flumed a quarter of a mile, and in no case is there any chance for a fire in the ash bank. In the coldest winter weather the flumes have worked perfectly, as the heat from the ashes keeps the water at a temperature above the freezing point. The water after performing its function naturally drains into the nearest stream, just as it would have done if it flowed direct from the column pipe without performing any useful work.

Economical Fire-Room Methods

A Method of Firing by Which the Greatest Efficiency Is Obtained From the Fuel

In recent years economical fireroom methods are not alone practiced by manufacturing establishments, in fact, they have been extended even to coal mines, where once no attempt was made to save fuel. In an article by F. R. Low in Bulletin 187 of the Sturtevant Engineering Series were given the data from which this article was prepared. George H. Dinman, consulting engineer of the American Woolen Co., realizing that the boiler room is the place to save fuel, has installed "Hibernian" automatic stokers, fans to furnish induced draft, economizers to reduce the temperatures of the escaping gases and raise the temperature of the feedwater from 105° F. to 185° F. Some people neglect to wash their children's faces with the excuse that they will get dirty again. At the plant mentioned, however, the fireroom is kept clean by not letting it get dirty. The interior of the boiler house is clean, light, and roomy, both in front and behind the boilers, consequently it is not necessary to knock the sides out in case repairs or changes are contemplated. There are at this plant 42 horizontal return-tubular boilers, 72 inches in diameter, with 20-foot tubes, which indicates that there is some coal being used. The record shown in Fig. 1 is an average indication of what is being done in the way of heat economy.

The inner diagram gives the variation in the temperature at which the gases go to the stack, and, as may be seen, this approximates 200° F. The outer diagram shows that the temperature of the gases as they leave the boilers is never above 500° F., and part of the time below 400° F. This remarkably low stack temperature is due to careful study on the part of experienced power-plant engineers, who desired to construct a plant that would generate power at the lowest possible cost by the utilization of every possible heat unit from the fuel burned under the boilers. To this end Sturtevant economizers were adopted to reduce the final temperature of the gases and while so doing raise the temperature of the feedwater from 105° F. to 185° F.

From the low stack temperature of the gases it might be assumed that an excess of air was admitted to the furnace and that this cooled them; but this is not so, for the company employs a chemist who comes each week, picks his own boilers and fires, and makes the gas analyses, records of which show little excess air. In the accompanying Table I the gas samples from boilers 6, 9, 15, 18, 28, 29, and 25 were obtained from the uptake just back of the front firebox doors; while samples from boilers 33 and 35 were taken from the center of the roof of the boilers. Samples from boiler No. 33 show what value the flue gas analyses may have in locating trouble with the fire; for instance, it was found after the 9:30 a. m. sample was taken that the fire-bed had a hole in one side through which excess air was flowing. This was remedied, and the 9:40 a. m. sample shows that the oxygen had decreased 6.7 per cent. The small percentage of excess air shown in the analyses represents a considerably less loss at the low temperature of the stack gas than would be the case at the usual temperature of most stacks, which is approximately 500° F. If it were possible to cool the gas entering the stack to the temperature of the air entering

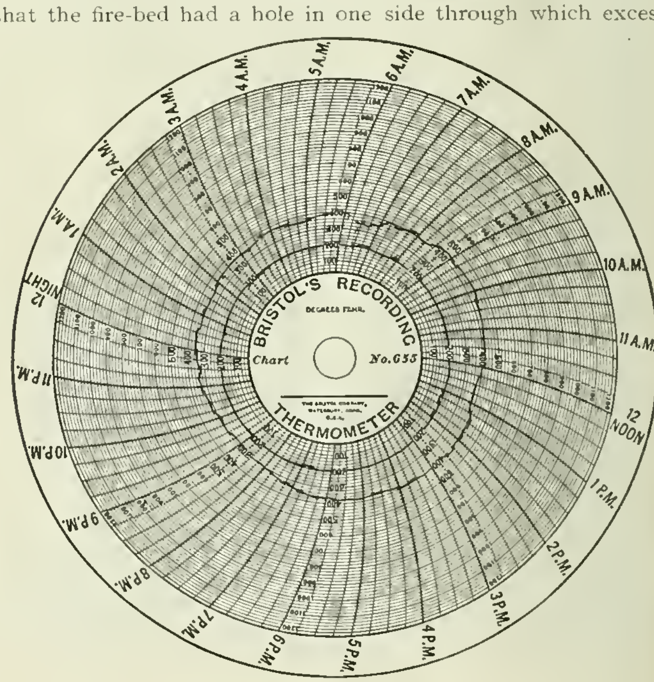

Fig. 1

the firebox it would be immaterial how much excess air there was, for none of it would go away hotter than it came. Table II gives the loss in dollars due to stack temperatures.

The woolen mill boilers are supplied with flat shaking grates and are fired by hand. The plant is divided into four groups of 10 boilers each, so that each group has 20 fire-doors and four stokers. The man at the end of the group fires the 1st, 3d, and 5th doors; the second man then fires the 7th and 9th doors; the third man the 11th, 13th, and 15th doors; and the fourth man the 17th and 19th doors. Each man puts on nine scoops of coal, and when the first man has finished coaling the 5th door, he trims the fire through doors 2 and 4, then goes and sits down in a comfortable chair provided for him. Fireman No. 2 having fired his two doors and trimmed his three fires, sits beside the first man in a second chair. After an interval of 8 or 10 minutes fireman No. 1, seeing fireman No. 4 finish his turn, gets up, coals furnaces through doors Nos. 2 and 4, trims fires through doors 1, 3, and 5, then sits down again. Fireman No. 2 commences to throw coal into No. 6 as soon as fireman No. 1 closes the door of No. 4, and as soon as he has fired 6, 8, and 10, and trimmed 7 and 9 he sits down.

Table II. Loss of High Temperature in Stack on Every $1,000 Worth of Coal Burned

Stack Temperature Degrees F.	Per Cent. of Total Heat Going Up Stack	Loss on Every $1,000 Worth of Coal Burned
200	4.34	$43.40
250	5.89	58.90
300	7.44	74.40
350	8.99	89.90
400	10.54	105.40
450	12.09	120.90
500	13.64	136.40
560	15.50	155.00

Temperature of outside air = 60 degrees. One pound coal = 14,500 B. t. u. Eighteen pounds of air per pound of coal.

And so it goes on like clockwork. Nobody has to be told when it is his turn, there is no bossing, nagging, nor bawling; the men work easily and systematically; there are never more than two doors open in the group at a time—that into which the man is shoveling, and that of the furnace which is being trimmed. The firing of alternate doors at considerable intervals insures that one side of each furnace shall be full of white-hot coal to burn the volatile matter from the fresh fuel fired to the other side, and the fire is carried some 14 inches in thickness all over the grates, giving no chance for air to get through without losing its oxygen to the white-hot carbon. If the load is light and coal is not being burned so fast but that the fires thicken up above 16 inches, under this treatment the number of scoops of coal per firing is reduced; but the stokers can get around fast enough so that nine scoopfuls at a time will supply all the coal the boilers will use at the greatest rate that they are ever driven.

At most boiler plants it is customary to use dampers and hold the steam pressure within a pound or so, but at this plant, instead of doing this, the men try to keep the air supply so it will burn the coal. Mr. Diman's argument is, that when the steam pressure becomes too high and the damper shuts off, the air supply is insufficient to burn the carbon of the coal to more than carbon monoxide, producing 4,450 British thermal units per pound of carbon, instead of burning it to carbon dioxide that furnishes 14,500 British thermal units per pound carbon. The loss due to dropping the steam pressure 15 pounds is not so much as dropping the percentage of carbon dioxide from 14 down to 8 by imperfect combustion.

Mr. Diman shows the loss due to incomplete combustion resulting in a low carbon dioxide CO_2 chimney gas on every $1,000 worth of coal burned in Table III.

With the use of Sturtevant exhaust fans the exhaust over the fire runs from .3-inch water gauge when the boiler pressure is highest to about .6 inch when the pressure is down, but even then enough air comes through the coal to burn it to carbon dioxide, and not enough to give an excess of air.

The fans have stops on the valves that control them, and when the fires are in good condition the amount of come and go will keep the pressure fairly regular under ordinary working conditions. Another fallacy discarded at this plant relates to the idea once generally prevailing that the more boilers one had and the slower they were fired, the better the economy, for then there was plenty of boiler surface to soak up the heat that might otherwise go up the chimney. This arrangement prevents the fires being run hot and therefore a quantity of gas is lost. At the American Woolen Mill plant the furnaces are pushed to get all there is out of the coal, burn the gas hot and take out by an economizer what heat the boiler does not absorb. Ordinarily the boilers furnish steam with less than 6-inch water gauge, but after the fires have been running some time this draft will not force air enough through them, and when the steam falls 15 pounds the whistle blows automatically and everybody goes to slicing.

Table III. Loss by Incomplete Combustion per $1,000 Worth of Coal Burned

Percentage of CO_2	Loss Per Cent.	Loss, Dollars
14	No loss	
13	1½	15
12	2½	25
11	4½	45
10	6	60
9	8½	85
8	11	110
7	15	150
6	19½	195
5	26½	265
4	32	320
3	53½	535

The tall chimneys that have been erected to create draft are, according to Mr. Diman, destined to be discarded. There is no question but that there is some ratio between the area of the grate and the area of a chimney, but since thickness of the fire, wind, and weather influence the draft, recourse is had to large high stacks, and then if the boiler plant is much increased, to still larger and higher stacks. The draft produced by chimneys depends upon the difference in pressure between a column of cool air outside and a column of hot air inside the chimney. It follows from this that the hotter the air inside the chimney the better the draft will be for any given sized chimney. At the American Woolen Co. plant, where the gas going up the stack is 200° F., a temperature probably lower than at any other boiler plant, there is a saving of more than 7 per cent. in heat, and this more than pays for the steam required to run the exhaust fans used to induce draft. It makes little difference what the weather may be, the fans furnish a sure draft independent of weather conditions and can be made to respond quickly to the demands of the engines for power.

Petroleum in Borneo is contained in regular occurrences of oil belts of narrow width but of great length, and the oil indications in British North Borneo coincide with remarkable similarity with those existing on the east coast oil fields, which induced the successful Shell Company to make their first trial borings. In both parts of the island the same geological conditions prevail, the oil being found in the Tertiary formation of the Miocene period, which contains the rich oil-bearing strata of this country. The oil here is associated with enormous gas pressure, most of the wells starting as gushers, the oil being generally contained in sandstone, as stated in a recent United States Consular Report. The petroleum-bearing lands of British North Borneo are those on which the most recent attention has been fixed, and they are, from geological and other indications, believed to bear an intimate relationship with and be closely allied to the deposits of Dutch Borneo.

Coal Combustion Recorders

The following paper was presented by Prof. Augustus H. Gill before the Congress of Technology at the Fiftieth Anniversary of the granting of the charter of the Massachusetts Institute of Technology:

By the simple determination of the carbonic acid content and temperature of the gases from a boiler furnace, its efficiency can be closely determined. By the investment of 10 dollars in premiums to keep the CO_2 at 12 per cent., an electric company in a Massachusetts city saved 40 tons of coal. This would seem to demand the attention of every manufacturer using coal.

The first analyses of chimney gases were made in 1827 by Beclet; they were sampled by emptying a bottle of water in the gases, and he found that in ordinary combustion only about half of the air was used. Bunsen in 1839 analyzed the gases from a blast furnace in Vackershagen and found that over 40 per cent. of the fuel was wasted; attempts were made to use this waste heat for raising steam. The analyses in those days were tedious and troublesome, a whole day being employed in taking a sample. Scheurer Kestner used 10 gallons of mercury and complicated trains of combustion and absorption apparatus. Now a result is obtained in five minutes and recorded—all automatically.

The first portable apparatus for gas analysis was devised in 1872 by Clemens Winkler, the discoverer of the rare element germanium. This apparatus, however, is troublesome to manipulate, is not jacketed, and hence unsuitable to the drafty boiler room. It, however, served a useful purpose in preparing the way for the Orsat apparatus, patented in 1873, and by October, 1874, found its way into more than 50 factories in all parts of Europe and even in America. It was used wherever carbon dioxide was generated—with all sorts of furnaces—puddling, melting, Bessemer, Siemens-Martin, boilers, gas producers, fermentation industries, beet sugar factories, sulphuric acid and alkali works.

The chimney gas to be tested is collected and measured over water or brine in a burette and successively forced into various absorbents contained in pipettes. The diminution in volume represents the percentage of the different constituents. The operation is done by hand and requires nearly a half hour for its completion. Three gases are determined, one of them carbonic oxide, indicative of imperfect combustion, which is shown by no other apparatus. The apparatus has the disadvantage of indicating what is transpiring in the furnace only at the time at which the sample was taken—a very brief interval —two or three minutes at most. Furthermore it requires an attendant to operate it. Its indications were so valuable, however, as to create the desire for an automatic device which should show the condition of the boiler furnace the same as the steam gauge shows the pressure. The first of these automatic devices was patented in England, in July, 1892, by Custodis and Duerr, of Munich. It consisted of a balanced glass globe suspended in a case into which the gas to be tested was drawn, and was a modification of the Lux gas balance. This invention was quickly followed by Arndt in September, 1892. Custodis and Duerr in 1895, then improved their first balance by adding another globe and making it recording.

This balance type of apparatus being constantly in motion resulted in the knife edges and planes wearing, thereby rendering it less sensitive, besides requiring frequent repair and adjustment. This type of recorder was superseded by the absorption apparatus of Arndt, in Achen, who received a patent in England, in December, 1896, for his "Ados" or heating-effect meter. Other patentees are Cederberg, of Denver; Simmance Abady, of London; J. C. Eckhardt, of Stuttgart; Sarco Fuel-Saving and Engineering Co., of New York; Uhling & Steinhart, of Newark; Salan & Birkholz, of Essen; G. Van Gilnern & Co., of Düsseldorf; and Hugh K. Moore, M. I. T. '97, Berlin, N. H. With these automatic devices usually a small stream of water furnishes the power to draw a current of gas from the uptake or chimney into a floating gasometer and force it through potassium hydrate into another gasometer which is connected with a recording device that shows the amount of carbonic acid absorbed.

This should be about 13 per cent., for if a greater percentage be obtained, the loss by the formation of carbonic oxide usually more than compensates for the increase due to carbon dioxide. A percentage greater than 13 means that the fires are too thick. A percentage less than 10 means either that the fires are too thin or there is leakage through the bricks themselves which form the setting or through cracks therein. In many cases this is sufficient to reduce the CO_2 percentage to 5 or 7 which means a total loss of from 36 to 26 per cent. of the fuel, or from 22 to 12 per cent. more than should be lost, or otherwise expressed it means nearly 5 to 2 tons of coal in every 20.

The percentage excess of air and percentage lost heat with the gases escaping at 518° F. for various percentages of CO_2 in the gases is as follows:

Per Cent. CO_2	Excess Air	Loss of Heat	Per Cent. CO_2	Excess Air	Loss of Heat
2	850	90	10	90	18
3	530	60	11	70	16
4	370	45	12	60	15
5	280	36	13	50	14
6	220	30	14	40	13
7	170	26	15	30	12
8	140	23	16	20	10
9	110	20			

Nor are these apparatuses solely applicable to the regulation of combustion; wherever an absorbable gas such as sulphurous or hydrochloric acid or chlorine is evolved an apparatus to suit the circumstances can be installed. This will permit of increased control of chemical operations and consequently increased economy.

Tin Plate in Trade of the United States, 1911

Tin plate makes a new record in two or three important particulars in the commerce of the United States for the fiscal year just ended. The imports are lower than in any year since the record of its importation was begun, the outward movement of American tin plate was larger than ever before, and the shipment of domestic tin plate out of continental United States for the first time exceeded the imports of foreign tin plate.

During 1892, the first full year for which figures are available, the production amounted to 42,000,000 pounds. In 1909, the last year for which figures are available, the production amounted to 1,371,000,000 pounds. In 1910 exports to foreign countries were slightly over 26,000,000 pounds and shipments to non-contiguous territory 34,750,000 pounds.

For the 11 months ending with May, 1911, the latest period for which figures are available, the exports to foreign countries amounted to 60,887,040 pounds, valued at $2,161,472, and shipments to non-contiguous territory 38,348,830 pounds, valued at $1,673,934, making total shipments from the United States for the 11 months period of 99,333,000 pounds, valued at $3,835,406, while for the same period the imports amounted to 91,557,586 pounds, valued at $2,892,149, thus showing an excess of shipments of domestic tin plate over imports for the 11 months period of 7,687,284 pounds.

The large shipments of tin plate to non-contiguous territory are chiefly on account of the fish canning industry in Alaska, and fruit canning in Hawaii. The receipts of canned salmon from Alaska amounted to 107,639,801 pounds in the 11 months ended May, 1911, and receipts of canned fruits from Hawaii amounted to $1,983,000 for the same period, practically all of which was packed in cans manufactured from American tin plate.

Answers to Examination Questions

Pennsylvania Anthracite Mine Inspectors, Scranton, May 25, 26, 1911; and Utah Mine Foremen

(Continued from August)

QUES. 32.—Why is the air at the surface of the earth more dense than that above the surface?

ANS.—The density of air and gases increases with the pressure, which is greater at the surface than above, owing to the weight of the upper air resting upon the air below. Atmospheric pressure decreases and the density of the air decreases the higher one ascends above the surface of the earth.

QUES. 33.—If powder smoke requires 2 minutes and 17 seconds to travel 149 yards in an airway 12 ft. × 19 ft., what quantity of air per minute is passing through that airway?

ANS.—The observed velocity of the powder smoke is $60\left(\frac{149\times 3}{2\times 60+17}\right)=195.8$ feet per minute. The average velocity of the air-current may be assumed to be, for a timbered airway, say eight-tenths of the observed velocity in the center of the entry; or, in this case, $.8\times 195.8=156.6$ feet per minute. The area of the airway is $12\times 19=228$ square feet, and the quantity of air passing is therefore $156.6\times 228=$ say, 35,700 cubic feet per minute.

QUES. 34.—What is the equivalent of a horsepower?

ANS.—In mechanics, 33,000 foot-pounds per minute, or about 2,545 British thermal units (B. T. U.) per hour. In boiler practice, the standard adopted to express a boiler horsepower is the evaporation of 34.5 pounds of water at a temperature of 212° F., into steam of the same temperature. In electrical work, the equivalent of a horsepower is 746 watts; the watt being the unit of electrical, or the power of a current of 1 ampere flowing under a pressure of 1 volt.

QUES. 35.—What is the increase of depth in the earth's strata for each degree of increase in temperature?

ANS.—The increase of temperature in the earth's strata varies in different localities and is not exactly proportional to the depth below the surface in the same locality. The average rate of increase of temperature in relation to depth below the surface, however, may be taken as 1° F. for each 60 feet of depth.

QUES. 36.—What is the decrease of pressure in pounds per square inch corresponding to a barometric fall of 1 inch?

ANS.—The corresponding fall in pressure is exactly equal to the weight of a cubic inch of mercury, or .4911 pound per square inch.

QUES. 37.—What is the difference in altitude of two places where the readings of the barometer are 29.1 and 27.8 inches, respectively?

ANS.—Assuming these readings were taken about simultaneously and not too far apart, the difference in altitude may be calculated very closely by first finding the average barometric pressure $\frac{1}{2}(29.1+27.8)=28.45$. Now, taking the average temperature for the two places at the time of observation as, say 56° F., find the weight of a cubic foot of air at this temperature and pressure; thus, $w=\frac{1.3273\times 28.45}{460+56}=.0732$. This weight of air causes a pressure per square inch for each foot of height, $.0732\div 144=.000508$ pound. The difference of pressure between the two places is $.4911\ (29.1-27.8)=.63843$ pound. The difference in altitude is then $.63843\div .000508=1{,}256$ feet. A rule of thumb often used allows 900 feet of vertical distance for each inch of barometric difference; or, in this case, $900\ (29.1-27.8)=1{,}170$ feet. This rule, however, applies better to readings below sea level, as in finding the depth of a shaft.

QUES. 38.—How much coal would there be in a tract of 250 acres, the vein being 22 feet and pitching 50 degrees?

ANS.—On this pitch, the given acreage corresponds to an area of $250\div\cos 50°=250\div .64279=388$ acres in the seam. It is customary to allow 100 tons per inch-acre as the possible extraction of coal; or in this case $100\times 388\ (22\times 12)=10{,}243{,}200$ short tons. This is a low estimate, at the present time, for anthracite mining.

QUES. 39.—What lesson may be learned from the Pancoast disaster?

ANS.—The chief lessons taught by this disaster are the following: (1) Build underground engine rooms wholly of incombustible material. (2) Use electricity for lighting instead of oil. (3) Never leave an engine room, pump room, stable, or other place in a mine where machinery is located, or any material or supplies are stored, unprotected or unguarded. Places so left should be locked securely by the person having the same in charge. (4) Instruct every worker in the mine how to get out by escapeways other than those in common use, and make all men use these means of exit frequently to insure their acquaintance with the same. (5) Place conspicuous signboards at all road junctures to point the way out; shape the boards so as to indicate the direction to be taken by feeling the board in the dark. (6) Arrange the best possible service in answering phone calls in the mine, and make a special ring the alarm signal to hurry all men out of the mine.

SELECTED QUESTIONS OF THE UTAH MINE FOREMEN'S EXAMINATIONS HELD IN CARBON COUNTY FEBRUARY 21, 22, 1911

NOTE.—Questions relating to the mining law have been omitted for the reason that they are readily answered by reference to the state mining law of Utah, a copy of which should be in the hands of every mining man.

QUES. 4.—Do you receive and read any instructive literature pertaining to the various systems of coal mining, and the requirements of safety in the operation of coal mines? What magazines of this kind do you take?

REMARK.—This question (to be answered by the candidate) is repeated here as being an exceptional style of question, and showing a proper desire on the part of the examiners to ascertain the amount of personal interest the candidate takes in mining matters and the study of mining conditions.

QUES. 7.—In your daily examination of the mine what four points of interest to miners, relating to the condition of their working places, would you watch?

ANS.—(1) The timbering of the roof and taking down promptly loose rock. (2) The mining and timbering of the coal face. (3) The manner of placing, charging, and firing holes in blasting the coal. (4) The manner of loading the coal, and cleaning up the working face, disposal of the waste and fine coal.

QUES. 9.—In your opinion, can sufficient water sprays be placed in the intake airways of a mine to so saturate the intake air that all coal dust in working places and travelingways will be dampened? State why.

ANS.—No. Because the air-current, though completely saturated with moisture by the water sprays, does not give up its moisture except there is a fall of temperature, which does not usually occur at the working face and elsewhere in the mine where dust accumulates; and, for the further reason, that more water is required to dampen the dust accumulations in mines than is commonly deposited at the working face by the air-current under the most favorable conditions.

QUES. 11.—Describe the use of the barometer in mining.

ANS.—The rise and fall of the mercury in the barometer shows the rise and fall of the atmospheric pressure. A sudden fall of pressure is accompanied by a corresponding expansion of the air and gases filling the void and abandoned places in the mine, with the result that the mine passageways and workings often become filled with gas; and it is necessary to increase the circulation or warn and perhaps withdraw the men. The aneroid barometer is much used to determine the relative elevation of different points on the surface.

Ques. 12.—When the barometer reads 23.20 inches, what is the pressure of the atmosphere (*a*) per square inch; (*b*) per square foot?

Ans.—The pressure is: (*a*) $.4911 \times 23.2 = 11.3935$ pounds per square inch; and (*b*) $11.3935 \times 144 = 1640.664$ pounds per square foot.

Ques. 13.—Explain the difference in the methods of producing an air-current by a force fan and by an exhaust fan.

Ans.—Assuming a centrifugal fan, the action of the fan is the same in each case, air being drawn in at the center and discharged at the circumference of the fan. The difference between a force fan and an exhaust fan lies wholly in the manner in which the fan is connected with the mine. A force fan is open to the atmosphere at the center, while its discharge at the circumference is connected with the mine. On the other hand, an exhaust fan has its central openings connected with the mine and discharges its air through a chimney into the atmosphere. In the former case the mine pressure is above that of the atmosphere, while in the latter case it is lower than the same.

Ques. 14.—Would there be a gain or loss in placing a stack of the same dimensions as the outlet of a fan and, say 50 feet high, so that the fan would discharge into the stack?

Ans.—For the same speed the fan would discharge less air and consume less power. The efficiency would be less as the fan would have to be run at a higher speed to produce the same quantity of air. The result would be a loss.

Ques. 15.—Describe the construction and uses of the water gauge and anemometer.

Ans.—The water gauge is a **U**-shaped glass tube, having both ends open and mounted on a wooden block. One end of the tube is longer than the other and bent at right angles so that it can be inserted in a hole in a brattice or partition, thus permitting the air pressure on the other side of the brattice to act on the water in that arm of the tube while the water in the other arm is exposed to the air pressure on this side of the brattice. The water level falls in one arm and rises an equal amount in the other. The difference between these two levels, as measured by the scale in inches, indicates the difference of air pressure on the two sides of the brattice. The anemometer is a vane with inclined blades mounted on an axis so as to revolve. A central dial registers the number of revolutions of the vane, each revolution corresponding to a single foot of air travel. By exposing this instrument in an air-current for 1 or more minutes and reading the dial the velocity of the current can be ascertained.

Ques. 16.—What pressure per square foot does a water-gauge reading of 1.85 inches indicate?

Ans.—The pressure is $1.85 \times 5.2 = 9.62$ pounds per square foot.

Ques. 17.—What is the total ventilating pressure in an airway 6 ft. × 7 ft. when the water-gauge reading is .5 inch?

Ans.—The unit of ventilating pressure is $.5 \times 5.2 = 2.6$ pounds per square foot. The sectional area of the airway is $6 \times 7 = 42$ square feet; and the total ventilating pressure is then $42 \times 2.6 = 109.2$ pounds.

Ques. 18.—An airway is 8 feet 6 inches wide at the floor, 9 feet 6 inches wide at the roof, and 8 feet high. The anemometer registers 1,125 revolutions per minute; what amount of air is passing?

Ans.—The average width of the airway is $(8.5 + 9.5) \div 2 = 9$ feet; and the sectional area $8 \times 9 = 72$ square feet. Assuming the reading of the anemometer is the average velocity of the air-current at this point in the airway, the volume of air passing is $1,125 \times 72 = 81,000$ cubic feet per minute.

Ques. 19.—Given a gangway 8 ft. × 10 ft. and 1,200 feet long, the pressure indicated by the water gauge being 2 pounds, and the air having a velocity of 500 feet per minute, what is the water-gauge reading, the quantity of air passing per minute, and the horsepower?

Ans.—Taking the coefficient of friction as $k = .00000002$, the calculated unit of ventilating pressure for this airway would be

$$p = \frac{k\,l\,o\,v^2}{a} = \frac{.00000002 \times 1,200 \times 36 \times 500^2}{80} = 2.7 \text{ lb. per sq. ft.}$$

However, the water gauge corresponding to a pressure of 2 pounds per square foot, as given in the question, is $2 \div 5.2 = .38$ inch. The quantity of air passing is $80 \times 500 = 40,000$ cubic feet per minute. The horsepower on the air is then

$$H = \frac{Q\,p}{33,000} = \frac{40,000 \times 2}{33,000} = 2.424 \text{ H. P.}$$

Ques. 20.—What is a dumb drift? Explain its object and show by a sketch its position in relation to the furnace.

Ans.—A dumb drift is an air-passage driven from a point on the main return airway, inby of the furnace, to a point in the upcast shaft above the reach of the flame or sparks arising from the furnace, as shown in Fig. 1. The furnace *f* is fed by a small scale of fresh air taken from the intake through the regulators at *a*; while the main return current is prevented from passing over the furnace by the stopping built at *b*, by which the current is made to pass through the dumb drift. The object is to prevent the ignition of the mine gases in the return current by the furnace fire.

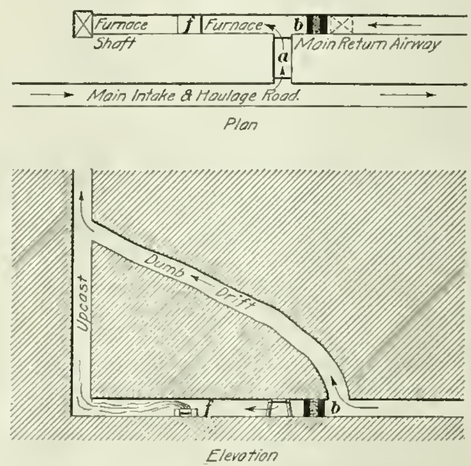

Fig. 1

Ques. 21.—Explain the principle of natural ventilation.

Ans.—The natural heat of the mine coming from the strata and arising also from the presence of men and animals, the burning of lamps, combustion of fine coal in the waste, etc., heats the mine air; so that the return current usually has a higher temperature than the intake current. This increase of temperature causes an air column to form in the mine entries running to the rise or dip, and in all slopes and shafts, because the warm air of the mine is lighter than the cooler outside air traveling on the intake. The difference in the weight or density of the air causes a ventilating pressure that produces natural ventilation.

Ques. 22.—(*a*) What is meant by the friction in airways? What is (*b*) the perimeter; (*c*) the sectional area; and (*d*) the rubbing surface of an airway 10 ft. × 12 ft., 5,000 feet long?

Ans.—(*a*) Friction in mine ventilation is the resistance offered by the mine to the passage of the air-current; it is due to the rubbing of the air along the sides, roof, and floor of the airways, and to the obstruction of the air passages by timber, roof falls, cars, etc., and the sharp bends or turns in the course the air is made to travel by the placing of doors, brattices, curtains, etc. (*b*) Perimeter is $2(10 + 12) = 44$ feet. (*c*) Sectional area is $10 \times 12 = 120$ square feet. (*d*) Rubbing surface is $44 \times 5,000 = 220,000$ square feet.

ORE MINING AND METALLURGY

The Cornwall, Pa., Magnetite Deposits

Description of a Remarkable Body of Ore and the Methods of Mining and Handling It.

That there has been considerable speculation over the genesis of the Cornwall magnetite deposit in Lebanon County, Pa., is due to its structure, composition, and geological surroundings differing materially from the magnetite deposits of New Jersey and New York.

Persifor Frazer, Jr.,* in Vol. V of the Transactions of the American Institute of Mining Engineers, says: "It is not quite certain how much of the magnetic particles with which these ores are mixed may have come from the trap itself. * * * It is likely that much is to be ascribed to this source; but, however that may be, it cannot but be of the greatest significance that the two plates of trap which occur near these mines inclose or cover the greater number of producing deposits."

FIG. 1. CORNWALL ORE MINES
No. 1 Steam Hoist to right; Robesonia Hoist in center near tracks; No. 2 Hoist and Substation on hill; Ore Bin and Stock Pile in middle.

The foot-wall of the Cornwall ore deposits is trap rock approximating basalt, that forms a kind of basin in which the ore is found. The hanging wall or cover immediately above the ore to the south of Middle Hill mine is limestone, and through this there is a nearly vertical trap dike that places the age of the former as older than the latter. As the country rocks are sedimentary it is not difficult to understand that they would naturally be shattered and fissured by the intrusion of the trap rock, and that the mineral solutions which accompanied the intrusion and continued for some time afterward would circulate through the fissures. It is presumed therefore that these deposits were formed by replacement and are not of magmatic origin as are the magnetite deposits of New Jersey and New York. This hypothesis is based on the fact that there is an almost horizontal bedding of the ore which indicates that stratification antedates the formation of the ore, in fact limestone is found alternating with thin streaks of ore that give the whole a banded and often a serpentinized appearance. On Grassy Hill there is a limestone outcrop that is covered with decomposed buff-colored clay that resembles the clay covering of limonite deposits. Traditional reports state that considerable red hematite was mined from one part of this hill, while to the north and west, adjacent to the trap wall, the greenish black magnetic ore was mined.

According to E. V. D'Invilliers, who, after a careful study and examination of the deposits wrote a monograph for the Second Geological Survey of Pennsylvania, "the original formation was made up probably of lime shales containing magnesia, silica, alumina, and iron pyrites. This probability is increased by the bedded and laminated stratification, and it is converted into a certainty by the fact that a considerable thickness of unchanged lime shale layers, passing upwards into solid beds of hard limestone, show themselves near the southern side of Middle Hill mine in the body of the ore mass. These unchanged lime shales at one place are seen resting upon the ore; at another place the limestone beds dip under the ore layers at the same angle and apparently change gradually into ore."

Conditions so far as exploitation goes have changed somewhat since Mr. D'Invilliers' inspection of Middle Hill Serpentine and other magnesian silicates are found near the junction of the limestone and particularly near the dike, which points rather conclusively to the alteration coming from solutions that were capable of metamorphosing the limestone.

It is possible that the Corn-

FIG. 2. OPEN CUT WORKINGS IN MIDDLE HILL

*Vol. V, Trans. A. I. M. E., page 142.

wall deposits, since they are not magnetite magmas like those of New Jersey and New York, may have been formed in one of two ways by the ascending thermal solutions: First, the deposits may have been a hematite mass that was changed by the solutions into a magnetic mass. Second, the deposit may have been limestone, or such as D'Invilliers describes, that was changed by solutions, in either case it is assumed on good grounds to have been formed by ascending solutions.

Fig. 3. Steam Shovel Loading Iron Ore

Dana, in his System of Geology, says: "Deville formed crystals of magnetite artificially by the action of hydrochloric acid on heated ferric oxide; and also by the decomposition of ferric oxide with boracic acid."

Prof. Thomas A. Eggleston, in Vol. V, page 131, of the Transactions of the American Institute of Mining Engineers, says that "some of the hematite ores of Lake Superior contain boracic acid," and he gave the following instructions for its identification:

"Pulverize, calcine, and moisten the pulp with sulphuric acid. Heat some of the mass on a platinum wire to expel the sulphuric acid, then moisten with glycerine, and flame. If boracic acid is present it will infallibly give a green flame." This ore gives a green flame, but it may be due to copper, which also gives a green flame.

The structure of the Middle Hill ore is mostly massive, with small pit marks here and there containing small crystals of magnetite, and through the ground mass, pyrite, chalcopyrite, and other minerals are found. D'Invilliers mentiones 25 different kinds of minerals as being found at these mines, the copper minerals being a cuprous variety of pyrite, chalcopyrite, covelite, cuprite, hydrocuprite, chrysocalla, malachite, and azurite. No analysis of the ore is free from copper. At one time copper was mined as a commercial proposition, approximately $175,000 worth being sold. This was mostly green and blue carbonates and chalcopyrite.

The gangue of the ore is sand, which in places seems to be laminated. The sand is fine and light colored, showing it has been leached, and frequently it appears in small thin folds and contortions like the various layers of hornblende, mica, and quartz in gneiss.

This indicates that acid solutions displaced the limestone, and the sand particles, being insoluble, segregated as found.

Mining operations are said to have commenced at Cornwall in 1740, which is 16 years earlier than at the Forest of Deans mine near Fort Montgomery, in New York state. Tradition states that artillery was made for the Continental army at the old Cornwall furnace.

From the three deposits in Big Hill, Middle Hill, and Grassy Hill over 20,000,000 tons of ore have been removed. The greatest quantity mined in one year was approximately 835,000 tons; however, with the present facilities this no doubt could be increased to 1,000,000 tons, if there was such a demand for the ore. The Lackawanna Steel Co. and the Pennsylvania Steel Co. are the principal consumers, the market for the ore being narrowed by its low tenor in metallic iron and its high sulphur. The ore, when exposed to the weather, is oxidized to some extent, and loses some sulphur. However, before being charged in a blast furnace it is roasted. An analysis of the ore in percentages is as follows: Silica, 15; alumina, 4; lime, 3.5; magnesia, 5.5; metallic iron, 48; sulphur, 3.5. After it is roasted in Gjers kilns the sulphur is reduced to about 1.07 per cent., and in this condition it is possible to smelt Bessemer pig owing to the extremely low phosphorus contents.

Ore is roasted in Colby furnaces very successfully with blast furnace gas by the Pennsylvania Steel Co.

In Fig. 2 is shown the open-cut workings in Middle Hill, taken from Big Hill in the foreground, which is practically worked out. Between Big Hill and Middle Hill the railroad tracks are supported on ore left there for that purpose. This view, although taken in 1908, does not materially differ from the conditions governing the mines today, although there have been a number of important surface improvements. Grassy Hill mine is to the rear and right of Middle Hill mine and does not show in the illustration.

The Middle Hill mine has been worked to a depth of 150 feet for approximately a half of a mile; however, there is a considerably greater area to be stripped and exploited besides 150 feet more depth before the bottom of the deposit is reached. In the process of mining, a comparatively light cover of soil and rock is removed, as shown in Fig. 3 on the top bench above the steam shovel. The removal is accomplished by putting down a series of drill holes, then chambering or bulling them, and finally loading and firing them with a battery. The cover is thus broken in sizes that the steam shovel can readily load into dump cars. When the cover has been removed a wide bench of ore remains that can be broken so that it falls to the bench on which the steam shovel is working, shown in Fig. 3. In this way there has been formed a series of four stopes or benches from which ore is mined. Fig. 4 shows a steam shovel on the floor of the third stope on the foot-wall side of the mine. The locomotive zigzags with the loaded cars from the lower to the upper stopes, although on the present main level the ore is delivered in 50-ton cars to the incline of the crushing and screen-

Fig. 4. Steam Shovel and Ore Car on Third Stope

ing plant. The ore car shown attached to the locomotive in Fig. 4 is a 50-ton car which dumps into a steel-foot frame pocket. To break down the ore it has been customary to put down a series of 18- to 24-foot drill holes with air drills on each bench, then charge and shoot the holes simultaneously. In this way a quantity of broken ore can be kept ahead of the steam shovels. Recently two small traction well-drilling machines have been installed to put down holes where depth greater than the air drills can furnish is desired. These are worked on benches ahead of the steam shovels, and although slower than air drills, their holes, being larger and deeper, probably even up the quantity of material broken over a given time. The ore broken from the stopes falls in all sizes, making it necessary to block hole extra large pieces and "block blister" smaller and more suitably shaped pieces. To "block blister," a piece of dynamite has a cap and fuse attached in the usual way, after which it is placed on the ore to be broken and covered with loose dirt. The dynamite, when exploded, breaks up the material into pieces that can be scooped up by the steam shovels, although that machine delivers pieces weighing 3 or 4 tons at times into the cars.

The extreme eastern hoist at the foot of Big Hill is known as hoist No. 1 of the Cornwall Ore Banks Co. This is operated by steam but is at present closed down. Ore from the Big Hill basin is taken through tunnels to the Cornwall Ore Banks Co.'s No. 2 hoist operated by electricity.

While a large tonnage of ore could be removed from the west end of the Middle Hill mine by cars attached to locomotives, at the present time all ore is hoisted at the eastern end of the Middle Hill mine up two inclines. At this end of the mine it is necessary to sink in order to form a stope that can be carried the length of the mine, and this stope, which is from 40 to 60 feet high is worked at right angles to the length, that is, the width, for about 400 feet.

The eastern incline in Middle Hill mine, shown in Fig. 5, is operated by the Robesonia Iron Co., who have the right to mine sufficient ore for one furnace only. This company loads ore directly into skip cars which are hauled by mules over several tracks on the main level to the steam hoist where they are hooked to the cable and hoisted from the pit.

At the top the ore is dumped directly into chutes that load the broad-gauge cars. This arrangement necessitates loading cars by hand and sledging up pieces of ore so the men can handle them. However, when in this condition the product is about ready for the furnace. Attention is called to the trap dike to the left of the incline, and to the small quantity of rock in this deep pit.

To the west of the Robesonia incline is a second, or No. 2, incline, shown in Fig. 6, which was constructed in 1909. This is a most interesting installation, consisting of a steel foot of frame, combined with crusher and skip-loading bin, and a steel

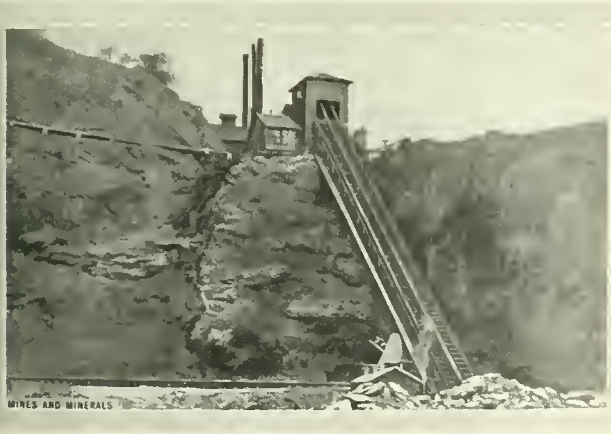

FIG. 5. EASTERN INCLINE, MIDDLE HILL MINE

head-frame combined with crushing, screening, and transfer arrangements. The foot-frame is 20 ft. × 30 ft. × 70¾ ft., and is covered, as shown in the illustration. The large 50-ton ore cars when loaded are run into the shed above the frame and dumped into a large hopper which, in Fig. 7, is termed an 85-ton grizzly. Whatever is small enough to pass through the grizzly bars falls into the 100-ton pocket from which the skip is loaded; but whatever passes over them is fed by a 9-foot rotary drum to a 60″×42″ Farrel jaw rock crusher. This machine will receive a piece of ore weighing 4 or 5 tons and crush it to 12-inch sizes. To work this crusher it requires 150-horsepower, 25-cycle, three-phase Westinghouse induction motor, making 860 revolutions per minute at 440 volts and 210 amperes. The feed-drum to the crusher sometimes becomes clogged by ore jamming, in which case if the pieces are large and cannot be started by bars, they are blasted. Occasionally a large piece of ore will fall over

FIG. 6. NO. 2, INCLINE AND SKIP-LOADING BIN

the mouth of the crusher in such a way as to lodge. To turn this so as to insert it in the jaws a compressed-air hoisting crane, installed for this purpose, is brought into use. The ore from the crusher falls to the 100-ton ore bin, where it joins the material that passed the grizzly. The ore from this bin is loaded into 10-ton iron skips by means of 6-foot diameter roller feeds. Along the foot-wall above the pit there is a water basin or ditch excavated, which catches the water from the foot-wall and leads it to a brook so that it does not enter the pit. It is only in times of thaws or heavy rains that water is plentiful in the slope sumps, and this is cared for by steam and electric pumps. The hoisting engineer is down in the foot-frame where he can see to the loading of the skip; in fact, he controls the motors that rotate the drums. However, he has an assistant who opens and closes the chute gates to the skips. The hoisting is done on two tracks by 10-ton skips attached to 1½-inch steel ropes that are wound on drums driven by electric motors. To hoist, the engineer moves a master switch to the right or left, and as the skip nears the dump at the head-frame, the power is automatically gradually shut off. As the dump is reached, the power is entirely turned off and the air brake goes on. At this point the skip is discharged and held by compressed air until the engineer releases it by reversing the lever. An end view of the crushing and screening plant attached to the head-frame is shown in Fig. 8. In this plant, motor-driven rolls and screens crush and size the ore previous to its being transferred by a 50-ton electric dump car to the 2,500-ton loading pockets, or 35,000-ton capacity stock-pile trestle. At the pockets the 5-foot roller feed-gates can load a 45-ton car in 4 minutes, including spotting and delivering to the railroad company's tracks. The ore from the stock pile is loaded by steam shovel into railroad cars in case there should be a temporary cessation of hoisting for any purpose. The head-frame, loading pockets, and stock trestle are connected by a steel viaduct which passes over the several railroad tracks, as shown in Fig. 1. The electric power for the various machines is generated at Lebanon, about 6 miles away from the Cornwall ore bank. At Lebanon a furnace belonging to the Pennsylvania Steel Co. has a Semet–Solvay by-product coke-oven installation that supplies sufficient gas to run three twin Westinghouse gas engines, each of 1,200 horsepower, for the electric power needed at the mines. These gas engines run 3,750-kilowatt Westinghouse dynamos that generate current

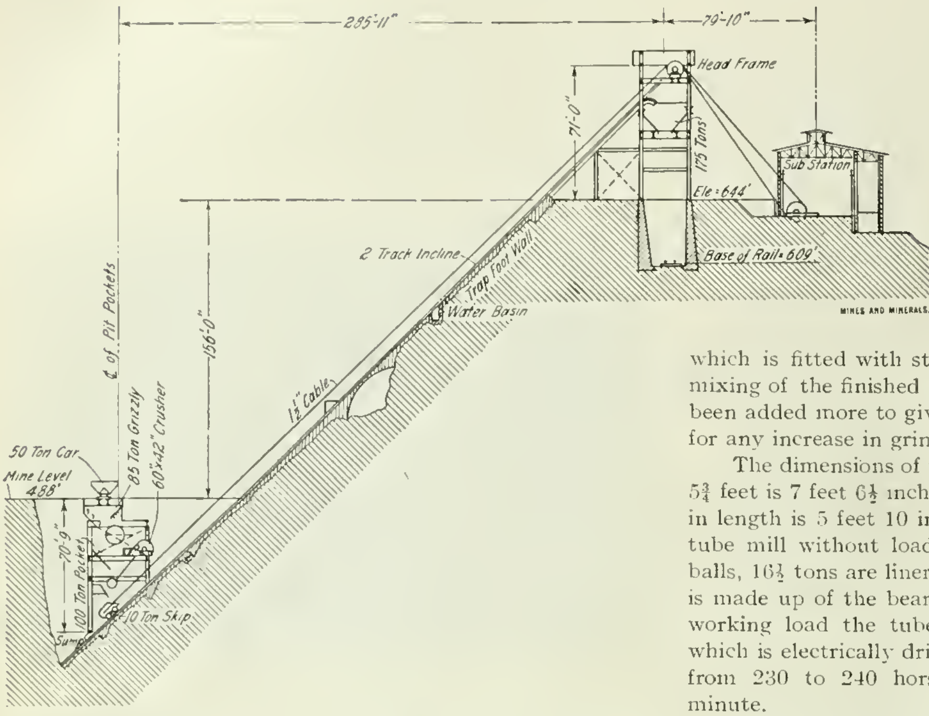

Fig. 7. Section Through Incline

at 440 volts, which is raised to 11,000 volts for transmission to Cornwall. To the rear of No. 2 head-house is the substation where the current is stepped down to 440 volts for use in the various motors. To take care of the heavy peak load in the skip hoist, a rotary converter is provided to give direct current for the 500-horsepower hoisting motor. An electrically operated Ingersoll-Rand air compressor, furnishing 3,200 cubic feet of free air per minute, supplies 13 compressed-air drills and other labor-saving machines at the mine.

The Giesecke Tube Mill

*By R. G. Mackie**

The Giesecke mill is a new tube mill introduced in the Transvaal, which has for its object the elimination of the gravity stamp; and in the experiment now being made, 50 stamps of the Geldenhuis estate are hung up, and the ore which ordinarily would have been supplied to them is going straight from the rock breakers, less the fines, of course, in sizes up to 7-inch diameter, and is coming away from the discharge end of the tube in a thick, smooth product of which nearly 81 per cent. passes a 200-mesh screen.

The consistency of the pulp is that of an emulsion carrying 28 per cent. of moisture. The mill itself has the appearance of an ordinary tube mill, except that a comparatively short length, less than one-third of the total length, which is about 24 feet, is over 2 feet greater in diameter than the rest of the barrel. The larger end of the mill, the feed end, does the first crushing, and is separated inside by a screen which prevents large particles escaping. The reduction work inside the mill is done by different sized steel balls falling on to a lining of iron plates about 2 feet in length, a foot wide, and 2 inches thick. One end of the plate is bolted to the shell of the mill so that the other end projects inwards about 9 inches from the inside of the tube surface. These liner plates overlap like the inverted leaves of the springs on vehicles.

The mill is charged with eight different sizes of steel spheres, varying in size from 4 inches in diameter to $1\frac{1}{4}$ inches, the four largest sizes being retained in the first compartment or breaking chamber of the tube. The smaller balls do the work in the smaller diameter but longer section of the tube. As the cubes of ore are passed into the tube by means of an automatic feeder, a water spray supplies all the water needed. The revolving of the cylinders causes crushing and grinding, and reduces every size and shape of stone in its travel to the outlet to a fineness and consistency almost like that of molasses. At the exit end of the tube is an elliptical shaped chamber which is fitted with steel arms inside in order to obtain better mixing of the finished product; but this section of the mill has been added more to give a cyanide solution better contact than for any increase in grinding.

The dimensions of the tube mill are, length 24 feet, of which $5\frac{3}{4}$ feet is 7 feet $6\frac{1}{2}$ inches in diameter, and the remaining 17 feet in length is 5 feet 10 inches diameter. The total weight of the tube mill without load is 68 tons, of which 23 tons are steel balls, $16\frac{1}{2}$ tons are liners, $15\frac{3}{4}$ tons tube or shell, and the balance is made up of the bearing ends, wheels, etc. When carrying a working load the tube holds 50 tons of pulp, and the mill, which is electrically driven by a 400-horsepower motor, requires from 230 to 240 horsepower, the revolutions being 24 per minute.

The mill is now crushing about 360 tons of ore per day, and the last grading analysis, taken from ore sized above fines to 7 inches, showed sizes to be as follows: +60 mesh, .5; +90 mesh, 5.6; +120 mesh, 6.7; +200 mesh, 6.3; −200 mesh, 80.9. The water feed was $28\frac{1}{2}$ per cent. of the material fed to the mill.

One special feature of the mill is that its lubrication is automatic, inasmuch as it is claimed that the grease boxes filled with Canadian grease, which are fitted over the bearings, need no attention for months. The mill can be started or stopped with the greatest ease in 5 or 6 seconds, by merely throwing over the lever, which clutches in or out as desired. Once started, the work proceeds automatically, as the mill requires no attendants, and as the product emerges from the outlet it is merely a matter of pipes or pumps to deliver where required. There is one unknown detail which remains to be determined, and that is maintenance charges.

* Resident Engineer, Geldenhuis Deep, Ltd., Cleveland, Transvaal.

American Gem Mines and Mining

A Description of Some of the Mines of Tourmaline, Turquoise, Sapphire, Diamonds, Etc.

By John L. Cowan

According to the reports of the U. S. Geological Survey, the value of precious stones,in their rough condition, produced in the United States increased from $208,000 in 1906 to $534,380.in 1909. It is certain, however, that the actual value of gem materials produced in this country is much greater than is reported by mine owners. It appears to be their idea that the market price of their products would be depreciated if the real magnitude of the production were known; and they seek to create the idea that their specialties are scarce, and therefore precious, by reporting a small output.

Furthermore, the development of American gem mining has been hampered by the fact that there are practically no experienced prospectors in the field capable of knowing a valuable gem material when they see it. Prospectors with few exceptions, are in search of gold, silver, copper, or other metallic wealth, and pay no attention to shining stones or bright-colored pebbles. The outcrops of some of the greatest gem mines in America were known for decades, and the shining crystals used as toys by the children, before some one happened along with the knowledge to recognize them as something having a cash value, or the curiosity to find out just what they were. Another cause for the neglect of American gem mines and American gem materials has been the scarcity of competent lapidaries in this country, capable of cutting and polishing native gems in the most attractive manner. Still other reasons may be found in the enormous number and variety of cheap "fake" gems (usually of French glass) on the market, and in the overshadowing importance of the metal-mining industries, leaving little temptation to any one to engage in the little-known business of gem mining.

However, there are now indications that American gem mines will be developed in the future to a much greater extent than in the past. The figures quoted from the report of the Geological Survey, showing that the output of gem materials was

Fig. 1. Washing Gems at Tourmaline Mine

multiplied by two and a half in the short period of 2 years, indicate an encouraging growth. The success of a few really great mines of this character has proved that this branch of mining may easily be as profitable, in proportion to the capital invested, as the production of gold, silver, and copper. It has been found that American gems that cannot be marketed at home will sell readily abroad, England absorbing the entire American production of sapphire, and China taking large quantities of pink tourmaline. In addition to these considerations, there are now in the more important gem-producing regions, and in all the large cities, skilled lapidaries, capable of cutting and polishing any gem material known, in such a manner as to bring out all its latent beauty and show it off to the best possible advantage.

With the gradual rise of the American gem-mining industry to a position of at least local importance, it is natural that there

Fig. 2. Himalaya, California, Tourmaline Mine

should be some curiosity as to how the more notable gem mines have been found. It is true of these, to an even greater extent than of gold and silver mines, that their discovery has usually been the result of a lucky accident. At all times there are hundreds of prospectors in the field, looking for indications of the precious metals; but no one ever thinks of prospecting for precious stones—at least not until the first paying mine in a given region has been found. Few of the tribe of prospectors, in fact, possess the technical knowledge to distinguish a precious or semiprecious stone from a worthless quartz crystal or bit of agate or chalcedony.

The most famous gem-producing district in the United States is in Riverside and San Diego counties, Cal. On account of the variety, beauty, and abundance of gem materials discovered in this district within recent years, it is sometimes called the "American Kimberley." On Pala Mountain is a property that has excited interest and curiosity for 60 years or more. It first attracted the attention of an Indian deer hunter named Vensuelada, who is said to have shown it to a prospector named Henry Magee. The rock formation contained numerous opaque pink crystals of tourmaline, which Magee thought must be cinnabar. So he located a quicksilver mine, and did considerable development work.

Assayers assured him that there was not the slightest trace of quicksilver in his most carefully selected samples, and he finally abandoned his claim, concluding that it was worthless.

Next the claim was located by Don Thomas Alvarado, a Mexican rancher of the neighborhood, who believed that the beautiful blue, pink, and gray minerals of the vicinity, studded with crystals, some opaque and some transparent, must be a peculiar variety of marble. In the course of his endeavors to find out the value of the "marble," Alvarado sent many specimens to mineralogists in New York and other cities; and at last a German scientist, familiar with the lithia mines of Europe, happened to see some of these in the cabinet of an Eastern curio collector. He at once recognized them as lepidolite; and, obtaining samples for analysis, found that this ore from Pala Mountain was as rich in lithia as any known in the world. Development for lithia-bearing minerals followed, and resulted in the incidental discovery of large quantities of tourmaline and other gem materials.

Rather more romantic was the manner of the discovery of the Pala Chief mine, in the same mineral zone. Some time in 1903, Frank A. Salmonds, proprietor of the trading store on the Pala Indian reservation, was returning from a fruitless prospecting trip through the mountains, when his attention was attracted to one of the numberless ant hills, such as may be seen by tens of thousands anywhere in the arid Southwest.

It was a ray of ruby light reflected from the commonplace cone to the traveler's eye that caused him to pause for a second look. Investigation showed that the ray of light came from a small red crystal, which the prospector felt sure was not garnet (commonly found in the ant hills), and which he suspected might be tourmaline. Examing an outcropping ledge near by, he found other crystals, and proceeded to stake a claim, which was developed into one of the great gem mines of California, producing tourmaline, kunzite, and other stones.

Across the mountain range from Pala is a still more famous gem-producing district—Mesa Grande. The initial discovery of the ledge in which the Himalaya tourmaline mine was finally located antedates the recorded history of that region. Crystals have been found in Indian graves, dug before even the Spanish missionaries reached California; and both Mexican and American cowboys have picked up others in the vicinity ever since the American occupation. In more recent years, children of the Mesa Grande district school used to frequent the locality, particularly after heavy rains, in order to gather up the glittering baubles. Sometimes they sold a particularly fine specimen to the school teacher, and considered themselves lucky if he gave up a dime in exchange. Sometimes an enterprising youngster would collect enough to fill a tobacco pouch, and sell the lot to one of the tourists stopping at Rancho Cereza Loma, 5 miles away from where the bright stones were found.

Fig. 3. Diamond Washing Plant in Arkansas

Many of these "finds" were colorless and transparent quartz crystals, but others were 6-, 9-, or 12-sided crystals, varying in diameter from that of a slate pencil up to 2 inches or more, in many shades of pink, red, green, and other colors. Of course many persons wondered what the stuff was, and some believed that anything so beautiful ought to be worth money. On several occasions specimens were taken to San Diego and shown to jewelers there; but the jewelers proved no wiser than the people of the back country. Most of them seemed to think that anything so common that it could be picked up from the ground could not have any value worth considering.

However, specimens were finally sent to New York for determination, and it was not long until agents of New York jewelers were on the ground. The spot where the crystals were picked up finally passed into the hands of the Himalaya Mining Co., and active work was begun on the development of the Himalaya tourmaline mine in 1898. It is conceded to be the world's greatest tourmaline mine, and its product, cut and polished in New York City, is now known all over Europe, America, and the Orient. It is particularly esteemed in China, where pink tourmaline (also known as rubellite) is held sacred to the gods. On the adjoining claim is located the San Diego Gem Mining Co.'s tourmaline property, which also has yielded a large quantity of fine gems.

While the world's most celebrated turquoise mines are those of Persia, on the slopes of Mount Ali Mirza, yet the mines of New Mexico, Nevada, and California, now supply the major part of this gem material used the world over. The turquoise mines of New Mexico are the most ancient mines of any description within the present limits of the United States, having been extensively worked long before the discovery of America by Europeans. It is said that in 1679 or 1680, 20 Indians at work in the mines near Los Cerillos (16 miles from Santa Fe) were killed by a cave-in at the workings, and that the great Pueblo Indian revolt of 1680, which resulted in the expulsion of the Spaniards for 12 years, was due to this earliest of recorded American mine disasters. The reconquest of New Mexico was accomplished by De Vargas in 1692–94, but the Indians had carefully obliterated every trace of the turquoise mines. Not for 200 years were they rediscovered. They were found by John E. Coleman, better known to the mining fraternity of the Southwest as "Turquoise John." The production of the Los Cerillos mines is controlled by the Tiffany company of New York.

In 1898, Amos de Meules, of El Paso, Tex., discovered promising indications of turquoise in the Burro Mountains of N. Mex., and a very small amount of superficial prospecting brought to light some fine gems. A few days later the discoverer was shot and killed by a Mexican boy, and the claims have ever since been tied up in seemingly interminable litigation.

Of late years the production of turquoise has had to take second place in importance in statistics of American gem production, being surpassed in value by the output of sapphire. In 1907, 230,000 carats of sapphire were mined in Montana. The annual production of this gem has been much smaller since then, being limited to avoid depreciating the value of the gem.

For years a little placer mining for gold has been carried on near the headwaters of the Judith River, and from time to time bright blue pebbles were picked from the riffles of the sluice boxes, where they had lodged. Not for a long time was it ascertained that these "pebbles" were real sapphires, equal in beauty and value to any that ever came from Ceylon or the Ural Mountains. Then followed a long, expensive, and discouraging search for the formation from which the gems had been carried by the water. It was found at last, on a fork of the Judith River, in Montana, fully 1,000 miles from the spot where the placer miners had first picked up the gems.

Probably no other kind of mining—perhaps no other occupation in which men engage—makes so strong an appeal to the imagination as diamond mining. From time to time diamonds have been picked up in every state of the Union, and gems of this kind have been sought for more persistently than any others.

In 1906, John M. Huddleston bought a tract of land in Pike County, Ark., 2½ miles from Murfreesboro, and 120 miles from Little Rock. In places the soil presented a very peculiar appearance, with greenish and bluish stains, leading Mr. Huddleston to suspect the presence of copper or lead. On the first day of August, while engaged in looking for indications of these, he picked up a small crystal. This he suspected might be a diamond, although he was not sure. That afternoon he started to ride in to Murfreesboro, when he noticed another crystal lying by the roadside. He dismounted and secured this also, and showed them both to jewelers in Murfreesboro, who assured him that they were real diamonds.

Huddleston and the members of his family thereafter put in their spare time looking for diamonds, but without success until late in September, when another stone was found.

Then the diamonds were taken to New York, and submitted to George F. Kunz for examination. He pronounced them to be unquestionably real diamonds, and recommended a thorough examination of the district in which they had been found. From that dates the beginning of diamond mining in Arkansas, but whether this will ever rank as an important diamond producing region remains to be seen. The stones are of fine quality, equal in every respects to the best stones of corresponding size found in South Africa. The formation, in a volcanic "pipe" of blue ground, or rather rock, (peridotite) is precisely similar to that in which the South African diamonds occur.

Up to the present time more than 1,500 diamonds have been found in the Arkansas diamond fields; and several diamond-mining companies have been organized. These are conducting experimental operations on a small scale; but whether diamonds will be found in sufficient quantities to justify the erection of extensive washing plants and the prosecution of diamond mining on a large scale, only the future can determine. However, the outlook is decidedly encouraging, and it is not improbable that diamond mining in Arkansas will soon dwarf all other American gem-mining industries in magnitude, importance, and value of the output.

A Remarkable Wire Rope

Usually the maximum loads lifted or hauled by wire ropes are amply provided for in the strength possessed by the ropes running under 2 inches in diameter. Occasionally in mining operations where heavily loaded cars must be hauled up steep inclines, stresses are brought upon wire ropes which can only be met by the use of very large sizes. Recently the John A. Roebling's Sons Co. made a haulage rope for the Spanish-American Iron Ore Co. which surpasses anything heretofore attempted in this line. The rope is 3 inches diameter, 7,810 feet long, and weighs 123,360 pounds. It has a breaking strength estimated at 377 tons. Heretofore, when very large diameter ropes have been required it has been considered necessary to increase the number of wires in the rope so as to keep the diameters of these wires within limits which would insure the rope taking bending stresses satisfactorily. Often the diameter of the drum has been a controlling factor, and even if very large ropes of the usual construction could have been obtained it would have been impracticable to use them because of the limited diameter of the drum on which they would have to be wound.

This remarkable rope is constructed of wires which a short time ago would have been regarded as impracticable for stranding into a rope to be bent around sheaves under heavy load. The plane upon which this rope is to be used forms a part of the Mayari railroad on the northeast coast of Cuba. It is 6,716 feet long and has a maximum grade of 25.13 per cent. The machinery has been built for hauling three loaded cars with a capacity of 112,000 pounds each up the incline at a speed of 15 miles per hour. The total weight of the loaded cars, added to the weight of the haulage rope, causes a maximum stress on the rope of about 140,000 pounds. The drums around which this rope is wound are about 20 feet in diameter. When they were designed it was thought that if a rope of larger wires than those generally employed could be obtained, it would be practicable to wind such rope around the drums under heavy stresses, and an advantage would be derived from the superior resistances of such wires to abrasion.

The Spanish-American Iron Ore Co. therefore ordered a rope 3 inches thick of six strands of 19 wires each twisted around an independent wire rope center 1⅛ inches thick. This center to consist of six strands of 19 wires each twisted around a hemp core. This construction, without precedent in rope making, called for wires for the outer strands ranging from .175 to .225 inch. To draw a wire nearly ¼ of an inch thick, possessed of the strength, toughness, and pliability of the finer sizes used for wire rope, calls for care and skill of the highest degree and imposes a task which but for recent improvements in the heat treatment of steel would be impossible of performance.

The manufacture of this wire was begun by producing a quality of steel which experience has shown is best adapted to the production of the highest grade of wire rope, from ingot to billet, from billet to rod, from rod to wire. The various processes of the manufacture were conducted until the proper number of coils of wire were ready for the stranding machine. These processes were subjected to the closest scrutiny and were accompanied by frequent and thorough tests such as bending, torsion, and direct tension. The results of these tests were satisfactory, and after the stranding was completed the manufacturers were confronted with the problem of loading the rope for shipment in such a way that it could be reloaded in a vessel in New York and conveniently handled on arrival at destination. To do this the length and weight of the rope had to be distributed over three reels loaded on two cars. This was accomplished by mounting an empty reel about 200 feet from the main reel on which the rope had been coiled when making, and revolving this reel until it had taken from the main reel a little more than one-half of the rope's length. The reel was then removed and another reel put in its place. The rope was looped around this reel so that when it revolved it took rope in equal lengths from both the main and the secondary reels. This was continued until one-third the rope was wound on each of the reels. The largest of these reels was 10 feet high by 9½ feet wide. The other two were 8½ feet high, one being 8 feet 10 inches and the other 7 feet 2 inches. The reels were then worked out of the shop on to a platform and put into cars alongside. The part of the rope between the reels was coiled on the bottom of the cars. The reels were lifted off the cars at the dock in New York and loaded on a steamer for Cuba, and unloaded at destination without mishap.

Systematic Tunnel Driving

An engineer who recently visited the Loetschberg Tunnel in the Alps, W. L. Saunders, quotes as follows: "When I arrived at the heading it was 9:30 A. M. The holes were being prepared for blasting. The blast took place at 9:35 A. M.; 5 minutes after the blast the men were in place removing the debris, and at a little after 11 A. M. the drill carriage was in place again and the rock drills were working. It usually takes from 25 to 30 minutes between the time at which the drilling is finished and the time at which the start is made to remove the debris; that is to say, 25 minutes for taking away the drill carriage, cleaning the holes, loading with explosives, and blasting. An additional 5 minutes are consumed in getting the smoke away by means of the ventilator, and then the men get to work at the debris. In order to assist the men a spray of water is discharged near the heading after the blast. This water is brought into the tunnel in a pipe placed within a larger pipe, which insulates it and keeps its temperature from being affected by the temperature of the tunnel."

Vanadium, Its Properties and Metallurgy

Different Ores and Where They Have Been Found. Method of Reducing. Uses of the Metal

*By F. W. Brady, M. E.**

Vanadium is a striking example of a metal discovered 100 years before the commercial world was ready for it. There are notable examples of things that the world wants and for which millions of dollars are being expended in the search, and there are others already discovered but which are too costly as yet to be practical, but the condition will likely always exist of men being born, and of elements being discovered "before their time."

In the case of vanadium it was the demanded improvement in steel during the last few years that has given it a chance to make good, and it has already "beaten the field" in the "free for all contests" of alloys for increasing the tensile strength and the elastic limit of steel. Its use in cast iron for increasing the strength and wearing qualities, and in the non-ferrous metals, has given promise of its coming supremacy in all kinds of foundry productions. The reason that vanadium has taken the lead for increasing the strength of steel is that while it makes the much desired increment in tensile strength, it does not cause any brittleness, hardness or lack of elasticity. Carbon, manganese, nickel, and chromium have been used heretofore and occupied the attention of metallurgists for the purpose of strengthening steel, but the dose always left some dregs in the system of the patient.

From the achievement of vanadium today and the indications of what it may do in the future, it must not be inferred that it has been discovered in abundance and that it can be extracted from the ores without a struggle. Nor is the present price and the metallurgical process as now used in its preparation anyway near to our ideal expectations.

The first discovery of vanadium was probably made by Professor Del Rio, in Mexico, about 1800, but both its existence and any suggestions for its use were very hazy for many years. Strange to say, the investigations which gave vanadium its name were those made in connection with the analysis of iron made from the magnetic ores of Taberg, Sweden. The name, though, is after their goddess Vanadis. The investigator, Sefstrom, who named the metal, found it in the highest quality Swedish irons and steels as a natural condition, but it was a long time from then until American metallurgists began deliberately to put it into the molten metal. French chemists also did some investigating to determine the value of vanadium in steel; however, it was not until after 1900, when the advent of the perfected automobile and the airship forced a demand for structural metals of maximum strength and minimum weight, that the production and use of vanadium have been given serious consideration. Heretofore, even after some of its usefulness was recognized, it was looked upon as one of those rare and ultra-expensive speculative elements, for till within 10 or 15 years ago the cost was figured at over $10,000 per pound, and no distinctly vanadium mines were known. It was found in minute percentages and in very widely scattered locations in combination with ores of copper, lead, silica, and in clays, sandstones, etc., in Spain, Sweden, France, Russia, Germany, Mexico, South America, and in many localities in the United States—Pennsylvania, Michigan, Colorado, Arizona, and others.

While there is a lively hunt going on for vanadium ores that will be profitable to mine, yet there are very few vanadium mines in actual operation. In the United States the leading one is probably that of the Primos Chemical Co., at New Meyer, Colo., which operates on a vanadium sandstone. The leading vanadium mine of the world is in Peru, located in the Andes range some 16,000 feet above sea level. There are two kinds of ore from this mine, the black sulphide with carbonaceous material and from 40 to 60 per cent. of sulphur; this ore can be lighted with a match. It is called patronite after the discoverer. The second is a bright red ore, which is a clay impregnated with vanadium oxide. The roasted sulphide ore which carries about 19 per cent. vanadium is the ore handled. It is mined mostly in open cuts, sorted, roasted, and sacked. Transportation is on the backs of llamas from the mountains to the lake country. Then by boat across the lake to the railway terminal, and by rail to the coast. Sailing vessels carry it to the wharfs in New Jersey and then it is freighted to the American Vanadium Co., at Bridgeville, Pa This company produces probably 75 per cent. or more of the vanadium supply. The ore is treated with sulphuric acid and transformed into vanadic acid. As to the characteristics of vanadium acid, it may be said that it is a dark, brownish powder that fuses into a brownish red or yellow mass, the latter color showing greater purity. When melted, it crystallizes into long brownish-purple needles.

The vanadic acid is fused with iron scale and aluminum, some iron shavings being added to give the required bulk to the charge. The crucible is a sheet-iron tank about the size of a barrel, that is lined with magnesite which is molded into place and dried for each charge. Each operation produces a button of ferrovanadium weighing about 75 pounds and carrying from 30 to 40 per cent. vanadium. The crucible operation is not carried on in the usual way by placing the entire charge before firing, but the method used is to start the action with a cartridge in the bottom of the crucible and then gradually add the charge up to the full capacity of the crucible. The ferrovanadium button is broken up and crushed, then sized with different mesh screens, each size of lump being most suitable for some particular service. The sizes range from that of one's fist down to a powder. Pure vanadium is a silvery-white metal. It can be melted only in the intense heat of the electric furnace. As a pure metal it is of no particular value. Its atomic weight is 51.27; specific gravity at 15° C., 5.5; and its specific heat is .1233 at 0° C. It is the alloys of vanadium that make the metal of such great commercial value. The most important of these alloys is the ferrovanadium, which is a hard, silvery-white alloy, produced by the chemical and aluminum-thermic process described above. This process gives an alloy carrying one-third vanadium and two-thirds iron that is free from carbon. It is especially important that the alloy be free of carbon because carbon destroys the beneficial action of vanadium and hence the necessity of the chemical process of manufacture. This alloy fuses at a much lower temperature than iron or steel, it is possible, therefore, with it to dissolve and distribute the vanadium through the molten metal.

When the open-hearth furnace is used for melting, the ferrovanadium is added directly to the molten charge and thoroughly stirred into it. With the cupola method of melting, the ferrovanadium is put into the ladle that receives the stream of melted metal and the mixing is done just before the pouring of the casting. With the crucible process of melting which is used in the manufacture of tool steels, the ferrovanadium and any other special alloys are all put into the crucible with the charge and a thorough mixture made before pouring the ingots. Vanadium was first used in tool steels because these being high priced would stand the extra expense of the new alloy. Gradually the price of vanadium alloys has been reduced until now they are available for use in the general run of steel castings, gray iron castings, and also in brass, bronze, babbitt, and aluminum.

In increasing the strength of cast iron from 10 to 25 per cent., depending upon the initial strength of the iron, and of steel to a much greater degree, one of the special attractions of the alloy for the manufacturers is the exceedingly small amounts of vanadium required. Less than two-tenths of 1 per cent. of vanadium is all that need be used for most work.

Vanadium has a strong affinity for nitrogen and oxygen,

* Scranton, Pa.

and its first uses were for coloring glass, pottery, dyeing, etc., and for making analine black, indelible inks, and the like. Therefore, some of the vanadium added to iron, steel, brass, etc., takes up the gases in the metal and passes off in the slag. This is beneficial to the metal as it makes it more solid and of even grain. But vanadium is not intended primarily for a flux, because the fluxing can be done with other and cheaper substances. As much as possible of the vanadium charged should remain in the finished metal. The vanadium is expected to unite with the iron which it both toughens and strengthens, and not over 10 per cent. should be lost in the slag.

The explanation of the action of vanadium in cast iron and steel is not altogether clear. A great deal is known, however, on the structure of alloy steels under different conditions of heat treatment. The use of microphotographs in the investigations of the structure of steel has added greatly to our fund of knowledge in this line. These photographs are made of transverse sections of the steel that have been etched with acid and greatly magnified by the use of a microscope. Those who have made the investigations state that the steel is composed of pure iron, called *ferrite*, and a chemical compound of iron and carbon, called *pearlite*. It is claimed that the vanadium unites with and strengthens the ferrite, and that it toughens the pearlite. The vanadium in the steel seems to scatter the carbides and prevent their uneven bunching as is done in carbon steels.

To those engaged in the mining industries, the advent of the commercial use of vanadium means much. By its use the operator can get better car wheels, axles, springs, drills, and tools, ropes—in fact, its application is possible in most any structure where it is desirable to get greater strength and wearing qualities, either with or without any increase of weight. Brasses, bronzes, bearing metals, aluminum castings, etc., also come in the list of improved metals by the use of very small percentages of vanadium. It is important, of course, for the purchaser of vanadium steels, castings, and alloys, that he get the real thing. It might be possible to find "vanadium steels" on the market which do not contain vanadium.

Some of the vanadium products made for the use of foundrymen and steel makers are as follows: Ferrovanadium, in two grades, each carrying about 35 per cent. of vanadium. One grade has a much lower melting point than the other, owing to its containing from 10 to 16 per cent. silica, 6 to 10 per cent. manganese, and 2 to 5 per cent. aluminum. The higher melting alloy contains less than 2 per cent. each of silica and aluminum. The alloy with the lower melting point has a distinct advantage in its being more readily alloyed with iron and steel. However, where the silicon, manganese and aluminum are objectionable, the higher melting alloy can be used. The price of these alloys is based on the percentage of vanadium contained, being $4 per pound for the vanadium. Hence, a 35-per-cent. alloy would cost $1.40 per pound, the drop in price within the last 10 years being most remarkable. Cupro-vanadium, alumino-vanadium, and mangano-vanadium, are other alloys made for special applications in steel, cast iron, bronzes, etc., costing about $1.50 per pound.

Manganese In Iron and Steel

Carbon may exist in iron mechanically mixed with it as graphite, or in chemical combination with iron, or in chemical combination with some third element contained in the iron, or in solution, if we admit that solution differs from combination.

Faraday, in 1822, first showed that steel when suddenly cooled dissolved completely in hydrochloric acid, but when previously annealed left a carbonaceous residue when thus dissolved.

Rinman, in 1865, observed that the quantity of carbon remaining undissolved when one and the same steel was attacked by cold hydrochloric acid differed greatly, being greatest in unworked steel and smallest in hardened steel, which sometimes yielded little or no carbonaceous residue. The carbon which dissolved he named hardening carbon, because chiefly found in hardened steel, and that which did not, cement carbon, because he found it chiefly in cement or blister steel.

Non-forgeable pig iron is saturated with carbon when the carbon content reaches 5 per cent., but in case manganese is present the carbon may go as high as 7 per cent. Gray pig iron with graphite may go from 3½ to 4 per cent., of which .3 to .5 per cent. is combined carbon. Wrought iron difficult to fuse can have a carbon content varying from .04 to 2.3 per cent. Wrought iron cannot be appreciably hardened. Steel capable of being hardened may have a carbon content of from .6 to 2.3 per cent. Manganese promotes the union of carbon in both molten and solid states. Highly manganiferous cast iron not only contains more carbon than other iron, but that carbon is ordinarily almost wholly in combination.

In annealed steel practically all the carbon is in the cement state, while in hardened steel the carbon is supposed to be in the hardening state. In tempered steel the immediate portion is in the cement state, and on the whole rather more in blue than in straw-tempered steel.

While manganese alloys with iron in all ratios, it is readily removed from iron by oxidation, and in this way it restrains the oxidation of the iron, while sometimes permitting the oxidation of other elements combined with it. Its presence increases the power of carbon to combine with iron at very high temperatures, say 1,400° C., and restrains its separation as graphite at lower ones. It prevents ebullition during solidification and the formation of blow holes, by reducing or removing oxide and silicate of iron, by bodily removing sulphur, by counteracting the effects of the sulphur which remain, as well as iron oxide, phosphorus, copper, silica, and silicates. While 1½ to 2½ per cent. manganese is universally admitted to cause brittleness, steel with 8 per cent. manganese is astonishingly ductile, with further increase of manganese the ductility again diminishes. Steel with 8 to 10 per cent. manganese, though extremely tough, is so hard as to be employed without quenching for cutting tools.

Oxide of manganese gives slags a strong characteristic green color and considerable fluidity. Manganese appears to volatilize with considerable rapidity at a white heat. A high percentage of manganese raises the melting point of iron, but small percentages may lower it. By increasing the solubility of gases and steel, manganese retains while solidifying the gas which it dissolves when molten, or by preventing the oxidation of carbon and the formation of characteristic oxides, manganese like silica probably less thoroughly hinders the formation of blow holes.

Manganese added to molten oxygenated iron removes its iron as oxide or silicate of manganese. Manganese appears to act upon oxygenated iron in two distinct ways, by reducing iron oxide, and by forming a readily separate double silicate of iron or manganese. It may act in both ways simultaneously. While iron oxide over in molten steel remains diffused or dissolved through the mass and renders it redshort, oxide of manganese if mixed with iron raises to the surface of the molten mass. Hence, as in the Bessemer and open-hearth processes of making steel the metal under ordinary conditions becomes slightly oxygenated. Manganese is usually added at the completion of these processes in the form of a manganiferous cast iron termed spiegeleisen or ferromanganese, and this reduces the iron oxide and is itself oxidized and scorified.

According to Osmund, manganese hinders the formation of cement carbon.

Chilian Mills and Amalgamation

A Description of the Early Form of Mill and of That Used at the Beresovsky Mine, Russia

By H. C. Bayldan

The following is an abstract from Bulletin No. 75 of the Institution of Mining and Metallurgy and deals with the slow-running "Chilian," or "edge-runner" mill, universally used in Russia for crushing gold ores as a preliminary to amalgamation, etc., in place of "gravity stamps," the standard machine in other countries.

The types of high-speed roller mill (30 to 40 revolutions per minute) now being used extensively and successfully in other parts of the world for regrinding middlings and as an addition to stamp battery plants, are not comparable with the mill described herewith, since they are used for a different purpose.

Vein mining commenced in Kotchkar district about 1867, when the method of crushing consisted in spreading the ore on the main thoroughfares where carts and other vehicles could pass over it; when sufficiently pulverized it was gathered up and washed in sluice boxes.

This method was superseded by preparing on hard ground a circular track, on which the ore was spread, and over which carts filled with stone, to make weight, passed until the ore was reduced to the requisite fineness for washing.

In 1868 other crushing appliances were tried, such as a cast-iron weight attached to the end of a pivoted rocking rod, and later gravity stampers, making from four to six blows per minute, operated by horses. The stampers, usually five in a battery, consisted of hardwood stems shod with cast iron, falling on an enclosed anvil mounted on a wooden foundation. The duty of this primitive gravity mill was from 2 to 3 tons per day dry crushing.

In 1870 edge-runners of rude construction were introduced consisting of a pair of stone runners about 7 feet in diameter

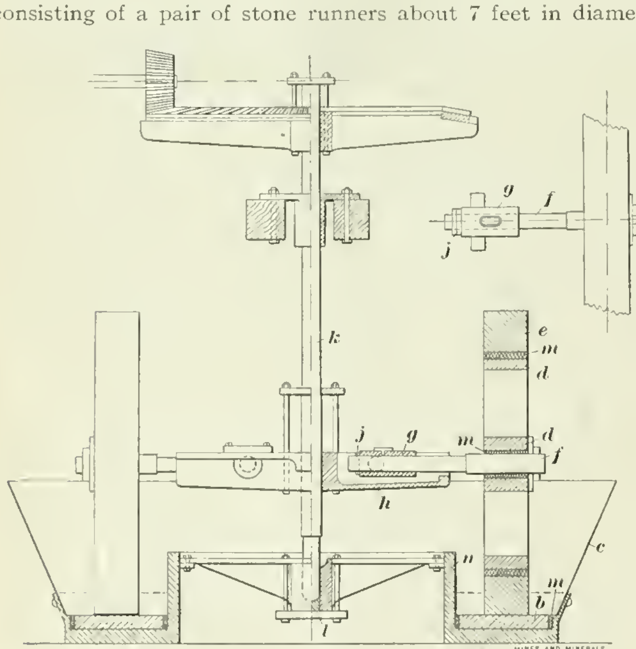

Fig. 1

by 18 inches in width, mounted on a horizontal wooden axle and revolving on an enclosed grinding track made of flat slabs of stone. These mills were operated by horses, much in the same way as a horse whim. The output per day, dry crushing, was from 2 to 3 tons, the runners making from 3 to 4 revolutions per minute.

Between 1871 and 1873 mills made with pans, grinding track, and runners of cast iron were introduced, these also being operated by horses; but, at about this time, a mill driven by steampower made its appearance and wet crushing with mercury was adopted.

It was not, however, until between 1880 and 1885 that steam-driven mills came into general use in Kotchkar, and

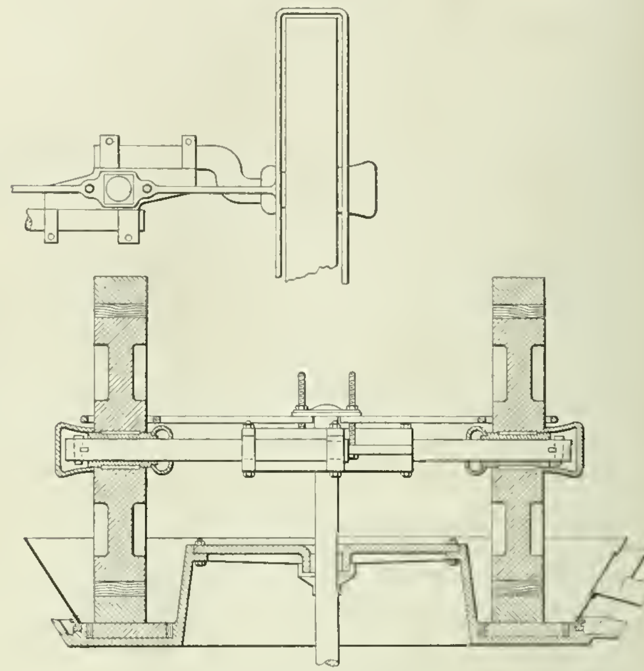

Fig. 2

important improvements took place in the design and capacity of the mill.

The design at this period was similar to that of the standard mill, Fig. 1, commonly used at the present time, with the difference that the earlier type had runners revolving on fixed axles, whereas the majority now in use have fixed rollers on revolving axles.

The mill consists of a circular cast-iron pan *a* from 7 feet to $10\frac{1}{2}$ feet in diameter (usually made in two pieces in the case of the larger sizes and in one piece in that of the smaller), to which are bolted wrought-iron sides *c* protected at the bottom by wearing plates. The cone *n* inside the pan is also protected from wear by wrought-iron liners.

The track *b* on which the runners travel is formed by from six to eight annular sections or dies, 3 inches to $3\frac{1}{2}$ inches in thickness, held in place by wooden wedges.

The runner consists of a cast-steel tire or wearing ring *e*, $5\frac{1}{2}$ feet to $6\frac{1}{2}$ feet in diameter by from 7 inches to 12 inches in width, and from 9 inches to 10 inches in thickness, fastened by wooden wedges *m* to a central casting *d*, which forms the boss of the runner.

The boss is provided with an annular recess for the reception of compensating weights when the outer ring becomes worn.

The runner is keyed on a wrought-iron axle *f* revolving in a cast-iron sleeve *g*, provided at the inner end with a collar bearing *j* to take up pressure due to centrifugal force.

This sleeve has two trunnions which fit in bearings recessed in the cast-iron center crosspiece *h*, and is free to move up or down vertically, allowing the runner to accommodate itself to variations in the height of ore feed.

The center crosspiece, transmitting motion from the vertical driving shaft *k* to the runners, fits on a square section of that shaft, and is capable of vertical adjustment to compensate for the wear of tires and dies.

This type of mill is notable for its simplicity, requiring little close or skilled attention, being in this respect comparable to a rock breaker of the jaw type.

It is of interest to note that the Beresovsky mill (considered until recently the most up-to-date Chilian milling plant in Russia), has rollers revolving on a crank-axle, see Fig. 2. In this instance the axle is free to move up and down, thus allowing the roller always to stand in a vertical position.

The objections to this mill are, that the speed must be kept low; and that the ore fed to mill must be broken so small as to pass a 1-inch ring.

The speed is 11 revolutions per minute, the mean radius to center of runner being 3 feet 9 inches, which gives a mean roller travel of about 260 feet per minute.

If this be increased, lateral play of the roller results from rapid wear of the brass bushing by the outside axle collar; in fact, a roller has been known to break away as a result of such play and go through the side of the mill, and a guard is now provided with the object of preventing this. The shock to the bushing when the mill is fed with coarse broken ore frequently causes a breakage of that part.

With this design of the mill, an increase of capacity may be obtained by increasing the weight of the runner, or increasing the number of runners from two to three.

A limit is soon reached beyond which there is no increase in efficiency as a result of increasing weight.

Three runners have been adopted in some of the mills in this plant, but owing to the speed limit their capacity is low.

The weight of each runner is 10,800 pounds, and the capacity with two runners is about 24 tons per working day of 24 hours.

In gathering data of some typical mills crushing ore very similar in hardness and general character, it was impossible to obtain accurate figures as to power required per mill, but it is estimated at between 7 and 12 horsepower.

The tailing is very fine, and of uniform, even grade, a small percentage remaining on the 30- and 60-mesh screens. The capacity of the mills is low, owing to the fact that they are all designed and run to avoid violent agitation of the pulp within the pan.

The mean travel of the runners seldom exceeds 300 feet per minute, the depth of the water above the ore is comparatively high, and the width of the pan is the minimum practicable, with the result that the motion of the pulp within the mill resembles that of water flowing in a launder.

The main objects in view are to crush the ore very fine, and to obtain the highest possible percentage of the gold by amalgamation and from the pan itself.

That the mills successfully fulfil these requirements is evident from the screening analyses and amalgam percentages obtained, but the economy of using such a type of mill in any but quite small plants is doubtful. Most of the mills are hand fed with ore broken to any size up to a 4-inch ring.

An automatic feeder similar to a "Challenge" is in use at the Beresovsky mill, which is understood to give satisfaction, although the reported objection to this type is that with wet, sticky ore it is unsatisfactory, which probably accounts for its very limited adoption in the mills throughout the country.

The foregoing remarks make it evident that the low capacity of the mills is due to the purpose for which they are primarily used; i. e., amalgamation. So long as this factor remains the guiding principle in the average milling practice of the country, but small advance in the development of the mill for maximum capacity may be anticipated.

With the above object in view, the mill capacity has been increased either by increasing the diameter of mills and the weight of the runners, or by increasing the number of runners from two to three. The latter, under these conditions, would appear to be the better of the alternatives, but this type of mill has not become popular.

The diameters of the mills have been gradually increased from 7 feet to 8 feet 2 inches, 9 feet 4 inches, and 10 feet 6 inches, with runners weighing from 3,600 pounds to 10,800 pounds each, but the increase in capacity with mills of large diameter is not commensurate with the extra floor space occupied; in fact, this type of mill compares most unfavorably with stamps on an output basis, in respect to power, space occupied, and first cost.

A comparison of two mills shows that, while the mean travel of the runners per minute in one is only 31.4 per cent. greater than in another mill, the capacity is 62.5 per cent. greater with 1-foot 3-inch diameter larger runner.

An investigation of the cause of the higher capacity led to the conclusion that this was due to the more violent agitation of the pulp in the pan, with the result that the discharged product was coarser, the percentage of +100 mesh being 37.3 per cent., while in the smaller mills it was only 17.33 per cent.

It was on the strength of these results that a Chilian mill was designed which embodied improvements suggested by experience with this type of mill.

The average weights of tires and dies worn out and discarded, taken from a number of mills, are: Tires, from 10 per cent. to 15 per cent. of the original weight; dies, from 36 per cent. to 45 per cent. of the original weight. The total cost per ton for tires and dies was 6.52 cents, or 1.192 pounds of iron.

Inside plate amalgamation is the standard practice in Russia. Clean-ups are made once in 24 hours, and mercury varying in quantity from 6 pounds to 8 pounds is added to each mill at intervals during the day, from 2 pounds to 3 pounds of this being introduced an hour before the clean-up, just previous to "running down" or ceasing to feed, in order to collect the amalgam.

The copper plates used are 4 feet 8 inches in length by 2 feet 4 inches in width, there being generally two or three to each mill, with rather deep and wide riffles or traps before and after each plate.

The plates are run hard and kept under locked covers until the clean-up, which is the only time they are touched during the 24 hours.

The slope of the plates varies in different mills, but is generally excessive and the water out of all proportion to the amount required to keep a free surface.

The clean-up takes place in the following manner: The men cease feeding an hour previous, and the ore already in the mill is run down as low as possible. The screens are then removed, water feed turned on full, and the pulp and amalgam on the plates swept with brooms. The riffles or traps catch the amalgam and heavy particles of iron during the "brushing out," and, in order to keep the riffles from becoming filled with sand, a man walks from one to another and agitates their contents by means of a T-shaped stick.

Any mercury and amalgam remaining in the mills after the preliminary brush out is finally removed by pouring water from a height out of buckets into the recesses while a man is violently brushing.

After the mills are cleaned up, the contents of each riffle are agitated by hand (the pulp passing over the plates into settling boxes, to be returned to the mill later) until only a few particles of iron, sand, and amalgam remain. The plates are then scraped down by means of "rubbers" to remove the excess of mercury splashed on them, and the contents of the riffle are discharged through side doors into dishes.

The amalgam is now cleaned, that from each mill being kept separate and retorted daily.

Mercury losses by this system of clean-up are somewhat high, owing to excessive handling and multiplication of volatilization losses from the daily retorting of small quantities of amalgam.

At the end of each month (sometimes after longer periods), the plates are removed and placed in a box through which live steam passes for from 1½ to 2 hours, the plates being then placed on a table and the amalgam scraped off by means of chisels;

mercury is afterwards added and rubbed in (this being considered superfluous in some plants), and the plates replaced.

This is really the only dressing the plates receive in the month. Modern amalgamation methods are imperfectly understood, but with the class of shiftman left in charge opportunity for stealing has to be reduced to a minimum; and to run soft plates, requiring dressing at regular intervals, would be out of the question.

In the Beresovsky mill the wash-up is greatly expedited by having the sides of the pan movable. At clean-up the whole of the side is raised by a lever arrangement, and the contents of the pan are flushed into an annular gutter which forms part of the lower casting.

Trade Notices

Centrifugal Pumps.—An improved line of centrifugal pumps has just been placed on the market by the Goulds Mfg. Co., of Seneca Falls, N. Y. These pumps are constructed in both single-stage single suction, and single-stage double suction types. Either type can be arranged for belt drive or direct connection to electric motor, gas, gasoline, or steam engine, or steam or hydraulic turbines. The single-suction, as well as the double-suction, pumps contain many special features of great importance from an operating and economical standpoint. In details of construction every point bearing on efficiency, durability, and convenience has been carefully considered, with the result that the Goulds Mfg. Co. claim great superiority for these machines. Mine managers interested in this class of pumps, and most progressive managers now are, will be cheerfully sent full details and what they are guaranteed to accomplish on request made to manufacturers.

Steel Derricks and Drilling Rigs is the title of a book of 54 pages, issued by the Carnegie Steel Co., describing the construction of drilling derricks of steel, and giving facts regarding their successful use. The book contains a large number of drawings showing details of construction and photographs of rigs and should be of value to all interested in deep drilling. It can be had upon application to the company.

The Relation of Size of Fan to Output.—In an engineering paper, mention was recently made of a fan 32 feet high handling 20,000,000 cubic feet per hour as being one of the largest fans ever built. It is stated by the American Blower Co. that at Clydach Vale pit of the Cambrian Collieries, Ltd., Glamorganshire, South Wales, is a Sirocco fan only 13 feet 5 inches in diameter which delivered on test 36,000,000 cubic feet per hour—nearly double the capacity of the 32-foot fan mentioned, and less than half the size.

The Chicago Pneumatic Tool Co. announces a change in the trade designation of the air compressors manufactured by them, which heretofore have been known as the Franklin compressors, their compressor works being located at Franklin, Pa. Because of the fact that its pneumatic tools, electric drills, rock drills, and other articles of manufacture are invariably identified with the name of the company, it has been determined to hereafter use the trade name "Chicago Pneumatic" as applying also to their air-compressor product.

Johns-Manville Building.—A 12-story office building is being erected on the southeast corner of Forty-First Street and Madison Avenue, New York City, for the H. W. Johns-Manville Co., who will occupy it about May 1, 1912, as the general offices and New York salesrooms of the concern.

The building, which has been designed so that all four sides will be attractive, will be known as the "Johns-Manville Building," and will be one of the few 12-story structures entirely occupied by a manufacturing concern for office purposes only.

It will be of fireproof steel construction throughout, and will contain two Otis pasenger elevators of the latest type. Each floor will have an area of 2,500 square feet, or a total area for the 12 floors and basement—which will extend under the sidewalks—of 34,500 square feet.

An unusual feature connected with this building will be the fact that the tenant manufactures and will furnish a considerable part of the equipment of the structure. Among the various materials which the H. W. Johns-Manville Co. will install will be asbestos roofing, asbestos plaster, linolite system of lighting, conduit for wiring, flushometers, sanitor seats, electrical accessories, waterproofing, Keystone hair insulator, asbestos wood, fire extinguishers, asbesto-sponge felted, and J-M Asbestocel pipe coverings, etc.

The name of "H. W. Johns-Manville Co." and "Asbestos and Magnesia" have so long been synonymous, that many will be surprised to learn that this company also manufactures a large line of electrical goods, plumbers' supplies, building materials, automobile supplies, cold-storage insulation materials, railroad supplies, etc.

Moisture-Proof Dry Battery for Use in Mines.—In mines where considerable moisture is prevalent it sometimes happens that the cardboard cartons of dry cells absorb so much moisture that when the cells are placed side by side, or on a metallic base, they become short-circuited. This causes them to run down and deteriorate quickly, thus necessitating frequent renewals and an attendant maintenance expense. The Western Electric Co., realizing this, has recently placed on the market a new, moisture-proof dry battery. This cell has been designed especially for use in mine, railway, and general telephone service where the batteries are subjected to moisture. The new cell has the same high efficiency, long life, high voltage, and great recuperative power as the standard "Blue Bell" battery, but the cardboard carton has been treated with a special impregnating compound which prevents moisture from reaching the cell proper. This will give sufficient protection so that the life of the batteries used in damp places will be as great as that of the batteries used in any other magneto service under ordinary conditions. The Western Electric Co. is employing 26,000 persons as compared with 29,000 in 1906, which was the largest number ever on the company's books at any one time. On January 1, 1909, there were less than 18,000 persons employed, which number was increased to 23,600, approximately, at the beginning of 1911.

The Goodman Mfg. Co., of Chicago, have recently arranged, through their Pittsburg office, with Mr. James R. Cameron to represent their line of electrical coal-mining machines and locomotives in northern West Virginia, with headquarters at Fairmount, W. Va. Mr. Cameron is thoroughly versed in the application of electrical machinery for coal-mining purposes, and this, with his wide acquaintance, will enable him to be of assistance to the operators in this section.

Mine Scales.—As the service demanded of mine scales is particularly severe, it is essential that they be as simple and strong in construction as is possible with the maintenance of accuracy. In addition, the varying conditions at mines require varying designs of scales. The Winslow Government Standard Scale Works, of Terre Haute, Ind., recognize the above facts. They manufacture 250 types of scales, ranging in capacity from 1 ton to 250 tons, and they have the men and facilities to solve any mine-scale problem. Every scale manufactured by them is guaranteed. Their catalog is sent free on request, and as it contains valuable scale information it is well worth having.

The Sullivan Machinery Co. announces that Mr. A. de Gennes, for a number of years general representative of the company at Paris, France, has retired from business. His successor, Mr. Hart O. Berg, whose address is 30 Rue Des Champs Elysees, Paris, will be in charge of the business in France under general direction of the European branch office at London, 814 Salisbury House, Mr. H. T. Walsh, manager. Sullivan diamond drills, rock drills, hammer drills, air compressors and their parts, will be carried in stock at Paris as heretofore.

Tin Deposits of El Paso County, Tex.

Geology and Location of the Deposits. Smelting Tin Ore with an Oil Furnace

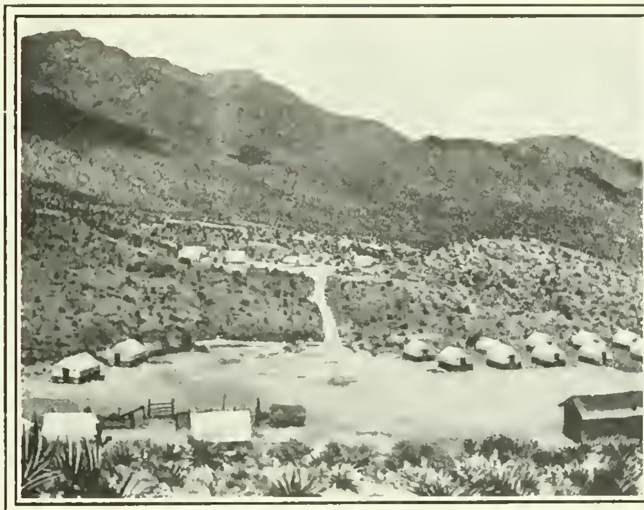
*By Regis Chauvenet**

Tin deposits are exceedingly rare in the United States.

During the South Dakota tin excitement some 30 years ago, several companies were formed, the largest of which is said to have absorbed $5,000,000. That there is tin in the region is certain; that no commercial quantities have yet been produced is equally so. Owing to a vast amount of fraud in the original placements, there are today many who believe that there is not a word of truth in any reports of the metal in that state. It has come to my personal knowledge that in the vicinity of Tinton, S. Dak., cassiterite has been found, and it is reported that the prospect improves with depth. Probably nothing has been developed averaging over half of 1 per cent. A small quantity of metallic tin was reported in the year 1906.

A small tin deposit has been known for many years in the "Temescal" district, San Barnardino County, Cal. Like most tin deposits this is in a granitic formation, and is disseminated in small fissures accompanied by tourmaline. By great expenditure of time and effort, enough of this ore was secured to make a small trial run, producing, it is said, about 200 pounds of the metal. This was many years ago, and it seems very unlikely that any further effort will be made to work the veins.

In North and South Carolina are small deposits of cassiterite, from which concentrate has been made for a number of years, and shipped abroad for conversion to metal. The tin in this concentrate is low, not because of defective work, but because of a replacement in the very body of the cassiterite by iron oxide.



EL PASO TIN MINING CAMP

In the 70's of the last century, Missouri had her tin excitement. The secretary of the "Missouri Tin Mining Co." called upon our firm to remonstrate because we declared they had no tin. The details of this conversation have passed from my mind, except one gem, characteristic of the metallurgy of the period. "The tin is there, and we know it," said the official, with some heat, "but we know as well as you do that it isn't in a condition susceptible of chemical detection."

Having often been called upon to examine so-called tin deposits with negative results, I had little expectation of seeing anything worth while, when sent to Texas in 1908 to report on a supposed tin prospect.

It was at the instance of my brother, S. H. Chauvenet, of Pennsylvania, that I made the first examination. He is now president of the El Paso Tin Mining and Smelting Co., which was formed to exploit the ground.

The property was mentioned in the United States Geological Survey bulletin by Weed several years ago, and the "El Paso Folio" gives it some description. One of the "blocks" into which the region is divided by the Survey has in fact been named "Cassiterite."

The deposit is about 12 miles, almost due north, from the city of El Paso, Tex. The range of mountains whose southern terminus is at El Paso, is known by several local names at various latitudes. Its proper geographical name would seem to be the San Andreas, but south of Las Cruces, N. Mex., it is called the "Organ" range, and this name changes again as the range crosses into the western arm of Texas, to "Franklin Mountains." The broad and low pass known as "St. Anthony's," just north of the boundary between New Mexico and Texas, marks the division of names.

The tin deposit is in the Franklin range, and on its east flank. On the west of the range flows the Rio Grande. On its east side stretches a great plain, or, as it is called in the Survey Folio, "Bolson." The range stops abruptly close to El Paso.

The geology of Franklin Mountain is treated at length in the "El Paso Folio," to which I would refer any who may wish to go into the matter in detail. The base of the range is granitic, the granite being surmounted by pre-Cambrian and Cambrian quartzites, and these again by Ordovician and Silurian limestones. This description applies to the east flank, and especially to that portion of it in which the tin is found. The tin is confined wholly to the granite, so far conforming to the general rule of its occurrence.

The sedimentary formations are broken by a great fault, of which they form part of the foot-wall. Thus the east flank of Franklin Mountain presents a bold escarpment with the Silurian limestone at the top and the granite at the base. It is stated in the "Folio" that on the west flank of the mountain, which is mainly a "dip slope," limestones of more recent age are found unconformably placed on the Silurian.

The "Bolson," which stretches far to the east, seems to be composed entirely of detrital material, and like most such plains is destitute of surface water. Its underflow, however, is considerable, and the city of El Paso gets most of its water by driving wells several hundred feet down in the "Bolson" a few miles north of town.

From this plain rises, to the west, first a "humpy" set of foot-hills, very largely composed of transported material, then a granite exposure at the base of the steep broken-off sedimentary series. The area of this exposure in which the tin is found is about 4,000 feet N—S, by an irregular width E—W, perhaps an average of a quarter of a mile.

Dikes run roughly east and west through the granite, though they are sometimes little more than an inch thick. They are often filled with a pegmatitic mass, that has become silicified, especially at contact with the country rock. With the silica cassiterite is found very commonly.

The main source of tin ore, however, is not in these "dikes" proper, but in the country rock close by. The dikes are rarely over 2 feet wide, but the "disseminated" ore occurs in lenses several feet wide and many feet in length, forming the more important basis for mining operations.

Locally called "cassi-granite" this ore might be better named "cassi-feldspar," for the granite shows very little quartz. Most of the ore might be correctly described as cassiterite disseminated in feldspar, the latter usually of a clear pink tint. However, this feature is not universal, some of the gangue showing feldspar and quartz mingled in true granitic fashion, and with cassiterite interspersed. Mica is wholly absent in

* Mining Engineer, Denver, Colo.

the tin-bearing portion. The discovery was made on "float" mineral of this "disseminated" kind, and until recently many thousand pieces could be picked up on the hillside.

Six of these "dikes" have been traced. They differ greatly in mineralization, also in the quantity of impregnated country rock to be found in their vicinity.

In one of the gulches on the hillside close to one of the dikes, some stream tin has been found. It is not abundant, though some of the ground has been moved and the material put through jigs in the mill. Occasionally "chunks" of pure cassiterite turn up; one found weighs about a pound.

Notwithstanding the fact that the "dikes" are not the chief source of ore, their utility, as indicating the proximity of disseminated ore, is obvious. At the most productive or No. 4 dike, the lenses are found exclusively on the south side of the dike, a phenomenon as yet unexplained, as exploration has not proceeded far enough to warrant assertions as to any law of deposition.

Naturally material that is supposed to carry enough to pay, is sent to the concentrating mill, however, not enough steady work has been done to determine an average mill run. It is estimated that ore under 1 per cent. can be mined and treated, although the average so far was much higher than that; but I am not prepared to say how much higher.

The disseminated ore is nearly black, rarely crystallized to the naked eye, is extraordinarily free from all other metals, and separates easily from its feldspar gangue. Thus, as a concentrating proposition it has: Great difference in specific gravity between ore and gangue; i. e., say 6.9 and 2.6; unusually easy separation of ore from gangue in crushing; and great purity of the product.

Oil Furnace at El Paso Tin Mine

Nature has conferred so many helpful concentrating features on the ore it would be a very poor appliance that couldn't recover product high in total saving and in assay. The tables used are the Sutton-Steele-Steele dry tables. After their adoption water was developed on the property, though not in great quantity, and jigs have been installed. The system of concentration is still under adjustment, but hitherto the concentrate carried from 56 to 71 per cent. tin, and it is expected that it will never be much under 70 per cent. tin. That means hardly more than 10 per cent. gangue, and smelting so rich a product is quite easy.

The work done has been largely in the nature of prospecting. The latest developments are said to be the best yet shown, though as the greatest depth attained is still under 100 feet, little can be said as to the size of the ore bodies.

Walter E. Koch has had charge of the furnace work, and some of the results are worth detailing.

The furnace is small with a reverberatory hearth 5½ ft. × 3½ ft., heated entirely by an oil flame. So far as I am aware no tin was ever produced before by such an appliance. The oil is dropped in the burner by gravity from a barrel placed about 50 feet from the furnace. A blast of air pumped by a small gasoline engine, carries the oil in through an annular space which surrounds the little oil pipe.

The flame is controlled by keeping the air blast constant and adjusting the oil valve, as a greater or less heat or reducing action is required. Not one of those interested had ever seen or heard of such a furnace for tin reduction, but as a similar appliance was in successful use in the East for heating billets, and as it evidently gave plenty of heat and a fine reducing atmosphere, it was adopted. A German firm working at Hanover and Hamburg wrote to ask the company to adopt their tin furnace, which they are working on Bolivian ores. Upon learning that we had adopted the oil burner, they wrote again, demonstrating the impossibility, indeed the absolute folly of such an attempt, offering to install their furnace for 2,000 marks. The oil furnace, by the way, cost about $2,000. However, when this message of gloom reached us, we had already shipped our first ton of tin, with a recovery of 92 per cent.

The little furnace which was erected as an experiment, will probably be retained as a part of the plant. It has four openings, which may conventionally be called N, S, E, and W. At the north end the oil and blast enter. Opposite on the S end, is a door through which the charge is rabbled. The charging door is to the west, the tap hole to the east. The hearth is slightly "dished," the lowest point being at the tap hole. The latter is plugged with a ball of damp clay during the running. The charging door is just large enough to enable the workman to throw a shovel full of ore to any part of the hearth, though the charge is better spread from the rabbling door.

Anthracite culm is used for the reducing agent.

The concentrate, mixed with the proper percentage of coal, is charged, about 200 pounds at a time, on to the preheated hearth. After each addition the flame is allowed to play over it for 20 or 30 minutes, before another charging is made. When about 800 pounds of concentrate has been introduced, the heat is maintained steadily, at about 2,000° F., but is raised to a higher temperature toward the close.

An electric pyrometer informs the workman of the temperature. It is necessary to "rabble" the ore on the hearth from time to time, to enable the very fluid metal to collect at the tap. The latter is opened at intervals by punching an iron bar through the clay plug that closes the hole.

The metal is of extraordinary purity. A remelting kettle was provided, as it was expected that "tossing" or "poling" would be necessary, but this method of refining is not needed. The metal runs from the hearth 99.80 fine; even the trivial impurity which is iron, is hardly an impurity when in such minute amount.

About 8 tons of tin have been shipped to date. It has averaged 3 cents per pound above the New York quotation, owing to its purity. In fact it not only classes as "grain tin," but is a very fancy brand at that. Tin is quoted today at 38 cents per pound, a very high figure.

The company was organized on a prospecting basis, but is already on the list of producers.

Copper ores are widely distributed throughout Nova Scotia. In a recent United States Consular Report it is stated that two belts of copper ore traverse the northern part of the peninsula and another crosses the southern part of Antigonishe County. In northern Cape Breton promising outcrops occur at Cheticamp and probably there is not a county in the province that cannot boast of a copper prospect. Yet of all these, probably but two, namely, Copper or Polson Lake, in Antigonishe County, and Coxheath, near Sydney, have been developed to any considerable extent. From these mines some thousands of tons of good ore have been taken out, carrying from 3 to 10 per cent. copper.

Empire Mine and Mill, Grass Valley, Cal.

A Description of the Methods of Mining and Raising the Ore, and the Milling and Cyanide Practice

By Al. H. Martin

The properties of the Empire Mines Co. are about a mile from the city of Grass Valley, the center of the leading quartz gold district in California. The Empire Mines Co. has an extensive acreage, and enjoys the unique distinction of having operated its property more continuously since its discovery than any other company in the district. The properties comprising the present Empire mine were mostly located in 1850, the veins occurring in diabase. The richness of the ore immediately attracted attention and the mine soon became the most important gold producer in the district. From the date of its location to the present time, it is estimated that the Empire has produced from $10,000,000 to $12,000,000, with the annual output averaging around $900,000 per year at this time. The property, after the North Star mine, is the leading producer in the district, with the veins proven to a depth of approximately 200 feet below the 3,500-foot level, the deepest working laterally. The vein shows much of its original quality and value so far as it has been followed, and indications seem good for its continuation indefinitely.

Headgear, Empire Mine

There are two ore bodies, known as the Rich Hill and Ophir Hill veins. These exist as one ledge in the Magenta claim, but branch out as two distinct veins when approaching the Empire property. In the lower levels the veins gradually approach until again they merge into one compact ledge. Near the eleventh level the veins cut across the diabase into granodiorite, but at the 1,600-foot point again strike into the diabase. The walls are sharply defined, with the space between these and the vein occupied by altered country rock. At several points faulting has appeared but the slips have never been of a serious nature and the vein has been easily recovered. The vein varies from 10 to 18 inches in width, and carries about $30 in gold per ton. Occasionally ore of remarkable richness is found, in fact some of the richest ore in the district has been taken from the property. At times these "pockets" have yielded from $10,000 to $50,000 in gold. The ore is free milling, with a small percentage of sulphides.

From the three-compartment shaft, levels are run at approximately every 100 feet and raises driven through to the level above, or within about 15 feet. At intervals, varying from 50 to 100 feet, auxiliary levels are driven on the vein. The raises are sent up from the center of the ore body, and by the mining method employed the vein is blocked out in such a manner that stoping can be carried on simultaneously in the different drifts. In some instances the driving of intermediate levels is avoided and stoping carried on at only one face. In either event the ore is easily handled from the various levels. At a convenient point above the last intermediate level is located the "go devil." This consists of a brake wheel and two drums, the friction regulated by the employment of a post brake. By means of this mechanism the cars in the stopes are raised and lowered. Double track is laid down the raise, with turn sheets placed at the points where drifts and raises are encountered. As the ore is broken in the stopes it is loaded into the cars and sent by gravity to chutes in the main level, where they dump automatically. As the stope is advanced the "go devil" is moved up further. When it is desired to keep the mechanism stationary, cables are strung over pulleys located above the turn sheet. In the latter case eare is always taken to either place the drums to one side of the track, or else at a sufficient height to permit the cars to pass under.

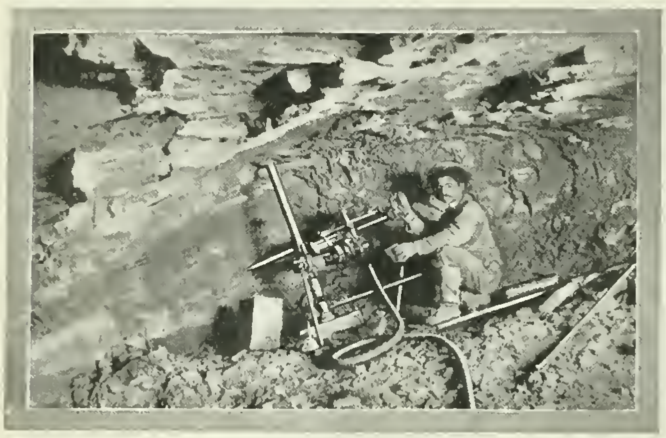
The cars on the main levels are hauled by mules, after being filled by gravity from the chutes. Owing to the flatness of the vein this special method of mining has been employed, as conditions in the Grass Valley district from a mining standpoint more nearly resemble those on the Rand in South Africa than the usual American ore bodies. The employment of the "go devil" or gravity plane and the method employed for stoping the ore has largely cut down expenses prevailing prior to the inception of these innovations.

Piston machine drills are employed for making holes for blasting. The level cars are discharged into bins in the shaft, which in turn feed the hoisting skips. The latter discharge automatically into bins upon reaching the surface. From the surface bins the ore passes through a gyratory crusher, which reduces it to a maximum size of 2 inches and drops it into bins beneath, from which it is loaded into cars and trammed to the mill bins. Automatic feeders deliver the ore to the forty 1,000-pound stamps, which drop 102 times per minute and crush through a No. 7 slotted screen. The stamps are arranged in eight batteries and have a total capacity of 90 tons per 24 hours. The pulp passes from the stamps to eight plain copper amalgamating plates 17 feet long by 4 feet 4 inches wide. Inside and outside amalgamation is employed, the outside plates being cleaned every 24 hours, and the inner ones twice monthly. From the plates the material passes to two Frue vanners, where the concentrate is collected. This is sold to smelters, the company making no provision for the treatment of concentrate on the ground.

The tailing is delivered to a Gates tube mill for regrinding and the product passes to the cyanide plant by way of a terra-cotta tile launder 425 feet long. The cyanide plant has a capacity of 150 tons per 24 hours, and everything has been arranged to facilitate the handling of material by gravity. The launder delivers to two settling cones and five sizing cones. The settlers have diameters of 8 feet 4 inches, with the sides having an incline of 50 degrees. The sizing cones are 4 feet 8 inches in diameter with the sides given a 70-degree slope. The sizing cones are fitted with hydraulic sizers and the product separated into sand and slime. The slime passes to four clarifying tanks by way of a galvanized-iron launder and sump. The tanks are 24 feet in diameter, 22 feet deep, and provided with false conical bottoms. The thickened slime passes through a $1\frac{1}{2}$-inch pipe, discharging 9 feet above the bottom of the tank, into a launder commanding the four agitating tanks. Each of the latter is 10 feet in diameter by 18 feet deep. Compressed air is admitted at a pressure of 10 pounds per square inch by way of a central cylinder nozzle. The piping extends throughout the tanks, insuring a continuous treatment of the slime under all conditions.

From the agitating tanks the slime flows to two vacuum filters, each having a capacity of 70 tons. A special pump was designed for the filter department and is proving highly satisfactory. This pump makes a 24-inch vacuum with 90 revolutions per minute and elevates the effluent to a $16' \times 20'$ storage tank, a distance of 41 feet. The slime cake is removed from the fillers by compressed air, instead of by the usual jet of water. The compressed air is delivered by an Ingersoll-Rand compressor which also furnishes the air for the agitation of the slime and aeration of the sand charges.

The sand underflow from the sizing cones passes to the leaching department, where it is delivered to four leaching tanks by an automatic distributor. The tanks have dimensions of 24 ft. × 10 ft. and are equipped with wooden filter bottoms of special design. The residue is sluiced to waste through an 18-inch terra-cotta launder. The effluent discharges to the sump tanks by way of two 4-inch pipes. There are four sump tanks, each 20 ft. × 10 ft. in dimensions. Two zinc belts near the sump tanks feed zinc dust automatically to a mixing cone



Stoping in Empire Mine

where a small quantity of barren solution is added. This is delivered to two $5'' \times 5''$ Aldrich triplex pumps. The solution is elevated by these pumps to two filter presses of 250 tons capacity. The filtered solution flows to the $20' \times 16'$ storage tank. Recovery is said to be excellent in every way, and the plant has proven very efficient. Formerly it was the practice to treat the tailing on canvas tables and Gates vanners, but the cyanide process has effected a much larger and more satisfactory recovery than the old method. The Empire Mines Co. is a close corporation. George W. Starr is manager.

Joplin District Zinc Notes

Wire-Rope Haulage in the Elizabeth Mine.—J. J. Thomas, of Webb City, has installed an underground rope haulage in the Elizabeth mine on the Avondale tract, east of Prosperity. The rope haulage operates over 350 feet of tracks, power being obtained from an electric motor stationed at the bottom of the 170-foot deep shaft. The haulage is on the endless rope system. Motors of five electric horsepower furnish sufficient power to handle a string of from 8 to 12 loaded cars, one man doing the work of running them to the shaft, where, by the old system of tramming, it required six men. About 500 cars a day are being handled by this cable system, although the drifts are not straight and there are a number of curves. It is stated that the cost of power for the cable line is 30 cents a day, and the saving in labor amounts to $125 per week.

The Midway Mine to Be Unwatered.—The old Midway mine in East Joplin, which was once a large producer of zinc ore, is to be pumped out. Pumps have been installed for this purpose and a new company intends to unwater the mine and go into the old workings, it being believed that with the modern methods of treating ore this old property will again pay.

Hill Top Drilling.—At the Catharine mine on the Mexico-Joplin land at Thoms Station, a drill hole is being sunk on the top of the highest hill on the lease. Heretofore, it has been customary to do drilling in the valleys, and all the prospecting has been confined to these places. The hill-top drilling is proving more successful in many instances and the prospectors are leaving the valleys for these high places both to drill and sink shafts.

Rapid Shaft Sinking at Johnstown, Mo.—The American Zinc, Lead and Smelting Co. are sinking a shaft on Davey Hill, at Johnstown. This shaft, which is to be one of the largest in the district, is 9 ft. × 16 ft. inside measurement. It is being rapidly sunk, at the rate of about 55 feet a week. Three shifts of men are at work in cleaning up and in drilling. It is hoped that the shaft will be completed in about 7 weeks, and then an air drift will be made from it to other shafts 1,000 feet away. This drift will be 8 ft. × 8 ft. in size and will be driven probably from both ends. If the enterprise proves as successful as is anticipated, a new mill larger and better than any on Davey Hill will be constructed and added to the active ore producers of the American company.

Jersey Bull Mine.—Rich zinc ore is being taken from the new shaft of the Jersey Bull Mining Co., operating on the Mexico-Joplin land at Thoms Station. Before the shaft was put down five prospecting drill holes were made and all five it is said went into ore, the clippings from one of the richer holes assaying 18.85 per cent. blende for 23 feet in depth. The shaft has reached this ore at 162 feet in depth, and is now working through it, but the company will sink to the bottom of the formation before turning drifts. Harry Hazel, one of the company, stated that a 200-ton mill would be erected as soon as the ground was sufficiently opened to warrant. The material now taken from the shafts is even richer than the drill holes indicated.

The Arkansas Zinc Mines.—The North Arkansas zinc field, which lies along the White River Railroad, is shipping from 15 to 16 cars of concentrates monthly. This concentrate is produced in what is known as the Rust Creek district, on Buffalo River. The shipping point is Buffalo, in Baxter County, and it is expected that by fall this district will be producing from 15 to 25 cars of zinc concentrate monthly.

Oklahoma Zinc District.—During the month of July the shipments from Miami, Okla., had been in excess of 1,000,000 pounds of blende. It is stated that this is due to the unloading of the big surplus heaps at the Turkey Fat and Newstate mines. Many of the mines of the Miami camp are running steadily and a good output is expected from now on.

Zinc Production in 1911.—Statistics compiled by the United States Geological Survey show that the production of spelter or metallic zinc from ore for the first 6 months of 1911 was 140,196 short tons, a gain of more than 5,000 tons over half the record output of 1910. Of this production, 5,135 tons was made from foreign ore. Spelter stocks were reduced from 23,232 tons to 17,788 tons. Imports remained about the same, but exports were nearly double those of half the preceding year. The apparent consumption of spelter was 135,497 tons, an increase of more than 12,000 tons over the half of 1910, but about the same as in half of 1909. The average price of spelter at St. Louis for the period was 5.36 cents per pound, the London average being .2 cent less per pound. During the latter part of May and the first part of June the average London price was about .1 cent higher than the corresponding St. Louis prices. Under this stimulus the May exports of spelter, zinc ore, and dross were largely increased over those of the preceding months.

Rescued After 76 Hours.—Joseph Clary was imprisoned in a prospect drift of the White Oak mine east of Joplin by the ground caving into the shaft and shutting off his escape. Three drill holes were put down without striking his place of imprisonment, but after about 3 days the fourth hole entered the drift and made it possible to feed and communicate with him. In the meantime haste was made in clearing the shaft so as to rescue him, and this was accomplished after 76 hours continuous work. Mr. Clary says that the water rose higher and higher, and it was up to his armpits when he was rescued.

Treating Low-Grade Zinc Ore

By Lucius L. Wittich

At the Hackett Mining Co.'s property, on a 40-acre tract owned in fee by the company, west of Joplin, Mo., the mill recovery is $2\frac{1}{2}$ per cent. ore, of which four parts are zinc blende and one part is galena. The blende will assay 61 per cent metallic contents; the galena will run better than 80 per cent. metallic lead. The ore is extremely "chatty," that is, the zinc blende and lead particles have a tendency to adhere to the flint, after crushing, and because of this it is difficult to prevent a considerable quantity of the metallic substances escaping in the tailing. Through the introduction of chat separators, flumes, and chat jigs, an additional recovery of one-half of 1 per cent. of the concentrates has been accomplished. The methods by which this additional recovery is secured are new to this district; and in some other respects the mill treatment is materially different from that employed locally.

Fig. 1 shows an exterior view of the Hackett plant which was built at a cost of $100,000 and which is perhaps the most substantially built mill in the Missouri-Kansas-Oklahoma district. It is a double-unit mill with a total daily capacity of 600 tons. Two shafts are in sheet ore at a depth of 200 feet. A third shaft has been planned and is to be sunk soon. When sufficient ore can be secured the mill is to be kept running double shift, handling almost 1,200 tons of ore a day.

That $2\frac{1}{2}$ per cent. of mineral to 1 ton of rock may be handled at a profit in proportion to the heavy initial investment, the recovery must be as complete as possible. To avoid a heavy tax on crushers and rolls, the sizing of the ore begins early and is followed more minutely as the milling process advances.

The main shaft is $5\frac{1}{2}$ ft.$\times 7\frac{1}{2}$ ft. and is cribbed with concrete between timbers down to the limestone, a depth of 40 feet, to prevent surface seepage. The frame cribbings, composed of $2'' \times 6''$ timbers, are built with a space between of 1 foot, this being filled with concrete. The foundations of the mill, the floors, and many of the outbuildings are of solid concrete. A well 1,000 feet deep supplies pure water. The company generates its own electricity for lighting the buildings and the underground workings. Gas engines run the mill and hoisters, but there is steam equipment for emergency.

From the hopper, the ore is fed to two grizzlies, one with the bars 4 inches apart, the other 1 inch. All mill material must pass through the 4-inch grizzly. If too large for this the pieces are broken with a sledge. From the larger grizzly the ore goes to an 18-inch crusher and then to a set of 36-inch rolls. All crushing is dry, the heavy expense of hoisting water to this elevation thus being avoided. The mill is equipped with two 18-inch crushers; two 36-inch rolls; four 30-inch rolls, and three 24-inch chat rolls, making a total of two crushers and nine sets of rolls. Undersize from the 1-inch grizzly goes to an elevator and is hoisted to an impact screen; it thus escapes the crushers and in this manner a heavy daily tonnage is diverted from passing through the crushers. Oversize from the grizzly goes to the crusher. From the first impact screen, undersize from a $\frac{3}{8}$-inch mesh goes to the rougher direct, while the oversize goes to a set of 30-inch rolls and is returned to the impact screen. Undersize from a second impact screen of 2-millimeter mesh goes to the cleaner direct; oversize goes to the rougher.

From the last three cells of the 6-celled rougher jigs the chats, which otherwise would escape in the tailing, are drawn off by the introduction of an ingenious device. At the foot of each of the last three cells on each set of roughers, making a total of six cells thus equipped, sheet-iron partitions are placed across the bed. These partitions are three feet long, enough to reach entirely across the cell, which is three feet wide and four feet long. The metal partition is as high as the dividing wall between the cells, and between it and the dividing wall a space of several inches is left. At the top the metal partition

FIG. 1. HACKETT MINING CO. MILL

is curved to fit securely to the partition wall. Horizontally across the metal partition, $1\frac{1}{2}$ inches from the screen of the cell, a slot, $1\frac{1}{2}$ inches wide is cut. This slot extends entirely across the partition with the exception of a small space left in the middle to make the device firmer. The cell, when properly bedded, is about $1\frac{1}{2}$ inches deep in zinc blende and lead. Just above this stratum is the layer of chat, and the slot in the metal strip permits this material, instead of passing off as tailing, to flow through into the opening between the metal strip and the dividing wall or end wall of the cell, whichever the case may be. A spigot on the exterior permits the chat to be drawn off and pass to the chat rolls, where it is ground finer and passed to the chat jigs and then to the sand jigs.

In the slime departments the equipment also is especially thorough. In the early days of mining development in the Joplin district, when only the rich ores were developed, little attention was given to reclaiming sludge ore. Tables and sand jigs were unheard of. The Hacket mill is equipped with eight tables. Four only are now being run. These four produce one ton of ore per day, valued at $40. This is greatly in excess of the cost of operation. Double partitioned settling boxes are used, and all slime possible is separated before the water passes to the settling tanks from which the final recovery of the fines is made. When the water finally reaches the sludge pond it is clear and contains barely a trace of zinc or lead.

Mining in Poverty Gulch Mine

The Shrinkage System of Mining. Method of Cost Keeping and Accounting

*By Charles W. Henderson, E. M.**

The shrinkage system of mining is adopted at the Poverty Gulch mine with overhand stoping. There are five raises for manways and for ventilation. At 6 feet above the levels a second or sublevel is driven. Every 30 feet along the main levels chutes are placed.

In stoping, these subdrifts are expanded to the full width and length of the ore body. No timber is needed, the miner standing on broken ore, only enough being drawn off to allow for the extra space occupied by the ore when broken.

The 154,900 tons partly blocked out when prospecting are now fully blocked out. Of this, 1,066 tons was sold when prospecting, and 6,490 tons were taken out in development (in running drifts), but not sold. There remains therefore 147,344 tons of ore blocked out. If 10 per cent. of the original ore is allowed for pillars, there remains 131,854 tons.

Sampling shows this ore to run from a trace of gold to 7.5 ounces per ton, with an average of 1 ounce per ton.

Stoping is started on the first level. Every ton of ore broken makes 21.5 cubic feet loose, or .423 of a ton is drawn off every day, leaving in stopes .577 of a ton.

There are 29,908 tons of ore above the first level. To mine this will require 25 men excavating at the rate of 200 tons a day, 150 days. During that time the production will be 85 tons a day, and there will be drawn off 12,750 tons, and 17,158 tons will be left in the stope.

The production can now be 200 tons a day from the first level alone, in case operations are delayed on the second, and there are 17,158 tons of ore broken in the first level and 101,946 tons available on the second level, so the requirement that there be a reserve 200 tons a day for 18 months, or 108,000 tons, is more than fulfilled.

From the time the prospecting is started to the day the mine is hoisting 200 tons a day, has been 894 + 150 = 1,044 days, or 50 days under the 3 years allowed for development so as to hoist 200 tons daily.

The ore is not all drawn from the first level at the rate of 200 tons a day, but stoping is started on the second level with the 25 men breaking 200 tons a day in the stopes, of which 85 tons a day is drawn off and 115 tons is drawn from the first level.

This plan of operation will continue for 149 days (17,158 ÷ 115), when all the ore is drawn from the first level and 29,800 tons has been broken in the stopes of the second level (12,665 tons having been drawn off, and 17,135 tons left in stopes), leaving 72,146 tons to be broken.

Naturally, during the above 149 days, the shaft would be sunk further, another level run, and ore blocked on the third level.

Assuming that no more development work is carried on and that all the ore blocked out is marketed.

However, to maintain an output of 200 tons a day after the ore is drawn from the first level and until all the ore is broken in the second level, 200 ÷ .423, or 473 tons, will have to be broken every day and 58 stopes will have to be worked until the second level is all broken The ore on this level is 72,146 tons, and to break this ore will take 72,146 ÷ 473 = 153 days, and if 30,600 tons is drawn off, there will be 58,681 tons left broken in stopes.

To exhaust the mine by drawing off the 58,681 tons in 200 tons a day lots, it will require 293 + days. The results of the mining will then be in time and tonnage as follows:

	Tons
150 days, 25 men stoping, 85 tons a day hoisted	12,750
149 days, 25 men stoping 200 tons a day	29,823
153 days, 58 men stoping 200 tons a day	30,600
293 days, no men stoping 200 tons a day	58,681
745	131,854
Taken out in development and not sold	6,490
Marketed	138,344
Marketed in prospecting	1,066
	139,410

To market the 138,344 tons and figure costs of operations during the time shipping was in progress, with pay roll, etc., the proceeding may be carried on as in Tables 1 and 2.

TABLE 1. ORGANIZATION* (SURFACE AND UNDERGROUND) ORDINARY AT MINE

Manager					
Mine Superintendent					Accountant and Paymaster
Mining Operations	Engineering Operations		Mechanical Operations		
2 foremen: 37 miners 3 trammers and muckers 3 timbermen	1 surveyor: (part year) draftsman and assistants (part year)	1 assayer	Master mechanic: 2 hoisting engineers 1 compressor man 1 electrician 1 machinist 1 helper 1 blacksmith 1 helper	Outside foreman: 1 carpenter 2 timber framers 13 ore sorters 2 laborers	1 bookkeeper 3 clerks 1 timekeeper 1 storekeeper
Underground	Surface				

* Production, 200 tons a day, 25 stopers, 12 men on development.

SHIPPING AND SELLING EXPENSES

	Per Year
Sampling	$ 3,000
Assay controls	225
Supervising	2,100
Freight and treatment $\left(\frac{549087}{2.04}\right)$	269,160
	$274,485

Ore Sorting.—During the 745 days of shipping, 138,344 tons are hoisted, giving an average of 186 tons a day. Of this 138,344 tons, 40 per cent., or 55,337 tons is fine and is sold without sorting; 16⅔ per cent., or 23,104 tons, is picked ore, and is sold after sorting; and 43⅓ per cent., or 59,903 tons, is waste.

GENERAL EXPENSES

	Per Year
Salaries of officers of company	$ 6,000
Office expenses	600
Insurance	3,200
Telegraph and telephone	340
Miscellaneous (Christmas gifts, etc.)	4,000
Books and stationery	500
Postage	400
Total	$15,040

SUNDRY EXPENSES

	Per Year
Legal expenses	$3,000
Taxes	500
Dues Mine Owners' Association	50
Expressage	300
Donations	600
Total	$4,450

Capital Required.—To the commencement of shipments, $124,965.90 was required, and as the receipts from ore sales during prospecting and development amounted to $121,324.47, there was a deficit when shipping commenced of $3,641.43, which is only apparent, as shipping could have been continued during development work. The cost of operations for 745 days, 2 years and 15 days, during shipments, was as follows:

* Part of a graduation thesis describing the prospecting, development, and mining in Cripple Creek, Colo.

150 days, 25 machine men, at $4.50	$16,875.00
150 days, 2 trammers, at $3	900.00
149 days, 25 machine men, at $4.50	16,762.50
149 days, 3 trammers, at $3	1,341.00
153 days, 58 machine men, at $4.50	39,933.00
153 days, 3 trammers, at $3	1,377.00
293 days, 3 trammers, at $3	2,637.00
For 745 days	$79,825.50

Table 2. Pay Roll Expenses for Labor

Superintendence	Per Day	Per Year (Of 365 Days)
Manager	$6.575	$ 2,400.00
Superintendent	5.753	2,100.00
Total superintendence	$ 12.33	$ 4,500.00
(Underground)		
2 foremen, at $4.50	$ 9.00	$ 3,285.00
37 miners, at $4.50	166.50	60,772.50
3 trammers and muckers, at $3	9.00	3,285.00
3 timbermen, at $3.50	10.50	3,832.50
Total underground	$195.00	$ 71,175.00
(Surface)		
1 assayer	$ 4.11	$ 1,500.00
1 surveyor (not permanent position)	2.05	750.00
1 draftsman (not permanent position)	1.31	480.00
Assistants to engineering operations	3.29	1,200.00
Master mechanic	5.00	1,825.00
2 hoisting engineers, at $4.50	9.00	3,285.00
1 compressor man, at $4	4.00	1,460.00
1 electrician	3.29	1,200.00
1 machinist	4.50	1,642.50
1 helper	4.00	1,460.00
1 blacksmith and tool sharpener	4.50	1,642.50
1 helper	4.00	1,460.00
Outside foreman	4.50	1,642.50
1 carpenter	3.50	1,277.50
2 timber framers, at $3.50	7.00	2,555.00
13 ore sorters, at $3	39.00	14,235.00
2 laborers, at $3	6.00	2,190.00
1 accountant	4.93	1,800.00
1 bookkeeper	4.11	1,500.00
3 clerks ($1,000 per year)	8.22	3,000.00
1 timekeeper	4.00	1,460.00
1 storekeeper	2.74	1,000.00
Total surface	$133.05	$ 48,565.00
Grand total	340.38	124,240.00

The cost of explosives during stoping and shipping was:

131,854 tons × 4 = 527,416 pounds powder, at $.127	$66,981.83
131,854 tons × 4.1 = 540,601 feet of fuse, at $.0035	1,892.10
131,854 tons × 1.4 = 184,596 caps, at $.007	1,292.17
	$70,166.10

The power and light costs for 745 days were:

Power for hoist, 87,200 kilowatt hours, at $.005	$ 436.00
Power for compressor, average 22 drills, 472,000 kilowatt hours, at $.005	2,365.00
Power for blower, 37,300 kilowatt hours, at $.005	186.50
Power for lights, 69,732 kilowatt hours, at $.005	348.66
Candles, 65,560, at $.0145	950.62
Total	$4,286.78

Value of Ore Shipped.—The 59,903 tons of waste has a gross value of $2 per ton = $119,806; the 138,344 tons of ore has has a gross value of 138,344 × $20.67 = $2,859,570.48; therefore, the 78,441 tons shipped has a gross value of $2,739,764.48, or $34.93 per ton, or 1.6896 ounces per ton.

Receipts From Ore Shipments to U. S. R & R.

Gross Weight Tons	Moisture Per Cent.	Net Weight Tons	Assay *Au* Ounces	Value Per Ton	Total Value
78,441	4	75,303.36	1.6896	$33.792	$2,544,651.14
Freight and treatment at $7 per ton					549,087.00
Net receipts					$1,995,564.14
All previous ore sales					121,324.47
Total receipts					$2,116,888.61

Recapitulation for 2.04 Years

All previous costs	$ 124,965.90
Repairs on plant and tools	12,000.00
Superintendence	9,180.00
Underground: Machine men and muckers	79,825.00
Underground: Two foremen	6,701.40
Underground: Three timbermen	7,818.30
Surface pay roll	99,072.60
Shipping and selling	559,949.40
General expenses	$ 30,681.60
Sundry expenses	9,078.00
Explosives	70,166.10
Power and lights	4,286.78
Water	6,000.00
Total cost of production	$1,019,725.08
Total receipts from 131,854 tons	1,995,564.14
Profit	$ 975,839.06
Profit per ton	7.41
Profit during active shipping	975,839.06
All previous sales of ore	121,324.47
Total profit	$1,097,163.53

Depreciation and Amortization.—In this case where a mine has built up the plant out of the earnings, there is no calculation for amortization to be made, and for depreciation 10 per cent. has been allowed per year on all previous plant and equipment costs.

J. R. Finlay, former manager of the Portland Gold Mining Co., of Cripple Creek, Colo., has devised a cost-keeping synopsis that seems to be one of the best of various systems. In this the natural subdivisions of expense are called stoping accounts, and include the cost of breaking the ore in the stopes and delivering it to the trammers; that is, the labor of miners, machine men, and shovelers, cost of explosives, operating machines, etc.; the cost of taking ore from the stopes and delivering it to the shaft, which includes the labor of trammers, cost of tracks, repairs on cars, etc.; the cost of timbering the stopes in labor and supplies; the cost of raising the ore to the surface, which includes the cost of power, labor, and repairs in operating the hoists, and repairs to shafts; the cost of concentrating ore by hand labor in the ore houses, loading it on cars and shipping it; also the cost of all repairs on ore houses; the cost of draining the mine; the cost of electric lighting and candles; the cost of sampling and assaying in the mine; a small amount of surface expense that cannot easily be charged to other accounts; all engineering expense; officers salaries and office expenses at the mine; directors' salaries and office expenses at Colorado Springs; insurance and taxes on all mining property; all legal expenses connected with the mine; the cost of all exploring work that has produced any ore.

The above accounts are considered to be indispensable at all times to the operation of the mine The following accounts are also indispensable to the sucess of the mine, but they represent investments and can be controlled in their amounts at the pleasure of the management. They are classed as plant and development accounts:

Drifts; cross-cuts; raises; dead work; exploring for ore. The cost of sinking new shafts is an account that has nothing to do with repairs or operation of shafts already completed.

The cost of cribbing in connection with the support of waste dumps is an account which is kept separate by reason of certain arrangements with railroad companies regarding this expense.

Machinery, buildings, investments in new plant is another account.

To the accounts mentioned are charged all the expenses incurred by the mine. The amounts charged will not necessarily correspond exactly with the total expenditures shown by the treasurer's statement because the mine accounts represent supplies that are actually used. It may happen that a certain amount of explosives, lumber, and timber, or supplies may have been bought that have not been used and are on hand. Whatever discrepancies there may be from this source will be very small. To the stoping accounts are charged all of the general expenses of the company, such as insurance and taxes, litigation, etc, To the plant and development accounts are charged only the labor and supplies used in doing the actual work. Not even the labor of the shift bosses is charged to these accounts; the idea being to have the statements in such shape that they will show exactly what expenses could be cut off by stopping any portion of the plant and development work that is going on.

In order to work out the above costs it is necessary to keep a number of other accounts, called distributed accounts, from the fact that they do not figure by themselves in the cost per ton, but are distributed into the above mentioned accounts. These are as follows: Cost of operating compressors; cost of operating hoists; electric plant; general expenses connected with tramming, such as oiling cars, laying and repairing tracks; general expenses connected with timbering, such as filing saws, etc., that cannot be charged out directly; machine shop; blacksmith shop; carpenter shop; machine drills; explosives; cost of lumber and timber purchased, together with expense of unloading and delivering it where needed; supplies; surface expense, such as labor used in taking care of the surface arrangements, unloading and disposing of supplies, etc.; fuel account, which includes the purchase price and the cost of unloading coal.

Copper Mining Notes

Greene-Cananea.—The Greene-Cananea Copper Co., Cananea, Mex., has resumed operations at the Puertocitos property, which has been idle some time. The operations will be conducted on a much larger scale than they were when the property was last in operation, and besides the quarrying there will be some underground work done. The ore body at the Puertocitos mine is said to be 800 feet wide at the surface with a band of richer ore in the center about 200 feet wide. The ore was formerly mined in benches 100 feet apart up to the time of ceasing operations, and work had been advanced 125 feet or more into the ore without a sign of passing through the carbonates. It is estimated that there are 1,000,000 tons of this ore yet to be mined.

The Greene-Cananea has practically completed the construction work that will do away with an expense which equaled last year 1½ cents per pound on the production. Figuring on the basis of last year this would reduce the cost of producing copper to 9¾ cents. The company has been producing at the rate of about 43,000,000 pounds per annum, but it is claimed that the property and the plant will soon be in a position to produce at the rate of 75,000,000 pounds per annum, and at a cost of 9 cents per pound.

Giroux Copper Property.—The five-compartment shaft of the Giroux mine will be sunk to the 1,800-foot level, thus making it the deepest shaft in Ely, Nev. To prevent the Alpha shaft of the old company caving into the 1,400-foot level of the present company a detour has been made about it. Because of the old shaft getting out of plumb and parting the 6-inch water column in three places, the timbers have been relieved of this weight by removing the column to the new shaft and holding it on I beams sunk in cement and not by the shaft lining.

Utah Copper Mills.—It is expected that the Magna and reconstructed Arthur mills of the Utah Copper Co. will have the capacity of treating 20,000 tons of low-grade porphyry copper-bearing rock daily. Neglecting Sundays, this is approximately 6,000,000 tons of rock yearly. If the recovery is 1.5 per cent. from 2 per cent. copper rock the output would be 180,000,000 pounds copper yearly.

Ray and Chino Mines.—D. C. Jackling, who developed and put in operation the system of milling followed by the Utah Copper Co., is so well satisfied with its success that he will probably introduce it at the Ray and Chino porphyry copper properties.

Shannon Copper Mine, Ariz.—Thompson, Towle & Co. assert that the Shannon Copper Co. is now producing its copper for about 11 cents per pound. The Shannon mine is at Clifton, Ariz. Recently the directors of the company voted to retire the last $59,000 of its outstanding bonds at par, this being the remainder of the $600,000 of bonds issued to pay for the smelter when the company was first organized. The company has, during the past few years, diverted about $700,000 of net profits derived from the production of copper back into the property, including the expenditure of about $200,000 on smelter reconstruction, $200,000 for additional properties, $250,000 of bonds retired, $40,000 for a water supply, $25,000 for new houses for employes. The Shannon-Arizona Railroad is said to be earning a surplus for the Shannon Copper Co. of between $20,000 and $30,000 per annum after meeting all interest on its bonds.

Kingston Camp, Ariz.—C. T. Brown, of Socorro and Magdalena, N. Mex., has been acquiring in one way or another by location or purchase about 30 claims of the Kingston mining camp. It is presumed that he is working in the interest of Phelps-Dodge Co. The Kingston ore is a low-grade copper ore but exists in immense quantities, and whether high-grade ore exists in the hills is a matter of speculation.

Calumet & Arizona.—There are few shares of the Lake Superior & Pittsburg Copper Co. that have not been exchanged for the Calumet & Arizona at Bisbee, Ariz. It is said that the combined properties make it possible to work more cheaply than when they were operated singly, and this means a reduction in the cost of production of copper.

Utah-Nevada Consolidated.—The alterations and improvements now being made at the Magna and Arthur plants of the Utah-Nevada Consolidated Copper Co. will shortly be completed. This will give the mills a daily ore capacity of about 20,000 tons, so that the company will be in a position to materially increase its output when conditions in the copper metal market warrant such action. The output of the Nevada Consolidated during the last 6 months is about that of the production for the first half of last year. This company is in a position to put out a much larger quantity of copper than it has been producing.

Calumet & Hecla.—While the courts are passing opinions on the attempt of this organization to merge its associate companies into one corporation, the company is doing considerable in the way of exploring lands it possesses and upon which very little work has heretofore been done. It is stated in *Iron Ore* that in one property in Ontonagon County rich copper mineral has been found with a diamond drill, and while this boring does not show a mine, it does show that there is a lode that is at least as rich at one point as anything yet revealed in the Michigan copper field. All the shareholders in the company are anxiously awaiting the decision of the courts in which opposition to the proposed merger has been started. Thus far the decisions have favored the Calumet & Hecla Co.

Hydraulicking with Waste Water

By Lucius L. Wittich

At the tailing plant of the Connecticut Concentrating Co., on a lease of the Granby Mining and Smelting Co.'s land, at Chitwood, a suburb of Joplin, Mo., waste mine water has been pressed into service and is successfully taking the place of two teams and two drivers, and is thus saving the operators a big financial item daily. The water is used to wash the tailings to the mill, a series of concrete-lined flumes, Fig. 1, having been constructed through which the material passes by gravity to the mill.

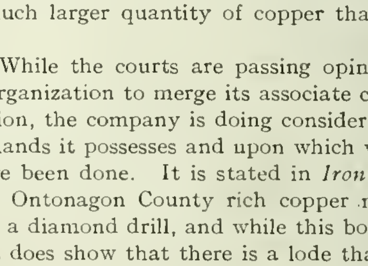


Fig. 1. Plan of Flumes

Where tailing heaps that are to be remilled are situated on a slight slope, this system of washing the dirt to the mill may be successfully employed, provided, of course, the water supply may be obtained at small cost; otherwise, the added cost of water would more than overbalance the money saved in the wages of teamsters and scrapers. In virtually all of the tailing operations of the Joplin district the common road scraper has been employed to convey the tailings to the mill. This process, of a necessity, is expensive, as the number of scrapers must be increased where the daily capacity of the mill is large. Due to the peculiar rolling character of the surface it would be possible in almost every instance to employ the hydraulic method as inaugurated by the Connecticut company, of which Lucius A. Barbour, of Hartford, Conn., is president, and Clarke Marshall, of Joplin, general manager. Mr. Marshall estimates that the daily saving is more than $10, and that this item will be materially increased when the plant is running full capacity.

The tailing heap to be worked contains approximately 1,000,000 tons of dirt, and the mill recovery to date has been about 1½ per cent. zinc blende. Around two sides of the tailing, concrete flumes have been constructed. A third flume extends directly beneath the pile, opening at a point high up the hillside and directly in the center of the tailing pile.

The flumes are 18 inches in width. Flume *a*, Fig. 0, circles to the south of the pile. At the upper end it is 4 feet deep and has a fall of 20 feet, emptying into the hopper *d*. Flume *b*, which runs beneath the center of the pile, has a fall of 40 feet. Flume *c*, which circles to the north, has a fall of 30 feet. All flumes are of equal width, are 4 feet deep at the upper ends, and all empty into the hopper, which is 12 feet in depth. From the hopper the tailing is elevated by bucket elevators to the screens, rolls, tables, jigs, etc.

Water for washing the tailing into the flumes comes from a centrifugal pump stationed in the sludge pond of the William mine, which is operated by the owners of the Connecticut. Thus the water is secured at a minimum expense. Were it not utilized in some manner it would go to waste. A 2-inch rubber hose, equipped with a 1-inch nozzle, is employed and a pressure of 100 to 200 pounds applied. This gives ample power to the stream that plays against the tailing. One man has charge of the hose and he is enabled to wash more than enough gravel into the flumes to supply the mill. By directing the stream of water this way or that way he is able to wash away any desired portion of the tailing heap.

In addition to the novel method of conveying the tailing to the mill, the Connecticut company has erected the only cyclone-proof plant in the district. By spending several hundred dollars extra to procure braces for the tailing elevator and other parts of the mill exposed to heavy winds, the company already has profited. Recently the district was visited by a severe cyclone that left many damaged mining plants. Although in the path of this storm, the Connecticut mill was not damaged.

The tailing is screened through a trommel of 1½-millimeter mesh, the sand passing directly to the tables. Only the chats from the rougher jig are reground, much of the waste being retreated in the form in which it is found in the tailing pile. As a result the second crop of tailing is composed largely of choice flint pebbles, from which virtually all the ore has been removed, and which is ideal material for use in concrete for building purposes.

Personals

R. B. Brinsmade is spending the summer in Mexico, and is examining mines in various districts.

Philip Godwill, of Bramwell, W. Va., has been visiting old friends in Scranton and vicinity.

J. R. Finlay has been engaged by the state of Michigan to estimate the ore in mines of that state for taxation purposes.

It is reported that Dr. L. D. Ricketts, general manager of the Green-Cananea Co., has been retained by the Arizona Copper Co. as consulting engineer.

Horace R. Lobdell, of Marquette, Mich., escaped death in the Porcupine fire by digging a hole in the mud and remaining therein until the fire passed over.

Edward L. Hermann, E. M., of Calumet, Mich., has returned from Porcupine, where he was at the time of the fire.

John C. Martin, of New York City, a coal mine owner in Cambria County, Pa., has gone for an extended trip to Europe.

Percy E. Barbour has changed his address from Tecoma, Nev., to care of Uwarra Mine Co., Candor, N. C.

W. J. Hall, of Wallace, Idaho, has been appointed assistant general manager of the Federal Mining and Smelting Co.

Rush J. White, former chief engineer of the Federal Mining and Smelting Co., has been appointed superintendent of the company's mines.

In the article entitled "Coal Mines of Dawson, New Mexico," which appeared in the June issue of MINES AND MINERALS, the name of the general manager was given as E. L. Carpenter. Since Mr. Carpenter's resignation T. H. O'Brien has been general manager.

Boyd Dudley, Jr., instructor in metallurgy and ore dressing at the Missouri School of Mines, has been granted a leave of absence for the school year beginning September 1, 1911.

H. A. Roesler, of Youngstown, Ohio, a graduate of the Missouri School of Mines, has been appointed instructor in metallurgy and ore dressing at that institution for 1 year. Mr. Roesler has had an extensive experience in metallurgical work, and is at present in the employ of the Carnegie Steel Co., at Youngstown, Ohio.

Stephen L. Goodale, A. M., E. M., Professor of Metallurgy in the University of Pittsburg, is spending the summer in Newfoundland, engaged in some special engineering work for eastern capitalists who have mining interests there.

A communication under date of July 24, from Mr. Geo. B. Hadesty, division superintendent of the P. & R. C. and I. Co., who is one of the party of engineers and mine officials accompanying Mr. Geo. S. Rice, of the Pittsburg Testing Station, United States Bureau of Mines, on an inspection trip to investigate European coal mining methods and safeguards against accidents, stated that the party had traveled about 2,000 miles through British coal fields, and learned a vast amount about British methods. They left Great Britain on July 25 for a trip of approximately the same length through continental coal fields. They expect to return home some time in September.

An esteemed correspondent and friend of MINES AND MINERALS, in a letter under date of August 10, says that the Personal Note in our August issue, crediting Mr. Baird Halberstadt, F. G. S., of Pottsville, Pa., with being the geological expert who established the identity of the B bed of the Lower Productive Coal Measures in the three suits instituted by farmers against the Berwind-White Coal Mining Co., is not in strict accordance with facts. It should have read that Mr. Halberstadt's investigations corroborated the contention of the company and other experts in the case that the bed being worked was the B bed. The nomenclature and identity of the B bed were definitely established by the surveys and reports of Mr. Edward V. D'Invilliers, geologist and mining engineer, of Philadelphia, in 1894, and even earlier than that through the report of Mr. Franklin Platt for the Second Geological Survey of Pennsylvania. In the trial of the case the testimony of Mr. Eugene A. Delaney, the very capable chief engineer of the company, coupled with his records clearly stated, showed conclusively the identity of the bed and left little for the succeeding experts' testimony to add. While our correspondent does not write with any idea of detracting from Mr. Halberstadt's professional ability, he is desirous that credit should be given where credit is due, a desire in which we know Mr. Halberstadt will join. While Mr. Halberstadt was employed as an expert in the case, and his report to the company corroborated fully the evidence of Mr. Delaney and others, he was not called as a witness because further testimony was not needed to sustain the contentions of the Berwind-White Company.

Relation of Forestry to Mining

Importance of Forests. Rules and Regulations Applying to Forest Lands and Mining Locations

*By J. F. Lawson**

The relation of forestry to mining is a subject which the people of this country have begun to consider only in the last decade. It is a large subject, too large to settle easily while as yet so little is known of forestry and of mining.

Those who are engaged in forestry know that their work has come to public attention during the progress of the great movement for the conservation of the natural resources of the country, and indeed, has been largely the occasion of that movement. As a part of that movement, the United States has employed a large number of men in the effort to keep trees growing upon portions of the public lands where it is believed their presence is indispensable to the public welfare, and where, so far as known, nothing else will grow. It is believed the forests now on the public lands can be kept as a great storehouse in which nature will constantly replenish supplies of materials useful in nearly every art known to man and in none more than in mining. It is desired that forestry shall be a handmaiden unto mining and to every other industry; that the natural resources committed to our care shall not be wasted but shall be developed and utilized to the fullest extent.

We bear in mind that the miner is also engaged in the development of our natural resources. Under circumstances of hazard, the miner has added untold millions to the wealth of the nation. From the underground storehouses where they lie unused, performing no service, bearing no interest, he drags forth the valuable minerals that they may be fashioned and refashioned into the structures and instruments most serviceable to man. Hidden in deep crevices or far shooting veins, as though buried by some slothful and unprofitable servant, the miner finds these treasures and delivers them over to the exchanger to be set at interest and to make more wealth for their possessors, who have already been made rulers over many. But nature must not be misjudged Whether the slow miserly accumulation of geologic ages or the instantaneous prodigality of volcanic upheaval, these treasures are the fruition of natural forces. Neither are these forces dead. Yet so slowly do they act that, compared with the time required to grind the golden path of the glacier. man runs his course like the flash of an electric spark. And if one looks forward toward another riving of the mountain's core whilst molten rocks form new veins to vivify a new mining district, it is evident that then will be no time or place for miners. It may be an opportune place for new-school journalists or a proper place for unregenerated lawyers, but not for miners. The harvest which nature has prepared can be garnered but once. The things which nature is doing now are studied only to learn what she has done in the past.

Slow is the growth of the forester's crop; so slow that the individual may hardly hope to gather the wealth of his lands but once. Therefore, the individual who came into possession of a forest has hewn it down to make room for a crop which turns to wealth more rapidly.

There have been established in all parts of these western mountains of the United States what are known now as the National Forests. In establishing these reservations it has not been the design to take exclusive possession of any tract except such as is believed to be better adapted to growing trees than to any other use. The administration of the Forest Service is directed to their management so that such areas will remain in trees for generation after generation until science demonstrates that they are worth more for something else.

* Law Office of Forest Service, Denver, Colo.

The people of the United States now own these forest lands, as they once owned all the other lands in the country. The people parted with the great bulk of their lands and almost immediately the forests thereon disappeared. Of the disappearance to make room for more valuable crops there can be no complaint, but millions of acres have been left a waste after the lumberman was through with them. Acting through Congress, to whom the care of these lands was committed, the people have adopted a policy of saving the forests on lands adapted only to forests by retaining the title and possession of the lands. That the people are entitled to do this needs no argument.

Article II, Section 1, of the Constitution, vests in the President the authority to carry into execution the laws passed by Congress. In the care of the lands, the members of Congress do not personally go upon the territory to protect it, but the Congress makes regulations regarding it, which, like other laws, are carried out as nearly as may be by the executive branch of the government.

The work of the executive branch is so great that, under the provisions of the Constitution and the authorization of Congress, it has been divided into various departments. In the Interior Department, the Commissioner of the General Land Office has charge of the public lands, their care and sale. In the Department of Agriculture, there is a Chief of the Weather Bureau, a Chief of the Bureau of Animal Industry, a Chief of the Bureau of Plant Industry, a Chief of the Forest Service, and other chiefs for various tasks committed to the department. The work of these bureaus is further subdivided, the chief of each branch and section working subject to the authority of his superior, until the final executive control is traced back to the President himself.

Such subdivision of authority is in accordance with the system of organization made under authority of Congress, specifically approved by each annual appropriation bill, and absolutely necessary to the transaction of public business. The acts of Congress and the orders of the President conferring upon the Forester, subject to the control of the Secretary of Agriculture and of the President, the care of the National Forests are as lawful, as constitutional, and as American in spirit as the command which the captain exercises over a battleship, or which the Commissioner of Patents exercises over the Patent Office.

The same necessity which required the setting aside of the National Forest lands and their administration under the auspices of the Government, requires a careful execution of the laws under which they may be appropriated to private use. Thousands of persons have taken advantage of the generosity of the Government and of the laxity in looking after its interests to locate mining claims where there are no minerals, and homesteads which they could not farm and never intended to farm. Every subterfuge which greedy and unscrupulous men could devise has been used to take from the people the title to valuable mineral lands, power sites, and large tracts of public domain, in a manner not contemplated by the law.

It is expressly set forth in the statutes that mining claims may be located only upon a discovery of valuable deposits, whether in lode or placer claims; that no location of a lode claim shall be made until the discovery of the vein or lode within the limits of the claim located; that 5 acres of non-mineral land non-contiguous to the lode may be patented when actually used for mining or milling purposes; and that patent shall not issue in any case until $500 worth of labor shall have been performed in the development of the particular claim located.

It must be observed that these are not rules invented by the Forest Service. They are the statutes of the United States, enacted in due form by Congress, upheld by the Land Office and the highest courts in an unbroken line of decisions running back more than 35 years. Originating in 1872, these statutes are a reenactment and general application of local regulations almost universally established long before by the miners themselves. State and local regulations, so far as they do not conflict with the United States statutes, are still recognized by these statutes and by the officers who enforce them. Such, for instance, is the law which protects the prospector in the possession of his claim while he is doing the work necessary to discover valuable mineral thereon. To obtain this protection against individuals who would try to work the same ground, he must comply with certain regulations, which may vary in different mining districts, regarding the giving of notice of his operations on the claim.

Very many cases have been found in the National Forests where men, disqualified under the homestead laws, have tried to hold non-mineral lands in exclusive possession by asserting some claim under the mining laws. Congress has prescribed the procedure under which reservoir sites may be taken—yet, notwithstanding, many persons have attempted to hold these sites indefinitely by locating them on placer claims, and have even received patent. Other men have covered large areas with mere locations which they do nothing to develop and only maintain in order to secure damages from persons who would cross them with rights of way for reservoirs, ditches, railways, or transmission lines. They have attempted to tie up large areas of fine timber by such mere paper locations, and to prevent such timber being used in the development of the mines and towns nearby. Such illegal holdings have in some cases been continued for upwards of 30 years, no effort having been made to apply for patent.

A possession of this nature amounts to an illegal appropriation of the land. It is contrary to the system outlined by Congress for the disposition of public lands. It operates to defeat the reservation of these areas for forest purposes; for unless the forests are to be properly administered they would better not be reserved at all.

The homestead laws grant to persons duly qualified the right to take up 160 acres of agricultural land; but because a man has exhausted his homestead right, or is otherwise unqualified, officers of the United States are not justified in so misrepresenting the circumstances as to give him his farm under the mining laws. To require him to expend $500 in mineral development, and to show a valuable discovery on each claim may deprive a poor man of a good farm which should be developed. The forest officers, however, have no more authority to report facts which do not exist in order to secure the allowance of a patent than they would have to make out a false pay roll in order to enable some one to tap the treasury. The right of the Forest Service and of the General Land Office to begin a general crusade to relieve poverty is no greater than that of the Treasury Department.

General Ore Mining Notes

California Zinc Ore Deposits.—The Uncompaghre zinc claims are located on Clark Mountain, 7,000 feet above sea level, in San Bernardino County, Cal. Clark Mountain is 20 miles west of the Nipton, while the property is 14 miles from nearest station on the Santa Fe Railway. The ore shipped from these claims to the smelters in Kansas averaged 44 per cent. zinc, 12½ per cent. copper, and 10 ounces of silver. One sample taken went as high as $4 per ton in silver and $4.14 in gold. Nothing is said relative to galena and pyrite, which in all probability will be found in an ore so mixed in metals as this.

Federal Mining and Smelting Co. declared its regular quarterly dividend on preferred stock in June, thus bringing the total disbursements to $6,421,000 on preferred stock and $2,718,750 on its common stock. The issued stock of this company is $12,000,000 preferred and $6,000,000 common. The company operates a number of mines in the Coeur d'Alene district, Idaho.

The New Hercules Mill, at Wallace, Idaho, is treating 400 tons of ore a day, and the claim is made that it gives a better extraction than any other concentrating mill in the Coeur d'Alene district. The Hercules mine, at Burke, Idaho, is said to be shipping from 500 to 600 tons of crude ore monthly to the smelter.

Ishpeming Iron Ore Development.—If the development of the iron ore lands west of Ishpeming proves successful it will demonstrate that this field is likely to extend in this direction. The mineral was found by the diamond drill and while the quality of the ore can be closely estimated by an analysis of the cores recovered, the quantity must remain uncertain. The most satisfactory and surest way to prove such deposits is to sink shafts and drive drifts; then the data obtained are thoroughly reliable, and from them the tonnage and approximate value can be estimated.

The Cleveland-Cliffs Co. built a change house for the men coming out of the North Lake mine which was connected with the shaft by a tunnel, the object being to prevent the men becoming chilled when they came from the mines in wet clothes. The same company is now constructing a change house at its Negaunee mine, in which will be hot and cold water baths, as well as shower baths. Any mining company which considers the comfort and health of its men will obtain more work per man than under unfavorable conditions.

Standard Silver-Lead Mill.—John A. Finch, of Spokane, president of the Standard Silver-Lead Co., operating at Silverton, British Columbia, states that satisfactory progress is being made with the installation of the 8,000-foot tramway and the 200-ton concentrating mill, and both were expected to be in operation in August.

Sale of the Le Roi, B. C., Mine.—The famous Le Roi mine, at Rossland, British Columbia, has been acquired by the Consolidated Mining and Smelting Co. for $250,000. The Consolidated company is a Canadian Pacific corporation and owns a smelter at Trail, British Columbia. It is a securities holding company and controls through stock ownership the Center Star, War Eagle, and St. Eugene mines, also the Rossland Power Co.

The Big Tunnel Mines, at Greenwood, British Columbia, probably the first mining enterprise in America subsidized by a municipality, reports a vertical depth of 1,200 feet with rich ore showings. The Tunnel company will, when the tunnel reaches a length of 5,000 feet, receive the first instalment of $50,000 which was voted by the citizens of Greenwood. At the present time the tunnel is 2,400 feet long and the lead was found at 1,800 feet from the mouth.

Hydraulicking on Salmon River.—The Hydraulic Placer Co. commenced washing for gold in the Salmon River, 15 miles below the junction with Snake River, in August after over a month's work repairing the ditch and the flume. Nine hundred feet of steel pipe leading from the pressure box 150 feet above the giants has been installed, so the company has an unlimited supply of water which can be delivered to the nozzles at a pressure of 65 pounds, and it is estimated that 1,000 yards of gravel can be washed every day. The mines are owned by Spokane people.

Tuscarora, Nev., Mines.—Word comes by way of Elko, Nev., that the old Tuscarora camp has taken a new lease on life. Two cyanide plants have been put into operation and the tailings from the old Dexter and Grand Prize mines are being worked. These mines were once famous for their rich ore, and it is not uncommon for mine cars of ore from these properties to run as high as $10,000. From them chunks of pure gold were frequently extracted. The actual work of unwatering the mines at Tuscarora has begun in a systematic and practical manner under the supervision of William A. Farish, Jr. Two large skips are raising water at the rate of 1,500 gallons a minute at the Dexter mine. As the other properties are at a higher elevation, it is probable that by unwatering the Dexter mine it will relieve the others. When work was begun the water was within 8 feet of the surface. It is now nearly a quarter of a century since active work was carried on at the Tuscarora mine. At the time of their closing down they were paying well, but a heavy flow of water was encountered, and this fact, coupled with the low price of silver, caused a cessation of activities in the mines. The recorded output of the Tuscarora mine is $40,000,000, and the depth of the deepest shaft is but 600 feet.

Gold Mining at Helena, Mont.—The Last Chance gulch, and others in the vicinity of Helena, produced over $100,000,000 between the years 1864 and 1870. This enormous output was from placers which have been long exhausted, or practically so, unless there are some cases where they may be worked with modern machinery in the form of dredges.

The quartz mines of the Helena district, within a radius of 20 to 25 miles, have scarcely been touched. Although it is evident, from the quantity of gold that has been taken from the gulch that there still remain properties which will pay; namely, Drum Lummon, Bald Buttes, Jay Gould, and others, it is proposed now to prospect the vicinity with a view to discovering the lode from which the placer gold was derived, and it has been suggested that the Commercial Club, of Helena, outfit a few prospectors and in other ways encourage those who are seeking to find the ore deposits. A history of gold mining in Montana is interesting reading.

Litigation between the Montana Co., Ltd., and the St. Louis Mining Co., which has covered a period of about 20 years, is now at an end, and the St. Louis company has become the owner of all the property of the Montana Co., Ltd., including the Drum Lummon and adjoining plant at Maryville. The St. Louis company is now actively engaged in repairing the 60-stamp mill and getting the property ready for active operation.

The Jay Gould mine, in the Marysville district, is again in operation after a number of years idleness. The new developments are so encouraging that it is the belief that the Jay Gould mine, which is owned largely by citizens in Helena, may perhaps equal its record of former years. This mine is within about 4 miles of the town of Marysville.

Hydraulicking at Round Mountain, Nev., is going on, but owing to conditions which prevail in that country the ground is apportioned to men who are called percentage workers. These pile their gravel near the sluice and in turn are permitted to wash it into the sluice. One block of ground averaged $21 per yard. This, however, was an exceptionally rich one. The season in this locality is limited, owing to the supply of water coming from the snow which melts from the mountains in the warm season.

Modoc Mine, Cripple Creek.—Word comes from Cripple Creek, Colo., that the Modoc mine has found a vein of silvernite which varies from 12 to 14 feet in width at a point about 35 feet from the shaft. The vein has now been opened on the 5th, 7th, and 9th levels, and a cross-cut is being run to open it on the 200-foot level. Samples taken from the ore piles have assayed from $1.40 to $2.40 per ton. On the 9th level the ore has been drifted upon about 40 feet and continues to hold up in value.

Dalton and Lark Mines, Utah.—Carbonate lead ore has been found in the Dalton and Lark group of mines at Bingham, Utah. The Bingham Mines Co. has been working sulphide ore in these mines by means of raises from the 950-foot level. On the 750-foot level there was 4 feet of shipping lead carbonate ore exposed, and from that depth to the surface the ground has not been worked. This find is considered important, because it is 8 years since this mine produced carbonate ore.

Goldfield Consolidated Report.—Preliminary report of the general superintendent, J. F. Thorne, of the Goldfield Consolidated Mines Co., shows that in May the company treated 29,410 dry tons, the largest tonnage handled in any single month in the company's history, and while the value, $882,000 gross, and $677,000 net, was below that of the two previous months, it was still considerably in excess of the amount required to maintain the payment of dividends at the present rate of 50 cents a share.

Prospecting in Colorado.—The revival of prospecting in Colorado seems to be producing results. Word comes from Silverton, Colo., that Jedson Belenger began prospecting in the old abandoned mine on Sheet Mountain about 9 miles west of Silverton. Here he found ore about 450 feet from the portal of an old tunnel which cross-cuts the vein at a depth of 350 feet below the surface. The vein is said to be fully 3 feet of solid lead and copper sulphide and averages about 2.44 ounces of gold and 231 ounces of silver per ton.

Directly east of Steamboat Springs, Routt County, in the Gore range of mountains, several gold-bearing deposits, which are both smelting and free milling, are said to have been found. Development work in tracing these veins is now going on, although enough pay ore has been found to make possible the working of such producers. In another section of Routt County where gold-bearing quartz is found, and near Hahn Peak, placer mining is reported near the junction of Grand, Jackson, and New counties. Several prospectors in this field are grub-staked by Denver people and with some private funds of their own. The general instructions to the prospectors stated that the name of Charles A. Johnson, president of the Denver Chamber of Commerce, is to be placed on location and discovery notices, as a one-half owner, and they are further to follow the requirements of the law in every particular. Other instructions are relative to opening the veins at several points, making sure that the vein on the surface outcrop intersects at least one end line, making the discovery shaft or cut 10 feet deep or more, etc., A prospector's geological map has also been furnished them, it being based on the geological map of Colorado constructed by Hayden.

Humbolt Basin, Ore.—Mormon Basin, sometimes called Humboldt Basin, is the oldest mining camp in eastern Oregon. Its existence dates back to 1862 when placer gold was first discovered there. The camp, after long idleness, is now attracting attention by reason of its quartz mining possibilities. The Rainbow mine has recently been purchased by the United States Smelting, Refining, and Mining Co. At the Humboldt mine, owned by the Oregon-Idaho Investment Co., a force of miners is engaged in development. Altogether there is an activity at Mormon Basin which exceeds anything that has occurred since the early days.

Montana-Tonopah.—Development and prospecting work is being kept up in the Montana-Tonopah mine, Nevada, and ore is being found in the different cross-cuts driven on all levels. The mill of this company is doing excellent work and is said to be recovering 90 per cent.

Mining Luck.—An instance of rapid wealth making is reported from Nevada. Legal advice given to the men who first located the National mines at National, Nev., was paid for by a block of stock in National company. After holding this stock 3 years it has been sold for $280,000. The National mine has been a sensational gold producer from the start, and such rapid wealth would probably not occur often, but you never can tell about lawyers.

Homestake, S. Dak.—According to reports from the Homestake Mining Co., of Lead, S. Dak., more rock is being hoisted with fewer men than during the period before the company's labor trouble. It is claimed that more efficient methods in the mine and less time is taken in explaining work, which, with the Slavonians frequently required the services of an interpreter, has much to do with the increased output. The last shipment of gold bullion was said to be the largest the company has had in years.

Florence, Idaho.—Modern machinery will be installed in the placer ground in the Florence, Idaho, district by a Spokane syndicate, headed by S. A. Anderson, formerly cashier of the Scandinavian-American Bank. The district was discovered in the summer of 1861 and the ground was successfully worked for years by white miners, who afterward abandoned it to Chinese. The principal work this season will be on the bars and benches along Miller Creek. Heavy-pressure hydraulic giants are being installed and the volume of water in the streams selected as the source of supply for the pipe lines is sufficient to insure the working of the ground until the beginning of cold weather. Pioneer prospectors now living at Lewiston, Idaho, who were among the first in the rush into Florence from Orofino, 50 years ago, are watching the work of the hydraulic, some of them believing that what yellow metal the "rockers" and sluices left was cleaned up by the Chinese, who worked the ground after the white miners went to other districts. On the other hand, Mr. Anderson and experts express confidence in the placers returning dividends.

Porcupine Forest Fires

The forest fires, that occurred in the Porcupine, Ontario, gold district of Canada have so greatly retarded development work that it has been urged that the government grant a year's extension to complete development work on claims.

On May 19 a bush fire practically destroyed the Hollinger surface plant, which was moving along nicely toward completion.

On July 2 another fire destroyed the buildings of the West Dome property and seriously threatened the Pearl Lake. On July 9 the brush again caught fire from smouldering fires probably, since several were reported at different places, and swept almost the entire district on both sides of Lake Porcupine and raged several days, causing destruction to life and property, and entailing much hardship on the survivors. This fire destroyed several towns besides individual houses. Those people who escaped seem to be well satisfied that it was merely a property loss with them. Pottsville and South Porcupine were completely burned, while Golden City was nearly so. Survivors from the fire zone tell of narrow escapes and of people perishing who sought refuge in Porcupine and other lakes.

Daniel Yost and C. A. Burdick, of New York City, the latter a mining engineer, plunged into Goose Lake, on the King-Porcupine property. Manager E. P. Ashmore and Captain Shovell and wife, of the Philadelphia property, were nearly overcome while making for Porcupine Lake, 3 miles away, but were rescued by four Italians who were fleeing on a hand car; but even then when they neared the lake it was necessary to jump from the car and rush into the water.

Morgan R. Cartwright, treasurer, and R. E. Cartwright, of the Pearl Lake property, had a narrow escape from the flames. The Success claim, although in the fire zone, escaped. The manager, Ralph A. Meyer, had planned to clear around the camps but had not done so; however, none of his 50 men were injured, and the property became a refuge for 30 men driven from the south camp of the Crown Chartered Co. H. C. Meek, manager of the Dome, with his family and four men, sought refuge behind some water barrels on a rocky prominence, and by the aid of wet blankets survived the holocaust, although some of the men were badly burned protecting Mrs. Meek.

The Dome mine, which is probably the most extensively developed of any in the Porcupine, had about finished its 40-stamp mill, and the company hoped to have started it in August.

At West Dome, Robert A. Weiss, manager, with his wife, daughter, Angus Burt, and some 27 others, sought refuge in a timbered shaft and were suffocated. At the Dome shaft several who had taken refuge therein perished, including John Taylor, a mining student at Toronto.

At Preston, East Dome, no lives were lost, although some entered an untimbered shaft and passed up water to others. Captain John Wilson and some of the employes lay in a creek and threw water over each other. At Dome 57 men rushed into a pond, and so escaped destruction.

At the Imperial mine 16 boxes of dynamite were lowered in the shaft, but the flames worked down the timbers and they exploded. Manager A. H. Crampton and Superintendent Joe Healy escaped and reported there was no loss of life at the Imperial. The Canadian Explosives Co.'s magazine containing 12 tons of dynamite exploded on the Foley-O'Brien property. A car of dynamite on the Lakeview-Porcupine exploded and added its quota to the general havoc.

The first reports coming from the fire zone exaggerated the loss of life, as is nearly always the case in times of excitement and uncertainty, and there was considerable anxiety experienced by those in Canada and the United States who had friends and relatives in the burned district until they heard definitely from them. The most noted prospector in Ontario, William Wilson, died from burns received while in the vicinity of the Dome mine.

Only a partial list of the money loss due to this fire ever can be given, as personal effects and property outside of the mining and railroad companies, which undoubtedly totals into thousands, will never be known. In addition to this loss of property, the loss in time will represent much to those whose money is invested.

A partial list of the damage done to mining companies is as follows:

Dome mines, all of their buildings, except Manager Meek's house. Loss close on to $800,000; loss includes all their shaft houses, new 40-stamp mill, almost completed, and large up-to-date compressor plant.

North Dome mines, loss $50,000; plant and camp destroyed.

Preston East Dome, loss $150,000; plant and camps.

Vipond, loss $100,000; plant and camps all destroyed.

Foley-O'Brien, total loss estimated about $100,000.

Philadelphia mines, loss about $50,000; buildings destroyed.

United Porcupine mines, loss $20,000; all camps burned.

Eldorado Porcupine, loss small, buildings destroyed.

Standard Porcupine, loss of buildings totaling $40,000.

Imperial, loss about $35,000; all plant and buildings.

West Dome mines, plant and buildings; loss $75,000 at least.

Crown Chartered, a total loss.

It is reported that the Hollinger, West Dome, Preston East Dome, and Dome companies have ordered machinery to replace that destroyed.

World-Wide Figures

Through study and observation of the volcanic outflow the geologist knows approximately the composition of the earth's crust to a depth of 10 miles below sea level. As Frank W. Clarke, of the United States Geological Survey, says in the "Data of Geochemistry," "this thickness of 10 miles represents known matter." The vastness of the figures which it is necessary to employ in the discussion of this 10-mile lithosphere, as it is termed, transcends ordinary human comprehension.

The volume of the lithosphere, including the continents elevated above the sea, is 1,633,000,000 cubic miles.

A cubic mile of average rock weighs 12,800,000,000 tons.

The volume of the ocean is 302,000,000 cubic miles.

The atmosphere is equal in weight to 1,268,000 cubic miles of water, which, however, is only one two-hundred-and-thirty-eighth of the volume of the ocean; yet this would be sufficient to raise the level of the ocean 45 feet on all shores and to submerge an important part of the continents.

One per cent. of the water of the ocean would cover all the land areas of the globe to a depth of 290 feet.

The salt in the ocean would make 4,800,000 cubes each 1 mile in dimensions, which, if spread over the United States, would form a layer 1.6 miles high.

In comparison with this outer 10-mile section of the earth's crust, the thin sheet of organic matter on the surface—the prairie and valley soils, the alluvial bottoms, and the rich table lands by whose products man lives—becomes a mere film, a skin.

The Elmore Flotation Process

The Specifications Showing the Original Claims for the Patents on Which the Process Is Based

The complete specification taken out by Francis Edward Elmore in 1900 (the first patent) relates to "improvements in separating metallic from rock constituents of ores by bringing a mixture of the pulverized ore with water into contact with more or less thick oil, which entraps the metallic constituents and allows the rocky constituents to pass away with the water. The thick oil is preferably the thick tarry residue of mineral oil after some of the more volatile constituents have been distilled off. When the pulverized ore has been mixed with water in quantity amounting to several times the weight of the ore, it is then mixed with the thick oil. The metallic constituents of the ore are retained in the oil, which does not even adhere to the previously wetted rocky or earthy ingredients, these being held in suspension in the water. The mixture of water with the earthy ingredients being allowed to subside as tailings, the more buoyant mixture of the oil with the metallic matters is separated from the oil, which can be used again for repeated operations. The tailing from the first operation may be again treated with oil in the manner described so as to recover such of the metallic ingredients as may have escaped the first treatment, and this may be repeated several times if necessary. Various apparatuses may be employed for operating." (Here is described one form which the inventor proved effective.) The claims in respect to this patent are:

"1. Process for separating the metallic from the rocky constituents of ore by mixing the pulverized ore, first with water in considerable quantity, then adding to the mixture an oil of the kind described, which adheres to the metallic constituents but not to the rocky wet constituents, allowing the water carrying the rocky material to subside while the oil carrying metallic constituents floats above, and separating the oil from these constituents, substantially, as described.

"2. For separating metallic from rocky constituents of ore, apparatus comprising horizontally revolving, helically ribbed mixing drums, subsidence vessels, a centrifugal drum for separating the oil, a tank provided with agitators, and a second centrifugal machine for separating the water arranged and operating substantially as described."

The complete specification of the patent taken out in 1901 by Alexander Stanley Elmore, relates to "Improvements in the process and apparatus for separating mineral substances by the selective action of oil." The specification goes on to say: The selective action of oil has been utilized for separating metallic substances from earthy or rocky constituents of ores. This has generally been done by pulverizing the ore and suspending it in a considerable quantity of water so as to make a freely flowing pulp, then mingling with it oil, preferably heavy oil, such as is obtained from petroleum after some of the lighter oils have been distilled from it. When the mixture rests, the oil, with most of the metallic substances entrapped in it, floats at the top, and is separated from the rocky or earthy matters which are run off with the water as tailings. The oil is afterwards separated from the metallic substances, usually by centrifugal action.

"In carrying on this separating process, it was discovered that in some cases a slight acidulation of the mixture greatly enhances the selective action of the oil, so that metallic substances, as well as other mineral substances, such as sulphur and plumbago, can be separated from the earthy matters, with which they are associated naturally, better than when there is no acid present. By this means some metallic substances can be separated from others, such, for instance, as sulphides from oxides. The acidulation may be effected either by adding a little acid to the oil, in which case an acid that will dissolve in or mix readily with the oil, but which is insoluble, or nearly so in water, as, for instance, oleic acid, is to be preferred; or the acid may be added to the aqueous pulp, in which case sulphuric acid may be employed or the acid cuprous liquors obtained in mine working. The quantity of acid added in either case is small, as it often need not exceed one five-hundredth part of the volume of oil or water employed in the operation. The quantity of acid required to produce the best results varies according to the character of the material treated, and is not confined to any definite proportion. Not only oil, but also certain other fluids, such as tar or varnish, exert in a greater or less degree the selective action for separating minerals, and it is to be understood that in this specification where the word oil is used it includes those other substances which exert selective action like that exerted by oil. If plumbago, elementary sulphur, or other similar substances of like character are present, the oil attaches itself to, or coats such particles, while it does not coat or attach itself to the rocky or earthy particles present." (Here follows a description of the apparatus for carrying the process into effect and separating the metallic particles.) It is briefly as follows:

"A freely flowing pulp of water and oil is brought into a mixer, consisting of a trough having a rounded bottom and a shaft carrying a number of inclined agitating blades. To this is added oil which is thoroughly mixed with the pulp and the metallic particles issue by an opening at the end of the trough into a separate tank, where the metallic ingredients adhering to the oil are floated to the top and the earthy or rocky ingredients subside and are allowed to issue by a pipe at the bottom. The metallic ingredients, with the oil, are discharged into a drum of a centrifugal machine, in which a separation of the metallic matters from the oil takes place, and the oil being taken away for further use. Another form of apparatus is given for effecting the separation after the selection has taken place in the trough by attaching to the end of the trough a weir, having a number of wave-like blades or baffles by which the stream of pulp and oil globules is thrown against an apron. This apron is preferably made of canvas or some fabric not injuriously affected by oil, and its surface is continuously supplied from a pipe with fresh oil, which is evenly distributed over the apron of the spreader. This oil surface takes up most of the oil globules from the pulp, and also picks up such particles of metallic subsidences as may have escaped selection by the oil in the mixer." The claims set out by the inventor are:

"1. In processes for separating minerals by the selective action of oil, the addition of a small quantity of acid to the oil or water employed in the process or to both, substantially as and for the purpose set forth.

"2. Apparatus for separating minerals by the selective action of oils, comprising a trough containing a shaft carrying inclined blades adapted to revolve within the trough, a settling tank partitioned at the top, and a centrifugal machine adapted to revolve within a casing, constructed and operating substantially as described.

"3. Apparatus for effecting separation of minerals by the selective action of oils and like substances, comprising a mixer of the oil with the aqueous pulp of pulverized mineral, an incline for downflow of the mixture having steps or baffles, an endless apron, means of distributing oil over it, and means of causing it to travel in a direction opposite to the said downflow, a conical revolving sieve adapted to receive the discharge from the incline, a nozzle for delivering a shower of water over one side of the sieve, and two launders adapted to remove the matters that pass through, and the matters that are washed over the sieve, respectively, substantially as described.

"4. The combination of a stepped incline for downflow of the mixed pulp and oil, with a traveling apron provided with a distributor of oil over its surface, substantially as described.

"5. The combination of a conical revolving sieve, a distributor of a water shower over part of the sieve, a launder adapted to lead off the matters washed over the sieve, and a launder lined with blanket adapted to lead off the matters that pass through the sieve substantially as described."

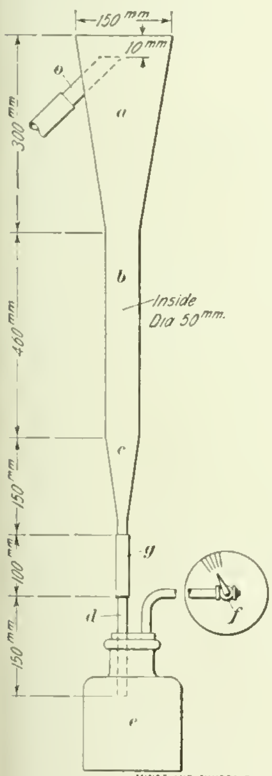
Laboratory Sizing Tests

*By F. Curtis**

The ore dresser, who, in his laboratory work, is content to dry screen his finely ground material will find that his results are at times very misleading. The tendency of the very fine material and the slimes to cement either to the larger particles or to form lumps consisting mainly of the fines is a matter of common observation.

As a means of avoiding this difficulty, some authors have recommended the employment of a method of wet screening. That the results obtained in this way are inaccurate can be demonstrated by a simple experiment.

If a sample, which will be, say, 20 per cent. on 40 mesh, is wet screened by any process of manipulation which may appeal to the experimenter, and the oversize is allowed to dry without removing from the testing sieve, it will be found that a not inconsiderable amount of the so-called oversize will of its own weight fall through the meshes. This amount will be greatly increased by gently jarring the sieve, showing conclusively that the screening has not been thorough.



Laboratory Sizer

It occurred to the writer that if some means of eliminating the slime from the sample could be devised, the remaining portion could be accurately dry screened. After considerable experiment, a classifier was hit upon, patterned closely after the tubular hindered settling classifier described by Prof. Robt. H. Richards.

In the accompanying sketch can be seen the design of the apparatus used in the laboratory at the Steptoe concentrator. The essential features are a settling cone *a*, a roughing column *b*, a teeter chamber *c*, a sorting column *d*, a pressure chamber and receptacle for the sample *e*, and a dial cock *f*, by means of which a very nice regulation of the flow of water to the apparatus can be maintained. A pinch cock can be used on the rubber connector *g* should it be desirable to interrupt the process of classification for any purpose. The apparatus can easily be constructed by any tinsmith at small expense.

The material to be sized is weighed out, about 1 kilogram being the size found most convenient in work. The classifier is partly filled with water and the pinch cock is closed on the rubber connector at *g*, the dial cock being set to give the desired current before this is done. Then the sample is charged in the apparatus, the pinch cock released, and the sorting begins. All overflow is caught and carefully settled and may be considered undersize of 200 mesh. It is well, however, to pass the overflow through a screen of this mesh, as this will prevent any light particles which are over this size being included in the undersize. It also serves to indicate the proper flow of water to use for sorting, as any considerable quantity of material remaining on the screen will indicate that the quantity is too large. Twenty minutes' treatment with a gentle rising current will remove practically all of the troublesome material, leaving a clean sand, which is drawn off, dried, and carefully screened, using any desired series of sieves. The undersize of the finest mesh can be added to the fines collected in the overflow. But it is often convenient to make each of these a separate sample.

It is found possible to secure tests on duplicate samples that will check very closely, also samples run by different persons will agree more nearly than when the checks are attempted with the dry screening.

A comparison of the results of both methods shows in all cases that the amount of mineral in the finest size is greater when the process described is used, the increase in mineral sometimes being as much as 75 per cent. When the material happens to be tailing, the importance of locating the exact point at which the greatest loss occurs cannot be overestimated.

Settling Chamber for Smelter Fume

*By J. I. Blair**

The general arrangement of this settling chamber depends on the principle, and makes use of the fact, that properly placed obstructions to the flow of a flume-laden gas cause such eddies as are seen in streams most prominently at the foot of bridge piers. Such being the case, it is assumed that more fume will drop out of suspension in such an arrangement as is here shown than would drop out of simply enlarged chambers, regular dust catchers, which depend on a swirling motion imparted to the incoming gas by placing the entrance at a tangent to one side

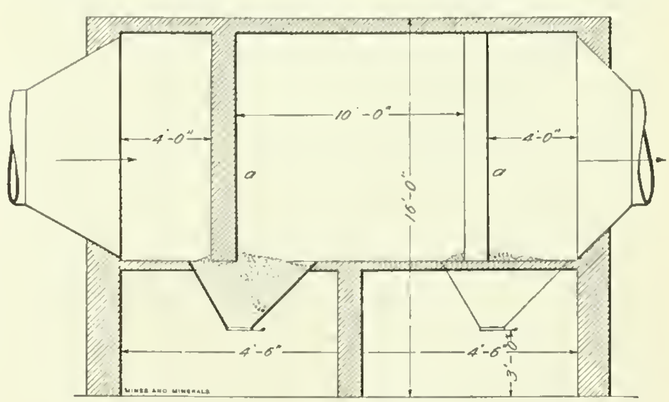

Fig. 1. Sectional Elevation of Fume Chamber

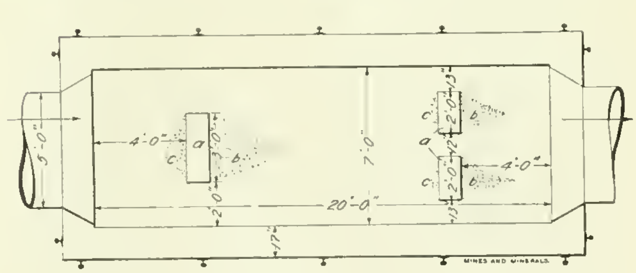

Fig. 2. Plan of Settling Chamber

of the circular chamber, or other devices which simply divert the course of the gas by abrupt turns, etc.

In Fig. 1 the position of the baffle walls, which are built of firebrick, are seen at *a*. The conduit pipe is flared out to cause the gas to meet the first wall evenly and avoid the accumulation of dust in the corners on either side of the entrance. The bottom of the baffle walls is arched over a trap door which per-

*Metallurgist, South Bethlehem, Pa.

mits the fume which collects in front of the wall at *c* to be raked down into the hoppers from which it is allowed to drop into a tram car beneath.

The roof of the chamber is arched over, and the bottom is made by two layers of brick on a sheet-iron bottom.

In Fig. 2 is shown a plan of the chamber. The sediment of fume is shown as it would occur at *b* and also at *c*. The method of bracing the chamber with 60-pound rails is also shown.

Colorimetric Estimation of Gold

In a recent number of the *South African Mining Journal* Mr. William Bettel gives the following method of estimating gold in cyanide solutions:

Existing methods for the colorimetric estimation of gold in cyanide solutions are, occasionally, unreliable, through impurities present in the solution or reagents producing alterations in tint of the gold-purple which are not constant in "depth," and therefore interfere when comparing tints with "standards." Certain organic matters which collect in the final gold precipitate are attacked and dissolved by aqua regia with production of a yellow or brown color, barely visible to the unaided eye, but quite sufficient to alter the color of the gold-purple, so as to render comparison with standard tints of the "purple of Cassius" impossible.

This organic matter may come (in one modification of the process) from commercial sulphuric acid used in acidifying the solution prior to driving off the *HCN*, followed by precipitation by the zinc-lead couple; in others, by organic matters present in the precipitant (aluminium powder or zinc fume), or the solution itself. In all processes it has hitherto been thought necessary to get rid of the existing cyanide in the solution prior to precipitation of the gold, and in so doing, two out of the three processes cause the precipitation of ferrocyanides. Ferrocyanides, when treated with aqua regia, produce among the products of oxidation, ferric salts and hydroferricyanic acid. In the final stage of the process, when adding stannous chloride for the production of the gold-purple, the ferric iron is reduced to ferrous which acts upon the ferricyanide, forming a greenish or bluish coloration; this may be very faint, but it alters the color of the gold-purple, rendering its standardization almost impossible. When the ferrocyanides, and the organic matters, already referred to, are present together, this difficulty of comparison is increased, and when, by the use of varying weights of the reagents containing the organic impurities such tints vary in intensity, close comparison is rendered quite impossible.

With a view to removing the difficulties referred to, I commenced a research on the precipitation of gold from dilute cyanide solutions, by various precipitants, and finally selected, for use, a finely divided zinc-copper couple, made from zinc fume diffused in the solution to be tested, after the addition thereto of a measured quantity of strong cyanide solution containing a certain quantity of cuprous cyanide (the additional cyanide keeping ferrocyanides, and zinc cyanide to be subsequently formed, in solution). The solution is then heated and stirred vigorously to keep the "couple" in suspension until the gold is precipitated. The precipitation I found to be rapid and practically perfect; the filtrate, on being retreated, failing to give an appreciable tint of the gold-purple, even when viewed in a very narrow test tube (to increase the column of liquor to be viewed in the direction of its length), and compared with distilled water in a similar tube. I estimate that the gold remaining unprecipitated will not exceed .5 grain per ton of solution. The results obtained with all classes of solutions agree with the precipitation plus fusion and evaporation methods.

The remainder of the process is, with the exception of a few manipulative details, essentially the same as that in present use. A measured quantity of zinc fume is, however, used for precipitation, and the alteration of tint due to impurities in the zinc fume is constant and therefore measurable, giving approximations sufficiently accurate for extractor-house work. The process is simple and can easily be carried out by the foreman in charge, or one of the shiftsmen. A test can be made in about 10 minutes.

For closer work, the final precipitate (free from ferrocyanides) is suitably treated for removal of zinc, and, subsequently, of the interfering organic matter. The resultant gold solution gives a "purple of Cassius" which, in all cases, can be exactly matched by the gold-purple produced from standard gold solutions. In all cases I prefer to remove suspended matters from the solutions to be tested, previously clarifying, if necessary, before measuring the solution for the test. This method, which is as perfect as any colorimetric process of its class can be, may be carried out in 17 to 20 minutes. The cost of the assay is trifling, while its advantages, especially in saving the time of the hard-worked assayer, are obvious.

Notes on Pyrite and Marcasite

Importance of These Minerals in the Formation of Ore Bodies. Causes of Deposition

In the *Journal of the Canadian Mining Institute*, Vol. XIV, appears the following paper by E. B. Wilson.

After examining a tin-white cubical specimen of striated pyrite, curiosity led the writer to examine the books of 15 mineralogists, to find if possible the exact difference between marcasite and pyrite. While unsuccessful, nevertheless sufficient information was gleaned to emphasize three material facts, namely:

That the writers of the mineralogies were rarely original.

That they were not sure of the difference between marcasite and pyrite.

That they all agreed on iron disulphide being a common dimorphous mineral.

Thinking possibly that geologists might supply the lacking information, several standard works were examined, but beyond finding that pyrite was found in igneous, metamorphic and sedimentary rocks of all ages, nothing new was ascertained.

Chemists' and geochemists' works were next examined without obtaining any definite information, but from the various kinds of literature there was gleaned so much material that ran contrary to natural conditions, that these notes were written with the hope that they will arouse sufficient interest to start an original and substantial investigation.

Geochemists seem to have given little attention to that mineral which probably more than any other has been the medium through which the most valuable ore deposits have been formed, or if this statement is incorrect it is because they have failed utterly to record their investigations.

When a new bed of coal is discovered, almost the first thing considered is its percentage of sulphur (pyrite). Frequently coal has been condemned hastily and wrongfully on this account, the samples analyzed having included the sulphur bands. It is improbable that sulphur ever exists in coal beds in combination with the carbon of the coal, for nature has segregated and usually separated the pyrite in layers or bunches. To find sulphur in coal cleatage is unusual, and when it is so found evidences of other impurities accompany it. Charcoal, mother coal, carbonaceous shale, clay and other rock material will precipitate pyrite from sulphate solutions, but probably not coal unless high in ash, according at least to the writer's observations. Charcoal, mother coal, and shale do not contain bitumen, yet they precipitate iron disulphide from solutions, by some unknown method.

Bloxam states that "pyrite is formed from ferrous sulphate by organic matter and its presence in coal appears to be accounted for in this way." This is in direct opposition to the hypothesis, yet it is believed that if Mr. Bloxam had examined coal beds, he would have found the sulphur in slate partings or in contact with the roof or floor rock enclosing the seam; further, that it was not precipitated by the carbon of the coal. Organic matter precipitates gold from auric chloride or gold cyanide solutions; it precipitates copper pyrite from copper sulphate solutions; and blende from zinc sulphate solutions. In fact the organic matter need only be charcoal to bring about the reaction. The writer can find no evidence that coal will precipitate these minerals from solution. It seems to be more than a coincidence that pyrite is found attached to shale and rock rather than to coal.

The following formulas are advanced as possible reactions, which however the writer has not verified:

$$2FeSO_4 + 2CaCO_3 + 2H_2O = FeS_2 + FeCO_3 + 2CaOH + H_2CO_3 + 8O$$

It is known that ferrous carbonate is soluble in carbonic acid and if hydrogen sulphide happened to be present the ultimate reaction might have been as follows:

$$FeCO_3 + 2H_2S = FeS_2 + H_2CO_3 + H_2$$

As pyrite in coal beds is in physical combination and not chemical, mechanical washing is practised to reduce the percentage of sulphur, sometimes with entire satisfaction.

The iron master maligns pyrite even more than the coal miner; in fact has no earthly use for it, yet he would be without a furnace had not pyrite furnished him hematite and limonite according to the following reactions:

$$FeS_2 + 2O = FeS + SO_2$$

$$FeS + 4O = FeSO_4$$

$$6FeSO_4 + 3O + 3H_2O = 2Fe_2(SO_4)_3 + 2Fe(OH)_3,$$

rusty quartz stain reaction.

$$FeSO_4 + CaCO_3 = FeCO_3 + CaSO_4 \text{ and}$$

$$2FeCO_3 + 5H_2O + O = Fe_2O_3 \cdot 3H_2O + 2H_2CO_3,$$

limonite reaction. In the case of a ferric salt,

$$2Fe_3(SO_4)_3(OH)_3 + 6CaCO_3 = 2Fe(OH_3 + 6CaSO_4 + 6CO_2 + 2Fe_2O_3,$$

hematite reaction or if the solution was ferric chloride,

$$2FeCl_3 + 3CaCO_3 = 3CaCl_2 + 3CO_2 + Fe_2O_3,$$

hematite reaction.

Passing to the copper matte smelter, it will be observed that he must have pyrite to produce matte; however, his case is exceptional. The lead smelter does not particularly care for pyrite if he can obtain iron oxide, but is forced to accept some of it as a rule. The zinc smelter penalizes the miner heavily if zinc ore contains more than 2 per cent. iron, which is equivalent to 4.25 per cent. pyrite, yet were it not for the weathering of pyrite the zinc smelter would have few rich oxidized ores and not so bountiful a supply of blende.

So much has been said and printed concerning the weathering of zinc-lead ores and their secondary concentration, that it is necessary in this paper to call attention merely to the relative weathering capacities. Iron has more affinity for sulphur than zinc or lead. It is therefore more easily weathered and less easily precipitated, a feature that aids in dissolving the other metal sulphides in the order given.

From the mineralogist's standpoint marcasite differs from pyrite in its color, being tin white instead of brass yellow; in its specific gravity being from 4.6 to 4.9 instead of 4.9 to 5.2, and in its crystal form being orthorhombic instead of isometric.

Pyrite like some other minerals is polymorphous, in that for some unknown reason it has more than one crystal form.

C. Mene observed some time prior to 1877 that iron disulphide of unaltered sedimentary beds is mostly marcasite, while that of metamorphic rocks is pyrite.*

Isolated crystals of pyrite are found in sedimentary rocks, and white iron pyrite is found in the metamorphic rocks in the anthracite region of Pennsylvania as well as pyrite. In Nelson County, Va., isolated cubes of white pyrite are found in aqueo-igneous rocks with striations as perfect as on brass-colored cubes. From observations, the writer is satisfied that it will require more than the dimorphism of iron disulphide to distinguish pyrite from marcasite. Stokes has noticed that much of the fibrous mineral usually called marcasite consists actually of pyrite† and the writer has seen pyramidal pyrite as brassy as any cubic pyrite.

"From the circumstances that marcasite is the characteristic form in sedimentary rocks, while pyrite occurs in plutonic rocks, Van Hise infers that marcasite is transformed into pyrite by pressure."‡ In regard to this Doctor Elsden says: "The transition does not appear to have been realized in the laboratory and nothing is definitely known of the conditions under which it takes place."

Aqueo-igneous rocks contain isometric brassy and tin-white pyrite. This does not fully agree with Professor Van Hise's theory, although it will be noticed that the brassy colored pyrite favors quartz, particularly if copper is present. "Iron disulphide is made artificially by heating iron with an excess of sulphur or heating ferric oxide or hydrate moderately in hydrogen sulphide

* Dana's System of Mineralogy, 1877, page 800.

† Bulletin No. 186, Geological Survey, 1901.

‡ Elsden Principles of Chemical Geology, page 111.

so long as it increases in weight." Iron disulphide made artificially for the generation of hydrogen sulphide by melting iron and sulphur, crystallizes when cooling in the isometric system, its appearance, however, does not approximate brassy pyrite, owing to the latter being formed from aqueous solutions.

Moses and Parsons in their Mineralogy state that "pyrite is being formed today by the action of hydrogen sulphide of thermal springs upon soluble iron salts. It has been developed in many rocks by the action of hot water on iron salts in the presence of decomposing organic matter." Both the above reactions are probable, although it is not necessary to have hot water; for example, "alum shale" is composed of carbonaceous matter, pyrite and clay. The pyrite when exposed to the weather will oxidize, form sulphuric acid and ferrous sulphate, that will act on the aluminum silicate and form aluminum sulphate. It is assumed that a reaction something similar to the following takes place based on the fact that silica abhors sulphur and cannot be forced into combination with it in a blast furnace.

$$2FeSO_4 + Na\,Al\,Si_3O_8 = FeS_2 + Fe\,Na\,Al\,Si_3O_{10} + 6O.$$

Dr. J. V. Elsden* in treating on "Equilibrium Conditions of Polymorphous Forms," says: "At any given temperature and pressure one of these forms is in general metastable with regard to the other, and the metastable form tends to pass spontaneously into the more stable variety. These polymorphous forms differ not only in their crystalline form and symmetry but also in their specific gravity, melting point and other physical properties. Theoretically it would be inferred that the denser forms are the more stable under high pressure." That there is a slight difference in specific gravity between the brassy and the white iron pyrites is due probably to impurities. Pure pyrite should contain 46.7 per cent. of iron, and 53.3 per cent. sulphur. Analysis of Louisa County, Va., pyrite is as follows: S 47.78, Fe 43.90, Cu 3.69, Zn 24, SiO_2 1.99, As .63, P .10. H. Reis authority. An analysis of marcasite, made by C. Mene, gave Fe 38.9, S 44.9, SiO_2 11.3, Al_2O_3 2.4, H_2O 1.7, and CO .3. The sample came from a bituminous coal bed according to the information given, although the writer thinks it came from a slate band. In Germany, what is termed marcasite, is found in such quantities below lignite beds as to make it worth mining for sulphuric acid manufacture. In Ohio it is found near the floor of a coal bed in the forms termed sulphur balls in just the right position to break the knives out of chain coal cutters. It is difficult to reconcile the mineralogists' and geologists' statements, for if the former are right the latter are wrong, and vice versa, besides when considered collectively the statements do not always agree with natural facts. Frequently pyrite contains gold, copper, and other heavy minerals, and naturally these impurities would increase the specific gravity, and in the case of copper alter the color. Pyrite containing copper sulphide is more generally weathered than pyrite, which leads to the supposition that degree of weathering is not to be depended on as a distinguishing feature.

Summing up, it is found that none of the surmises or theories of the mineralogists, geologists and geochemists so far as pyrite is concerned are entirely tenable, and that the true difference between pyrite and marcasite, if any exist, will be found in their chemical composition. It also may be possible to tell from these analyses the amount of an impurity necessary to alter the form of a crystal from cubical to rhombic, besides obtain other data that will advance the now almost scientific study of ore deposits.

From the casual study outlined in these running comments, the deductions are:

That iron sulphide is precipitated from solutions by substances that may unite with the sulphide in sufficient quantity to change its crystal form.

That the color and specific gravity of iron sulphide deposited from solutions may be changed by the impurities entrained during a crystallization; further that carbonaceous matter will furnish a whiter color and less specific gravity than a metallic substance.

That neither coal nor quartz alone will precipitate pyrite.

That organic matter free from bitumen, most metallic oxides, some sulphides, and some metals, will precipitate pyrite.

That marcasite and pyrite are not safely distinguished by the physical or mineralogical tests advanced.

Process Fakes and Business Men

The value of the expert practical metallurgist in protecting the otherwise shrewd business man against swindling schemes which have too often proved easily successful, is crisply set forth in a recent article by Arthur D. Little, chemical engineer, of Boston.

A curiously large number of gold bricks are gilded by chemical methods, invariably applied by amateurs, who have nevertheless utilized most ingeniously some few scraps of chemical information. The surprising thing about the industry is the character and quality of its clientele and the psychology of the selling arguments. Hard-headed business men, enriched by dearly won successes, who have learned to trust their judgment, and who have demonstrated their capacity for affairs, men who turn a box of strawberries upside down, and require a pastor's certificate of character from the office boy, these are the best prospects. They listen, they witness a demonstration, they calculate profits, and they are lost.

After all, the psychology of the transaction is not so obscure. It is because they have learned to trust their own judgment in the things they know about that they are led to regard it as equally trustworthy in case of something about which they only think they know. They have so long ignored expert assistance in their ordinary affairs that when the extraordinary occasion arises they feel quite competent to cope with it alone.

There is, too, unfortunately, still a certain atmosphere of mystery around the processes of chemistry as viewed by the average mind, which clouds deduction and seems to justify the otherwise unreasonable. "Chemistry accomplishes so many extraordinary things, why not this one which I have seen with my own eyes?"

As examples of successful "process" swindles, Mr. Little sketches briefly the Jernegan "sea-water gold" process and other fakes, including that for converting water into burning fluid.

Dangerous as these more grossly fraudulent schemes have proved to would-be investors in the past, there is often even greater danger in propositions put forward with the best intentions by half-informed inventors and promoters. While, therefore, it can be amply demonstrated that no class of investments can be counted on for larger and more regular returns than those in well-considered enterprises based on chemistry, no one untrained in metallurgy should consider such investments without expert advice.

The application of the principles of chemistry to the Bessemer process of making steel has added, directly and indirectly, according to the estimation of Abram S. Hewitt, $2,000,000,000 yearly to the world's wealth. The ingenious adaptation of the conditions of alkali manufacture to chemical facts and principles enabled Mond & Solvay to pay 100 per cent. dividends for many years on a capitalization of $20,000,000. In New England an original capital of $20,000 has, through the wise development of a chemical process, grown in a decade to a surplus of $1,000,000.

These instances are only a few of many similar ones of varying importance, but it should be borne in mind that the development of such industries requires not only knowledge of chemical science but mechanical and business matters as well.

Mines and Minerals

Vol. XXXII—No. 3. SCRANTON, PA.—OCTOBER, 1911—DENVER, COLO. Price, 25 Cents

PUBLISHED MONTHLY AT SCRANTON, PA.

ESTABLISHED 1881

WESTERN EDITORIAL OFFICE: 1221-1222 First Nat'l Bank Bldg, Denver, Colo.
CHICAGO OFFICE: 1006 Michigan Ave.

Entered at the Post Office at Scranton, Pa., as second-class matter

Address all business communications to MINES AND MINERALS, Scranton, Pa.

CABLE ADDRESS, "RETSOF, SCRANTON"

LONDON OFFICE: INTERNATIONAL BUILDINGS, KINGSWAY, LONDON, W. C.
SOUTH AFRICAN OFFICE: MANSION HOUSE CHAMBERS, ALDERLEY STREET, CAPE TOWN.
NEW ZEALAND OFFICE: 63 DIXON STREET, WELLINGTON.
AUSTRALASIAN OFFICE: 83 PITT STREET, SIDNEY.

SUBSCRIPTION RATES

Single Copies .... 25 cents
Yearly Subscriptions, including postage:
To United States, Mexico, Cuba, Porto Rico, Hawaii, and Philippines. $2.00
To Canada 2.50
To all other countries 3.00

The date after your name on the wrapper is that of the month to which your subscription has been paid. If you do not want to continue your subscription after that time, kindly notify us.

Notice to discontinue or change of address should be sent to the Scranton office.

When notifying us of a change of address always give your FORMER as well as your present address.

TABLE OF CONTENTS

Removal of Western Office

THE Denver office of MINES AND MINERALS, which for some years has been in the Equitable Building, has been removed to pleasant and commodious rooms 1221-1222 First National Bank Building. Mr. Geo. F. Duck, western editor, extends a cordial invitation to all mining men to make this office their headquarters when visiting Denver.

Postponement of the American Mining Congress Meeting

THE fourteenth annual session of the American Mining Congress, which had been arranged to be held at the La Salle Hotel, Chicago, on September 26 to September 29, has been postponed until October 24 to October 28, inclusive. The postponed meeting will be held at the La Salle Hotel according to the original arrangements.

The postponement was ordered by the committee that President Taft might attend and address the convention on his return trip from the West.

During the five days of the meeting MINES AND MINERALS will have an office in Room 1845, La Salle Hotel, near the headquarters of the Secretary of the Congress. Members of the Congress and visitors are cordially invited to make this room their headquarters during the session. Mail addressed to members in care of MINES AND MINERALS will be looked after and promptly delivered.

The Calumet and Hecla Consolidation

IT IS interesting to note that the valuation placed on certain Michigan copper mines by J. R. Finlay is 34.7 per cent. less than the appraisements made by the engineer of the Calumet and Hecla on those properties included in the proposed consolidation. The opposition comes from some of the stockholders of the smaller companies who imagine the consolidation is a scheme to increase the declining values of the Calumet and Hecla at their expense. They appear blind to the objects of the consolidation, are unable to appreciate that the men most largely interested in the smaller companies are the ones to propose the consolidation; nor are they able to believe that high financeering is not the purpose in view. Mr. Finlay's report shows that the Calumet and Hecla directors are exceedingly liberal in their valuations, but if it did not, the history of the former management and the fact that the present officers are the sons of their fathers counts for much, for as the twig is bent so is the tree inclined.

Michigan Mine Valuations

FARMERS in Michigan believing that they were unjustly burdened with taxes while mines and manufacturing enterprises were lightly assessed, demanded that an expert should be hired to place a valuation on the ore mines in the upper peninsula.

J. R. Finlay, who was engaged by the state for this purpose, rendered his report in August. In the report, stock valuations are ignored as speculative, appraisements being based on ore in sight. After making suitable deductions for mining, milling, smelting, refining, and transportation the value of the copper mines on Keweenaw peninsula was placed at $69,815,000.

The estimated value of the iron-ore mines is $119,485,000, a figure so startling to the iron-ore operators they are undecided whether they belong in the humble or the proud and haughty class. Before just taxation can be based on such a mighty valuation large deductions must be made from its face value; for instance, the changes in the grade of ore in the mines reduce its value, fluctuation in market conditions affects its price and the increasing cost of supplies and labor, the deterioration of the plant, the expensive improvements that must be installed to compete with other iron mining states more favorably situated, are factors which Mr. Finlay could not anticipate in making his estimate.

Michigan citizens should consider the number of tradesmen and others dependent on the mines and the importance of the mines of their state relative to its common prosperity; also they should remember that Wisconsin and Minnesota are iron-ore producing states which are sharp competitors.

The Election of State Mine Inspectors

SOME years ago, when the bill providing for the election of state mine inspectors for the anthracite regions was before the legislature of Pennsylvania, this journal strenuously opposed it as a piece of mischievious legislation detrimental to the best interests of both mine operators and miners.

It is just as much opposed to the system now as it was then, and in view of efforts being made to make the position an elective office in other states, we deem it wise at this time to again express our views in the hope that no other state will make the same blunder as did Pennsylvania.

In the first place the position of mine inspector should be a non-partisan one. The sole qualification should be technical ability coupled with high moral character and that element sometimes called diplomacy, or tact, but generally known as common sense.

While the law in Pennsylvania provides that all candidates for inspectorships in the anthracite regions must have successfully passed an examination before a board of examiners appointed by the several courts before they can have their names placed on the ballots, this does not take away the necessity of a political campaign with its accompanying evils and the payment of campaign expenses out of a possible salary already too meager to ensure the state holding a good man permanently.

As the privilege of voting for a state mine inspector cannot legally be restricted, the successful man may be the choice of farmers, merchants, saloon keepers and other classes in no way directly interested in mining, and therefore absolutely unqualified to judge as to the qualifications of the candidate.

In fact in many election districts if there were two candidates for a vacancy and one through superior fitness for the office had the support of a large majority of the mine officials and mine workers, an inferior man, through political influence and possibly by unfair and illegal methods, might be elected. Again in a strong Republican district the best qualified man might be a Democrat and as a result he would be defeated, or *vice versa* in a strong Democratic district the same fate would await an able Republican.

That such instances have not so far actually been the case in the anthracite regions of Pennsylvania has been due to the fact that the number of men certified by the examining boards as being qualified for the position has been practically limited to the number of vacancies to be filled.

There is only one way in which to secure the best type of men as state mine inspectors. That is to have an examining board, appointed by the governor or the court, composed of equal numbers of mine owners or mine superintendents and intelligent miners with a competent mining engineer as the odd member of the board. This board of examiners should be sworn to hold a fair and honest examination and report the actual results to the appointing power. The report should cover not only the technical qualifications of the candidates, but should also cover their general fitness based on their answers to carefully considered questions calculated to draw out their ability to carry out the provisions of the mine law with least possible friction. The matter of the candidate's politics, nativity, or religious belief should have no influence on the standing given him by the examining board. Then the governor should be required by law to issue a commission to the man who passed the examination with greatest credit regardless of his political affiliations. In this manner and with sufficient salary to make the office worth as much or more than a mining corporation will pay for the services of a man of like ability, competent men can be secured. Mere technical ability and good character is not enough to make a man a good mine inspector. The writer was personally acquainted, some years ago, with an inspector of most commendable moral character and exceptionally well qualified for the position in a technical way, but he was a failure as an inspector, owing to his irascible temper, which had him almost continually at odds with both the mine officials and the miners in his district.

COAL MINING AND PREPARATION

Universal Mine Plant and Shafts

Modern Twin Collieries, Concrete-Lined Shafts and Permanent Structures of the Bunsen Coal Co., Near Clinton, Ind.

*By A. F. Allard**

Universal plant of the Bunsen Coal Co., of Westville, Ill., a subsidiary of the United States Steel Corporation, is situated in Vermilion County, Ind., 5 miles southwest of Clinton, Ind., and is reached by a branch track extending 2½ miles, connecting with the C. & E. I. Railroad. In the ch ice of a location for this plant, which is situated in a broad valley with an unexcelled position, careful consideration was given to every detail connected therewith. Many new features for a coal-mining plant were added and the most modern methods of construction and installation were adopted to make this plant absolutely fireproof and structures permanent; also the knowledge gained from many years' experience has been applied perfecting it, so that it stands today without a rival. The appropriate name of "Universal" is taken from the Universal Portland Cement Co., which brand of cement was used exclusively for all of the concrete work, and every pound of material used in the construction of this plant was made by some of the subsidiary companies of the United States Steel Corporation. The combined mines, comprising the No. 4 and No. 5 coal seams, will have an output of 3,300 tons of coal per day.

The complete plant above ground was designed by and built under the supervision of the Roberts & Schaefer Company, consulting engineers of Chicago. All of the improvements, including the mining plant, sinking of shafts, etc., were carried on under the general direction of Clay F. Lynch, general superintendent of the Bunsen Coal Co., and the construction engineer of the company who was in charge of the field work. The two steel tipples and head-frames, one for each hoisting shaft, were erected by the Illinois Steel Co., and the contract for the mine buildings was awarded to the Nicola Building Co., of Pittsburg, Pa. The latter are all constructed of reinforced concrete, including the floors and roofs of buildings. The window frames and sash are all of steel, fitted with pivoted ventilators, making the buildings absolutely fireproof. Fig. 1 is a view of the twin tipples and head-frames before covering.

Departing from the ordinary procedure of lining coal-mine shafts with timber, the Bunsen Coal Co. have made their own designs and have used concrete for this purpose throughout the entire depth of the two main hoisting shafts and ventilating shaft. These shafts are the first of their kind and size to be successfully sunk in the Indiana coal fields. Two circular-end design concrete-lined hoisting shafts were sunk at a distance of 190 feet apart. The ventilating shaft is located 400 feet from the No. 5 hoisting shaft.

The shaft contract was awarded to Walter F. Patterson, of Pittsburg, Pa. Ground was broken for the No. 4 hoisting shaft October 24, 1910, for the No. 5 hoisting shaft on December 14 of the same year, and for the ventilating shaft on February 11, 1911.

The No. 4 and No. 5 hoisting shafts are the same size, of circular-end design, with rectangular side walls, and measure 21 feet 10 inches long by 10 feet 10 inches wide in the clear on the center lines of the axes. The No. 4 shaft has a depth of 228 feet and the No. 5 shaft a depth of 131 feet below the top of coping to the bottom of the No. 4 and No. 5 coal seams.

Each shaft is provided with a sump 10 feet in depth below the cage landing. The shafts are divided into four compart-

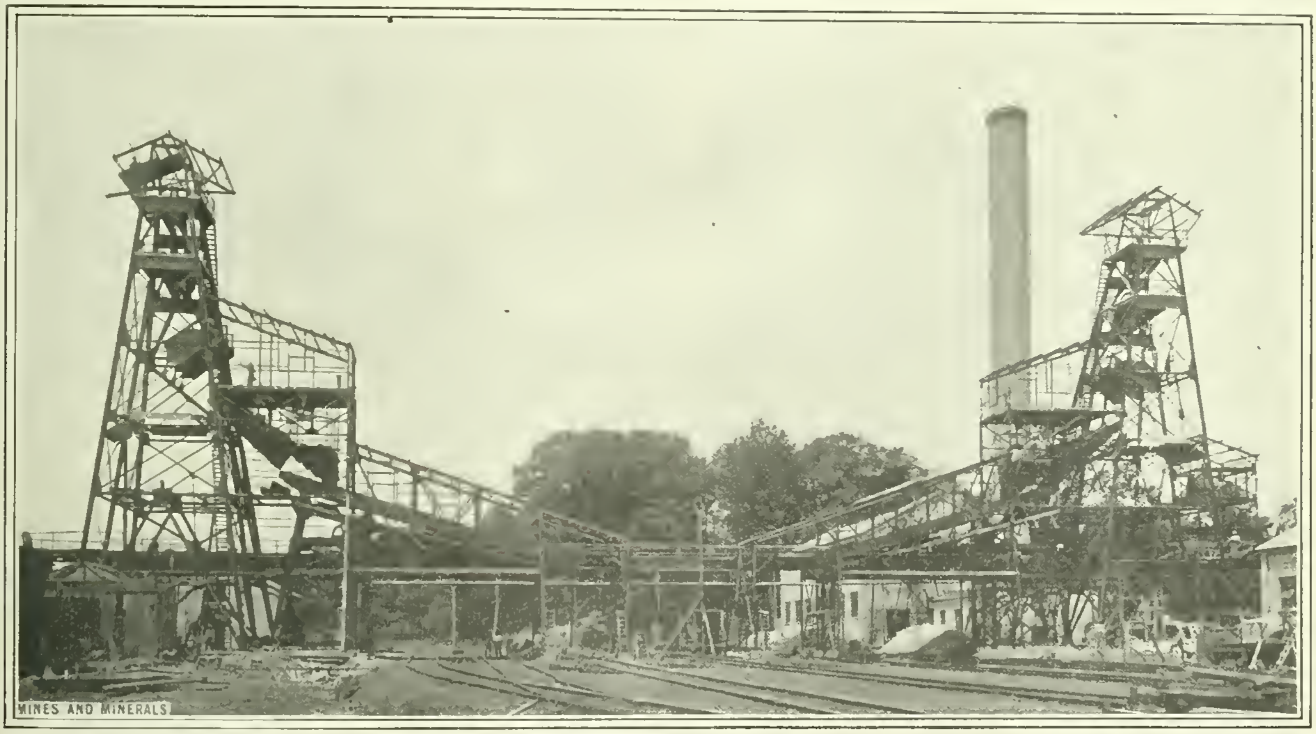

Fig. 1. Twin Tipples Before Covering, Universal Mine

* Construction Engineer, H. C. Frick Coke Co.

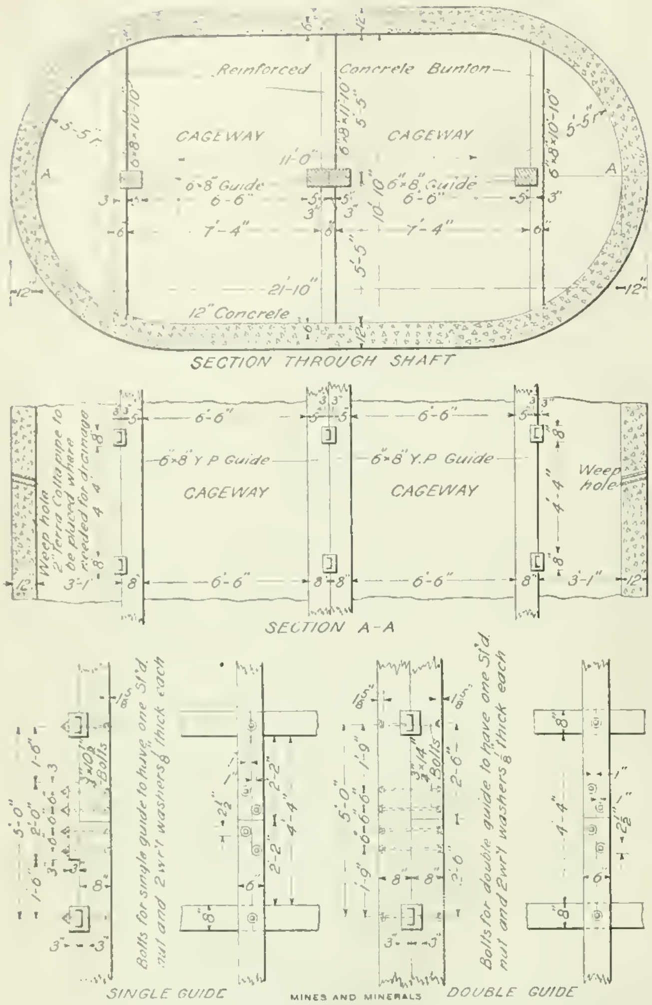

Fig. 2. Section, Elevation and Details of Shaft Lining

ments, containing two cageways and two pipeways. The circumference of the inside of the concrete lining is 56 feet, with a clear opening area of 211 square feet, comprising 168 square feet for the two cageways and 43 square feet for the two pipeways.* The ends of the shafts conform to a radius of 5 feet 5 inches. The shaft buntons are 6″×8″ concrete, reinforced with 6-inch steel channels, spaced 5 feet center to center. The cage guides are 6″×8″ yellow pine and are bolted to each of the concrete buntons. Fig. 2 shows a section and elevation of the shaft lining and fastening of the guides to the concrete buntons.

The ventilating shaft, of circular-end design with rectangular side walls, provides for a separate airway and stair compartment leading to each of the No. 4 and No. 5 coal seams. The section leading to the No. 5 or upper seam measures 31 ft. 2 in.×11 ft. 4 in. in the clear on the center lines of the axes. This section has a depth of 171.5 feet below the top of coping to the bottom of the No. 5 coal bed, and is divided into four compartments, containing two airways and two stairways. The circumference of the inside of the concrete lining is 75.3 feet, with a clear opening area of 325 square feet, comprising 83 square feet for airway to the No. 5 seam, 98 square feet for the airway to the No. 4 seam, and 144 square feet for the two stair compartments. The airway for the upper seam is 7 ft. 4 in.×11 ft. 4 in. and for the lower seam 8 ft. 8 in.×11 ft. 4 in. in the clear. The ends of the shaft conform to a radius of 5 feet 8 inches. After leaving the upper seam the single airway and stairway is carried down to the lower seam; this section measures 17 ft.×11 ft. 4 in. in the clear on the center lines of the axes, and has a depth of 100 feet from the bottom of the No. 5 seam to the bottom of the No. 4 seam. The depth from top of coping to the bottom of the lower seam is 271.5 feet. The circumference of the inside of the concrete lining is 47 feet, with a clear opening of 165 square feet. The two main airways are separated by a 12-inch reinforced partition wall, which extends from the top coping to the bottom of the upper seam. The stairways are separated from the air compartments with a 5-inch reinforced concrete curtain wall. This wall is tied in and supported by 6″×8″ concrete buntons reinforced with 6-inch channels, spaced 5 feet center to center. These buntons also stiffen the concrete side walls of the shaft and support the beams which carry the steel stairs. Fig. 3 shows a section and elevation of the shaft lining and the division of compartments. Fig. 4 shows the design of the steel stairway leading to each seam in the ventilating shaft.

Steel Shoes.—The steel shoes used for the sinking of the No. 4 and No. 5 hoisting shafts, from the surface of ground to the solid strata, were of rectangular design forming an open caisson, and measured, when set up ready for sinking, 17 ft. 6 in.×26 ft. 6 in. The side and end plates are ½ inch thick. The corners were all stiffened with 6″×6″×⅞″ angles. The angle for supporting the 12″×12″ jacking timber was riveted to the side and end plates and extended around the entire shoe on the inner side; these angles were also 6 in.×6 in.×⅞ in., the top flange being 14 inches from the bottom of plate or the cutting edge of shoe. The shoes used for both shafts were of the same size with the exception of the height; at the No. 4 shaft this was 6 feet while at the No. 5 shaft an 8-foot shoe was used.

The jacking timber was bolted to the side and end plates of the shoe with 1-inch bolts, spaced alternately 11 inches apart. At each corner and under the timber ¾″×6″ plates for stiffening the corners were riveted to the main angles. The shoe when completed for the No. 4 shaft weighed 12,000 pounds and for the No. 5 shaft 17,800 pounds.

The steel shoe used for the sinking of the ventilating shaft was designed to conform to the shape of the concrete lining 24 inches thick. The plates were ½ inch in thickness, having a vertical depth on the back line of lining 26 inches, and run

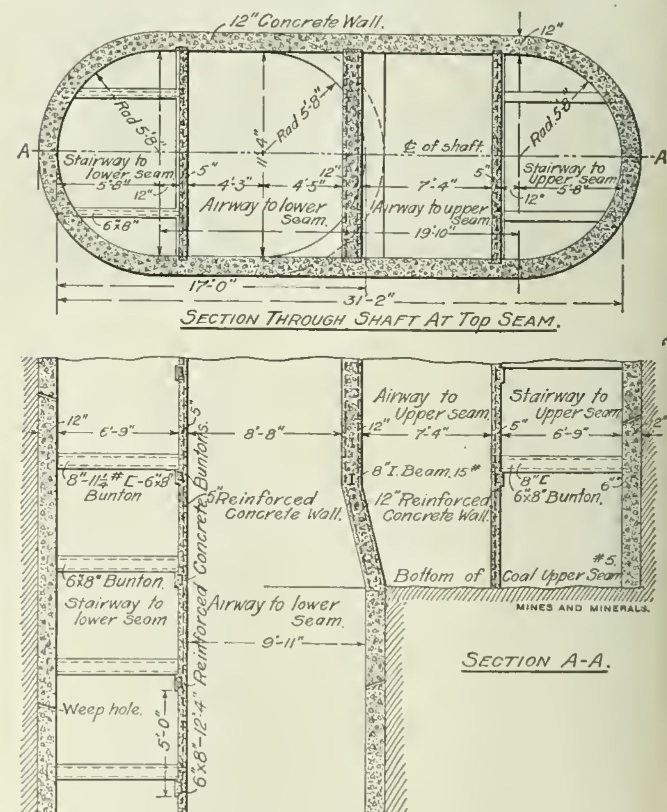

Fig. 3. Section and Elevation of Shaft Lining

on an angle of 45 degrees from cutting edge to the inner side of lining. The side pieces are 19 feet 10 inches long and seven segments with splice-bar connections formed the end circles. The first section of concrete poured filled the inside of shoe, which was fastened to the lining wall with $\frac{1}{4}'' \times 2\frac{1}{2}''$ bonding bars spaced 18 inches apart around the entire shoe; these bars were bolted fast to the cutting edge. At the top, to prevent buckling, $\frac{3}{4}$-inch bolts spaced every 3 feet were bolted to the plates and through the concrete. This shoe had a total weight of 11,500 pounds. Fig. 5 shows the design of steel shoe used at the hoisting shafts and Fig. 6 the design of steel shoe used at the ventilating shaft.

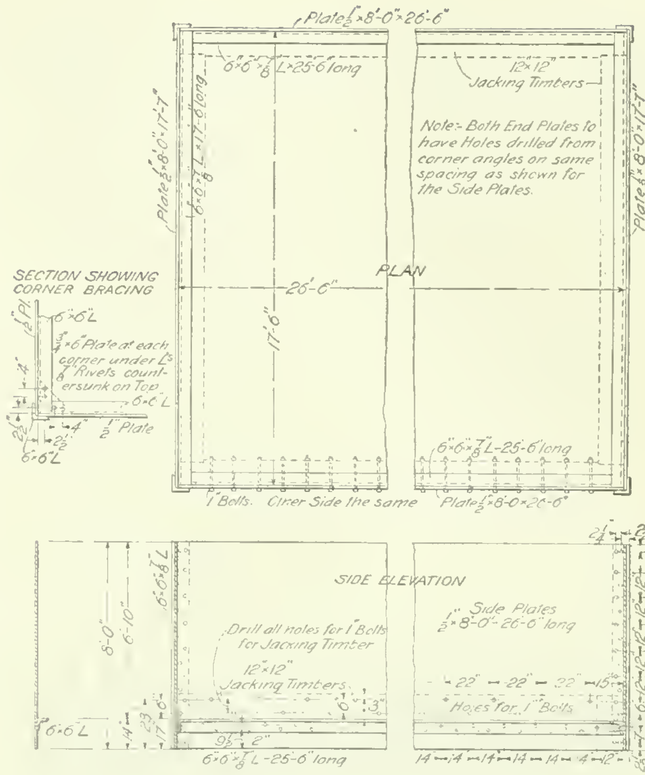

FIG. 5. STEEL SHOE USED AT HOISTING SHAFTS

Wooden Forms.—Wooden forms were used for all of the concrete-lining work at the three shafts. At the two hoisting shafts the inside form only was necessary, the concrete filling into the sides of the rock excavation. At the ventilating shaft both inside and outside forms were used until the concrete caisson at this shaft was anchored to the solid. The forms were generally made in six units, the two circular ends and two units for each side; these when bolted together formed the complete section around the entire shaft and measured 5 feet in height. The lagging was $1\frac{1}{2}'' \times 6''$ tongued-and-grooved yellow pine, stiffened on the sides, in center and at top and bottom with $1\frac{1}{2}'' \times 6''$ chord pieces. The segments for the circular ends were cut from $1\frac{1}{2}'' \times 12''$ boards. The entire form in position was braced with three rows of $4'' \times 6''$ cross-pieces, placed at top and bottom of each form and bolted to the framework. Before concreting the surface of the lagging next to the concrete, the surface was given a coat of oil, permitting the forms to be easily released after the concrete was set. Fig. 7 shows the end view of the forms set to place, ready for the pouring of the concrete.

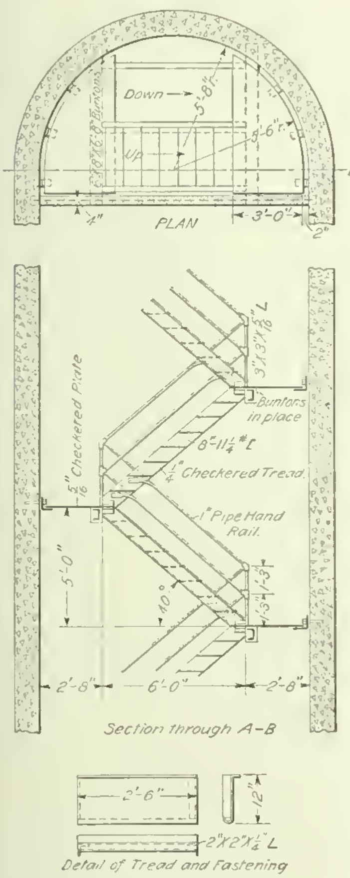

FIG. 4. STEEL STAIRWAY IN SHAFT

Sinking and Concreting.—The same method of sinking and concreting was adopted for both No. 4 and No. 5 hoisting shafts; namely, for sinking, the use of a steel shoe for guiding the curbing timber through the soft strata. The shoe was forced through this material by screw jacks placed around the jacking timber and using the weight of the curbing timber to jack against and sink the shoe. Each $2\frac{1}{2}$-inch jack used had a capacity of 10 tons. At times as many as 30 were in use. The shoe at the No. 4 shaft was sunk and landed at a depth of 42.5 feet below the top coping and anchored in the blue drift. Mattocks were then used to chop out the stiff clay, and, as excavation was made, $8'' \times 10''$ skin timber was placed and carried down 40 feet below the shoe. At a distance of 68 feet from top of shaft, and after going through the 30 feet of blue drift, sand and gravel heavily charged with water were encountered for a depth of 18 feet. The pressure at this point made it impossible for the men to place the last $3\frac{1}{2}$ feet of skin timber before reaching the hard cemented gravel. Three-inch sheet piling in 5-foot lengths was then used to close up the gap, and driven to the solid with sharpened points. The upper ends of the piling were well spiked to the timber lining. On account of not being able to penetrate the hard gravel with the piling, the heavy pressure from sand and water began to exert itself at the bottom of the piling, making it necessary to place the first section of concrete shaft lining without delay. A base for supporting the first section of concrete was cut out around the entire shaft to a width of 30 inches and the entire space between the clearance line of shaft and face of timbering was filled with concrete to a vertical depth of 5 feet. From this point to the top of coping the concrete lining was placed with an average thickness of 27 inches on each side and 18 inches thick at the circular end of the shaft.

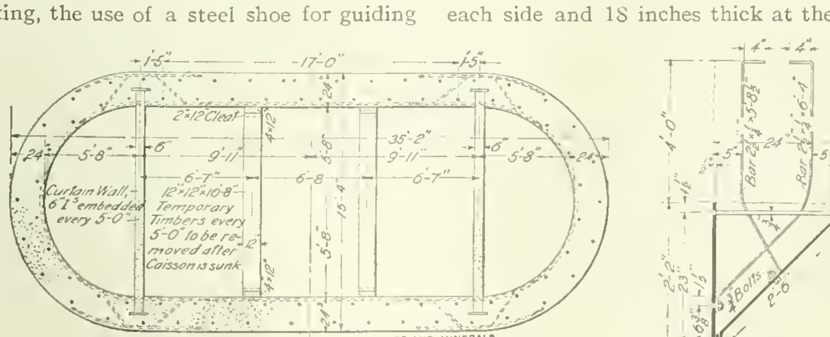

FIG. 6. STEEL SHOE USED AT VENTILATING SHAFT

To save concrete yardage at the four shaft corners, $6'' \times 8''$ diagonal pieces spaced every 5 feet were placed and covered with 1-inch tongued-and-grooved boards. These were placed in advance of the concreting and the corners filled in with sand as the lining advanced. Before concreting was started at each of the hoisting shafts, the first excavation was made to a depth of 90 feet below the surface of the ground. All excavating was done to the full measurements of the outside perimeter of the timber, and of the concrete lining where timber was not used in solid ground. The excavation was kept to a correct line by plumb bobs suspended from a template placed above the opening. Derricks were used at each shaft for a depth excavated of 90 feet below the surface, when wooden head-frames replaced these for the completion of the shafts. The method of placing the wooden forms and concrete was the same for each shaft; namely, at a point some 5 feet above the bottom of the excavated portion of the shaft a wide supporting base was made, usually 30 inches wide, extending around the entire shaft, this base supporting the several sections of concrete lining immediately above without the use of hitch timbers or other temporary planking. The forms were lowered in sections, nailed and bolted in position at the bottom and brought to the proper lines of the shaft. The concrete was then mixed in a cubical mixer located at the top of shaft, poured into bucket, lowered and the mix distributed in the form by means of a movable chute supported on a temporary platform at the top of each form section.

The concrete buntons were placed in their respective openings as the concrete lining advanced and were carefully fastened

Fig. 7. Forms in Place at Ventilating Shaft

on the correct center lines and poured together with the concrete walls; however, at the No. 5 shaft the buntons were made and poured on the surface, the ends being concreted in with the wall sections when the latter were being concreted. After the first form was completely filled another form was immediately placed above and bolted fast to the previous section, and the correcting operation continued until the entire excavation was closed in. Four complete form sections, or 20 vertical feet, were usually poured before the removal of the bottom form. No forms were removed until the concrete had set at least 24 hours.

Progress and Method of Sinking the Ventilating Shaft.—The method adopted for the sinking of the concrete caisson of the size and design at this shaft was entirely new for coal-mining purposes. The inside dimensions are 31 ft. 2 in. × 11 ft. 4 in. with a clear opening area of 325 square feet. The concrete lining wall is 24 inches thick for a depth of 96 feet below top of coping and has a surface area of 163 square feet, or 6 cubic yards of concrete per vertical foot of shaft, each vertical foot weighing 12 tons. The entire section was sunk by the weight of the concrete to a depth of 84 feet below the top of coping, through sand and gravel strata, at which point the steel shoe and shaft walls were landed on the solid rock. The total weight sunk to this point was 1,000 tons. The first excavation was made with derrick to a depth of 10 feet below the surface. The wooden form sections for this depth were then placed in position and filled with concrete. As the weight of the concrete placed settled the shoe, excavation was made on the inside to permit of another 5-foot section of concrete to be placed on the top, and the operation repeated until the solid rock was reached. At times the side pressure was so great that the concrete walls would not readily sink, when by flooding the outside with water the friction was lessened and the lining walls settled. To tie together each 5-foot section of lining wall, 1″ × 4′ round steel bars were used, in bent form, spaced 2 feet apart around the entire section and gripped 2 feet into each section. It often happened that one end of the shaft settled more than the other, when mucking at the lower end had to be stopped and continued at the high end until both came to the same level; however, when the shoe was landed the entire shaft was found to be close to the plumb lines. The advantage of sinking by this method, through soft ground, over that of using curbing timber and jacking the shoe down by hand was not only in the progress made, of 35 feet per month at this shaft as compared with 25 feet per month made at the No. 4 and No. 5 hoisting shafts, but also the saving in cost by eliminating all timber and pouring the concrete and erecting the forms on the surface. Fig. 8 shows this shaft, with the concrete walls exposed above the surface before settlement. When the picture was taken, 60 feet of concrete lining was placed. This shaft is undoubtedly the largest concrete caisson ever sunk in this country, by this method, for coal-mining purposes.

Curtain Walls in Ventilating Shaft.—These walls divide the stairways from the air compartments leading to each of the upper and lower coal seams. They are 5 inches thick extending the entire width of the shaft and continuous between buntons from top to bottom. The wall was poured in panel sections between the concrete buntons. The reinforcement consisted of American Steel and Wire Co.'s No. 4 triangular mesh, which was attached to ⅜-inch steel frames which were set in position between the two wooden forms, and the entire panel section of wall concreted. The concrete used was composed of one part cement to four parts of screened gravel. To obtain a good bond between the curtain wall and the shaft lining walls, 3″ × 4″ strips were carried in the shaft lining and removed when the different panel sections of curtain wall were being poured, making the compartment perfectly air-tight. No work was done on the curtain walls until the shaft lining was completed. Fig. 10 shows the steel frame which supports the reinforcement.

Waterproofing Shaft Lining.—Waterproofing in the No. 4 hoisting shaft was started at the temporary water ring, 41½ feet below the top of the coping, and the following method was used: Strips of 2″ × 6″ plank laid vertical and spaced 2 feet apart in the clear were spiked to the inside face of the 8″ × 10″ curbing timber. The strips were carried up to a point 6 feet below the top of coping. For a distance of 8 feet above the water ring and where the water pressure was the greatest a double layer of 1″ × 4″ tongued-and-grooved flooring boards were used. These were nailed horizontally to the 2″ × 6″ strips. All water running between the skin timber was then conveyed back of this lining and between the intervening spaces of stripping into the water ring. For conveying the water from the ring through the concrete shaft lining four 4-inch pipe bleeders were placed. After the concrete had thoroughly set these bleeders were screw capped and all water entering the shaft was shut off. From a point 8 feet above water ring to the surface, a single layer of flooring boards was sufficient. All boards were primed and given a coat of waterproof paint, this work being done on the surface. After the lining boards were in place a coat of hot asphalt was applied in sections over the entire surface. A layer of Johns-Manville asbestos, waterproof, four-ply fiber was placed; the fiber was applied against the hot asphalt, adhering same to the lining without nailing. Each section of fiber was laid with a 3-inch lap. After the fiber was placed a second coat of asphalt was applied to the paper, and this in turn given a coat of heavy waterproofing compound of "Leak-No" brand, placed just ahead of the 5-foot sections of concrete lining when being poured.

At the No. 5 hoisting shaft the waterproofing was carried down to a distance of 85½ feet below the top of the coping. The only difference in method used at this shaft was that 1"×4" strips were used back of the lining and these were laid diagonally on a 30-degree pitch and spaced 12 inches apart in the clear. These strips ran from the center line of the shaft to each of the four corner pockets; the water was then conveyed to the ring. The tongued-and-grooved lining in this shaft was all laid vertically and only one layer used throughout. However, the method adopted in each shaft proved satisfactory and made each shaft absolutely watertight. Fig. 9 shows the view at the top of the shaft looking at the waterproofed lining before the concrete walls were placed. Fig. 11 shows the method of placing waterproofed lining.

Materials Used in Permanent Work.—All concrete for lining the shafts is composed of one part Universal Portland cement to five parts of Wabash River gravel. The reinforced concrete buntons and partition walls are composed of one part cement, two parts sand and four parts of screened gravel. No crushed stone was used in any of the concrete work. Cement for the entire work was of "Universal Brand," manufactured by the Universal Portland Cement Co., of Chicago, Ill. Frequent tests and analyses were made by this company of the gravel used in the work, from samples submitted from time to time during the progress of work, to determine the percentage of silt and voids. From this material concrete briquets were made and tested for tensile and compressive strengths. The only timber used in the three shafts were the 6"×8" yellow-pine cage guides in the No. 4 and No. 5 hoisting shafts.

Progress of Hoisting Shafts.—From an inspection of the weekly progress, the bottom of the 5-foot coal bed was reached April 14, 1911, in the No. 4 shaft at a distance of 235 feet below the top of the coping. The bottom of the 5-foot coal bed was reached May 26, 1911, in the No. 5 shaft at a distance of 131 feet below the top of coping. The time to complete the sinking and placing of the concrete lining covered a period of 26 weeks in the No. 4 shaft, and 22 weeks in the No. 5 shaft, from the start of the work of excavating, showing a progress of 40 feet per month in the No. 4 shaft and 30 feet per month in the No. 5 shaft, for the completed work. The progress shown was very fair considering the bad ground and the extra work of jacking the steel shoe a distance of 42.5 feet in the No. 4 shaft and 85.5 feet in the No. 5 shaft through the sand and gravel strata, placing the heavy curbing timbers and handling the water, which amounted to about 400 gallons per minute in each shaft.

Bottom Arches and Landings.—At the bottom of each hoisting shaft the approaches leading to the cage landing on both the loaded and empty sides are of concrete. The arches have a clear span of 17 feet 4 inches and have a minimum thickness of 24 inches for the side walls and crown. These arches extend a distance of 12 feet from the face of shaft lining. On the empty side the extension for 22 feet has a clear span of 17 feet 4 inches and accommodates the automatic car lift installed; from this point for a distance of 56 feet to the switch for empty-car run-around, the span is 9 feet in clear. The roof in both of these sections is protected with 15-inch I beams weighing 42 pounds to the foot and spaced every 4 feet, center to center. These are supported by the concrete side walls and covered with 4-inch reinforced concrete slabs. Arches of an 8-foot span, having a minimum thickness of 18 inches, extend a distance of 12 feet from both ends of the shaft lining, and connect with the cross-entries and manway around the shaft bottom. An archway of 4-foot span is placed in the side walls for entrance to the manway. At the intersection of all arches with the concrete walls in the shaft lining, steel bars were placed for reinforcement. The extension on the loaded side has a clear span of 11 feet 6 inches for a single-track bottom, which gives ample room for the men to work on each side and is extended for a 40-wagon storage at the bottom. The extension is of 6-inch concrete side walls and 8-inch concrete block arch which rests on the side walls at the spring line of the arch. These blocks were all made on the surface in steel forms, and joints broken on the radial center lines. The blocks were placed in position in the entry as the excavation advanced, each block being cement plastered into place from each of the side walls until the keystone was placed, perfecting the arch ring. This method of construction eliminated all forms and arch centers, also the pouring of concrete in the entry. The concrete blocks for this work were all made on the surface and molded in steel forms. Fig. 12 shows the concrete arches at the bottom landing and Fig. 13 shows the reinforced concrete slabwork and section of heading where concrete side walls support the I beams for roof protection on the empty sides. Fig. 14 shows the design of steel form for making the concrete block arch of 17-foot 4-inch span and used on the loaded sides approaching the cage landings at the bottom of each hoisting shaft.

Mine Drainage.—The mine drainage will be taken care of by the installation of one single, horizontal, direct-acting, simple type, 20"×10"×30" mine pump located near the bottom of the No. 4 hoisting shaft and a 12"×7"×12" pump, of same pattern, will handle the water met with at the No. 5 hoisting shaft.

Fig. 8. Ventilating Shaft, Concrete in Place Before Settling

Mine Tracks, Etc.—The main haulage roads will be laid up with 40-pound steel rails and the room entries with 16-pound steel. The gauge of track is 42 inches. Experiment, at this mine, will be made with portable track and steel mine ties, manufactured by the Carnegie Steel Co., both on the main haulage roads and room entries. Portable track switches, with steel mine ties, will also be installed. At the bottom of each hoisting shaft, on the empty side, there will be placed a Robert Holmes single automatic car lift, operated by steam, for the transfer of empty mine wagons from the cage to the empty-car run-around. For the mine haulage, Jeffrey 6-ton, 250-volt, electric mine locomotives, with single-end control, will be used for each coal seam. Both the Jeffrey and Sullivan, 250-volt, electric chain coal-mining machines will be used for the cutting of coal.

Permanent Equipment.—The boiler house, located near the No. 5 hoisting shaft, is 47 ft. 4 in.×71 ft., and contains four class "S" Stirling water-tube boilers set in two batteries, each boiler rated at 374 horsepower, operating under a pressure of 125 pounds per square inch. Room is reserved for the future addition of two more boilers, should the same become necessary.

Playford improved chain-grate stokers are installed at each boiler, the stokers being operated by an 8″×10″ vertical steam engine. A special No. 5, two-section, horizontal, Stilwell feed-water heater and purifier, open type, suitable for heating 12,000 gallons of water from 50 to 210 degrees, supplies the feedwater for boiler use. The water is delivered by two 12″×7″×10″ Worthington horizontal duplex feed pumps.

The boiler ashes are conveyed in steel buckets which are mounted on wheels and run the entire length of the boiler house, on rails, in an enclosed concrete-lined tunnel, which is 5 feet 6 inches wide by 7 feet 9 inches high. The ashes are run to the end of tunnel, and, for their conveyance to the field dump a steel structure is provided and extends a distance of 400 feet from the boiler house. This will carry an electric hoist with motor-driven trolley, having a capacity of 1½ tons and an available lift of 45 feet, with a lift speed of 40 feet per minute, operated by a 6-horsepower motor and a trolley travel with a speed of 250 feet per minute with a 4-horsepower motor.

A reinforced concrete coal bunker for the storage of boiler coal is erected inside of the boiler house, having a capacity of 250 tons. The bunker is divided into six panels, 14 feet center to center, and is 84 feet in length. The entire body is hung and supported by reinforced concrete columns. The bunker

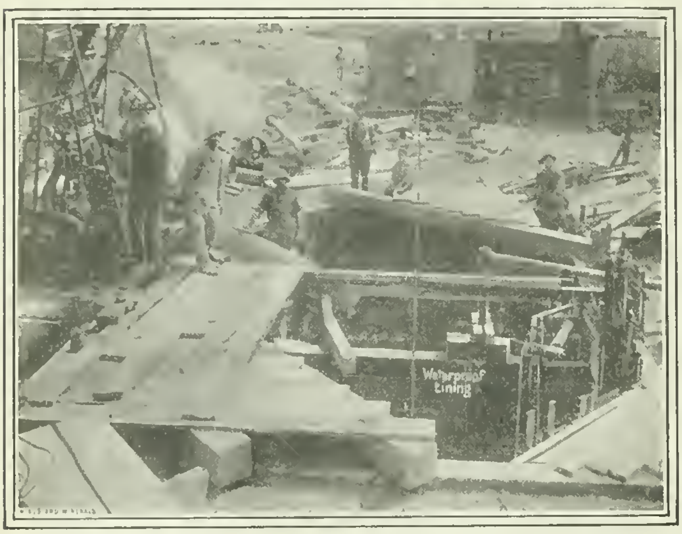

Fig. 9. Waterproof Shaft Lining

top is 15 feet in width and has a depth of 9 feet 7½ inches with circular-shaped bottom, which hangs with a clearance of 16 feet 8 inches from the floor. Twelve steel outlets for feeding coal to the boilers are provided in the bottom; each of these connect to 12-inch diameter gravity feed-spouts.

Two electric-driven 5″×12″ flight conveyers will deliver coal for boiler use into the coal bunker. One conveyer driven by a 10-horsepower direct-current motor will operate from the No. 4 hoist shaft, and the conveyer from the No. 5 hoist shaft will be driven by a 15-horsepower direct-current motor.

Draft for the boilers is obtained from a reinforced concrete stack, erected by the Alphons Custodis Chimney Construction Co. The stack is 181 feet high, from bottom of the foundation, and 10 feet inside diameter, the wall thickness is 16 inches and 10 inches for a height of 52 feet, and 8 inches thick from this point to the top of chimney. For the first one-third of its height the chimney is of double-wall cons uction, having an outer shell of concrete and an independent fire lining, with an air space separating both. The stack is equipped with outside ladder and a 4-point lightning rod. For support of the chimney a heavily reinforced square concrete base was placed, measuring 35 feet by 7 feet deep.

The power house is 47 ft. 4 in.×71 ft. It contains three Western Electric Co. generators, each of 200-kilowatt, 250-volt, direct-connected to 18″×21″ Erie engines with automatic cut-off slide valves and inertia governor, regulated 1½ per cent. above or below normal speed. These generators will be used to furnish power for the mine-haulage motors and the electric coal-cutting machines installed in each seam. A 25-kilowatt, 125-volt, steam, turbine generator, running 3,500 revolutions per minute, is provided for lighting the buildings, tipples and

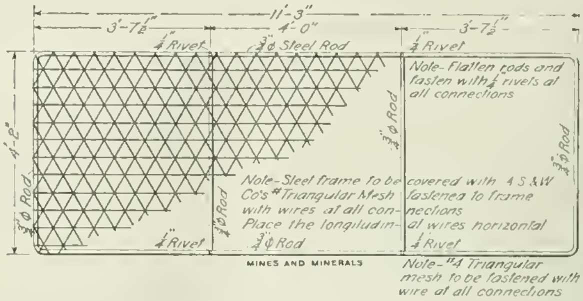

Fig. 10. Steel Frame Supporting Reinforcement

shaft bottoms. A 5-ton-capacity, hand-power, chain block, overhead traveling crane, with a span of 42 feet 4 inches, supplied with a trolley, will handle all parts of machinery necessary to remove. Ample floor space is provided for future installation. A feature in this building was the placing of a basement with 5 feet clear headroom, making it easy of access to reach conduits and steam lines, the latter in case of leaks, without tearing up the floor. Fig. 15 shows an interior view of the boiler house, concrete bunker, and column supports.

The hoist engine houses are each 30 ft. 3 in.×35 ft., located at each shaft, and house Danville hoisting engines. The engine for the No. 5 shaft is 20 in.×36 in., with 72-inch drum, and for the No. 4 shaft 24 in.×36 in., with 84-inch drum, both engines being direct acting. The hoisting cage ropes are 1¼-inch diameter. The mine cages operated by the engines are of the self-dumping type and were made by the H. C. Frick Coke Co., at their Everson, Pa., car shops, the cage platforms being 6 feet 6 inches wide by 11 feet long.

The two fan houses, each 12 ft.×27 ft., cover a Buckeye 20″×30″ self-oiling type, high-speed engine, of heavy design, working under 125 pounds steam pressure, placed in parallel on either side of the ventilating fan, which is erected between them and direct-connected thereto. Both engines are controlled with Anderson emergency stop valves, permitting the quick cutting-off of the steam from both engines.

The ventilating fan is a Clifford-Capell type blower fan, designed for reversing, and capable of a delivery of 250,000 cubic feet of

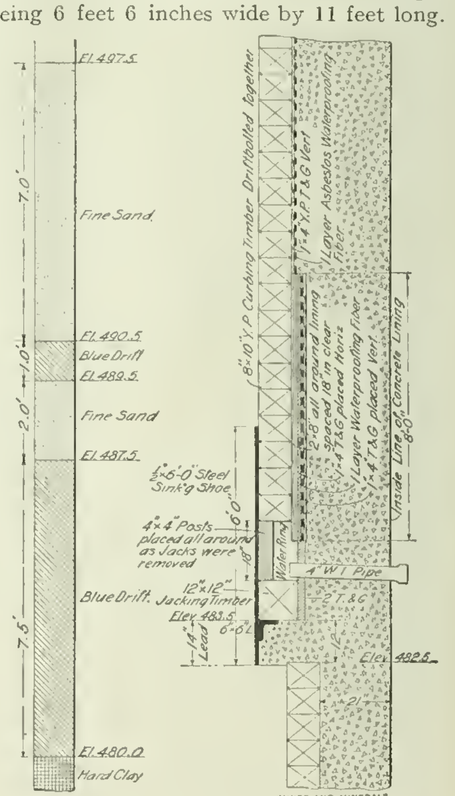

Fig. 11. Placing of Waterproof Lining

air per minute against a mine resistance represented by a 5-inch water gauge. The fan is 5 ft. 6 in. × 20 ft. with double inlet. Doors are provided in the drift to regulate or shut off entirely the flow of air into either of the air compartments, should it become necessary.

The repair shop is 30 ft. 3 in. × 91 ft., divided with concrete partition walls into three parts, for blacksmith, machinist and electrician. The shop is equipped with lathes, planers, drill presses, power hammer, pipe-cutting and threading machines, forges, hand and circular saws and bending machine. The machinery is all belt-driven by power from a 50-horsepower electric motor.

The plant office building is 34 ft. × 40 ft. and is built of smooth-faced concrete blocks. It is 2½ stories and is provided with sleeping and bath rooms. This building has an excellent location, overlooking the yard tracks and plant.

Other buildings include stable, 38 ft. × 50 ft.; granary, 28 ft. 6 in. × 35 ft.; storehouse, 23 ft. 8 in. × 45 ft. 8 in.; pump house, 11 ft. × 15 ft.; and power house, 20 ft. × 25 ft. The roofs of the main buildings are covered with reinforced-concrete tile, colored red on the surface, and make a good appearance in contrast to the white concrete walls.

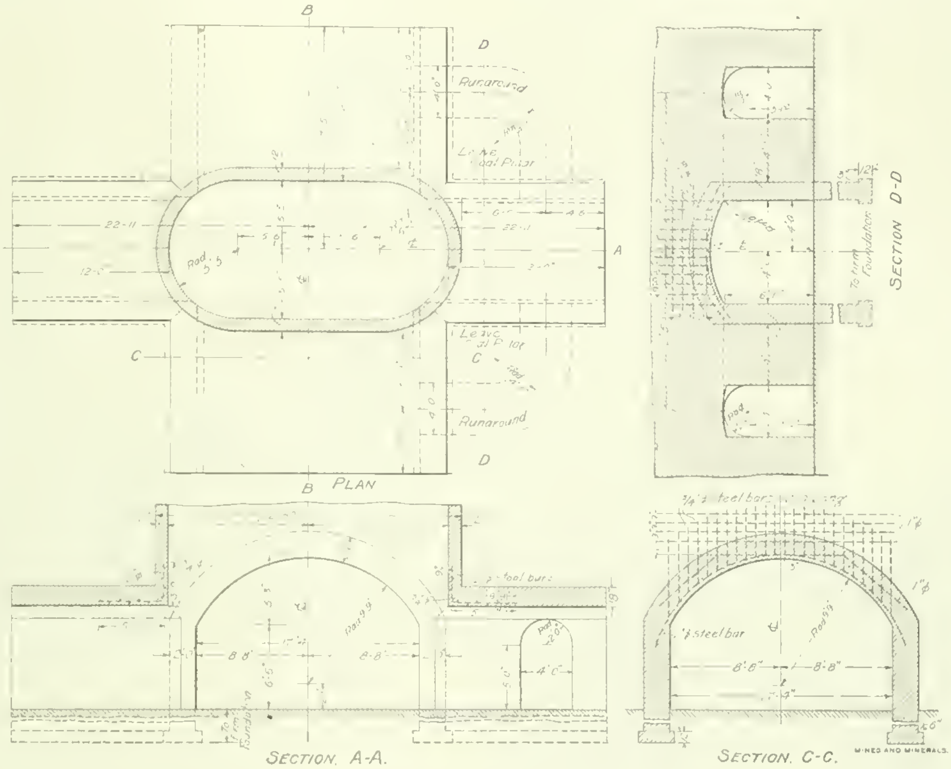

Fig. 12. Concrete Work at Shaft Bottom

The powder house is located along the railroad siding, 800 feet from shafts, and is of sufficient size for the storage of two carloads of explosive, which is transported by narrow-gauge track from the powder house to the shafts.

The steam line piping for the entire plant was made at the Everson car shops of the H. C. Frick Coke Co., which company also received the contract for erection.

At the No. 5 tipple there is an electric freight elevator. The platform is 7 ft. 6 in. × 10 ft. 6 in., and the elevator has a capacity to lift 4,000 pounds in addition to weight of the car. The hoist is operated by a 10-horsepower direct-current motor of 250 volts. The elevator is provided with automatic engine stop and safety brake. The purpose of instalment was for the conveying of mine cars or material from the shop or surface to the No. 4 tipple, by way of the rock-landing track, without stopping the hoisting of coal from the shaft. Reinforced concrete floors are provided in the scale room, around sheave wheels, and in the runways around the shaker screens on each tipple. Both tipples are provided with bar and shaker screens for the loading of lump, nut, and slack coal. Three tracks at each tipple will take care of the output for each grade of coal. The railroad tracks are all on a gravity

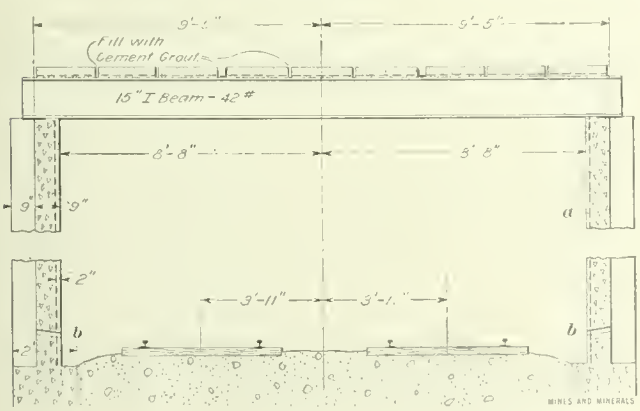

Fig. 13. Section of Heading, Showing Concrete Slab Work

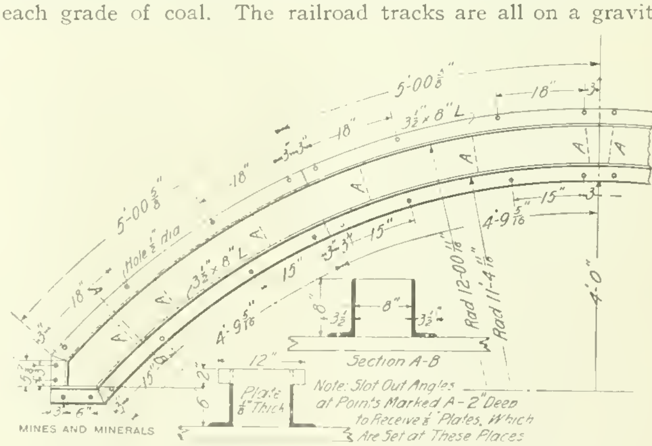

Fig. 14. Steel Form for Making Concrete Block Arch

The miners' bath house is 31 ft. × 62 ft., and is situated near the ventilating shaft. There are 20 individual wash bowls located along one side of the building, while on the opposite side there are 15 shower heads provided. Rows of seating benches are placed to accommodate 75 men. Hot and cold water is supplied. The men's clothes are raised in brass rings by means of chain and pulley and suspended near the ceiling, lock and key being provided for each man.

grade and sufficient room is provided above the tipples for the storage of 80 empty railroad cars. Between each set of tipple tracks a run-around track is provided, leading to the main-branch tracks.

Water System.—The water supply for the entire plant is taken from two 12-inch pipe-cased wells, sunk into the sand and gravel water-bearing strata to a depth of 35 feet below the surface of the ground. The location selected for these wells was at a point where the gravel basin was found to be the deepest, and was determined upon by driving a line of bore holes. The pump house situated at this point contains two $10'' \times 36''$ Cook's single, direct-acting, deep-well pumping engines, driven by steam. These are fitted for 9-inch suction and 4-inch discharge pipes. In each well is placed a brass $12' \times 9''$ patent Cook strainer, with slot openings $\frac{8}{1000}$-inch in width. The pumps deliver the raw water into two tanks, each with a capacity of 70,000 gallons. The water at this point is chemically treated and filtered and piped by gravity into a concrete waterproofed lined cistern, located just outside of the boiler house. The cistern is 15 feet in diameter by 15 feet deep, and has a capacity of 20,000 gallons of purified water. The "Buda" water softening system, of intermittent type, with a capacity of 10,000 gallons of treated water per hour, was installed. The purified water for boilers and plant use is stored in a steel tank, 35 feet in diameter by 35 feet in height, having a capacity of 250,000 gallons. This tank is supplied by water from the cistern and discharged into the tank by two steam-driven, duplex, $10'' \times 8'' \times 15''$, fresh-water pumps, located in the boiler house. The water head from this tank is 75 feet, and sufficient for all supply purposes and fire protection. The water lines are all of steel-line screw pipe, coated both on the inside and outside with asphalt. The main lines are 6-inch and branch lines to fire plugs 4-inch diameter. The hot-water supply for the bath house and office building is taken from a vertical hot-water heater, 5 feet diameter by 11 feet high, located in the boiler house, having a capacity of 1,600 gallons. A light-pressure $6'' \times 4'' \times 6''$ hot-water pump discharges the water at a temperature of 160 degrees to these buildings through 2-inch covered galvanized steel pipe. Fig. 16 shows a view of the water-purifying plant, concrete stack, and the boiler house, during construction.

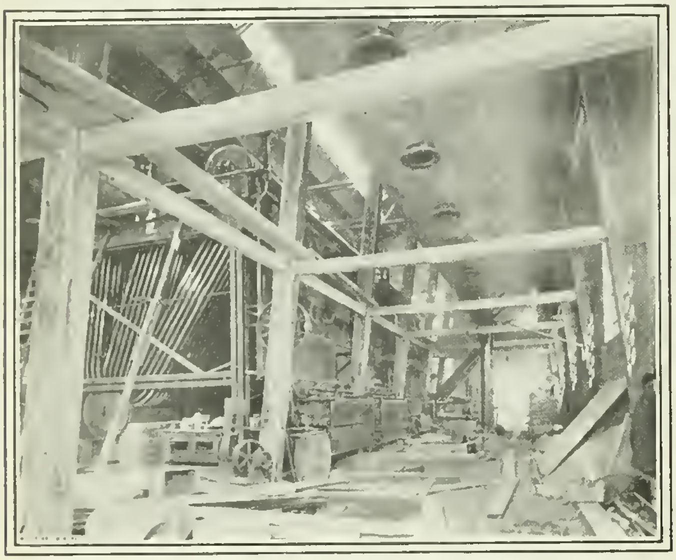

Fig. 15. Interior of Boiler Plant

Company Houses.—Erection is under way for the following frame dwellings: one superintendent's house, three 5-room single tenement houses, five 8-room double tenement houses, and six 3-room, 1-story, tenement houses. These dwellings will be used by the bosses and men required to stay at the plant. When the mines are in operation it is the intention to run a miners' train to the plant from Clinton. The houses will be supplied with electric lights and purified water. A 4-inch high-pressure water line, with double fire plugs at regular ntervals, will afford ample fire protection. Hose houses, 6 ft. 8 in. $\times$ 6 ft. 8 in., and hose-drying towers, 7 ft. $\times$ 7 ft. and 35 feet high, will be erected at the shaft site, and also at a convenient point adjacent to the company houses.

The No. 4 shaft has an area of 211 square feet inside, and was concreted to the coal, a depth of 235 feet. The greatest progress made in excavation in any one week was 21 feet; and the greatest depth concreted in any one week was 36 feet. A summary of progress is as follows: Total number of weeks worked, to reach bottom of coal, 26; average depth sunk per week (sinking 22 weeks), 10.7 feet; average depth of concrete lining placed per week (concreting 11 weeks), 21.4 feet; average depth of sinking and concreting for 26 weeks, 9 feet; average depth of sinking and concrete lining placed per month, 40 feet. Steel shoe carried down $42\frac{1}{2}$ feet below top of coping.

No. 5 shaft at the Universal mine has an area inside of 211 square feet, and is concreted from the surface to the coal, a depth of 131 feet. The greatest depth excavated in any one week was 16 feet, and the greatest depth concreted in any one week was 51 feet. A recapitulation of progress follows: Total number of weeks worked, to reach bottom of coal, 22; average depth sunk per week (sinking 17 weeks), 7.7 feet;

average depth of concrete lining placed per week (concreting 5 weeks), 26.2 feet; average depth of sinking and concreting for 22 weeks (per week), 6 feet; average depth of sinking and concrete lining placed per month, 30 feet. Steel shoe carried down 85½ feet below top of coping.

The total depth, 171.5 feet, of No. 5 ventilating shaft was lined with concrete. The inside area of the shaft is 325 square feet. The greatest progress in excavating was made during the

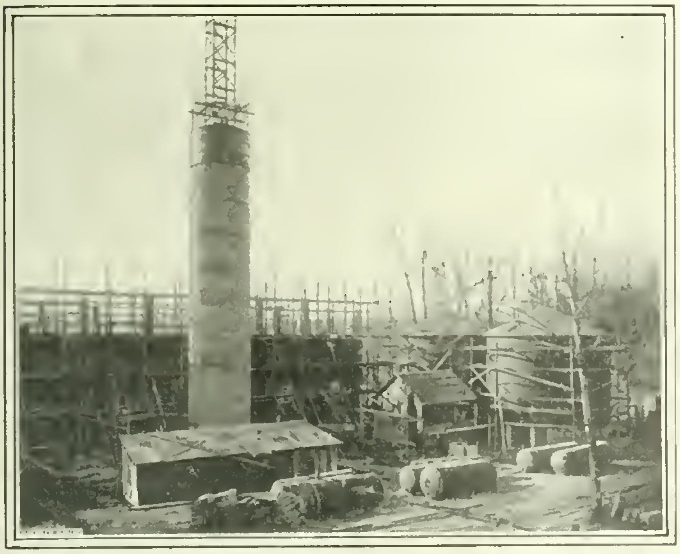

Fig. 16. Water Purifying Plant, Stack, and Boiler House

week ending June 16, when at a depth of 126 feet, 20 feet was excavated. The most concrete lining placed in any one week was during the week June 9, when at a depth of 91 feet, 35 linear

feet was put in place. A summary of the progress of excavating and concreting is as follows: Total number of weeks worked, to reach bottom of No. 5 coal, 20; average depth sunk per week (sinking 18 weeks), 9.5 feet; average depth of concrete lining placed per week (concreting 15 weeks), 11.4 feet; average depth of sinking and concreting for 20 weeks, 8.5 feet; average depth of sinking and concrete lining placed per month, 34 feet. Steel shoe and concrete caisson carried down 84 feet below the top of coping by the weight of the concrete.

Mechanical Laboratory Sampler

To keep the standard of market coal normal large coal companies are continually making tests to ascertain the heat units in the coal they are shipping. This procedure is a check on the preparation and also a check on the inspector, and is particularly important where coal is prepared in a wet way.

Frequently coal is condemned by its looks, because the muddy water in which it was prepared has dried and thus spoils its lustre but not its heat units. It is hard to convince the average consumer of this, however, and the coal companies do not try, their position being that the consumer is to be pleased.

To make sure of their position, however, in the matter of shipments they sample the coal as it is being prepared for market and this tells the tale. The Philadelphia & Reading Coal and Iron Co. keep continually sampling and testing, the latter being done at their chemical laboratory at Pottsville. As the samples come in they are broken in a laboratory jaw crusher run by a small motor. After this operation the crushed coal is placed in the hopper *a* of the sampler shown in Fig. 1. The coal falls through the ¾-inch aperture in the bottom of the hopper on to a riffle sampler—that which falls in the grooves, being one-half, slides down to the chute *b* and is deflected to the next set of riffles. The discard takes the direction given it by the chute *c* and goes to the bottom of the case that encloses the riffles. The lowest riffle sample goes by chute *d* into the sample box *e*, which is a drawer that can readily be removed and inserted at will. The discharge at *f* is so arranged that all dust and discarded coal goes outside the laboratory where the latter can be removed readily. Assuming that the sample is 100 pounds, then when it reaches the sample box it is reduced to 6.75 pounds. In case the sample was 50 pounds it would be placed in the first side hopper or *g* and be reduced to the same quantity, or in case it was a 25-pound sample it would be placed in hopper *h*, and so on, the final sample being 6.75 pounds. The sample is removed from the sampling box, reduced to its proper size and placed in a labeled bottle until it is tested for its heat units in a calorimeter, or analyzed if that be the object.

Taken as a whole this is the most up-to-date and convenient coal sampler known, and the writer wishes to acknowledge his appreciation to Messrs. A. G. Blakeley and E. M. Chance, of the Chemical Department, for their kindness in allowing the use of their drawing and information concerning so useful an apparatus. General Manager Richards encourages the

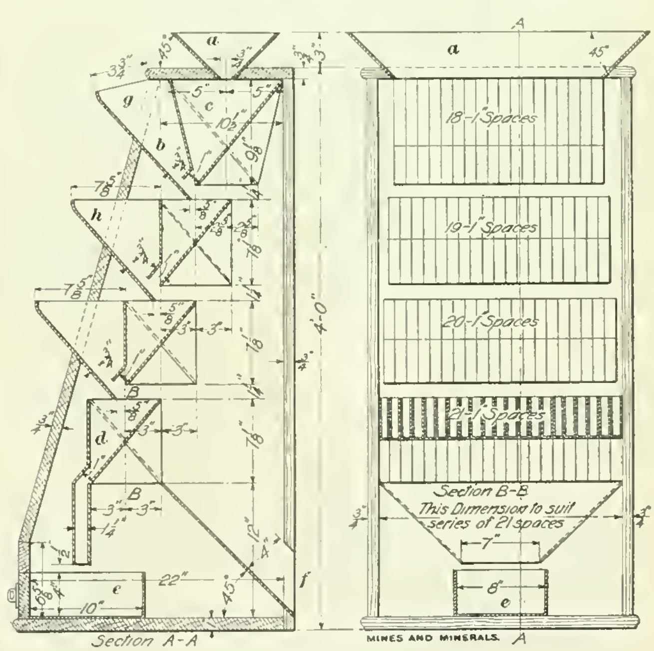

Fig. 1. Laboratory Coal Sampler

men under him to make improvements in their various lines and in so doing aids the industry as well as the company and his subordinates.

This sampler might be adopted for making near analyses of coal by means of specific gravity solutions. Such physical tests of jig products would materially assist the jig tender in keeping his machines properly keyed to their work.

The Puritan Mine

Some Interesting Features in the Equipment of One of the Newer Colorado Coal Mines

By Joseph Watson *

About 4 miles northeast of the town of Erie, Colo., and not far from Denver, is the Puritan mine of the National Fuel Co. Its situation on the flat plain which terminates a short distance to the west in the foot-hills of the Rocky Mountains is extremely favorable to economic surface construction and operation. At the same time, the shape of the property, 1 mile in length from north to south and ½ mile in width, lends itself to the modified three-entry retreating system of mining, which has been adopted. The surface equipment consists of the head-frame, machine shop, boiler house, etc., usual in a plant of 2,000 tons daily capacity, to which extent the mine is developed and is arranged to be operated with the minimum amount of labor. When running at a rate of 1,000 tons per day or less one man is sufficient to dump and weigh the coal, but beyond this tonnage a boy would be required to remove the checks from the pit cars. Ventilation to the extent of 115,000 cubic feet of air a minute is produced by an 18′×5′ Sterling fan direct-connected to a 12″×20″ engine. The fan is at present arranged as a blower but may be quickly changed to an exhaust when desired.

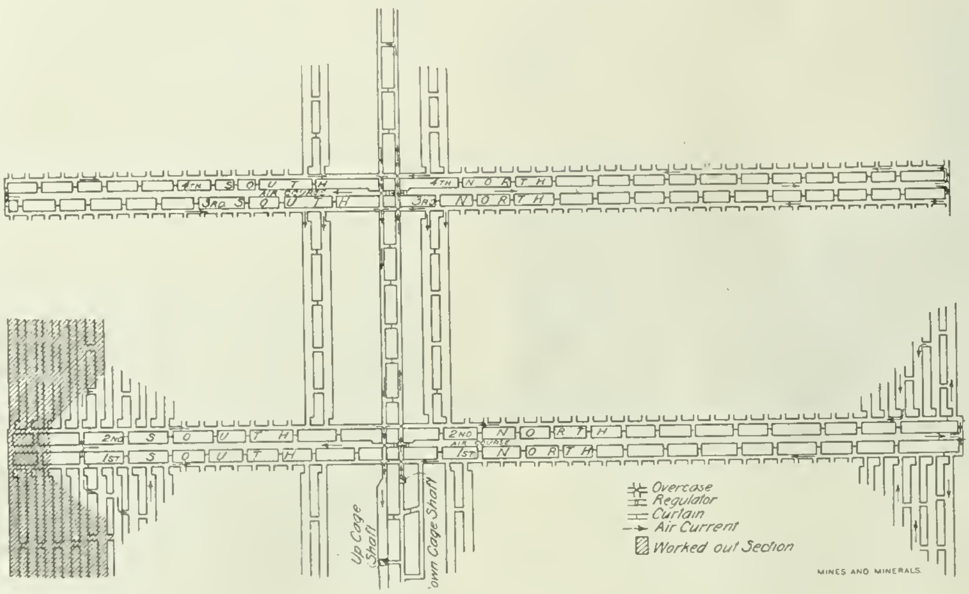

Fig. 1. Map of Puritan Mine

The coal, a perfectly clean lignite, is found in a practically horizontal position at an average depth of 125 feet from the surface. With a soapstone roof and a sandstone floor the seam maintains a uniform thickness of 10 feet. Owing to the rapid disintegration of the roof when exposed to air, 2 feet of top coal is left up in the rooms and 3½ feet in the entries, but the major portion of this is recovered when the pillars are drawn. The loss of some of this upper coal in the pillars is in a measure offset by the saving in entry timber, the roof coal being sufficiently strong to sustain the roof without support.

Sinking was begun on the hoisting shaft on February 17 and was completed on May 3, 1908, to a depth of 122 feet. This shaft has three compartments, two, each 5 ft. 10 in.×7 ft. 4 in., being used for the self-dumping cages, and the third, 2 ft. ×7 ft. 4 in., containing the pipe and electric wire lines. Immediately after beginning to drive the main entries, the air-shaft was started and was finished by August 30, 1908. This shaft is divided into two compartments, 6 ft. 1 in.×7 ft. 8 in. and 2 ft. ×7 ft. 8 in., respectively, and is timbered with 4-inch white pine planking set skin to skin.

Mining, as the map indicates, is carried on upon a modified three-entry system, the modification consisting in that the main entries, which divide the property lengthwise in half, are double instead of triple. This change was made to reduce the cost of entry driving, but in order that the velocity of the air current of 115,000 cubic feet per minute may not be excessive on these two entries, the first room on each cross-entry is maintained as a return. It will be noted that the main haulage road, with the fan arranged as a blower, is the return airway instead of the intake. As the mine does not generate explosive gas, this is safe and the cagers, etc., are much more comfortable, particularly in winter. The main entry and air-course are each 10 feet wide with a 30-foot pillar between them.

The butt, or cross, entries are triple and spaced 500 feet apart, the middle one, the air-course, being driven 16 feet wide to save in yardage. Rooms are turned with 40-foot centers (room width 20 feet) from each of the two haulage entries and after being driven 250 feet the pillars are drawn at once. While the cross-entries are advancing the room necks are turned and the switches laid, but no wide work is begun until the entries reach the boundary of the property. When this occurs the rooms are widened out in retreating order from the face to the mouth

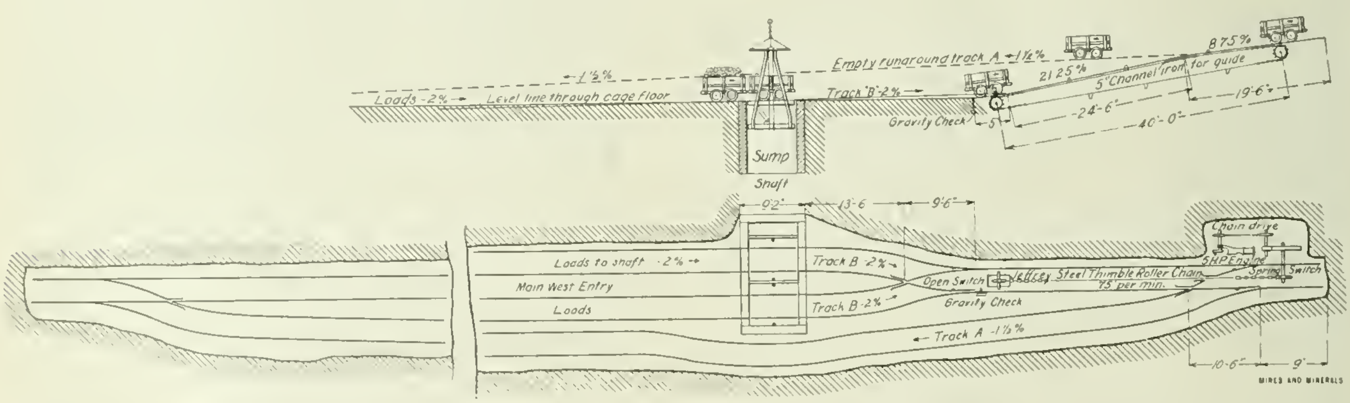

Fig. 2. Plan of Section of Shaft Bottom and Caging Arrangements

* General Superintendent, National Fuel Co., Louisville, Colorado.

of the entry and when the innermost room reaches the limit of length, 250 feet, pillar drawing commences, the entry stumps being brought back at the same time.

The mine is entirely without doors and while the necessary overcasts were expensive, their cost was soon met by the saving in trapper's wages.

The coal is undercut by air punchers and the hauling done by mules, but arrangements have been made for a motor haulage when the workings are sufficiently far advanced to render the change advisable.

The caging is done from the west side of the shaft, Fig. 2. The loaded car siding has a gradient of 2 per cent. so that when a car is released it runs easily to the foot of the shaft. After being bumped off the cage (which is provided with automatic keeps releasing the car when the cage is landed) by the oncoming load, the empty car runs down a grade of 2 per cent. to the foot of a chain haul which elevates it sufficiently for it to run over an automatic back switch and, on a grade of $1\frac{1}{2}$ per cent., to the empty siding on the west side of the shaft. The haul will handle three 2-ton capacity cars per minute, or 180 per hour, or a greater tonnage than that for which the surface plant is designed. The haul is 40 feet long between centers of foot and head sprockets and consists of a Jeffrey Mfg. Co.'s steel thimble roller chain having a safe working load of 6,000 pounds. The haul is designed for a traveling speed of 75 feet per minute, although it is usually run somewhat faster, say, at a rate of 100 feet per minute. The chain has a grip or dog, which comes in contact with an angle iron bolted to the bottom of the car, riveted to it and spaced so that there is no possibility of an empty coming down the haul meeting one coming up before the down car has had time to take and clear the switch leading to the empty siding. The car haul is driven by a 5-horsepower upright steam engine connected to a countershaft by a chain drive. This countershaft has a 7-inch pinion which meshes with a 48-inch spur gear on the main drive shaft. The cost of the machinery was under $400, and that of installation, including the heading back of the shaft, under $1,000, and has resulted in saving the labor of two men on a tonnage of 1,000 tons per day.

Experience has shown that placing the empty car elevator immediately back of the shaft, instead of in front of the shaft and about midway on the empty car siding as is usually done, results in less cost of installation and operation with fewer delays due to car being "hung up" on the back switch. As ordinarily arranged, there is room on the empty siding for 10 to 12 cars from the back switch to the foot of the elevator and this distance is saved by placing the haul immediately back of the shaft. At least 100 feet of wide work at the foot of the shaft is saved with a resultant decrease in the cost of construction and maintenance, particularly in the item for timber. Also cars are never hung up on the back switch as the elevator provides for a sufficient grade for the empties to run easily and quickly to the proper siding.

Although additional capital is required, the retreating system of mining has proven more economical in the end. The cost of track maintenance is small, less timbering than usual is required as the entries are free from squeeze and creep, and a maximum percentage of lump coal is recovered. The ventilation is also easy to maintain as there are no large open spaces to be aired, better and purer air is secured for the miners by the use of separate splits for each entry, and the number of brattices to be kept up diminishes instead of increases as the workings advance.

⚒ ⚒

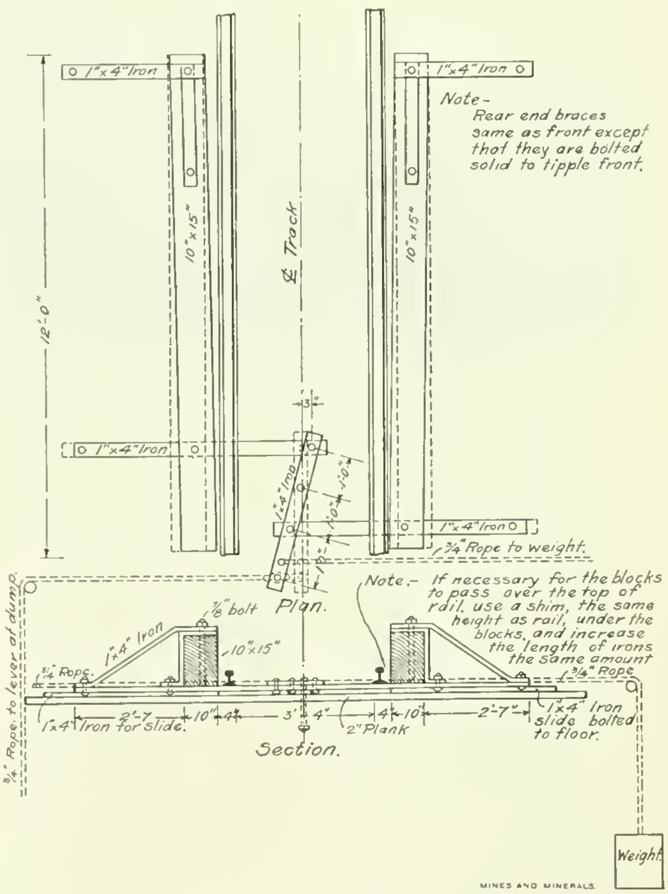
The petroleum wells of Ontario in 1910 yielded 14,723,105 gallons of oil, valued at $559,478. This is a decrease of 3,756,442 gallons as compared with the production of 1908. The refineries, of which there are two in Ontario, distilled a total of 35,530,918 gallons of crude oil last year. Of this, 16,015,527 gallons was domestic and 19,515,391 gallons imported.

Safety Blocks at Castle Gate Tipple

As the loaded tracks on coal-mine tipples are always built on a 1- to 2-per-cent. grade in favor of the loads, in order to pass the cars over the dump by gravity, some device is necessary to prevent the loaded cars from passing over and wrecking the dump. The usual method is by spragging the cars, a dangerous and somewhat uncertain practice. Fig. 1 is a sketch of a device that has been installed and successfully used for this purpose of blocking the cars at the Castle Gate tipple of the Utah Fuel Co.

This device is very simple, is easily and cheaply constructed and can be used on most any tipple, eliminating at least one man or boy, the spragger.

This pair of blocks consists of two 10"×15" timbers, bolted solid to the tipple floor at one end and movable at the other. The two timbers are connected by the pieces of 1"×4" iron, these being connected by a $\frac{3}{4}$-inch steel-wire rope to a lever located near the dump, so that the man in charge at the dump can operate it conveniently.



Safety Blocks, Castle Gate Tipple

When the blocks are closed, as they are at all times except when a car is being dropped through, the distance between the two timbers, at the lower end, is less than the distance from outside to outside of the car wheels and of course the trip cannot pass through.

When the dumpman wants a car, he releases the lever, the weight opens the blocks, and, as soon as one car has passed through, the blocks are again closed, thus holding the remainder of the trip.

While this arrangement was not designed to stop a runaway trip, it has been of service on several occasions in stopping trips traveling at greater than normal speed, which, had sprags been depended on, would have no doubt passed over and wrecked the dump, causing not only the loss for repairs but the loss due to an idle mine as well.

Waste-Heat Coke Ovens

Savings Possible, Illustrated by Plants at Stag Cañon, New Mexico, and Others

There is one coal company in West Virginia that although making coke burns approximately 82 tons of coal per day under a 3,800-horsepower boiler plant. In New Mexico there is a coal company that uses approximately 2,400 horsepower and produces this power from the waste heat of 218 beehive ovens. This is a mere drop in the bucket when the total number of beehive oven plants in the United States that waste coal is considered.

In studying the economy to be derived from the use of waste-heat ovens that most excellent coal known as the Pittsburfg bed is taken. Theoretically this coal should furnish 68.38 per cent. coke on an average; practically it yields 64 per cent. coke and requires 1.562 tons of coal to make 1 ton coke.

Assuming that the heating value of 1 pound of coke is 13,000 British thermal units, then $\frac{64}{100}$ pound produced from 1 pound of coal would represent 8,320 British thermal units. The heating value of Pittsburg bed coal is 15,300 British thermal units per pound and the loss in heat units during the process of coking is 6,980 British thermal units per pound, and it is this lost heat which, if utilized, would evaporate theoretically 7.2 pounds water. Owing to the radiation of heat from ovens and flues, not much if any over one-half the waste oven heat could be conducted to boilers, and even this quantity would depend on the location of the boilers relative to the ovens. It is authoritatively stated that the best water-tube boilers will absorb about 70 per cent. of heat, hence in this calculation it is assumed as possible to evaporate $7.2 \times .5 \times .70 = 2.52$ pounds water with the waste heat from each pound of coal coked.

If 6 tons of coal are charged into an oven every 56 hours or 1,876,800 pounds per year, and assuming that the coal if burned under boilers would evaporate 10 pounds water per pound of coal, the saving in coal from the waste heat of one oven would be $\frac{1,876,800 \times 2.52}{10 \times 2,000} = 236$ tons per year. If this coal is worth $1 a ton at the mine each oven would save $236 per year. As a ton of coal in New Mexico is worth more at the tipple than in Pennsylvania it is probable that over $51,000 in coal is saved yearly by the 218 waste-heat ovens. This is conservative, for the cost per ton at the tipple is considered rather than the selling price, and consequently includes no profit.

Carrying the approximate calculations to West Virginia, where it is assumed coal is worth 90 cents f. o. b. cars, the saving in coal due to waste-heat ovens in a 3,800-horsepower boiler plant would be nearly twice that at the New Mexico plant, or $100,000 per annum.

It has been, and still is, argued that the extra cost involved in the construction of beehive ovens is unwarranted where there is no demand for gas in the vicinity of the ovens, and the argument prevails, and will for sometime to come, that waste-heat beehive ovens have not proved successful or they would have been adopted by some of the larger coke companies. While this argument appears sound, and there have been several failures when trying to use the waste heat from beehive ovens, the fact remains that there have been successes also, which suggests that the failures were due to the oven adopted, or some other cause. At Gary, W. Va., one kind was condemned because of the low percentage of volatile matter (16 per cent.) in the coal.

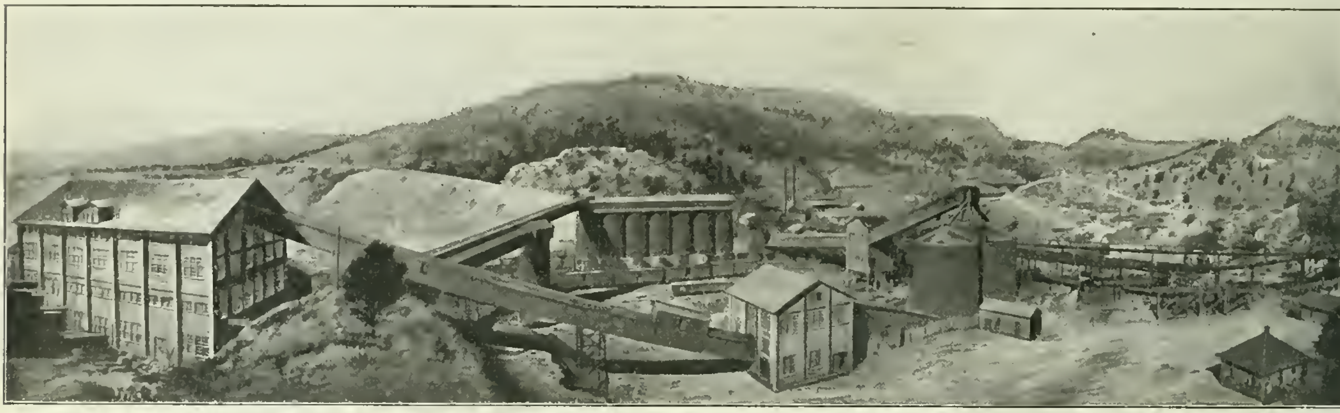


Fig. 1. Plant of Stag Cañon Fuel Co., Dawson, New Mex.

Besides the economic advantage in the use of waste heat for fuel, its comparative cheapness permits the use of increased machinery to do work otherwise neglected or performed by manual labor; again it permits of steam heat for buildings in winter, thereby lessening the consumption of coal and preventing coal chutes and slack bins from freezing in winter.

Where low-volatile coal is coked it will be found that if

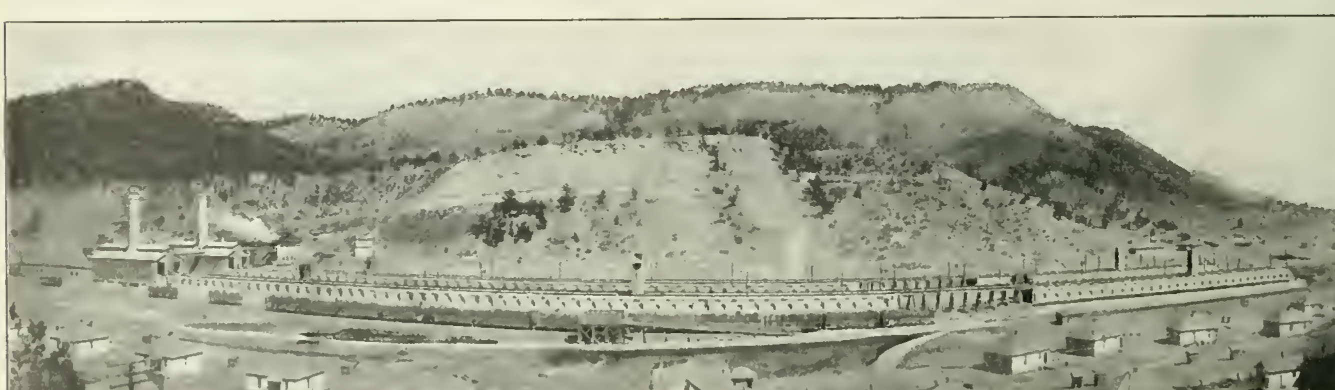

Fig. 2. Boiler Houses and Under-Flue Coke Ovens Dawson New Mex.

crushed fine before being charged into the oven better coke will be produced and less breeze made, and this operation requires power.

In many instances it is necessary to wash coal in order to prepare it for market, a remark which leads to another; viz., that much good coking and steam coal is being condemned on account of sulphur showing in the analysis. Sulphur in all probability does not enter into combination with bituminous matter and if found in coal beds it is in the form of a sulphate or sulphide of an alkali metal or as iron pyrite, in any case it is as a mechanical and not as a chemical mixture in the coal bed. If one will observe the location of pyrite when associated with coal, he will find it in the roof, floor, and partings, but not as a rule in the coal bed proper, therefore an analysis high in sulphur indicates that the coal will probably be high in ash, and likely to clinker. The impression prevails that sulphur causes clinker. This is erroneous; in fact, it is a preventative, for iron does not unite with silica until all sulphur has been oxidized, and even then, provided the coal is low in ash, clinkers will not be likely to form. If then the coal is crushed and washed, much now condemned can be made available for coking and also for steaming.

By permission the following is abstracted from J. E. Sheridan's paper* descriptive of the Stag Cañon Fuel Co., at Dawson, N. Mex. Twenty-seven electric motors, having an aggregate capacity of 1,159 horsepower are operated in conveying the coal from the tipple, through the crusher house and washery until it is delivered in the seven cylindrical steel storage tanks each 20-feet diameter, 40-feet high and holding 300 tons of slack coal.

There are 570 coke ovens in the operation, 124 of which are ordinary beehive ovens, 13 feet in diameter, the remainder being English under-flue ovens, 11 feet in diameter. Each oven is charged with 6 tons of slack coal and makes 52 per cent. in weight of 48-hour coke. An average analysis of the coal is as follows: Moisture, 1.8 per cent.; volatile matter, 37 per cent.; fixed carbon, 49.3 per cent.; ash, 12.5 per cent.; British thermal units of the coal, 13,291. The analyses of the coke furnished by General Manager T. H. O'Brien are as follows: Beehive: moisture, .2; volatile matter, 1; fixed carbon, 82.1; ash, 15.8; Under-flue: moisture, .2; volatile matter, 1; fixed carbon, 82.1; ash, 15.9.

*Trans. A. I. M. E., February, 1909.

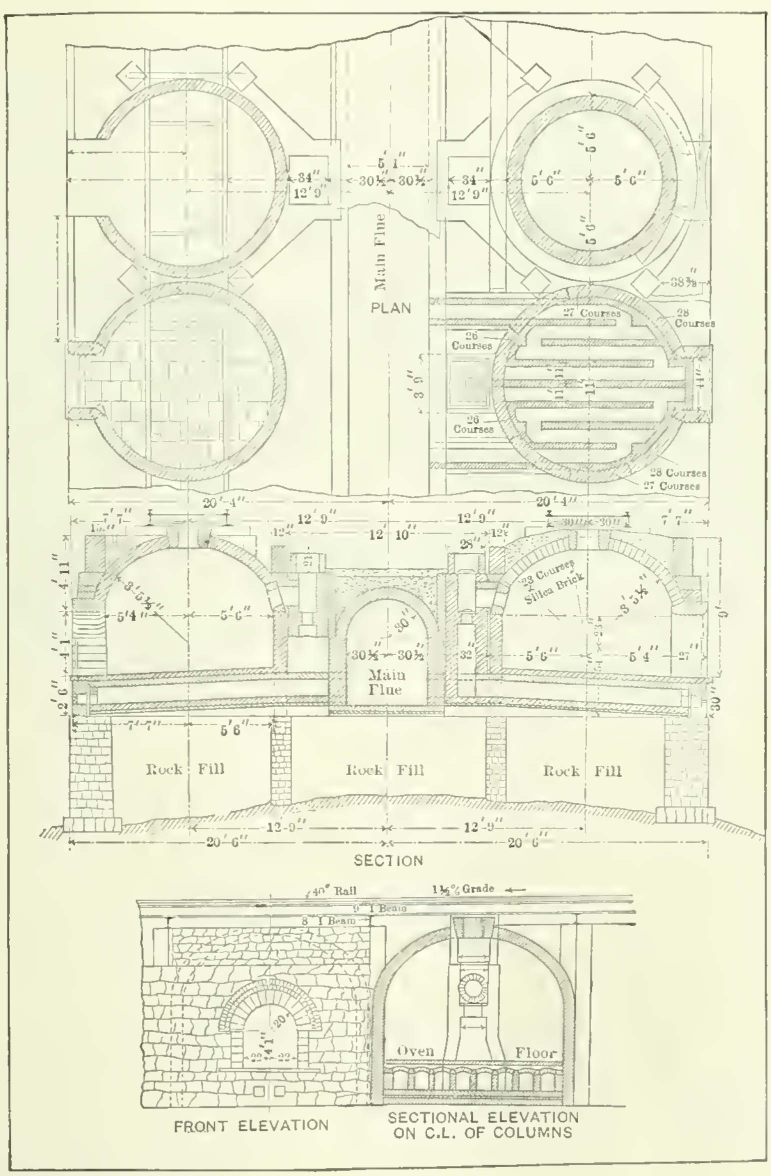

Fig. 3. Details of Under-Flue Coke Ovens

In Fig. 2 is shown a general view of two parallel strings of under-flue coke ovens with boiler houses to the left between batteries of each string.

These under-flue ovens built in blocks of 54 and 58, are an innovation in this country, for which reason the details of their construction are given in Fig. 3, while their general outside appearance as shown in Fig. 2, does not differ materially from the regulation beehive oven.

The gases are partly burned in the oven and the flame escaping through the flue in the side of the arch, passes downward into the horizontal flues below the oven tile where coursing through them it finds an exit to the main flue between the ovens leading to the boilers. A cross-section of the main flue at the pair of ovens farthest from the boiler plant has an area of 20.6 square feet, and this is increased by dropping the flue bottom two bricks at each pair of ovens until at the down-cast of the boiler plant the sectional area is 52.73 square feet.

Pyrometer readings, at the boiler houses, show that the gases are delivered under the boilers at temperatures varying from 1,800° to 2,600° F., and leave the stack at temperatures of from 600° to 1,150° F.

At present the heated gases from only 218 ovens of the 446 under-flue ovens are being utilized, the return from the other 228 ovens being allowed to pass off through chimneys. Here are vast reserves of power that can be utilized to increase the capacity of the power plant as the mines increase in extent and production. There is one coke puller in use at the coke ovens, electrically driven by two General Electric motors, one of 20 horsepower and the other of 17.5 horsepower. This is shown in Fig. 4 to have an elevator and basket chute arranged so that the coke may be loaded and spread in the car to the best advantage.

In the October, 1909, Mines and Minerals, there was an article, by R. D. Martin,* on "The Mexican Coke Industry," in which he described beehive ovens with waste-heat flues that were used in Agujita and Lampacitos, Mex. The construction of the oven and flue for utilizing waste heat is, as shown in Fig. 5, quite different from the New Mexico oven. The flue, shown in the course of construction in Fig. 6, is about 450 feet long and is located between block ovens, except midway of the flue for a distance of 8 ovens, where there is a single line of ovens so as to

*Contractor, Agujita, Coahuila, Mexico.

allow room for the boilers and stack to be recessed. The heat is conducted from each oven to the main flue as follows: On top of the usual trunnel head there is laid another ring 10 inches high, with a 10-inch section cut out of it on the side opening toward the main flue. On top of this cut ring another trunnel head is placed. There is an opening in the arch of the main flue in line with the opening in the cut ring on top of the oven. A flue 10 inches high connects the two openings. By placing a lid on the trunnel ring there is no place for the heat to escape except through the small flue into the main flue, thence through the right angle flues under the boilers and through to the stack. The firebox in the boilers give a temperature of 2,600° F., the test being made with Saeger cones. Mr. Martin estimates that each oven can be counted on to produce 12 boiler horsepower, with coal that has the following average analysis: Volatile matter, 21.1 per cent.; fixed carbon, 67.4 per cent.; ash, 11.5 per cent. The coke made in beehive ovens has approximately the following analysis: Fixed carbon, 83.3 per cent.; ash, 15.2 per cent.; volatile matter, 1 per cent.; and moisture, .5 per cent.

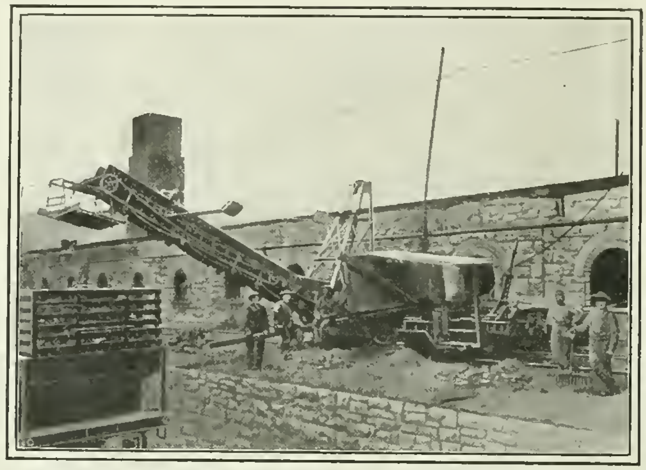

Fig. 4. Electric Coke Puller

In the July, 1905, issue of Mines and Minerals, Howard N. Eavenson, Chief Engineer of the United States Coal and Coke Co., describes the waste-heat ovens at the No. 1 works of the Continental Coke Co. A section of the center of this oven is shown in Fig. 7. It was found that, on account of the insufficiency of draft, the last 10 ovens will not burn properly when connected with the flue. In spite of minor troubles, Mr. Eavenson says the flue is considered a success, since the 40 ovens furnish the heat needed for the boilers, save about 19 tons of coal daily, and $2.25 in labor. At this plant 6 tons of coal in an oven gives about the same number of heat units under a boiler as 1 ton of coal fired. Mr. Eavenson says further that the ovens connected with the flue burn a little more coal than those not connected, although there is no difference at all in the quality of the coke. From the percentage of coke made at the Stag Cañon Fuel Co.'s plant it is also evident that there is some additional loss in fixed carbon due to the flue draft, over the loss due to coking in the ordinary beehive oven.

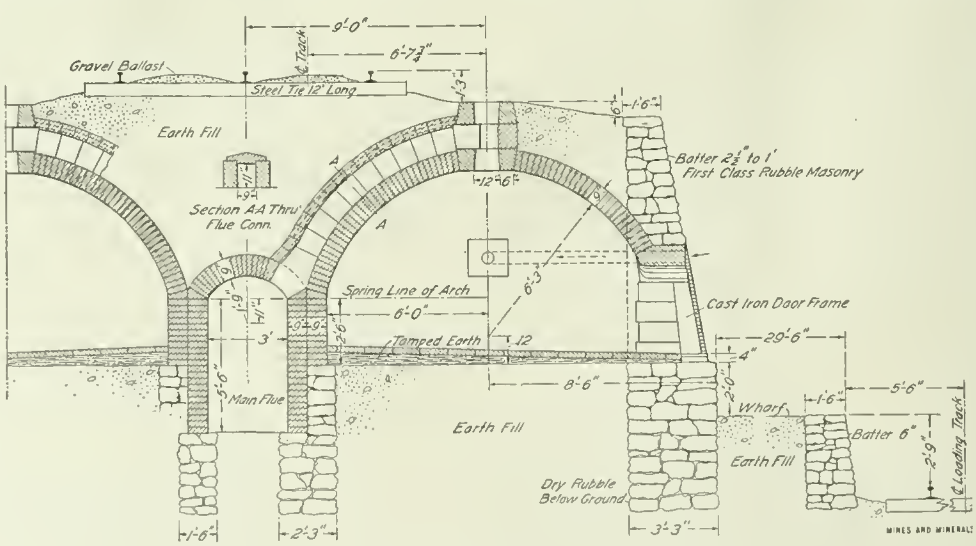

Fig. 5. Construction of Ovens and Flue for Utilizing Heat

Sir Lowthian Bell estimated that there was 10 per cent. increase in yield in retort coke ovens over beehive ovens and modern practice proves his estimation conservative, therefore if 5 per cent. additional loss is to be added to the Pittsburg bed coal and 59 per cent. recovered as coke, the saving in the using is nearly 18 tons from every 40 of the ordinary beehive ovens. In a recent article in Mines and Minerals, on "Retort Ovens in Mexico" their value as waste-heat savers was pretty thoroughly shown.

Book Review

Department of Mines, Mines Branch, Ottawa, Can., Annual Report of the Division of Mineral Resources and Statistics on the Mineral Production of Canada, during Calendar Year 1909, by John McLeish, B. A.

Annual Report of the Minister of Mines for the Year Ending December 31, 1910, being an account of mining operations for gold, coal, etc., in the Province of British Columbia, Bureau of Mines, Victoria, B. C., Can.

Iron Mines and Mining in New Jersey, Volume VII of the Final Report series of the State Geologist, by W. S. Bayley, is now ready for distribution. It is a volume of 512 pages, bound in cloth, and accompanied by two large maps showing the location of all iron mines and prospects in the state. In addition to general discussion of the character, occurrence and origin of the bog iron, limonite, hematite and magnetite ores, there are detailed descriptions of all the mines and prospects with many analyses of the iron ores. The report contains numerous mine maps and other illustrations. It will be sent to those interested upon receipt of 25 cents to cover cost of mailing. Application should be made to Henry B. Kummel, State Geologist, Trenton, N. J.

The Copper Handbook, tenth edition, by Horace J. Stevens, of Houghton, Mich. Eighteen months have been spent in an absolutely complete revision of the mine descriptions and statistical section of the book. The new edition, Vol. X, contains 1,902 octavo pages of text, and describes 8,130 mining companies, mines and attempts at mines, this being much the largest number of titles given in any work of reference on mines. As in preceding years, there are several hundred pages devoted to the history, technology and uses of copper.

Connecticut Geological and Natural History Survey, Volume III, includes Bulletin 13, "The Lithology of Connecticut"; Bulletin 14, "A Catalog of the Flowering Plants and Ferns of Connecticut Growing Without Cultivation"; Bulletin 15, a second report on the "Hymeniales of Connecticut."

Trade Notices

A New Trolley Ear.—The General Electric Co. has recently placed on the market a new mechanical clamping ear, known as Form M, especially designed for use on overhead construction in and around mining and industrial properties. The ear consists entirely of forgings and punchings of steel, thus eliminating entirely such imperfections and variations as are common to iron castings. This feature also permits of using small light sections of great mechanical strength resulting in an ear giving a maximum clearance from passing trolley wheels and a minimum height from the center of the wire to the top of the clamping nut. The new ear is made up suitable for round, grooved and figure 8 wire and has either japanned or standard sherardized finish. The Form M ear, when used in connection with form H-3 suspension of the mining and ceiling type, renders possible an increase in head room of 1 inch to 2½ inches.

Demonstration of Electric Mine Lamp.—Recently a demonstration of the Pilley electric mine lamp was made in the Marianna mine before the officials of the company and others. As a result the company has placed an order for 1,000 lamps and expects to increase the number to 2,500 during the year.

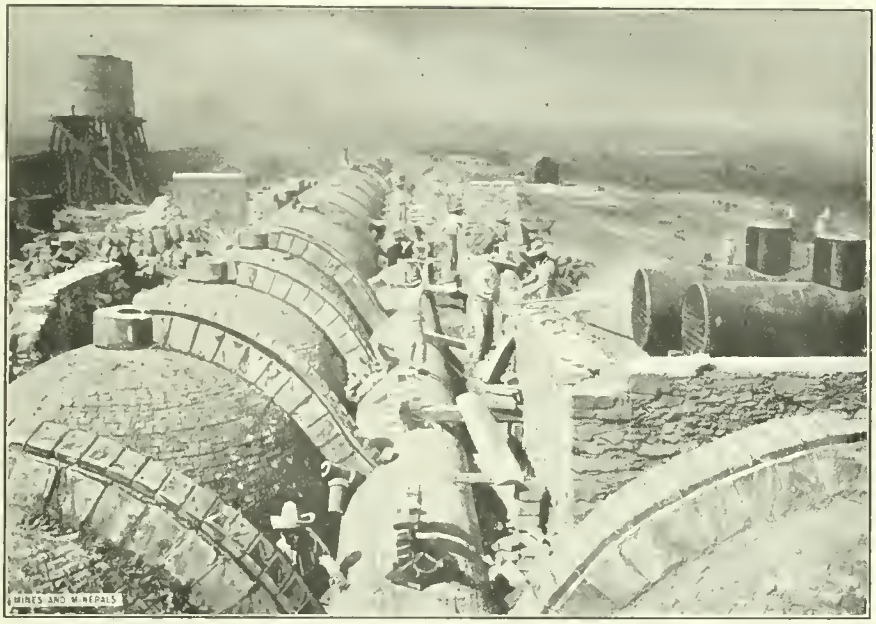

Fig. 6. Ovens and Waste-Heat Flue Under Construction, Mexico

Western Electric Co.—Arrangements have been completed whereby the Western Electric Co. will open a new house at Richmond, Va., where a complete stock of telephone apparatus and supplies, power apparatus and general electrical supplies will be carried. Mr. H. W. Hall, formerly manager of the Denver house, will have charge of the Richmond organization, and with him will be associated specialists on the various lines handled.

Core Drills of Large Size.—In a new catalog recently issued the McKiernan-Terry Drill Co. show the rapid progress that has been made in the development of the core drill for drilling large holes. The book shows illustrations of what has been accomplished and gives valuable data in regard to costs. It will be sent free upon application.

A Gravity Return Car Dump.—The Jeffrey Mfg. Co., of Columbus, Ohio, has just issued an illustrated bulletin descriptive of a new and practical automatic return car dump especially designed for small tipples and where space is limited. It not only delivers the coal without excessive breakage, but is also economical from a labor-saving standpoint, and permits the handling of an increased output. A full-sized dump has been erected at the Jeffrey Co.'s plant at Columbus for the purpose of trying out the mechanism and for demonstration purposes. Mine managers who cannot conveniently visit Columbus to see the dump in operation can learn the details of the mechanism and its method of operation by sending for Bulletin No. 44A, which illustrates and describes it in a remarkably clear manner.

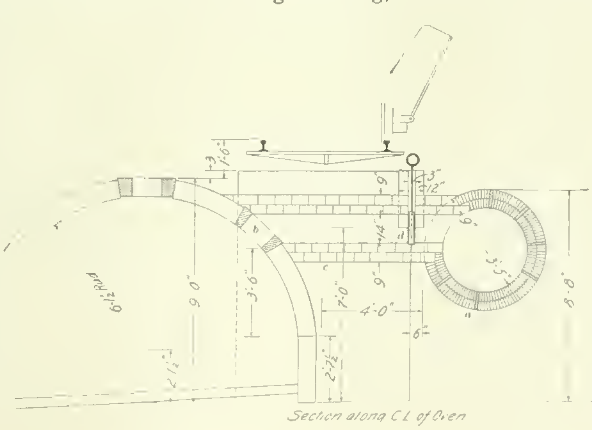

Fig. 7. Section of Oven, Continental Coke Co.

Automatic Safety Mine-Car Cages.—For handling mine cars at shaft bottoms and on tipples and inclines, the automatic safety mine-car caging machine, made by the Mining Safety Device Co., of Bowerston, Ohio, has shown high efficiency, enabling cars to be handled promptly and without danger of accident to either men or machinery. Recently one of these devices has been installed at the mines of the Glen Ayr Coal Co., Terre Haute, Ind.; and two for the Superior Coal Co., Gillespie, Ill.

A New Feature of the Gandy Belt.—Owing to unscrupulous dealers and manufacturers endeavoring to palm off inferior goods as Gandy belting, the Gandy Belting Co., in addition to prominently marking the genuine Gandy belting at intervals with the Gandy trade mark, consisting of a coil of belt and a bale of cotton laid across, have, beginning September 1, painted one edge of each roll or piece of belting green, while the rest of the belt will remain red, as formerly. The foundation of the Gandy belt is a very heavy cotton duck woven in the duck mills of the Gandy company. The sewing machines, on which the belts are stitched, are built in their own machine shops, and especially designed so that they sew with an imbedded stitch, making the surface of the belt smooth and holding the plies solidly together. The belt is then treated by a secret process to render it water, heat, and steam proof. All Gandy belting is thoroughly stretched and seasoned before it leaves the factory, and is invariably uniform in width. It runs straight and true and will not slip or harden. Belt users who know the Gandy belting, and those who desire Gandy quality in belting, are advised to look for both the trade mark and the green edge.

Lunkenheimer Picnic.—When the National Association of Stationary Engineers held their twenty-ninth annual convention in Cincinnati, in September, and 3,000 were entertained by the Lunkenheimer Company of that city, the engineers and their friends were taken on a steamboat to Coney Island picnic grounds. There were refreshments, dancing, and athletic events and at noon the crowd were feasted, burgoo and barbecued beef being special features of a menu of great variety.

Annual First-Aid Contests

The annual first-aid contests of the employes of the coal companies in the anthracite regions of Pennsylvania give evidence of the interest taken in the subject by the companies and the men. There has been special interest this year on account of the first-aid exhibition to be held in Pittsburg in October, at which first-aid corps from all parts of the United States will exhibit before President Taft and other notables, and teams will be sent by most of the anthracite companies.

LEHIGH & WILKES-BARRE COAL CO. CONTEST

On August 26 the Lehigh & Wilkes-Barre Coal Co. held their annual exhibit at San Souci Park, near Wilkes-Barre, and corps to the number of over a hundred members took part.

Groups of teams contested in the first six events and a pennant was awarded to the winner in each. The winning corps then competed in the seventh event, the prizes for which were a bronze medal for each member. The successful corps was that from Baltimore shaft of the Ashley District.

The medals were presented by General Manager Huber, who, on behalf of the company, thanked the contestants for the faithful work they had done in training, and expressed appreciation of their high efficiency. The training was under the supervision of Dr. F. L. McKee.

At the conclusion lunch was served to over 600 members and invited guests.

D., L. & W. CONTEST

On August 31, 32 teams representing collieries of the D., L. & W. Co. competed in first-aid contests at the Scranton Y. M. C. A., and the work of the corps was witnessed bv a large number of prominent mine officials from Wyoming and Lackawanna valleys. Teams from Nanticoke to Scranton and vicinity were represented.

A handsome silver cup, donated by the superintendent of the coal department of the company, was awarded to Captain Benjamin Lewis' team, representing the Woodward colliery, of Edwardsville. Captain Pierce's team from the Scranton district was a close second, and received honorable mention from the judges. The teams demonstrated extraordinary skill in the work accomplished by systematic training. The judges were Doctors Wainwright and Smith, of Scranton. and D. H. Lake, of Kingston.

FIRST ANNUAL FIRST-AID MEET PITTSBURG COAL OPERATORS' ASSOCIATION

The first annual first-aid meet of the Pittsburg Coal Operators' Association was held at Arsenal Park, Pittsburg, on September 9. Thirteen teams took part in the competition, and perhaps 500 men, representing practically all the coal companies of Western Pennsylvania, witnessed the meet. The showing made by all of the teams was remarkably good, considering the fact that some of them had received their first instruction in this work as late as 2 weeks previous to the meet.

Five special problems were given for the teams to solve, the winning team in each event being presented with an appropriate prize. Problem No. 5 was called the feature event, and the team winning this event was presented with a banner, which they are to hold for 1 year, and which must be won three times before it becomes the permanent possession of any team. This was won by the team representing the Pittsburg-Buffalo Co.

The judges were Dr. M. J. Shields of the American National Red Cross, Dr. J. B. Stoner, Surgeon of the United States Public Health and Marine Hospital Service and Mr. John C. Patterson, of the Youghiogheny & Ohio Coal Co.

The following is a list of the companies that were represented by competing teams: Pittsburg Coal Co., 5 teams; Berwind-White Coal Mining Co., 2 teams; Seanor First-Aid Association; Brier Hill Coke Co.; Pittsburg Terminal Railroad and Coal Co.; Pittsburg-Buffalo Co.; Ellsworth Collieries Co.; The Rochester & Pittsburg Coal and Iron Co.

S. A. Taylor, secretary and treasurer of the Pittsburg Coal Operators' Association, in an appropriate address, at the close of the program presented the prizes to the winning teams.

In the forenoon the testing laboratories of the United States Bureau of Mines were inspected and special experiments of educational value were performed by the employes of the Bureau.

PHILADELPHIA & READING FIRST-AID CONTEST

On Saturday, September 9, the first-aid corps from the various collieries of the Philadelphia & Reading Coal and Iron Co. held their seventh annual competitive drill at Lakeside Park, East Mahanoy Junction, Pa., to which about 2,000 employes and invited guests of the company, with three brass bands, were brought on special and other trains at the expense of the company.

Just as the contest was about to begin it commenced to rain, driving the crowd to whatever shelter could be found. Arrangements were quickly made, however, to continue the contest in a large pavilion on the grounds, and it was carried through as planned, showing the ability of the first-aid men to deal successfully with the unexpected under favorable conditions. The rain, which continued all the forenoon, also upset the plans of the caterer, to whom the company had entrusted the furnishing of dinner for the crowd, but he likewise rose to the occasion and though a little later than had been planned, was able to administer much appreciated "first-aid to the hungry" to the somewhat moist crowd.

The first contests were between the corps of each district, and the winners competed in the finals. This latter contest was of special interest, as the winning corps, in addition to receiving the pennant, is to be sent to the first-aid exhibit at Pittsburg in October.

The following are the winners of the finals and their percentages: Phœnix Park, 99; Wadesville, 99; Draper (outside), 98; Big Mountain, 97; Brookside, 97; North Mahanoy, 93; Knickerbocker (inside), 92; Reliance (outside), 91; Hammond (inside), 90.

In announcing the results, General Manager Richards stated that in the seven annual contests that have been held, over 3,000 men have competed, and considering the high standard of efficiency shown by all the contestants, the power for good exerted by that number of trained men scattered through the various collieries would be hard to estimate. He mentioned a case where a man severely burned in the mines was brought to the hospital, after being treated by one of the first-aid corps, and was found to be so carefully prepared that the surgeons were able to defer further bandaging or disturbance of the patient until he had had time to recover from the shock, which might easily have proved fatal with less prompt and skilful treatment.

It is worthy of note that the name of the corps doing this excellent work has not appeared among the list of winners in the contests of the last 3 years, which shows that the skill among the rank and file of the first-aid men is high.

The contests have become of great interest, and the personal acquaintance and evident good feeling between the officials and men are matters for congratulation to both alike.

FIRST-AID CONTEST PENNSYLVANIA COAL CO. AND HILLSIDE COAL AND IRON CO.

On September 2, the annual first-aid contest of the Pennsylvania Coal Co., and the Hillside Coal and Iron Co., was held at Valley View Park, Inkerman, Pa.

In addition to the contest proper, there was a demonstration of mine accidents. A piece of track had been laid, and on this two mine cars came together, showing how men are so often injured, and first-aid was administered to the supposed victim.

There was also built upon the grounds a representation of part of a mine gangway; this was filled with dense smoke, and men with oxygen helmets went in and brought out one of their number, who was supposed to have been overcome by the heat, and administered first-aid treatment. This event was extremely realistic and served to remind many of those present of occasions they would rather forget.

The contest consisted of five events, and seven teams entered.

The Board of Managers were W. P. Jennings, Henry T. McMillan, Dr. John B. Mahon, F. H. Coughlin, Dr. F. F. Arndt, Dr. M. J. Shields. The Secretary and Assistants were W. B. Evans, F. D. Conover, D. M. Howell. The judges of the contest were Dr. W. G. Fulton, former Major 13th Reg., N. G. P., Dr. J. W. Geist, Captain Medical Corps, 9th Reg., N. G. P., Dr. J. J. Rutledge, Mining Engineer, United States Bureau of Mines.

Events 1, 3, and 4, consisted in the treatment of patients supposed to be injured by falls, burns, and explosions.

The second event was to show three different ways of rescuing a man who had been overcome by an electric shock and had fallen on a live wire. It was of especial interest on account of the ingenuity shown by the contestants in devising means of rescue from whatever was at hand.

The fifth event consisted in dressing various severe injuries, putting the patient on a stretcher, and carrying him over a number of obstacles. This was contested for by full teams. The prize was a silver cup, and in addition the winning team will be sent to the First-Aid Exhibit to be hèld at Pittsburg, on October 27, all their expenses to be paid by the Pennsylvania Coal Co. and the Hillside Coal and Iron Co. The following percentages were made by the teams in this event: Avoca Central, 100; Dunmore No. 5, 96⅔; Mayfield, 95; South Pittston, Clarence, 93⅓; Forest City, 90; Plains, No. 14, 88⅔; North Pittston, Barnum, 75.

After the contest, H. M. Wilson, Engineer in Charge, United States Bureau of Mines, Pittsburg, addressed the company and presented the cup to the winning team.

Among those present was Dr. M. J. Shields, the founder of first-aid work in this country, now field representative of the American Red Cross Association, and in charge of the special Red Cross car; also Charles Enzian, Engineer of Bureau of Mines, in charge of United States rescue car for the anthracite regions; and Dr. J. J. Rutledge, Mining Engineer, Bureau of Mines, Pittsburg.

At noon, lunch was served to all present.

As similar contests are being arranged all over the country the following method of rating the contestants may be of interest

DISCOUNTING TABLE FOR FIRST-AID CONTEST

1.	For loose or "granny knot"	05
2.	For a loose bandage	05
3.	For loose splint	05
4.	For wrong artificial respiration	05
5.	For not stopping bleeding	10
6.	For not taking care of shocks	10
7.	For not doing the most important thing first	05
8.	For slowness in work	05
9.	For Captain's failure to command men properly	05
10.	Awkward handling of patient or stretcher	05
11.	Failure to be aseptic	05
12.	Failure to entirely cover wound	05

National First-Aid Field Day

At Pittsburg on October 30 and 31 there will be held a National Mine Safety Demonstration under the joint auspices of the American Red Cross, the Pittsburg Coal Operators' Association and the United Mine Workers of America, assisted by the United States Bureau of Mines. The Board of Managers are: H. M. Wilson, representing United States Bureau of Mines; Dr. M. J. Shields, representing American Red Cross Society; S. A. Taylor, representing the coal operators of the United States; Francis Feehan, representing the United Mine Workers of America; John Laing, representing the State Mine Inspectors; Thos. B. Dilts, representing Industrial Department of International Y. M. C. A. First-aid teams from all parts of the country, will be present and President Taft, Governor Tener of Pennsylvania, and other prominent men will take part.

On October 30, at the Arsenal Grounds, 40th and Butler streets, beginning at 9 A. M. and closing at 12 M., there will be a demonstration of the work of the Bureau of Mines, with exhibit of detonation of permissible and other explosives in the steel-lined gallery filled with dust and gas. There will also be exhibits and tests of mine safety lamps in the lamp gallery; of electric sparks in gallery No. 2 in the presence of an inflammable mixture of air and gas; of training in rescue work with oxygen helmets; of investigations and tests of explosives; views of smokeless combustion of coal; briquetting of coal and lignite, etc.

At 2:30 P. M. there will be an actual explosion at the experimental mine of the Bureau of Mines at Wallace Station, near Bruceton, Pa. Train leaves B. & O. Railroad depot, Pittsburg, at 1:30 P. M. This mine has been opened and equipped by the Bureau of Mines with instruments for recording pressures, speed of travel of detonation wave, with various equipment for the making of actual mine explosions due to gas and dust, and their observation and study; also of conducting tests of coal-cutting machines, gasoline motor, electric motor, and other mine locomotives, and apparatus under working conditions within a mine.

On October 31, will be the first national mine-safety demonstration, held at Forbes Field, Pittsburg, Pa. The demonstration is under the management of the United States Bureau of Mines, the parade of miners under the auspices of the United Mine Workers of America. The following is the program:

At 9 A. M., at Forbes Field, Pittsburg, Pa., will be an exhibit of skill in first aid to the injured by teams of five miners from various coal operations in the United States, five separate events to be exhibited.

At 10:30 A. M. will be a demonstration by the Bureau of Mines in steel-lined mine gallery 200 feet long, of a permissible shot, followed by an explosion of black powder detonated in the presence of coal dust, with a resulting explosion of coal dust ignited by the non-permissible explosive, followed by a demonstration of rescue work. Men equipped with oxygen helmets will enter the gallery stair still filled with smoke and poisonous gases, will bring out injured men, and give them artifical respiration and first aid. There will be also a demonstration in dangerous practices within gaseous or dusty mines.

At 11:30 A. M., President Taft will deliver souvenir prizes to participants. Short addresses by the President, Governor Tener of Pennsylvania, and others will follow.

Following will be a parade of 19,927 miners, each of whom will represent one of the 19,927 men killed in the coal mines of the United States in the last 20 years. The miners will march in review before the President's stand, and then to special cars on Forbes Street, which will carry them to the river front where they will witness the marine parade.

From 2 to 5 P. M. the President will review the marine parade in honor of the centenary of the opening of steam navigation on the Ohio River.

At 7:30 P. M. there will be a dinner to President Taft at Hotel Schenley.

Coal Mining in Michigan

Geology of the Coal Measures—Saginaw Valley Mines Methods of Working

Except from the statistics relative to the output of coal furnished by the United States Geological Survey and the Commissioner of Labor, little is known of the Michigan coal field outside of that state. Alfred C. Lane, in Vol. VIII of the Michigan Geological Survey, gives as exhaustive a report as conditions will warrant and among other matters relative to the coal fields of this state says: "The coal area is variously estimated from 6,500 to 8,000 square miles, but the average thickness of the coal will not be more than 1.75 feet."

Taking account of the coal known to be over 2 feet thick, he estimates that there are 8,025,600,000 tons to be mined in Michigan. In the 1911 "Coal Trade" is the following statement: "Despite the claims of geologists as to resources, coal men are apparently agreed in the opinion that the Saginaw Valley, including Saginaw and Bay counties, which contain practically all the coal in Michigan worth mentioning, will never be anything more than a source of supply for the district which it now serves; namely, upper part of the lower peninsula and a portion of the upper." Whatever claims other geologists put forth, Mr. Lane, who wrote in 1903, practically states that as an export proposition the Michigan coal fields are not in a position to compete with other states; however that may be, any field that can average for several years 1,653,000 tons of coal per annum, and raise production for home consumption to 2,035,800 tons, as this field did in 1907, is entitled to something more than local consideration.

FIG. 1

Coal is said to have been mined near Jackson in 1835, also at Grand Lodge, Eaton County, in 1838. While some coal is yet mined in those counties the principal output for the past 12 years has come from Bay and Saginaw counties. The output by counties, as reported by the Commissioner of Labor for 1910, is as follows:

	Tons
Bay	720,677
Eaton	1,898
Genesee	13,151
Ingham	1,873
Saginaw	661,188
Shiawasse	8,530
Tuscola	64,257
Total	1,471,574

The map of the lower peninsula of Michigan reproduced in Fig. 1 was compiled by A. C. Lane and shows the coal area of Michigan. Owing to the unconformity of the strata, to the excessive glacial erosion and subsequent deposits of moraine, a large part of the interior coal as located on the map is conjectural, except where holes drilled for water or brine have verified its existence. The boundary or edge of the coal basin has been pretty closely determined by outcrops as well as by drill holes. The coal beds of the basin are therefore better known where they outcrop, and least known in the center of the basin, where the cover is thickest. A section of the lower peninsula furnished by Mr. Lane in the Michigan Report mentioned is reproduced in Fig. 2 and his hypothetical correlation of the Michigan coal beds places them in the Lykens Valley group of the Pottsville series. The reasoning he advances for his correlation (see Table) is that the fauna, flora, particular limestones (l. s.) and sandstones (s. s.) are indicative of the Pottsville and Lower Carboniferous formations in Pennsylvania, Ohio, and elsewhere.

Though the limestone underlying the coal series is equivalent to the Maxville in Ohio and the top of the St. Louis limestone of the Mississippi River, both being known as Lower Carboniferous rocks, the age of the coal beds cannot be directly inferred, inasmuch as there is a general unconformity between it and the beds. Some distance beneath the coal series there is a sandstone known as the Napoleon or Upper Marshall which can be followed in outcrops or in drilled wells for about two-thirds of the coal basin. This bed is considered the equivalent

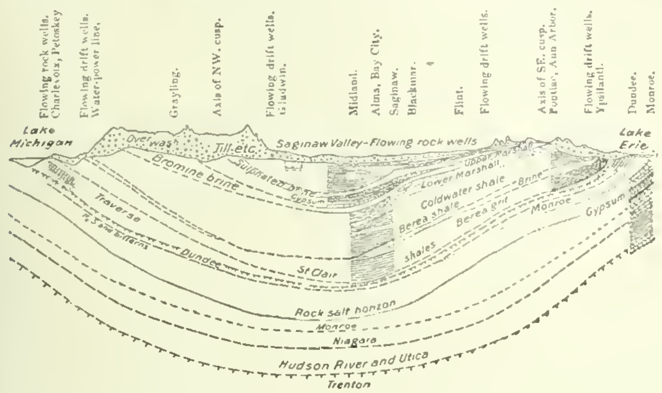

Fig. 2. Cross Section, Lower Michigan Basin

of the upper Logan of Ohio, and beneath it or outside of it no coal in commercial quantity has been found or is likely to be found.

Correlation Table

Pennsylvania	Ohio	Michigan
Lykens No. 1 coal / Homewood s. s.	Tionesta / Upper Mercer l. s.	Upper rider coal / Ligula shale
	Lower Mercer	Upper Verne coal or Monitor coal
	Massillon sandstone	Lower Verne coal
Lykens Nos. 2 and 3 / Conoquenessing s. s.	Wellston / Jackson Hill / Quakertown	Middle rider
	Massillon s. s.	Sandstone
Sharon conglomerate	Sharon coal / Sharon conglomerate	Saginaw coal
Lykens No. 4 / Brookside		Lower rider
Lykens No. 5 / Big Bed		Lower coal
Lykens No. 6		Lower beds toward center of the basin

Mr. Lane finds that the beds decrease in thickness with depth, often being cut out entirely by erosion or replaced by sandstone, etc. Usually the beds above the coal are reported as black shales, and they are likely to be weak. Owing to erosion, coal is found at times directly beneath clay, sand, and gravel, or other unconsolidated rocks, where it is practically unworkable. Sandstone roof is a wet roof in this field and at several mines black bituminous limestone full of shells forms the roof. The floor beneath the coal is usually reported as fireclay or shale.

Analyses of Michigan Coals

	Lower Verne Bay County	Upper Verne Bay County	Saginaw Standard
Specific gravity	1.32		1.26
Moisture	8.71	3.78	10.67
Volatile matter	38.45	41.18	33.59
Fixed carbon	41.16	49.34	53.80
Ash	11.68	5.70	1.94
Sulphur	2.72	2.50	1.01
British thermal units	12,359	13,489	12,868

Minor undulations, known as "rolls" and "swamps," occur independent of the basin as a whole. In the swamps the coal is said to be thicker than in the "hog backs" or "rolls." Also in the swamps the coal is likely to be capped by a rider or thin seam. It will be noted in Mr. Lane's section that he has found it convenient to name the coal beds: Upper rider, Upper Verne, Lower Verne, Middle rider, Saginaw, Lower rider, Lower coal. The variations of these beds in this field are such that no one extends over the entire coal basin.

Michigan coal is not all of the same quality and is not all poor. The Verne seams, while rather high in sulphur, are caking coals. Analyses of the Lower Verne, Upper Verne, and Saginaw coals, made by J. H. Williams, are given herewith.

Saginaw Valley Coal Mining

In the Saginaw Valley the coal tipples are placed in level fields with no vestige of life about them and no buildings except those connected with the plants. Owing to this, the first impression of the visitor from other coal fields is that of loneliness, amounting almost to a feeling of desolation. There are good reasons for not having company houses, stores, etc. at these plants, which may be explained in a few words. The coal beds of the Saginaw Valley are not continuous, as in other fields, but are pockety; it would therefore be folly to construct a mining village and abandon it before the construction account had been wiped out; further, the surface is not owned by the coal companies, but by farmers, who till the soil. Most of the

Fig. 3. Method of Working

miners live in towns nearby the mines and are carried to and from their work in special trains, in some cases at the expense of the operators and in others they pay a small fare. The Consolidation Coal Co., of Saginaw, has wash houses at its mines where the miners change their clothes previous to taking the trains or going into the mines.

The method of caring for the change house is somewhat different from that of other places, in that the miners hire and pay the wash-house attendant, thus making it feasible to have matters to suit their own convenience. It is the duty of the attendant to have water and towels ready when the men come from the mine; to see that the shift clothes are properly dried and aired over night; and to keep the house clean and neat.

The writer saw some of the miners leave the trains in Saginaw, and noticed that they resembled more nearly expert mechanics in their street clothes than miners coming from work.

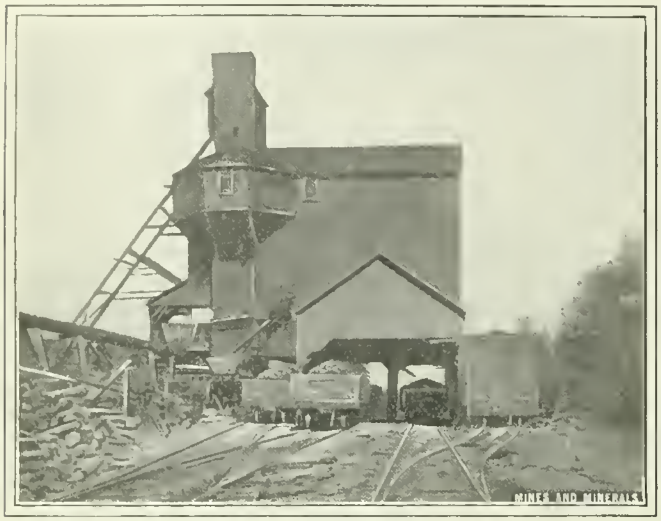

Fig. 4. Riverside Tipple

They are paid twice monthly, are most all English speaking, and have the air of satisfaction that goes with prosperity.

If, as is stated, the Michigan coal is not likely as an export commodity to enter into competition with coal in other states, the fact remains that it must be an excellent coal that can rob it of its natural market. Outside of the lower peninsula of Michigan little is heard of the Saginaw Valley coal, nevertheless a field that can produce 2,000,000 tons of coal, as this did in 1907, is no mean factor in the coal situation in lower Michigan.

The largest coal operator in the state is the Consolidated Coal Co., which operates nine mines in Saginaw and Bay counties and which has three more practically ready to commence operations. Two of their mines southwest from Saginaw are named the Riverside and Shiawasee. The former is near the Tittabawasee River, surrounded by trees with a mere trail for a wagon road leading to it; the latter is near the Shiawasee River, approximately 3 miles away from the Riverside. All operations in this vicinity are worked through shafts that vary from 165 to 185 feet in depth, showing that the coal beds are practically horizontal in this vicinity. There are numerous rolls in the beds, however, which make it necessary to do considerable dead work at times to keep the traveling roads at a uniform grade. Each mine has two timbered shafts to comply with the law, one for hoisting and one for escape in case of accident. The main or hoisting shaft has three compartments, two 6 ft.×6 ft. for cages and one 2 ft.×6 ft as a pumpway. The head-frame is attached to the tipple, consequently the latter is practically over the shaft, a position which would be exceedingly dangerous were there no second shaft and were it not used as an upcast. Realizing this, the downcast is placed quite a distance from the upcast and is supplied with a blowing fan. The advantage of a blowing fan in this field is further enhanced by its preventing ice accumulating in the hoisting compartments during cold weather. In some cases the fans are driven by steam engines, in other cases by electric motors; in either case they are convertible into exhaust fans by changing a door. The air shafts, 8 ft.×8 ft., are fitted with stairs having an angle of 45 degrees, so that in case of accident the men can leave the mine without difficulty. All shafts are lined from the surface down, owing to the cover near the surface being unconsolidated material. As a rule the roof of the mines in the vicinity of Saginaw is slaty shale which flakes badly when exposed to the air; in places sandstone replaces the shale. The floor is usually fireclay but there are instances where the clay is wanting and sandstone forms the floor. While the coal bed varies in thickness from 2 feet 6 inches to 3 feet 10 inches, owing to rolls and swamps, a fair average would be 3 feet at Saginaw.

The mines are worked double entry with cross-entries driven in pairs at right angles to both main entries, as shown in Fig. 3. Entries are driven 18 feet wide with about 18-foot pillars between them. Cross or butt entries are spaced 300 feet apart, with 6-foot breakthroughs every 60 feet. For haulage purposes, entries are carried 5½ feet high, which makes it necessary to brush the roof and take up floor in the vicinity of Saginaw. The main entries are kept free from refuse while the cross-entries are used as gob entries in which to stow the waste. All traveling roads are timbered with posts and cross-bars to keep the slate from dribbling down on them. Pillar-and-room mining is followed in this field, it having proved better suited to the conditions which govern such matters, namely, a bending roof which will follow the mining. Room centers are 40 feet apart with rooms 30 feet wide. What appears peculiar to one accustomed to thicker coal beds, is the absence of a rib on the cross-entry side of the main entries where rooms are turned at right angles the same as from cross-entries and worked for 150 feet parallel with the cross-entries. This system is being abandoned, Mr. Andrew Stevenson, Mine Inspector of Michigan, informs the writer, and instead of only room-neck pillars being left on the main entries, a rib from 8 to 16 feet thick is substituted and rooms turned from the cross-entries.

Rooms are driven 150 feet long to meet those worked from the next nearest cross-entry beyond them. Breakthroughs, 6 feet wide, are made 30 feet in from the entry, for at this point the air is bottled up and becomes bad in such wide rooms. The next breakthrough is made 60 feet from the first, and as the rooms are but 150 feet long, only two are needed. Roadways are made through the center of the rooms and are timbered the same as entries, provided the roof requires such treatment. All undercutting is done by machines.

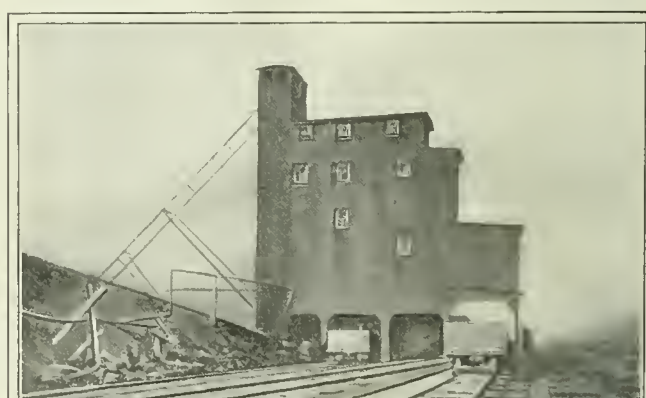

Fig. 5. Shiawassee Tipple

No undercutting is done with the pick, but considerable mining is done by shooting off the solid. Black powder is used almost exclusively, although some miners use dynamite in deep holes for the purpose of shattering the coal. For instance, a miner will put a hole in the solid face about 12 feet deep, then charge it with three or four sticks of dynamite and fire. The coal is not blown out but shattered so that it can be picked readily. This is termed "pick mining." Each miner drills, loads, and fires his blasts just previous to leaving the mine; in this way the mine is kept free from powder smoke during working hours. When, however, the mine is not fully developed, shooting is practiced twice daily, but the men are not permitted to go back to their work until 3 hours have elapsed after firing. Fuse is used entirely for blasting, no squibs being allowed. With such regulations there are few accidents from powder. All mining is done on contract according to union scale, the miners being paid by the ton for all coal which passes over a ⅞-inch diamond-bar screen. The coal is blocky and hard, does not readily air slack, in fact favors block coal in physical appearance. Practically all coal is removed from the mine, and although the smallest sizes are mixed with slate and fireclay, nevertheless, when washed, they make excellent steam fuel. The miners hire the check weighman as in other places. Mules are used for gathering and delivering steel cars which, when loaded, hold about 1,000 pounds of coal. The miners push the cars from the entry to the room face and should the room exceed 150 feet in length they demand 3 cents per ton extra for their labor. From the partings the cars are hauled to the shaft in various ways. Head-and-tail rope, tail-rope, endless rope, and electric locomotives are in use. At the latest-opened mines, the shaft bottoms and partings are lighted by electricity and in such mines electric locomotives are adopted, provided the irregular conditions of the floor can be remedied without excessive cost. Where swamps are met water is generally found in these mines as elsewhere, and small electric pumps are employed to force it to the sump at the main shaft. Usually the quantity of water is not excessive, a steam pump with 6-inch column pipe being able to raise it to the surface. The advantages derived from using a steam pump in the main shaft are, that it aids ventilation and further assists in keeping the shaft free from ice in winter. Fig. 4 shows the Riverside tipple and Fig. 5 the Shiawasee. It will be noticed that they are enclosed and constructed higher than those in more southern latitudes. At first glance they resemble an anthracite breaker on a miniature scale, or a head-house at an ore mine. The arrangement and construction of these tipples is the result of experience, consequently they are well suited for their purpose. Self-dumping cages are used, and after the coal is riddled over the ⅞-inch bar screen it is weighed in a basket. From the basket it passes over or through shaking screens and is sized into domestic lump, steam lump, run-of-mine, stove, nut, and slack, before going by gravity to the cars.

The weather in Michigan is exceedingly cold in winter, which makes it a matter of necessity to enclose the tipple, as shown in the illustrations.

Because of the coal beds in the vicinity of Bay City being from 4 to 6 feet thick the output from a mine will be from two to three times as much as at Saginaw; however, the coal pockets not being continuous it is necessary to prospect thoroughly a piece of land with Keystone drills before any actual mining work is performed. After prospecting, calculations are made to estimate the tonnage and determine the amount of investment that the property will stand and yield a profit. Unless one is well posted practically on the conditions which prevail in the Michigan field there is very apt to be money lost in coal-mining enterprises; however, with the right men in the business there is money to be made, provided competition is not so excessive as to over supply the limited market for this coal.

Obituary

FRANCIS L. ROBBINS

Francis Le Baron Robbins, of Pittsburg, Pa., the promoter of and for several years president of the Pittsburg Coal Co., died at Chicago, on September 8, in the fifty-seventh year of his age. He was born at Ripon, Wis., but in boyhood removed to Pennsylvania, where his father had entered into the coal-mining business with the late John Arnott. As a mere boy he entered the employment of the firm, and before he reached the age of 21 he was superintendent of the Pittsburg and Walnut Hill Coal Co. Later he organized the Robbins Coal Co. and the Willow Grove Coal Co., and still later he became financially interested in the Pittsburg Consolidated Coal Co. In 1899 he succeeded in consolidating a large number of mines in the Pittsburg Coal Co. and his management of the company, in spite of several adverse circumstances, was a successful one.

He retired from the presidency of the Pittsburg Coal Co. in 1906, and for a year thereafter was president of the Monongahela River Consolidated Coal and Coke Co. He retired from the latter position on account of ill health.

Mr. Robbins was active in politics, and he was prominently mentioned as a successor to the late M. S. Quay, as United States Senator from Pennsylvania.

Conservation of Minerals

The Contribution of the Mining Profession to the Conservation of Our Natural Resources

Dr. Henry S. Drinker, the able President of Lehigh University, in an address delivered, in August, at the exercises commemorating the twenty-fifty anniversary of the Michigan College of Mines, reviewed and summarized what the mining engineering profession has done in the last generation for the conservation of the natural resources of the country.

He first called attention to the fact that in a report made in January, 1869, to the Secretary of the Treasury, on "The Present Condition and Prospects of the Mining Industry," Dr. Rossiter W. Raymond foreshadowed the lesson of economy in the development of our mining resources, when he spoke of "the protection of the country against reckless and wasteful mining, by the inculcation of sound principles, and the enlightenment of the miners as to their best interests." Continuing he said:

"It is a fact not generally known or appreciated that this matter of the need of conservation of our natural resources, particularly of our mining and timber resources, to which the general public is only just awakening, has been the subject of careful study and outspoken warning by our engineers for years, and there is no body of men who have contributed more valuable knowledge and suggestion in this matter than the American Institute of Mining Engineers, founded in May, 1871. This society of engineers has done incalculable good in the last 40 years in developing technical knowledge, research, and discussion by its meetings and publications, and in its history, the Institute, beginning with the notable discussions on 'Waste in Coal Mining' and on 'Technical Education' in the early seventies, up through the succeeding years, has taken leadership in the consideration and study of many important matters pertaining directly to conservation and engineering education."

He called attention to the fact that, at the first meeting of the Institute held in Wilkes-Barre, Pa., in May, 1871, which he, as a young engineer, attended, a committee was appointed "To Consider and Report on the Waste in Coal Mining." This action followed the presentation of a thoughtful paper on the subject by the late Richard P. Rothwell, in which, even at this early period, the waste resulting from mining under short-term leases was referred to as follows:

"The system of leases under which the operator pays for coal shipped, but not for coal wasted, and for the larger sizes frequently a larger royalty than for the smaller sizes, greatly aggravates the evil. When the leases are, moreover, for short periods, the combination of conditions is most mischievous. It then makes no difference to the lessee how much coal is wasted or left in the ground. His efforts are directed to getting to market as much coal as possible of the most saleable sizes in the given time."

Mr. Rothwell's statement was practically repeated in a paper read by Mr. John H. Harden, at the Boston meeting of the Institute, in February, 1873, when he said:

"It has been said that lessees have not the opportunity of making the best of the mine for themselves or the owner, owing to the short period over which their tenure frequently extends; this should be remedied; every facility consistent with the proper working of the mine should be given, nothing reasonable withheld, as on the lessee rests the greatest share of contingencies and risk."

The Institute's Committee presented a preliminary report at the second meeting of the Institute held at Bethlehem, Pa., in August, 1871, in which valuable recommendations were made. It was found as time went on, that the work started by the Institute Committee required the authority and backing of the State for its successful prosecution. Largely through the efforts of the late Eckley B. Coxe, the Legislature of Pennsylvania, in 1889, passed an act creating a "Coal Waste Commission." Mr. Coxe, who had been chairman of the Institute Committee, was made a member of this Commission and became its chairman, and the Commission made a valuable and exhaustive report in May, 1893. In discussing methods of mining the Commission made this wise comment:

"It is one of the best evidences of engineering skill when the coal that must be sacrificed is determined and deliberately set apart for that purpose at the time the colliery is opened out, or very soon thereafter," and in commenting on "Avoidable Waste by Mining," they said:

"When any given territory is to be worked, a much larger percentage of coal can be gotten out if the conditions in which the coal occurs are carefully studied, and a general system of working decided upon and thoroughly carried out from the beginning."

Doctor Drinker comments on these views in the following rational manner:

"How obvious it is that these wise suggestions can only be carried out when the mining operations are conducted on a large scale, with ample capital, under conditions of actual ownership or under leases of such long term as will financially justify such a plan of working, and that they would be impracticable where mining is to be pursued in small operations with limited capital where speedy returns must be exacted on the capital invested."

He also referred to the valuable papers presented at the joint meeting of the American Society of Civil Engineers, the American Institute of Mining Engineers, the American Society of Mechanical Engineers, and the American Institute of Electrical Engineers, held in New York, March 24, 1909, to consider the matter of the "Conservation of Our Natural Resources." At this meeting Doctor Raymond read an admirable and exhaustive paper on "Conservation by Legislation," which among other subjects dealt with the conservation of coal. Later Mr. Edward W. Parker, Statistician in charge of the Division of Mineral Resources of the United States Geological Survey, read at the Spokane meeting of the American Institute of Mining Engineers, in September, 1909, a paper on "The Conservation of Coal in the United States."

Quoting from Doctor Raymond's paper, Doctor Drinker said:

"I remember well what Eckley B. Coxe said to me, that salvation for the anthracite region, and its store of natural resources, lay in the control of the collieries by capitalists who had other aims than immediate profit from the coal; and that the acquisition of such control by great railway companies, whose interest it was to make anthracite the basis of a profitable freight business for generations to come, was not only the best, but the only remedy for the reckless and the irreparable waste which the system of 'hogging' the mines under short leases had brought about."

Doctor Raymond further added (speaking of Mr. Coxe's prediction):

"The results verified his prophecy. The great railway companies operating the anthracite collieries have put more money into preliminary deadwork and costly machinery; have been the pioneers of rational forestry for the provision of permanent supplies of mining timber; have enforced economy in every department of production; have trained and employed the most skilful engineers and experts; in short, have redeemed from immediately impending rack and ruin the whole anthracite industry."

Quoting from Mr. Parker's paper, Doctor Drinker said:

"Most of the members of the Institute are cognizant of the suits brought by the Government against the anthracite operators in Pennsylvania, or the combination of interests commonly known as the 'hard coal trust.' No defense of any illegal combination in restraint of trade is intended, but there are some facts which should not be lost sight of; and unfortunately those whose opinions are based upon the 'news' given to us by the daily press are likely to be governed by *ex parte* testimony. The present situation in the anthracite region is one that has been developed through sheer necessity, if the conservation of the supply of anthracite and the prolongation of the life of the fields in the best interests of the people were to be attained in any other way than through government control, and government control did not seem to be materializing. I believe that even Doctor Raymond will subscribe to the statement that a good part of the history of anthracite mining has been one of profligate waste in the mining, preparation, and use of that precious supply of fuel; and this has only been remedied, none too soon, and could, under the circumstances, only be remedied by the close control and conservative management which have been brought about in recent years. And I might pause here to pay a merited tribute to such men as Doctor Raymond, Eckley B. Coxe, P. W. Sheafer, Franklin B. Gowen, William Griffith, and a few others through whose efforts many reforms which lessened the waste of anthracite were effected. They were the pioneers in the battle for conservation, and a monument should be erected to them.

"The securing by the Reading Railroad for its offspring, the Philadelphia & Reading Coal and Iron Co., of the great coal reserves it owns today, was the beginning of a great movement which was foreseen by those in a position to see. The Reading company was temporarily bankrupted through its guarantee of the debt thus incurred, but the possession and control of those coal lands are indirectly the most valuable assets of the railroad at the present time. More than this, however, in the ultimate economy of things, has been the preservation of thousands of acres of coal lands from reckless spoliation. The way was paved for the safe and sane control of the anthracite industry, albeit by a trust, and a stop was put to the cut-throat competition and extravagant methods which in earlier years had resulted in losses of millions of dollars in money and more than millions of tons of coal.

"Under former conditions in the anthracite regions, when it was not considered necessary to give thought to the morrow, and indeed up to the time when the Anthracite Coal Waste Commission made its report, it was estimated that for every ton of coal mined and sold 1.5 tons were lost. The greater part of this loss was in the coal left in the ground as pillars to protect the workings, while millions of tons of small coal or screenings were thrown on the culm banks which now form unsightly mountains in the coal regions. Improved methods of mining and of preparation have of late years reduced the percentage of waste, so that at present the recovery will average about 60 per cent. and the loss about 40 per cent. * * * A careful study of conditions in the anthracite region will convince the most skeptical that no robbery of the public is now being carried on."

In expressing himself Doctor Drinker said:

"In view of the rather superficial utterances that have been put forth during the last year or so on the general conservation question, it would seem to be the duty of engineers to keep in touch with this matter, and to do their share toward shaping the policy of the Nation to a course based on reason and technical knowledge, rather than on sentimental diatribe. I think that a greater danger today to the public interests is threatened by the untrained, spasmodic, semipolitical and careless presentation and handling of these matters before the public, by men on whom their importance has suddenly dawned, than even by a continuance of the wasteful methods of the past.

"It is dangerous for a man untrained in engineering to venture opinions on questions like the conservation of coal and the development of water-powers, which require the judgment and experience of engineers. The trouble with many of the plans for coal and water-power conservation proposed by men untrained and inexperienced in engineering and in business methods, is, that their plans are ideal rather than real; their dicta negative rather than positive, and their remedies theoretical rather than practical. You have doubtless observed that the fear that is uppermost with such men is often rather that our public resources will pass into the control of what they they term the 'monopolistic interests of the few,' than the crucial question of what is the best plan or system for the economic winning of our natural resources in the interest of the public. What engineers should urge and impress upon the public mind is the importance of looking at these industrial questions in a wholly cold-blooded, business way—without any obsession or oppression of undefined hysterical fear of the results or dangers of a so-called corporate monopoly that are often as visonary as the nursery tales of bogies to frighten children into being good. Corporations, as we know, are, as a rule, only aggregations of capital to promote some useful industrial or transportation purpose; they are, like other agencies of the day, capable of use and of abuse. Strychnin is a virulent poison used ignorantly, or for an evil purpose, but it is a valuable medicinal remedy in the hands of the physician; and under the recent broad decision of the Supreme Court the reasonable function of the large corporation has been defined. Attorney-General Wickersham in his recent address at Hancock (across the bridge), in this state, summarized this in a few pointed words when he said (in reference to the Sherman Act):

"'But when the Supreme Court said we must read this statute as reasonable men and give it an interpretation that will not strangle all trade, but which will prevent any undue restraint, prohibit all contracts and combinations that are intended to interfere with the natural course of trade, then the court gave us a means of preventing those evils which led to the enactment of the law.'

"In taking wise and broad measures to avail best of our undeveloped natural resources, the need is not so much to withdraw and set them aside for the use of future generations as to be sure that they are not wasted in their use by the present generation. Let our natural resources be utilized, following the natural laws of supply and demand, with due regard to the essential factor that private capital will never venture into the proper, broad, economic exploitation of these resources without the assurance of a sufficiently permanent tenure to insure an adequate return. And let us give due recognition to the thought that conservation may be overdone by the undue and unwise stimulation of such popular demand for drastic control that we may dwarf the business development of our present and coming generations by conserving resources now urgently needed, especially in Alaska and in the West, only to set them aside for the needs of an indefinite future when other agencies may have been found to take their place. Do not let us be blinded or misled by the fears of the uninformed, or by what is equally dangerous, the narrow view of the partially informed, who fear industrial dangers they have never actually faced, and preach a crusade against evils that are so theoretic that practical men know them to be imaginary.

"The difficulty, and the probable error, in criticizing all large development enterprises as being so-called monopolies, is that the superficial critic is apt to consider and discuss the situation on one side only. The conservation—the careful mining—of our coal, and the economic development of our latent water-powers, for instance, can only be managed properly by the investment of large capital, and this can today be supplied only by the association of many individuals, having capital to invest, into large corporations controlling such aggregate capital, or by the Utopian plan of state or federal ownership and the use of the public funds in an industrial enterprise. As to corporations, the stronger they are the more surely are they in a position to handle the mining problem conservatively and economically. The economic mining of coal—the proper development of a water-power site, involve purely expert questions, but it takes capital to command the best expert talent.

"The question—the practical question—is, how is the public today—how are our future generations, to be best benefited by conservation? It would be nonsensical to say that we do not wish our coal, or our water-powers, to be leased to, or availed of, for the present generation, simply because we wish to preserve them for future generations.

"The question is whether the present generation needs these resources; if it needs them, the need is exactly that which would be supplied were they held for succeeding generations. It seems to me that the main thing to be guarded against is that the natural resources still in the ownership and possession of the national government shall not be so disposed of that they can be acquired at a comparatively low price now, to be held wholly speculatively, for development in an indefinite future; surely this can easily be guarded, because there are few corporations who can command large sums of money to be locked up for a return a century hence. Stockholders want a quicker return for their money. But again, how easily this principle can be distorted or misapplied by an honest but narrow and inexperienced enthusiast; for any large enterprise must be enabled to acquire a sufficiently large body of coal, or a sufficiently long lease of water-power, to at least secure a sinking fund return on capital subscribed or borrowed. Proper conservation of our natural resources does not mean throwing open their exploitation to the wasteful methods and inexperienced handling of individual operators with the unnecessary duplication of plants and the waste of capital involved in uneconomic individual operation. Conservation of our natural resources does not mean the conservation of the individual operator. As a rule it points to reasonable cooperative effort lawfully exercised in the interest of that economy in methods resulting from operating on the larger scale that conserves our resources for the benefit of the consumer and prevents their waste by the producer. Much of the twaddle that is talked and written arises from a sentimental sympathy for the individual operator who is often the worst enemy of true conservation. As a rule there is no more wasteful system of mining than that pursued by the small individual operator. The man who owns, or leases, a small mine, or who leases a large mine for a limited period, on limited capital, is almost certain to mine extravagantly. He absolutely must get all he can out of it in the cheapest way possible. He is not concerned with laying out deadwork ahead—with planning far in advance so as to take out the largest possible amount of coal or mineral in the most economical way. He has the power, within certain bounds, as a rule, under his lease, to so operate as to get the largest amount out of the mine in the cheapest and quickest way possible, practically regardless of the waste in mining. Moreover, the small individual operator is, as a rule, absolutely indifferent to the interests of the public, whereas a large corporation, doing business not for a limited term, but for time, must so conduct its business as to be content with a moderate and reasonable profit on a product mined economically, and with a far-seeing eye to the conservation and avail of all its resources, and to the just treatment of its customers.

"These suggestions as to the individual operator apply equally to small corporations not possessing sufficient capital and strength to mine economically and with an eye to the future.

"When we talk of large aggregations of capital it is well to consider the good they have done, and can do, with the apprehended evil. It will not do to assume broadly that what is mistermed the 'monopolizing' of our coal interests, for instance, results in waste of our natural resources and in injustice to the public.

"Perhaps one of the best summaries of this great conservation question now before our people, and in which the engineering profession is so interested, and in regard to which our mining profession has so great a duty to perform, was given by Dr. C. W. Hayes, Chief Geologist, of the United States Geological Survey, in an address some time ago at the University of Chicago, when he defined conservation as 'utilization with a maximum efficiency and a minimum waste,' and said:

" 'The reform that is needed through the country as a whole must gain its motive power not from sporadic instances where true business methods prevail, or from the well-intentioned enthusiasm of the few, but from the well-informed intelligence of the many. The campaign for conservation must be one of education.

" 'There appears to be an unfortunate confusion in the minds of certain advocates of conservation. They have apparently confused conservation of natural resources with destruction of the trusts, and the mixture has resulted in pure demagoguery. * * * Any one who has studied conditions attending the development of mineral deposits must have been impressed by the fact that those deposits held by large companies are being developed and utilized with a view to prevention of waste, in accordance with the principles of conservation, to a much greater extent than are the deposits held by small companies or by individuals.

"This matter, particularly in connection with the prospective development of our coal in Alaska, was gone into quite fully in the 'Investigation of the Department of the Interior and of the Bureau of Forestry' by the Joint Committee of Congress (the Pinchot investigation), and Mr. George Otis Smith, the Director of the United States Geological Survey, in testifying before this Commission, said:

" 'Take the condition of the anthracite regions. As I understand it, the present conditions—we are talking from the standpoint of conservationists—the present situation, where large interests more or less control the whole field, is much preferable to the former condition of a large number of small operators who only took out a part of the coal and wasted more than they took out.' And again in his testimony he said: 'It is not monopolization that is the conserving agent, it is not the monopoly that conserves: it is the large unit that conserves. And I should say that the operation of the coal mines by the large and strong interests which control also the railroads in a given field would be a conserving practice, because it would involve large units. * * * I want to see the Government, by law, control the large unit. There is no use of arguing for the development of large units in industry, unless at the same time the control of the large units is given to the Government. But the large unit in itself is the thing to be sought. The day is past for small operation in any industry of this country, and if we wish to bring back the old conditions, and which still persist; if we wish to encourage the existence of small operations which mean nothing but wasteful competition, I think we would be working directly against the operation of natural law and I do not think that natural law ought to be opposed either by executive order or by legislative enactment.' "

Raise Goats on Coal Lands

A new companion to the coal miner threatens to butt in, in the person of the festive goat. Last year over 14,000 of these animals passed through the Chicago slaughter pens.

At any rate, goat culture is now an attractive proposition from the money making, if not the gastronomic standpoint, and capital is giving it attention. The matter is receiving the favorable notice of mine owners. Thousands of acres of coal lands are scrubby and declivitous hillsides, unsuited for agriculture. Goats will graze on shrubs and climb the steepest hills, where nothing else can live. They defy dogs and are of anti-race-suicide principles, in a marked degree. It is announced that the experiment of raising goats on waste mining lands is to be given a trial. If it works out with profit the plaintive bleat of Nanny and the playful antics of Billy in trying to take a fall out of other creatures that cross their paths, will be familiar to coal-mining regions generally. No other form of industry is so wasteful as that of mining.

Underground Safety Appliances

Protection of Shaft Bottoms, Haulage Appliances, Electric Wires, Stables, Rope Crossings, Etc.

*By Stephen L. Goodale**

In the September Mines and Minerals, the various safety appliances and regulations in use at the mines of the H. C. Frick Coke Co. were described. The care shown in choosing and adapting means for the prevention of accidents continues into the mine itself. A number of the devices employed underground will be described, and finally the scheme of working, to which we may refer in connection with systematic timbering.

Emphasis has already been laid upon the fact that prevention of accident is the end sought, and much less attention is given to provision for accident. Even of the latter, however, care has been taken, as will be outlined. As the President of the company says "the oxygen helmet apparatus and first aid to the injured are all right in their place; but spending so much time on them rather than changing the conditions in and about the mines to prevent accidents is like putting the wagon before the horse. The thing to do is to prevent accidents."

The shaft in a mine is a dangerous place, where many accidents occur. Any means to lessen the danger of working in or near the shaft is a matter of much importance in mining. The fence about the top of the shaft has been described; in these mines, the bottom of the shaft is shut off from the haulageway by a gate. This is operated automatically by the cage in such a way that when the cage is not at the landing the gate is there. As the cage approaches the landing it engages a device which raises the gate out of the way. It will thus not be possible for any person to get into the hoisting compartment except when the cage is ready to take passengers. These gates, shown in Figs. 1 and 2, need no further explanation.

Considerable small coal drops from the wagons in hoisting and finds its way to the shaft bottom and must occasionally be cleaned out. The shaft is generally but a few feet deeper than the level of the landing, and were a cage to descend while a man is working in the shaft he would almost surely be killed. A heavy chain is hung across the shaft between the timbers and across both compartments of the shaft; the cage is then allowed

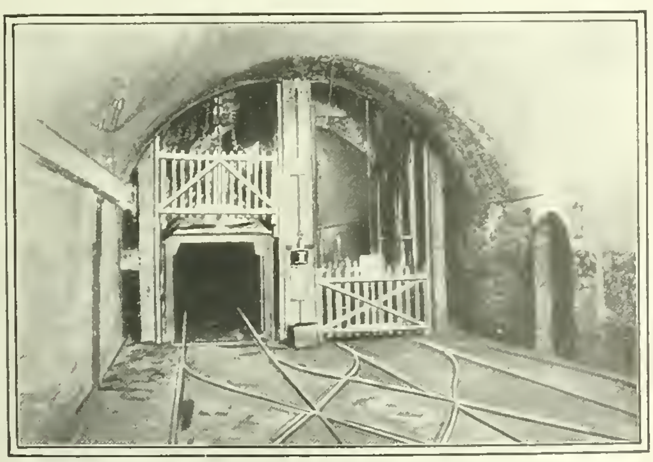

Fig. 1. Cage at Shaft Bottom, Gate Open

to descend and rest its weight on this chain, and then only is a man allowed to enter the shaft and to shovel out the accumulation of coal there.

The arrangement for handling men at some of the shafts is very good, indeed. For instance, at the Leisenring No. 1, there is a waiting room just beside the hospital room near the shaft, the gate to which is locked and the key carried by the cager. As miners are coming from their work at irregular times, the cager allows a sufficient number to gather to make an ordinary cage load, and then unlocks the gate and allows these men to go to the surface. This waiting room is especially important at this mine because of a heavy grade down which the loaded coal wagons reach the shaft.

A temporary fence is sometimes also provided set some feet from the shaft and when men are being hoisted not more than

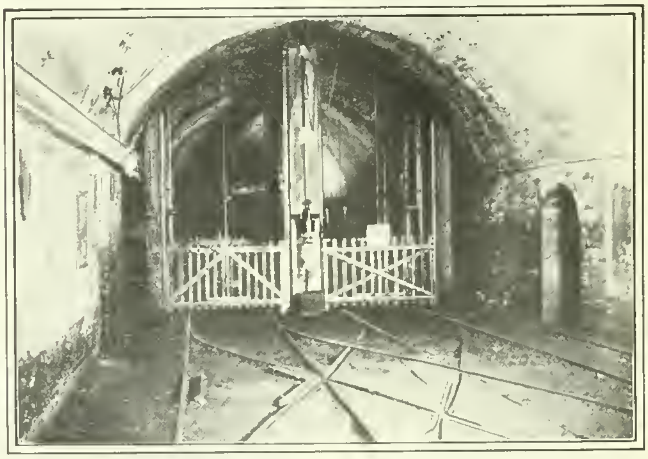

Fig. 2. Gates Closed at Shaft Bottom

one cage load of men is allowed inside the fence at one time, thus preventing crowding at the cage. There is set somewhere in the track approach to the shaft a derailing switch, simply one rail that can be thrown over to make a break in the track. The shaft is kept free from high-pressure water or air pipes in the more recent mines, these being provided for by special bore holes. The cages are provided with the usual dogs to catch in case of a failure of the hoisting rope, and each cage has two hand rails at a convenient height for men to steady themselves by.

The air-shaft is inspected every day, a different man each day. At Continental No. 1, for instance, at present the inspection is as follows: Monday, Fireboss Barton; Tuesday, Fireboss Moore; Wednesday, Fireboss Hirnornski; Thursday, Mine Foreman Jim Moore; Friday, Head Carpenter Pierce; Saturday, Machinist Griffith. This makes sure of a very careful inspection each day, for no man would want to be caught in an oversight of failing to notice some dangerous condition. The men also inspect the fan. The fans are usually run as pressure fans to blow air into the mine; but the housing is so arranged that with very little trouble they can be changed over to suction. Gates at the fan house prevent any one from reaching the air-shaft except when necessary. The ladders in these shafts are made and placed so that it would be possible for a man to climb out of the mine without any light if necessary.

Article 2 of the rules and regulations of the company states the amount of air required for ventilating, and it is twice the amount demanded by the state law. In addition, the efficiency of ventilation is very high; that is to say, of the amount of air blown in, a very high percentage is actually received at the working places. An anemometer is used for the measurement of the air-current, and the air velocity and cross-section of the heading is measured. At the Continental No. 1 such readings are taken once a week at 14 places, inlet and outlet to the mine, at the entrance to each section of the mine and at the last cross-cut in each section in accordance with the state law. A check measurement is made once a month also.

Rope haulage, compressed-air locomotives, or electric locomotives are used in the different mines in addition to animal power. Each kind of haulage requires certain safeguards of its own, as well as the care necessary in general for any underground transportation of large tonnages.

* Professor Mining University, Pittsburg.

In the system of tail-rope haulage it was formerly necessary for a man to ride on the front end of each trip in order to release the rope at the proper point, as shown in Fig. 4. Andy Horn while on this job devised a hook catch for the rope so that the rope could be disengaged by the engineer simply letting the rope slack off when he wished to release the trip. The rope then drags on the track and slips off the hook. This arrangement is shown in Fig. 5; and Fig. 4 shows that riding the trip was not a safe occupation.

Where electric haulage is in use the trolley wire is protected by boards supported from the roof as shown in Fig. 3. These strips extend well below the wire on one side in an ordinary haulageway and down on both sides of the wire at any crossing where the wire might be touched on either side. This is necessary because of men carrying tools over their shoulders and because the neck and shoulder seems to be a particularly vulnerable point of attack for an electric current.

Fig. 3. Protection of Trolley Wire

When compressed-air haulage is in use, recharging stations must be arranged for so that the locomotives shall always be within reach of such a station from the last one. The pipe at these stations is set on very heavy timbers, and the valve set with a handle extending behind these timbers to protect the man who is setting the valves from any accident, such for example as not closing a valve properly which might cause a pipe to fly about when released, etc.

Repair rooms for locomotives are built with the floor about 2 feet below the track level so as to afford access readily to the under parts of the machine. The roof may be arched and stirrups hung from a girder bent to the arch section and built into the top part of the concrete or masonry of the arch. Chain blocks suspended from these stirrups may be used to lift any part of or even the whole locomotive if necessary.

A visit to the stable is one of the most interesting things in an inspection of one of these mines. The stables are built either with an arched roof of masonry or concrete or with a roof supported by steel beams placed about 4 feet centers and covered with a lagging composed of slabs of reinforced concrete 4 ft. × 2 ft. and of a thickness of 4 inches or more as necessary at any particular place. In one stable the only wood used is a strip along which to carry the lights and a box for the curry combs. Everything else is metal or concrete, such as the feed boxes which are concrete, the swinging pole between two horses which is a 2-inch pipe. A large concrete watering trough (said to be built without any reinforcement) is set in a large stall adjoining the stable, and here the horses are washed off with the hose when they come from work. Lengths of hose are kept at both ends of the stable and several fire extinguishers are also kept in readiness for use. The stable floor is brick, draining to one end for convenient cleansing. There is a steel door at each end of the stable. The ventilation is under perfect control. Hay is brought into the stable baled and not loose, being usually brought down in the fire-proof steel wagon. In Fig. 6 is shown one of the stables, although a little more wood is used in this particular place than mentioned above, the swinging poles being of wood. It is unfortunate that it is not possible to have the horses in this view, for it would be difficult to find in any industrial stable a finer lot of animals, but it would scarcely be safe to ignite a flashlight with the horses there for fear of frightening them.

At the Continental No. 1, where an endless-rope haulage is used the rope crosses a manway at one point, and Fig. 8 shows the crossing which is just like an old fashioned country stile. At one side is a bull wheel around which the rope is carried and there is a railing along this side of the stile.

Switches are operated as far as possible with a long lever set back in a niche in the wall with room enough for the man operating the switch. Where it seems to be necessary or advisable, spring car stops are placed on the track, which operate to stop a car unless they are opened by hand. In the main landings where possible the flooring is built up on a level with the tops of the rails; or where this cannot be done conveniently the narrow place between the rails at a frog is filled with a plank to prevent a man or animal from being pinched there and held. Sharp corners between haulage roads are built up of concrete piers to prevent squeezes, the concrete used consisting of coke ashes, slate, and cement.

The clearance along tracks on all haulageways is 3 feet, which is twice that demanded by state law. This clearance is kept uniformly on one side of the track, and is indicated by having the wide side whitewashed, as shown in Fig. 8. In

Fig. 4. Old Way of Releasing Tail-Rope

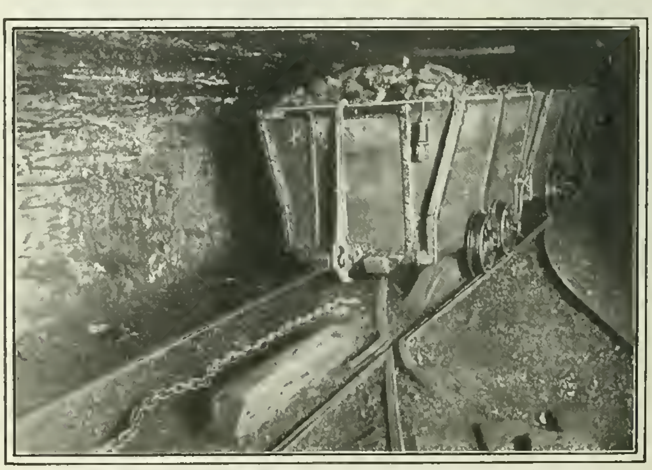

Fig. 5. New Arrangement for Releasing Tail-Rope

addition to having the wide side, recesses are cut into the wall at this side at regular distances apart and whitewashed.

In connection with a plan like this it is well to note that unless it is absolutely uniformly carried out through any mine it may become a source of danger. If in most places in a mine there is this clearance but it is lacking at a certain part of the mine, a man accustomed usually to the safety is very apt not to be careful in the dangerous place.

Signboards are placed at many points throughout the mines directing the way to manways, to the shaft, or to other parts of the mine, so that a person could find his way out of the mine by means of these signs. Other signs are also posted indicating places where there is special danger, being painted with white letters on a red background—the directional signs being white letters on a black background. Dangerous portions of the mine are fenced off, also abandoned workings, so that miners shall not wander into the same.

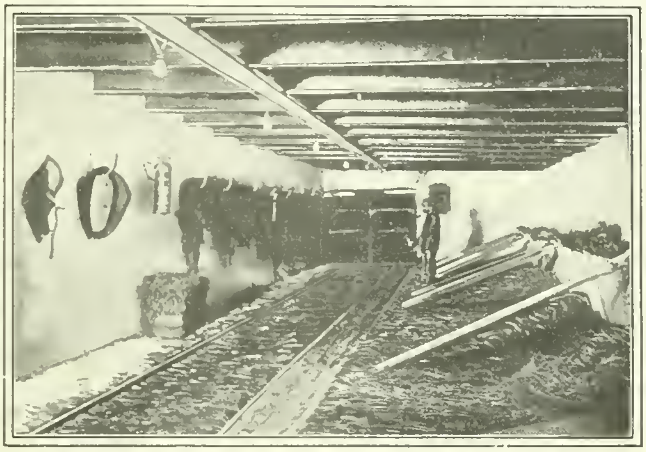

FIG. 6. UNDERGROUND STABLE, H. C. FRICK COKE CO.

At the Continental No. 1 is an interesting crossing called "The Jim Moore Arcade." It was necessary to cross a haulageway to get from the manway at the landing of the shaft. To avoid having the men continually crossing this busy haulage, a drift was cut through the rock over this haulage so the men can pass in safety; and while, at present, this passage debouches upon the landing directly on the return track for empty cars about 2 feet below the landing proper, it is probable that the arcade will be extended over this empty return track to the main landing.

At all underground engine rooms, pump rooms, etc., where necessary, there are similar guards on the machinery to those described on the surface.

A number of points of technical interest might be described but that is not within the scope of the present paper. The pump lines and high-pressure air lines are carried from the surface into the mine through special bore holes, the pipes themselves being encased in cement, in the case of air pipes to protect the pipe, and in the case of water pipes so that the concrete itself shall form a pipe when the acid waters have eaten out the original column. Permanent brattices are built up solid either of brick or with concrete made of slate from the mine and sand and cement brought in from the outside.

This company established the first rescue and first-aid station in the bituminous coal fields of the United States aside from those established by the government. Three such stations are now maintained; that at the Leisenring No. 1 mine has now graduated more than 100 men. Each man is given 12 lessons, the first of ½ hour, then six lessons of 1 hour each, three of 1½ hours each, and three of 2 hours. The practice chamber is fitted up to represent a mine and kept full of poisonous gas so that the helmets are necessary for use in the chamber. The usual sort of practice work is given. Now the men are to be trained to team work to make them more efficient and also to keep them in practice. A certificate is issued to each man on completion of the course, and a card also which is required to enable any man to use the oxygen helmet at a time of accident.

Important as this rescue work and the appliances are, however, it is of far greater importance to keep everything about the mine so that they will not be needed. The prevention of accident will do far more good than a lot of rescue work carried on after accidents have happened.

One reason for the great increase in the number of accidents in late years is that operators have probably not made changes in their methods of operation to meet the changed conditions of mining. When mining in the drift mines with no shaft or hoisting, and the workings shallow and open practically direct to daylight, the problem of ventilation is very simple. Usually there is no gas to contend with, and enough surface water soaks in to prevent dry dust and awful dust explosions. The problem of gas is felt today to be thoroughly under control, requiring sufficient ventilation, requiring that old workings and gobs be swept free of gas, requiring frequent tests in order to know of its presence and amount, and all this can be handled by controlling the air-currents so that they shall travel where required and be of sufficient volume. In all gaseous mines safety lamps can be used, and lamps are now available which are really safe. The great volume of air blown into the mines is warmed simply by its passage through the workings; therefore, it takes up very large quantities of moisture, constantly drying out the walls, roof, and floor of the passages, and thus the quantities of fine coal which accumulate and are con-

FIG. 7. CROSSING OVER HAULAGE ROPE

FIG. 8. SHOWING CLEARANCE ON SIDE OF GANGWAY

constantly subjected to this drying become dry and dusty, and the problem of dust is a most serious one. In mines that show this drying tendency the Frick company place fine sprays in the airways where the air may take up additional moisture to correspond with its increased temperature in the mine and so prevent this drying. The air in its return from the working places is passed along the fracture line mentioned later, and so the gas is kept washed down off the gob. Overcasts for the carrying of an air-current across some entry are substantially built as

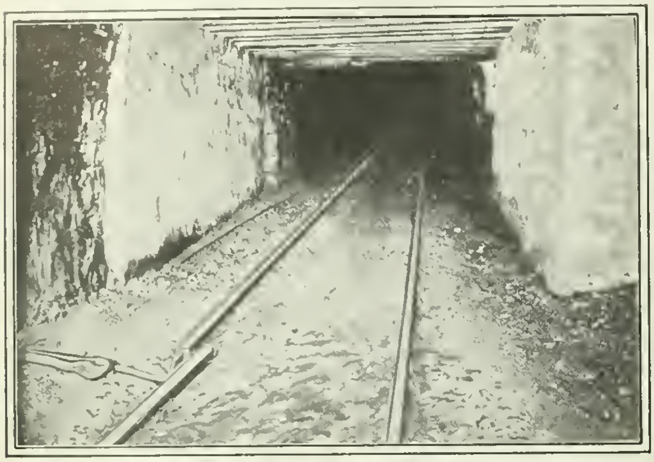

Fig. 9. Showing Construction of Overcast, Also Derailing Switch

shown in Fig. 9. The problems peculiar to hoisting and safety about the shaft have been handled on the principle—as indeed have all the safety appliances—that it is necessary to make the mines not only so safe that men will not be hurt, but so that they positively cannot be hurt.

Plan to Get More Large Coal

Payment for coal upon a run-of-mine basis is unsatisfactory to the operator and should be to the miner as well. Coal is almost invariably sold upon a sliding scale of prices determined by the size the consumer demands; the larger the size, the higher the price. Of all the sizes, that bringing the lowest price is slack, which varies in size in different districts between that passing through a $\frac{3}{4}$-inch to that passing through an $1\frac{1}{4}$-inch screen. The selling price of slack coal also varies widely at certain seasons of the year, whereas that for lump remains fairly constant within narrow limits, and again the price at which slack is sold is more below the price paid for digging mine-run coal than the price of lump coal is above it. As an illustration, when the price of pick mining in the Pittsburg district is, say, 85 cents a ton, the selling price of lump coal during the Lake season will be $1.10 to $1.20, while the price of slack will vary about 75 cents as a maximum to as low as 35 cents. Adding a labor cost of 15 cents to each ton, the nominal profit on lump coal is from 10 to 20 cents and the loss on slack coal from 25 cents to 65 cents. Any method of mining or any system of payment that will reduce the proportion of slack in run-of-mine is, therefore, welcome to the operator.

If coal is paid for upon delivery to the tipple regardless of its condition, the miner naturally "gets it out" with the least possible labor. This means shallow mining, misplaced holes, excessive charges of powder and, consequently, an increased number of accidents. In order to save his muscles the miner usually risks both life and limb.

In order to overcome the disadvantage of paying upon a mine-run basis, that is for all the coal mined regardless of its condition, and at the same time to offer an incentive to the miner to produce a greater percentage of lump, one of the larger companies is trying out a plan which, after three months trial under rather adverse and irregular commercial conditions, promises very satisfactory results. The mine-run coal is weighed in the car as it comes from the mine. After screening, the lump coal is weighed separately. The difference in these weights gives that of the fine coal which comprises the nut, pea, and slack.

In order to arrive at a just price for these two grades the proportion of each in the mine run was determined from the weights of coal sold for a period of three years. Knowing the proportions of lump and fine coal and having the mine-run price, it was easy to deduce a price for each grade separately. Any increase in the proportion of lump coal means an increased income for the miner and vice versa.

With an irregular run, as stated, the plan is giving good results, indicating a decrease in the proportion of fine coal of about 9 per cent. (about 7 per cent. in the pea and nut combined and 2 per cent. in the slack) and a corresponding increase in the amount of lump.

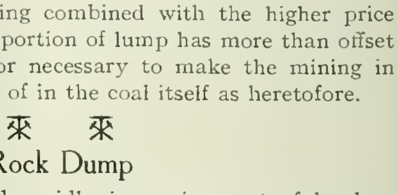
The reduction in the amount and cost of the powder used by reason of proper mining combined with the higher price received for the larger proportion of lump has more than offset the slightly increased labor necessary to make the mining in the soft underclay instead of in the coal itself as heretofore.

Rock Dump

The already high and rapidly increasing cost of lumber, particularly of the larger sizes needed for the posts and caps of rock dumps, renders advisable the adoption of devices which will increase the width of the dump per unit of length. As ordinarily arranged, unless excessive shoveling be done, rock dumps of the end-discharge type rarely give a top width of more than the length of the tie, say, about 5 feet.

In the August issue of Mines and Minerals was described the machine in use at Cokedale which gives a top width of rather more than 54 feet, and here is noted one used at the Cameron mine, Walsenburg, Colo., which, while the top width resulting from its use does not approximate to that obtained at Cokedale, is much simpler in construction.

The dump consists essentially of three plates of $\frac{1}{2}$-inch iron 3 ft. × 4 ft. in size. To the top plate are bolted a pair of mine rails with the ends bent up into horns. This upper plate revolves on the mine car axle, *e*, the bearings for which are supported upon a mine rail and bolted to the middle plate. A piece of channel iron, *d*, is bolted to the middle plate and upon it the dump falls back after a load of rock has been discharged. The upper plates as a unit revolve upon the two annular pieces of iron, *b*, 22 inches in diameter. The kingpin, *c*, is 1 inch in diameter and the plates, where it passes through them, are reinforced by a piece of $\frac{1}{2}'' \times 3''$ bar iron. The lower plate is supported by four short lengths of 12-pound mine rail.



Rock Dump at Cameron Mine

This dump, handled by 2 men, gives a top width of from 10 to 12 feet or rather more than double what it would if of the end-discharge type. The trestle has therefore to be advanced only one-half as fast as usual and the saving in materials and labor is obvious.

As this dump was made from materials on hand at the mine, certain changes might be advisable if specially constructed. The dump might be mounted on a truck for ease in moving forward, bars or channels might be substituted for the plates, and, in order to reduce friction, the upper portion may be made to revolve upon small wheels or rollers instead of flat rings.

However, it admirably fulfils the idea of adding to the available top width of the dump and is to be commended therefor.

Oscillating Screens and Concrete Construction

Editor Mines and Minerals:

Sir:—Will some reader of Mines and Minerals advise the writer if there are any concrete tipples in this country using shaking screens. Is it advisable to use a concrete structure with oscillating screens imparting constant vibration to the structure? J. E. B.

Stearns, Ky.

Early Watering of Mines and Employment of Shot Firers

Editor Mines and Minerals:

Sir:—On page 66 of the September number of your magazine you request your readers to advise you if they know of an earlier date than May, 1895, on which watering of dust was practiced, or shot firers were employed in American mines. If you will turn to the proceedings of the Mine Inspectors' Institute that was held in your city, or to my second annual report as Chief Mine Inspector of this state, on page 11 you will find a complete history of when shot firers were first employed in what was then the Indian Territory. You will find that shot firers were employed in 1885 in the mines of Krebs and Savanna, Indian Territory. I was one of the first men employed to fire shots. Up until that time I did not think that anything but firedamp could cause an explosion in a coal mine, but I was soon convinced that firedamp was not a necessary factor in producing explosions, and that coal dust and cold air when mixed formed an extremely explosive mixture, and a shot overcharged with powder that will create an intense heat and flame will cause it to explode. I insisted that the company sprinkle the dust, which was done, although it did not stop explosions. The same year I used the exhaust of the pump, and the more I studied and experimented the more convinced I became that steam was a solution of the problem. We laid pipes and allowed steam to escape into the intake airway; the steam as it escaped warmed the air, making the mine's condition practically the same in winter as in summer, and we had no windy shots or explosions while we used the steam. These experiments were all made in 1885. I am sending you under separate cover a copy of my second and third annual reports in which you will find all the information you desire. Pete Hanraty

McAlester, Okla.

Early Shot Firers

Editor Mines and Minerals:

Sir:—Regarding Mr. Watson's article on shot firers and road sprinkling. He may have originated the latter in sprinkling with hose and nozzle, but watering roads in coal mines was established in Indian Territory, now Oklahoma, long before the time Mr. Watson speaks of. I was then a driver and watered the entry roads many times. We used a common water car with a 3-inch crescent-shaped pipe attached to one end of the car. On April 1, 1885, an explosion occurred in Savanna mine No. 2, 20 miles south of McAlester, Okla., on the M., K. & T. Railroad. The mines were very gaseous and also dusty. No. 1 and 2 mines employed shot firers a year previous to this explosion, which took place April 12, 1885. The shot firers who were killed in this explosion were Hugh Dooley, Davey Jones, and Charles Parsons. Also one driver and one rope rider, Bert French. There was one more shot firer whose name I cannot recall and 12 rescuers lost their lives in this accident, making a total of 18 men. This was practically a new mine, the slope was down 18 levels, or about 1,500 feet. It was a double slope with two tracks and entries turned 300 feet apart on both sides. All stoppings were put in with rock, lime, and sand. This slope was so badly wrecked by the explosion it never was reopened. The readers of Mines and Minerals will find that shot firers were employed long before Mr. Watson speaks of, as this was nearly 27 years ago. Wm. Clarke

Bowen, Colo.

Coal-Dust Explosions

Editor Mines and Minerals:

Sir:—I notice in your issue for September an article by John Verner, State Mine Inspector of Iowa, in which a quotation from Professor Payne's evidence at the Monongah inquiry is made as follows: "Had there been sufficient air to support combustion, the almost incredible pressure of 21,600 pounds per square foot would have been reached with a temperature of 4,683° F."

Mr. Verner does not say that he considers it "incredible," but the experiments made at Altofts in England and Lievin in France show that it is not nearly so high as is actually developed in experimental galleries.

Assuming that the experiences of the men referred to by Mr. Verner were actually as related by them, then it follows that there is no "pioneering cloud of dust" traveling in front of an explosion of coal dust, and the explosion must therefore be due to the dust normally in the mine ventilation, and not to that deposited on the perimeter of the roadways.

Personally I am pleased to see on page 81 another of Mr. Verner's communications, viz.: "Lessons to Be Learned From Recent Disasters," in which he says that a mine cannot be rendered immune from explosions under any conditions by the application of moisture; and this emphatically supports my long time opinion on this subject. (See my article on the subject of watering in Mines and Minerals in 1903.)

James Ashworth

Watering Dust in Utah

Editor Mines and Minerals:

Sir:—In the September number of Mines and Minerals there is an editorial entitled "An Historic Mine," in which the statement is made that the first watering of dust in mines of this country was done in the Como mine No. 5 of Park County, Colo., in 1895.

I desire to correct this statement, as it can be proven that sprinkling by hose and also spraying the intake air by means of steam and water was employed in the Castle Gate mine of the Utah Fuel Co. as early as 1892.

For proof of this I beg to refer you to the report of the United States Inspector of Coal Mines for the Territory of Utah for the year 1892. Mr. Robert Forrester, deceased, then United States Inspector and later geologist for the Utah Fuel Co., reported as follows:

"The dust of the mine is very inflammable, and extra precautions have to be taken for the safety of the workmen employed therein.

"The dust is kept in a very wet condition by means of water pipes laid throughout the entire mine, and water is taken to the working faces by a hose. Two men are employed at this work regularly.

"On the intake airways there are vertical water pipes at regular distances, with a ½-inch pet cock at the top. The water emerging from these pet cocks is struck in a horizontal direction by steam under a pressure of 30 pounds per square inch (escaping from a pet cock of the same size), the water being blown into a fine spray and the most of it being taken up by the air passing along the gallery.

"On the outside the hygrometer frequently registers a difference of from 20 degrees to 35 degrees between the wet and dry bulb thermometers, and at a point 1,500 feet from the mouth of the mine the difference registered seldom exceeds 1 degree, while at the far end of the mine, 4,000 feet from the mouth of the mine, the air has been fully saturated for over a year past."

This report is dated March 4, 1893, for the year 1892. Farther on in the report is given a table showing relative humidity, dew point, and grains of water per cubic foot of air for each month of the year 1892, which proves conclusively that sprinkling was in full practice in this mine in January, 1892, and was probably installed previous to that.

Owing to the fact that most of the writers on this subject have been eastern men unfamiliar with coal-mining operations in Utah, the gentlemen in charge of the mines at that time have been given little credit for the work they did. The facts are that methods were employed in Utah years before they were in other parts of the country and the operators of that time were really pioneers in the use of electricity, sprinkling, and electrical firing of shots from the outside after all the men were outside the mine.

A. C. Watts,
Chief Engineer Utah Fuel Co.

Answers to Examination Questions

Utah Mine Foremen's, February, 1911, and Selected Questions from Illinois Examinations, 1910

(Continued from September)

Ques. 23.—What are the general requirements in regard to the construction of doors, overcasts, and stoppings? State their several uses.

Ans.—The general requirement is that all doors, overcasts, and stoppings in mines shall be substantially built of incombustible material and made air-tight. Doors should be hung so as to close with a slight fall with the air-current. As far as practicable, doors should be located where they will not endanger the lives of drivers or runners. Doors are used in mines to deflect air-currents and permit the passage of men and coal. Overcasts are used to conduct one air-current over another that crosses its path; an overcast is often used to obviate the use of a door and supply a separate air-current to a certain district or pair of entries. Stoppings are employed to close the openings of abandoned places and cross-cuts no longer needed.

Ques. 24.—A rectangular airway 8 ft. × 10 ft. is 5,000 feet long; what must be the length of an airway 6 ft. × 6 ft. that will have the same amount of rubbing surface?

Ans.— $\frac{8+10}{6+6} \times 5{,}000 = 7{,}500$ ft.

Ques. 25.—Explain the principle of the safety lamp.

Ans.—The flame of the lamp is surrounded by a chimney of wire gauze, or glass and wire gauze, by which it is completely isolated from the atmosphere outside the lamp. The mixed air and gases enter the lamp through the meshes of the gauze, the gas often burning inside of the lamp chimney, which may at times become filled with flame. The metal wire absorbs the heat of the flame in proximity to the gauze, and thereby reduces the temperature of the burning gas below what is required to maintain the combustion, and the flame is therefore extinguished and prevented from passing through the gauze as long as the gauze keeps sufficiently cool.

Ques. 26.—Describe in detail the Davy and Wolf safety lamps, or other makes of lamps with which you are familiar.

Ans.—The Davy lamp is an oil vessel surmounted by a gauze chimney, the top of which is protected by a gauze cap that fits over that portion of the chimney. The Wolf lamp is a special lamp designed to burn naphtha. The chimney is of glass surmounted by gauze which is protected by a steel bonnet. The lamp requires an igniter being placed in the lamp owing to its being readily extinguished. The volatile nature of the oil causes the lamp to heat quickly in gas, which renders the lamp unreliable for testing purposes. The American Beard-Deputy lamp is a Marsaut type, admitting its air below the flame and having a double-gauze chimney with or without bonnet. The glass is 3½ inches in height. The lamp burns ordinary sperm or cottonseed oil, gives a good light, and with an indicator shows as low as ½ of 1 per cent. of gas by the plain incandescence of the platinum wires of the indicator.

Ques. 27.—Explain fully what regulations you would adopt for the use of safety lamps in mines.

Ans.—There should be an adequate number of safety lamps of an approved pattern kept on hand at every mine, ready for use in time of need. Safety lamps should not be introduced in a mine as long as it is possible to maintain a safe condition of the mine atmosphere by means of an ample ventilating current properly distributed. In districts of a mine where safeties are required at the working face the use of open lights should be strictly forbidden. The use of mixed lights in any district of a mine should never be allowed. All safety lamps used in a mine, except the lamps of the fire bosses, should be the property of the company and in charge of a duly authorized person who shall direct the entire care of the lamps and their delivery to workmen. All fire bosses should own and care for their own lamps. None but fire bosses should be allowed to carry lamp keys or have the same in their possession in the mine.

Ques. 28.—Which are the most dangerous gases met with in coal mines?

Ans.—All mine gases are or may be dangerous.

Ques. 29.—Name the gases met with in coal mines, giving their symbols, and their effect on the human system. State which are explosive and which non-explosive.

Ans.—Marsh gas or methane (CH_4); if breathed, pure methane would suffocate, but mixed with sufficient air it produces only a slight dizziness. Carbon monoxide (CO); extremely poisonous causing death. Carbon dioxide (CO_2); causes headache, nausea, pain in back and limbs, and death by suffocation. Hydrogen sulphide (H_2S); poisonous, deranges the system and causes death. Olefiant gas (C_2H_4); its effect on the system is similar to that of marsh gas. With the exception of carbon dioxide, all these gases form explosive mixtures with air.

Ques. 30.—What is afterdamp, and why is it, at times, so much more fatal and dangerous than at other times?

Ans.—Afterdamp is the variable mixture of gases that remains in the mine workings as the result of an explosion of gas or dust, or both combined. The deadly nature of the afterdamp is determined chiefly by the percentage of carbon monoxide it contains. When the supply of air, at the moment of explosion, is limited, the combustion is incomplete and carbon monoxide is formed, which is extremely poisonous and renders the afterdamp more quickly fatal than when the explosion takes place in a plentiful supply of air, and carbon dioxide results.

Ques. 31.—(*a*) Could you depend absolutely on a safety lamp for the detection of all gases produced in a coal mine? (*b*) What other methods would you adopt for the detection of gases?

Ans.—(*a*) No; neither carbon monoxide nor hydrogen sulphide should be sought with the lamp. (*b*) The former should be sought by observing the behavior of a small caged mouse, which is prostrated and rendered helpless by this gas in about one-twentieth of the time required to produce the same effect on a man. The latter gas is best detected by its peculiar odor.

Ques. 32.—Describe the action of the flame of a safety lamp when exposed to the different gases found in coal mines.

Ans.—Marsh gas elongates and increases the size of the flame, producing also a pale-blue flame cap, only visible when the gas approaches 3 per cent. Olefiant gas associated with marsh gas renders the flame more violent and disturbed, and the cap is not as plainly seen. Carbon monoxide lengthens the flame and increases its brightness somewhat. Carbon dioxide dims and reduces the size of the flame till it is finally extinguished if sufficient gas be present. Hydrogen sulphide is never present in sufficient quantity in mines to produce any effect on the flame of a safety lamp.

Ques. 34.—In mines where fires due to spontaneous combustion are common, what is the first evidence that such a fire is in progress, and what means should be taken to extinguish the same?

Ans.—The experienced miner easily detects the existence of such fire by the peculiar odor or taint given to the air in the vicinity. Later the presence of the fire is revealed by the increased temperature of the adjoining workings.

Ques. 36.—State in detail what should be done to reduce the number of accidents due to falls of rock and coal, and movement of mine cars.

Ans.—Increase if possible the efficiency of the inspection of all working places. See that the required supplies of timber and caps are delivered promptly to the men; and insist that the work of securing the roof in all working places shall receive attention before the work of loading coal is begun. Instruct miners how to timber their places properly. Make it the first duty of all miners to sound the roof in their several working places upon first entering the same in the morning and after firing a shot. Provide good haulage roads of sufficient width to allow persons to pass cars on one side of the track at least. Keep tracks in good order, well cleaned and timbered. Arrange suitable turnouts with automatic switches, making the straight track the loaded track. Have inside drivers observe strict rules in regard to passing point. Avoid placing doors at the bottom of grades where cars may not be fully under control. Provide refuge holes for door boys. Provide suitable traveling-ways and allow no traveling on rope- or motor-haulage roads.

Ques. 37.—Where does the most dangerous dust lie, on the floor, walls, gob, or timbers?

Ans.—The dust that accumulates on the walls and timbers is not only on the whole finer and more easily thrown into suspension in the air by any disturbance, but it has generally absorbed more oxygen and is more inflammable and dangerous than the dust that lies on the floor.

Ques. 38.—How tight should props be set or wedged in rooms and entries?

Ans.—Room timbers, in particular, should only be wedged tight enough to insure that the post will not fall out, or cannot be knocked out easily. The settlement of the roof will always tighten the post, and all post timbers should be closely watched to determine the action of the roof and its progress.

Selected Questions of the Illinois (1910) Examinations Held at Springfield, Illinois

Note.—The following questions, selected from different examinations, are here numbered consecutively. The date and kind of examination and number of the question follow each question; indicated as follows: (*M*) mine managers'; (*E*) mine examiners'; (*H*) hoisting engineers' examination.

Ques. 1.—If a 42-horsepower fan is producing 113,224 cubic feet of air per minute in a certain mine, what volume of air will a 50-horsepower fan produce at the same mine, under the same conditions? M., Q. 3, 1-17-10

Ans.—Assuming equal efficiencies, the air volume will be proportional to the cube root of the power; or the volume ratio will equal the cube root of the power ratio; thus, calling the required volume x,

$$\frac{x}{113{,}224} = \sqrt[3]{\frac{50}{42}} = \sqrt[3]{1.190476+} = 1.06, \text{ nearly}$$

$$x = 113{,}224 \times 1.06 = \text{say, } 120{,}000 \text{ cu. ft. per min.}$$

Ques. 2.—What thickness of pillars should be left around the shaft bottom, in the Illinois, No. 5 seam, the coal being 4 feet 10 inches high and the shaft 450 feet deep; while the average cover is 475 feet? Underlying the coal is 2 feet of fireclay and under that 3 feet of lime rock. Overlying the coal is 2 feet of slate and above that 8 inches of cap rock; above that again 12 feet of sandstone overlaid with shale, clay, and soil. What should be the thickness of pillar between the main entry and return airway? What thickness of pillars should flank the main entry and airway, dividing them from the rooms? What should be the thickness of the cross-entry pillars in this mine? The shaft is in the center of a coal field of 640 acres. M., Q. 4, 1-17-10

Ans.—The diameter of a circular, or the length of side of a square, shaft pillar should be, in this case, $6\sqrt{D \times t} = 6\sqrt{450 \times 4.83}$ = say, 280 feet. To determine proper width of entry pillars it is important to first ascertain as nearly as possible the safe width of opening (w) under the given conditions. This will depend chiefly on two factors, the strength of the roof rock and the depth of cover. In the absence of practical data, divide the strength of the rock (say, 1,500 pounds per square inch) by the depth of cover in feet, extract the square root of the quotient and multiply by the thickness of the rock in feet; thus, $w = 12\sqrt{\frac{1{,}500}{475}} = 21+$ feet. If the overlying material is firm hard strata this width of opening may be increased 25 per cent., giving in this case, say 26 feet. In the present case, the main entry pillars should be 25 feet wide; the pillars flanking the main entry and air-course 30 feet, and the cross-entry pillars 20 feet wide.

Ques. 3.—If 3.5 horsepower is required to circulate 10,000 cubic feet of air in three airways, each 6 feet × 5.5 feet in section, what horsepower will be required to produce the same circulation in a single 10′ × 10′ airway; all the airways being of the same length? M., Q. 5, 1-17-10

Ans.—The combined perimeters and the total area of cross-section for the three airways are $o = 3 \times 2\ (6 + 5.5) = 69$ feet; $a = 3\ (6 \times 5.5) = 99$ square feet; for the single airway, $o = 4 \times 10 = 40$ feet, $a = 10 \times 10 = 100$ square feet. The power producing circulation is proportional to the perimeter and inversely proportional to the cube of the area; or the power ratio, in this case, is equal to the product of the perimeter ratio and the cube of the inverse area ratio; thus, calling the required horsepower x,

$$\frac{x}{3.5} = \frac{69}{40}\left(\frac{100}{99}\right)^3 = 1.778, \text{ nearly;}$$

$$x = 3.5 \times 1.778 = 6.222 \text{ H. P.}$$

Ques. 4.—How many acres and tons of lump coal can be mined from the following described piece of land: Commencing at the southwest corner of the northwest quarter of Section 25, thence running due north 500 feet; thence, N 85¼° E, 532 feet; thence, N 81¾° E, 733 feet; thence, N 76½° E, 521 feet; thence, N 79½° E, 665 feet; thence, S 75¾° E, 336 feet; thence, due south 816 feet; thence, westerly to place of beginning? The average thickness of the coal in the seam is 4 feet 6 inches; allow 27 cubic feet of coal in place per ton, 20 per cent. for waste, and 30 per cent. fine coal? M., Q. 6, 1-17-10

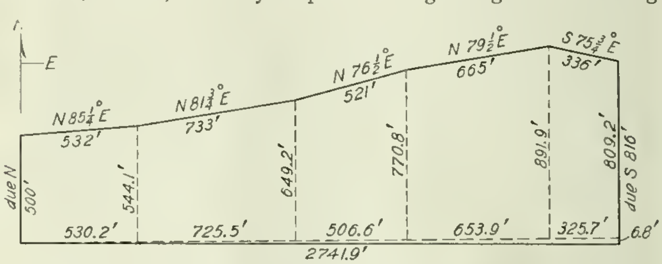

Fig. 1

Ans.—Following is the traverse and Fig. 1 is the diagram of the survey:

Course	Distance	N	S	E	W
Due N	500	500.0			
N 85¼ E	532	44.1		530.2	
N 81¾ E	733	105.1		725.5	
N 76½ E	521	121.6		506.6	
N 79½ E	665	121.1		653.9	
S 75¾ E	336		82.7	325.7	
Due S	816		816.0		
		891.9	898.7	2,741.9	
			891.9		
			6.8		

The area of the survey is calculated as follows:

	Square Feet
530.2 × ½ (500 + 544.1)	276,791
725.5 × ½ (544.1 + 649.2)	432,869
506.6 × ½ (649.2 + 770.8)	359,686
653 9 × ½ (770.8 + 891.9)	543,620
325.7 × ½ (891.9 + 809.2)	277,024
½ (6.8 × 2,741.9)	9,322
	1,899,312

Area of survey 1,899,312 ÷ 43,560 = 43.60+ acres.
Mineable lump coal, estimated, .50 (1,899,312 × 4.5) ÷ 27 = 158,276 tons.

(*Continued in November issue*)

Scientific coal mining requires that the plan of mine be so arranged that main entries be driven to the boundary lines of the property. From this point rooms should be driven in panels so that all coal may be speedily removed. In the end this system pays the operator.

ORE MINING AND METALLURGY

The Pioche, Nevada, District

Interesting Geological Conditions. Mines Made of Value by Improved Transportation Facilities.

*By R. M. Bell**

The famous old camp of Pioche is the county seat of Lincoln County, Nev. It is reached by way of the main line of the San Pedro Railroad to Caliente, thence by a branch line 32 miles in length running north to Pioche.

The name would imply that a Frenchman was one of its first citizens, and the fact that a double row of old locust trees borders its main street, which add a homelike touch to a general desert aspect, would also indicate that the advance agents of the Mormon church were in at the making of the new camp.

The general typography of the surrounding country is typical of Nevada. A broad desert valley 10 to 15 miles wide extends north for 75 miles above Caliente, with an elevation varying from 4,000 to 6,000 feet above sea level, and is bordered on either hand by prominent north and south mountain ranges composed of a vast accumulation of ancient sedimentary formations and igneous rocks that reach a maximum elevation of 9,500 feet above the sea level.

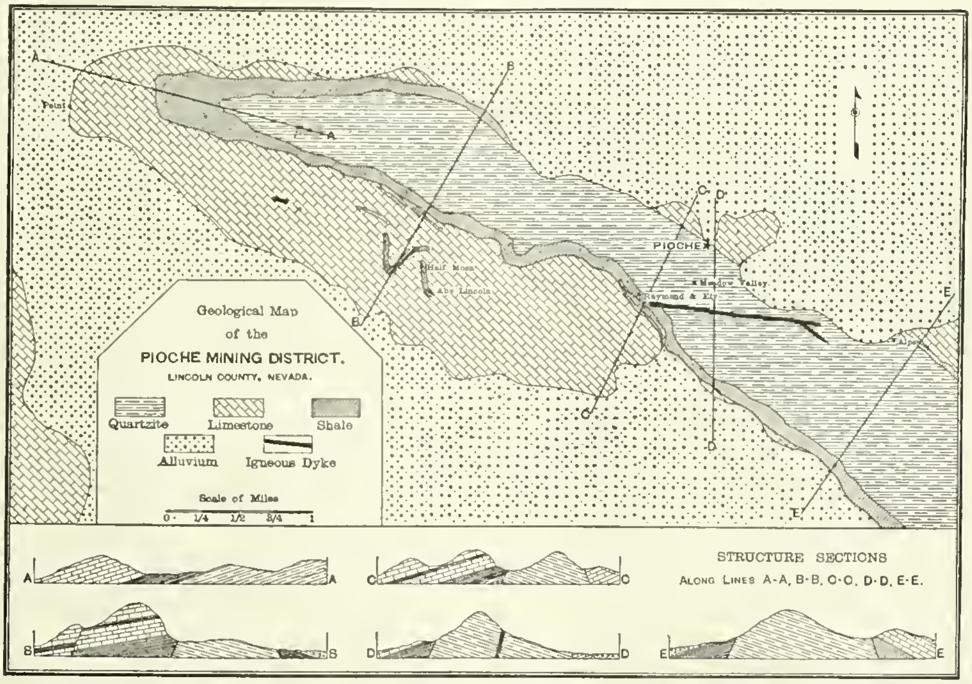

Fig. 1

The Ely mining district is the legal name of the recorded district immediately surrounding Pioche. This name should be changed by petition to avoid confusion with the Ely copper district further north. The recorded mining district covers a low mountain ridge that strikes obliquely across the main valley with a general trend a little north of west and south of east. This uplift presents a topographic freak, and is probably due to a buried laccolite of igneous matter relatively rich in metals, and the source of the district's rich mineralization.

The Pioche ridge, shown in Fig. 1, is separated from the main west range by a valley of erosion a mile wide and dying out to the east before it reaches the opposite range. It is 15 miles long by about 3 miles broad.

The Pioche mines were discovered in 1869. The nearest railway point at that time was on the Central Pacific, at Winnemucca, Nev., 300 miles to the north. The principal mines were rapidly located, as their rich ores outcropped to the surface in many instances, and a wild stampede from the north soon followed. In 1872 the camp had a population of 10,000 people, and tradition says it was about the wildest proposition in western mining life ever recorded, since its daily paper had from one to half a dozen men for breakfast as common news items. The original claims were located only 200 feet wide under the old law and owing to the complex system of parallel and intersecting fissures, conflicting claim lines, and confused apex rights to the rich ore bodies, the costs of fighting men to protect their rights soon constituted a big item in the running expenses of the principal companies.

In 10 years subsequent to their discovery the main quartzite fissures of the Raymond-Ely and Meadow mines had been stoped in a close succession of rich ore shoots 2 to 6 feet thick for a continuous stretch of 2,000 feet and to a depth of 1,200 feet, and had yielded a gross output of $20,000,000 at a net profit of $5,000,000. The ore was a friable quartz gangue, containing lead carbonates associated with silver chloride and native gold, and is said to have averaged over $200 per ton, of which 20 per cent. was gold and the balance silver. The ore was treated by the pan grinding and amalgamation process. Dry Valley and Bullionville being the principal milling points, 6 and 12 miles distant, respectively.

The early cost of mining and milling, as given in the government reports, averaged $75 per ton, and an accumulation of 150,000 tons of tailings at the milling points, containing an average value of 8 per cent. lead, will give an idea of the difficulties the pioneer mill men and metallurgists met and overcame.

The veins were dry down to a depth of 1,200 feet, where water and base ores were encountered. The latter were equally rich in gold and silver but contained too much lead and zinc to admit of a profitable extraction of the precious metals by milling, and so the industry rapidly waned.

In years subsequent to 1879 several attempts at smelting were made with an additional yield of something like $10,000,000 from these and neighboring mines, but with coke as fuel for this purpose, hauled long distances by rail and overland by wagon freight from Modena, Utah, 140 miles distant, very little profit could have been made.

* Formerly State Mine Inspector of Idaho.

With the recent advent of the San Pedro Railway into the camp, it has taken on a new lease of life, and activity has been stimulated all along the line. The camp has a present population of about 1,200 people. There are already a dozen gasoline mining plants in operation, ranging from 10 to 100 horsepower capacity, engaged in shaft sinking and mining development enterprises, and also a score or more of operations with temporary equipment of whip, whim, and windlass. Results in rich ore development are being obtained that give promise of rewarding the San Pedro for its advent with one of the most important sources of mineral traffic in the West. The richness and permanency of the ore deposits are established and their number and variety are remarkable.

Geological Conditions.—After arriving at Pioche, the writer ran across a technical review of the geology and ore deposits of the district, published in 1906 by Prof. F. J. Pack, Professor of Geology at the University of Utah.

The geology of Pioche is simple as to the variety of its formations, but has some rather complicated structural features due to faulting and erosion.

The main east-west uplift is a simple anticlinal fold rising at Mt. Ely to a maximum elevation of about 1,000 feet above the general level of the valley. The main axis of the ridge is heavy bedded, low dipping Cambrian quartzite of medium grain, stained reddish at the surface, but white and vitreous

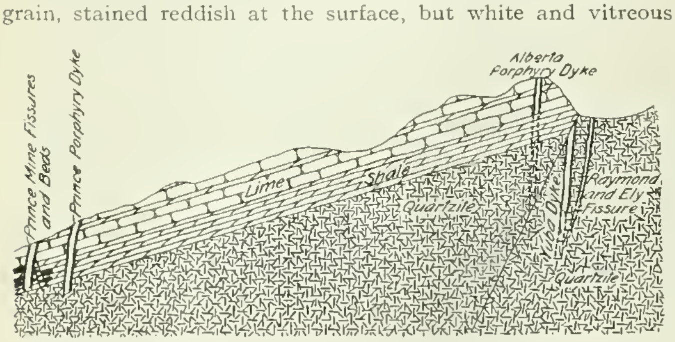

Fig 2

underground, without any secondary cleavage, but in places shattered.

The quartzite is flanked with conformable beds of clay shale, probably 500 feet thick, carrying a rich array of Cambrian fossils.

The main shale beds are succeeded by 400 or 500 feet of massive blue and gray limestone beds that have been greatly reduced by erosion, and disturbed by faulting, bed slipping, mineralization, and the intrusion of an important series of igneous dikes, as shown in Fig. 2.

The main west range is probably of similar origin to Pioche ridge, but on a broader scale. Its eastern base and for some distance up is composed of Cambrian limestones that are said to shade up into Silurian and higher horizons to the west and to represent a total connected series of ancient sediments fully 20,000 feet thick.

This west range is cut into segments by lines of northwest and southeast faulting and erosion. These features are locally called gaps and passes, of which Stampede Gap and Bristol Pass are examples.

Stampede Gap is 10 miles west of Pioche, and the mountain to the south of it for 15 miles in length, with its center 7 miles southwest of Pioche, is richly mineralized, and carries the Mendha and other properties that have made a bow to the mining world in the matter of rich ore production. This section is known as the Highland Mountains, and the Highland district.

North of Stampede Gap and extending to Bristol Pass, 15 miles farther north, is another mountain of heavy bedded blue and gray limestones, breccia conglomerates, and intrusive dikes, known as the Jack Rabbit Mountain, with the Bristol, Day, Onondago, Hillside, Star, and other noted and promising ore deposits and producers near its northern end.

The west slope of this main range was not visited, but it is said that its altered sedimentary formations have been ruptured by a north and south outburst of gigantic monzonite, along the borders of which a rich array of contact metamorphic minerals occur, including large bodies of iron, garnet, and epidote, associated with rich silver, copper, gold and ore samples, and that some very interesting prospects are there in evidence.

The Pioche Record mining district above outlined, including Highland, Jack Rabbit, and Bristol, can practically duplicate in form and physical features all the more successful silver-lead and lead-silver ore deposits in the United States, and is sufficiently developed to identify the types. The flat bedded and contact deposits of Missouri and Leadville, associated with limestone, shale, and quartz porphyry are in a strong measure represented by the Mendha, Half Moon, Old Timer, Point, and Demijohn mines. The vertical fault fissures and ore-bearing shear zones of the Coeur d'Alenes are represented by the Raymond-Ely, Yuba Dike, Susan Duster, and Greenwood veins, while the great lens-shaped chamber deposits, and the bed-connected contraction and fault fissuring that have been such rich ore producers in Utah are represented by the Prince Consolidated, Day, Bristol, Star, Hillside, and others.

The ore deposits of Pioche are practically intact and uninjured by erosion, like those of the Coeur d'Alenes, and can be depended on to stand development and last in depth, except where locally displaced by faulting and leaching, to the point of original precipitation of the ascending mineral solutions that produced them.

This condition is demonstrated by the fact that the richest bonanza ore shoot of the Raymond-Ely mine was covered at its crest by 100 feet of shale in such a position on the quartzite axis of the uplift as to preclude the probability that it was ever connected through or exposed at the surface, except perhaps by a thin flat feeder in the shale bed.

The bonanza footwall fissures of the Prince Consolidated mine apex under 200 feet of limestone in the big gossan ore body, and the lower, flat-dipping, bedded deposits connect with those fissures at 300 and 400 feet deep.

The rich bedded ore body at the Mendha mine, carrying an average of an ounce in gold, 20 per cent. lead, and 20 ounces silver, was discovered at the bottom of an 800-foot incline shaft and vertically under 400 feet of limestone. It connects at this point with a vertical fissure that carries a different class of ore. This rich bedded deposit of silicious ore is probably rooted in a big vertical porphyry dike that traverses the limestones a few hundred feet to the south, which would form a good avenue of development and an easy formation in which to clip the ends of this and other associated ore-bearing beds of the Mendha group, and at the same time test out the ore-bearing possibilities of the dike itself. The famous Yuba dike ore shoots are all blind at the surface, and the big 30-foot ore body of sulphide mineral in the Susan Duster mine apexes as such at 10 feet under the surface.

The Raymond-Ely and Meadow Valley mines were operated entirely on a steep dipping fissure vein in the quartzite, that strikes nearly east and west and dips south at an angle of 60 degrees. From the 1,200-foot level of the Raymond-Ely shaft a cross-cut, driven south a few hundred feet, encountered a large porphyry dike striking due east and west, and also dipping south at an angle of 80 degrees. This dike is over 50 feet thick and consists of an extremely altered quartz porphyry. Within its structure, but lying next to its quartzite footwall, a body of massive black zinc-lead iron sulphide ore, several feet wide, was encountered, and a winze was sunk on it 300 feet below the 1,200-foot level, from which some drifting was done and ribs of clean galena ore encountered that were very rich in silver and gold. This is what was christened the Raymond-Ely

"Black Lead." Its discovery created quite a stock boom at the time, but the ore was too base to be of any value to the early-day operators.

The same dike was later found by a cross-cut at the 900-foot level of the Meadow Valley No. 5 shaft, 1,000 feet east of the first point, where a shoot of lead carbonate ore 200 to 300 feet long, rich in gold and silver, was worked nearly to the surface and produced over a million dollars worth of ore, on the Mazzeppa claim. A thousand feet further east, on the Yuba claim, another ore shoot was worked through an incline shaft 1,200 feet deep, and ore to the value of a million dollars extracted at this point.

This great stretch of rich ore-bearing porphyry fissures is owned jointly by the Nevada-Utah and Ohio-Kentucky companies. It is accessible at three points, varying from 300 to 1,200 feet deep, and could be rapidly put in shape for quite a heavy production of rich ore, which it must doubtless contain.

East of the Yuba claim the same dike is covered for a stretch of half a mile by the property of the Boston-Pioche Co., which is pushing down a 1,000-foot incline shaft on it that is already over 800 feet deep, and at the 300-foot level, where some little drifting was done, several carloads of the characteristic Yuba lead-silver ore were taken out and shipped last year; when drifting has been commenced at the deeper levels in this new shaft some very important strikes of rich ore can reasonably be anticipated.

This great ore-bearing porphyry dike is at present best exposed in the Pacific tunnel, where it has been cross-cut at a depth of 280 feet, drifted on and stoped for a length of 200 feet and a height of 50 feet.

To the writer this porphyry ore deposit presents the most attractive feature of the Pioche district, by reason of the striking structural similarity and probable origin, to some of the steady dividend-paying silver-lead ore deposits of north Idaho—notably the Standard, Mammoth, and the Hecla mines at Mace and Burke.

The Hecla mine is a nearly vertical zone of closely parallel shearing that followed an original dike-filled fissure of diabase porphyry in quartzite walls. This deposit was lean and carried very little commercial ore in the first 300 feet of depth below its apex. It gradually improved as development progressed, and at the 300-foot level it carries an ore shoot 1,000 feet long and up to 25 feet wide, consisting of two wide bands of galena ore, separated by extremely altered clayey diabase rock 5 feet thick and often showing a third central lensy streak of rich ore in the middle of the dike, and replacing its substance with galena.

A section of the Yuba dike deposit at the Pacific tunnel shows a smooth slickensided quartzite footwall, above which is a foot to 18 inches altered porphyry carrying disseminated lead-carbonate ore. A little past the center of the dike is a wider zone of fissuring and replacement that is 2 to 10 feet thick, accompanied with smooth, slickensided walls, and along the smooth slips kidneys and small lenses of friable quartz and clean, hard, carbonate ore occur, containing 50 per cent. lead, 200 to 300 ounces silver, and $20 to $30 gold per ton, while balance of the space is filled with white, chalky, kaolinized porphyry gangue, and disseminated sandy carbonate of lead, constituting a first-class concentrating ore containing average values of 2 to 8 per cent. lead, with 3 to 4 ounces of silver and 50-cents gold to each unit of lead. A similar altered porphyry ore zone follows the smooth quartzite hanging wall of the dike at this point, and I was informed that in the adjoining Yuba shaft workings in places diagonal stringers of rich ore connected the two south ore courses and commercialized the whole body from 10 to 20 feet wide.

These porphyry ore bodies are dry, stand well with little timbering, and owing to the light, chalky nature of the gangue, the lead and most of the silver and gold are readily recovered by ordinary wet methods of concentrating, and whatever silver chloride and fine gold escape into the tailing can be readily recovered by leaching.

Method of Smelting With Oil

Heat Generated Outside the Stack and Only Enough Coke Used to Reduce the Oxides

This article was written with a view to using petroleum as a blast-furnace fuel, and deals mainly with smelting concentrates, but in such smelting little slag is made in comparison with ordinary blast-furnace smelting, consequently fair criticism is invited and will be appreciated.

This article is to place before metallurgists a system of smelting ores of copper or lead carrying gold and silver, to a lead base bullion or to a copper matte, or to base copper metal. Heat for this system is produced by the use of a hydrocarbon fuel, such as petroleum, burned in a combustion chamber out of contact with the ores, instead of coke or charcoal being charged in with the ores, as in the present practice.

Oil, gas, coke, or charcoal is burned in a combustion chamber outside the blast furnace stack, and the heat generated is conveyed to the ores in the stack through suitable flues to a point immediately below the tuyeres, and such heat is subject, for intensity and quantity, to easy, absolute, and instantaneous control.

Burning coke or charcoal for the production of heat, in contact with the ores being smelted tends, in most instances, to modify the result sought when smelting ores for their gold, silver, copper, and lead, on account of the high percentage of glowing carbon, or else on account of air blown in to burn such fuel.

In the reduction of lead oxide or of copper oxide, atmospheric air or oxygen has no part, because it is the contained oxygen of these minerals that is sought to be eliminated, and any air blown in is an opposing factor.

The production of heat within the blast furnace by burning coke in contact with the ores, as in the old system, involves blowing into the furnace quantities of air which comes in contact alike with the coke, unreduced oxides, and with the reduced metal in the sublimed condition. Its mission is to oxidize, or burn the coke for the production of the heat necessary for smelting, but while it does this it also oxidizes some reduced metal and by contact with oxidized mineral it resists the reduction of such mineral to metal. It is only by the predominance of the reducing atmosphere of the burning coke in the blast furnace that the method in common use succeeds, and, manifestly, smelting is done in spite of the oxidizing tendency of free air blown into the stack. Always some of the oxidized mineral is blown upon by the air blast and so resists the reducing tendency of the furnace atmosphere, and some metal that has been reduced in the reducing atmosphere predominant is oxidized by the air blast and sent to the dust chamber, or to the slag as a silicate.

No air should ever be blown into a reducing furnace, other than the little that may be requisite for burning carbon to the monoxide to increase the reducing action of the furnace atmosphere.

A simple laboratory illustration of the reactions involved in smelting lead-gold-silver ores to a lead base bullion is to take a glass tube, seal one end and half fill it with roasted lead ore, mixed with about half its bulk of coarsely pulverized charcoal. Stop the open end of the tube, leaving a small aperture for the escape of gases. Heat the tube over a Bunsen burner until the contents are red hot, when the charcoal will have absorbed or combined with the oxygen of the ore and the lead will be in the form of metal as base bullion carrying the gold and silver of the ore. As the process goes on, the heated gases evolved flow outward at the opening in the end of the tube, thus preventing the ingress of air, and the process of reduction to metal is finally complete.

Atmospheric air, if admitted to the highly heated ore and fuel in a blast furnace, is counteractive of the reactions involved in the ore-reducing process; and proportionately to the amount of air admitted is the result compromised by imperfect or incomplete reduction, and the reoxidizing of some of the metal already reduced in the form of vapor.

The usual method of lead smelting is subject to this adverse condition, for it is physically impossible to blow the necessary quantity of air to burn the fuel without exposing some of the already reduced metal to its direct action. Hence, chiefly, the necessity for capacious and expensive dust chambers in general use. This also is a prolific cause of lead silicates in slag.

The perfect system consists in the introduction of the necessary quantity of heat to the ore to insure the reactions involved when conditions are right; and conditions are right when the roasted ore and the necessary fluxes are introduced into the blast furnace with sufficient coke or charcoal to take up and react with the oxygen contained in the roasted ore, thus leaving the metal so reduced free to fall down into the crucible.

The ideal method of introducing the necessary heat into the blast furnace without the presence of air with its counteractive oxidizing influence is to burn petroleum or other hydrocarbon in a combustion chamber and to conduct the heat so generated, together with the gases of combustion, through suitable flues into the blast-furnace shaft, and thus into contact with the ore to be smelted. The roasted ore is heated then to the smelting temperature and the desired reactions secured without any possible contact with the atmospheric air.

The small amount of coke or charcoal charged into the furnace should be just sufficient in proportion to furnish carbon to combine with the oxygen of the ore; more than this would be waste of material. The exact proportion of coke or charcoal necessary for this purpose is readily calculated.

The following illustrates a typical instance of such calculation: Assuming 1,000 pounds of charge with 15 per cent. lead and 30 per cent. iron in the charge, the lead as oxide, PbO, in a roasted lead ore, and the iron as ferric oxide, Fe_2O_3, in the form of hematite added as flux. Then 207 parts by weight of lead combine with 16 parts by weight of oxygen; therefore, $150 \times \frac{16}{207} = 11.6$ pounds oxygen combined with the lead; 12 parts by weight of carbon combine with 32 parts by weight of oxygen; therefore, $11.6 \times \frac{12}{32} = 4.35$ pounds carbon, are necessary to combine with the oxygen in the PbO.

The iron being in the form of Fe_2O_3 must be reduced to ferrous oxide, FeO, to combine with silica to form slag. In Fe_2O_3 there are 112 parts iron and 48 parts oxygen, therefore; $300 \times \frac{48}{112} = 129$ pounds total oxygen in the hematite; one-third, or 43 pounds, of which must be combined with carbon to reduce the Fe_2O_3 to FeO to combine with the silica and form slag. As 12 parts of carbon combine with 32 parts of oxygen, it requires $43 \times \frac{12}{32} = 16.12$. pounds of carbon to reduce the 300 pounds of Fe_2O_3 to FeO.

This makes $4.35 + 16.12 = 20.47$ pounds carbon necessary for each 1,000 pounds of charge, to which, if coke is used, add 16 per cent. to cover ash, moisture, and waste, making a total of 23.74, practically 24 pounds of coke to 1,000 pounds of charge, equal to 2.4 per cent. of the weight of the charge, for absorbing the oxygen in the roasted lead ore and reducing the lead, and in combining with the excess oxygen in the hematite to reduce it to FeO. Charcoal is the preferable form of carbon for this purpose, and about 2 per cent. of the weight of the ore charge is required, on account of its less percentage of ash, than assumed for coke.

Carbon dioxide, incident to burning petroleum in a combustion chamber, passes into the blast furnace and comes in contact with the glowing coke or charcoal, insuring the reduction to carbon monoxide of any such carbon as may have escaped contact with roasted ore at combining temperature. This CO gas permeating every space and coming in contact with every particle of the roasted ore, insures complete reduction of the oxidized lead ore to metal.

The same results may be attained as effectually without the use of coke or charcoal charged with the ore, by simply blowing into the combustion chamber an excess of oil over the equivalent of oxygen necessary for its complete combustion, thus generating any proportion of carbon monoxide in the furnace that may be necessary for the complete absorption of the oxygen in the roasted ore. This latter method, however, is not susceptible of so easy and accurate regulation, unless by the use of an entirely independent apparatus for injecting a predetermined quantity of the hydrocarbon to the smelting zone of the furnace shaft.

If the ore to be smelted is an oxide or carbonate of copper, the smelting process is the same as above and the product is black copper, carrying whatever gold and silver is in the ore.

In case sulphide-iron-copper ores carrying gold and silver are to be smelted to a copper matte, the process is modified by omitting the reducing agent. As in the foregoing case, the heat generated in a combustion chamber by burning petroleum or other hydrocarbon there, is passed with the gaseous products of such combustion, through suitable flues directly into the blast-furnace stack and thus into direct contact with the ores to be smelted, imparting to them the necessary heat, and the smelting process at once goes on. If the ore charge carries no more sulphur than is necessary for the matte, then no free air is blown into the blast furnace. If otherwise, and there is an excess of sulphur with its combined iron, then sufficient air must be blown into the blast furnace in the usual way to oxidize the sulphur.

A large amount of heat is produced in oxidizing the excess iron and sulphur in the ore and the amount of heat necessary to be produced from petroleum in the combustion chamber is reduced, and a saving of fuel is effected, the ultimate calorific value of the surplus iron and sulphur being utilized in the smelting operation, which proceeds with certainty and regularity unknown to other methods.

Supports for Feed Wires

At the Robison mine, of the C. F. & I. Co., Walsenburg, Colo., the method of supporting the feed wires upon the timbers having proved unsatisfactory, Mr. John Graham, superintendent, has used the following with satisfactory results. Having a considerable amount of 2-inch old iron pipe on hand this was cut into 5-foot lengths and bent into the shape shown in Fig. 1; the holes for the four porcelain insulators being drilled or punched as found convenient. After being set in holes drilled in the rib for the purpose the legs of the brackets were cemented in place.

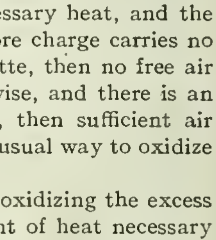

Fig. 1

In order to drill the holes, an ordinary post drill was mounted so as to be adjustable for height on the planking of a mine car on the side opposite to that on which the brackets were to be placed. The car, after having been loaded with brackets and cement sufficient for a shift, was dropped down the slope and stopped wherever necessary to drill the holes.

Aside from being an ingenious method of working up old material and of assuring the placing of the brackets at a uniform height above the rail, the system of doing the work cannot be too highly commended. By mounting the drill on the car, no labor is lost in moving it from place to place, and the material being in the "drill car" is where wanted when needed and time is not wasted in looking it up, as is too often the case.

Surveying and Sampling Drill Holes

Methods of Determining Course of Hole and Methods of Sampling Cores and Drill Sludge

In a paper read before the Lake Superior Mining Institute, at the August, 1911, meeting, E. E. White, after referring to previously described methods of controlling the curvature of diamond-drill holes, and the determination of their inclination by hydrofluoric acid tests, described the methods that have been developed by the Cleveland-Cliffs Iron Co. in the Lake Superior district, as follows:

After considering several methods of determining the course, as well as the inclination of drill holes, two were chosen for trial, one of which has proved satisfactory, the other moderately so. In non-magnetic rock formations the old method of a compass suspended in gelatine is successfully used with improvements worked out by Mr. George Maas and myself. Mr. Maas has patented his improved compass and his idea of using a thermos bottle in connection with the compass and gelatine. In magnetic formations a method of marking the drill rods is used in connection with hydrofluoric acid tests. This method was described to Mr. J. E. Jopling by Mr. John Deacon, superintendent of the Republic Iron and Steel Co.'s properties at Negaunee, who used it in testing diamond-drill holes at the Cambria mine. We did not find it as successful as using a compass, but it is the only method which I know that is practicable in magnetic formations.

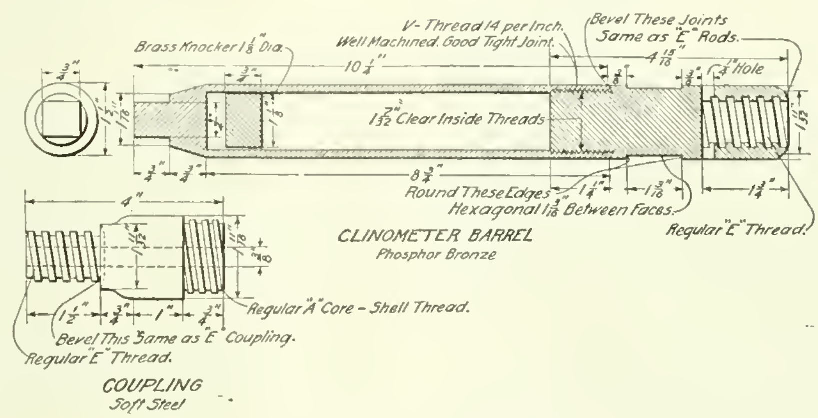

Fig. 1. Drill Hole Clinometer

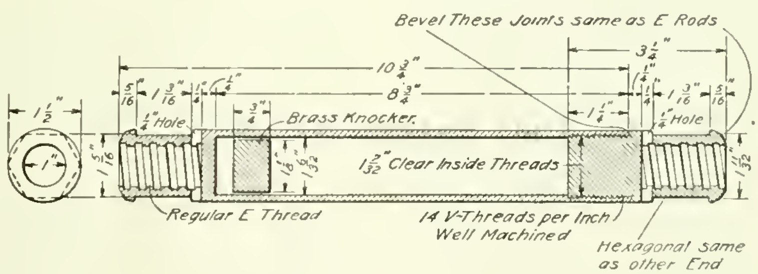

Fig. 2. Phosphor Bronze Drill Hole Clinometer

Surveying in Non-Magnetic Formations.—Figs. 1 and 2 show the cases used to test for inclination and course. The latter shows the case used when it is desired to make more than one test at the same time, as it may be inserted at any point in the drill rods at the same time that the first case is used at the end of the rods. As it is desired to use as large a glass tube in the case as possible, and as the outside diameter is limited by the size of an "E" hole, a material was selected which combined the greatest possible toughness and tensile strength with non-magnetic properties. Phosphor bronze was chosen, which is entirely non-magnetic, and for which the manufacturers guarantee a tensile strength of 70,000 pounds and elastic limit of 55,000 pounds per square inch. By using a case of dimensions given in Fig. 1, a glass tube 1½ inches outside diameter can be used, and according to Nystrom's formula for the collapsing strength of small tubes $P = \frac{4Tt^2}{f\,d\,V\,L}$, using a factor of safety of 4, this case should be safe in a hole 3,300 feet below water level. A little wicking is used to make a perfectly tight joint.

The compass invented by Mr. Maas is shown in Fig. 3. Its advantage over the old forms of compass used for this purpose lies in the fact that it is pivoted in a cage which prevents its coming in contact with the glass tube and insures its swinging freely in the gelatine. The cage is below and rigidly attached to the float, which is made of cork.

The most accurate and satisfactory method of testing the course of a hole is to use the compass in a glass tube open at each end and about 6 inches long. A section of rubber stopper is forced into the tube, leaving about 1½ inches for acid at one end and 4 inches for gelatine at the other. A small weighed portion of dry gelatine is carried to the drill and dissolved on the ground in a certain quantity of water, care being taken that the water has no chance to evaporate while dissolving the gelatine. The proportions are so chosen that when dissolved the solution will keep liquid as long as possible after being lowered in the drill hole and yet will become perfectly solid when cold. For instance, using Nelson's improved brilliant gelatine we use 5-6 gram and dissolve it in 50 cubic centimeters of water. In a hole where the rods can be lowered in 20 minutes or less, a 1½-inch tube is used with paper wrapping. When it takes from 20 to 30 minutes to lower the rods a 1-inch tube is used with several wrappings of paper. If deeper than this, a thermos bottle is used, and by using a paper wrapper the gelatine may thus be kept liquid 50 minutes. The time the gelatine remains liquid was determined by tests in ice water at 43° F., which is the temperature of the underground water.

In the first two cases when the thermos bottle is not necessary the dissolved gelatine is poured into the tube and heated as hot as possible by immersing the tube in water heated to boiling by live steam. When hot the compass is dropped in and a stopper placed in that end, then about 1 inch of dilute hydrofluoric acid is poured into the other end and that end closed. The tube is then wrapped in paper and placed with gelatine end up in the bronze case, which is attached to the bottom of 20 feet of brass "E" rods and lowered into the hole, losing as little time as possible. The brass rods are screwed to the bottom of the regular drill rods, an "A" to "E" reducing coupling being used if the hole is being drilled with "A" rods. The bronze case and brass rods are made for an "E" hole so that they can be used in either case. If two tests are to be made at the same time, another tube and compass are placed in the case shown in Fig. 2 and inserted in the drill rods at the proper point, using 20-foot brass rods on each side.

The tube is left stationary in the hole 50 minutes after the rods are lowered, giving the gelatine time to cool and set and the acid time to etch a good line. It is found that acid diluted with 12 parts of water gives best results. It is diluted in the office and carried to the drill in hard rubber bottles with screw tops, which are much more convenient than the paraffine bottles used at first.

When the tube is brought to surface the positions of the north and south ends of the needle are marked on the glass with a diamond point and the tube washed out and the compass dried to prevent rusting. This tube forms a permanent record of the inclination and course of the hole at the depth where the test was taken.

The thermos bottle is $1\frac{1}{4}$ inches outside diameter and consists of two clear glass walls with a vacuum between, as shown in Fig. 4. When it is necessary to use this the hot gelatine

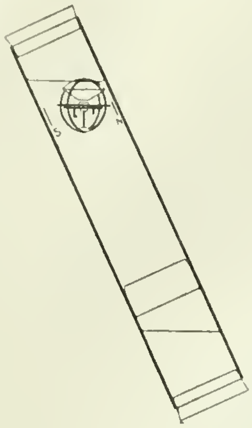

Fig. 3

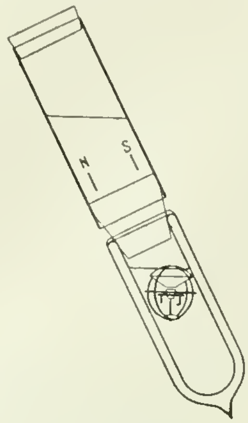

Fig. 4

and compass are placed in the bottle and the bottle closed by a rubber stopper. The stopper also closes one end of a $1\frac{1}{8}$-inch tube 3 inches long, serving to connect the bottle and tube and preserve them in the same relative position, as shown in Fig. 4. Dilute acid is placed in the tube, the other end

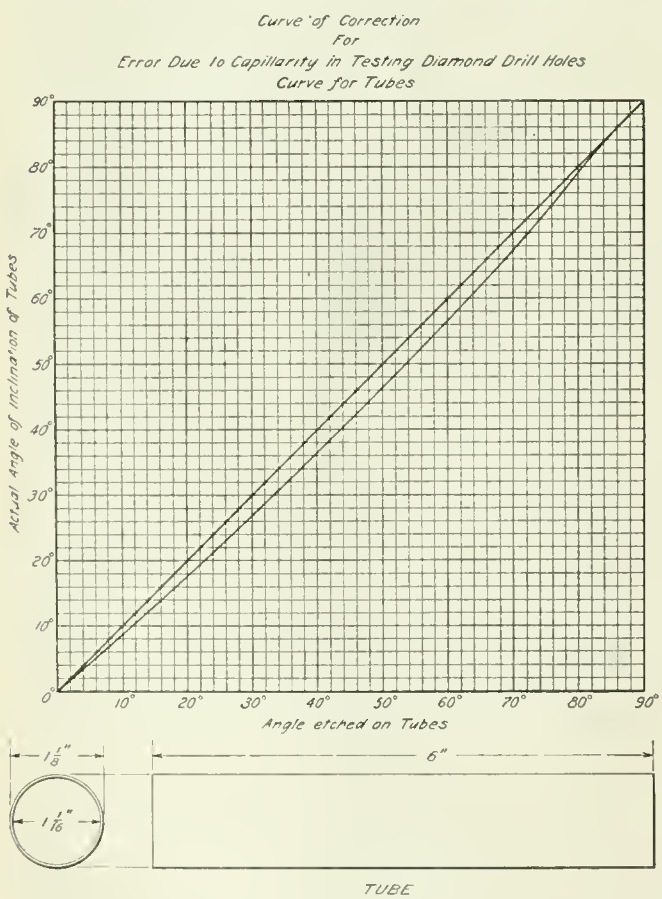

Fig 5

closed, and the tube and bottle placed in the bronze case and lowered into the drill hole. It only takes the gelatine $1\frac{1}{2}$ hours to solidify in the thermos bottle, so that it is usually left in the hole only 50 minutes after the rods reach the bottom, just long enough to get a good etching. It may be left in the hole over night, however, but in that case the acid is diluted more. When the tube is brought to surface the north and south points are marked on it, corresponding to the position of the compass needle in the thermos bottle. The tube then forms a permanent record of course and inclination just as the 6-inch tube does.

In either case the inclination is read in the goniometer described and shown by J. E. Jopling in the Transactions of the Lake Superior Mining Institute for 1909, and is corrected for capillarity according to a curve which is prepared for each size of tube, by testing tubes at known angles according to the method described by Mr. Jopling. Fig. 5 shows a curve for $1\frac{1}{8}$-inch tubes. It will be noted that for these larger tubes the correction is only $3\frac{3}{4}$ degrees at 45 degrees, which is the max-

imum. The angle can be read to $\frac{1}{2}$ degree and I feel certain that the results of tests for inclination can be relied upon to within 1 degree.

To determine the course of the hole the tube is placed in the goniometer with the graduated circle set at 0° so that the tube is vertical. If the inclination of the hole is steep the tube is twisted until the etching shows the dip to be either directly toward or away from the eye; that is, until the cross-thread bisects the ellipse etched on the glass. If the inclination is shallow it is more accurate to twist the tube so that the dip is to the right or left of the observer and in the plane of the graduated circle. The goniometer is next placed on a protractor so that the tube comes vertically over the center, and, by sighting down over a straightedge placed in line with the north and south points marked on the tube, the point of the compass toward which the hole dips may be determined. Figs. 3 and 4 show tubes with acid, gelatine, compass, and north and south points marked, just as they are taken from the drill hole. I intend to have another goniometer made with horizontal circle to measure the course as well as vertical circle for the inclination, but have not had an opportunity to do so as yet.

We have found the method described above very successful, and two tests at the same point almost always agree. When this is not the case more tests are made, and so far we have always been able to ascertain which are wrong. We have made tests at a depth of 2,000 feet, but it would probably be difficult to go much deeper without using more insulating wrapping around the thermos bottle than is possible with a bottle and case of dimensions now used.

Depth

Fig. 7

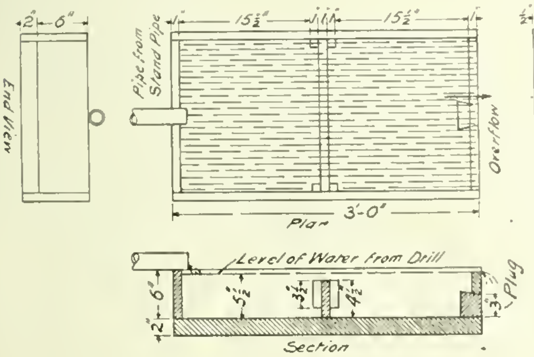

Fig. 8. Sludge Box

The precautions to be taken are three in number: (1) That the compass swings perfectly free, that is, that it does not catch on the cage and that the gelatine keep liquid long enough; (2) that there is no local magnetic attraction in the rock formation; (3) that the compass is not affected by the steel drill rods or casing or by other iron in the hole. The first precaution is easily taken; the second can only be judged by a knowledge of the formation and by taking tests at different depths. If these are concordant there is probably no appreciable magnetic attraction. The third precaution is important. We use 20 feet of brass rods and so have no iron within 20 feet of the compass. Tests with 10 feet, 20 feet, 30 feet, and 40 feet of brass rods at the same depth gave the same reading in a hole dipping 50 degrees north 45 degrees east, so that 20 feet is conservative.

Surveying in Magnetic Formations.—When the rock formation is known to be magnetic, or when several tests with the compass do not agree, there seems to be no way of determining the course of a hole but by lowering the rods in such a way that the test tube can be oriented at any point in the hole. We have done this by the method suggested by Mr. Deacon. The rods are first screwed together in one or two long lines on the surface just as they will be lowered into the hole, with the bronze case at the end, all the joints being made as tight as usual. Great care is necessary that no twist be left in the rods when screwing them together on the ground. This trouble is not experienced when there is snow, as the rods slip easily on the snow and no torsion can be introduced. When the ground is bare it may be avoided by placing level planks at short intervals for the line of rods to rest upon and not allowing them to touch the ground at any point. If not over 500 feet in length the rods will turn on grass without leaving any twist in the rods.

When all connected, each joint that is to be broken, usually every second joint, is marked with a chisel so that it can be screwed up again to exactly the same place. They are marked exactly on top as they lie on the ground, so that when the rods are in the hole the marks will point in exactly the same direction. The joints are then broken, being careful not to disturb any joints which are not marked.

Dilute hydrofluoric acid is poured into a glass tube and the tube marked with a diamond and placed in the bronze case so that the mark on the tube corresponds with that on the case. The tube is then lowered into the hole, being careful to exactly match the marks at every joint. The mark on the last rod is placed directly in front of the drill and this direction determined, which is the direction of the mark on the glass tube. The tube is left stationary at the bottom of the hole for about 50 minutes, when acid diluted 12 to 1 is used, and then withdrawn and washed. To determine the course of the hole another mark is made exactly on the opposite side of the tube and the course found by using the goniometer and protractor, as described in connection with the gelatine test.

This method of course only gives accurate results when the rods turn easily in the hole so that there is no twist in the rods when lowered. This is usually the case except in very deep holes or where the inclination is low or where the curvature is excessive. In these cases, unless the hole is rifled, the twist may probably be removed by raising and lowering the rods several feet a few times after the rods are in the hole. Precaution should be taken

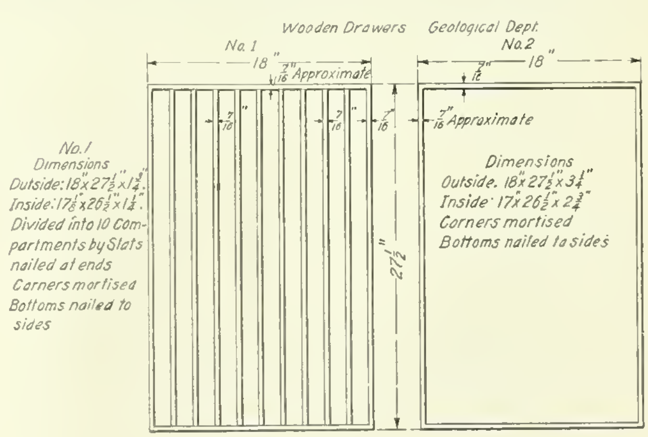

Fig. 10

that the tube cannot turn in the bronze case, either by wrapping with paper or by using a stopper which fits the case snugly. Our tests by this method do not always agree, and are apt to be 10 degrees or 20 degrees anticlockwise from the course as determined by compass in a non-magnetic formation. One reason for this seems to be that in lowering the joints the rods work tight or loose because of the friction of the rods revolving in the hole.

Daily Reports.—Fig. 6 shows a report form filled out by the drill men every shift for the drill foreman and the head office, and Fig. 7 a sample tag which is placed in every bag of core or sludge. The record of time of drilling and footage of each diamond bit is kept to obtain data on the several stones in the bit with the idea of determining which are the most economical. These tests have shown that the wearing quality of the stone depends considerably upon the specific gravity and upon the structure.

Although it is important to have the drillmen report the amount of core saved from each material, yet they rarely measure it accurately, and if the analyses of core and sludge are to be combined, as described below, the core is remeasured when it reaches the office.

The following directions for saving samples are posted in the drill shanties and enforced by the inspector:

Directions for Saving Sludge From Diamond-Drill Holes. Set the standard sludge box just below the floor of the shanty and in such position that there is room to siphon off the water and take out the sample without moving the box. Connect a **T** to the top of the standpipe or casing and lead a pipe from to the sludge box must be cleaned out into the sludge box and either the pump must then be stopped or the **T** turned so that the water will not be discharged into the box. Carefully remove the partition in the box so as not to stir up the sludge any more than necessary; and when the sludge is settled, siphon off the surplus water, being careful to keep the end of the siphon near the surface of the water and not disturb or draw off any of the fine sludge at the bottom of the box. To use the siphon, fill with water a 3-foot length of large size flexible hose, and with one hand on each end place one end beneath the surface of the water in the box and the other end on the ground 8 inches or more below the top of the box. When both ends of the hose are released the water will flow out of the box and may be allowed to flow until it is seen that the sludge is beginning to go off with the water. Then remove the hose and thoroughly mix the sludge in the box to a mud. This must all be removed from the box and placed in a pan on the boiler to dry. The pan must be at least 8 in. $\times$ 12 in. $\times$ 1 in. deep, with flat bottom, and must be thoroughly cleaned

it to the nearer end of the sludge box, at such a height that it will either be level or slant toward the sludge box and just rest upon the top of the box, and of such a length that it will not project more than 1 inch beyond the edge of the box. The pipe must not be more than 2 feet long, and if longer than 1 foot must be split on top for the foot nearest the sludge box, so that if sludge collects in the pipe it may be seen. Set the box level so that water will overflow evenly across the whole width at the far end, and wedge the partition firmly so that it is in close contact with the bottom of the box. The top of the partition should be 1 inch below the water level. The box is now ready to receive the sample, and drilling may be started.

While drilling, care must be taken that no water from the drill hole escapes around or over the **T** except through the pipe leading to the sludge box. Care must also be taken that there is no leak from the box and that the 3-inch plug at the end of the box is tight. Sludge samples must be taken for every 5 feet drilled or less, preferably from even 5-foot intervals; that is, from 460 to 465, 465 to 470, 470 to 475, etc.

When a sludge sample is to be taken drilling must be stopped and the hole washed out clean. The pipe leading each time before a sample is put in it to dry. If enough water cannot be drawn off without disturbing the sludge so that the sample can be contained in this pan, a larger pan must be used. All the sludge must be saved and the sludge box cleaned thoroughly. When the sludge has been cleaned out, remove the 3-inch plug at the end of the box and wash out the box with a pail or two of water, then replace the plug and partition and drilling may be started again.

The sludge must be labeled, giving the depths between which the sample was taken, when it is placed on the boiler to dry. It must all be saved and turned over to the inspector. Sludge must always be saved when drilling in iron formation or in any other ferruginous or red material. While drilling in material from which a sludge sample should be saved, if the water is lost, if the sludge does not come up with the water, or if the sludge is contaminated with material caving from higher up in the hole, drilling must be stopped immediately until the hole is put in such condition that good sludge samples can again be obtained, or until the inspector gives orders that drilling may proceed.

Whenever the drill runs into or out of ore, provided the band of ore or rock is 1 foot or more thick, drilling must be stopped and the sludge box cleaned out immediately, without waiting to complete the 5-foot run. When the drill runs out of ore, continue taking and saving sludge samples for at least 20 feet, no matter what the material, so that it may be determined whether the ore is caving.

Keep the core separate from the sludge, and each time core is pulled label it with the depths between which it was recovered. Each run of core must be kept separate and all core must be saved and turned over to the inspector. When the core is pulled, if it is found that more core is saved than the proportion of 1 foot of core to 10 feet of drilling, the sludge box must be cleaned without waiting to complete the 5-foot run, and the sludge labeled and saved separately. If sludge from a shorter distance than 5 feet is in the box at the end of the shift's work, and if less than the above proportion of core is saved, the sludge may be left in the box provided the shanty is locked and the box is inaccessible from outside the shanty. If anybody can get at the box, however, and if there is no watchman, the sludge must be removed from the box, dried, labeled, and placed with the other samples.

The standard sludge box is shown in Fig. 8.

When the samples reach the office they are carefully examined and a daily report of all drilling made out on the

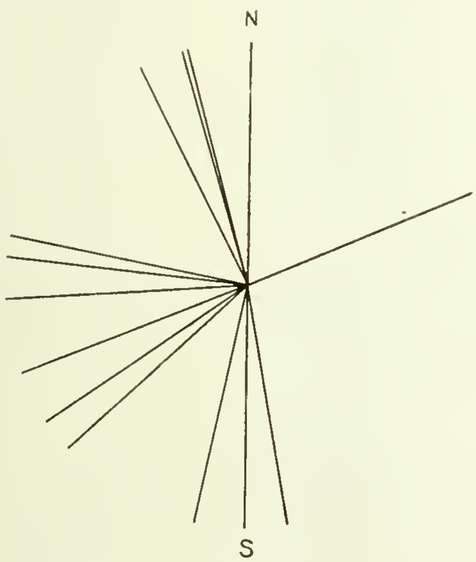

FIG. 13

form shown in Fig. 9. Samples of all core and of all sludge which runs above 40 per cent. iron are preserved in a room and in cabinets designed especially for the purpose. A few pieces of core are saved from every run and the rest sent to the laboratory for analysis if ore formation, or thrown away if not. A little of each sludge sample is placed in a small pasteboard tray with a temporary label, 10 feet to a tray, until the analysis is complete. Each 10 feet of sludge sample which runs over 40 per cent. is then placed in a gelatine case and preserved in the same drawer with the ore. Gummed paper labels are used for both core and sludge and the samples preserved in the drawers shown in Fig. 10.

Interpretation of Analyses.—Mr. W. J. Mead has described our method of combining core and sludge analyses in an article in the *Engineering and Mining Journal*, of May 6, 1911, except that we used a formula in the method which I described to Mr. Mead several months ago instead of the diagram which he has developed from it. Since other engineers may also be interested in the formula, I give the derivation below:

Let A = diameter of bit outside of carbon;
B = diameter of bit inside of carbon;
C = feet of core saved in "D" feet drilled;
D = feet drilled;
S = volume of rock actually ground to sludge;
T = volume of rock actually saved as core.

Then, $$S = D\left(\frac{\pi A^2}{4} - \frac{\pi B^2}{4}\right) + (D - C)\frac{\pi B^2}{4}$$

and $$T = C\frac{\pi B^2}{4}$$

Hence, $$\frac{S}{T} = \frac{D(A^2 - B^2) + (D - C)B^2}{CB^2} = \frac{DA^2}{CB^2} - 1$$

DIMENSIONS OF BITS

	Inside of Carbon	Outside of Carbon
Standard "A" bit	1"	$1\frac{13}{16}$"
Standard "E" bit	$\frac{27}{32}$"	$1\frac{9}{16}$"

Hence for an "A" bit $$\frac{S}{T} = \frac{1.813D^2}{C} - 1 = 3.29\frac{D}{C} - 1$$

and for an "E" bit $$\frac{S}{T} = \frac{1.563^2 D}{.844^2 C} - 1 = 3.43\frac{D}{C} - 1$$

To obtain an average of the sludge and core analyses giving the proper weight to each, the sludge analysis should evidently be multiplied by S and the core analysis by T, and the sum of the products divided by $S + T$. The result is the same and the operation simpler to multiply the sludge by $\frac{S}{T}$ and the core by 1 and divide by $\frac{S}{T} + 1$; hence, the rule for an "A" bit is to multiply the sludge analysis by $3.3\frac{D}{C} - 1$, add the core analysis, and divide the sum by $3.3\frac{D}{C}$. Since the core is rarely pulled in 5-foot runs we find it just as simple to figure the ratio from the formula as from Mr. Mead's diagram.

Mr. Mead did not mention the method of obtaining the average analysis which he formerly used, namely, to weigh out proportionate parts of core and sludge and combine them for analysis. This method is ingenious but is open to objections: (1) If it is found later that the hole was caving and the sludge of no value the core analysis is also rendered valueless; (2) in order to get true analyses it is advisable to send the whole sample for analysis except a small portion kept for record, whereas if weighed out, a portion must be rejected.

We only run iron on the 5-foot samples, with phosphorus if over 40 per cent. iron, and manganese if there may be over 1 per cent. or 2 per cent. We occasionally combine several of the 5-foot sludge samples and make a complete analysis for iron, phosphorus, silica, lime, magnesia, alumina, manganese, sulphur, titanium, and loss by ignition.

After combining the core and sludge analyses the results are further averaged in continuous runs of ore of the same grade. We call from 45 per cent. to 50 per cent. iron lean ore, 50 per cent. to 57 per cent. second-class ore, and above 57 per cent. first-class ore.

Representation of Results.—As soon as possible after the first of the month the record of material drilled through the previous month is compiled from daily reports and averaged analyses. This is carefully checked over with the core and then recorded permanently in the drill book. This is a loose-leaf book with pages shown in Figs. 11 and 12. The reports of the drillmen and analyses of samples are copied in this book daily and it forms the complete and permanent record of drilling. From this book tracings are plotted which are blueprinted for the various parties entitled to receive the information. Figs. 14 and 15 show the printed forms on tracing cloth used for this purpose. They are of the same size as the loose-leaf sheets in the drill book and are bound in covers of the same size.

Cross-Sections of Drilling.—For scientific location of drill holes cross-sections must be made through previous drill holes, preferably at right angles to the strike of the formation, showing the holes plotted according to the surveys for inclination and course, and showing the material encountered. We make these on cross-section tracing cloth ruled in inches and tenths, on a scale of 50 feet to the inch. The sections may be superposed and compared, and the cross-section ruling makes it easy to read distances and areas without a scale. On these tracings the geological boundaries of formations and the outlines of ore bodies are drawn in soft pencil, which prints satisfactorily but may easily be erased and changed if further drilling shows the first assumptions to be wrong. When necessary longitudinal sections are made and taken in connection with a plan and cross-sections give a very good idea of the structure.

Deflections of Drill Holes.—In an article written for the *South African Mining Journal* of June 11, 1910, and again in an article in the same journal of March, 1911, Mr. J. S. Curtis gives an interesting theory of the cause of bore-hole deflections with results of experiments which he made to substantiate his theory. He endeavors to show that the influence of terrestrial magnetism should cause vertical drill holes to deviate to the north in the Southern Hemisphere, and states that this is the case in the great majority of holes, although the direction may be changed by the character of the country rock.

In our experience the latter feature is much the more important and from results of our drilling I should not say that the great majority of drill holes deviate either north or south in all districts. If the strata are flat and uniform the holes may do so, but if the strata dip steeply this is not the case. In one district where the dip is steep we are certain of the course of 14 holes which deviated from the vertical and these are shown in Fig. 13. Of these holes one went approximately north, one approximately south, one northeast, five northwest, one southeast, and five southwest. Putting it in another way, seven deviated to the north and seven to the south, while two deviated to the east and 10 to the west. If these results show anything they only show that the majority of the holes deviated to the west, but equally to the northwest and southwest.

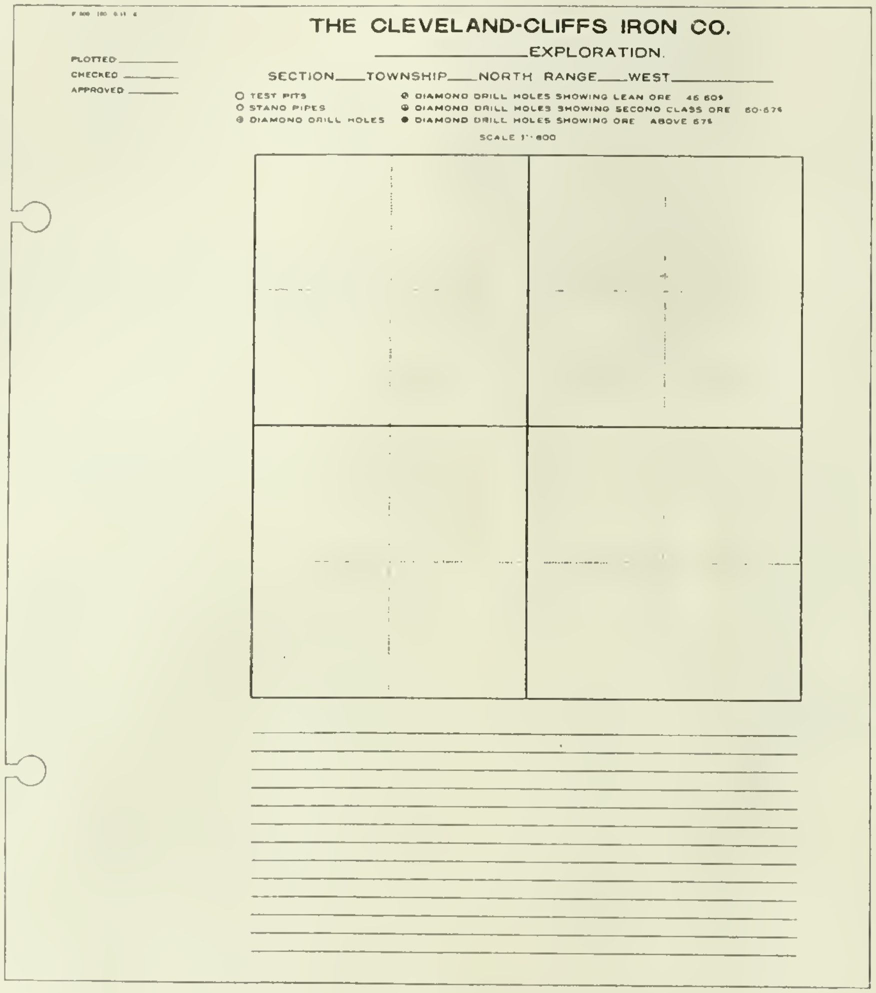

Fig. 14

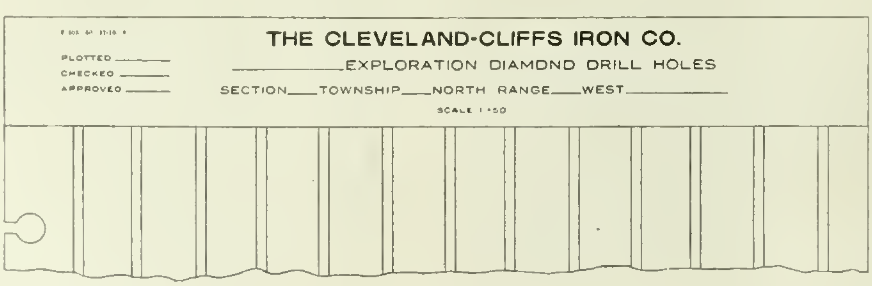

Fig. 15

It is very difficult to keep vertical diamond-drill holes straight and I believe that a hole can be located with more assurance of striking a certain point in depth if it is given an inclination of 85 degrees against a steeply dipping formation than if it is started vertical. We have only drilled two holes with this inclination, with the results as in Table 1.

These two holes are not enough to generalize upon, but they certainly keep straighter than vertical holes in the same district. In addition to that we knew in which direction the holes were going, which we do not know when we start a vertical hole. In my article in the *Engineering and Mining Journal* of September 17, 1910, I gave a series of curves showing the curvature to be expected in an inclined hole when dipping against a steep jasper formation. I would change the curve for a hole started at 85 degrees, as that seems to be a critical angle under these conditions and the hole does not flatten as would be expected.

Table 1

Depth Feet	No. 1 Degrees	No. 2 Degrees
At surface	85	85½
At ledge	86	86½
200	86	
400	85	87¾
500	87½	
600	87	
800		88½
1,200		85½

In view of the sometimes surprising curvature of drill holes I feel that all holes should be tested for both course and inclination at 100 feet or 200 feet intervals, whether started vertical or at an angle, otherwise there is no telling where the ore or other strata cut really occur. We recently started a vertical hole which at a depth of 800 feet was found to have an inclination of only 51 degrees from the horizontal. Another hole started at an angle N 54° W was found to be running N 64° E at the bottom.

Ore Mine Inspection in Missouri

Progress Made in Reducing Mining Risks by Inspection. Peculiar Dangers in Zinc Mines

By Lucius L. Wittich

In no other mining district, perhaps, is the problem of efficient inspection so difficult of solution as in Southwest Missouri, where hundreds of mines must be visited, and where the possibility of fatal accidents is intensified through the fact that virtually all of the operations are of a temporary nature, the result being that careless methods are often pursued.

The zinc-lead mines of Southwest Missouri extend to the border line of Kansas, where inspection of metal mines is lax, and the contrast between conditions in the two states is rather startling. Kansas spends large sums in protecting the lives of her coal miners, but the vigilance does not extend to the extreme southeastern corner of the state, where zinc and lead are produced from properties that would be closed in the twinkling of an eye were the same care exercised that is manifest in the coal-producing areas. The careless, haphazard method of development is found so long as one keeps over the line in Kansas. Cave-ins are numerous and serious accidents, considering the number of mines in operation, are more numerous in Kansas than in Missouri. In the two states geological conditions are the same; formations of ore deposits are identical; zinc blende brings as much in Kansas as in Missouri; lead is worth just as much in one state as in the other; market conditions that prevail in Missouri hold good in Kansas; mining costs are virtually the same in both states; in fact, the district is as one, save for the hypothetical line that divides it and save for the various state laws that have made conditions different. Through legislation, mining conditions have been made excellent in Missouri while in Kansas little or no effort has been made to improve the situation. With the fact established then that precautionary measures are productive of good results, and that state laws and conscientious inspection can work wonders in safeguarding human life, methods by which these ends are attained may prove examples from which other operators can secure beneficial ideas.

Fig. 1. Lowering Men in a Tub

Fifty-one miners were killed in the Joplin district mines in 1909. Improved conditions resulted in the list of fatalities being reduced to 32 in 1910. Less than 12 have met death up to date this year, and unless some unforseen calamity occurs, the death record this year will be the lowest in years.

Falling boulders and slabs and premature explosions led the list. To prevent death from falling roof is largely a problem of precaution. Where proper care is given to the excavation of drifts, the possibility of such mishaps is reduced to a minimum. Premature explosions often can be attributed to carelessness, therefore operators should employ only trustworthy men to handle explosives. Recently enacted state laws regulate the handling of explosives, a feature of the new bill being that only a 24-hours' supply of powder shall be kept underground at one time. Whether or not such a state law is in existence, a mine operator should observe this rule, which is one of common sense. It should be as easy to keep mines in good condition in a state where the laws are lax as in one where the laws are rigid, but the operator unhampered by the suggestions of an ever-inquisitive inspector, often fails to keep his mine in a safe working condition; and forgetful of the safety of his employes, is occupied entirely in producing the greatest volume of concentrates at a minimum expense.

The hazards of mining begin when the miner steps into the tub to be lowered to his day's work. In 1910, three men perished in the Joplin district from falling from tubs, either in being hoisted from the ground, or in being lowered. One perished from walking up on a "boulder pop," for which, of course, the mining company was in no manner responsible. Proper knowledge of the nature of high explosives, however, would have been invaluable to the victim. Three men were killed from falling material in shafts, the carelessness of hoister men and of the victims themselves being jointly responsible for such disasters. Three were killed by foul air, caused by failure to blow out the gaseous fumes after firing holes in a winze. Other miscellaneous catastrophes made up the total of 32 for the year. Serious non-fatal accidents numbered 23, a material decrease from the previous year's statistics. In the non-fatal accidents, falling slabs caused six, squib shots caused five, careless hoister men who dropped men into shafts caused two, mistakes in signals to hoister men, causing men to be bumped against the sides of shafts when lifted out, caused two, and the others resulted from various causes, all of which could have been avoided had proper precautionary methods been observed.

The number killed has been about four to each 1,000 employed, according to figures compiled for four years by the State Bureau of Mines, covering accidents in the Joplin district. These startling figures resulted in more vigorous efforts to prevent mine disasters. Human life is beginning to be reckoned as a factor far more important than the production of minerals, and the nation-wide crusade looking toward better mining conditions must of necessity bear fruit.

It is not that the mining practice is at fault in the Joplin district; because the mining practice is the result of years of experience and development not only locally but elsewhere, other methods having been found adaptable, in many cases, for use in the Joplin district. The fault is not with the practice, but with abuses of the practice. One of the first steps taken was to secure the enactment of laws that would prevent such abuses. The need of such laws was imperative, and in an address before the Joplin Commercial Club, December 17, 1909, Charles P. Wallace, urged operators to lend their influence in securing the passage of a number of bills which later became state laws. One of these measures fixed the responsibility of the mine owner. It outlined the types of cases in which he would be held responsible for injury to his employes. It clearly defined what precautionary and sanitary methods should be employed, and thus acted as a powerful factor in influencing operators to better mining conditions. It was one of several bills enacted that looked toward conservation of the highest moral type, conservation of human life.

Twenty-five per cent. of fatal accidents, caused by falls of roof, could be classed as unavoidable; of the remaining 75 per cent., some are caused by carelessness in not properly trimming the roof; some by carelessness in not properly timbering the ground; some by carelessness on the part of men working in places known to be dangerous in order to "beat wages," but the majority by carelessness in excavating ground so wide that the roof cannot possibly stand for any length of time with the few pillars left. Pillars left to support the roof, as in Fig. 2, should be of proper dimensions to hold up the great weight above. The formation of the ground regulates to a great degree the distance at which the pillars should be left standing. In sheet ground, where the roof is of flint or cotton rock, 35 to 40 feet is considered a reasonable distance between pillars, and where the roof is from 8 to 12 feet high the pillars should average 18 to 20 feet in thickness. In the sheet-ground districts little or no timbering is required, and for this reason alone especial care must be taken to keep the roofs in good condition. In soft-ground mining heavy timbers are employed, as in Fig. 3, and these supports hold back the caving ground, but in the sheet formation no supporting timber is employed; when a boulder or slab breaks loose it comes down without warning. Sheet ground operators are beginning to realize that pillars, left in the form of the five spots on a die, are much more satisfactory than pillars left standing in even rows. It is not uncommon to find sheet-ground mines in the Webb City district where the excavations are hundreds of feet wide. As far as the eye can reach no supporting pillars can be detected. It appears that one is standing in a vast, underground plain over which stretches an endless roof of solid rock, held in place by some invisible power. But such operations are being discouraged. Operators who persist in conducting such development are forced to shut down their mines. At present, 12 producers in the Joplin and Webb City camps are idle because the inspectors have served notice that development cannot continue until certain laws are observed. Two shafts, for instance, must be connected with the drifts in cases where the inspector believes the lives of the miners would be endangered where only one shaft is used. To observe this law, companies often sink a second shaft for ventilation purposes, but more often, especially where the mill capacity is large, ore is hoisted from both shafts, as shown in Fig. 4.

Fig. 2. Pillars in Disseminated Zinc Ore

Operators in the sheet-ground districts realize the danger from falling slabs. Even if they have had no bad accidents, they have been compelled from time to time to take down slab after slab of roof until the handling of so much waste has eaten up the profits for months at a time; and in some cases it will be impossible to take up stope solely for the reason that the ground was cut too wide originally. The falling of slabs is simply the result of the ground's efforts to arch itself, the roof as left by the miners having of necessity been left flat. Heavy blasting, necessary in sheet-ground mining, also helps the natural action of the ground.

Too frequently the greed for more ore has resulted in dire catastrophes. Indirectly the fault may lie with the operator, although personally he may have little or nothing to do with the manner in which his mine is worked. The superintendent, anxious to produce results, will make the demand on the ground foreman for "more dirt," and the foreman, even though he may know that he is violating the laws of common safety, also desires to cinch his position, and it is "up to him to deliver the goods." The order for "more dirt" is passed down to the machine men and the shovelers. All may realize that the ground is being butchered, but they likewise appreciate the fact that if they do not care to do as ordered, some other man will. And so it is that there are excuses for the practice, but valid reasons are impossible to find.

Former Mine Inspector Wallace is opposed to the stope method of mining. First, ascertain the thickness of the ore deposit and plan to carry it all in one cutting, is his advice. Large pillars should be left on at least two sides of the shaft—far enough apart, or else a cutting should be made in each of them on the side next to the shaft, so that the tub hooker will have adequate room in which to work without being exposed constantly to the dangers of falling missiles from the shaft. To insure a substantial roof it is important to cut the ground high enough to avoid the seams of ore, as these form weakened spaces between the rock and permit it to separate. By cutting the roof too high, a decomposed cotton rock is encountered, which is not substantial. After the stratum that is to be used as cap rock is selected care should be exercised to follow this stratum as uniformly as possible. The constant "burning" of the roof by holes bedded too high is a prolific source of troublesome slabs.

With the introduction of more economical milling processes each year, and with the continuation of substantial prices for zinc ore, operators have shown a tendency to go into old worked out ground to handle thin dirt that could not have been mined profitably a few years ago. In such mines it will be found frequently that no pillars have been left, the previous operators having drawn the supports, which contained rich ore. The ground, in such cases, is treacherous, and it is necessary to employ artificial supports. Timbering at the best is a poor substitute for the original pillars of solid rock, but by constructing pens of sawed timber and filling the same with boulders, a fairly substantial brace is obtained. These must be kept tightly keyed up to the roof or they lose their value as supports.

A position that should be considered of greatest importance in every mine where timbering is not employed is that of "trimmer," but this important person too often is overlooked; for the trimmer is not a producer of ore, and it takes ore to meet the pay roll. The machine men, the shovelers, the tub rustlers, the tub hookers, the mill men, the blacksmiths, all play their part in the production of ore, but the roof trimmer produces nothing. And it is with this mental picture that many operators leave the trimmer's position until the last to be filled. Sometimes it is never filled. The trimmer should be equipped with the necessary ladders for scaling the highest places in the mine; in some of the disseminated ore districts, excavations are made up to 150 feet in height, and the pillars, necessarily, are much farther apart than in the sheet-ground mines. A very small boulder falling from such a height and striking a workman squarely on the head would inflict a serious wound, and would probably cause instant death. Little powder should be used in the trimming of roofs. Bars, wedges, moils or hammers, should be used and the loose rock removed without shooting.

But all the dangers of mining do not lurk in improperly mined rooms nor in badly trimmed roofs.* Precaution is needed in every feature of the industry. Shafts may be improperly timbered. Clever operators may conceal such defects from the inspector; in fact, the inspector must possess a keen insight into human nature, and above all else must be "one of the boys" if he hopes to learn of the mining defects that are of real importance and which should receive immediate attention. Often a few confidential words with a spade hand, will be of untold value to the inspector who has the ability to get the confidence of the miner boys, and many has been the valuable bit of information received in an off-hand way while enjoying an evening's "gabfest." W. S. Brown, the inspector, had spent an entire afternoon inspecting a mine in the North Webb City field. Apparently the workings were in the best of condition. Drifts seemed in good shape, shafts were properly timbered, ventilation was good and the explosives were stored far enough from the plant to prevent serious disaster in case of a blow-up. But two days later Mr. Brown closed the mine. He hadn't found any defect during his inspection. He had left the property convinced that every letter of the law was being obeyed. That night a spade hand jokingly remarked:

"Bill, you didn't recognize your old shaft did you?"

Mr. Brown was puzzled. The spade expert then explained that one of the two shafts at the mine inspected that day was one sunk by Mr. Brown himself 20 years before. The inspector then recalled the fact that a serious cave-in had occurred in his old workings years before. Mr. Brown knew that no human power could have refilled the great gap left by the sliding ground. He knew also that conditions could not be safe where such a cavity existed. Next day he made a return visit to the plant. Half way down the shaft he gave the signal to stop. High above his head a rather surprised hoister man complied with the signal. He couldn't perceive why the inspector should wish to terminate his downward journey while yet more than 50 feet above the platform. But Mr. Brown was thoroughly posted on the course he intended to pursue. He tapped the sides of the cribbing, and at one place a hollow, far-away sound was the result. He then gave the signal to be hoisted. He hunted up the superintendent, and gave instructions to have a portion of the cribbing removed. As a result, a vast, gloomy cavern was exposed to view. The roof and walls of this cavern were treacherous. A cave-in* of the pit, although walled off by cribbing from the mine workings, would have meant a serious disaster. The mine was closed until a new shaft in virgin ground, could be sunk.

Not only is the inspector required to visit the mines of the district and see to it that their operation does not conflict with the law, but he is also required to make weekly reports to the State Bureau of Mines and Mine Inspection, of which George Bartholomaeus is secretary. These reports cover every conceivable detail of information regarding the mine on which the report is made. Operators are required to give information concerning capital stock, number of stockholders, number of employes, volume of production, kind of ground handled and many other features.

*The caved-in shaft that held Cleary captive several days is a case similar to this.

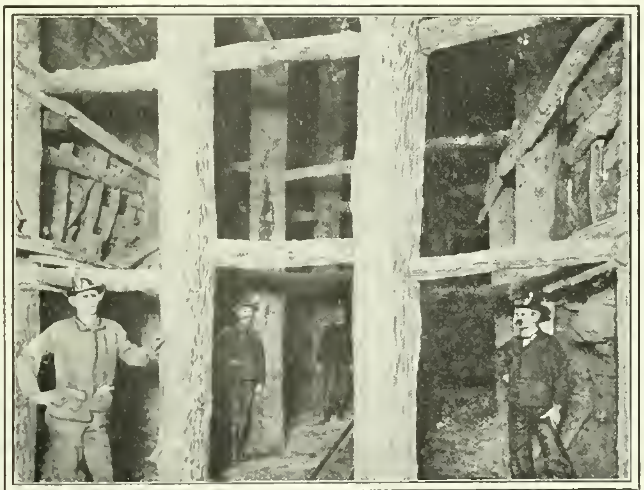

FIG. 3. TIMBERING IN SOFT GROUND ZINC MINE

As the use of powder is a necessity in zinc and lead mining, especially in the sheet ground and in the disseminated ore districts, knowledge of the proper methods of handling explosives is requisite. In fact, operators have shown a disposition to regard the proper care of explosives as more important than the proper handling of ground.

Enter almost any of the larger zinc and lead mines of the Joplin district and you will see, posted here and there, printed rules and regulations concerning the usages of explosives. Owing to the type of the mining, dynamite is the chief explosive employed, although black powder is used in some of the soft-ground workings.

Powder magazines should be stationed sufficiently far from mine buildings, derricks, etc., to insure little damage in case of an explosion. In addition, the magazines, to be of real value in cold weather, must be heated with steam radiators. Frozen powder can be thawed out in steam-heated magazines, and the danger attaching to some of the common methods of thawing out powder on the back of the "dog house" stove is averted. In heating the magazines, exhaust steam only should be employed, and the temperature should never be permitted to get above 95° F. A safe temperature is 80 degrees, and if this is maintained continuously results will be found satisfactory. Steam pipes must not come in contact with the explosives, for which shelves, or racks, should be provided. The farther the explosives are removed from the steam lines the better; and a rule that is observed by all powder companies and which should be observed by all mining companies is this: Never keep caps, oils, or other combustible substances in the same magazine with powder.

Only enough powder for a day's supply should be taken underground at one time but in addition to this precautionary measure, a safe place should be provided in the ground where the possibility of its being exploded by a "squib" shot, "boulder pop," or by other causes, is reduced to a minimum. An excavation of sufficient size should be made in a remote drift, or as far as possible, at least, from the scene of greatest activity, and over this opening should be placed a heavy frame door, securely locked. Keys should be carried only by the ground foreman and the powder man. Another excavation, also securely walled in, with a heavy door, should be made some distance from the powder magazine, and in this can be stored caps and fuse. No flame should be permitted to come near these magazines. Where mines are not lighted with electricity, the powder man should be careful to leave his lamp at a safe distance before taking supplies from the underground storage places.

Hard ground makes it necessary to use heavy charges in blasting. The first step is to drill a series of holes, with machine drills in hard ground, and with hand drills in medium ground, and in these holes are placed the first shots, known as the "squibs," which open larger cavities into which greater quantities of powder may be placed. Squibs should be prepared by the powder man or the ground foreman and hung at a convenient place some distance removed from the magazines. They can then be secured by the machine men as needed.

Promiscuous firing of "boulder pops" is not tolerated in well-regulated mines. In heavy blasting, huge boulders often are thrown out, and these, in turn, must be broken. It has been a common practice in the past to fire these indiscriminately, at all times of the day or night. As in regular blasting, "boulder pops" should not be fired when the drifts are filled with workmen. During the noon hour, or preferably at the close of the shift, where the mine is operated only during the day, are the best times for blasting. The danger from possible flying fragments of rock is not only thus averted but more time is given for the smoke to clear away, and sanitary conditions are thus maintained at a higher standard.

Much could be said also of the right and wrong ways of loading holes. Common sense in the matter of tamping bars and tamping material should be observed, but it is not uncommon to find metal tamping bars in use and loose gravel employed as packing for the shots. Wooden tamping bars, only, should be used. Steel bars may strike sparks from the flint and the powder may be exploded. To hasten operations in order that the maximum amount of ore may be produced, too many powder and machine men have formed the habit of using steel nails in the ends of wooden tamping bars to "railroad" the sticks of dynamite through rough holes. Many premature explosions might be explained by the single steel nail in the wooden bar. If nails must be used for this purpose, copper wire will answer as an excellent substitute, and copper will not strike a spark.

In charging holes so that all air spaces are filled, a firm pressure of the tamping bar is all that is needed. Hard tamping in hard ground, even though the tamping bar be of wood, may result disastrously, as separate particles of flint may thus come together, and the powder be exploded. Soft clay or coal dust make excellent tamping materials.

"Going back on a shot" is another common method by which miners have met death or serious injury. Three-quarters of an hour should elapse before the miner approaches a missed hole, after the fuse has burned out. Squib shots have the habit, sometimes, of waiting a ridiculous length of time before going off. Powder should never be extracted from a failed hole, but a new squib should be installed after the hole has been thoroughly cleaned out.

A rule, which if followed generally, would result in much good would be to drill, whenever possible, a full round of holes a day in advance for the next day's shooting. By squibbing them at night, they are cool for the next day's shooting, and the possibility of disaster from loading a hot hole is eliminated. To load a hot hole is the height of folly.

In shaft sinking and in driving drifts from shafts, electric firers should be used. This does away with the possibility of the miner being caught by the shot.

In addition to these suggestions, a hundred and one details of minor importance, but each bearing directly on the safety of the miner, might be mentioned.

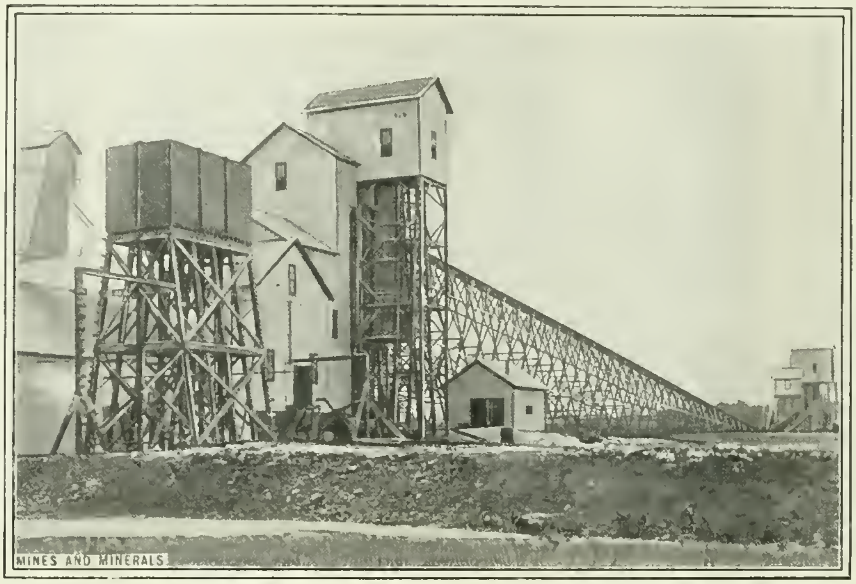

Fig. 4. Zinc Mine Hoisting Ore from Two Shafts

Only experienced hoister men should be employed. Several times daily they have the lives of the entire underground crew in their hands. Careful inspection of all hoisting machinery, cables, tubs, etc., should be a daily duty. Men should be hoisted and lowered at a moderate rate of speed. The desire of humorously inclined hoister men to play practical jokes on new employes has sometimes resulted in injuries. There are wiser methods of perpetrating practical jokes than by jerking a man out of a shaft at a breakneck speed.

Until recently hand rails around the tops of shafts were seldom seen. A state law says these must be installed. The mouths of the shafts must be protected so that objects cannot fall in. Ice and snow must be kept away in winter in order that the workmen, in coming up and in going down, may have substantial footing. Icicles forming along the sides of cribbing should be trimmed away daily, just as treacherous-appearing boulders in the roofs of drifts should be trimmed. Loose cribbing, too, should be carefully watched, and repairs made at once. Sprinkling of dusty mines should be a regular duty. Miner's consumption, which has claimed many one-time robust workmen, is caused largely by the tiny flint particles that are breathed into the lungs. The sprinkling of drifts will eliminate, to a great extent, this menace.

Companies operating on a large scale above all others have been advised to post rules throughout their workings. Printed rules are good in small mines as well as in the large, but the operators of the latter class have been appealed to in particular. Every operator possibly will have his own ideas in what should be included in the rules and regulations, but they should be along practical lines that will help save human lives, rather than along lines frequently observed in other classes of business, where the printed advice is profusely distributed "to observe the wishes of your superiors," etc. The rules should set out in bold type the best methods of safety. Unnecessary shouting and hallooing underground, and especially upon the part of men being hoisted, should not be tolerated. Crowding about the top or bottom of the shaft at whistle time should be prohibited. Rules regarding the handling of explosives, the cutting of drifts, the trimming of roofs, rules covering every detail of the development, in fact, should be posted, and have been posted in a few of the larger producers.

The improved conditions in the Southwest Missouri district are the result of education and evolution; but while the process of education is in progress men are still being killed and crippled. Big strides have been made in the right direction. There is yet room for improvement. For much of the information incorporated the writer is indebted to W. S. Brown, State Mine Inspector, and Charles P. Wallace, former inspector.

Spaerocobaltite, cobalt carbonate $CoCO_3$, occurs in small rose red to velvety black spherical masses. Crystallizes in rhombohedra. Hardness, 4. Specific gravity, 4.02 – 4.15. Streak, peach blossom red. Found in Saxony, Germany, and in Cobalt, Canada.

Notes on Chilian Mills in Russia

Special Features of an Improved Mill—Method of Feeding. Capacities and Efficiencies

By H. C. Bayldon

This paper was presented to the Institution of Mining and Metallurgy, London, England, and printed in Bulletin No. 75. It is reprinted at this time because of the general interest being taken in this kind of grinder by those in charge of large mills. Like the stamp mill it is a comparatively crude machine which it seems difficult to replace as a crusher. Mr. Bayldon divided his paper in two sections, this being the second and dealing with the improved Chilian mill which he has adopted.

The chief features of the plant are: The mill building, the automatic belt feeder, and the improved Chilian mill.

The mill building is a framed-timber structure, the walls of which are enclosed with a double thickness of planking, interspaced with fireproof tarred building paper, the roof being covered with a double thickness of $\frac{3}{4}$-inch boards also interspaced with the tarred paper and covered with iron.

The joints between sides and roof were carefully made tight with a sawdust filling.

It was generally held by the local authorities that this style of building would prove unsuitable for such a cold climate as Siberia, but it has proved to be entirely successful, being easily warmed with little trouble or expense by a simple steam-heating system. In fact, this type of structure is more easily warmed and kept at an even temperature in winter than the typical heavy log buildings of the country.

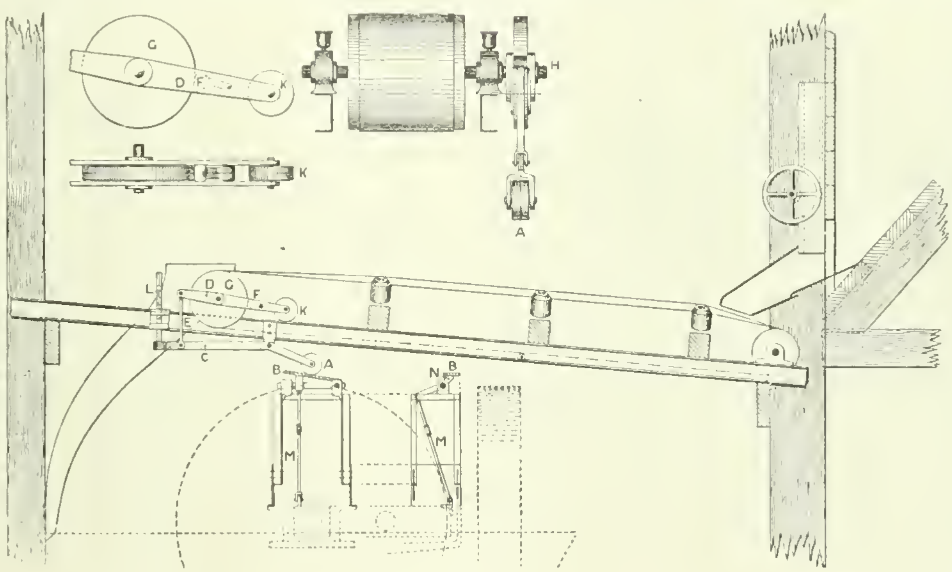

Fig. 1

It was realized that this plant, to be a success, must have the mills fed by some automatic means, especially as a big output was anticipated.

The feeder of "Challenge" type, generally adopted in Chilian mills in Russia, was recognized as not being suited to the special conditions, and, at the suggestion of S. J. Speak, an overhead belt feeder, operated either by the mills themselves or by independent mechanical means, was decided upon.

Various designs were prepared and considered, and it was decided eventually to make the automatic belt feeder, illustrated in Fig. 1, at the mine workshops. This feeder has now been in continuous operation for nearly a year and has proved to be most satisfactory in its operation.

The following short description will make its action clear: At every revolution of the mill the roller *A* is pressed upwards by means of a slide *B*, and the motion transmitted through the lever *C* to the double-armed lever *D* connected by a tie-rod *E*, causes the claw *F* to engage and push forward a friction wheel *G* keyed to the shaft *H*, to which is fixed the belt driving pulley. Thus the traveling belt is moved a certain distance forward with each revolution of the mill Roller *A* is brought back to its original position by the balance weight *K*, on end of the lever *D*.

The length of belt travel or feed is regulated in the first place by an adjustable screw spindle *L*, serving as a stop for the lever *C*, and by the Chilian mill itself in the following manner:

If more material be treated by the mill than is brought forward by the feeder set to a certain quantity, the runners will, when compared with their ordinary position, come to stand somewhat deeper, owing to the material in the pan becoming gradually less and less.

By the lowering of the runners, the tie-rod *M* connected to the runner sleeve will be pulled down, causing the lever *N* to turn upwards and give a more upright inclination to the slide *B*; the stroke of the roller lever *C* increases, and in conformity that of the friction-claw lever also, the mill thus getting more material until the ore layer in the pan has again reached the ordinary height.

By the same means, if the ore layer is too deep, the slide is automatically lowered and the feed reduced.

It will thus be seen that, while the feeder may be adjusted by means of a setscrew to a fixed rate of belt feed per stroke the amount of ore feed for this rate remains practically constant, owing to the automatic regulating of the belt travel by the mill itself for variation in the amount of ore on the belt.

The only wear of consequence is in the discharge hopper (which is provided with renewable liners) and in the belt. The cost for these renewals is estimated at .42 cent per ton.

A section of the Chilian mill with the special features of its design is shown in Fig. 2. The wearing parts other than the tires and dies are brass lined.

The pan is made narrow at the grinding track, but the width rapidly increases owing to the sloping of the inside cone.

By keeping the width of the track narrow, the percentage weight of the die discarded when worn out is reduced; while by increasing the width of the pan as rapidly as possible above the grinding track, a more violent wash of the water is obtained, which holds the fine ground stuff in suspension and enables the water to carry it out of the mill rapidly, thus indirectly effecting an increase of mill capacity.

The screen opening, which is 48 inches in width, is similar to that of a stamp battery, the idea being to enable chuck-blocks of varying height to be used.

The clean-up is made through an opening 24 inches in width, closed by an iron slide, at the back of the mill.

The contents of the mill are flushed out through this opening into a special clean-up box shown in Fig. 3.

The six Chilian mills in the plant are driven by two motors, each of 50 horsepower. Three of the mills are run at 14 and the remainder at 16 revolutions per minute.

The capacity of the mills at present is limited to about 39 tons each, any output beyond this per mill causing excessive overload.

The information given here has been obtained from a series of tests, made under ordinary working conditions at odd times when favorable opportunity offered, a full and complete record under varying conditions being beyond the author's means. In all trial runs, however, care was taken in measuring quantities and speeds as well as in taking pulp samples. The capacity of the mills and power required with different belt-feeds was checked, not only during the trials, but over long periods.

Dimensions, Etc., of Mill

Diameter of fan	10 ft. 3 in.
Distance between center of runners	8 ft. 6 in.
Revolutions of mill per minute	14 and 16
Mean runner travel per minute	340 ft. and 427 ft.
Diameter of runner	72 in.
Width of face of runner	12 in.
Weight of runners (each)	10,000 lb.
Weight of tire alone	6,040 lb.
Weight of dies (set)	4,880 lb.
Size of discharge opening	44 in. × 8 in.
Gross weight of mill	23 tons

One series of tests was omitted, which the writer would have liked to make; namely, with regard to the effect of size of feed on capacity; while other tests which might have afforded useful information have not yet been practicable.

The maximum desirable size of ore feed, calculated by Philip Argall's* formula for rolls, is a 3.4-inch cube, and the average ore feed of these mills is:

	Per Cent.
+3 inches square	5.7
+1½ inches square	42.5
+ ¾ inch square	27.6
− ¾ inch square	24.2
	100.0

The same author recommends reduction in the ratio of 4 : 1 for greatest efficiency with rolls,† but this would not apply equally to Chilian mills, although the increase of the mill might be obtained with a finer ore feed.

The results obtained with the mills running at 14 revolutions per minute are given in Table 1:

Table 1

Belt Feed Per Revolution of Mill Inches	Output Per 24 Working Hours Tons	Power Required Per Mill Horsepower	Increase in Belt Feed Per Cent.	Increase in Output Per Cent.	Increase in Power Per Cent.	Decrease in Output to Increase in Belt Feed Per Cent.	Increase of Power With Decrease of Output Per Cent.	Ore Crushed Per Horsepower Per Day. Tons
2.50	36	14.70						2.45
2.75	39	16.27	10	8.33	10.7	1.67	2.37	2.40
3.00	42	17.32	20	16.66	17.8	3.34	1.14	2.42
3.60	51	23.62	44	41.66	60.7	2.34	19.04	2.16

The second half of the Chilian mills in the plant has only quite recently been altered to run at 16 revolutions per minute, and, as the runner tires are already partly worn, results as to capacity with the different belt feeds at this speed are not comparable with those in Table 1, or sufficiently reliable for publication. Trials, however, indicate that the increase in capacity is at least proportional to the 14 per cent. increase in speed, and that the decrease in crushing efficiency with the heaviest belt feeds is less. The load on the motor is also more even. The author is of the opinion that these mills could be run at 20 revolutions per minute with advantage, but to do so would necessitate replacing the collar bearings of the runner axles with ball bearings.

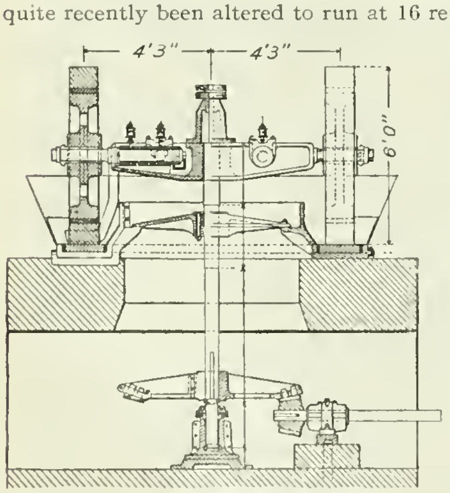

Fig. 2

It might be inferred, from a study of the above table, that the horsepower required with a belt feed of 3 inches is probably low. This could not be confirmed, but that for the other feeds has been checked on various occasions.

It is interesting to note that an increase in the depth of ore on the dies does not act as a cushion to the same extent as in stamp mills, for it is found that, with an increase in the feed of 44 per cent., the apparent decrease in output is only 2.34 per cent.

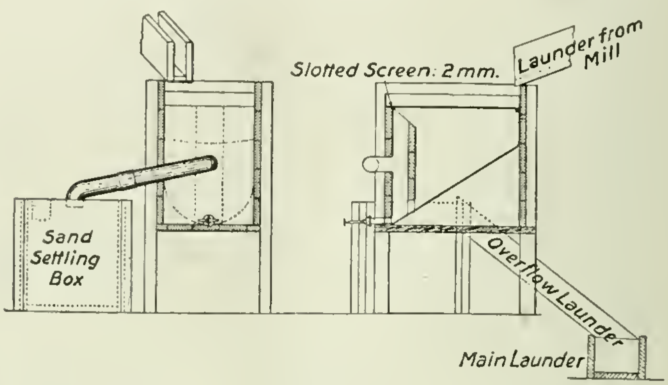

Fig. 3

Mill Product.—The averages of a number of screen tests made are given in Table 2:

Table 2

1 Millimeter Screen	Belt Feed, 2¾ Inches Rev. of Mill, 14. Capacity With Feed, 39 Tons Water Ratio, 4.8 : 1. Height of Discharge, 10 In. Screen, ½ mm. Slotted (.0196 Inch)	Belt Feed, 2¾ Inches Rev. of Mill, 14. Capacity With Feed, 39 Tons. Water Ratio, 5 : 1. Height of Discharge, 10 In. Screen, 1 mm. Slotted (.039 Inch)	Belt Feed, 2¾ Inches Rev. of Mill, 16. Capacity With Feed, 41 Tons. Water Ratio, 5.3 : 1. Height of Discharge, 10 In. Screen, 1½ mm. Slotted (.059 Inch)
+ 30 (.016 inch)	.17	.56	.70
+ 60 (.0083 inch)	5.20	8.10	8.72
+100 (.005 inch)	16.37	20.23	21.20
−100	78.26	71.11	69.38

While the product from these mills is fine and of very even grade, the percentage of −100 product is much less than in the majority of the Chilian mills used in Russia.

A comparison of a great number of results with 1 millimeter screens shows the greatest fluctuation of +60 product, and the −60+100 to be the most constant.

The factors which govern the height of discharge best suited for any mill and the water-to-ore ratio are: (1) speed of mill; (2) length of screen opening and mesh of screen used.

The rapidity with which the pulp is discharged after being ground to the requisite fineness indirectly influences the efficiency or capacity of the mill; and this depends on obtaining the most efficient water action within the pan.

If the height of discharge is too great, or too much water is used, the tendency will be for the particles to rise in strata according to their specific gravity, and the percentage of +60 in the discharged product will be low. On the other hand, if the height of discharge is too low, or too little water is used, the ore layer becomes partly uncovered, and therefore, at each revolution of the mill, particles sufficiently crushed are not all offered facility to rise in the water current and do not receive equal opportunity to discharge.

The +60 product is the most sensitive to any small variations in either of the above respects and, as already remarked, shows greatest fluctuation.

*Transactions I. M. M., 1901-1902, page 254.
†Ibid., page 253, et seq.

In the mills running at 14 revolutions per minute, it has been found from experience, confirmed by sizing tests, that a height of discharge of 9 inches to 10 inches, and a water ratio from 4.5 : 1 to 5.5 : 1, with 1 millimeter screens, gives, all things considered, the best results.

The water is regulated to form a thin layer about 1 inch to 1½ inches in depth immediately behind the runner, and advances in front in a high wave.

To obtain this ideal action with ½ millimeter or 1½ millimeter screens, keeping height of discharge constant, less water is required with the former and more with the latter.

The most suitable height of discharge will vary with different speeds, and can be lower with a slower running mill.

The screen opening in these mills could be longer with advantage, for, to take an instance, the limit of capacity without undue loss in efficiency, using a screen with ½ millimeter opening, is about 39 tons; and it is also, if anything, better to use a screen with 1½ millimeter opening when running the mills at their greatest capacity, although it is to be noted that the latter screen does not influence the size of the discharged pulp.

The product from the mills at 16 revolutions is slightly coarser than at 14 revolutions. The mechanical efficiency of mill works out as follows for the product with ½ millimeter and 1 millimeter screens:

		Per Cent.
Mill feed	+ 3 inches	5.7
	+ 1¼ inches	42.5
	+ ¾ inch	27.6
	− ¾ inch	24.2
	1.172 inches	100.0

That is, 100 per cent. mean, based on common law of average.

TABLE 3

1 mm. Screen	Aperture	E. U. Factor	Sizing Tests, 1 mm. Screen Per Cent.	Pulp E. U.	Sizing Test, ½ mm. Screen Per Cent.	Pulp E. U.
30	.0166	17.8	56	.0910	.17	.03
60	.0083	20.8	8.10	1.6800	5.20	1.08
100	.0050	23.0	20.23	4.6500	16.37	3.76
−100	slimes	27.0	71.11	19.2000	78.26	21.13
			100.00	25.6300	100.00	26.00
E. U. of mill feed =				−.6900		−.69
Work done by mill per unit				26.3200		26.69

Total work done in 24 working hours:

$$39 \times 26.32 = 1026.48 \qquad 39 \times 26.69 = 1040.91$$

$$\text{Efficiency: } \frac{1026.48}{16.27} = 63.09 \text{ per cent.} \qquad \frac{1040.91}{16.27} = 63.97 \text{ per cent.}$$

Two copper amalgamation plates, each 4 feet in width by 10 feet in length, are used for each mill. The feeding of mercury to the mills is similar to ordinary practice and for the reasons that the plates are run hard and kept under locked covers. The important difference in procedure is that the clean-up is made through the opening behind, and the plates are therefore not interfered with except for dressing once a day and removal of amalgam.

TABLE 4

	No. 2 Mill	New Plant
Time of clean-up for each mill	20 min.	15 min.
Gold recovered from amalgamation	58.74%	61.3%
Mercury losses per ton crushed	.69 oz.	.36 oz.
Amalgam recovered from mills	81%	73.9%
Amalgam recovered, plates	18%	24.6%
Amalgam recovered, sundry sources	1%	1.5%

That the small alterations and changes in the general lay-out of the mill, and in the clean-up and amalgamation practice, are an improvement on the usual practice may be inferred from the comparison with No. 2 mill, section 1, which was treating exactly the same ore as shown in Table 4.

The higher percentage of amalgam recovered from the plates in the new plant is primarily due to the more violent water action within the pans.

Reliable figures for wear of tires and dies are not yet available for the new mills, but careful measurements have been made and it is estimated that the net wear of tires is from .62 pound to .65 pound, and of dies .28 pound per ton crushed.

The weight discarded when these parts are worn out will probably be from 9 to 10 per cent. in the case of tires, and 35 per cent. in that of dies.

The wrought-iron outside liners last about seven months.

The life of slotted screens is about 1,200 tons of ore crushed, each screen costing $3.56.

The author would summarize his observations from the running of this improved plant as follows:

The mill is an extremely simple crushing machine, requiring no skilled supervision and very little attention, and is almost "fool-proof."

Temporary failure of the feeder has no other effects than to reduce the capacity of and the power taken by the mill, which is in marked contrast to the effect on a stamp mill if the battery is not immediately hung up.

The mill produces a product of uniform fine even grade, and its mechanical efficiency as compared with stamps, producing in one operation a similar fine-ground product, is vastly superior. The most suitable water-to-ore ratio by weight with these mills is low and compares favorably with that required with stamps.

If the amalgamation plates could be in a separate room and run soft, the running time lost, due to "clean-ups," dressing plates, etc., could be greatly reduced, while it would be possible to run three days or more without making a clean-up of the mill itself. The most suitable capacity at 14 revolutions per minute may be taken as 42 tons per 24 working hours. At the higher capacity of 51 tons the mill is overtaxed.

A throw of about 3 inches for the belt feeder appears to be the most suitable. To put through a higher tonnage with a mill speed of 14 revolutions, it would be advisable to provide a feeder with a wider belt. The mill at 16 revolutions could be run for a capacity of 50 tons, and at 20 revolutions for from 60 to 65 tons.

If this mill were converted into a three runner, which could be done at little expense or trouble, the capacity would be increased 50 per cent. for each speed. The mill, however, as it stands, compares favorably with stamps on a tonnage basis in respect of space occupied, and in initial cost and cost of erection the advantage is also with the former.

Finally, the author is of the opinion that, if the same amount of thought and attention were devoted to the development of the capacity of this type of Chilian mill as has been devoted to the heavy stamp tube mill combination in South Africa, it would prove a serious rival and give a product nearer to the ideal aimed at on that gold field.

Radium Minerals in Australia

A recent discovery of radium in the northern part of South Australia, near Mount Poynter, according to Vice-Consul Baker, of Sydney, is said to be developing satisfactorily, rich ore being raised from workings already started, this ore being described as uranophane, a hydrous silicate of uranium and calcium. Uranophane is regarded as a product of pitch blende, and when pure contains 67 per cent. of uranium trioxide. Another locality where radium-bearing ores have been discovered is the Wodgina region in the Pilbarra gold-field district, in Western Australia. A new ore of uranium has been found here. It is termed pilbarite, and is of an ocherous yellow to lemon-yellow appearance, very much like carnotite. Pilbarite contains 27 per cent. of uranium, with some oxide of lead and other substances.

Relation of Forestry to Mining

The Necessity of Preventing the Reckless Exploitation of Timber Lands in Mining Regions

*By J. F. Lawson**

Forest officials in reporting the facts in regard to mining claims, are doing precisely the work they are paid to do; but they are not merely protecting the people in their right to maintain the forest; they are also protecting the people in the maintenance of the policy sought to be carried out by the mining laws. If any essential requirements of the law be dispensed with, the lands will be appropriated in a way not contemplated by Congress, and in a way seriously to hamper the mineral development of the country.

If patents are to be secured to thousands of acres of valuable timber land by an evasion of the mining laws, and if timber is stripped off for the profit of the perpetrator of such fraud, the timber will not be at hand when the honest miner wants to use it to develop a mine. The title of the land having passed, the prospector will no longer have free access to it, nor the expectation of owning it if he should find mineral thereon. The timber land is not the only land which would pass out of the reach of the prospector if the laws are to be evaded. The law does not contemplate, when a man makes a strike, that he or any one else should obtain, besides his first claim, all the ground he can stake out around about, unless he makes a new discovery and does the required work on each claim.

In the early days of the mining camps this regulation was enforced by the presence of hundreds of miners who would "jump" a claim on which the holder was delinquent in assessment work. In those days there was no complaint of the law working a hardship. And the United States has the right to enforce its regulations in all cases, even though no one else for the time being is wanting the land. If the provisions of the law be not enforced, these vast bodies of mineral land will be taken up by speculators who will hold them until somebody on neighboring property does the work to make the holding valuable. The great bulk of the public domain would soon pass into the hands of men who would hold it and fence it as grazing lands, to the detriment of the small cattleman as well as to the detriment of the whole people. There would soon be little left of the public mineral lands which the prospector would be free to locate for the valuable mineral he could find.

The speculator is a far-seeing man who does not take chances with his money. He looks ahead for returns at the expense of others. The mineral resources of the country will never be developed by speculators. The prospector is a different sort of person; he seeks the risks which the speculator scrupulously avoids. All he has and all he can borrow he will spend digging into the earth. He is the person for whose benefit the mining laws are framed. Give him access to the lands and he will develop the mineral resources. The United States, by holding the title to the mineral lands sacredly in trust until such a man comes who is willing to do his assessment work, until he actually makes a discovery, is doing more to promote the mineral development of the country than all the stock jobbers and advertising promoters that ever lived.

It may be granted that the mining broker cannot well float stock to secure money to make a discovery and to develop a mine until he has patented his claim; but the laws were not formulated for the benefit of that kind of schemers. The patent is a certificate of the Government that a valuable discovery has been made; and promoters have no right to ask the Government to indorse and recommend their mines to prospective investors unless they have in fact made a valuable discovery. The mining laws are designed to enable men to make mines and not to promote the sale of them.

* Law Office of Forest Service, Denver, Colo.

The genuine miner and the honorable mining engineer will be willing to make their money out of the earth and will not insist upon the right to take it from the tenderfoot. There is no reason in public policy why large unexplored areas should be given to fraudulent promoters in order to enable them to fleece unwary investors. You have seen or will see entries of large tracts of land, chosen with little regard for their mining possibilities, that have never been developed, or, if worked at all, have been worked with so little regard to the simplest rules of mining that the money invested has been absolutely wasted. It has been of no value even in proving the character of the ground upon which it was spent. Every dollar so wasted in unprofitable mining is lost to some legitimate mining enterprise. It is not merely sunk in a hole in the ground; its loser has become a walking signboard to advertise the uncertainty of mining and the unreliability of mining engineers. A fraud upon the United States and upon the Forest Service is equally a fraud upon the mining fraternity. No class of men has greater interest than they in an honest and faithful enforcement of those laws of the United States which were designed to encourage the development of the mineral resources of the country.

The Forest Service is but an entering wedge for the broader and truer policy of conservation. In parceling out his reality Uncle Sam had certain policies in view; among them, especially, that of promoting the greatest good of the greatest number of its citizens. He meant to be impartial to his nephews. We have now a machinery of law more or less efficient to prevent the individual from being robbed of the fruits of his labors. There will presently be found some more effective way to prevent any one man from seizing more than his share of the natural resources which should be regarded as the heritage of all.

In working out the policy for the conservation of resources, the state will exercise a constantly increasing supervision to see that these human forces are better conserved than they have been in the past.

They are not all saints in those amalgamated orders of high-graders and dynamiters, but such as they are they average as good as we average anywhere. Thieves are thieves whether in overalls or automobile coats. The anarchist in rags is as respectable as the magnate who runs a railroad train through the constitution and the laws. The same moral obliquity which permits one man to fill his pockets with picture rocks has permitted another to steal a mine. Some steal railroads; others can only steal rides upon them. There is a growing belief that if some way were found to stop the great piracy it would be easier to stop the petty pilfering. It is easy to see in some communities the balance disturbed between uplifting forces and degrading influences. Cannot the law reach out and restore the balance or even restrain the downward tendency?

You in the West are familiar with the mining camps; you know their sturdy, reckless life; you know also the contagion of the surroundings where men see millions staked and lost and other millions won without a risk. You think it absurd that the state must look out for men so well able to look out for themselves. But you forget the missed shot or the rock fall in the lonely stope. You do not see these men, as a result of their hardships, broken in fortune, health, and spirits, with their families a charge upon the communities in which they have sought refuge.

Once the West was far off and thinly peopled; wages were high; but there is no more distance. The swarming life of Europe and Asia is now at hand willing to earn a bare sustenance, whether at Scranton or Coeur d'Alene, at Spring Valley or Ketchikan. The scum of the earth and the cream of the earth's greatest race are here working side by side to make the dividends which enrich stockholders and make the prosperity which upbuilds cities and states.

I have been bred in the law and am disposed to see things done in an orderly way. I must yet confess to an impatience with that manner of statesmanship which can do nothing because unable to agree whether it should be done by the general government, by the state, or by the cities, or whether it should be left to be done by the corporations. The lawyers say that ours is a government of limited powers, and it has its peculiarities. But the constitution has always been equal to every task found necessary to impose upon the national government. When the people of the United States find it necessary, in the preservation of their own lives and the promotion of their own welfare, to pass any laws regarding the mining industry they will find in that document unexpected powers. By Article I, Section 8, the Congress of the United States was given power to lay and collect taxes, duties, imposts, and excises; to pay the debts and provide for the common defenses and general welfare of the United States. When there shall be chosen to that Congress men who are interested in doing the work, rather than in finding excuses for not doing it, it will no longer be necessary to cast about in the power to regulate commerce or in any other obscure clauses to find ample authority.

I recently went through one of our western forests looted by the tie choppers of a great railroad. It was as though a butcher had gone through a herd, stripped the loin steaks from every beef and left the animals to die. From a dozen townships these magnificent lodgepole pines, running nearly 100 feet in height, without a limb, had been felled that two ties might be taken from the butt. Props enough to have timbered all the mines of Wyoming were lying there to rot or to become tinder by which the forest should be burned when a careless smoker or a stray bolt of lightning passed that way. Certain it is to come as that the mine explosion will follow the accumulation of fire damp, yet for the present the forest lies a colossal ruin. The lodgepole is as gregarious in its habits as man. Robbed of their society and separated from its fellows, it goes down before the tempest. As I looked there upon the dead and dying trees, windfall and waste lying in inextricable and impassable confusion—a strange, fantastic comparison came to me. Suppose, I thought, the lives of men were as delicate and their bodies as indestructible as these trees and that it were not the fashion to bury our dead out of sight. The earth would presently be encumbered with such evidence of disregard for human life and limb, when set over against the human greed for gold, that the entire remaining population would arise en masse and annihilate the unmasked doctors and the convicted captains of industry. The *corpus delecti* of a great crime has been buried. But the crime remains and some day the murder will out.

Himalaya Tourmaline Mine

By John Cowan

The Himalaya tourmaline mine, at Mesa Grande, is owned by the Himalaya Mining Co., of New York. The company's agent in charge of the property is J. Goodman Braye, Jr., who was born in Australia, of African parentage, and who came to America when only a lad to make his fortune. He is now in sole charge of the greatest tourmaline mine in the world, so that his career furnishes proof that the accident of race or color is no bar to achievement in this country.

Externally the Himalaya tourmaline mine is as commonplace and uninviting as any coal mine. From 1898 until 1905 operations were conducted by surface or bench digging. Then the overburden of earth became so great that its removal was unduly expensive, and in the rainy season trouble was experienced with the caving in of the sides, so a tunnel was driven for a distance of several hundred feet, following the gem-bearing vein the whole way. This vein varies from 18 inches to nearly 4 feet in thickness. The tourmaline occurs in irregular pockets, mingled with talc, hydrous mica, and an extraordinary variety of other minerals, some of which possess some value, while others are worthless. Among these are lepidolite, quartz crystals, orthoclase, spodumene, muscovite, beryl, hornblende, spessarite and essonite garnet.

The entire mass of material in the pocket is removed, taken outside in mine cars, and conveyed to the washing plant, which is remarkable only for its simplicity. A hose is first turned upon the material, which sufficiently clears the large crystals and other minerals for their identification. Many of the small crystals are covered with tightly adherent talc and clay; so that the mass of small, broken mineral is placed in a suspended barrel, to which a hose is attached, permitting a steady stream of water to be poured in. An outlet in the end of the barrel permits the escape of the water. The barrel is shaken vigorously for as long as may be necessary for the removal of the clay and talc, and the material is then emptied upon trays. The tourmaline crystals and other gem materials worth saving are then picked out by hand.

The tourmaline crystals are sorted with respect to size and quality, varying from small, pencil-like crystals, not more than an eighth of an inch in diameter, up to crystals 2 or 3 inches in diameter. In these crystals almost all the colors of the rainbow may be found. Tourmaline is known by various names, depending upon the color. The red or pink transparent variety is called rubellite; the violet-red, siberite; the blue or bluish-black, indicolite; Berlin blue, Brazilian sapphire; green, Brazilian

Fig. 1. Sorting Tourmalines at Mesa Grande

emerald; yellow or amber is known as Ceylonese peridot; colorless tourmaline as achroite; black, with resinous fracture, as aphrizite; and brown or greenish-black as dravite. All these varieties are found at Mesa Grande.

It is difficult to make a general statement of the value of tourmaline as a gem material, this depending upon its freedom from checks and flaws, its transparency, color, luster, and hardness. The great mass of tourmaline as it comes from the mine is worth but a few cents a carat, on account of checks, cracks, bubbles or lack of transparency, or the colors being too pale. Whatever value such material has as a jeweler's material arises, in the main, from the cutting. But flawless tourmaline, of exceptional hardness, suitable for cutting in the same manner as diamonds is worth from $5 to $20 per carat. Material has been taken from the Himalaya mine that no one but an expert could tell from ruby; and specimens of green tourmaline are sometimes found that almost rival the emerald in appearance. So while some crystals are worth no more than quartz crystals or garnet, others of exceptional hardness and coloring nearly rival the diamond in value. The range of hardness is great, some specimens being 7, some 7.5 and some 8, in the scale in which the hardness of the diamond is 10.

China offers a ready market for all the pink tourmaline not readily absorbed by the American and European demand. Late in June the sale to Chinese dealers of many thousands of carats of this material from the Mesa Grande, was reported. Every year (in common with most other highly colored gems) tourmaline is coming more and more into favor, and is enhancing in price. However, in this country it does not yet enjoy the popularity it merits, as a distinctively American gem. One advantage it possesses is in the fact that it cannot be successfully imitated, owing to certain peculiar optical properties. Plates cut from transparent crystals, parallel to their length, are much used in experiments in optics, on account of their remarkable polarizing action on light.

Tourmaline is found in Burmah, India, Siberia, Germany, Brazil, Maine, Massachussetts, Connecticut, New York, and California; but in most sections its occurrence is haphazard and uncertain, not justifying systematic mining operations. Nowhere are gems found so abundantly or of such remarkable size, beauty, richness and variety of coloring as at Mesa Grande. Only the Himalaya and San Diego mines are in operation, but the Esmerelda mine, a mile and a half distant, has yielded some fine gems and may give a good account of itself hereafter. Numerous other prospects have been located in various parts of San Diego and Riverside counties, but their value is problematical.

General Ore Mining Notes

High Financiering in Mine Claim Shares.—Occasional publicity such as the following received from August Wolf, of Spokane, Wash., may have a salutary effect in time. L. E. Collier, receiver of the Naomi Gold Mining Co., says, in a report filed in the Spokane County Superior Court, that 65 cents of every dollar received from the sale of stock was paid as commissions to L. L. Ratliff, sales manager, and there is no trace of the remaining 35 per cent. The company, which is capitalized at $1,500,000, exchanged its capital stock with W. D. Irwin for mining claims in Oregon, says the receiver. Afterward Irwin transferred back 500,000 shares of the stock, which was held as treasury stock, and it was this stock that the company turned over to L. L. Ratliff as sales manager. The company did not file its articles of incorporation in Oregon, where the property is located. The debts amount to $4,000, including assessment work.

Spokane Interstate Fair.—L. K. Armstrong, superintendent of the mining department of the Spokane Interstate Fair, is making preparations for a convention of mining men from all parts of Washington, Oregon, Idaho, Montana, and the province of British Columbia at the fair in Spokane the week of October 2. The Spokane Mining Men's Club and the Spokane Chamber of Commerce will cooperate with Mr. Armstrong in making the meeting the most important of its kind in this part of the country.

Republic Gold Mining Camp.—According to Charles H. Goodsell, deputy United States Mineral Surveyor, 15 mines in the Republic camp have ore ranging from $40 to $50 per ton. The principal value, however, is in the low-grade ore, of which there are millions of tons suitable for milling. In the Lone Pine and Surprise mines, for hundreds of feet along the workings below the Jim Clark tunnel or Bonanza shoot, there are large quantities of ore running from $9 to $16 a ton. This will make a large percentage of profit when handled and milled on the ground. Instead of shipping this ore, the company is forwarding a grade running from $35 to $45 a ton, which is found in numerous ore shoots and is so clean that it can be loaded on to the cars without sorting. The adit in the Knob Hill struck ore 100 feet from the portal at 125 feet below the surface. This vein was followed for 200 feet and a raise of 75 feet showed $60 ore. The mine now has ore blocked out that will net $100,000. It is shipping a carload a day, and the last 75 cars have averaged $43 a ton net. The operating, shipping, and smelting expenses are about $10.

Kendall Mining Co., operating the Kendall gold mine, at Kendall, Mont., paid its 81st dividend, bringing the total to $2,005,000 paid to August 24. It was the usual monthly disbursement of 2 cents a share, or $20,000, the company's capital being $500,000. The dividends paid so far this year total $80,000. The company is a Spokane corporation, controlled since its inception by Messrs. Finch and Campbell.

Stewart Mining Co. says in its first semiannual report that mine operations in the Coeur d'Alenes during the first 6 months of 1911 resulted in concentrator returns of $299,435.40, ore returns of $21,373.98, and miscellaneous revenues of $300.23, a total of $321,309.61. The total expenses of the mine and company were $180,513.51, leaving a profit for the 6 months of $140,796.10.

Cleveland Mine, Idaho.—Federal Mining and Smelting Co. has taken a bond for $400,000 on the Cleveland mine, near Mace, Idaho, adjoining the Standard-Mammoth group, which the corporation acquired from the late Thomas Greenough and Peter Larson for $3,000,000 about 7 years ago. The Cleveland is owned by Mrs. James Leonard, of Spokane, William R. Leonard, of Denver, and Richard Wilson and Walter McKay, of Portland. It is understood that the Standard-Mammoth ore bodies extend into the Cleveland property, to the line of which the former has been worked. Charles Sweeney, former president and F. H. Brownell, president of the Federal; started negotiations for the option at a conference in Seattle several months ago. Clayton Miller, of Spokane, general manager of the Federal properties, confirmed the report of option, but declined at this time to give any details. The company, which is one of the largest producers in the Coeur d'Alene district, has been paying about $210,000 quarterly in dividends for some time.

Zinc Ore in Idaho.—Herbert Salinger, of Salt Lake, Utah, representing the Paragon Consolidated Co., of Paragon, Idaho, has closed a contract by which a market is provided for the zinc concentrate and lead-silver concentrate produced by the Blackhorse concentrating plant. The lead product will be marketed in Salt Lake, while the zinc product will be forwarded to the Kansas smelters. The Blackhorse mill is operated every other month and the management produces up to 300 tons of zinc concentrate on the 30-day runs, and half of this tonnage of lead concentrate. Plans are now on foot to revamp the mill so that it will produce 15 cars of concentrate a month.

Platinum and Tin.—Those interested in the rarer common metals will learn with regret of the closing of the platinum mine at Rambler, Wyo., and of the mine and smelter of the El Paso Tin Mining and Smelting Co., El Paso, Tex. These operations, by reason of their limited tonnage, were unimportant factors in our production of either of these metals, but they enjoyed the unique distinction of being the only platinum mine and only tin smelter in the United States, and thus, as a matter of national pride, their suspension is regretable. With the closing of the Gap (Pa.) mine many years ago the United States ceased to figure as a producer of nickel; the production of platinum, except from black sands, is cut off by the closing of the Rambler mine; our only tin smelter is closed, although some concentrates may still be expected from South Dakota and the Carolinas, and the output of mercury has long been on the decline. It is odd that these four metals, platinum, tin, nickel, and mercury, while found at widely separated points in the United States, are, with the exception of mercury, nowhere met in commercial quantities. Whether they do not exist commercially or whether systematic and diligent search will discover them is problematical and rather doubtful. In the matter of searching the United States Geological Survey might be of material assistance in indicating where to prospect and where not.

Cripple Creek Ore Shipments.—The output of Cripple Creek for August was the largest for any 31-day period this year, amounting to 79,067 tons of ore with a value of $1,367,115, or

2,446 tons, valued at $36,592 more than in July. The shipments of low-grade ore were exceptionally large.

Golden Smelter, Colo.—Officials of the North American Co. report that the company's smelter at Golden is now handling more ore than it has at any time since the plant was acquired by the present owner. The ore comes principally from Clear Creek, Gilpin, and Boulder counties, much of it from mines that the company owns or holds under lease and operates on company account. The policy of the management in getting hold of more property, and thus making certain of a continuous supply of ore, is maintained. Recent acquisitions are Decatur, Helmer, National, and the Mammoth mines in Gilpin County. It is also getting a supply of custom ore that shows that the operation of the plant is stimulating mining activity in the sulphide belt of Northern Colorado.

Idaho Springs Ore Shipments.—Shipments of smelting ore and concentrates from Idaho Springs so far during 1911 show an increase over the shipments of a year ago. Three mills are in operation—the Jackson, the Hudson, and the Newton. H. B. Clifford, of New York, who holds leases on a number of mines near Idaho Springs, reports that Thos. A. Edison has agreed to make experiments with the ore of the district, and to try to work out a more economical and profitable method of treatment.

Testing Old Placers.—H. J. Reiling, manager and one of the principal stockholders of the French Gulch Gold Dredging Co., is making tests on the gravel of the Peabody and Fortune placers in the Tarryall district of Summit County. The ground contains 4,000,000 cubic yards of gravel that is said to average 25 cents a yard. Mr. Reiling and his associates have deposited $22,500 in a bank to hold a 90-days' option. The French Gulch dredge is now paying.

Camp Columbine is among the latest aspirants to fame in the mining districts of Colorado. It is situated on the southern side of Mount Rosely, 10 miles south of Idaho Springs, and 60 miles west of Denver. H. G. Groth, who has been working a prospect on the mountain for 7 years, reports the discovery at a depth of 45 feet of ore that runs $8,500 a ton. The assay that gave this high value was made on a picked sample, but Groth says that he has ore in large bodies that runs well in both gold and silver.

Potash Deposit in Nevada.—It has been known for some years that potash deposits have existed in Nevada and Utah, but no attempt was made to utilize them owing to the market for such products being in the eastern United States, where the German potash held control. Reports from Goldfield, Nev., state that a potash deposit will soon be opened in Railroad Valley, in Nye County, about 75 miles from Goldfield. The surface deposit shows from 6 to 7 per cent. potash, and it is believed that it will increase in purity with depth.

Camp Terrill, Nevada's latest mining strike, is causing the usual commotion. The first find carried $1,200 per ton; since then a second find is reported carrying 50 cents to the pound in silver. A. G. Price, of Fallon, is quoted as saying that "there are 11 ledges traversing the original locations, all of which have been opened sufficiently to show that they carry ore." From a shaft 107 feet deep on the original claim an abundance of water is being pumped by gasoline power, and the locators of the camp have a fine garden which they irrigate with this water.—*Fallon Eagle.*

Central, Nev., Placers.—Two miners cleaned up $450 by washing 5 days at Central. On the Fulkerson claim, to the east of Central, there are 400 feet of underground workings on pay gravel from 1½ feet to 3 feet thick that yields $16 per yard. "Dry Wash" Wilson is still employing over 25 men in his placer workings, the plant being kept busy day and night washing the auriferous gravel. No figures are given out for publication.

Quicksilver Mining.—According to H. D. McCaskey, of the United States Geological Survey, there are two producing quicksilver mines in Nevada. From 35 tons of this ore 5,250 pounds of quicksilver was produced. In California there are 15 producing mines whose ore averaged .5 per cent. per ton, or 10 pounds. From 115,305 short tons of ore 15,825 flasks weighing 75 pounds each was obtained. The average price in 1910 at San Francisco was $44.51 per flask; at New York, $47.06. The two producing quicksilver mines in Texas produced 8,221 tons of ore, yielding an average of 1.5 per cent. metal, or 30 3 pounds per ton. The entire output in the United States was 123,562 short tons, which averaged .6 per cent. metal.

Comstock Lode's Mexican Mine.—This mine broke its record for weekly ore extraction recently, there being 745 mine cars hoisted with ore that totaled $34,417.45. The previous weekly record was about $26,000 in ore. The ore came from the 2,500-foot level, and 168 cars averaged $113 per ton, being the richest ore and largest tonnage from any one place in this mine. Considerable good ore has been found recently in various places on the Comstock lode.

Anaconda Mine, Mont.—The Anaconda management is so well satisfied with the results being obtained from the hoisting of ore by compressed air, that it has determined to enlarge the compressor plant to a sufficient capacity to provide power for all the company's mines. It is expected that the Diamond mine will be started up this week under the new system.

The station at the 2,800-foot level of the North Butte has been completed and cross-cutting will begin immediately to get between the fault planes encountered on the 2,000-foot level and which later developments have shown to diverge widely with depth.

Park City Mines Consolidation.—All the legal details toward consolidating the Daly Mining Co. and the Ontario Silver Mining Co., at Park City, Utah, have been arranged, so that these two properties can be merged. This would bring together two of the famous old producers of the country, which have many millions in dividends to their credit. It is proposed to create a new corporation to take over both the former incorporations. This corporation is to be capitalized at $1,500,000, divided into 300,000 shares of $5 par value. The capital stock is to be alloted so that 75,000 shares will go to the Daly for its property and 150,000 shares to the Ontario, with 75,000 shares in the treasury for development uses.

Changes in Colorado School of Mines.—A number of important changes are noted in the faculty of the Colorado School of Mines, Golden, which recently opened for the fall term. George W. Schneider and Carl A. Allen, both graduates of the institution, succeed Arthur J. Hoskin and Alwyn C. Smith as professor and assistant professor of mining. The place of Frank H. Cronin, who has returned to the East, has been filled by the promotion of Assistant Professor R. B. Otis. William G. Haldane, G. Montague Butler, and Ransom S. Hawley have been advanced from assistant to associate professorships of metallurgy, geology, and mechanical engineering. Mr. Siegfried Fischer is now instructor in place of fellow in physics. Mr. F. S. Titsworth, E. M., a graduate of the school, is lecturer on mining law, vice Joseph S. Jaffa, resigned. The faculty has been greatly strengthened by the appointment of Dr. Regis Chauvenet at one time president of the school, as special lecturer on mining and metallurgy.

Fatal Fire at Giroux Mines.—On the night of August 23, 10 men, comprising the night shift at the new shaft of the Giroux Consolidated Mines, at Ely, Nev., were caught by a fire originating apparently on the 1,200-foot level. The men boarded the cage, stopped at the 1,200-foot level, where half their number left in the endeavor to escape through the old Alpha shaft, 700 feet away, and the remainder continued to the surface. Those leaving at the 1,200-foot level were all overcome and killed, while of those who continued to daylight, one died on the trip, and the remaining four are in the hospital, seriously injured. It will be remembered that 3 years ago two men were killed and four others were entombed for 46 days on the 1,000-foot level of the Alpha shaft of this same mine.

The Forest of Dean Mine

An Old Iron Mine Producing High Grade Ore. Ancient and Modern Machinery Working Together

One of the oldest mines in the United States is known as the Forest of Dean, having been worked, according to Doctor Beck, so early as 1756. It is situated about 5 miles west of Fort Montgomery on the Hudson River, in Monroe Township, Orange County, New York state. The mine is in what is termed the Highlands of the Hudson. In such a location it is necessary to load and unload the ore twice to place it on the river boats or on the West Shore Railroad which skirts the river at Fort Montgomery.

The first stage of the ore transportation is in tram cars, which are hauled by steam locomotives for about three miles to a point on a high hill above a lake, where it is dumped into ore bins and loaded into Bleichert aerial tramway buckets which transport it to the loading bins on the Hudson. At one time it was carted from the mine railroad to Fort Montgomery. This, however, was when the mine was being worked by the Forest of Dean Iron Ore Co. and before it came into the hands of the present owners, the Hudson River Iron Ore Co. Previous to the latter's ownership the output was probably not over 90 tons per day, and this amount was subject to fluctuation in the iron-ore trade. The conditions which prevailed at that time were considerably different from those at the present time, for not only had this ore, which is non-Bessemer, to compete with the excellent ore from Tilly Foster mine, but also with the Lake Champlain and Sterling Iron and Railway Co.'s magnetites. Tilly Foster mine which was near Brewster, N. Y., has since then been worked out, and most of the Sterling Iron and Railway Co.'s mines that produced Bessemer ore have been abandoned. The ore is shipped to the iron blast furnaces on the Hudson, to those in New Jersey, and to the furnaces in Northeastern Pennsylvania. It is but recently that its output has been increased to 300 tons per day and this requires that the mine be worked night and day.

Magnetite is one of the common minerals in the crystalline rocks of the pre-Huronian. It occurs as an accessory mineral

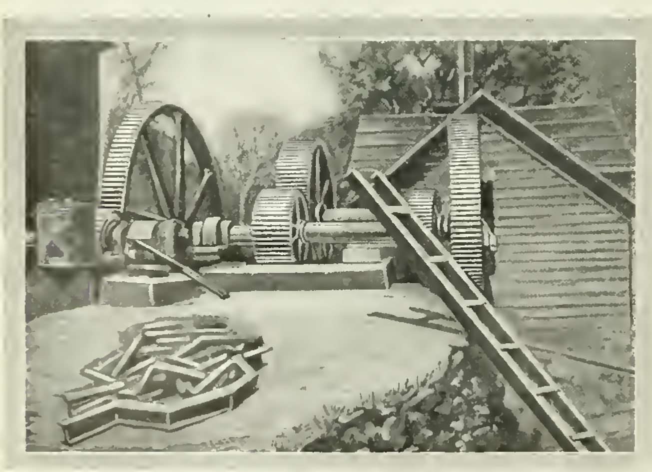

Fig. 1. Pump Gear at Forest of Dean Mine

in the granitic and gneissic rocks of the Highlands and in a more or less irregular belt of similar rocks which run through Orange and Rockland counties, New York, into New Jersey. The beds are not continuous in these rocks, but here and there the magnetite magmas have segregated, forming irregular-shaped pockets or thin-sheeted beds. The ore shows lamination and not infrequently coarse cleavage; it also varies to a certain degree at each mine in chemical and physical properties. In instances the ore deposit may carry phosphorus, titanium, or sulphur in sufficient quantities to render that particular ore body practically valueless. The ore frequently varies in phosphorus content at the same mine, and the phosphorus mineral, being apatite, can be discerned with the eye. The crystallization also varies in the same bed from almost cryptocrystalline to coarse buckshot crystals. One deposit may have alternate thin beds

Fig. 2. Head-House, Forest of Dean Mine

of ore and rock; another deposit horses of rock completely surrounded by ore; or again the rock may be continuous but may widen and thin in lens-like form along the strikes, the ore decreasing or increasing in quantity to conform with space occupied by the "horse," as at the Scott mine in Rockland County. Usually the ore is on both sides of the "horse." The beds are sometimes faulted and folded and the lenticular ore bodies thin out at the ends and with depth until they are lost completely. In general the strike of the ore is northeast and southwest with a dip southeast and the pitch or hade to the northwest.

The Forest of Dean ore body is a large prism-shaped mass 120 feet high by 90 feet wide, its form being due probably to its having been folded upon itself. It dips northwest at an angle of about 23 degrees and has been worked along this slope for a distance of about half a mile. The working slope is on the footwall which is gneiss. There is a horse of rock which divides the ore at the roof and which indicates that the magma was subjected to a synclinal fold. The most remarkable feature about this horse of rock is that it is granite with a small streak of trap rock frozen to it, a phenomenon which does not, it is believed occur at any other magnetite mine in the Highlands of the Hudson or in New Jersey, the horses in the other mines being usually feldspar and greenstone.

The gangue of this deposit was originally red and white feldspar, but pieces of gangue composed of red and white feldspar and a small quantity of white calcite are found with coarse magnetite crystals disseminated through it, giving it almost the appearance, when it is not closely observed, of the franklinite of Franklin Furnace, New Jersey. The ore is medium fine crystalline as a rule, but friable when inclining to shot-like structure. The ore as shipped averages more than 60 per cent. metallic iron and it is not difficult to pick specimens carrying 70 per cent. metallic iron. According to an analysis taken in the days of hand cobbing, the ore averaged about as follows: Silica, SiO_2, 5 per cent.; alumina, Al_2O_3, trace; lime, CaO, 5.51 per cent.; magnesia, MgO, 1.19 per cent.; oxide of iron, Fe_3O_4, 83.56 per cent. = metallic iron, 60.5 per cent.; phosphoric acid, P_2O_5, 2.30 per cent.; carbon dioxide, CO_2, 1.05 per cent.; water, .20 per cent.

The mining is done in benches, the roof being supported by pillars of ore left under the horse of rock which forms the upper part of the pillar. This leaves two series of stopes from which a large quantity of ore can be broken in a day. Air drills are used on the stopes, the compressor being so arranged that it can be run by steam or water-power, usually by the latter when the supply of water will permit.

The hoisting and pumping were at one time done by water-power, but the 40′×6′ overshot waterwheels were not equal to the task of raising a large tonnage, and water-power hoisting was abandoned for steam power. The mine water is raised in a vertical shaft about 900 feet northeast from the mouth of the slope. In this shaft there is a 12-inch plunger pole pump that is run by waterwheels. The gearing for this purpose which was the only part available for illustration, is shown in Fig. 1, mounted on a high masonry foundation. The waterwheel is

Fig. 3. Shift Going into the Forest of Dean Mine

geared to the large wheel to the left and the crank-wheel on the right to the intermediate gears. To the right of the crank-wheel is shown the pitman that works the walking beam or pump bob inside the house to the rear of the gear train. The L to this house covers the shaft. The more one considers the difficulties with which the early mining engineers had to contend, the more respect one must have for their ingenuity; and when it comes to mining the ore, their methods of working seem to be as up-to-date as those of the present generation. This, of course, does not apply to the use of machinery but to the methods of mining.

A view of the head-house at the Forest of Dean mine is shown in Fig. 2. The ore is hoisted up the slope in cars to the top of the head-house (which is arranged so as to be a continuation of the slope) and is dumped automatically over a grizzly. The ore that needs crushing passes over a grizzly to a jaw crusher, from which it falls to a traveling belt. The fine ore goes directly to the ore bins. The traveling belt is the picking belt from which the small quantity of rock which is in the ore is picked by men accustomed to the work. The ore remaining on the belt passes up an incline and drops to the loading pockets, from which it is loaded by gravity into the train cars to be hauled to the wire rope tramway. When sufficient rock has accumulated in the rock bin it is loaded by gravity to cars and hauled to the nearby dump pile. The tower in the foreground carries the hoisting rope to the hoister situated some distance away toward the pump shaft. This arrangement while awkward, answers every purpose and concentrates the machinery where the coal can be delivered handily. Electric signals are arranged to connect top and bottom of the shaft, the head-house, and the engine room.

At the place marked *a*, Fig. 2, are seen the remains of an old Catalan forge that was used probably in the time of the Revolution if not previously. The fortifications along the west bank of the Hudson and so on through Orange and Rockland counties were evidently to hold the British in check and prevent their capturing the mines, which produced the iron so much needed for weapons by the Continentals. This old forge was constructed of sandstone walls, and pieces of sandstone are found with the slag melted to them so intimately as to make it necessary to break the stone to separate the two.

Taken as a whole the Forest of Dean ore deposit is one of the most interesting magnetite deposits to be found in the United States, and the whole plant with its modern and antique machinery is about the only mining proposition in the East which now unites the present with the past.

Duralumin

Duralumin is the name given to a series of light and tough alloys, invented by Herr A. Wilm, of Sehlachtensee, near Berlin. One of this series contains 90 to 95 per cent. of aluminum, and has nearly the same properties as good Bessemer steel, except that its specific gravity is only about 2.8. This metal has great value not only for aviators but also for manufacturers of cartridges. For this manufacture a hardness of 160 at the base is required to prevent expansion with the blow of firing. The hardest alloy of this series reaches 125 in its natural state, which may be increased by cold hammering to 174, taken by the Brinell test. By using one of the hardest of the alloys and treating the metal hot, the hardness is reduced so as to lighten the operations to which it is submitted. For airships the stretch under extension must be over 8 per cent. Tests show that the new alloy breaks at 88,000 pounds per square inch.

An Ore Mine Tromp

By Harold Lakes

As ventilating a mine is a problem that is of interest to all miners, the method described in the drawing will perhaps solve some of the difficulties. Unlike many other ventilating apparatuses, it costs nothing after it is once installed and goes on at all hours, day and night.

Fig. 1 shows a method of ventilating a mine by the use of the water it makes. This method is common in many camps but seems to be unknown in others.

A tunnel can be ventilated for 1,000 feet or more if ample water flows from it. As the water flows from the tunnel into the flume, it is carried out on to the dump until it reaches a point where it can have a fall of about 15 feet or more. Then

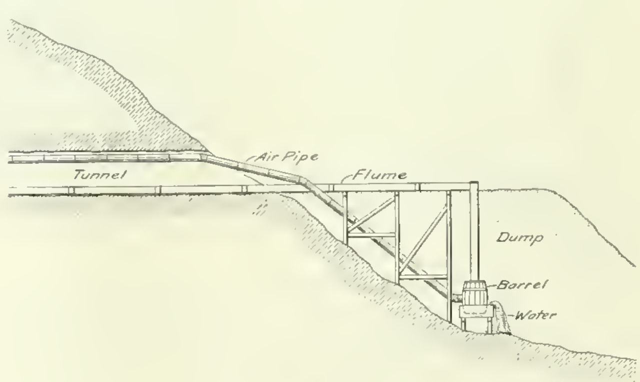

Fig. 1. Ore Mine Ventilator

it falls through a box made of four boards nailed together as nearly air-tight as possible. This box is connected to the inverted barrel as shown. The connection should be air-tight. The air pipe from the tunnel also connects with the barrel about in the middle of the side. This inverted barrel sets in a box which must be a few inches above the bottom of the barrel. The water as it flows from the bottom of the barrel rises over the box and flows away as indicated. The water flowing out in this manner and dropping some 15 or 20 feet causes a suction which will almost put out the flame of a candle in 1,000 feet through a 6-inch air pipe.

Copper Smelting Furnaces

Recent Practice in Construction. Method of Calculating Capacities of Given Sizes

By Chas. C. Christensen

Before deciding on the proper plant for the smelting of copper ore, it is absolutely necessary to determine whether it will be more profitable to convert the copper of the ores to be treated into a "matte" or into black copper; that is, into unrefined metallic copper. This question depends almost wholly upon the character of the ore whether it is sulphide or oxide. The main circumstance which determines the production of either matte or black copper, or of both products in smelting copper ores, is the presence or absence of sulphur in the ores or in the smelting mixture. If we have to deal with sulphuret ores, or with ores which contain sulphurets or sulphates, the production of matte will depend on the degree of preliminary roasting to which the ores have been subjected before they are melted in the cupola.

After deciding on these matters and erecting a plant suitable for the desired product, the success of the smelting depends in such large degree on no other single condition as on the proper composition of the smelting charge as it is put into the furnace. It is the province of the metallurgist in charge of the works to determine the proper composition of this smelting mixture and to give the directions for making this mixture out of the different ores and fluxes, which are available in each case.

For small plants there are two methods of making smelting mixtures. One way, which is followed frequently, is to keep each kind of ore and flux separate in different bins, and to weigh a certain quantity of each class of ore and flux constituting the smelting charge, separately for each charge; dump these together at the charge door of the furnace, and mix them as they are thrown into the furnace, a horizontal layer in alternation with fuel. This method leaves the correctness of the smelting charge altogether to the care and attention of the weigher and feeders. Another plan, much more to be commended, is to mix the different ores in the proper proportions in large quantities, and to draw from this mixture such quantities as are wanted for a single charge, thus leaving only the correct weight of the whole charge to the weigher, and not the correct proportion of the different ores and fluxes. This method is evidently the safer of the two.

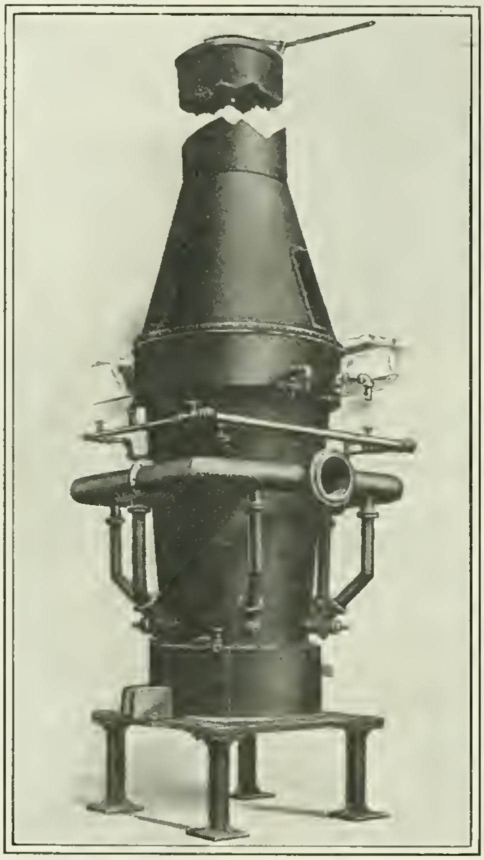

FIG. 1. ROUND COPPER FURNACE

The capacity of a blast furnace, in tons of ore, depends chiefly upon the quantity of fluxes required, pressure and volume of blast and the fusibility of the charge.

The size of a furnace is determined by its internal area at the tuyere level. The limit of width has been found to be 54 inches for rectangular furnaces and consequently 54 inches diameter is also the limit of round furnaces. For the length of a rectangular furnace there seems to be no limit, furnaces over 100 feet in length are in operation in the United States today. The smaller sizes of round furnaces will smelt approximately $4\frac{1}{4}$ tons of ore and fluxes per square foot of area at the tuyere level per day of 24 hours. Following this rule a round copper smelting furnace of 20 tons capacity per 24 hours should have an area at the tuyere line of $\frac{20}{4\frac{1}{4}} = 4.7$ square feet or about 30 inches diameter. A 30-ton furnace should have an area of $\frac{30}{4\frac{1}{4}} = 7.06$ square feet or 36-inch diameter and a 50-ton furnace $\frac{50}{4\frac{1}{4}} =$ about 12 square feet or about 48-inch diameter. For larger rectangular furnaces this rule must be modified. At Washoe smelter, Anaconda, when they were running an 87-foot long furnace, they treated as much as 2,800 tons of charge per day of 24 hours, which, figuring maximum width 54 inches, will give a smelting capacity of 7 tons per square foot of area at the tuyere line. This furnace has since been lengthened to 126 feet.

For middle-size rectangular furnaces, smelting capacity, however, will not exceed 5 to $5\frac{1}{2}$ tons per square foot of area, or, as an example, 450 to 500 tons per 24 hours for a 54″×240″ furnace. Small rectangular furnaces will even run as low as the round furnaces. A 44 in.×96 in. for example, should not be rated over 100 tons capacity.

Fig. 1 shows a well-designed round copper furnace. The bottom of the furnace consists of a heavy cast-iron plate resting upon four short columns and having hinged drop doors under the bottom of the furnace shaft. The water-jacket is of steel plates, the inner plate being flanged out and connected to the outer plate by a riveted joint on the outside of the jacket, leaving the inner shell completely smooth without any rivets or staybolts exposed to the heat. The outside sheet of the jacket is extended down to the bottom plate to form the curb of the furnace. A sheet-steel wind box encircles the outside of the jacket, suitable tuyere openings being provided from the wind box into the interior of the furnace. Above the jacket is a sheet-steel hood of conical shape provided at the feed-floor level with an opening for charging the furnace. The hood terminates in a steel stack passing up through the roof of the building. These round furnaces are manufactured in different sizes and of the smelting capacity referred to above.

Fig. 2 illustrates an up-to-date rectangular copper smelting furnace. The bottom of this furnace is formed by a heavy cast-iron plate, resting upon cast-iron columns placed on the furnace foundation. The jackets rest directly upon the bottom plate, but are also supported from the mantle frame by suitable hangers, so that when the bottom plate is lowered the jackets remain in position suspended from the mantle frame. The jackets are made in sections of steel plates with joints on the outside, and are stayed between the inner and outer sheets by crowfoot steel stays. No rivet heads appear anywhere on the inner sheets of the jackets. One side jacket section is provided with a recess at the base for a rectangular tapping jacket used for draining the furnace when blowing out of service. One end jacket is provided at its base with a recess for inserting a rectangular breast jacket, in front of which the trap spout is set and through which the molten material flows to the settler. The breast jacket and trap spout are made either of bronze or of steel plates, as they are constantly in use and require very durable materials to give satisfactory service. All jacket sections are provided at their edges with strong lugs and bolts for securing them to each other, and the entire set is bound by steel I-beam binders on each side, and both ends of the furnace held together at the corners by strong U bolts. All jackets are provided with inlet and outlet connections for cooling water and handholes at the base for cleaning.

The tuyere boxes are bolted rigidly to the back of the jackets and connected to the bustle pipe by light steel tubing. The bustle pipe is made of steel plate provided with a main flanged nozzle for connecting it with the main blast pipe, and suitable nozzles on each leg for connecting the tuyere pipes.

The mantle frame is of heavy steel I beams and rests upon four cast-iron or steel columns at the corners of the furnace. A cast-iron plate rests upon the mantle frame, forming a base for the brickwork of the shaft. The furnace shaft is made of good common brick and lined on the inside with 9 inches of firebrick. At the charging-floor level openings are provided in each side of the shaft, the full length of the shaft, for charging the furnace. The bottom and sides of these openings are protected by heavy cast-iron plates and the top of the opening is formed by a steel I-beam lintel frame which carries the brickwork of the shaft above the charging openings. Stationary light steel curtains hung from the lintel frame are provided to cover the charging opening to within 12 to 18 inches of the floor level, leaving just opening enough below the curtain to shovel the charge into the furnace. The curtains can be easily removed for barring down, furnace inspection or other purposes. The top of the furnace is covered by a pyramidal-shaped steel hood terminating in a connection for a round steel stack and downtake.

These rectangular copper-smelting furnaces are made in different widths and lengths to suit capacity and locality, as already referred to above.

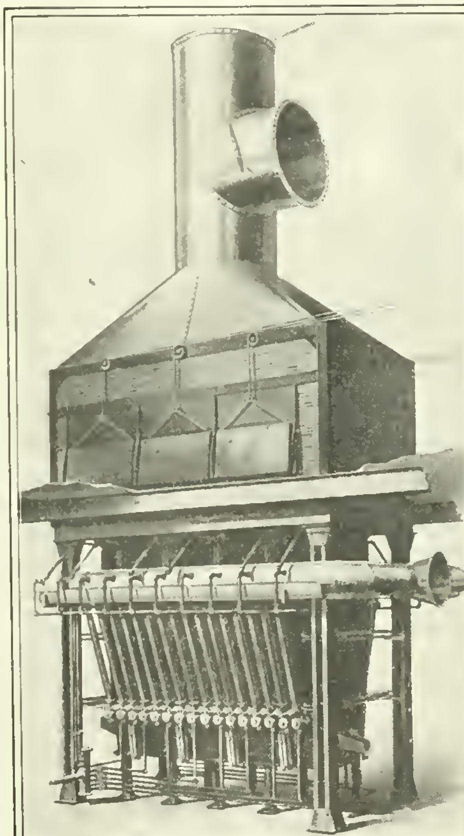

Fig. 2. Rectangular Copper Furnace

Joplin Zinc Notes

James F. Callbreath, Secretary of the American Mining Congress, with temporary headquarters at Washington, D. C., has appointed B. K. Blair, of Joplin, a member of a special committee of five to aid in securing mining statistics. George W. Riter, of Salt Lake City, is to be chairman of the committee. A. W. Warwick, of Denver, is another member of the committee. The remaining two have not been named. The resolution creating the new committee was adopted at a recent meeting of the members of the Utah chapter of the Congress. Mr. Blair is secretary of the Zinc Ore Producers Association.

After numerous delays due to caving ground, the Tri-City Mining Co., under the new name of the S. V. & D. Mining Co., has begun operations on a large scale in the Carthage, Mo., camp. Homer P. Sewell, former owner of the mine, recently sold the property to eastern capitalists, who intend to erect a concentrating plant with a capacity of 200 tons per shift.

Sublessees on the Paoma Mining Co.'s land in the west part of Joplin are sinking to the 160-foot level where ore has been located in drill holes. Previous operations have been conducted at a depth of 100 feet.

The Stolfus-Cassel mine on the Berry & Pieksen lease of the Pinkard land, at Joplin, has been sold to George Dimmick, Jr., of Huntington, W. Va., and L. H. Gormley, of Joplin, for $4,000. Ore, which is found in soft ground at a depth of 112 feet, is treated on hand jigs.

The Moler-Smith Mining Co., operating an open-cave mine in the Carl Junction, Mo., camp, has ordered a core drill which is expected to arrive in April. The bottom of the open pit is now 80 feet, and in this floor the first core drill holes are to be sunk to a depth of 500 feet. Core drilling was introduced into the Joplin district last fall by the Oronogo Circle Mining Co., and it has proven successful. Another company planning to operate a core drill soon is the White Dog Mining Co., working in the sheet-ground area north of Webb City, Mo.

A remarkable depth of ore development has been attained at the Center Creek Mining Co.'s property, in the Webb City, Mo., camp, when it is taken into consideration that this tract was one of the pioneer grass-root producers of the district. For years the land turned out heavy shipments of zinc and lead ores from shallow gouges, the ore being found within a few feet of the surface. Gradually operations have been extended deeper, the ore formations being almost continuous down to the 200-foot level at which depth two leasing companies, the Pasadena Zinc Co., and the Mercedes Mining Co., are now operating. The latter company is producing ore which runs 10 per cent. in zinc blende, with some lead.

Six miles east of Carthage, Mo., a district that has been dormant for years is taking on new life and several good producers of calamine, zinc blende, and lead are being opened. The new mines are in the Reeds Station camp and much of the development is of a comparatively shallow nature. Among the steadier producers are the Lone Star and the Magnet mines, while a new property known as the Jack Rabbit is beginning to find its way into the list of the producers. Another property that is attracting attention is the Sampson mine, where a large deposit of pocket ore has been blocked out.

In the Quapaw, Oklahoma, camp, where many of the mines were closed because of the scarcity of water, operations were resumed following the heavy rains early in March. The drought resulted in a big curtailment in the ore production from that camp. Farther to the southwest the mines of the Miami, Okla., camp are running steadily but are selling little ore, the turn-ins since the first of the year having been insignificant. As a result the surplus of zinc blende has grown to approximately 4,000 tons, the largest surplus of any single camp in the district. Producers are holding for higher prices.

William Lanyon, a multi-millionaire of St. Louis, will be in the market for Joplin zinc ores again within a year if his reported plans to erect a large zinc smeltery at Hillsboro, Ill., materialize. Mr. Lanyon formerly operated zinc smelteries on an extensive scale in Pittsburg, Kans.

C. S. Bankard has purchased the Alpha mine at Spring City, Mo., from Adam Scott. He intends to increase the capacity of the mill, which now handles 100 tons per shift. Prospect drifts, at a depth of 105 feet, have been driven into encouraging ore formations.

Calculations in Ore Concentrations

Method of Algebraic Calculations for Close Regulation of Concentrating Operations

*By Rudolph Gahl, Ph. D., Morenzi, Ariz.**

The size of American concentrating plants, especially of those treating copper ore, has very greatly increased in recent years. When we consider the enormous sums of money represented by the ore treated in these plants and how great might be the financial loss due to slight errors in mill operation, the necessity of keeping close watch on the work becomes apparent.

It is not possible to so thoroughly control a plant of this kind as it is to regulate, say, an electric central station, where a number of ammeters and voltmeters will indicate precisely the operation of the plant. The best indicators which the concentrating man has at his command are screen tests and assays, but a great deal also depends on his ability properly to interpret the readings of these indicators. To do this successfully requires the application of some mathematics, and it is my desire to show in this paper how much can be done in this direction by simple algebra. I do not claim that the relations that I shall develop are new, for others have already applied algebra to problems of ore dressing: but the methods used and results obtained do not seem to have become well known, probably because the textbooks give but little, if anything, on the subject. It is my hope that by communicating the information to this Association, I may save others the trouble of working out such problems for themselves.

The Value of the Assays.—Let us consider in the first place the information which the assays of heads, concentrates and tailing will give us regarding the saving which a concentrator is making. Let x equal the weight of the ore put into the mill, with y and z the respective weights of concentrate and tailing produced from the x quantity of ore. The assays of ore, concentrate, and tailing may be designated by a, b, and c, respectively.

Then the two facts, that the weight of ore equals the combined weights of concentrate and tailing, and the amount of copper, or other valuable constituent, in the ore equals the combined amount of copper in concentrate and tailing, are expressed by the two equations,

$$x = y + z \qquad (1)$$

$$ax = by + cz \qquad (2)$$

The absolute quantity of ore milled is immaterial to the calculation of the saving, inasmuch as these equations apply equally well to large or small amounts of ore passing through the mill. Therefore we may consider the treatment of 1 ton of ore, and make $x = 1$. Our equations then become,

$$1 = y + z \qquad (1a)$$

$$a = by + cz \qquad (2a)$$

If we eliminate z between these equations we get,

$$y = \frac{a - c}{b - c} \qquad (3)$$

Now y, according to our definition, is the weight of concentrate produced from 1 ton of ore. We will get the saving by dividing the amount of copper in the concentrate by the amount of copper in the 1 ton of ore, or the saving which may be represented by S, is expressed by the equation,

$$S = \frac{by}{a}$$

Substituting this deduced value of y in equation (3) we get the following equation for the saving,

$$S = \frac{b(a - c)}{a(b - c)} \qquad (4)$$

This formula contains no weights and it is clear, therefore, that the saving of a concentrating plant may be calculated from the assays of the ore, concentrate, and tailing without knowing anything about the quantities used or obtained. For example, a concentrator operating on 3-per-cent. copper ore may produce concentrate carrying 17 per cent. Cu and tailing with .7 per cent. Cu. What saving has been made? Substituting the values in formula (4) we find approximately 80 per cent.

In plants where ore and concentrate are weighed (the weight of the tailing being taken by difference), the results of this formula can be checked against the saving calculated by other methods. There are three more possibilities, which in our terms are as follows:

$$S = \frac{by}{ax} = \frac{\text{copper in concentrates}}{\text{copper in ore}} \qquad (5)$$

$$S = \frac{by}{by + cz} = \frac{\text{copper in concentrates}}{\text{copper in concentrates and tails}} \qquad (6)$$

$$S = \frac{ax - cz}{ax} = \frac{\text{copper in ore} - \text{copper in tails}}{\text{copper in ore}} \qquad (7)$$

If the weights and assays are all correct, these four methods should check. In practice, of course, they do not check exactly. An example of the results obtained by the four methods in a certain copper concentrator, for several consecutive months is as follows:

Method of Calculation	Saving		
(1) Assays only	77.48	78.59	80.33
(2) Weights, and assays of ore and concentrate	78.09	80.73	79.00
(3) Weights, and assays of tailing and concentrate	77.64	79.11	80.02
(4) Weights, and assays of ore and tailing	77.52	78.69	80.27

These four methods of calculation are not independent of each other. If the amount of copper in the ore as calculated from weight and assays equals exactly the amount of copper in concentrate and tailing as calculated from their weights and assays, all four methods will give the same results; but if there is a discrepancy, the methods will give discordant results. In the latter case it will depend entirely on specific conditions which method is the most trustworthy; whether, for example, one sample is more reliable than another, or whether the weights can be relied upon, etc.

In the derivation of the formula for the saving calculated from assays only, equation (3) has special interest.

If we recall that y means that fraction of the ore which makes up the concentrate, we see that it is equivalent to the "rate of concentration." For instance, in the example of an ore carrying 3 per cent. copper, and giving concentrate of 17 per cent. and tailing of .7 per cent. copper, we would find for y the value .141, or expressed as a common fraction $\frac{1}{7.09}$, which is equivalent to the statement that 7.09 tons of ore have produced 1 ton of concentrate, or that the ore has been concentrated 7.09 into one.

This equation is interesting from another standpoint. The rate of concentration is expressed by the assays of the ore, concentrate, and tailing; therefore it will hold true for copper, gold, or silver assay, or any other set of chemical determinations. All of these determinations cannot be made with equal exactness, and when we have a practical problem of determining the rate of concentration from a set of assays, such determinations will be chosen as are most reliable.

On the other hand, the fact that the rate of concentration can be calculated in so many ways, permits us to eliminate y and compare the different assays directly. If, for example, a, b, c, represent assays for gold; a_2, b_2, c_2, assays for sulphur; and a_3, b_3, c_3, assays for iron or any other constituents in ore, concentrate, and tailing, respectively, the relations will hold true, thus:

$$\frac{a - c}{b - c} = \frac{a_2 - c_2}{b_2 - c_2} = \frac{a_3 - c_3}{b_3 - c_3}, \text{ etc.} \qquad (5)$$

* Reprinted from the *Western Chemist.*

I have not at hand any assays to show the application of this equation, but it is clear that it will allow the calculation of a complete analysis of the tailing if a complete analysis of the ore and concentrate and only one assay of the tailing be given.

Value of Screen Tests.—Thus far we have been considering only the information which the assays give in solving problems that come up in ore concentration. Let us now introduce the sizing screen and see what additional information we can gain by its use.

Take for example a problem of this kind: A certain concentrator disposes of its tailing in the following manner: After classification in cone classifiers, the spigot discharge contains the coarse sand with a little water, and is used to build a dam across the mouth of a gulch adjoining the tailing end of the plant. The overflow is conducted into the basin thus formed, where the suspended solid matter settles, liberating clear water which is again used in concentrating. The question arises, what percentage of the tailing goes to the dam and what percentage to the pond. This problem can easily be solved by making some sizing tests on the general tailing and the two products of classification mentioned.

Let the total quantity of the tailing be represented by x; that part going to the dam by y, and the portion going to the pond by z. Then we have the equation,

$$x=y+z \qquad (6)$$

If we screen the samples of each material on, say, a 100-mesh screen, we will have a certain fraction of each sample remaining on the screen which we will call α_{100}, β_{100}, and γ_{100}. If we screen a general tailing sample we will evidently get the same percentage of 100-mesh material as if we split this sample into the part which builds the dam and the part which feeds the pond, screened these two samples separately and combined the corresponding sizes. This fact is expressed by the equation,

$$\alpha_{100}\, x=\beta_{100}\, y+\gamma_{100}\, z \qquad (7)$$

Since these two equations in no way depend on the actual quantity of tailing represented by x, we can make $x=1$. Then,

$$1=y+z \qquad (6a)$$

$$\alpha_{100}=\beta_{100}y+\gamma_{100}z \qquad (7a)$$

or by the elimination of z,

$$y=\frac{\alpha_{100}-\gamma_{100}}{\beta_{100}-\gamma_{100}} \qquad (8)$$

This equation naturally holds true for any other screen size and if we screened on a 200-mesh screen we would have,

$$y=\frac{\alpha_{200}-\gamma_{200}}{\beta_{200}-\gamma_{200}} \qquad (8a)$$

The screen to be used in a given case depends on the material to be screened, the principal point to be observed being the selection of the screen which will give the most nearly correct results. It is to be understood that screening does not give exact results, for no screen is absolutely uniform; but those who have made wet screen tests often enough to become proficient will admit that screening on fine sizes, say from 100-mesh down, is fairly accurate. Although the error in screening expressed in percentages may be greater than the error in assaying, there are cases in which the results based on screen tests are much more reliable.

In the case under consideration the screen tests were as follows: Percentage on 100-mesh, general tailing, 44.4; tailing to dam, 75.2; tailing to pond, 3.1.

Substituting the screen results on 100-mesh screen in our formula, we find that 57.3 per cent. went to the dam and the balance of 46.7 per cent. to the pond.

This problem could have been solved from the assays only. The same set of samples used for the screen test was assayed with the following results:

	Cu *Per Cent.*
General tailing	.85
Tailing to dam	.72
Tailing to pond	1.16

Our formula (3) will solve this problem. Although we have deduced this formula for relations existing between ore, concentrate, and tailing, it holds for any case in which one product is split into two other products, or where two different products are combined into one. I must emphasize the fact that the two products into which one is split, or which are combined into one, must be different, for if they are the same the problem cannot be solved and if they are nearly alike the error in the result will be great. Therefore if there is but little difference in the assays of the products, screening will give better results, but if the material is of practically the same size the assays should be the basis of the calculation. Returning now to dam problem, let a represent the assay of the general tailing, b the assay of the coarse tailing and c the assay of the fine tailing; y will represent the fraction of the tailing going to the dam. Using these assays in the formula we get as a result,

$$y=70.5 \text{ per cent.}$$

This is decidedly different from the figure 57.3 per cent. which we obtained from the screen tests, and is evidently not reliable. This is due to the fact that the differences between the assays of the three products are so small that they are not a safe basis of calculation. This, then, is a case where screen tests give much more reliable results than assays.

That the assays are really conformable with the screen tests can be shown by calculating the assay of the general tailing from the assays of the coarse tailing (dam) and the fine tailing (pond), making use of the proportion between the two found by screening. The calculated general tailing assay, according to this, would be,

$$a=bx+cy$$

$$a=.91 \text{ per cent. } Cu$$

This checks the actual assay within the limits of the ordinary cyanide assay for copper, and shows that the results by assaying have not contradicted the results obtained by screening.

But we are able to solve this problem in still another way, by considering the percentage of water carried by each one of the materials in question. We have the equation for the dry pulp,

$$a=b+c \qquad (9)$$

If we call the weights of the wet pulps A, B, and C, respectively, the following equation is also true,

$$A=B+C \qquad (10)$$

If α, β, γ, represent the percentages of solid matter in A, B, and C, respectively, we will have the following equations:

$$a=A\alpha \quad A=\frac{a}{\alpha} \qquad (11)$$

$$b=B\beta \quad B=\frac{b}{\beta} \qquad (12)$$

$$c=C\gamma \quad C=\frac{c}{\gamma} \qquad (13)$$

Substituting these values in equation (10) it follows,

$$\frac{a}{\alpha}=\frac{b}{\beta}+\frac{c}{\gamma} \qquad (14)$$

Since it is again unessential what quantities we consider, make $a=1$. Then,

$$1=b+c \quad c=1-b \qquad (15)$$

$$\frac{1}{\alpha}=\frac{b}{\beta}+\frac{c}{\gamma} \qquad (16)$$

By eliminating c in the two equations

$$b=\frac{\beta(\alpha-\gamma)}{\alpha(\beta-\gamma)} \qquad (17)$$

The moisture samples taken gave the following results,

$\alpha=13.1$ per cent. solids

$\beta=42.5$ per cent. solids

$\gamma=\ 6.9$ per cent. solids

By substituting these figures in our equation

$$y=56.5 \text{ per cent.}$$

which represents the percentage of dry tailing that would go to the dam. This checks the result obtained from the screen tests, which was 57.3 per cent.

It seldom happens, however, that problems in the distribution of pulp are as easy as this one. If three products are combined into one, or one is split into three, the calculations are more complicated. For example, a concentrator produces three final tailing products, by the following treatment: the coarsest ore is treated on Wilfley tables, the next finer on one set of vanners, and the finest on still another group of vanners. The tailings from all three sets of machines are combined into general tailing. The question arises, what percentage of the general tailing originates from the Wilfley tables, and what percentage from each set of vanners. This question could be solved by screening the different tailing samples. Let us call,

a_{30} the fraction of general tailing remaining on 30-mesh screen.

b_{30} the fraction of Wilfley tailing remaining on 30-mesh screen.

c_{30} the fraction of 1st vanner tailing remaining on 30-mesh screen.

d_{30} the fraction of 2d vanner tailing remaining on 30-mesh screen.

a_{200} the fraction of general tailing on 200-mesh screen, passing 30-mesh.

b_{200} the fraction of Wilfley tailing on 200-mesh screen, passing 30-mesh.

c_{200} the fraction of 1st vanner tailing on 200-mesh screen, passing 30-mesh.

d_{200} the fraction of 2d vanner tailing on 200-mesh screen, passing 30-mesh.

β the fraction of Wilfley tailing in general tailing.

γ the fraction of 1st vanner tailing in general tailing.

δ the fraction of 2d vanner tailing in general tailing.

Actual screening showed that only a portion of the general and Wilfley tailing remained on the 30-mesh screen, and the vanner tailing contained only negligible portions of such material. This furnishes the equation,

$$\beta\, b_{30} = a_{30} \qquad \beta = \frac{a_{30}}{b_{30}}$$

from which β can be calculated.

For the screenings passing through 30-mesh and remaining on 200-mesh the following equation will hold true,

$$\beta\, b_{200} + \gamma c_{200} + \delta d_{200} = a_{200}$$

But according to our assumption,

$$\beta + \gamma + \delta = 1$$

and by eliminating δ we get

$$\gamma = \frac{a_{200} - d_{200} - \beta(b_{200} - d_{200})}{c_{200} - d_{200}}$$

The actual screen tests for one day were as follows:

$a_{30} = 17.7$	$a_{200} = 36.8$
$b_{30} = 40.7$	$b_{200} = 53.9$
	$c_{200} = 44.0$
	$d_{200} = 9.3$

The calculation gives the following results,

$\beta = 43.5$ per cent.

$\gamma = 23.3$ per cent.

$$\beta b_{200} + \gamma c_{200} + \delta d_{200} = a_{200}$$

$$\beta + \gamma + \delta = 1.$$

The elimination of γ furnishes the equation,

$$\delta = \frac{a_{200} - c_{200} - \beta(b_{200} - c_{200})}{d_{200} - c_{200}}$$

$\delta = 23.3$ per cent.

As a check on this calculation $\alpha + \beta + \gamma$ may be formed which should add up to 100 per cent.

This may be sufficient to show how similar problems may be solved. If it is necessary frequently to determine what percentage of the total tailing originates from the different machines in a concentrator it may be wise to install mechanical appliances for this purpose. At my suggestion the Detroit Copper Co. has done this in the following way: The tailing launders from the different groups of machines are conducted separately to the bottom of the mill. There separate sample slots are provided for the discharge from each launder. These slots are of equal width and are operated by the same mechanism, consequently the samples cut out by them are proportional to the total amount of tailing. I may mention, by the way that the three streams of tailing are combined after passing their respective sampling slots and that a sample of this general tailing product is taken through a slot which is operated by the same mechanism that actuates the three sampling devices mentioned above.

Of course the assay of the general tailing can be calculated from the weights and assays of the three separate tailing samples. The comparison between the calculated and assayed general tailing sample furnishes a check on the work of sampling and assaying.

Distribution of Pulp.—The question may be asked whether it is of so great importance to know just how the pulp is being distributed in a mill, and whether the mill man cannot tell from the appearance of his machines whether the distribution is correct. A comparison between actual determination and estimates from appearances of the machine has shown that such estimates are in no way trustworthy. There will be one distribution of pulp which will give the minimum loss, and the only question is whether the results obtained by that distribution are sufficiently better than any others to warrant exact determination of the proper conditions. I will try to illustrate this by again referring to a practical case. In a certain concentrating plant two vanner feeds are made. The separation of the two feeds is made in V-shaped box classifier in which, however, no hydraulic water is used, so that only a rough classification is made, throwing the greater part of the sand and the smaller part of the slime to the first set, and the rest of the sand and the bulk of the slime to the second. The question now arises, how much feed should each set of vanners carry?

Some tests showed that if the best possible saving of copper was desired, only a very small feed should be carried per machine, and that increasing this load increased the loss of metal. But such a policy could not be carried out in a commercial plant as the question of operating cost would enter. An extremely light load would be impossible, for only a relatively small profit would remain after deducting operating costs, which in the case of a small load would form a serious item.

Let us call metallurgical saving the percentage of valuable metal recovered. If we deduct from this figure as many per cent. as would pay for the operation of the machine, we will get what we may call commercial saving. Now the commercial saving is the best, or expressed mathematically, has a maximum for a greater load. Assuming, for example, a copper value of 15 cents per pound, curves may be drawn which it is assumed will represent commercial saving for the coarser vanner feed, as 5½ tons, and the finer vanner feed, as 8 tons.

This would mean that the feed should be distributed between the first and second sets of vanners in the proportion of 11 to 16 in order to get the most economical load, and it shows the value of the method in guiding the concentrator foreman in the distribution of pulp. In arriving at this conclusion the assumption has been made that by changing the size of the classifier spigot discharge, the nature of the two feeds is not changed. This assumption will be safe when the existing distribution is not very different from the one found best by the method.

The result indicated; viz., that a vanner treating a coarse feed should receive a smaller load than a vanner treating a slime feed, may seem surprising in view of the fact that a slime table should receive a very small load in order to make a good saving. I think also the fact that a slime vanner carrying its best load will make high tailing and a vanner treating coarse material will produce low tailing would induce some mill managers to take the feed away from the slime machines and increase the load on the coarse.

Nevertheless, considered from the standpoint of the curves this would be a mistake. The explanation lies in the fact that this slime feed contains such a large percentage of what has been called absolute slime, on which concentrating machines cannot effect a saving by any means, that the proportion of copper that can be saved is very small and would not pay for the operation of the large number of machines necessary to save it. A coarser feed, however, contains only a small percentage of this extremely fine slime, and for this reason the recovery will be high in every case. But even though it may be high already, it may pay to try to increase it by distributing the pulp over more machines.

There is one point that I would like to emphasize in this connection; that the tailing assay gives no information regarding the work which a machine or plant is doing. The only criterion is, does the tailing contain mineral in a form that can be saved by wet concentration. It is not easy to determine this point and the only place where its determination is attempted, as far as I am aware, is in the concentrator of the Green Cananea Co., Cananea, Mexico. Although the methods in use for this purpose may not be perfect, it seems to me that by adopting some such plan we shall be able to distinguish between avoidable and unavoidable losses and learn to eliminate the former.

Lake Superior Mining Institute Meeting

The sixteenth annual meeting of the Lake Superior Mining Institute, which was held on the Minominee Range, August 22, 23, and 24, was successful in every way. To furnish sleeping accommodations for the members and visitors, three Pullman cars were chartered by the committee of arrangements so that with these, the hotel, the four private cars, and private houses, none were obliged to remain up all night. During the first day and night the session was held at Crystal Falls, the county seat of Iron County. Here the ore dryer at the Hollister mine was inspected and the Tobin and Bristol mines visited. In the early evening the members were entertained with a barbecue and vaudeville at Idlewild by the Crystal Falls Commercial Club, and later a business session was held at the Court House. Alexander M. Gow gave an interesting and instructive illustrated lecture on "Some Safety Devices of the Oliver Iron Mining Co."

Wednesday the members and visitors left Crystal Falls by special trains to visit the Baltic and Caspian mines. After a social session at the Baltic mine club house, trains were taken to the Caspian mine. From the Caspian mine the trains went to Iron River where the second session was held, at which F. W. Denton and Graham Pope, both of Houghton, were elected president and vice-president, respectively, and it was decided to hold next year's meeting at Houghton, Mich. During this session the following papers were read: "Surveying and Sampling Diamond-Drill Holes," by Edwin E. White, Ishpeming, Mich.; "Tobin Mine Sub and Caving System," by Fred. C. Roberts, Crystal Falls, Mich.; this paper was read by Professor Speer, as Mr. Roberts, being president, occupied the chair; he took part, however, in the discussion; "The Relation of Mining Interests to the Prevention of Forest Fires," by Thos. B. Wyman, Secretary-Forester, Munising, Mich.; "Square Set Mining," by Floyd L. Burr, Vulcan, Mich.; "Top Slicing and Caving System in Stambaugh District," by W. A. MacEachron, Iron River, Mich.; "Check System of Time Keeping," by Jas. D. Vivian, Crystal Falls, Mich.; "Boiler Setting and Coal Handling," by J. S. Jacka, Crystal Falls, Mich.; "Electrical Operating Plants of Penn Iron Mining Co.," by Frank H. Armstrong, Vulcan, Mich.; "Social Surroundings of the Mine Employe," by C. E. Lawrence, Iron Mountain, Mich. Besides these several others were read by title.

William Kelly, general manager of the Penn Iron Mining Co., requested that Charles Kirchhoff, president of the American Institute of Mining Engineers, be called on for a speech. During some happy remarks he suggested, as this was an era of combinations, that the Lake Superior Mining Institute affiliate with the American Institute of Mining Engineers. This suggestion was later put in the form of a motion by Mr. Kelly and carried. It does not mean, however, that the Lake Superior Institute will dissolve, but will continue as heretofore. After the business session a trip was made to Sunset Lake, where about 350 people were royally fed with clams, lobsters, fish, chicken, and corn. It was called a clam bake; however, the eastern men considered it a revelation, and came to the unanimous conclusion that Rhode Islanders had something to learn from Michiganders in this line The Institute members were indebted to the Iron River Commercial Club for this entertainment and no greater compliment could be paid them than to have the epicure Parker, of Washington, throw up his hands and say: "Hold, McDuff, I've had enough," while the orchestra, concealed in the woods, played slow music.

On Thursday the members left Iron River for the Loretto mine where the course of the Sturgeon River was changed to permit mining to be carried on to better advantage. From this place automobiles conveyed the members to the Penn Iron Mining Co.'s hydroelectric power plant at Sturgeon Falls, and then to Vulcan, where lunch was served in the coaches. Automobiles then conveyed the visitors to Brier Hill, Chapin, and Pewabic mines. At Twin Falls the construction of a dam was in progress, and at the "C" Ludington shaft probably the largest of all Cornish pumps was inspected. This ended one of the most strenuous and enjoyable institute meetings ever held anywhere. The various committees who had charge of this meeting would have been congratulated publicly for the executive ability shown in so smoothly directing and caring for so large a crowd, but excellency is always modest and unfortunately no opportunity was found whereby the guests could express their appreciation of the kindnesses shown.

Personals

W. J. Murray, vice-president and general manager of the Victor American Fuel Co., left Denver in his car on September 7 for a month's vacation in California.

Dr. E. R. Buckley, past president of the American Mining Congress and state geologist of Missouri, has returned to Rolla after spending the summer at Jarbidge, Nev., in professional work.

Robert McAlister has resigned the superintendency of the Crested Butte, Colo., mines, of the Colorado Fuel and Iron Co. Mr. McAlister is mayor of his town and well and favorably known throughout his state as chief of the State Board of Examiners of coal mine inspectors.

The preliminary committee in charge of the entertainment of the American Institute of Mining Engineers, while in Los Angeles from October 5 to 8, consists of Seely W. Mudd, chairman, Theodore B. Comstock, secretary, W. H. Wiley, R. H. Simpson and Charles Colcock Jones. As there are 80 local members of the Institute in Los Angeles, this, combined with the well-known hospitality and attractiveness of the city, insures to the visitors a more than usually pleasant time.

W. Bert Lloyd, has resigned the superintendency of the Yankee Fuel Co., Yankee, N. Mex., to engage in business in Trinidad, Colo. His place will be filled by Mr. Jack Reese, until now, superintendent at Tercio, Colo.

John Dalzell, former State Commissioner of Mines of Colorado, is now manager of the Copeland Sampler at Cripple Creek.

J. E. Himes, manager, of the Talmage Mining Co., Goldfield, is in St. Louis. He expects to return shortly.

Eugene McAuliffe is appointed general coal agent of all Frisco lines, with office in St. Louis, and the office of the general fuel agent in Chicago is discontinued. In addition to the duties heretofore performed by the general fuel agent for the operating and purchasing departments, he will assist the traffic department in the solicitation and handling of coal traffic.

Charles T. Van Winkle has resigned the position of superintendent of the Magna plant of the Utah Copper Co. and opened an office as mining engineer at Scott Building, Salt Lake City, Utah.

H. C. White, formerly secretary and sales manager of the J. Geo. Leyner Engineering Works Co., of Denver, Colo., has resigned.

R. B. Brinsmade has resigned as professor of mining engineering at West Virginia University and has accepted the position of superintendent of the Flojinales mines, Hidalgo, Mexico.

Arthur J. Hoskin, formerly professor of mining engineering at the Colorado School of Mines, Golden, after a summer spent at Alma in charge of the topographic work of the state geological survey, has opened an office for the practice of his profession at 308 Commonwealth Building, Denver.

H. H. Sanderson, of Danford & Sanderson, civil and mining engineers, Trinidad, Colo., has been for the past few months in Wyoming, Utah, and Nevada, in connection with the Draeger rescue apparatus for which his firm is western representative.

Morgan T. Townsend, well known to many of our subscribers as western circulation manager of Mines and Minerals is now representing the Stearns Roger Mfg. Co., at Leadville, Colo.

Percy E. Barbour, formerly of Salt Lake City, Utah, and more recently of Tecoma, Nev., is now at Candor, N. C., in charge of gold-mining and milling operations.

Sumner S. Smith, engineer in charge of United States Bureau of Mines Rescue Car No. 4, with headquarters at Rock Springs, Wyo., has been in Alaska since July. He recently accompanied Secretary of the Interior Fisher and Dr. Jos. A. Holmes, Director of the Bureau of Mines, on a trip of inspection through the coal fields of that territory. Mr. Smith will remain in Alaska for some time.

Franklin B. Guiterman, Manager for Colorado of the American Smelting and Refining Co., is expected in Denver about October 1 from a three months' trip on the continent.

H. N. Spicer, Metallurgical Engineer, 333 Cooper Building, Denver, Colo., recently returned from Terry, S. Dak., where he has been making examinations and tests for Lundberg, Dorr & Wilson.

It is announced that Francis Church Wilson, Mining Engineer, of New York City, has been appointed assistant professor of mining at the University of Illinois, under Prof. H. H. Stoek, former editor of Mines and Minerals.

J. C. Roberts, engineer in charge of United States Rescue Car No. 2, with headquarters at Trinidad, Colo., has been in Pittsburg, Pa., for some time where he will remain until about November 1. Upon his return it is intimated that Mr. Roberts' headquarters may be transferred to Denver.

Thomas C. Harvey, formerly of Forest City, Pa., and well known to the anthracite region of his state as captain for three successive years of the winning team in the first-aid contests, and at present foreman of United States Bureau of Mines Rescue Car No. 2, is in charge thereof while the car is laid up at headquarters in Trinidad, Colo. Mr. Harvey trained the local first-aid teams for the contest held in Trinidad on September 28.

George W. Evans, geologist, of Seattle, Wash., has accompanied Secretary Fisher on his personal tour of inspection through the Alaska coal fields. Mr. Evans, it will be remembered, mapped the Alaska fields and wrote the interesting articles on the Controller Bay Coal Field that appeared in Volume 30, Mines and Minerals.

Louis D. Huntoon, for the past seven years professor of mining and metallurgy at the Sheffield Scientific School of Yale University, announces that he has opened offices at 42 Broadway, New York City, for the general practice of mining engineering.

M. Baumgartner, of Spokane, Wash., is managing properties in the Bay Creek district, near Wardner, Idaho.

M. Snellus, chief mine manager of the Blanchet-Gamatot Syndicate of Paris, has charge of the Elk City, Idaho, properties, recently purchased by the syndicate from John and Edward F. Massam, of Spokane.

Ralph D. Brown has been appointed Instructor in Civil Engineering at the Missouri School of Mines. Mr. Brown is a graduate of Miami University, and of the Civil Engineering Department of the University of Ohio. Since 1909 he has been in the employ of the O'Gara Coal Co., at Harrisburg, Ill., as assistant engineer.

Sidney S. Schmidt, a graduate of the Missouri School of Mines, and at present a chemist for the Washoe Smelter at Anaconda, Mont., has been appointed assistant in mineralogy at Northwestern University. He will take the place of A. J. Ellis who resigned to accept an appointment on the United States Geological Survey.

J. B. Tyrrell, mining engineer and geologist of Toronto, Can., has returned from a short visit to London, England.

J. A. Nolan has recently been appointed western sales agent of the Mining Safety Device Co., of Bowerston, Ohio.

Louis Bendit has been placed in charge of the Hope Engineering and Supply Co.'s western sales department with office in the New York Life Building, Kansas City, Mo.

John T. Abell is interested in the Stratford Development Co., recently incorporated with a capital of $100,000 to handle mining lands in Mexico.

Frederic A. Potts has been able to leave the hospital in New York, where he was being treated for ptomaine poisoning. It was at first feared that he was suffering from appendicitis.

Governor Tener has appointed the following gentlemen as delegates from Pennsylvania to the fourteenth annual session of the American Mining Congress, at Chicago, October 24-28:

E. R. Pettibone, superintendent, Delaware & Hudson Co., Dorranceton; W. D. Owens, division superintendent, Lehigh Valley Coal Co., Pittston; Thomas Thomas, division superintendent, Lehigh Valley Coal Co., Wilkes-Barre; H. G. Davis, district superintendent, Delaware, Lackawanna & Western Railroad Co., Kingston; S. J. Jennings, inspector of Pennsylvania Coal Co., Pittston; C. F. Huber, vice-president and general manager, Lehigh and Wilkes-Barre Coal Co., Wilkes-Barre; Robert A. Quinn, manager, Susquehanna Coal Co., Wilkes-Barre; W. J. Richards, vice-president and general manager, Philadelphia & Reading Coal and Iron Co., Pottsville; W. H. Davis, superintendent, Coxe Brothers & Co., Hazleton; Jesse K. Johnston, general superintendent, Charleroi Coal Works, Charleroi; D. G. Jones, general manager, Pittsburg-Buffalo Co., Canonsburg; S. A. Scott, general superintendent, Monongahela River Consolidated Coal and Coke Co., Pittsburg; J. D. O'Neil, general superintendent, Merchants Coal Co., Pittsburg; A. W. Calloway, general superintendent, Rochester & Pittsburg Coal and Iron Co., Punxsutawney; A. D. Harmon, general superintendent, Keystone Coal and Coke Co., Greensburg; Harry Whyel, general superintendent, Whyel Coal Co., Uniontown; W. R. Calverley, general superintendent, Berwind-White Coal Mining Co., Windber; O. W. Kennedy, general superintendent, Orient Coke Co., Uniontown; Leslie H. Webb, 115 Chestnut St., Philadelphia; Frank H. Bailee, H. K. Porter Co., Pittsburg; Leo Gluck, Pittsburg Coal Co., Pittsburg.

A. W. Warwick, mining engineer, of Denver, and secretary of the Colorado chapter of the American Mining Congress, is in New York as representative of the Moore Filter Company.

Leroy A. Palmer, mining engineer of Salt Lake City, Utah, and well known to our readers, will be a resident of Denver after October first.

Charles A. Fuller, of Idaho Springs, Colo., who originally drove the Roosevelt Deep Drainage Tunnel, at Cripple Creek, Colo., has been placed in charge of the 1,500 foot extension thereof recently decided upon by the directors.

TABLE OF CONTENTS

Mine Inspectors' Qualifications in England

ACCORDING to a recent decision by the Home Secretary of Great Britain, adopted evidently on the advice of the Civil Service Commission, the scheme of examination for Inspectors of Mines has been changed. In future, candidates must pass a written and oral examination in the elementary branches, also in coal, ore, and stone mining, in law relating to mines and quarries and also in electricity.

The examination is hedged in a way that precludes political or social influence aiding in the candidates' appointment, and further, the salary is an inducement to good men.

In the compensation of Mine Inspectors, Great Britain is pursuing a wise course. The man of proper character with sufficient ability and judgment to be an efficient mine inspector is naturally qualified for, and is likely to make, a first-class mine manager. By increasing the remuneration, the British government makes the salary of its inspectors equal to or greater than mine owners pay for the services of good men, and thus removes the liability of good inspectors resigning to accept better paying positions with corporations or extensive individual mine owners.

Another excellent feature of the British plan is that capable inspectors practically hold office during life or good behavior, and their tenure of office is not dependent on politics. This obviates frequent changes, which necessarily militate against efficient service. An inspection district naturally includes a number of collieries. If a mine owner hesitates to make changes in the management of one mine because a new man cannot produce best results until by months of experience he becomes familiar with the extensive workings and conditions therein, naturally a new mine inspector, having supervision of a number of mines, cannot become familiar with each one of them nearly as quickly, and as a result he cannot give as efficient service as one who is already familiar with them through several years' experience.

Rational Sociology at Mines

FOR a number of years some mine owners and mine managers, imbued with a desire to improve the domestic conditions of their employes residing in the mine villages or "patches," have experimented on the lines of furnishing better houses with modern conveniences for the mine workers to live in. Others have gone further and encouraged social and athletic enterprises as well. These movements were always commendable in their inception, and though in some instances considerable expense was incurred, they seldom produced satisfactory results.

The substitution of labor from central and southern Europe for the former labor originating in northern and western Europe, filled the mining villages with populations almost entirely unfamiliar with the customs and habits of the former class of labor. The result was the unsanitary crowding of the houses, with consequent increased untidiness and the lack of cleanliness so essential to proper sanitation. The Slavs, Italians, and other races who had come from direst poverty and ignorance in their native lands, simply followed the habits and customs they had acquired from many generations. This was true of the masses. There were of course marked exceptions to the rule, but these were few.

Some mine managers when opening a new mine and erecting a new village went so far in their efforts to improve conditions as to pipe water into the houses, and put in bathrooms and water closets. In most of these cases, the tenants of the houses used the bath tubs as coal bins and the water closets as depositories for garbage. In course of a few months or a year, conditions in the model villages were not much better than before. The trouble was, not that the improved conditions were not necessary, it was because the people for whom they were intended were not educated up to and accustomed to them.

The H. C. Frick Coke Co. has gone about improving the sociological conditions of its employes in a rational manner, and is meeting with encouraging success.

Mr. Thos. Lynch, president, ably assisted by Mr. W. H. Clingerman, general superintendent, and the local superintendents are working on the following plan:

The miners' houses, which are ordinarily well-constructed frame buildings, are kept in excellent repair and are painted Indian red with white trim. These colors are selected because they have been found most durable in the coke regions, where the paint is subject to the action of the gases and soot in the smoke from the coke ovens. Water is either piped into the kitchens or is convenient to the back door. The streets of the mining villages are graded and drained with concrete gutters and terra-cotta drains. The sidewalks are graded and constructed so as to be mudless. Fences are straightened up and painted. Cesspools, that were formerly holes in the ground lined with plank, are made of concrete. Chicken coops and other outbuildings stuck together from old lumber and slabs by the workingmen are being removed and replaced by structures erected of good lumber by competent carpenters. The villages are thus made neat, attractive, and clean. Care is taken by the officials to scatter through the villages families who are either naturally neat and cleanly, or who have learned to be so. Newcomers moving into the vacant houses are notified that they and their families must keep their houses and the surroundings as neat and clean as do their cleanly neighbors. A regularly appointed inspector is constantly on the job, and cleanliness and sanitation are enforced. In course of a comparatively short time the example of the more cleanly people has its effect, and a habit of domestic cleanliness is formed, and practically all take more or less pride in keeping things neat and clean.

To secure and encourage personal cleanliness the company is putting in free swimming pools at each of its villages. That at the Leisenring No. 1 plant was the first, and is typical of the others. It is pleasantly located within a stone's throw of one end of the village. It is rectangular in form, built of concrete, and is 80 feet long by 40 feet wide. It ranges in depth from 2½ feet at one end to 7 feet at the other. It is surrounded by a concrete walk on which are benches and all is enclosed by a neat and strong iron-pipe fence. Two bath houses with hot and cold shower baths are provided, one for males, the other for females. Each person using the pool is required to take a shower bath for cleansing purposes, then don a bathing suit, or trunks in the case of children when they can swim, and sport in the clean and frequently changed water of the pool. Back of the bath houses is located a dancing platform, which is available for use in summer for open-air dances or similar amusements. To aid in inculcating personal cleanliness, the two new public school houses at Leisenring No. 1 (and this may be the case in other localities) are equipped with bathrooms. Children who come to school in a dirty or filthy condition are not sent home, as was the case formerly. If old enough they are required to take a bath themselves. If very young, the teacher gives them the required bath, and they or their parents are notified that they must, in the future, be just as clean when they come to school. Already the compulsory bath is looked on by the school children as a disgrace, and as a result they are almost invariably neat and clean when they go to school. Thus, early in life they are acquiring habits of personal cleanliness.

By this rational system of gradually elevating the population and accustoming them to habits of cleanliness and sanitation, great results are being achieved, and the time is not far distant when the people who are being thus educated will fully appreciate bathtubs, bathroom accessories, and other conveniences and will use them as they should be used.

In addition to the foregoing provisions for the benefit of their employes, the H. C. Frick Coke Co. also encourages athletics among the young men, and each of its many plants has a baseball team, all of them being in a league with regularly scheduled games, and prizes are awarded the winning team.

While all that the H. C. Frick Coke Co. is doing may not be practical at other plants, part of the system can be advantageously adopted, and better results will be obtained than by trying to get people who are not educated up to them, to rationally use bathrooms and what are today necessities to Americans, but which in the not far distant past, were only luxuries.

COAL MINING AND PREPARATION

Safety Through Systematic Timbering

Method of Mining Used by the H. C. Frick Coke Co. That Results in Safety and Economy

By Stephen L. Goodale *

More men are killed or hurt about the coal mines by falls of slate or coal than by any other one cause. To minimize this as far as possible the management of the H. C. Frick Coke Co. requires that posts shall be set in rooms and all working places with a short cap on top, as shown in Fig. 1, and at a distance apart not to exceed 4 feet 6 inches, whether the conditions seem to the miner to demand it or not; and where the roof seems according to the judgment of an experienced mine foreman, to demand more support, either a third piece, a cap spanning over the tops of two posts, is required, or the posts must be set closer than 4 feet 6 inches. This matter is not left to the judgment of the miner, who will almost always take greater or less chances in his mining, but is determined by competent officials of the mine, and the work is done under close supervision of these officials.

Fig. 1. Timber in Working Place

The scheme of mining somewhat resembles long-wall retreating in most of the mines at present. In opening a new property on this system, roadways would be driven to the boundaries of the property radiating from the landing at the bottom of the shaft until a sufficient number had been driven for the convenient working of the mine, these roadways constituting the main thoroughfares of the mine, and the number of them depending largely on the output desired. The location and manner of driving these roads, whether in triple or quadruple entry, will depend on engineering features at the individual properties. By triple entry is meant that there are three parallel main entries into the workings of the mine with two 60-foot pillars of coal separating them. In the quadruple system there are four such entries separated by three 60-foot pillars of coal. In the latter system two of these entries would be used for airways, one for a haulway, the other for a manway. The two outside entries would be used for ventilation. From these main roads another series of roads is driven 250 feet apart and called "butt" entries or headings, because they are driven on the butt cleats in the coal. These "butt" entries are usually driven parallel in pairs with the pillar of coal between—each entry being about 9 feet wide and the two entries are driven about 50 feet apart between centers. These butt entries, shown in Fig. 2, will be driven only in that portion of the mine from which it is intended to completely mine the coal without any long delays—when it is intended to work the mine on the retreating system, near the boundary of the property and remote from the shaft. By means of the main thoroughfares, sometimes called "flats," and the butt entries leading from them, there are a series of working passageways to the various parts of the property which it is intended to mine first. Of course, a large amount of coal is obtained from this work of driving the various entries, and secured too at no great increase of expense over that from any other work; but it is all nevertheless the development work of the mine, although the real mining, by which the bulk of the coal is secured from the property is only ready to begin.

Next, rooms 12 feet wide, designated by numbers *1*, *2*, etc., in Fig. 2, are driven from the butt entries, beginning near the boundary of the property, and subsequent rooms are driven from points on the butts successively nearer the shaft, and from 40 to 80 feet apart, depending on conditions in different mines. The butt entries and rooms have blocked the section of coal to be removed into pillars or ribs, perhaps 240 feet long and of a width varying in different mines between 40 and 80 feet. Through each of these pillars there is also driven a breakthrough parallel to the butt entry and either 50, 100, or 150 feet from it. This is not shown in Fig. 2, but it is staggered in adjoining pillars to prevent a continuous line of weakness later in the mining. The breakthroughs are driven to assist ventilation and get air conveniently to the men working in the rooms—the course of the air-current at this stage of development being carefully directed so as to prevent gas accumulating in the workings. Fig. 3 shows a breakthrough where the coal has been mined from the rib on the left, and what coal is left in the center is merely to keep coal free from slate. The rooms may be, and often are, driven some considerable time before it is intended to completely clean out the coal in a certain section of the mine; but it is preferable to develop a section and then to go on at once and extract all the coal from a panel in a systematic manner. When this is done, the room roofs are not likely to fall in and necessitate the expense of handling rock and retimbering; besides, there are many air-courses which do not materially aid in ventilating the mine, but which, if not watched, might seriously interfere with the miner's safety. Room No. 1 would be driven first; before No. 1 is driven very far the second room is started, and so on, it being desired to have each room opened as soon as it is needed for a passageway in working the rib, but not too much before that. It is only necessary that room No. 4, for instance, be driven through to the "gob"—the mined-out and fallen-in section—by the time the first slice has been taken from the end of rib No. 3, and that room No. 3 should have been through by the time the first slice had been taken from the end of rib No. 2, in order that the ends of the ribs may be kept in the proper line.

Butt entries are driven first in that portion of the mine from which it is planned to completely mine the first coal, which would be near the boundary of the property and remote from

* Professor Mining and Metallurgy, University Pittsburg.

the shaft, when it is intended to work the mine on the retreating system. Generally the advancing and retreating systems of working are so combined as to meet to the best advantage the requirements of time of commencing production, the rate of production, and the continuance of a uniform rate throughout the life of the mine. When it is desired to begin producing at the regular rate very early in the development of the mine, butt entries are driven and a room and rib section started at any convenient place on the property, taking care, however, to leave ample pillars for the protection of the shaft and the main entries, and to so locate the section as to make convenient the later work when the surrounding coal will be mined. That is, in this case some sections would be taken on the advancing system. This will quickly provide rooms for a large number of men to work; and it is essential for the economical working of the mine throughout its life to plan so as always to have rooms for the necessary number of men to maintain production. The mine development and the advance system of mining are so planned as to avoid the necessity of maintaining at any time during the life of the mine very long roadways for only a small section of mining. Enough blocks of coal are left to be worked on the retreating system to maintain a reasonable proportion of production from any section of the mine somewhat proportionate to the length of roadway that must be maintained to get it out.

This combination of the advancing and retreating systems of working results in a better distribution of the capital cost of development than is secured when straight retreating work is carried on, and in a lesser late expense for maintenance of roadways than in the case in wholly advancing work, and thus means economical mining.

In addition to the above, certain local physical features must be considered, such as surface streams, topography, proximity of other workings, and anything else which may affect ventilation, drainage, or in any way the safety and economy of mine working. For instance, at one mine the presence of a surface stream made it advisable to delay mining under the stream until as late as possible in the mine life to reduce pumping costs; and in the development of the other portion of the mine it happened that it was more convenient to carry on a part of the early development from an adjoining mine through an entry which was later sealed up when the development had reached the desired stage.

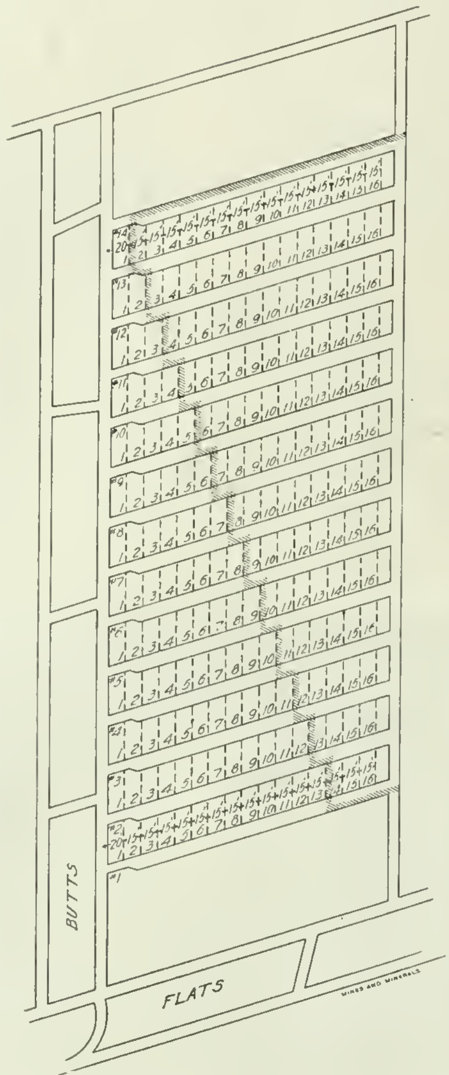

Fig. 2

In the work of development, and up to the point of driving the rooms, the question of roof support is usually a comparatively simple one, because there are only narrow roadways driven through solid coal, the strength of which and of the rock above is usually such as to make necessary very little or no artificial support. At the main landings near the bottom of the shaft, steel mine supports may be used, or the roof may be arched with masonry or concrete, for these passages must be kept open long enough to make permanent supports advisable. In many of the manways and haulageways some timbering or support is necessary, but in general it is sufficient to keep loose rocks cleaned off, when the passage may assume a natural arch shape. Sometimes it is necessary to build a wall between two roads which approach each other at a sharp angle, and sometimes masonry pillars are built as supports for the steel beams used to make haulageways safe.

Having described the general plan of the mine, a more careful discussion of the "rib drawing" follows, to show the importance of systematic timbering. First, consider the order of mining in a block of coal some 250 feet by 1,000 feet, more or less, this block having been developed by the butt headings driven across it at 250-foot centers, the butts being reached from the shaft by the main entries or flats mentioned, and the rooms between the butts. The ribs are the sections of coal left between rooms, extending in length 250 feet between two butt headings, Fig. 2, and being in width from 30 up to 72 feet, it being from 42 to 84

Fig. 3. Looking From Room Toward the Gob

Fig 4. Laying Track

feet between rooms, center to center. Each room is 12 feet wide and systematically timbered. Timbers or posts must be set as shown in Fig. 1, along the center of the room, and not more than 4 feet 6 inches apart, and kept up to within 6 feet of the face of the coal when mining by hand.

The method of working out the individual ribs is on a retreating order. Numbers are painted in white, on the rib of each room, starting with No. 1, 20 feet from center line of butt heading and each of the following numbers on 15-foot centers, to the end of each room. This system is to be strictly adhered to in all rib workings. The 15-foot steps, as shown in use at Continental No. 3 mine, where rooms are on 40-foot centers, will vary to meet the conditions at other mines, where different length of steps and room centers are used. Ribs thus marked will aid mine inspector, engineers, mine foreman, fire boss, rib men, etc., to determine the exact location of fracture lines without taking measurements. A 15-foot slice is taken from the end of rib No. 14, Fig. 2; next a second 15-foot slice, numbered 16, is taken from rib 14 and a first 15-foot slice from rib No. 13 at the same time. Next the third slice, numbered 15, from rib No. 14; the second slice, numbered 16, from rib No. 13, and the first slice from rib No. 12 at one time, and so on. Fig. 2 shows that the mining of all but one slice of rib No. 14 is completed, all but two slices of rib No. 13, and so on until from rib No. 2 have been taken only four slices — the mining being along a straight line on one side of which are the open rooms and from the other side of which the coal has been completely mined, as shown in Fig. 5.

The control of this line along which mining is conducted, which may be called the "line of fracture," is very important. It will not do to have one rib extended considerably beyond the line, nor can other ribs be permitted to be drawn before the proper time and so leave the line of fracture bowed in; for in either case the weight above is likely to squeeze down the promontory of coal and cause it to be lost The fracture line is about 22 degrees off the butts, which is about as small an angle as can be used and properly protect the men in this work. The use of a greater angle would require the opening up of too many rooms at one time, besides which the pressure would be more likely to cause squeezes. In order to keep the fracture line straight, without too much measuring, the sections are now regularly marked off with numbers on the sides of the rooms and the ribs also are numbered so that in the daily mining it is possible for foremen and others to check up the correctness of the fracture line without surveys. If the men in rib No. 14 are working on slice No. 2, those in rib 13 would be working on slice No. 3, in rib No. 12 on slice No. 4, and a simple inspection of these numbers will inform the foreman whether the men are working in the right places or not.

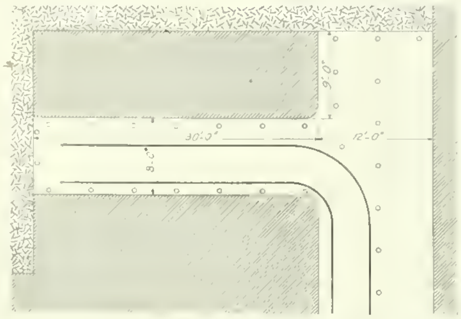

FIG. 5

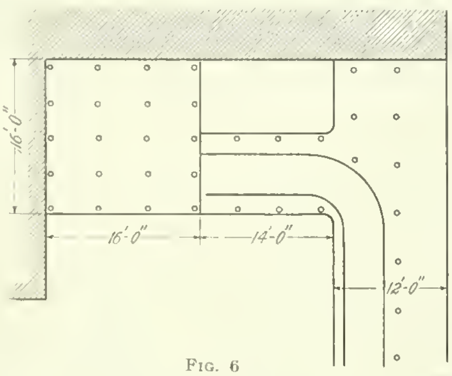

FIG. 6

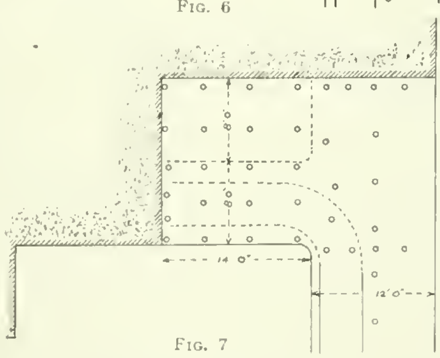

FIG. 7

The method of working out the individual slices varies slightly in detail at different mines. At one mine, for instance, where the rib is 30 feet wide, as in Fig. 5, an 8-foot heading is driven across the rib from room to gob at right angles to the room and leaving a 9-foot stump of coal at the end of the rib. This heading must be posted with two rows of posts, one along each side, and the posts not more than 4 feet 6 inches apart. The track is laid from the room, as shown in Fig. 4, in through this heading as the work progresses. The illustration also shows 23, the marks left by the fire boss during his round of inspection. This 8-foot opening holes through to the gob at a point which was recently caved after the coal had been taken from work in the next rib. There is thus left the stump of coal with gob on two sides, and the miners take this out in two sections, first picking down and taking out that part farthest from their room and setting rows of posts, according to the regulations for systematic timbering given in Fig. 11. When this first section of coal is out the track is removed; extra posts are set as a breaking line, and the place is in the condition shown in

FIG. 8. TIMBER READY TO BE DRAWN IN ROOMS

FIG. 9. REMOVING TIMBERS

Figs. 6 and 8. As many as possible of the posts in this 16'×16' room are next pulled by the chain and dog shown in Fig. 9, after which, sooner or later, the roof falls in, as shown in Fig. 10. Next the remaining half of the stump of coal is mined out, the track drawn back in to the room, and a section 16 ft. × 26 ft. is ready for the posts to be drawn and the roof caved in. Figs. 7 and 8 show the conditions just before the drawing of these timbers.

This work of rib drawing is dangerous. Great care and watchfulness must be observed, and long experience is necessary; therefore, the company requires either the rib boss or the fire boss to be present when a fall is made; i. e., while the timbers are being drawn after the mining of the coal from the end of the rib. The importance of systematic timbering is very great, because it is in the work of rib drawing that many are killed.

Fig. 10. Edge of Fall

It may be well at this point to introduce some very excellent statements prepared by Mr. Austin King, Chief Mine Inspector of the H. C. Frick Coke Co., in regard to timbering, including his definition of systematic timbering, which he has kindly permitted the author to use.

PRESSURE AND PROPS

"The pressure exerted by the roof of a mine may be divided into two parts, which may be termed the major and minor pressure. The minor pressure is the pressure exerted by a few feet in thickness of the roof material or strata, which, in the coke region corresponds to, or consists of, the roof coal and shales up to that usually known as the "Checker," and varies from 5 to 7 feet in thickness, though more generally the latter.

"The major pressure is irresistible and is, roughly, about one and one-quarter times the thickness of the cover in feet, expressed in pounds per square inch. It is this pressure which splits up large pillars and causes "squeeze," or, where bottom yields easily, "creep," and sometimes both. It would be useless, therefore, to set props, no matter how strong, to resist it. It is possible, however, to provide props having such characteristics, and to vary the manner of setting them, so that, while supporting the maximum load permitted by the kind and quality of the timber in them, they will gradually yield to the major pressure and still retain their form and strength as props.

H. C. FRICK COKE CO.

Regulations for Systematic Timbering

IN ROOMS exceeding 10 feet in width, posts must be set as near the center of the room as practicable, and the distance between centers must not exceed 4 ft. 6 inches. In rooms where coal is mined by hand, the distance between the last post and the face must not exceed 6 ft. In rooms undercut by machine the distance between the last post and the face shall be such as, in the opinion of the Mine Foreman and the Mine Inspector, affords the best protection for the workmen.

IN ALL RIB OR PILLAR DRAWING, where the coal can be reached without additional track, a line of posts not exceeding 4 ft. 6 inches between centers must be set in the working places, and when widening out, other posts not exceeding 4 ft. 6 inches between centers must be set parallel, and at right angles, to the first line. In rib or pillar drawing, where additional track must be laid when cutting over near the end of the rib or pillar, posts not exceeding 4 ft. 6 inches between centers must be set in line on both sides of the opening; and in the following named mines, CROSS BARS or collars must be set over them. The idea of setting these cross bars across the track, where the roof is comparatively good, is that they may give warning, by their condition, of any unusual condition in the roof, as the presence of smooth slips or great weight; therefore, where the roof is usually of good character, they may be of lighter weight than where bad or dangerous conditions are known to exist.

In all mines, when the GOB is reached, a line of posts shall be set around its edge; the distance between such posts, or between the post and coal, must not exceed 4 ft. 6 inches between centers.

In order to carry out the above regulations, it is necessary that rooms be kept in line with the sights set by the Engineers.

The Mine Foreman and his assistants must see that more posts than those required in the foregoing rules are set, if in their opinion, the conditions of the working places demand them.

These regulations are issued with a view of reducing the number of accidents from falls of roofs and sides; and the exercise of the best of judgment and the maintenance of STRICT DISCIPLINE are necessary in order to obtain the maximum amount of benefit from their enforcement.

Fig. 11

"The quality so much desired in props is known as 'elasticity,' and we want enough of this quality to yield to the major, or entire, pressure and at the same time to be of sufficient strength to support the loosened pieces of roof immediately overhanging the excavated portion of the seam, giving a prop that will suffer the least damage from use under heavy pressure. Props of this kind are usually made from the softer woods, as fir, larch, and some pines. In these we have great elasticity rather than great strength.

"The most desirable props, then, are in this particular weaker than the rigid ones, because, while being somewhat elastic, they prove the safest and most serviceable. It may, therefore, be seen that a prop made from the hard woods might be more costly and at the same time less safe and serviceable. The perfectly rigid prop, as, for instance, a cast-iron one, such as were used in mines 50 or more years ago, is not a suitable one. In it we have great strength but no elasticity, no brooming or curling up, and as the enormous pressure settles on it something must give way, and this something is always the rigid prop.

"The purpose in setting props, or, in fact, any other timber in mines, is to protect the workmen from injury from falling fragments of roof which have been loosened or broken by the pressure, or from a roof of loose or non-cohesive character, and to prevent the lower stratum of roof from falling when it is desired to keep it up while extracting coal or other minerals. When we fail to accomplish this purpose we must admit either the uselessness of setting props, or that an insufficient number were set. Another purpose of setting props is to resist the tendency of the roof and floor to approach each other and thus keep airways, waterways, or other roads open.

"Every prop should be set under a cap or cross-bar, and as safety depends so much on them, we cannot be in the least niggardly or careless in their use. And when they are set in such a way that each will bear its full share of the load they are intended to support, it constitutes what is known as 'systematic timbering.'

"In order that props should give the best support, they should not deviate from a straight line more than $\frac{1}{2}$ inch to each foot in length, and the cap put on them should cover the top as completely as possible, so as to distribute the load over their surface to prevent them splitting.

"The stronger the roof is, the stronger the props required, because the roof, if broken, is in much larger pieces; conversely, where the roof is broken and tender, the props set must be more numerous, and if these required are set so thick as to interfere with the carrying on of the work, or the ventilation, cross-bar sets with lattice-work lagging must be substituted.

"Where there is a strong roof and bottom, the props should be set so as to permit the roof to ease, or gradually settle down, or the bottom to heave, and thus prevent the breaking of the prop or prolong its usefulness as such. Under such conditions they should not be driven very tight, and in such cases caps of soft timber should be used, otherwise the invariable result is at first a bent, and later on a broken and useless prop. To accomplish and extend the same purpose, 'tapered' props have been introduced which have given great satisfaction, both from a safe and economic standpoint. The face of the tapered end is usually about 3 inches in diameter and is about one-fourth of the area or section of the body of the prop. An eminent colliery manager, in charge where these have been used exclusively for years, said recently: 'I find that the increased usage of timber, caused by the laws requiring systematic timbering, has been nearly counterbalanced by the longer life of tapered props.'

"Other things being equal, the strength of a prop varies directly as the square of the diameter, and inversely as the length. The ratio of the diameter to the length of the prop, in order to have equal power of resisting compression and deflection, is 1 to 12. However, if by reason of physical defects, such as knots, splits, worm holes, or disease, the wood is weaker, the diameter of the post should be increased.

"The crushing strength of timber usually furnished in mine props is as follows: Hickory, 9,500 pounds per square inch; black oak, 7,300 pounds per square inch; red oak, 7,200 pounds per square inch; chestnut, 5,300 pounds per square inch.

"Taking chestnut as having the average strength, and allowing 75 per cent. of the material, or 12 square inches in a prop of that wood, to be sound and straight in fiber, it would require a total pressure of $5,300 \times 12$, or 63,600 pounds, to crush it. Since, however, the prop is 8 feet long, the crushing weight would be $63,600 \div 8$, or about 8,000 pounds., or the weight of a section of roof of average material covering about 12½ square feet, or a space of about 3 ft. $\times$ 4 ft. in area, which would be supported by a chestnut prop if the roof were loose for 5 feet above the cap piece."

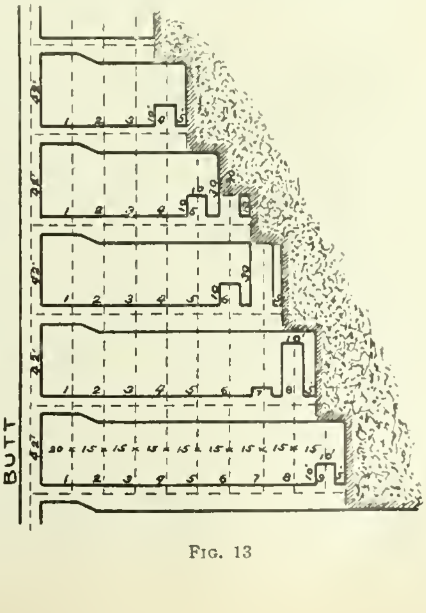

Fig. 13

Special attention should be paid to the above definition of systematic timbering, "the setting of props in such a way that each will bear its full share of the load they are intended to support."

The H. C. Frick Coke Co., which operates its mines and coke ovens on the policy that "safety is the first consideration," has adopted, printed, and distributed the "Regulations for Systematic Timbering," shown in Fig. 11.

Fig. 12

In order that the manager and engineers may follow the progress of mining and pillar drawing, a daily report of the work done is placed on the form Fig. 12 and signed by the mine foreman. The report covers the mine section, number of butt entry, number of rib or room pillar, number of slice as marked off in Fig. 2, or check number, the name of the fire boss in charge of this section in the mine, the name of the rib boss who has charge of pillar-drawing operations; number of posts set to support the roof while drawing the pillar; the number of posts drawn and recovered; the number of props lost; the number of inches of coal left in this part of the mine to support the roof; and the condition of the room, with remarks. The form is reproduced in Fig. 12, with the remarks printed in as received in the office. The foreman finds stamped on the blank report furnished him the phrase "Safety the First Consideration," which at once calls his attention to the company's desire to protect its miners in every possible way. From the report it will be seen that in this matter of systematic mining and timbering the loss of timber is not nearly so great as where props are left standing indefinitely in a room. When 76 per cent. of the props stood in robbing pillars are recovered the rib boss is doing good work.

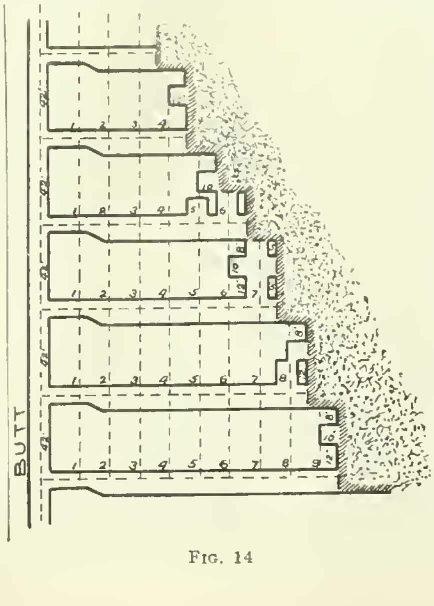

Fig. 14

Certain details of this work naturally differ, according to local roof and floor and pressure conditions in the mines. Where the roof pressures are heavy the ribs are wider, that is, the rooms are driven at perhaps 84-foot centers. At the Continental No. 3 the detail order of work at the end of the ribs is slightly different, as shown in Figs. 13 and 14. At this mine the coal is hard and the bottom soft.

The purpose of the present paper is to call attention to the safety of the miners, which is insured as far as possible in this work by requiring the regular timbering, not leaving the amount of the timbering optional with the miner. A very important matter in addition to this, however, is the large recovery of coal made in mining on this plan. The recovery is said to average about 90 per cent., and in some cases to reach 93 or 94 per cent., depending on conditions, particularly the quality of coal near the floor and roof, and the character of roof and floor at any point. The present recovery of coal depends also on the thickness of the seam being worked, for 3 inches of coal left in the roof of a 5-foot seam will be a larger per cent. of the total coal than 3 inches left in the roof of a 9-foot seam. A layer of coal may sometimes be left on the roof if the roof coal is of a poor grade, high in sulphur or phosphorus, but usually in this district only to protect the mines because the coal withstands the action of the air better than the slate.

Systematic timbering in itself is a comparatively simple matter easily explained; but there is required for an adequate understanding of its importance a knowledge of many complex conditions. The present paper is an attempt to describe sufficient of these conditions and the system of mining employed by the H. C. Frick Coke Co. to make clear the importance of what this company has done in this line toward promoting the safety of their miners. Strangely enough one of the greatest obstacles met with in this work is the enforcing of the regulations, that is, securing officials for the mines who will themselves follow closely the regulations and enforce their observance by others under their authority. Strict discipline is the only means of securing the proper observance of the regulations, and is the means employed. Finally, it may be said the motto "Safety the First Consideration" applies to the mining of the coal and systematic timbering of the working places in the most remote sections of the Frick mines, as well as the more conspicuous portions of the plant above ground.

General Haulage of Coal

The following paper was read at the monthly meeting of the employes of the Victor-American Fuel Co., by James Cameron, Superintendent:

The question of hauling is one of the most important factors to be considered; it plays a part in nearly everything around the mine, from the boiler house to the face of the workings, whether it is rope, electric, or mule haulage, or all three of them.

The first thing to be considered is the boilers; they must be kept in good shape so they can produce at all times enough steam to run the engines and generators without being pressed too hard.

It is essential at all times that a good head of steam be kept up, but not blowing off; to insure this, competent firemen are necessary; men who will look after the boilers and furnaces and use the strictest economy with both fuel and water, and at all times be on the lookout for leaks, both in the steam and water lines, as nothing wastes money faster than steam leaking from joints or water running away from poorly packed pumps and valves.

In the power house, where high-speed engines and generators are running every hour of the day and night, it is an important factor in the question of hauling to have a careful, sober, and steady man to be in charge; a man who is not rattle-headed, but a man with a cool head and a good disposition; if he is not so, he can be the cause of losing lots of time during the day's work; for instance, if the motors happen to be pulling all at the same time on a very hard pull, overloading the generators and throwing the circuit breaker; if the engineer is not alert he can be the cause of losing much time by being slow in putting the circuit breaker back in place. Should this happen several times a day it can readily be seen it will cause the loss of output of many tons of coal in the day's run which would be avoided by having a careful and steady man.

The hoisting engineer, the man who stands on his feet all day long waiting for the signal to go ahead or back up, as the case may be, also can cause many delays during the working day if not careful, steady, and quick in action, both in starting as well as stopping trips, and it stands this man in great need to keep his temper when a trip is off the track; many engineers get hot when trips are off the track and lose their heads, thus causing unnecessary delays.

Before entering the mine there is one more important matter, and that is the stable where the mules are kept and the care they get. It is important that mules have the best of care and be fed at the proper time; they should be fed in the morning at least 2 hours before going into the mine. I have never had the experience of water being kept in front of the mules in the stable, but it strikes me as being a very good thing, for if the mules coming out of the mine sweating, more especially on a cold frosty night, they may not feel like drinking, but after they have been in the stable a little while they may then feel like drinking and it is there for them. Here is a place, like the boiler house, where a careful, watchful man can save many dollars by being careful with the feed. Not that he is to starve the mules, but he should give them enough to eat and see that none is wasted; it is the amount that is wasted that raises the price of feed per head above what it ought to be. The stable boss also should render all the assistance he can toward getting everything ready in the line of repairs to harness, seeing that the mules that have lost shoes during the day's work have been replaced; this should be done in conjunction with the drivers and the driver boss; if there is not a driver boss, the mine boss should assume the responsibility.

The next important thing is getting the mules and drivers out of the stable in the morning on time. A quick, prompt start in the morning with everybody on hand is essential to a good day's run. After they are started from the stable get them into the mine to their working places as quick as possible and keep them busy until dinner time. The men in charge should be around the partings about this time and see that the drivers do not stop too soon for dinner; much time can be lost at this stage of the game if the men in charge do not attend to this. They should also be on the partings at starting time after dinner to see that the drivers start promptly and are kept busy until quitting time. These points should be watched closely, for many tons of output can be lost at these stages.

Another thing to be considered is the convenience of partings in the mine. The more convenient the partings are to the working places the more coal can be pulled per driver, and consequently the price of hauling decreases. It is not a good thing to have too many drivers coming into one parting unless the parting and the hauling roads to it are so arranged that no more than two drivers be on the one road at the same time.

In a mine where motor haulage is used, it is important that the motors be kept in first-class shape, also the trolley, and feed-lines, and the bonding; the pit cars should also be in the best condition to insure perfect hauling. A great deal depends on the motorman for success. A good man, one who can do slight repairs if anything should happen to his motor during working hours, saves a great deal of lost time.

One of the last and most important parts to be taken into consideration is the maintenance of the tracks; this is the most essential part to be played; the better the tracks are kept the more success in hauling coal

First-Aid Contests East and West

Rocky Mountain District, at Trinidad, Colo.—Anthracite, at Shamokin and at Inkerman, Pa.

The first annual Helmet and First-Aid Contest of the Rocky Mountain District, which took place on the grounds of the Las Animas County (Colo.) Fair Association, at Trinidad, was in many ways an event of importance. First-aid work in Colorado dates from the arrival of the United States Bureau of Mines rescue cars, early in November of last year; however the training officially given the miners probably does not cover a longer period than 6 months, yet with this limited instruction the Bureau turned out 17 first-aid and 8 helmet teams. It is largely due to the hard work of the men, to cordial cooperation on the part of the producing companies, to regular instruction by the companies' physicians, and those in charge of the instruction cars of the larger companies, to the enthusiasm of J. C. Roberts, engineer in charge of the Bureau of Mines Car No. 2, and above all to the skill, long experience and infinite patience of Thos. C. Harvey, foreman of Car No. 2, that the meeting was such an unqualified success and that the teams were so evenly matched that the judges were able only after long deliberation to justly award the prizes.

There was a first-aid contest participated in simultaneously by the 17 first-aid teams, and a helmet contest in which each of the 8 teams in this class worked singly.

The four events in the first-aid contest were as follows:

1. One-man team: Man's left hand mashed, bones crushed, and cut in palm of right hand. Dress with first-aid packet.
2. Two-man team: Man lying on live wire. Burned on back. Treat.
3. Four-man team: Fracture of spine in middle of back. Treat and carry patient 50 feet.
4. Full team: Man injured by premature blast. Face burned, right arm broken between wrist and elbow, simple fracture. Left thigh broken between hip and knee, compound fracture with profuse bleeding. Properly care for injuries and transport 50 feet.

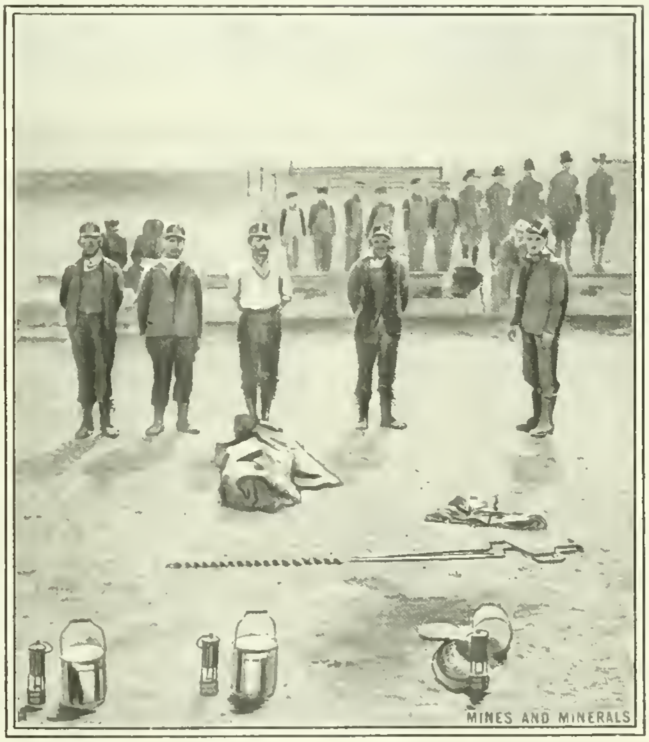

FIG. 1. PRIMERO, COLO., FIRST-AID TEAM, 1ST PRIZE

After all the teams announced their readiness for inspection, the judges, consisting of Drs. M. W. Glasgow, of the American Red Cross car, and D. G. Thompson and G. W. Robinson, of Trinidad, entered the demerits on their respective records, and another event was started. At the outset each team was given a credit of 100 points in each event, or a total credit of 400 for the contest. After deducting all the demerits from the total credit of 400, a division by four gave the final percentage of the team. It is a pleasure to note that with the exception of three teams the final percentages were all above 90 and that with the leaders the differences were but a fraction of 1 per cent.

The first prize, a silver cup, given by subscription, was awarded the Primero, Colo., team, captained by Bert Pollard, with C. D. McGinnis, Frank Urfer, Joe Boyd, Robert Scott, J. Lukenbaugh, and Geo. Fortune as a crew.

The second prize, a surgeon's first-aid emergency chest, also given by subscription, was won by the Starkville, Colo., team, captained by B. Hanley, and composed of A. Dennison, J. Marzer, Geo. Charters, H. McDougal, and J. Olson.

Judging was rendered difficult by the nearly equal skill and ability of the competing teams and by lack of judges, of which only three were available. Another time the suggestion of having a judge for not more than three teams and who shall decide on the merits of different teams in each event (to eliminate the "personal equation" and to prevent any possible charge of favoritism) will probably be adopted. It was impossible for three judges to cover the entire work of the 17 teams in an absolutely thorough manner and perhaps many good points were missed, but, on the other hand, as many demerits were probably overlooked, so that the outcome would have been the same. The perfect team work and ability to do the right thing at the right time certainly qualified the Primero team for first place, regardless of the many novel features used by them in the way of improvised splints and bandages and the device of Dr. W. V. Gage, of affixing a tin-covered first-aid package to the side of the dinner buckets.

All the teams had high ratings in the first and third events, but in the second, had the work been actual instead of imaginary, most of the teams would have been subjects for first-aid work themselves. In this event but three teams remembered either to insulate themselves or to short-circuit the imaginary live wire before proceeding to handle the patient, and the winning team was one of these three. In this same event 10 teams failed to draw out the tongue of the patient, and the winning team was one of the seven which did.

In the fourth event the common failures were, leaving underclothes over the wound (four), failure to treat for shock (three), poorly applied splints (three), and failure to treat for compound fracture (three).

The Thos. C. Harvey splint for broken back, and the method of using lighted safety lamps for warming a patient (where warmth was necessary) and also devised by Mr. Harvey, were used, one or the other, by all the teams. In the first aid-events, too much praise cannot be given to the "patients" whose endurance under rather painful surroundings was of most material assistance to all the teams.

The helmet events took place in a specially-constructed building filled with sulphur fumes. The work was double and consisted in

1. Entering the mine with a full team and carrying a roll of brattice cloth across an overcast and back again to daylight.
2. Reentering the mine, finding an unconscious man, bringing to daylight across the overcast and applying the customary means of resuscitation,

The judges in this event were H. H. Sanderson, mining engineer, of Trinidad, Thos. C. Harvey, and W. D. Scofield, the first-aid miner of the Bureau of Mines car, No. 2. The system of demerits employed was the same as in the first-aid events and resulted in awarding the first prize, a silver cup given by subscription, to the Morley, Colo., team, composed of J. C. Davidson, captain, Ernest Reich, Thos. Warrick, Joe Bell,

Fig. 2. View of Field at Shamokin,

Joe Mutz, Joe Woznica, and E. F. Gaines. The second prize, a Draeger half-hour oxygen apparatus, presented by Messrs. Danford & Sanderson, of Tinidad, was awarded to the Hastings, Colo., team, D. H. Reese, captain, A. E. Thompson, H. A. Winters, E. Spencer, and P. Francescone.

The Morley team did magnificent work and the absolute control of their captain and the implicit obedience of the men illustrate two of the most important, if not the most important, factors in actual rescue work. Strange to say all the teams were demerited for failure to use a life line and for failure to properly test for gas.

One of the most interesting events of the entire program was the first-aid contest between the boys of the Sopris public school and the Boy Scouts of the same place, who went through practically the same series of tests as did the elder relatives, of many of them in the regular series. After a severe struggle the first prize, a silver cup, given by Dr. T. J. Forhan, went to the Sopris School boys, captained by James Stratton, with Tom Hill, George Allen, Charles Costa, James Viecello, and Francis Burns as the corps. Teams from Dawson Loretta, and Koehler, N. Mex., and one team from Somerset, on the "western slope," came a long distance with their apparatus to enter a contest under unfamiliar surroundings.

The presidents of two of the largest companies were at the field and practically every superintendent and foreman in the district was on hand to encourage his teams. The attendance from among the miners was large and many brought their families for the day. James Dalrymple, chief inspector of coal mines and his three deputies, Messrs. Oberding, Douthwaite, and King, were on hand, and there were representatives from coal companies in Utah, New Mexico, and Wyoming, which did not enter teams but which sent official representatives to study the work.

Fig. 3. Morley, Colo., Helmet Team, 1st Prize

The commissioner of mines (metal) for the state, Thomas R. Henehan, and three deputies, Messrs. John R. Curley, of Leadville, W. H. Paranteau, of Central City, and Samuel Treais, of Montrose, were also present. It is a fact, perhaps not generally recognized, that the percentage of fatal and non-fatal accidents is greater among metal than among coal miners and it is a matter of congratulation that the commissioner of mines was able to see what the coal miners could do, to the end that those with which his department is concerned in the metal mining districts may be encouraged to take the same steps for the relief of suffering and the rescue of those overtaken by accident.

In every way the meeting was a success, and to Messrs. J. V. Thompson, William McDermott, Mark O. Danford, and H. H. Sanderson, the committee on arrangements, much praise is due.

Glen Lyon's First-Aid Victory

The second annual first-aid contest between the employes of Susquehanna Coal Co., Mineral Railroad and Mining Co., Summit Branch Mining and Lytle Coal Co., was held September 16, at Edgewood Park, Shamokin, Pa.

Invitations to this meet were sent by Robert A. Quin, general manager of these companies to officials of the other anthracite collieries, a large number of whom were in attendance, besides about 1,000 others. This being an annual event, it is made a holiday in which President Morris Williams, Vice-President George H. Ross, and General Manager Quin, act as hosts. The other officials also assist in the entertainment and all are to be congratulated on the happy and smooth way in which so large an affair was conducted. Dr. F. L. McKee acted as announcer of events, Gen. C. B. Dougherty, assistant general manager, as master of ceremonies, and Chas. K. Gloman, secretary.

Division superintendent of the Susquehanna Coal Co.

n 41 First-Aid Teams Contested

entered 11 teams that had been trained by Doctor McKee. Division superintendent of the Mineral Railroad and Mining Co. entered 20 teams, trained by Dr. J. M. Maurer.

The doctors were also interested in this event from the fact that the surgeon who trained the team that won the full corps event was to receive a silver medal. The judges for the

Division superintendent of the Summit Branch Mining Co., Wm. Anman, entered 6 teams, trained by Dr. G. M. Stites.

Lytle Coal Co., D. V. Randall, superintendent, entered 2 teams, trained by Dr. B. C. Guildin.

Susquehanna Coal Co., Shaft P. O., E. A. Van Horn, superintendent, entered 2 teams, trained by Doctor Mauer.

In all there were 41 teams, which, with the subjects, made a total of 264 men engaged in the elimination contests in the forenoon. After lunch, in which 800 guests took part, 27 teams contested for prizes and a trip to the first-aid meet at Pittsburg, October 30.

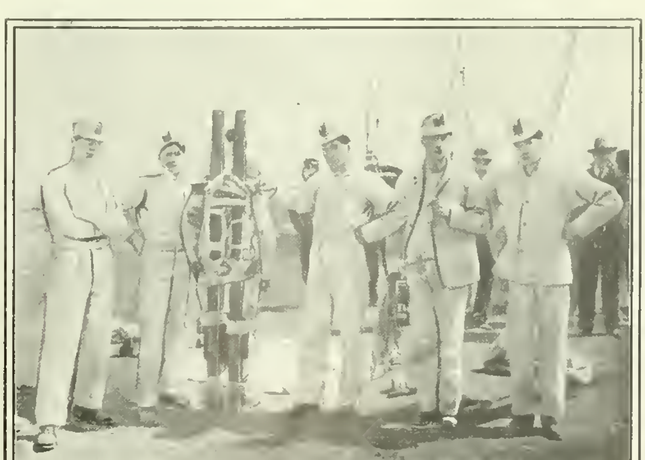

Fig. 6. Starkville, Colo., First-Aid Team, First Prize

occasion were Major Ralph W. Montelius, Surgeon 4th Brigade, N. G. P., Major W. Clive Smith, Surgeon 9th Regiment, N. G. P., and Captain J. C. Biddle, Assistant Surgeon, 8th Regiment, N. G. P.

The winners in the final events were:

One-man event: Lytle, inside.—Matthew Kaufman; James F. Simons, subject. Prize, French Bronze medals.

Two-man event: Glen Lyon No. 6, outside.—Elias Negosh, captain; Frank Bonsock; Andrew Barron, subject. Prize, French Bronze medals.

Three-man event: Glen Lyon No. 6, No. 7 shaft.—James Mulhern, captain; Anthony Dougherty; Costic Terkowski; Andrew, Seletski, subject. Prize, French Bronze medals.

Full-team event: Glen Lyon No. 6, outside.—James Sack, captain; Frank Bonsock; Stanley Prush; George Perkins; Elias Negosh; Andrew Barron, subject. Prizes, Silver Cup, Gold Bronze medals and trip to Pittsburg, October 30.

Dr. F. L. McKee won the silver medal.

As the ground was damp and soggy from rain the night before, canvas was put down for the teams to work on. Through the kindness of Manager Quin, Mines and Minerals is able to furnish score cards used at this meet which was the largest that so far has taken place in this country. Fig. 4 is the form used by the judges in the elimination and final contests. Fig. 5 is the form used in scoring time and in final schedule of scorers.

After the judges determine the points they are transferred to the final schedule, Fig. 5, which is also the time sheet for score of events.

A view of the field during the contest is shown in Fig. 2.

Inter-Company First-Aid Contest

The third annual contest between the first-aid teams of the mining companies of the northern part of the Pennsylvania anthracite region was held at Valley View Park, Pa., on September 16.

Nearly all the companies of this region have held contests among the first-aid teams of their own mines and the winners of these were entered in this inter-company contest, which was under the auspices of the American Red Cross. Sixteen teams were entered as follows:

Fig. 7. Red Cross Medal

Delaware, Lackawanna & Western Railroad Co.: Bellevue, John M. Jones, captain; Sloan, William King, captain; Brisbin, John Price, captain; Woodward, Benjamin Lewis, captain.

Lehigh Valley Coal Co.: Pittston, James Clark, captain; Prospect Colliery, George Hileman, captain; Centralia, Harper Minnick, captain; Hazleton, Earnest Crabtree, captain.

Scranton Coal Co.: Pine Brook, Arthur Young, captain.

Hillside Coal and Iron Co.: No. 5, Dunmore, Fred. Campbell, captain; South Pittston, James Pollard, captain; Mayfield, Michael Roberts, captain.

Pennsylvania Coal Co.: Law Shaft, William Creedon, captain.

Forty Fort Coal Co.: Isador Hochriter, captain.

Parrish Coal Co.: Parrish and Buttonwood Collieries, Thomas Maggs, captain.

Price-Pancoast Coal Co.: Thomas Cook, captain.

The Board of Managers were: Dr. M. J. Shields, field representative of American Red Cross, N. J. Coughlin, C. E. Tobey, Frederick Chase, Dr. D. H. Lake, Dr. F. F. Arndt, Dr. J. V. Birtley, Charles Enzian, of United States Bureau of Mines, Col. R. A. Phillips, W. P. Jennings, Atherton Bowen, Doctor Walter Lathrop, Dr. J. F. Jacobs, James McCorty.

The secretaries were: R. I. Vail and W. H. Charles.

The judges were: Major Charles Lynch, U. S. A., Major J. H. Allen, U. S. A., and Capt. A. W. Williams, U. S. A.

The contest consisted of five events as follows:

First event, one man contest. Fracture of bones of nose with severe bleeding, caused by the kick of a mule. Stop bleeding and dress with first-aid packet.

Fig. 8. Silver Cup Contested for by Anthracite Companies

Second event. Explosion of keg of powder, severe burns of face, hands, and front of chest. Dress.

Third event. Three-man contest. Man lying on live wire, remove and treat.

Fourth event. Right collar bone broken, left foot badly crushed, but not bleeding severely. Dress.

Fifth event, general team contest. Man unconscious and suffering severely from shock. Wounds, right hand smashed with cuts in palm bleeding freely, severe scalp wound with hemorrhage from artery, simple fracture upper third left thigh. Treat and dress.

The first event was won by the Brisbin team of the Delaware, Lackawanna & Western Co.; the second by the Law Shaft team of the Pennsylvania Coal Co.; the third by the team of the Forty Fort Coal Co.; the fourth by the Hazleton team of the Lehigh Valley Coal Co.; the fifth, which was the general contest for the Muckle Cup, was won by the Brisbin team of the Delaware, Lackawanna & Western Co., second place being taken by the Centralia team of the Lehigh Valley Coal Co., and third by the Mayfield team of the Hillside Coal and Iron Co.

A bronze medal of the American Red Cross, a photograph of which is shown in Fig. 1, was given to the winners in each of the first four events.

The prize for the fifth contest was the silver cup, Fig. 2, which was presented in 1909, by Mrs. Muckle, of Philadelphia, to be contested for and to become the property of the winner able to hold it in three successive contests. This was the third annual contest for this prize, the winners up to the present being: Avoca team of Pennsylvania Coal Co., in 1909; Woodward team of the Delaware, Lackawanna & Western Co., in 1910; and Brisbin team in the present 1911 contest. Also a bronze medal was awarded to each member of the winning team. The Brisbin team and the Woodward team were both sent to the first-aid meet at Pittsburg.

A Woman Mine Worker

In the Derby, England, *Mercury*, of September 22, is an account of the death, at Brynn, in the Wigan coal field, of Kitty Grayson, at the age of 92, who was believed to be the last of the pit women of the old days. When the act of parliament came into operation prohibiting women and girls, as well as boys under the age of 10 years, from working below ground, she was a young pit woman. In order to evade the act she disguised herself as a man, and continued to work in the mine for nearly 12 months, when she was discovered by the government inspector. In consequence of her experience of colliery life she was often called in to render service after mining disasters. Of her 13 children only two survive. She has, however, numerous grandchildren and great-grandchildren.

Coal Mining in Arkansas

The Location, Geology, and Extent of the Fields. Methods Employed in Cutting the Coal

The following is taken from various parts of the Arkansas Geological Survey Report, Part I, Coal Mining in Arkansas, by Prof. A. A. Steel, and deals with the geology and entry driving in Arkansas:

The Arkansas coal field lies in the valley of the Arkansas River between the western border of the state and Russellville. It has roughly the shape of a Roman capital L with its base along the Oklahoma line. It is about 33 miles wide and 60 miles long, but it is only in the eastern and western parts of this area that the Hartshorne coal is probably thick enough or sufficiently free from partings to be of economic importance. Still, some 300 to 320 square miles will probably contain coal which may be mined. In places, the coal is over 8 feet thick, and when clean and of good quality, it has been mined where no thicker than 18 inches. The Hartshorne seam will probably average about 3 feet thick, and assuming this thickness over 310 square miles, that part of this bed which lies in Arkansas once contained something like a billion and a quarter tons of coal. The small amount of coal above and below the Hartshorne horizon may be nearly equivalent to that already mined, which was about 26,800,000 tons up to the end of 1909. At an average "recovery" of 80 per cent. in mining, the state will therefore yield only about 850,000,000 tons, but at the present rate of mining, this will last for 350 years. The rate of mining will probably increase.

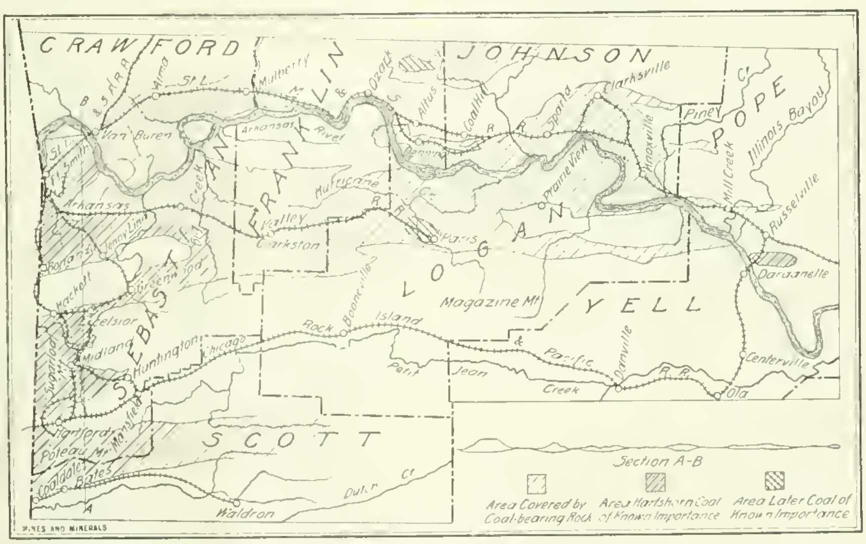

FIG. 1. MAP OF ARKANSAS COAL FIELD

Fig. 1 is an outline map of the Arkansas coal field, redrawn from the geological map in Mr. Collier's report.* It shows the counties, railroads, larger towns, and the coal mining camps. On this map is indicated the area underlain by the Hartshorne sandstone. This is the area ordinarily spoken of as the coal bearing area. The exact limits of the Hartshorne sandstone under Magazine Mountain and the eastern part of Poteau Mountains were not worked out by Mr. Collier, because the coal bed in these places is supposed to be of no value. A little coal has been mined from beds that are below the horizon of the Hartshorne sandstone. These are of importance chiefly south of Dardanelle. Unfortunately, the locations of these beds were not worked out sufficiently to be shown on the map. They are relatively unimportant.

Upon this map is indicated the area in which the Hartshorne coal is of known importance. Coal cannot be mined from every acre of this area because there are many small tracts in it that contain only faulty or thin coal. They are often too small to map, and the exact location of many of them will not be known until all of the good coal has been mined. This faulty coal occupies a considerable proportion of the areas of the mines already opened. Since the best part of the coal seam is opened first, there will be a larger proportion of faulty coal in the remaining parts of the Hartshorne seam. The amount of this faulty coal has been guessed at in placing the ultimate recovery of the coal at the low figure of 80 per cent.

* Bulletin U. S. Geological Survey, 326

There are coal beds lying at a considerable distance above the Hartshorne horizon. These are of importance only at Paris near the center of the coal field.

Attention should be called to the fact that the largest part of the unmined area of thick Hartshorne coal lies beneath Sugarloaf and Poteau mountains. These tracts constitute by far the largest portion of the Arkansas coal reserves, estimated above. Unfortunately, most of this coal is under from 1,000 to 3,000 feet of rock and cannot be profitably mined until the price of coal is largely increased. It will, therefore, not be long until the scarcity of Arkansas coal becomes severe. It is hoped that there will be an opportunity to estimate as closely as possible the time that the relative cheap supply of coal will last. The newer workings of the mines, which are approaching the base of Sugarloaf Mountain, indicate that there is danger that the coal under it will be badly mixed with slate. This will reduce the reserve of good coal. The deeper coal is, however, harder than the more shallow coal.

Except in the small semianthracite coal mines all the entries and slopes are driven by a single method, which is called cutting.

Fig. 2 shows in plan the normal condition of a narrow entry in a single bench coal after all the loose coal has been loaded out. The drill holes are ready for blasting in the night, or the shots are prepared, as the miners say. The narrow part which is generally 4 feet wide is called the heading. The T-shaped notch alongside of this is the cutting and is dug out by the miner, who kneels on the bottom and uses a light short pick. The cutting is from 4 to 6 feet long and only sufficiently wide to crawl into far enough to reach the end. It is made in from 2 to 4 hours, depending upon the skill of the miner and the hardness of the coal.

In the soft coal of Arkansas all holes for blasting are drilled with a breast auger. The cutting shot at *a*, Fig. 2, is placed about half way between the roof and floor on the side of the heading opposite the cutting. The hole is drilled 8 to 10 feet deep and from 2 to 4 feet on the solid, which means that it goes this far beyond the end of the cutting. When the powder explodes, all the coal between it and the cut is blown into the cut and heading. The coal which is too tight to be blown out is shattered and cracked, sometimes even beyond the end of the drill holes, as shown in Fig. 3. The shattering of the coal greatly reduces the labor of making the next cutting which is on the other side of the heading in the position shown by the dotted lines, and follows the hole just blasted. For the purpose of so shattering the coal more powder than necessary to loosen it is always used. The amount of powder is reckoned by the number of inches in the length of the cartridge. A 1½-inch cartridge has about 1 pound of powder for each 17 inches, and a 2-inch cartridge, which is more commonly used, 1 pound for each 10 inches. The ordinary 9-foot shot with 5½ feet of cutting is generally charged with from 36 to 42 inches, or 3½ to 4 pounds of powder. Except in the low-coal, two men work in each entry.

One of the pair is usually a skilled pickman who does the cutting or head work, while his partner does most of the shoveling or back work. Most of the miners get in a cutting every day, so 2 men should drive an entry 5 or 6 feet per day. The rate per month of 20 working days is seldom more than 75 feet.

After the cutting is far enough ahead the miner puts in the back shot *b* which is usually 9 or 10 feet long and throws out

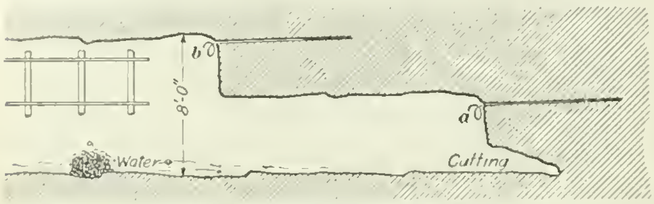

Fig. 2. Plan of Entry Ready for Blasting

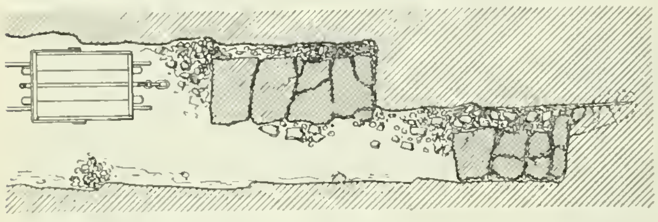

Fig. 3. After Blasting

a strip of coal from 4 to 5 feet wide with 30 inches or 3 pounds of powder. The less skilful miner generally blows this coal down so as to nearly fill the heading, and since he must be able to get at the cutting early to finish it before the end of the day, he must keep the heading well in advance of the back shot or there is no room into which to shovel the coal from the cutting shot. As the car cannot be brought nearer than the back shot these miners have much extra labor in shoveling the heading coal back to the car. Under these conditions there is very little air-current in the heading and gas is liable to accumulate and burn the miner when he takes in his light. For this reason some foremen require that the back coal be first cleaned up before any one goes into the heading.

On the other hand, the skilful miner can so gauge his powder that the coal is merely well loosened for easy picking down, as shown in Fig. 3, but he runs the risk of leaving the coal too tight, so light shooting can only be done when the coal seam is uniform. When the light shot is successful the miner need shovel the coal but once before he can load it into the car, but occasionally he cannot get at the heading until after the back coal is cleaned up. In this case he loses time unless there are plenty of cars.

When there are two benches in the coal seam, they are sometimes so tightly frozen they can be shot out together. Usually, however, the middle band is so soft or loose that the holes will not always break top and bottom. In this case the heading is driven in the easier bench, and generally the back shot of that bench is fired next. If the top bench is left, it is then shot down by two light shots on each side of the entry, fired just after the back shot has loosened the coal below, or sometimes not until the coal from the back shot has been shoveled out. Since the solid coal along the side of an entry or room is always called the rib, such shots along it are known as rib shots. In rare cases one center shot brings down all the top coal. If the bottom bench is left, two rib shots are always used. These rib shots are fired alternately first on one side of the entry and then on the other, and each shot is about half its length ahead of the last. This makes a kind of cutting for the next shot, and the entire block of coal is pushed partly into this space and so shaken loose from the bottom or from any hard middle band above it. In a few cases the benches are not so easily separated. Then the cutting is made in only one bench as usual, but the other bench is shot out of the heading before it is widened, so that a single back shot will widen both benches.

In case there is a considerable quantity of waste between the benches of coal, there would be a little delay and expense in hauling it out. To avoid this, the entries in Arkansas are often driven 12 to 14 feet wide by putting in another row of back shots behind the first row, or on the other side of the heading. This widening of an entry is called slabbing it. The track is then laid next the upper side of the entry, and waste piled along the lower rib.

Fig. 4 is the plan of such a gob entry. It shows also a room neck and a cross-cut from the air-course, and the way the bottom bench is usually taken up. If the middle band is so soft as to be easily shoveled off the lower bench without blasting, it is usually cleaned out of the heading before the back shots are fired. Where quite hard, it is always left until the bottom shots are fired. These, if properly charged, shake the rock loose from the bottom bench, and break it up for easy picking without mixing coal and rock. Fig. 5 is a cross-section of a gob entry.

As gob entries are necessarily wide, the roof is weak, and generally at least one row of props is set alongside the track. The bottom of the prop is first set upon the floor and a cap piece about 4 inches wide, 15 inches long and 1 or 2 inches thick is held against the roof while the prop is set under it at a small angle from the vertical. The prop is then securely wedged into place by driving it plumb, with an ax or sledge. If the roof is unusually weak, as where the coal is near the surface, it is supported over the roadway by cross-bars. These are logs 6 or 8 inches in diameter, reaching from side to side of the road and placed as close together as is necessary. The ends of the cross-bars may be held up by cutting hitches to form a little shelf of coal, if it is hard. Very often the coal is too soft or the entry too wide for hitches, and an upright post

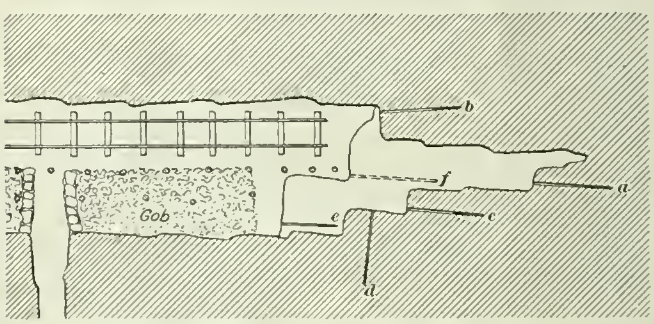

Fig. 4. Plan of Triple-Bench Entry

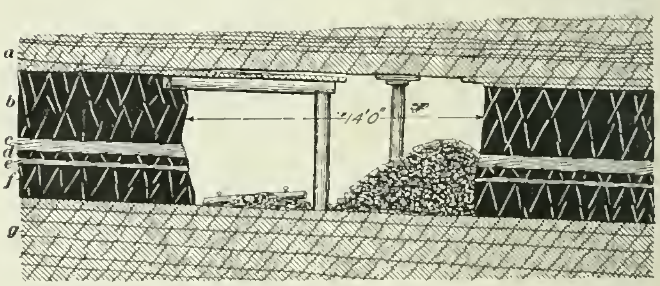

Fig. 5. Cross-Section of Entry

or leg is set under one or both ends of the cross-bar. Fig. 5 shows such a cross-bar with a hitch at one end and a leg at the other.

When the coal seam is too thin to give the height required for a mule, the entries are usually made higher by brushing them or blasting down the rock over the roadway. The roof at all of the mines in Arkansas where brushing is done is so hard that the holes must be put in with some kind of a post drill. These are called machines or at times Hardsocg drills, since that firm supplies most of the drills used in this coal field.

In harder rock a ratchet drill, most frequently of the Nixon make, is used. An iron post with a jack-screw at the end is supplied with the drill to hold it against the rock, but in some cases the miner sets up a temporary prop as a substitute for the regular post. The drill operates in the same way as a machinist's ratchet used for drilling holes in metal. When the drill is rotated by the ratchet handle, the thread bar in the pipe opposite the auger is screwed forward at a rate depending upon the hardness of the rock.

The holes for blasting down the roof are drilled upward at a slight angle to reach a little more than the required height above the rail. A single row of shots over the center of the track is enough to break the entire width, and each shot breaks the rock to a sufficient height for some distance beyond the end of the hole. The rock is usually blasted with black powder, which causes the hole to run ahead farther. Sometimes a stick of dynamite is added to break the rock into smaller pieces if it is hard.

Brushed entries are nearly always wide to provide room in which to pile the waste rock, and that part of the roof which is not to be shot down must be securely propped. A line of breaking props only 12 to 16 inches apart is set along the edge of the brushed part of the entry to break off the slabs of slate loosened by the shot. If the rock is very hard, a triple row of props, as shown in Fig. 6, is sometimes used.

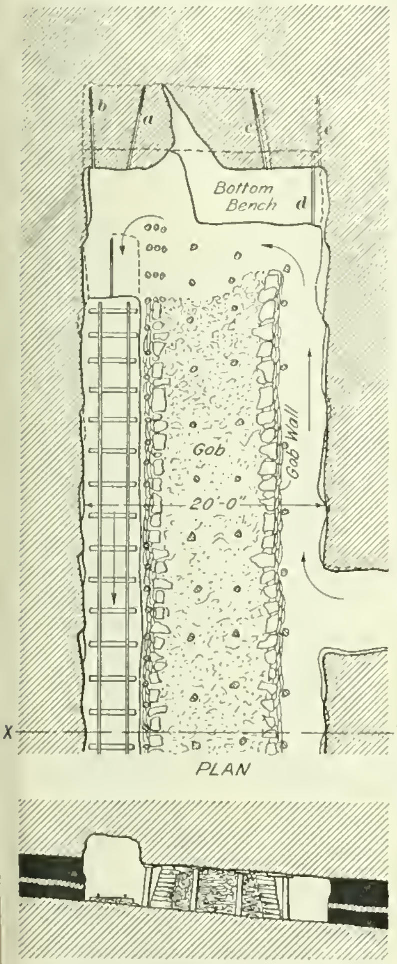

Fig. 6. Brushed Entry

Fig. 7 is an ideal view of a brushed entry in higher coal. This shows also the heading and the cutting. The block of coal to be removed by a back shot is shown upon the left side of the picture, but is somewhat obscured by the drill. A machine used for drilling the hole for the brushing shot is shown in position, and the end of the last brushing shot can be seen in the roof in front of the machine. (For the sake of clearness, the width of the brushing has been shown wider than usual and the gob space behind the breaking props is correspondingly narrow.) The rock removed from the roof is carefully stacked only when there is but little room in which to put it. Quite frequently the roof slate is piled along the roadway in the middle of the entry only, so the air, coming from a cross-cut behind it is carried on to the face of the entry before returning. This greatly helps the ventilation.

If, as at some of the semianthracite mines in Spadra and Russellville, there is enough waste to fill the space, a gob wall of the larger flat stones is built along the outer edge of this waste to maintain the passage for the air-current. Fig. 6 shows the plan and section of such an entry, and also the method of driving it in the hard unexplosive coal. This is the method used in the rooms at these mines. The slanting shot is more heavily loaded than the others, and is fired first, generally breaking the coal as shown. The next day the shots *a*, *b*, *c*, and *d*, will all be fired. The hole *d* is in the bottom bench and reaches only a foot or so into the solid under the top bench and is not heavily charged. On the following day after this coal has been loaded into cars, the shot *e*, and a rib shot in the bottom bench under shot *c*, with possibly another opening shot will be fired. If the middle band is hard rock, that bench which most easily separates from the band rock is shot first. If both benches are loose, the thicker one is shot first.

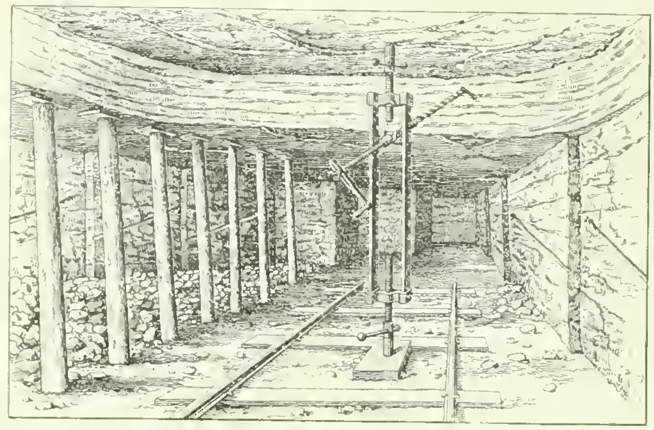

Fig. 7. Brushed Entry in Higher Coal

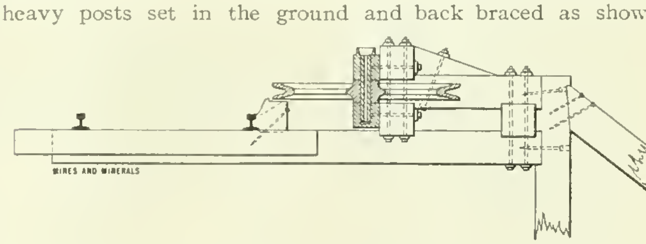
Instead of shooting down the roof, or top brushing, room for the mules in the entries in low coal can be made by digging into the floor or taking up bottom as it is usually called. This is also known as bottom brushing. In Arkansas this is done only when the roof is hard sandstone which cannot be drilled by any kind of auger drill.

Rope Sheave for Curves

A. J. Reef, assistant chief engineer, Victor-American Fuel Co., Denver, sends us the accompanying sketch of a very satisfactory self-oiling sheave wheel used on heavy grades in connection with heavy loads at the Radiant mine of his company.

It will be noted that the axle of the wheel, which is of steel, and upon which the wheel is shrunk, is made unusually long in order to withstand the heavy strain to which it is subject. The axle runs in cast-iron upper and lower boxes bolted to heavy posts set in the ground and back braced as shown.



Rope Sheave

Through the center of the axle is bored a ¼-inch hole and to its top is fixed a funnel-shaped cup for oil. The bottom of the lower box is made convex to provide a bearing (in part) for the axle, but more particularly is intended as a receptacle for oil, which, fed in through the funnel, passes down through the central hole and, by capillary attraction, up between the shaft and the boxing.

Mr. Reef suggests that where this single hole does not afford sufficient lubrication, holes at right angles to the shaft might be bored from its outer bearing to the inner oil tube, and, further, that it might prove an economy in oil to use an automatic oil cup instead of the funnel

Tentative Plan of Shaft Bottom

Arrangements for Handling a Large Output on Single-Deck Cage in Shortest Time and at Lowest Cost

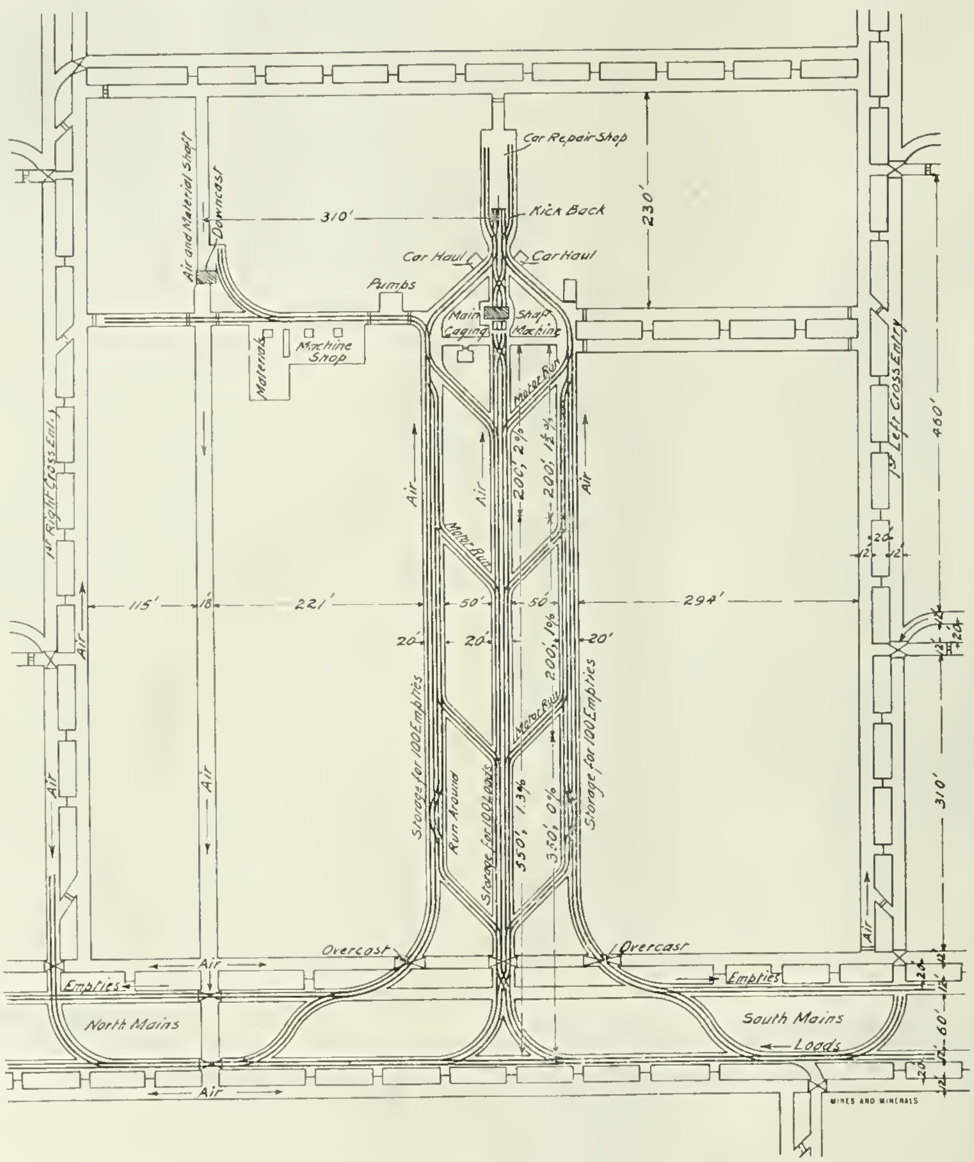
*By William B. Crawford**

[Editor's Note.—This article on a proposed shaft bottom was written by request, in order that the readers of Mines and Minerals might have an opportunity to express their views fully on a subject which is yearly growing in importance.]

On the other side of the Atlantic two- and three-decked cages are employed to approximate an output which in this country is accomplished on a single-decked cage. For economical reasons both inside and on the surface, single-decked cages are preferred, but they can only be adopted where shaft bottoms are suitably arranged for moving large quantities of coal quickly.

In opening a shaft mine, the arrangement or lay-out of the shaft bottom is of prime importance and should be given the closest study and attention to devise the plan or system best adapted to meet the requirements of the particular case.

Several plans for standard shaft bottoms have been proposed, but as a matter of fact, no one plan can be accepted as standard for all shaft bottoms, each individual case requiring special arrangement to meet the local conditions and requirements.



Plan for Shaft Bottom

In a general way certain plans can be followed, keeping in mind local requirements and treating each case independently, with the idea of accepting only such part of any plan as will meet all conditions to best advantage.

The plan herewith submitted is not intended as a standard lay-out to cover all cases and conditions, but is designed to meet the requirements incidental to mining a 5-foot seam of coal, lying fairly regular, and to produce the maximum tonnage in the shortest limit of time and at the least cost.

The production and economical operation of any shaft mine depend largely upon the speed and accuracy with which the mine cars are handled at the shaft bottom and returned to the working place, and to accomplish this in the shortest time and in the surest and most practical manner is the result aimed at.

The main shaft will be 15 ft.×26 ft. in the clear outside of timbers, by 600 feet in depth, and will have two hoisting compartments each 7 ft. 4 in.×13 ft. in the clear, and also a compartment 5 ft.×13 ft. in the clear for a stairway, piping, wiring, and signals.

The air-shaft will be 14 ft.×20 ft. in the clear, outside of timbers, with a hoisting compartment 7 ft. 4 in.×12 in. in the clear, equipped with man and material hoist.

Tracks will be 48-inch gauge; mine cars will hold 4 tons of coal, and it is calculated that the maximum production will be 4,000 tons per 10 hours.

The mine will be laid off in panels and worked on double-entry room-and-pillar system, rooms being turned on 60-foot centers and driven up from 30 to 40 feet in width, as conditions may determine.

Main cross and butt entries will be driven 12 feet in width and on 32-foot centers, leaving only a 20-foot pillar between entries. This is in order to facilitate the making of breakthroughs and the rapid progress of development work possible thereby. The support for these entries is secured by the heavy pillars left on either side of the pairs of entries.

All haulage is on return air, separate entries and tracks being provided for loads and empties and so arranged as to prevent interference between haulage locomotives and trips from the same and opposite side of the mine, it being intended that locomotives from the south mains shall use the right-hand loaded tracks and empty yards exclusively, and that those from the north mains shall use the left-hand loaded tracks and empty yards exclusively, only crossing to the opposite sides in case of necessity, such as occasioned by wreck or breakdowns of some kind on their respective hauls.

The main bottom or approach for loads is 700 feet in length from the main shaft to the curves turning in from the main

* Coalwood, W. Va. General Manager Virginia-Pocahontas Coal Co.

haulways and on a gradient toward the shaft of from $1\frac{3}{10}$ to $2\frac{2}{10}$ per cent. This approach is double tracked and provided with crossovers at convenient points to allow the placing of loads on either track at any desired point.

Motor runs are cut through at intervals of about 175 feet to the empty yards. These yards are each 500 feet in length with three tracks and provided with crossovers and switches at each motor run, so that the locomotives can reach any desired point in the string of standing cars and be able to pick up their empties either in front or behind the locomotive and return to the workings without delay.

Loaded cars, after being cut loose from the locomotive, are dropped to the shaft by gravity, being controlled by their brakes and are handled on and off the cages by automatic caging machines, placed directly in front of the shaft. The empties leaving the cages, run on to a kick-back and are shunted to the the foot of the car hauls, passing around on either side of the shaft, which delivers them to the top of the empty yards, from which point they are allowed to travel by gravity down into the yards to be made up into trips as desired.

The space beyond the kick-back will be equipped as a car repair shop and cars can be passed into or out of the shop on either side of the kick-back, storage room for "cripples" being conveniently located on the pair of butts crossing immediately behind the car shop.

Pump room, machine shop, material and supply depot, office and other stations are conveniently located around the shaft bottom as shown. All are to be lined and arched with reinforced concrete and provided with steel doors.

The system of ventilation may be either by blowing or exhausting, although in the present case, a force fan will be used and the main hoisting shaft will be the upcast. Concrete overcasts are to be placed wherever necessary, and doors eliminated, except on butt entries and passageways.

The mine will be equipped with electric locomotives, coal-cutting and loading machines, telephone and signal system, and the most approved equipment for fighting fire and mine-rescue work.

Refuge chambers and first-aid stations will be located at suitable points in the mine and every attention will be given to the providing of the greatest possible safety both to those employed and to the mine itself.

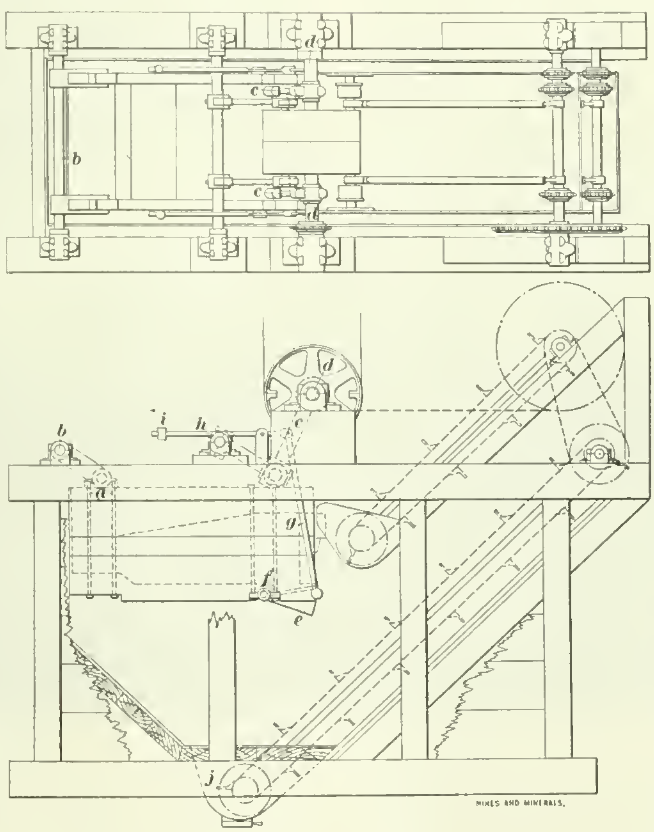
Our Cover Picture

Since the discovery of gold in 1903 by Messrs. Meyers, Murphy, and Taylor at what is now Goldfield, Nev., it is estimated that $42,000,000 has been taken from the ground. Probably one-half of this amount came from the mines included in the Goldfield Consolidated properties. In 1910 the Goldfield Consolidated mill, shown on the front cover, took fire. It was so quickly repaired, however, that the dividends from the mines were only slightly impaired.

The B. & K. Coal Jig

By N. R. Marvin

The chief points of interest in the newly developed B. & K. coal jig are the motion given to the pan and the automatic slate discharge. The pan is suspended in the jig box by hangers *a* suspended from shaft *b* at one end in such a way that with plunger rod *c* connected by eccentric to shaft *d* at the other end, it is given a horizontal oscillating and a vertical reciprocating motion. These combined motions cause the material in the pan to travel forward at the same time that the slate and coal are separating by gravity. Between the points of coal and slate discharge there is a space 12 inches to provide ample margin of safety in the adjustment of the automatic slate discharge. The slate gate *e* is pivoted at *f*, the other or free end is attached by reach rod *g* to the lever *h* with a balance weight *i*.



B. & K COAL JIG

When the bed of slate becomes so deep as to overbalance the counterweight *i* on the lever the gate *e* opens and permits the slate to flow out into boot *j* of the hutch, from which it is removed by scraper line shown. The slate gate opens intermittently but at frequent intervals when the jig is working at full capacity. The pan is of iron with its bottom perforated with ¼-inch diameter holes for buckwheat, pea, and nut coal, and it is given 85 strokes or shakes per minute, each having ⅞-inch travel forwards and the same number and travel backwards. The pan for jigs making stove and egg coal is perforated with ⅜-inch diameter holes and given 82 shakes per minute with a travel of 1 inch forwards and backwards. It requires little power and little water to run these jigs, while they have a large capacity, as will be seen from the table of tests made at the Midvalley Coal Co.

In the test of buckwheat (run-of-mine) the quantity of slate in coal is far below the amount which will pass inspection, whereas the test of buckwheat (condemned coal) is well within the passing limit, thereby showing possibilities of control by adjustment with the B. & K. jig.

Test of Double B. & K. Jig at Midvalley Colliery No. 2. Pea coal, run-of-mine, input to jig, $15\frac{75}{112}$ tons per hour; output, 75 per cent., or $11\frac{88}{112}$ tons per hour of coal containing 7 per cent. slate, and 25 per cent., or $3\frac{99}{112}$ tons per hour, of slate containing 2 per cent. coal.

Buckwheat, run-of-mine, input to jig, 21¼ tons per hour; output, 88 per cent., or 18¾ tons per hour, of coal containing 2½ per cent. slate, and 12 per cent., or 2½ tons per hour, of slate containing 1 per cent. coal.

Buckwheat, condemned coal, input to jig $21\frac{1}{5}$ tons per hour; output, 94 per cent., or 20 tons per hour, of coal containing 7½ per cent. slate, and 6 per cent., or $1\frac{1}{5}$ tons per hour, of slate containing 2 per cent. coal.

Stove coal, run-of-mine, input to jig $26\frac{58}{112}$ tons per hour; output, 63 per cent., or $16\frac{8}{112}$ tons per hour, of coal containing 1½ per cent. slate, and 27 per cent., or $10\frac{50}{112}$ tons per hour, of slate containing 2 per cent. coal.

Heilwood, the Model Mining Town

An Example of Modern Method of Treating the Living Problem in an Isolated Camp

Tucked away in the eastern central part of Indiana County, Pa., is a mining town not on the railroad map or timetable. This town, called Heilwood, belongs to the Pennsylvania and Maryland Steel companies, who own the surrounding country for many square miles. While not extravagant with their money, they have built this town with the evident object of securing a good class of miners and retaining them. The Cherry Tree and Dicksonville Railroad, a branch road jointly operated by the Pennsylvania and New York Central, has a station near Heilwood called "Possum Glory," and if one desires to see this model mining town (not model mines, as they blow up) he must take this road or drive from Barnesboro, 12 miles distant. At Heilwood the operatives of the Penn-Mary Coal Co. live in luxury, if their dwellings and surroundings are compared with those of most mining towns; indeed, the town has the appearance of a well-kept country village. The coal mines, five in number, give employment inside and out to about 1,000 men, and if to this number the women and children be added the population of the town of Heilwood will approximate 2,000.

The company officials understanding that General Manager H. P. Dowler, who lives at Heilwood, is more in touch with the conditions that effect the welfare of this little community than an absent official could be, rely on his judgment in the matter of expenditures for the common good of all concerned.

Realizing that Heilwood is to be a permanent town that must increase in population as more mines are opened and the present mines are more extensively developed, all buildings are constructed in a substantial manner and with a view to present and future sanitary conditions. The town, situated on high ground, affords good drainage facilities and is systematically blocked with streets that provide a certain number of 50′×150′ building lots in each block. From the illustrations it will be seen that single houses have been constructed with a view to family privacy. Each house has plumbing that connects it with a town water system which supplies excellent water from two wells 800 feet deep, and which insures freedom from sickness due to impure water. The management states with satisfaction that not only are the people clean and healthy, but that there has never been a case of typhoid fever that originated in the village. The houses and town streets are lighted by electricity. Frequently the phrase "mining camp" is used by writers, and it is usually suggestive of a place of shacks littered with garbage, tin cans, old shoes, a possible dead cat or something similar; it will be observed, however, that the term village has been used in this article and it is not amiss, for the unattractive attributes to the camp are wanting.

All coal mined by the Penn-Mary Coal Co. is shipped to the plants of the Pennsylvania and Maryland Steel companies, where it is coked in by-product ovens or used for other purposes in the manufacture of steel, and this policy is likely to be continued indefinitely. The company, basing its policy on the experience of other coal companies, refuses to sell land in the vicinity of Heilwood, the reason being that land once gone from its control offers an opportunity for undesirable citizens to obtain a foothold in the community.

It was understood, however, that in such a comparatively isolated place arrangements must be made to entertain commercial travelers and visitors, and to that end a hotel was built. There is a law in Indiana County that makes it illegal to treat (which must appeal to the fellow whose best girl has a fancy for bonbons, ice cream, and soda water), and since it is almost necessary for some miners to have beer, there is an irrigating station connected with the hostelry, but so regulated that drunkenness is frowned upon. Opposite the hotel there is a restaurant, not a cafe, where one can obtain lunch except when the proprietor shuts up and goes home to meals. The justice of the peace has his office next door with a large sign fronting the hotel that is calculated to inspire the same feeling as the sign "Beware of the Dog." As a rule miners are religious, and to afford them spiritual nourishment two churches have been built, one for the Roman Catholics and one for the Protestants.

Fig. 1. The Town of Heilwood, Pa.

Going up the street, the Heilwood Company store attracts attention. This department store, which is independent of the Penn-Mary Coal Co., is managed by J. M. Thompson. Aside from its general cleanness and neatness it has a butcher shop that is new and interesting. Most of the fresh meat is obtained from native cattle, and since such meat is tough when sold shortly after killing, it is customary to hang the dressed carcass in cold storage for 10 days before distributing. We know of no other coal company which goes to such lengths in order to please its employes, and even then the meat is sold from 10 to 20 cents less per pound than equally good meat in eastern Pennsylvania. A short distance from the store and on the same side of the street is the general office of the Penn-Mary Coal Co. This is an attractive brick building with roomy offices downstairs and excellently appointed engineers' offices upstairs. The building is steam heated and electric lighted, with fireproof vault for storing such valuables as are likely to be destroyed by fire. Opposite the office and some distance back from the street is the handsome colonial residence of Mr. Dowler; however, he has not cornered Heilwood residences, as can be seen by reference to Fig. 3. At the end of the main street is a park in which there is an imposing buff-colored brick building. This is the public school building, erected and maintained by the company for the benefit of the children of its employes. At present there are 250 pupils with a corps of competent teachers. Opposite this building there is a fine dormitory erected for the women teachers who room and board there. This building is supplied with modern improvements, which no doubt is comforting to those who have been wrestling through the day with budding statesmen and suffragettes.

FIG. 2. PENN-MARY HOSPITAL

In a mining town of the size of Heilwood there is always more or less sickness among the women and children, besides the men incapacitated through injuries received at their work in the mines. To make sure that the sick and injured are properly treated the Penn-Mary company erected a hospital, which, while not large, is probably the best appointed in the state. In it there are wards for children, men, and women, besides private rooms, all of which are equipped with steel furniture, sanitary base boards, and curved wall angles to guard against the lodgment of disease-breeding germs. Mr Dowler has furnished a room in this building for the sick who need privacy, that contains handsome furniture all in enameled steel that resembles oak. The doors in the interior of the building are steel, but enameled or veneered to resemble wood. Doctor McKinley, the resident physician and surgeon, had much to do with the design of this hospital and its furnishing. Being up to date and bearing in mind the disadvantages under which he was compelled to work in city hospitals, he instituted improvements which have been incorporated in this building. The operating room has a glass ceiling which furnishes an abundant supply of light during the day; it is also equipped with electric lights and portable electric lights and reflectors for night operations.

FIG. 3. HOUSE OF GENERAL MANAGER AT HEILWOOD

Whenever an injured man is brought from the mine he is taken in the basement of the hospital, washed, placed on a cot and elevated to the operating room where his wounds are properly dressed.

There are several sterlizing appliances in the building and such water as is needed for washing wounds is filtered and sterilized before being applied. Connected with the establishment is an X-ray machine imported from Germany and said to be the only one of its kind in this country. The spark is not generated in the usual way by glass plates but by means of rotating parts revolved by electric motor. In the basement there is an X-ray room, bathroom, steam laundry, kitchen, nurses' dining room, boiler room, and storeroom.

It must not be imagined that because the company has built a hospital at this early stage of its career it fails to take every possible precaution to prevent accidents in the mines. No manager wants a man injured and most managers suffer mentally when an accident occurs, particularly if it happened through his negligence; however, so long as there is mining there will be accidents, which may be minimized if the men will cooperate with the management and not assume risks.

Trade Notices

Rubber Footwear.—Miners who work in wet places must wear rubber boots if they expect to keep their feet sound and free from sores. The conditions surrounding wet work are such that a poor quality of rubber will not wear long. Owing to the price of rubber having advanced steadily in recent years unscrupulous manufacturers use adultered rubber to keep down the price and induce people to purchase their goods. The Mishawaka Woolen Mfg. Co., of Mishawaka, Ind., had such difficulty in buying satisfactory rubbers to go with its all-wool boots and socks that it undertook the manufacture of rubber boots and shoes, with the avowed object of making the best possible footwear for mine service. Their goods, under the trade name of "Ball Band" met with such success it is claimed that 8,000,000 people wear "Ball Band" footwear. The manufacturers claim that they put $1,000,000 extra value into their footwear each year over what would be necessary to turn out ordinary fairly good boots and shoes. Most dealers can supply "Ball Band" goods, but if not, the manufacturers will see that the user is supplied if he will write to them direct, giving the name and address of the dealer from whom he buys his shoes.

FIG. 4. HOUSES AT HEILWOOD

New Fans.—J. R. Robinson, engineer, Pittsburg, Pa., is now installing for the Poston-Consolidated Coal Co., at Athens, Ohio, a fan of 60,000 feet capacity; one for the Beech Bottom Coal Co., Wellsburg, W. Va., 80,000 feet capacity; one for Hutchinson Coal Co., at Reynoldsville, W. Va., 125,000 feet capacity; one for Madeira-Hill-Clark Coal Co., at Wilsonburg, W. Va., 150,000 feet capacity; one for Pennsylvania Coal and Coke Co., Cresson, Pa., 150,000 feet capacity; one for Keystone Coal Co., White Station, Pa., 150,000 feet capacity, one for

Cascade Coal and Coke Co., Sykesville, Pa., 300,000 feet capacity at 6-inch water gauge; one for Federal Coal and Coke Co., Grant Town, W. Va., 300,000 feet capacity at 12-inch water gauge.

You Can Save Assay Expenses.—The Way's Pocket Smelter Co., of South Pasadena, Cal., reports an unusual demand for their outfits from persons who wish to use them for experimental purposes, and for testing ores in connection with their study of mineralogy. The company is now supplying a cabinet of ores at a low cost, and by testing these with Way's process, the person can get a knowledge of ores and minerals that is worth a year's reading of books.

New National Electrical Code Rules.—The new rules in regard to insulated wires and cables that have been adopted by the National Board of Fire Underwriters went into effect on October 1. The Hazard Mfg. Co., of Wilkes-Barre, Pa., has issued a booklet showing the new specifications and also describing Penn wires and cables, which are made to conform to the requirements of the new rules in all particulars. Full information is also given in regard to the Hazard 30 per cent. Para, and the Keystone 25 per cent. Para rubber insulation which is used by the company in the manufacture of covered cables for all electrical work. Dealers are allowed till July 1, 1912, to dispose of stocks on hand and after that time only wire conforming to the new specifications will meet the approval of the National Board of Fire Underwriters. The Hazard company will send a copy of the booklet on request.

Pile Hammers.—The increasing use of sheet piling in excavating running ground has brought about the development of driving appliances. The McKiernan-Terry Drill Co. has issued a bulletin entitled "Pile Hammers," describing the machines and giving facts regarding accomplishments in actual work. It is worth sending for by any one interested in the subject.

Modern Coal Mining Plants is the name of a booklet issued by Roberts & Schaefer Co., Chicago, containing some fine pictures of coal mining plants built by them in different parts of the country. Many of these are of large capacity and all are examples of the best modern practice. This booklet is No. 22 and will be sent on application.

Tests of Turbine Pumps.—"Comparative Tests of Large Engine- and Turbine-Driven Centrifugal Pumps," is the title of an article by Francis Head, Member of American Society of Mechanical Engineers, which recently appeared in one of the technical journals and has been reprinted by the DeLaval Steam Turbine Co., of Trenton, N. J. "Steam Turbine Centrifugal Pumps and Other Centrifugal Machinery," is a 32-page booklet issued by the same company, illustrating and describing the several lines of machinery manufactured.

Need of a Good Light.—The importance and economy of having plenty of light for men to work by is beginning to be appreciated by mine operators, and endeavors to furnish this have been made along several different lines. One of the brightest lights and at the same time simplest and cheapest is the acetylene lamp. Among the newest of these is the lamp made by the Maple City Mfg. Co., of Monmouth, Ill. This lamp is charged with calcium carbide and water in the usual manner, but has a number of points in regard to durability and accuracy of adjustment that must be seen to be appreciated. The lamp furnishes a 10-candlepower light at less cost than oil. The company will send a sample lamp free to any mine superintendent writing for it on a company letterhead.

Stope Drill Contest. The committee of the *South African Mining Journal*, under date of September 23, in commenting on a pamphlet entitled "Results of the Stope Drill Contest" which has been widely distributed in the United States and which had the appearance of being published by the *South African Mining Journal*, says: "This pamphlet was not issued by our office, does not quote us correctly, and has been published without our knowledge."

The Goulds Mfg. Co. opened a branch house at Ohio and Franklin Sts., Chicago, Ill., on November 1, to handle their business in the Middle Western territory, including the states of Indiana, Illinois, Michigan, Wisconsin, Minnesota, and Iowa. This branch will take over the entire business of the present Goulds company, with the exception of their line of centrifugal pumps. The branch house will exploit the new line of volute centrifugal pumps, which are made in the Seneca Falls factory along with the rest of the company's complete line, including hand-lift, force, and windmill pumps, spray pumps, both hand and power, rotary pumps, centrifugal pumps, air compressors, vacuum pumps, etc., in fact, all types of pumping equipment for every service.

Will Make Steel Cars.—The Hockensmith Wheel and Mine Car Co. have taken up the manufacture of steel cars and erected a special shop for this purpose. It is a steel and brick structure 100 ft. × 200 ft. in size and near to the other shops comprising the plant. Railroad tracks enter and cross through one end, by which all material is delivered, and on which the finished cars are loaded under its roof. The shop is equipped with the latest improved machinery for shaping and preparing the steel plates, and an overhead electric traveling crane for handling the material throughout the shops. The company proposes to equip their steel cars with their patent angle-bar truck in which is incorporated cold-rolled steel axles, and special axle box, and the straight-spoked annealed "Eureka" wheels. This truck has given satisfactory service in the principal districts of the United States, British America, and Mexico, and will be a strong feature of the new steel cars. In addition to these improvements, there has recently been built a large annex to the smith shop, the capacity of the electric power plant has been doubled, and the floor space in the foundry increased, so as to admit increase of from 500 to 900 annealed mine car wheels per day.

Asbestos Roofing.—Asbestos roofing is looked upon as a natural protection against all destructive elements, because it is made of a natural mineral that has already proved to be practically indestructible by not being injured by exposure to the elements for centuries. According to the process used by the H. W. Johns-Manville Co. in making the "J-M" roofing, several layers or sheets of asbestos felt are cemented together with Trinidad Lake asphalt—the same as used for street paving. This makes an all-mineral roofing that is practically as permanent as the brick walls or any other inorganic part of a building. Fire cannot get through an asbestos roof from the surface; and from underneath, only after the sheathing boards and timbers have burned away and allowed it to fall. A white surface "J-M" asbestos roofing has been made for use where comparatively low summer temperatures are desired on the inside of the building. A test made at a Cleveland, Ohio, clothing factory in the summer of 1908, showed a difference of 18 degrees between a black and a white-surface roof, the thermometers being suspended 4 feet below the under side of the roof. While formerly asbestos roofings were laid with copper flashings, by the "J-M" process the entire roof, including flashings and gutters, can be laid with the asbestos roofing.

Emergency Treatment.—To get the best results from the ordinary first-aid outfits some knowledge in regard to methods of using the materials in them is necessary; and where regular first-aid instruction is not possible a good book is the next best thing. To meet this need, Johnson & Johnson, of New Brunswick, N. J., who are well-known manufacturers of first-aid and surgical material, have had prepared a book entitled "Johnson's First-Aid Manual" which gives, in plain language, with many illustrations, full instructions for treatment of emergencies, both with the materials furnished in the usual first-aid packets or with such materials as may be obtained anywhere. Besides these directions it contains valuable information as to sterilization, care of sick room, treatment in cases of poisoning, and handling of contagious diseases. This book is furnished free with the first-aid outfits sold by this company. Its price, postpaid, is 50 cents

Mine Survey Notes

As descriptions of several systems for keeping mine survey notes have appeared in MINES AND MINERALS during the past year, the system herewith described may be of interest for purposes of comparison. This system of note keeping has the following points to commend it.

No special form of book is required, as any standard engineers' field book will do.

It is simple, as all the data concerning any station in a mine are recorded in the note book, on the same line as the station.

Sketches can be made showing the working places just as they actually are in the mine at the time of the survey. A draftsman may be called upon to make a map of a mine, portions of which are completely worked out, from notes taken years before. This he cannot do without accurate sketches, hence their almost absolute necessity.

When called upon at the mine to locate two entries to connect, or similar work, the engineer is saved the time and trouble of making a new traverse or survey, which he would of necessity have to do if his latitudes and departures were recorded in an office book probably a hundred or so miles away. The books required for this system are: the entry books Fig. 1, room books, Fig. 2; and an office copy of both entry and room books copied from them and kept in a safe place, only for use in case the field books should become destroyed or lost.

On the opposite side of the page sketches are made showing the plus to the center of all cross-cuts, sumps, manholes, rooms, etc. While no attempt is made to keep these sketches to scale, they are supposed to look as nearly as possible like the entries being surveyed. On this page is also shown a section of that part of the coal seam which is being worked, at each survey station, or at least every 300 feet.

The survey stations are of course put in as needed, but regular extensions are made every 3 months, the plus to the face from the last station being shown in the sketch, with its survey letter, the date of the survey letter being shown in the corner of the page. These survey letters are also used on the maps instead of a date.

In the front of the entry books two sets of indexes are made, one showing the page of the book in which any entry survey may be found, the other indexing the station numbers in consecutive order, showing on what page of the note book and in what entry they are located.

The room notes are kept in a separate book, similar to the ones used for entry notes but both sides of the sheet may be used for sketches as no transit notes are recorded.

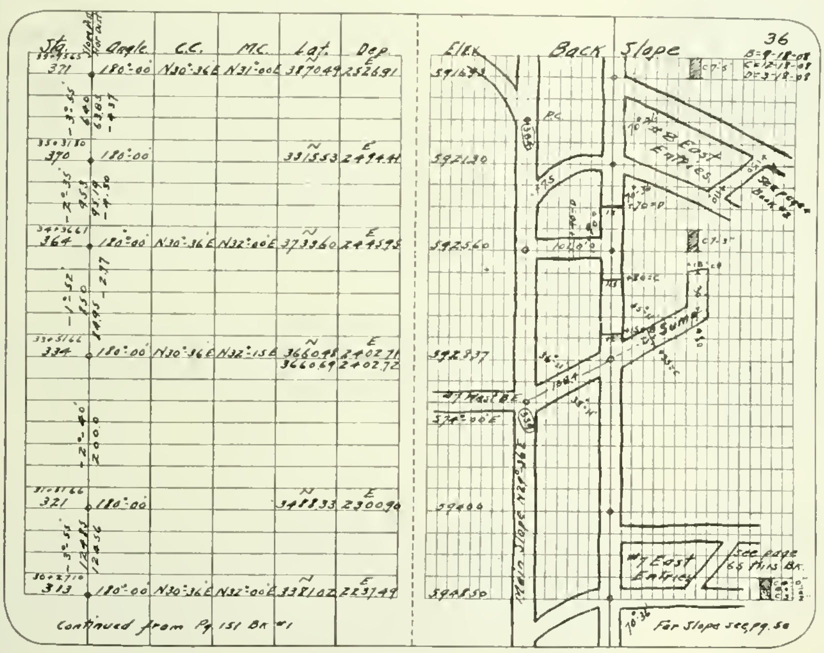


FIG. 1. ENTRY BOOK

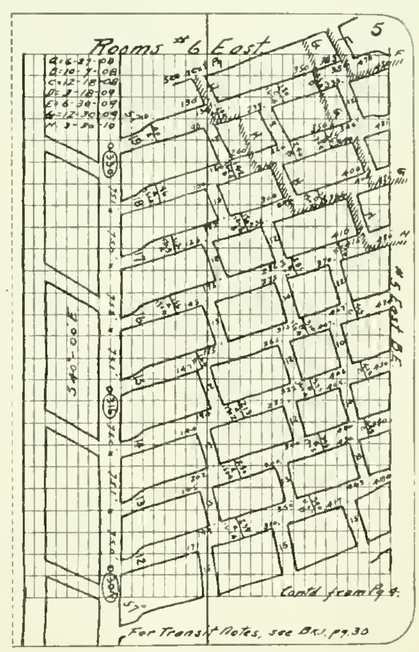

FIG. 2. ROOM BOOK

In the entry books, column one is used for the station number, also the profile +. The station number is stamped on a miners' brass check and fastened on the survey plug with the same spad to which the engineer takes his sight.

On the line between columns one and two is recorded the vertical angle and slope distance. The difference of elevation, and horizontal distance are recorded on the opposite side of the line, when calculated in the office.

Column two is used for the deflection angle, whether right or left, column three for the calculated course, column four for the magnetic course, column five for the latitude, and column six for the departure. The elevation as calculated from the vertical angles is recorded on the opposite side of the page.

Where a tie is made the error in chaining is shown by recording the latitude and departure, as calculated from parallel entry survey, under the latitude and departure of the survey station to which the tie was made.

In taking the room notes the distance between rooms on the entry is carefully measured and recorded, also the angle at which the rooms are turned off the entry is recorded at one or more places. The rooms measurements are made from the survey line on the entry and all cross-cuts right and left are located by measurement, a small dot in the notes showing the point measured too.

At the time of each quarterly survey the engineer takes sights in the rooms by hanging plumb bobs on the sight spads, and measurements are taken from either side of this sight line to the ribs. The width of cross-cuts is also recorded.

While the room is advancing, the distance to the cross-cuts and face is recorded, along with the width of the room and the survey letter, inside the room on the sketch. When the room pillars are being pulled the distance from the entry to the gob line is recorded on the pillar to the left of the room in which the measurement was taken. This avoids any confusion between the old and new figures.

As in the entry notes the date of each survey letter is recorded on each page.

The index for the room notes is merely a matter of indexing each entry in consecutive order as they are found in the book.

Coal Mine Shaft Pillars

Proportioning According to the Compressive Strength of the Coal of Which They Are Made

It is believed that William Griffith, E. M., of Scranton, Pa., first suggested the proportioning of mine pillars according to the compressive strength of the coal of which they were made. To carry out his ideas the Scranton Engineers' Club, in 1900, appointed a coal-test committee who reported in 1903. While their investigations were not entirely satisfactory, they were at least in the right direction and were worthy of a more general and thorough discussion. Joseph Daniels and S. D. Moore of Lehigh University took up the subject as a thesis, and their deductions differed materially from those of the Scranton Engineers Club committee, and while not entirely satisfactory, were another step in the right direction.

In discussing the strength of coal and the proportioning of shaft pillars according to that strength, it is necessary to go somewhat into the literature on the subject. A writer says: "It is impossible to give exact rules or formulas for determining the size of pillars. Each case in practice requires special consideration, and in laying out mine pillars in a virgin field it is well to find out what the current practice is in similar fields."

This writer is correct when he says each mine requires special consideration, but is it not illogical to advise one to go into another field to find out a matter that requires special consideration at each mine, no two being the same in any one field? The rule of thumb suggested is equivalent to using a ton of iron where 500 pounds would answer, and such practice involves no engineering skill. As a practical example of the variation in the strength of coal, tests made with 2-inch cubes of anthracite from the Lehigh field withstood 4,500 pounds pressure per square inch before the first crack appeared and 5,400 pounds before crushing. On the other hand a 2-inch cube from the Lackawanna field failed at 1,500 pounds per square inch and crushed at 2,182 pounds. This comparison between one of the strongest and one of the weakest coals in the two fields shows that each mine is a problem in itself.

The difference in compressive strength is not so remarkable to those who know the degrees of metamorphism which prevail in the different anthracite fields. Following the leader has caused great loss in the past, and "hindsight" has not been as beneficial in coal mining as it might have been had each mine not offered a problem and frequently several problems by itself. If this statement be true, then it is not within the province of the mining engineer to hunt for the proper sized pillars in other fields. The mechanical engineer uses no such tactics, neither does the civil engineer, but both base their work on the strength of materials, and calculate accordingly. Taking the average specific gravity of coal rocks at 2.5, one cubic foot would weigh 156.25 pounds, and prism 1 square inch base and 12 inches high 1.085 pounds. For calculation, assume that the coal rocks have a pressure of 1 pound per square inch for every foot in depth or that the pressure per square foot is $p = 150\ d$. The squeezing is not the maximum crushing strength but the point where the first crack occurs, and will be greater for soft tough coal than for soft weak coal. According to our formula the depth at which mining must cease in the Lehigh coal would be less than 4,500 feet below the surface, while in the Lackawanna field it would be less than 1,500 feet below the surface. Where insufficient coal is left in pillars a squeeze is brought on and the coal snaps and cracks without crushing at once. The strength of coal has not all to do with the size of pillars; for instance, soft floors require large pillars to prevent creep, and weak roofs require small rooms in order to obtain support from more numerous pillars; however, the proportioning of pillars and rooms is not the subject of this article, and, as T. Lawson would say, the foregoing is preliminary to reaching the system.

Several formulas for shaft pillars have been advanced that on comparison show a difference in size varying from 4,356 square feet to 90,000 square feet for a depth of 300 feet, and from 8,649 square feet to 360,000 square feet for a depth of 600 feet. To further mystify the reader the authors as a rule fail to furnish data to explain how they have deduced the rules they advance. Andre says: "Up to 450 feet in depth shaft pillars should be 105 feet square and for greater depths an increase of 15 feet on each side for every 75 feet of increased depth." According to our assumption, at 450 feet depth the pressure would be 450 pounds, and at $450 + 75 = 525$ feet depth the pressure would be 525 pounds per square inch. If then a pillar 105 feet square can withstand the pressure at 450 feet, the size of the pillar required at 525 feet depth would be $450 : 525 = 105 : 122.5$ square feet which agrees closely with Andre.

Dron's plan for determining the size of shaft pillars is to "draw lines enclosing all surface buildings that it is necessary to erect about the head of a shaft, and make the shaft pillar so that solid coal will be left outside these lines all around for a distance equal to one-third the depth of the shaft." This rule would furnish sufficiently large pillars and make the underpinning to houses in the anthracite cities safer, as it would virtually prevent mining in Scranton, Wilkes-Barre, and other places, therefore this plan seems to be perfunctory.

Hughes tells the reader to "leave 1 foot in width of pillar for every 1 foot depth of shaft." A shaft 450 feet deep would have a 450-foot-square pillar containing 202,500 square feet while Andre's pillar for this depth contained 11,025 square feet. Hughes' rule therefore also seems perfunctory.

Wardle says: "Shaft pillars should not be less than 40 yards square (120 feet square) down to a depth of 60 fathoms (360 feet) and should increase 10 yards on a side for every 20 fathoms increase in depth."

Since the pressure is 360 pounds per square inch at 60 fathoms, it would be 450 pounds at 75 fathoms and the size of the pillar at the latter depth would be $360 : 450 = 120 : 150$ feet square. According to Wardle's rule this pillar should be 142.5 feet square.

Pamely furnishes the following rule: "Allow a pillar 120 feet square for any depth less than 300 feet; for greater depths increase the pillar 15 feet for every 60 feet in depth."

Since the pressure is 300 pounds at 300 feet depth, at 450 feet the pillar should be $300 : 450 = 120 : 180$ feet square; according to Pamely's rule however the pillar would be 157.5 feet square. The discrepancy increases with depth in Pamely's rule.

Merivale gives a formula for shaft pillars which is $S = \sqrt{\frac{D}{50}} \times 22$, in which S = length of the side of the pillar in yards and D equals the depth of the shaft in fathoms. He does not state what the constants 50 and 22 represent. Assume two shafts 300 and 450 feet deep, then according to this rule the pillars would be, respectively, 66 feet square and 81 feet square. If a pillar 66 feet square is able to support a pressure of 300 pounds per square inch then it should be 99 feet square to support a pressure of 450 pounds per square inch.

The sizes of shaft pillars derived by the rules of the various authorities at 300-, 450-, and 600-foot depths are as follows:

Authority	Depth 300 Feet	Depth 450 Feet	Depth 600 Feet
Merivale	66 ft. sq.	81.0 ft. sq.	93 ft. sq.
Andre	105 ft. sq.	120.0 ft. sq.	140 ft. sq.
Wardle	120 ft. sq.	142.5 ft. sq.	200 ft. sq.
Pamely	120 ft. sq.	157.5 ft. sq.	240 ft. sq.
Hughes	300 ft. sq.	450.0 ft. sq.	600 ft. sq.

Nothing is said by these writers concerning the excavations that must be made in these pillars for the shaft and its underground approaches. Taking Andre's pillar of 105 feet square at 300 feet depth, assume that it will withstand a pressure of 300 pounds per square inch, and assume that the shaft is

10×20 feet or 120 square feet in area, and the underground approaches through the pillar are 10 feet wide. The pillar without excavation would cover an area of 11,025 square feet and this would sustain a pressure 45,000 pounds per square foot. After the shaft and the entries are excavated the pillar will be reduced 1,250 square feet, thus leaving 9,775 square feet to support the pressure formerly sustained by 11,025 square feet; that is, the pressure has increased on the pillar to 9,775 : 11,025 = 45,000 : 50,754 pounds per square foot. Under such conditions, if the squeezing strength was 300 pounds per square inch the safety limit would be passed by making the excavations.

It becomes evident from the calculations that the size of shaft pillars is not to be based on any rule, but on the squeezing strength of the mineral that must sustain the pressure after excavations have been made. Naturally with such great differences in the rules advanced for shaft pillars, which were probably based on the author's experience in some one particular field, the mining engineer must have great faith in his authority to follow him, and it appears to be safer for him to follow the leader whom he knows than the authority he does not know.

Steel Mine Timbers in the Dodson Colliery

*By R. B. Woodworth**

The Dodson colliery of the Plymouth Coal Co. is noted as the place at which culm flushing was first tried out, in 1891, by Gilbert Jones, general superintendent, under the direction of Mr. John C. Haddock, now president of the company.

The timbering in the pump room of this colliery has been a matter of difficulty owing to movement of the strata above it. The original wooden timbering consisted of 18-inch to 22-inch round sticks of white pine, yellow pine, and oak placed 2 feet center to center. A great deal of trouble was experienced from these timbers becoming forced in close upon the pipe lines with the possibility of breaking them. As new timbers were placed, they were put in between the sets already in, so that eventually the pump room had timbers practically skin to skin. It is estimated that the entire pump room was retimbered in wood once a year.

The pump house is 100 feet long, 8 feet high in the clear,

Wood Timbering

and 18 to 22 feet wide. Beginning with April 16, 1910, the 70 wooden sets of mine timbers were replaced by 48 steel sets made up of 18-inch, 55-pound, and 20-inch, 65-pound I-beam collars and 6-inch H-beam legs, weighing 23.6 pounds per foot. The last set was installed about December 15, 1910.

* Carnegie Building, Pittsburg, Pa.

From the statement below it will be noted that the total cost for timbering once with wood was $2,415, and the total cost for timbering in steel $2,889.09, or a difference in first cost of not quite 20 per cent. The steel cost at the mines slightly over two and a half times the cost of the wooden sets, and it also

Steel Timbering

cost 33⅓ per cent. more for placing. Fewer sets were required, however, and the ultimate rate was thereby lessened.

The comparative cost of the two installations is shown in the statement below, prepared by Mr. Haddock:

Wood	
Number of sets	70
Average diameter of timber, inches	20
Quality of timber—yellow pine and oak.	
Average weight per set, pounds	4,150
Cost per set f. o. b. cars mines	$12.00
Cost per set for placing	$22.50
Cost per set in place	$34.50
Total cost for timbering	$2,415.00
Life of timber set, year	1
Steel	
Number of sets	48
Size of collars, 18-inch beam, pounds	55
Size of collars, 20-inch beam, pounds	65
Size of legs, 6-inch H-beam, pounds	23.6
Quality of steel—structural grade.	
Average weight per set, pounds	1,483
Cost per set f. o. b. mines	$31.47
Cost per set for placing	$30.00
Cost per set in place	$61.47
Total cost for timbering	$2,889.09

The higher cost of placing the steel is due to three causes:

1. The charge of taking out the old timber, which, however, was insignificant, as the steel was placed a set at a time by forepoling ahead, the condition of the roof being very bad and there being loose material for an unknown distance above.

2. Great care was taken with the steel to line it up properly and provide a good base, which was made of a solid concrete wall built the full length of the pump room on each side. This solid concrete base is unnecessary with the wood and might have been omitted with steel, but its use means a real betterment in the construction.

3. The steel was placed without interfering with the operation of the pumps, which necessitated very careful handling and added something to what the expense would have been had the room been free from obstructions.

It is apparent that while the first cost of the steel construction is greater than that of wood, it will have much more than paid for itself if its life extends over 15 months only, and that every additional length of time it stands will mean that much less in cost of maintenance. The first steel has now been in place 16 months with no sign of deflection in the collars, and what is better, with no evidence of fracture in the concrete where any overloading of the steel would immediately show.

The Cost of Mining Coal in Iowa

Total Wage Cost and Itemized Costs Per Ton From Figures for Three Years, 1907 to 1910

*By Edward A. Sayre, E. M.**

The following is a synopsis of a thesis entitled "The Cost of Mining Coal in Iowa," based on the actual cost of mining at the Eagle No. 2 mine, located at Des Moines, Iowa.

The Eagle No. 2 was sunk in the summer of 1907. The cost tables cover the first three years of the mine's life, namely, November 1, 1907, to April 1, 1908; April 1, 1908, to April 1,1909, and April 1, 1909, to April 1, 1910. The tonnage during those periods was as follows: 9,774, 21,692, and 28,376 tons of lump. As the coal hoisted is composed of approximately 70 per cent. lump and 30 per cent. steam, the total hoist of mine-run coal would be 43 per cent. greater than the above figures. 75 per cent. to 80 per cent. of this tonnage was hoisted during the 7 months from September 1 to April 1, the mine running but part time on a small output the remainder of the year. During the height of the season, the mine hoisted from 150 to 200 tons of lump per day. The entire output was sold locally in Des Moines, Iowa.

The Eagle No. 2 is operated on the room-and-pillar system of mining. Eight-foot or 12-foot entries are driven with 22 feet of pillar between them. Rooms are turned off the side entries with 8-foot room necks 12 feet in length. The rooms are widened to 23 feet and driven in for 150 to 175 feet. Twelve feet of pillar is left between rooms. The coal varies in thickness from 3 feet 6 inches to 7 feet 4 inches, the average being 4 feet 6 inches to 5 feet. The mine is dry, no pumps being put below for 1 year after sinking.

The mine is located in subdistrict No. 3, all the mines of this subdistrict being operated under union agreement with the United Mine Workers of America. During the above periods of time, the following scale of wages was paid:

Lump per ton	$1.00
Mine run per ton	.69
8-foot entry per yard	1.97
12-foot entry per yard	1.91
Room turning	5.04
Brushing (top or bottom) per inch of thickness per yard of advance of the room or entry	.05⅜
Drivers, timbermen and daymen, per day	2.56
Top labor, per day	1.90

The following tables are all based on the hoist of lump coal. To find the cost of a ton of mine-run, the results should be multiplied by .7.

Under the above scale of wages, the total wage cost was found to be as follows:

Table 1. Total Wage Cost of Mining

Date	Hoist	Wages	Cost Per Ton
1907-1908	9,774	$15,658.68	$1.602
1908-1909	21,692	36,876.38	1.700
1909-1910	28,376	48,437.44	1.707

In the following tables, the total wage cost (Table 1) is divided into the total wage cost below ground (Table 2), and the total wage cost above ground (Table 3).

Table 2. Total Wage Cost Below Ground

Date	Hoist	Wages	Cost Per Ton
1907-1908	9,774	$13,974.11	$1.430
1908-1909	21,692	33,400.53	1.540
1909-1910	28,376	44,320.28	1.561

* From the Iowa State College Engineer.

Table 3. Total Cost Above Ground

Date	Hoist	Wages	Cost Per Ton
1907-1908	9,774	$1,684.57	$.172
1908-1909	21,692	3,475.85	.160
1909-1910	28,376	4,117.16	.145

In explanation of Table 3, the method of handling coal on top is as follows: The coal is hoisted, weighed, dumped on two platforms, and from thence loaded into wagons by teamsters. The wage cost above ground includes the wages of dumper, helper, two platform men, a top boss, engineer, night watch, and blacksmith.

The total wage cost below ground (Table 2) is divided into the Wage Cost to Miners (Table 4) and the Wage Cost to Day Men Below Ground (Table 5).

Table 4. Total Wage Cost to Miners

Date	Hoist	Wages	Cost Per Ton
1907-1908	9,774	$12,397.61	$1.268
1908-1909	21,692	28,676.08	1.322
1909-1910	28,376	36,326.64	1.280

Table 5. Total Wage Cost to Day Men Below Ground

Date	Hoist	Wages	Cost Per Ton
1907-1908	9,774	$1,576.50	$.161
1908-1909	21,692	4,724.45	.218
1909-1910	28,376	7,993.64	.282

The total wage cost to miners (Table 4) is further divided as follows:

Table 6. Total Wage Cost to Room Men

Date	Hoist	Wages	Cost Per Ton
1907-1908	6,987	$ 7,814.80	$1.118
1908-1909	14,190	16,657.94	1.174
1909-1910	22,466	26,311.72	1.171

Table 7. Total Wage Cost to Entrymen

Date	Hoist	Wages	Cost Per Ton
1907-1908	2,787	$ 4,582.81	$1.644
1908-1909	7,501	12,018.14	1.602
1909-1910	5,909	10,014.92	1.694

These tables show that during the first year 71 per cent. of the coal came from rooms and 29 per cent. from entries (development work); the second year 65 per cent. and 35 per cent., and the third year 79 per cent. and 21 per cent., respectively. They show an additional cost of approximately 50 cents per ton for entry coal compared with the coal obtained from rooms.

The wage cost to day men below ground (Table 5) is divided into the wage cost of haulage (Table 8) and the wage cost of all other day men below (Table 9). This latter table includes the wages of pit boss, timbermen, dirt men, trackman, cager, and trapper. The haulage was done entirely by mules.

Table 8. Total Wage Cost of Haulage

Date	Hoist	Wages	Cost Per Ton
1907-1908	9,774	$ 585.60	$.060
1908-1909	21,692	1,625.04	.075
1909-1910	28,376	2,644.01	.093

Table 9. Total Cost of All Other Day Men Below

Date	Hoist	Wages	Cost Per Ton
1907-1908............	9,774	$ 990.90	$.101
1908-1909............	21,692	3,099.41	.143
1909-1910............	28,376	5,349.63	.188

As 75 to 80 per cent. of the coal is hoisted during the 7 months, from September 1 to April 1, the wage cost is much less during that time than during the summer. In fact, there is a severe loss in all local mines during the summer owing to the small output. To show the increased cost during the summer time, Table 10 is appended:

Table 10. Cost of Day Work, Summer and Winter

	Haulage	Other Day-Men	Total Below	Total Above	Total Day Work
November, 1907, to April, 1908....	.060	.101	.161	.172	.334
April, 1908, to September, 1908....	.106	.217	.323	.249	.572
September, 1908, to April, 1909.....	.068	.127	.195	.141	.336
Average for year....................	.075	.143	.218	.160	.378
April, 1909, to September, 1909....	.102	.295	.397	.258	.655
September, 1909, to April, 1910....	.091	.161	.252	.116	.369
Average for year....................	.093	.188	.282	.145	.427

From the above it is seen that the day wage cost is approximately 30 cents per ton more in summer than in winter.

For the purpose of comparison with other mines, Table 11 is added showing the detailed cost of Tables 4, 6, and 7:

Table 11

Year	Coal	Extras	Yardage	Day Work	Room Turning	Total
1907-1908						
Total to miners............	1.00	.034	.212	.015	.006	1.268
Room men................	1.00	.018	.072	.019	.009	1.118
Entrymen................	1.00	.076	.564	.004		1.644
1908-1909						
Total to miners............	1.00	.043	.255	.016	.008	1.322
Room men................	1.00	.028	.121	.013	.012	1.174
Entrymen................	1.00	.070	.510	.022		1.602
1909-1911						
Total to miners............	1.00	.025	.208	.038	.009	1.280
Room men................	1.00	.021	.104	.035	.011	1.171
Entrymen................	1.00	.039	.606	.049		1.694

The cost of coal from 12-foot entries for the 3 years was as follows: $1.612, $1.639, and $1.693, respectively. The cost of coal from 8-foot entries for the 3 years was as follows: $1.731, $1.475, and $1.760. The surprising shrinkage in the cost of 8-foot entries during the second year was due to the fact that several hundred feet of 8-foot entries were driven in thick coal (6 feet or over) during that time. The average thickness of top or bottom removed for height in the 12-foot entries were 17.5, 15.1, and 21.1 inches during the three years.

The second part of the thesis takes up the costs of operation of the mine. Among them are the following: Royalty, $.135; timber, $.037, $.057 and $.076 for the 3 years, respectively; wooden ties and trackage, $.016, $.018, $.016; water for boilers (purchased from the Des Moines Water Co.), $.008, $.006, $.005; liability insurance, $.016, $.012, $.010. The larger costs of operating, namely, expense of management, repairs and depreciation, amortization, interest on capital invested, shrinkage, taxes, and cost of power, are treated at length in the thesis, but space prevents their proper discussion in this synopsis. It may be stated, however, that these costs make up a considerable proportion of the total cost of mining coal.

The third part of thesis considers the selling expense of the business, namely, advertising, bad accounts, rents, salaries of clerks and incidentals.

In conclusion, the writer desires to state that the mining costs at the Eagle No. 2 should bear some definite relation to the costs at the other mines in the district. This should be especially true of the wage cost of mining. Undoubtedly, there are small variations but the totals should not be far apart. It has been the thought of the writer that if the operators of this district should compare their cost tables, they could, without question, effect a saving in their mining expense by each one adopting for his own use the particular systems that have been tried out and found most profitable in the other mines.

Stock Pile Fires

Where it is necessary to stock bituminous coal for winter use or to guard against shortage, it is customary to take precautions against fire. Bituminous coal should not be piled in

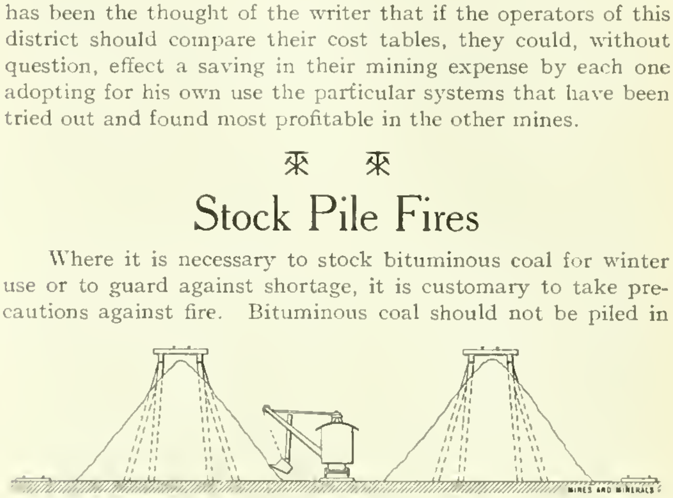

Fig. 1

heaps exceeding 20 feet and these heaps should not be continuous in breadth, so that in case of fire steam shovels can be put to work at once to dig out the fire. The piles should be arranged as shown in Fig. 1 and may have indefinite length. When coal is stocked in this way chances for heating to the point of ignition by oxidation are lessened.

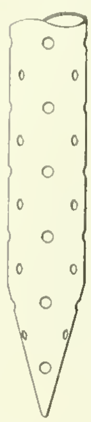

Fig. 2

In case steam shovels are not available or are not warranted by the size of the stock pile, a fairly sure method of extinguishing the coal in case it should catch fire is to drive pipes perforated with small holes, as in Fig. 2, down to the bottom of the pile where the fire is located, and then attach the pipes to a pump and force water through them. The futility of endeavoring to put out a coal fire by throwing water on the pile is due to only a portion of the water reaching the fire owing to its going in other directions mostly, being converted into steam before it reaches the fire, or if the steam reaches the fire it probably is dissociated and provides hydrogen and oxygen for combustion. By the use of these pipes the water reaches the fire in such a manner as to cool down the pile and put out the fire if it has not extended too far.

The readers of Mines and Minerals are indebted to H. D. Conant, superintendent of the Lake Superior Copper Smelter, for this wrinkle. He has had occasion more than once to effectively put out a coal-pile fire by the use of one or both of these devices.

Institute Meetings

The winter meeting of the Coal Mining Institute of America will be held in Pittsburg, Pa., at the rooms of the Engineers' Society of Western Pennsylvania, December 19, 20, and 21. The Institute will meet in joint session with the Engineers' Society one day or evening as the guests of the Society. Papers to be presented before the Institute should be sent to C. L. Fay, Wilkes-Barre, Pa., who is secretary of the Institute. The program for the meeting will be announced later.

The next annual meeting of the Gas and Gasoline Engine Trades Association will be held at Hotel Hollenden, Cleveland, Ohio, December, 5, 6, 7, and 8. Albert Stritmatter, secretary, Cincinnati, Ohio.

The winter meeting of the West Virginia Mining Institute will be held in Fairmont, W. Va., in December. All communications to the Institute should be addressed to E. B. Day, secretary, 108 Smithfield St., Pittsburg, Pa.

Coal Dust

The Influence of Compression, Percussion and Detonation in Causing and Transmitting Explosions

By James Ashworth

There is one topic connected with coal mining which never seems to wear out, viz., that of coal dust, and although governmental commissions, committees of mining societies, and many mining men have investigated and experimented, yet very frequently a recrudescence of the subject comes along and rouses some section of its mysteries into active life. Thus the publication of the report of the First Series of the British Coal-Dust Experiments, which were made at the expense of the Mining Association of Great Britain; the French Government's experiments at Lievin; and the Austrian Government's experiments, have all added something to our knowledge. Many explosions in the United States, a few in Canada, and some also in England, have demonstrated forces and effects, the sequence of which is a subject on which leading authorities are widely divided. One need only to take up any issue of Mines and Minerals for several months past, to find this fact amply substantiated; for instance, in the September issue, there is the report of a discussion by some members of the Institution of Mining Engineers

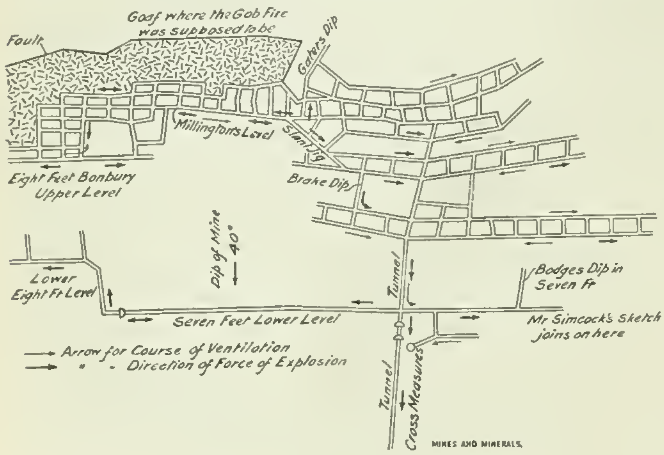

Fig. 1

in England, on "Coal Dust and Zone Systems," the original paper having been written by Mr. E. O. Simcock, who, if the present writer is not mistaken, was the patentee of a protective dust-zone system, and therefore his present writing goes to show that he no longer considers a zone of incombustible dust of any practical value in preventing or controlling the flame of a coal-dust explosion.

For many years the writer has persistently opposed the notion that spraying, dampening, or watering roadways, is of any practical value in controlling the extent of an explosion, after it has once been originated. It may also be remembered by some of your readers, that he has also shown that no system of "zones" can control a present-day explosion in a mine where there is firedamp as well as coal dust because the effect of compression, percussion, and detonation must all be taken into account. Very few mining men have as yet acknowledged the influence of either or any of these factors, and therefore the unbelievers ought to take particular notice of the following quotation from page 150 of the Report of the British Coal-Dust Experiments committee: "The indiscriminative use of the word 'detonation' as applied to explosion having resulted in some confusion, Prof. H. B. Dixon has kindly contributed the following note, in which, as the originator of the term 'detonation wave' he explains its significance. It is of course quite permissible to speak of an explosion as being accompanied by a loud detonation—signifying a loud noise; but it is probable that by use in this way the wrong application has arisen. The important question to decide is whether the 'detonation wave' (explosion wave) can be developed by the explosive combustion of a gas or of coal dust.

"The expression 'L'onde Explosive,' coined by Berthelot, and its English equivalent, 'The Explosion Wave,' signify that flame which passes through a uniform gaseous mixture with a permanent maximum velocity. The rate of the 'explosion wave' is a definite physical constant for each mixture; the 'explosion wave' travels with the velocity of sound in the burning gas which itself is moving rapidly forward en masse in the same direction, so that the explosion 'wave' is propagated far more quickly than sound travels in the unburnt gas.

"When an explosive mixture is fired by a spark or flame in a long tube, the flame is usually propagated along the tube with an increasing velocity until, at a certain distance from the ignition point (according to the nature of the gases), the 'explosion wave' is set up—if this can be propagated through the mixture.

"The firing of a fulminate in such a mixture sets up the 'explosion wave' at once.

"In other mixtures the 'explosion wave' cannot be set up under ordinary conditions, e. g., in mixtures of firedamp or of coal gas and air. In these cases the flame is propagated irregularly or with vibratory oscillation, and the flame is sometimes spontaneously extinguished. Whereas the pressure in the 'explosion wave' is constant, it is quite irregular in 'vibratory' explosions.

"In the 'explosion wave' each layer of gas is compressed so suddenly that it is raised beyond its ignition point by the heat of compression, and in burning it compresses in turn the unburnt layer in front of it. The chemical combustion is much more intense and rapid than in the ordinary flame of explosion, and as a result the gases cool much more quickly behind the 'explosion wave.'

"I use the word 'detonation' to express the burning taking place in the 'explosion wave,' since a detonator when struck burns in this way itself and sets up an explosion wave in explosive gases round it."

In Mines and Minerals for December, 1908, Vol. XXIX, page 238, Fig. 6, is a reproduction of a photograph of a "double explosion" at the downcast end of the Altofts Testing Gallery, Experiment 21, and to the writer's mind this may be accepted as a graphic demonstration of the opinion of Professor Dixon when he penned the concluding paragraph of the note quoted above.

During the Altofts experiments there were at least two other demonstrations which the writer believes to have been detonations, viz., Nos. 13 and 25.

What the writer wishes to draw particular attention to, is the stern fact, that if compression, percussion, or detonation, have the effects which he believes they have in propagating an explosion of mixtures of air, firedamp, and coal dust, then it is useless to spend so much energy in arguing about the value of zones, without such zones can be made to negative those effects which at present ignore or jump across them, and thereby render them useless.

It is regrettable that the plans of parts of the Blackwell and of Talk o' the Hill collieries should give such very limited information; for instance, the explosion at the latter colliery was not in the part shown (which is a portion of the Seven Feet Banbury), but in the Eight Feet Banbury, Fig. 1, and there were also other influences bearing on direction and extent of the explosion flame and force. For instance, the main force was expending itself in the Eight Feet Banbury and in the opposite direction to what it was in the Seven Feet mine, viz., outwards toward the shaft, and the influence stated in the last paragraph but one of Professor Dixon's notes might also have been exerting an important effect.

The writer would also call the attention of those who think that detonation or some such effect is not demonstrated in what is now known as a coal-dust explosion, to the report on the experiments at Lievin. The average rate of the speed of the coal-dust flame was 500 feet per second along a gallery 750 feet long, but it was found that near the mouth of the gallery the velocity increased very suddenly up to 3,300 feet per second, and that the consequent high pressure was created almost instantaneously, viz., in .02 part of a second.

On one occasion about 30 feet of the end of the gallery was destroyed and blown away, although its static bursting pressure was 570 pounds per square inch, and one end open to the atmosphere.

This effect was similar to that demonstrated in experiments Nos. 13 and 25, at Altofts, and all three require more elucidation than they have yet received.

The underground experimental gallery at Pittsburg offers very suitable conditions for the investigation of these great pressures if the roadways are of sufficient length. The writer is absolutely certain that the actual speed of an explosion is very greatly underestimated, and that the "pioneering" cloud of dust is not a factor in extensive colliery explosions.

The issue of MINES AND MINERALS for September also shows that "double explosions" occur under very ordinary conditions, and moreover are not uncommon, and therefore that this subject requires a great deal more attention than it has heretofore received.

There is one other point, which although it does not perhaps directly affect the question of detonation, yet is almost invariably found in the neighborhood of the place of origin of a large colliery explosion, and it is that of a considerable free air space, such as the entry to an adjoining roadway, or a large cavity in the roof. This assumption is supported by the demonstrations at Altofts. If in the underground experimental gallery at Pittsburg, such a space is provided, it will add immensely to our knowledge of how coal-dust explosions are propagated.

Detonative blasting has displaced the old way of igniting a charge of explosive, but the writer has no hesitation in saying that it has unfortunately introduced another danger which is doubly dangerous, because its existence is not recognized.

Personals

J. A. Burgess is in charge of the Nevada Wonder mine, Wonder, Nev.

F. G. Cottrell has been appointed by the Bureau of Mines to take charge of a special investigation of the smelter-fume problem.

Waldemar Lindgren, of the United States Geological Survey, will soon commence the work of bringing the study of the geology of the Tintic district up to date.

William Fleet Robertson, provincial mineralogist for British Columbia, has been examining the Hazleton mineral district in the Skeena River country.

E. N. Zern has resigned as superintendent of No. 8 mine of Jamison Coal and Coke Co., to accept the assistant professorship of coal mining at the University of Pittsburg.

J. C. Roberts, engineer in charge of Mine Rescue Car No. 2, returned to Trinidad September 11. It is reported that Mr. Roberts will make his headquarters in Denver and have charge of both cars No. 2 and No. 4, at Trinidad, Colo., and Rock Springs, Wyo., respectively, joining either as emergencies may require.

John Arnott has been appointed superintendent of the Crested Butte mine and ovens, and of the Floresta anthracite mine of the Colorado Fuel and Iron Co., vice Robert McAllister, whose resignation was noted in October.

Sumner S. Smith, formerly in charge of Mine Rescue Car No. 4, whose departure for Alaska has been noted in this column, has been appointed United States Mine Inspector for that territory. Mr. Smith's headquarters are not yet certain, but will probably be very largely "in the saddle."

H. H. Sanderson, of Danford & Sanderson, mining engineers, has returned to Trinidad after an extended trip throughout the West. While in Nevada he used the oxygen helmet apparatus familiar to our coal readers at the fire in the shaft of the Giroux Consolidated Mines Co., Kimberly, and had some interesting experience with the same on the 2,250-foot level of the Ward shaft, Nevada City, where the temperature is 155 degrees.

Geo. R. Delamater, formerly in charge of the United States Bureau of Mines coal-testing station, at Denver, is practicing his profession, with office at 1710 Glenarm St. As in the, past, Mr. Delamater is making a specialty of coal-washing methods and machinery.

J. V. N. Dorr, metallurgical engineer, 709 Equitable Building, Denver, has been appointed manager of the Mogul Mining Co., Pluma, S. Dak.

C. W. Henderson, statistician, United States Geological Survey, Denver, spent September and October in the field near Central City, Colo.

W. J. Murray, vice-president and general manager Victor-American Fuel Co., returned to Denver, October 15, after an extended trip to the Pacific coast.

G. W. Evans, who recently visited Alaska coal fields with Secretary Fisher, has returned to the fields in the interest of the Bureau of Mines.

G. A. Goodenough, of the University of Illinois, has been promoted from Associate Professor of Mechanical Engineering to Professor of Thermodynamics.

F. C. Lincoln, S. B., Massachusetts Institute of Technology, 1900; E. M., New Mexico School of Mines, 1904; A. M., Columbia University, 1906, Ph. D., 1911; for 3 years Professor of Geology and Metallurgy at the New Mexico School of Mines, for 3 years Professor of Geology at the Montana State School of Mines, and for the past year in practice in New York City as consulting mining engineer, has been appointed Associate Professor in Mining Engineering at the University of Illinois.

Arthur Lakes, Jr., mining engineer, of Denver, has taken charge of the Ymir-Wilcox Development Co.'s mines at Ymir, B. C.

Joseph T. Berry, Jr., E. M., formerly of Butte, Mont., is now superintendent of the Dan mine, near Baker, Ore.

Wm. H. Armstrong, former mill superintendent for the Dos Estrellas Mining Co., El Oro, Mex., is connected with the Mexico Mine and Smelter Supply Co., at Mexico City.

O. E. Jager, former assistant superintendent at the Velardena smelter, in Mexico, has been appointed assistant superintendent of the Cerro de Pasco smelter in Peru.

F. M. Chase, assistant to S. D. Warriner, Vice-President and General Manager of the Lehigh Valley Coal Co., was on October 1 appointed General Superintendent of the company, with headquarters at Wilkes-Barre, Pa. The promotion follows faithful service for years on the part of Mr. Chase, and his advancement is a source of satisfaction and pleasure to the subordinate officials of the company, and all others who have been thrown in contact with him in his former positions.

Dr. M. J. Shields, field representative of the American Red Cross, has started a thorough course in first aid for the H. C. Frick Coke Co. The lectures commenced on September 26, at Latrobe, and the operations of the company were divided into five districts—Latrobe, Mt. Pleasant, Connellsville, Uniontown, and Brownsville. To start with, as a nucleus, about 500 men will be trained, which will be about one out of 30 of the employes.

E. N. Zern, superintendent of the H. C. Frick Coke Co. from 1908 to date, and an experienced mining engineer, has been appointed Assistant Professor of Coal Mining in the University of Pittsburg School of Mines. Mr. Zern is a graduate of Pennsylvania State College, serving as instructor in mining and mineralogy there for several years before taking up field work. H. B. Meller, a member of last year's faculty of the School of Mines, has been advanced from instructor in mining to assistant professor of metal mining. Mr. Meller studied in the University of Pennsylvania, Michigan College of Mines, and University of Pittsburg, receiving his E. M. degree from the last-named institution in 1910. He has had a number of years practical experience.

Appointment of H. M. Inspectors

The following rules in regard to the appointment of inspectors of mines in Great Britain have recently been issued by the Home Office, London.

Inspectors of mines and quarries are appointed by the Home Secretary after a competitive examination limited to candidates who are nominated by him. In addition to the chief inspector and the electrical inspector, there are: Divisional inspectors, with salary of £750, rising by £50 a year to £1,000; senior inspectors, with salary of £500, rising by £20 a year to £700; junior inspectors, with salary of £300, rising by £15 a year to £450. The divisional and senior inspectorships are filled by promotion from the rank below and the vacancies for new appointments arise only in the rank of junior inspectors. Application for a nomination to compete for the appointment of junior inspector are made on forms furnished which must be filled up carefully in the applicant's own handwriting and must be accompanied by one or two testimonials, based upon personal knowledge of the candidate, indicating what experience he has had in mines, and giving information as to his character and fitness for the appointment. The form, when filled in, must be returned direct to the Private Secretary, Home Office. Nominations are given only by the Home Secretary, on the advice of a Home Office committee of selection who consider all applications impartially on their merits. No recommendations or testimonials are considered unless based on personal knowledge of the candidate's character and attainments. Candidates are therefore particularly advised in their own interest not to seek political or social influence, which will prejudice rather than assist their candidature. Nominations are only given when an examination to fill a vacancy is about to be held. The attention of candidates is specially directed to this, and to the fact that of the numerous applicants only a very limited number, namely, those who appear, after careful consideration and inquiry, to be the best qualified in every way for the position, can be given the opportunity to compete. It should be distinctly understood, therefore, that any candidate who spends time and money in preparation before he receives a nomination does so at his own risk. Nominated candidates receive not less than a month's notice of the examination. Every candidate must hold a first-class certificate under the Coal Mines Regulation Act, and must, within 5 years previous to his application, have been employed for 2 years as manager or undermanager of a coal mine, or in some other responsible capacity requiring regular attendance underground in a coal mine. An exception to this rule is allowed in the case of sub-inspectors. Practical knowledge and experience of metalliferous mining and quarrying will also be taken into consideration. The prescribed age for candidates at the time of examination is between 23 and 35 years, but an extension up to 45 is allowed in the case of a candidate who has served as a subinspector, with a certificate of the civil service commissions, from a time when he was under 35. No exception can be made to this rule.

Candidates must qualify in each of the subjects numbered 1, 4, 5, and 6, and must also obtain such an aggregate of marks in all the subjects numbered 1 to 8 taken together as to satisfy the civil service commissioners. Subjects 9 and 10 are optional, and only one of them may be offered. The fee for the examination is £6. A candidate is further required, before he can be appointed, to satisfy the civil service commissioners as to his character and that his age is within the prescribed limits, and that he is physically fit for the work. An inspector upon first appointment is subject to 2 years probation. He must give his whole time to the official duties assigned to him, and he may be called on to reside in any part of the United Kingdom. Traveling expenses are paid. An inspector's tenure of office, increments of salary, promotion, and pension, are dependent on good conduct and efficient service. Inspectors may be called on to retire at 60 years of age, and retire in any case at 65.

The following are the subjects of examination:

	Maximum of Marks
(1) English	400
(2) Elementary mathematics	200
(3) Elementary geology	200
(4) Coal mining	1,000
(5) Ore and stone mining	300
(6) Electricity in mines	300
(7) Law relating to mines and quarries	200
(8) Oral examination	400
(9) Chemistry	400
(10) Physics	400

SYLLABUS

English. Includes composition, the writing of reports and précis writing, but does not include indexing. Attention is paid to handwriting and spelling in this as in other subjects.

Elementary Mathematics. Will include arithmetic, algebra to quadratic equations, plane geometry, plane trigonometry to the solution of triangles.

Elementary Geology. Outlines of physical geology, including the physical characters and chemical composition of rock-forming minerals and the classification and description of rocks; elements of stratigraphy and with special reference to the British Isles; the construction and interpretation of geological maps and sections; the occurrence of coal, stone, and metalliferous minerals.

In this subject there will be a laboratory test in addition to the written test.

Coal Mining—theoretical and practical, including systems of sinking and working, methods of supporting roofs and sides, mechanical engineering applied to coal mining, theory and practice of ventilation, surveying and making of plans, use of explosives, mine gases and their analysis, prevention of accidents, rescue work, and the restoration of mines after explosions and fires. Mining hygiene.

Ore and Stone Mining—theoretical and practical, including methods of sinking and working, methods of supporting excavations, mechanical engineering applied to ore and stone mining, ventilation of metalliferous mines, prevention of accidents. Ore dressing. Mining hygiene.

Electricity in Mines. Installation and use of electricity in mines, including the practical units of measurements and the use of simple measuring instruments; transmission and use of electricity by alternating and direct currents; the construction of cables, and the jointing and testing of cables; earthing; the rules as to the use of electricity in mines and the prevention of accidents.

Law Relating to Mines and Quarries. Knowledge of the coal mines regulation acts, the metalliferous mines regulation acts, the quarries act, and the rules and orders made thereunder.

Oral Examination. Questions may be asked on coal mining, ore and stone mining, and electricity.

Chemistry. The principles of inorganic chemistry and the study of the occurrence, modes of preparation, and properties of the principal elements and their more important compounds. Questions may be set on the chemical principles involved in the commercial preparation of important inorganic substances. Elementary organic chemistry.

In this subject there will, in addition to the written test, be a laboratory test which will include the preparation and analysis of inorganic substances.

Physics. Will include heat, light, sound, electricity, and theoretical and applied mechanics.

In this subject there will be a laboratory test in addition to the written test.

Correspondence

Geometry

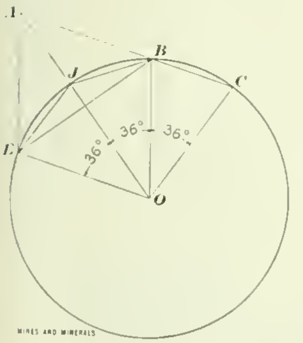
Editor Mines and Minerals:

SIR:—The following problem may be of interest to many of your readers:

To prove that the square of the side of a regular inscribed pentagon is equal to the square of the side of a regular inscribed decagon plus 1.

In the accompanying figure, with O as a center and radius equal to CO, construct a circle as $C\,B\,J\,E$.

Then draw four radii $C\,O$, $B\,O$, $J\,O$, $E\,O$, 36 degrees apart then the chords $C\,B$, $B\,J$, $J\,E$ will be equal to the length of a side of a regular inscribed decagon, also the chord $B\,E$ will be equal to the length of the side of a regular inscribed pentagon because it is the chord of 72 degrees.



The angles $C\,O\,B$, $B\,O\,J$, and $J\,O\,E$ are each equal to 36 degrees, and as the triangles $C\,B\,O$, $B\,O\,J$, and $J\,O\,E$ are each an isosceles, the angles $O\,C\,B$, $C\,B\,O$, $O\,B\,J$, $B\,J\,O$, $O\,J\,E$, and $J\,E\,O$ are each equal to 72 degrees.

The angles $C\,B\,O + O\,B\,J = 144$ degrees.

Then the angle $A\,B\,J$ will equal 36 degrees.

But as the angles $A\,C\,O + C\,O\,B + B\,O\,A = 144$ degrees, then the angle $O\,A\,C = 36$ degrees also; therefore, the triangle $A\,B\,J$ is isosceles and the line $A\,J$ equals the chord $J\,B$.

Then the triangles $A\,C\,O$ and $C\,O\,B$ are similar, then are relative sides proportional.

That is $A\,O : O\,C :: O\,C : C\,B$.

Now if we let D equal the side of a regular decagon, and 1 equal the radius of the circle, then the equation becomes

$$1+D : 1 :: 1 : D \text{ or } D+D^2-1. \qquad (1)$$

Transposing, $$0 = 1 - D - D^2 \qquad (2)$$

We also find that $A\,J + J\,O = A\,B + B\,C$. But $A\,J = B\,C$, then $A\,B = J\,O$. Also, $J\,O = B\,O = E\,O$, and $A\,E = A\,B$.

Therefore, the figure $A\,B\,O\,E$ is a parallelogram and the diagonals are perpendicular to each other. That is, the line $B\,E$ is perpendicular to the line $A\,O$.

Now let P equal the line $B\,E$ or the length of the side of a regular pentagon. Then,

$$\left(\frac{1+D}{2}\right)^2 + \left(\frac{P}{2}\right)^2 = 1 \qquad (3)$$

Then $$1 + 2\,D + D^2 + P^2 = 4$$

or $$P^2 = 3 - 2\,D - D^2$$

$$0 = 2 - 2\,D - 2\,D^2 \qquad (2)$$

$$P^2 = 1 + D^2$$

Watering Dust and Employment of Shot Firers

Editor Mines and Minerals:

SIR:—I see in your September number, on page 66, under the title, "An Historic Mine," you state: "To Mr. Joseph Watson, the superintendent of Como No. 5 mine, at Como, Park County, Colo., and now general superintendent of the National Fuel Co., at Louisville, Colo., must be given the credit of having adopted this system 5 years earlier than the date set by Mr. Rice, viz., May, 1895. It also seems probable that to Mr. Watson is due the further credit of having first employed shot firers in the mines of our country.'

"If any of our readers are advised of an earlier date than May, 1895, on which watering of dust was practiced, or shot firers were employed in American mines, we shall be glad to hear from them."

I was appointed State Mine Inspector of Missouri in January, 1889, after a disastrous explosion had occurred in Mine No. 6, owned and operated by the Keith & Perry Coal Co., and located about 4 miles north of Rich Hill, Mo., in which 23 men lost their lives. The explosion took place while shots were being fired. Shortly after I was installed into office a slight explosion took place in one of the Rich Hill Coal and Mining Co.'s mines, in which several men were burned, but none fatally. These accidents, together with others that had recently taken place while shots were being fired, led me to believe that firing shots in certain mines was dangerous to human life and to property, and that the fewer men in such mines when the shots were being fired the better, so I at once wrote to Mr. Newberry, who was the Representative from Bates County, urging him to try and pass a shot-firing law, which I had outlined. The bill was passed at once. This bill required that shot firers be employed to fire the shots after the miners and other employes had retired from the mine. This bill only applied to dusty mines and mines producing light carbureted hydrogen gas. As soon as the law became effective, shot firers were put on at the mines around Rich Hill, Mo. This was in the summer and fall of 1889.

The law proved to be a good measure, for during the next 2 or 3 years no less than four explosions took place in the vicinity of Rich Hill, which would doubtless have cost hundreds of valuable lives had the old method of every man firing his own shots been in practice.

In regard to sprinkling mines with water, G. R. Sweeney, superintendent for the Keith & Perry Coal Co., introduced the system in Mine No. 7, near Rich Hill, in 1891, after an explosion that took place October 7 of that year. He used pipes along certain entries, and hose; also water boxes in other parts of the mine.

I do not know of any shot firers being employed in American mines prior to 1889, nor of sprinkling mines practiced prior to 1891.

C. C. WOODSON

Arbitration in the Southwest

Editor Mines and Minerals:

SIR:—Replying to your inquiry of recent date referring to my appointment as permanent arbitrator for the Southwestern Interstate Coal Operators' Association and the United Mine Workers of America, I beg to say that the appointment was made mutually at the conclusion of a 5-months suspension in 1910. The salary and expenses of the arbitrator are borne equally by both operators and miners. The period covered is for the life of the biennial contract. Full time is devoted to the four states covered by the Interstate District: Kansas, Missouri, Arkansas, and Oklahoma, covering about 35,000 to 40,000 men and involving probably $30,000,000 of property.

The Arbitration Board consists of the commissioner for the operators or his deputy, and the District President in the district where grievance arises, or his deputy, and your humble servant as permanent arbitrator, and all questions arising under the written terms of the biennial contract or under the customs and usages of the mining industry that are proven to be permanent customs and usages, are matters of mediation and arbitration and in all cases where the representatives of the operators and the United Mine Workers of America are unable to agree, the arbitrator holds a hearing. The case is presented by written briefs, statements, affidavits, or oral evidence, and if either party requires it, personal inspection of the physical properties of the mine or parts of the mine under dispute, after which a written decision is issued by the arbitrator to each side, which is final and binding on all concerned

The contract provides the penalty of 50 cents per day per man for a strike where the miners are at fault for such strike and $1 per day per man where the operator is at fault for a shut-down or lock-out. A few of such decisions have been rendered for strikes of short duration and both operators and miners have complied with the decision in the matter of fines or other directions required under the contract.

It is, I think, conceded by all parties that there are less strikes and shut-downs under this system and more permanent and regular employment than under the old system of "strike and arbitrate afterwards, providing you can agree," and it is further believed that with some slight modifications, we shall have a simple, efficient, and permanent method for the adjustment of disputes and a prevention of the loss of employment and consequent loss of wages, a system which I believe bespeaks for the successful settlement of industrial controversies and if adopted generally would be a guarantee against the interruption of business in all production, transportation, and commercial lines. W. L. A. Johnson

Topeka, Kans.

Watering Mines

Editor Mines and Minerals:

Sir:—I note an editorial in your issue of September in which reference is made to an alleged statement in Bulletin No. 425 of the United States Geological Survey (Bulletin No. 20 of the United States Bureau of Mines) about watering mines with hose and nozzle.

The quotation that precedes the statement in the editorial is correct, but the assertion that follows: "and he gives that date as being the time of the first use of water in laying the dust in American mines," has no basis in fact. If you will examine page 73 of Bulletin 425 of the United States Geological Survey (or page 77 of Bulletin 20, Bureau of Mines) you will not find that there is any statement as to what mines first employed the system of watering by hose and nozzle. The reason for referring to Utah was that it was the first, and I think the only, state in which the law requires systematic use of hose. As far as any individual mine is concerned, I think it would be very difficult to determine where watering by use of hose was first employed in this country. Geo. S. Rice

Pittsburg, Pa.

Catalogs Received

Allis-Chalmers Co., Milwaukee, Wis., Bulletin No. 1068, Direct-Connected Corliss Engines, 8 pages; Bulletin No. 1070, Barometric Condensers, Type "B," 12 pages; Bulletin No. 1074, Direct-Current Motors and Generators, Types "H" and "HI," 12 pages; Bulletin No. 1078, Alternating Current Generators, 16 pages; Bulletin No. 1082, Engine-Driven Direct-Current Generators, Types "I" and "IW," 16 pages; Bulletin No. 1083, Direct-Current Motors and Generators, Type "K," 20 pages; Bulletin No. 1211, Feeders for Roller Mills, 4 pages; Bulletin No. 1519, Barometric Condensers, Type "AN," 12 pages.

Obituary

John Bond Atkinson

John Bond Atkinson, President of the Kentucky Mining Institute, and a pioneer coal operator of Western Kentucky, died at his summer home, near Wrightstown, N. J., on September 21. Mr. Atkinson went to Kentucky when a young man and took pride in advancing the interests of the state. He was successful in business affairs and gave freely to the cause of education. He served as an official of the state, contributed to the betterment of agricultural conditions, to the cause of forestry, and to the conservation of lands. During his long career as the foremost coal operator in that state he was an engineer of notable ability, eminent in the field of mining not only in his own state but elsewhere.

He was always kind and generous and grew more so with age. The builder of his own fortune he found great satisfaction in the knowledge that he assisted others to also build; he will be missed by a large number of Kentucky citizens.

Centrifugal Mine Ventilators

The Construction of the Guibal Fan Compared with That of a Centrifugal Ventilator of the Newest Design

The fan, while not as expensive as some other machinery, is the most important about the coal mine. Upon it depends the lives of the underground workers to such an extent that with each year's development of a mine the state mine inspectors use greater care in seeing that the laws governing ventilation are enforced. Mine fans should be purchased with a view to serving the mine during its life, and as the extent of a mine can be calculated as a usual thing, the factors that make up the strength and efficiency of a fan are matters of considerable moment. While apparently a crude apparatus, the numerous elements which enter into the construction of a fan, coupled with the changing conditions inside the mines with which it must contend, present problems which antagonize theory to such an extent that only practical experiments will furnish an exact basis for a fan's construction. During the past few years, mine fans have received more attention from mine managers than in any previous time, with the result that the Guibal fan, which was once considered the acme of ventilators, is about obsolete, so far as manufacturers are concerned.

In order to lead up to the improvements that have been made in scientific fan construction, the best fan of 25 years ago is here compared with a new fan made by the J. C. Stine Co. It is to be understood that the centrifugal mine ventilator

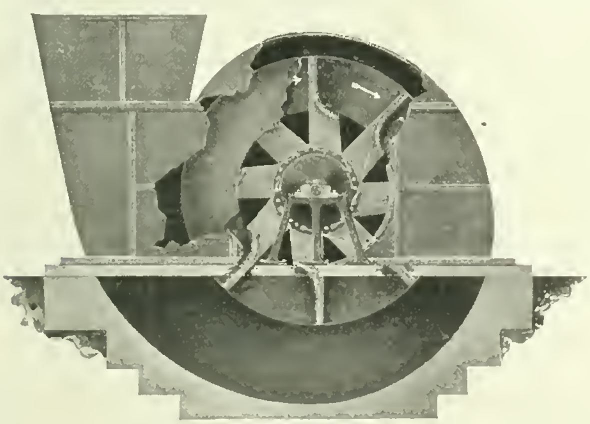

Fig. 1. Showing Curve of Fan Blades

depends upon its power to create vacuum, and to fully discharge the compressed air between its blades in such a manner that back pressure will not interfere with the intake air. There is a general similarity in the principles that govern the workings of the centrifugal fan and centrifugal pump; both depend on the pressure of the atmosphere to fill the void created by the swiftly moving blades; also both depend upon the movement of the blades to create a pressure above that of the atmosphere and so permit a discharge from the machine. The tendency of the machines is to whirl the fluids between their blades and cast them off at a tangent to the circle described in their movements, with a force that will produce pressure. At this point the similarity of the two machines might be said to cease, were it not that, to prevent back pressure due to friction of the discharged fluids, both are equipped with spiral casings that gradually reduce the speed, and so the friction, without reducing the pressure.

The atmosphere being a compressible fluid offers a much more complicated problem in a centrifugal fan than the incompressible fluid with which the centrifugal pump deals. Owing to the expansion of air the centrifugal fan cannot discharge the entire quantity compressed between its swiftly moving blades in an instant, consequently the Guibal fan carried part of the air cut out beyond the point of discharge; and since there was no chance for the air to discharge until it reached the throat of the casing there was friction between the swiftly moving air and the casing which further interfered with efficiency. The modern fan overcomes the first defect by using a spiral casing which

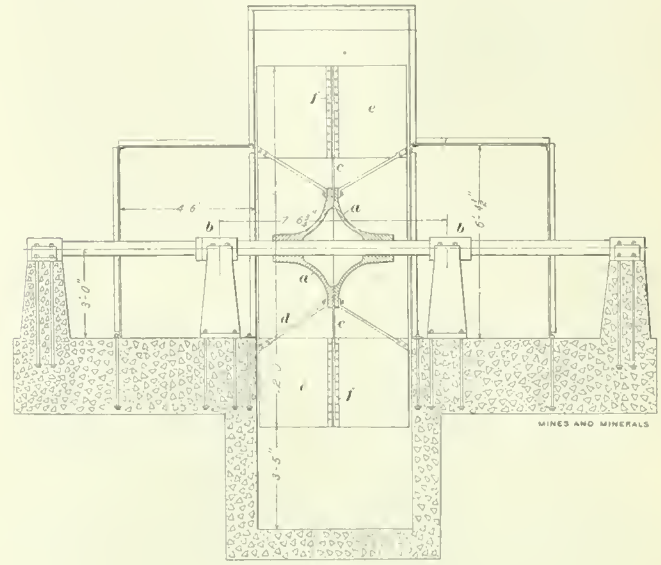

Fig. 2. Section Through Fan

permits it to discharge the compressed air in a continuous stream, in fact the volume of air discharged in one revolution is more than two times that discharged by the Guibal fan of the same diameter running at the same speed. To overcome the second defect the fan blades are encased; this prevents friction between the air and the fan casing as well as eddies and baffling. The Guibal fan blades are fastened to spiders keyed to the fan shaft near the intake in the casing. This arrangement necessarily baffles and prevents a free flow of air to the fan. To overcome this defect the blades of the modern fan here considered are centrally fastened to cast-iron cones by heavy steel plates, an arrangement which permits a free and continuous flow of air to the fan. The heavy cast-iron cones, shown at *a*, Fig. 2, are carefully fitted to the shaft and are spread from the center toward the journal boxes *b* for the purpose of reducing torsional or bending strains to a minimum and to gradually turn the stream of air entering through openings on each side of the casing toward the blades. The cast-iron

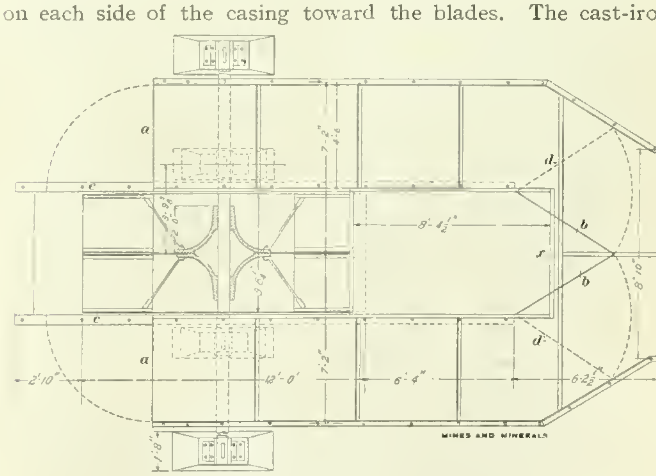

Fig. 3. Reversing Arrangement

cones are fitted to the shaft so as to form a hub with the steel plates *c* as spokes. Where the plates are inserted in the hub all parts are machined and the plates shaped so that when bolted to the hub they interlock and fill the entire circle of the hub. To make the parts rigid and to secure them in alinement, three bolts are passed through each plate and hub. Sway rods *d* are bolted to the hub and also to the fan blades *c*. It was customary to give the fan blades of the Guibal fan a slight backward rake for the purpose of allowing the air to discharge more readily than would be the case should the blades come to the throat at right angles. In the fan here described the blades are curved forward from the inlet opening as shown in Fig. 1 to allow the air to slide forward and discharge radially at the circumference. Experiments show that more air will be discharged with less power expended when this form of blade is used.

The blades are riveted to the angle irons *f*, which are also riveted to the arm plates *c*, an arrangement which adds to the stiffness of the arms. The sides of the blades are riveted to angle bars that in turn are riveted to the fan casing which, as stated, forms part of the fan. The Guibal fan was used almost entirely as an exhaust fan; this fan can be used either as an exhaust fan or a blower by opening or shutting the doors shown in Fig. 3. When it is desired to use the fan as an exhaust the door in the chimney is lowered by a pulley and rope to cover the opening *x*; when, however, the fan is to work as a blower the door is raised to prevent the air passing out of the chimney. The plan shows the arrangements of doors in the air passages for converting the fan from an exhaust to a blower. When used as an exhaust fan the doors are in the positions *a* and *b*; when used as a blower the door to the chimney is closed and the doors swing to the positions *c* and *d* to close the air passages. This forces the air coming through the doors *a c* into the fan and so through the opening *x* into the mine.

Book Review

The Practice of Copper Smelting, by Prof. Edward D. Peters, of Harvard University, is the latest on copper. The book has 619 pages of reading matter, including 121 illustrations The publishers are McGraw-Hill Book Co., New York and London. Price $5. Doctor Peters' intention of replacing his "Modern Copper Smelting" with this book is praiseworthy so far as the younger generation is concerned, but he will hardly accomplish his ambition with the older generation, for the dissemination of knowledge like the conservation of energy or Tennyson's brook, "goes on forever." Were this otherwise he could not have compiled this present book The "Practice of Copper Smelting" consists of the author's studies and those of others engaged in practical operations, and he makes use of the investigations, comparisons, discussions, and results obtained to arrive at the fundamental principles of the subjects treated. These are: Ores of Copper; Sampling Copper Ores; Methods of Copper Extraction; Behavior of Ores at High Temperatures; Roasting; Blast Furnace; Blast-Furnace Smelting; True Pyrite Smelting; Partial Pyrite Smelting; Reverberatory Furnaces; Reverberatory Smelting With Wood; Blast Furnace *vs.* Reverberatory; Fines; Production of Metallic Copper From Matte; Refining of Copper; Flue Dust and Smoke; Slags; Miscellaneous, including furnace construction. Doctor Peters, in his introduction, writes: "Among many sources of information it is proper to designate particularly the Anaconda Copper Mining Co., whose attitude toward the scientific investigator constitutes a personal favor to every student of metallurgy." With the assistance of the personnel of this most progressive copper company and others to whom he refers, he has been able to produce a book which will remain a classic for some years. When coupled with his "Principles of Copper Smelting," the metallurgist's library is complete, so far as dry copper treatment is advanced to date.

Rock Minerals, by Joseph P. Iddings. Price $5. John Wiley & Sons, New York, publishers. This second edition has been revised and enlarged by the addition of 80 minerals. "The study of rocks and their mineral components involves so many kinds of investigations, chemical, physical, mineralogical, and geological, that no petrologist is likely to follow all of them to their ultimate limit, but must content himself with some special branch of the subject, leaving to others the work in other branches." "The student beginning the subject of petrology needs at least an introductory knowledge of the branches of science that underlie mineralogy in order to apply certain of the principles to the study of rocks." This book is not intended to do away with mineralogy, but to determine rock minerals by physical tests and optical properties when in thin sections. Part I covers the general principles involved and the methods to be followed in research. Part II is descriptive mineralogy and involves a long list of minerals.

Mining Law for the Prospector, Miner, and Engineer. H. W. MacFarren, author, offers a very satisfactory apology when he states that "the present standard books on the subject are the production of mining attorneys, and are more valuable for practicing attorneys than for miners." In addition to the hardships and natural difficulties involved in prospecting, several more have been recently tacked on, chief of which is the chance of developing another's "near claim," particularly if a good vein is discovered. The value of Mr. MacFarren's book will be appreciated by engineers, miners, and prospectors who realize the number of "buzzards" hovering over and ready to pounce on the man who makes a find and take it from him. To these men—not the "buzzards"—the book will appeal and find a ready sale. The price is $2 postpaid. Published by the Mining and Scientific Press, San Francisco, Cal.

The Mineral Industry, Vol. XIX, edited by Albert H. Fay. Published by McGraw-Hill Book Co. Articles for this volume have been prepared by 76 different authors. The table of contents shows 56 different subjects of commercial importance to the mining and metallurgical industry, besides special chapters on Sulphur Smoke of Metallurgical Works; Dredging; Mining Practice; Ore Dressing and Coal Washing; Assaying and Sampling; Mineral Statistics. The "Mineral Industry" is well known to all miners and metallurgists. As a reference book it is a necessity. Each year new subjects like Fixation of Atmospheric Nitrogen, difficult to obtain, and then piecemeal, are added. How much better Vol. XIX is than Vols. XVIII, XVII, XVI, and XV only those can tell who have them.

Meinzer; Water-Supply Paper No. 277, Ground Water in Juab, Millard, and Iron counties, Utah, by Oscar E. Meinzer. Professional Paper No. 75, Geology and Ore Deposits of the Breckenridge District, Colo., by Frederick Leslie Ransome.

Answers to Examination Questions

Questions from Illinois Examinations, 1910, for Mine Managers, Mine Examiners, and Hoisting Engineers

(Continued from October)

QUES. 5.—A door, 5 ft. × 6 ft., is placed on a main entry 800 feet from the bottom of downcast shaft, and between two cross-entries driven east 1,200 feet. All entries are 6 ft. × 8 ft. in section; the velocity of the air-current is 500 feet per minute, barometer 30 inches, temperature 60° F. What is the pressure per square foot and the total pressure acting to keep the door closed? M., Q. 7, 1-17-10

ANS.—The pressure acting to keep the door closed is the difference of pressure between the two sides of the door, which is due to the resistance offered by the cross-entries to the passage of the air-current through them. This difference of pressure at the door is

$$p=\frac{k\,l\,o\,v^2}{a}=\frac{.00000002\times 2,400\times 28\times 500^2}{48}=7 \text{ lb. per sq. ft.}$$

The total pressure acting on the door to keep it closed is then $5\times 6\times 7=210$ pounds. The distance of door from downcast shaft, and density of the air, as determined by the barometer and temperature are not considered here, as they do not affect the question practically.

QUES. 6.—Give the dimensions of a mine car built to hold 3,000 pounds of coal when the height of the coal in the seam is 4 feet 6 inches; there is a good roof and 2 feet of fireclay underlies the coal. Give sizes of wheels and axles. M., Q. 8, 1-17-10

ANS.—A ton of mine-run bituminous coal will occupy 40 cubic feet of space, and 3,000 pounds of this coal will require $\frac{3,000}{2,000}\times 40=60$ cubic feet, which must be the cubic capacity of the car. Then, adopting the style of mine car shown in Fig. 2, and taking the track gauge as $g=42$ inches, the inside width of the car at the bottom is $g-6=42-6=36$ inches, and at top $g+8=42+8=50$ inches. Using 18-inch wheels the depth of the lowest section of the car is $\frac{d}{2}=\frac{18}{2}=9$ inches. The area of this section, in Fig. 2, is therefore $36\times 9=324$ square inches. The depth of the middle section (Fig. 2) is 7 inches, and its area $7\times\frac{1}{2}(36\times 50)=301$ square inches. If the coal is undercut at the face so as to take out 10 inches of the under-clay the total headroom from floor to roof would be 4 ft. 6 in. + 10 in. = 64 inches. Then, allowing 6 inches for ties and rails, 9 inches for half-diameter of car wheels, 3 inches for half thickness of axle and car bottom; the two lower sections of the car being $9+7=16$ inches deep, if the top section is made 16 inches, this will leave $64-(6+9+3+16+16)=14$ inches for topping of coal and roof clearance. Call the coal topping 6 inches and the roof clearance 8 inches. The depth of coal in the top section, including the topping is then (Fig. 2) $x=16+6=22$ inches, and the area of coal in this section is $50\times 22=1,100$ square inches. This gives for the total sectional area of coal in the car $324+301+1,100=1,725$ square inches, or $1,725\div 144=$ say, 12 square feet. The clear, inside length of the car must then be $60\div 12=5$ feet. Use 2½-inch, square, Swedish-iron axles.

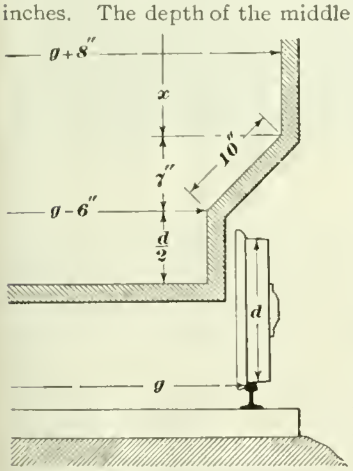

FIG. 2

QUES. 7.—What load will break a 10″×10″ white-oak beam, 12 feet between supports, uniformly loaded its entire length? M., Q. 10, 1-17-10

ANS.—For a uniform load W, Bending moment $=\frac{W\,l}{8}$ when the beam is supported at both ends (Fig. 3). The bending moment of any beam is equal to the moment of inertia of the beam, divided by the distance of the extreme fiber from its neutral axis; or,

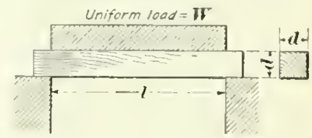

FIG. 3

in this case (square beam, side $=d$) $\frac{d^4}{12}\div\frac{d}{2}=\frac{d^4}{12}\times\frac{2}{d}=\frac{d^3}{6}$; and multiplied by the fiber stress (f). Hence,

$$\frac{W\,l}{8}=\frac{f\,d^3}{6}; \text{ or } W=\frac{4}{3}\frac{f\,d^3}{l}$$

All the dimensions of the beam are expressed in inches; thus, $d=10$ inches; $l=12\times 12=144$ inches. The breaking strength (ultimate fiber stress) of white oak may be taken as 10,000 pounds per square inch; or $f=10,000$. Then,

$$W=\frac{4}{3}\left(\frac{10,000\times 10^3}{144}\right)=92,592+\text{ lb.; or say, } 46\tfrac{1}{4}\text{ tons}$$

QUES. 8.—A pair of hoisting engines have cylinders 30 inches in diameter; the stroke is 60 inches; the steam pressure 90 pounds per square inch. How many revolutions per minute will they be running when generating 1,000 horsepower? M., Q. 14, 1-17-10

ANS.—With only the data given it would not be possible to answer the question asked, as it is necessary to know the mean-effective steam pressure in the cylinders. Assuming, however, the steam pressure is 90 pounds at the throttle and the engines cut off at, say ⅝ stroke, then

$$\text{M. E. P.}=.9\,[.904(90+14.7)-17]=\text{say, } 70 \text{ lb. per sq. in.}$$

The total mean pressure exerted in one cylinder is then $.7854\times 30^2\times 70=49,480$ pounds. In order that this cylinder shall develop 500 horsepower (1,000 horsepower, two cylinders), the piston speed must be $\frac{500\times 33,000}{49,480}=333.4$ feet per minute; or, since the stroke is $60\div 12=5$ feet, the engines must run at $333.4\div 2\times 5=$ say, 33⅓ revolutions per minute.

QUES. 9.—The temperature of the air in the downcast shaft of a certain mine is 60° F., and that in the upcast 100° F. The quantity of air entering the mine as measured in the downcast is 20,000 cubic feet per minute. Each shaft is 15 feet in diameter. What is the velocity of the air-current in each shaft, respectively? M., Q. 16, 1-17-10

ANS.—The sectional area of each shaft is $.7854\times 15^2=176.7$ square feet. The velocity of the air-current in the downcast is then $20,000\div 176.7=113.18$ feet per minute. Assuming that the pressure on the air is practically the same in each shaft, the difference being very small, the air volume, and for the same area, the velocity of the current, each varies with the absolute temperature. In other words, the velocity ratio is equal to the absolute-temperature ratio. Thus, calling the required velocity in the upcast x,

$$\frac{x}{113.18}=\frac{460+100}{460+60}=\frac{560}{520}=\frac{14}{13}$$

and

$$x=113.18\times\frac{14}{13}=121.88 \text{ ft. per min.}$$

QUES. 10.—How far can a pair of entries be driven without a cap showing on a safety lamp, if the air-current at the upcast is 4,000 cubic feet per minute, and assuming that the coal gives off 1 cubic foot of marsh gas in every 90 feet of each entry? Give the proportion of gas and air in the mixture. M., Q. 17, 1-17-10

ANS.—With the unbonneted Davy, burning ordinary sperm or cottonseed oil, it is possible to detect the first cap when there is 2.5 per cent. of marsh gas in the air-current, which, in this case, would result from $4,000 \times .025 = 100$ cubic feet of gas. At the rate of 1 cubic foot of gas given off by each 90 feet of entry it would require $100 \times 90 = 9,000$ feet of entry to produce this quantity of gas; or one-half this length of double entry, say 4,500 feet. The proportion of gas to air in this mixture is 2.5 volumes of gas to 97.5 volumes of air, making 100 volumes of mixed air and gas; or 1 of gas to $\frac{97.5}{2.5} = 39$ volumes of air; expressed as 1 : 39.

QUES. 11.—How long will it take an air-current of 20,000 cubic feet per minute to make the circuit of a $10' \times 10'$ airway 12,000 feet long? M., Q. 18, 1-17-10

ANS.—The velocity of the air-current, in this airway, is $\frac{20,000}{10 \times 10} = 200$ feet per minute. The time required for air traveling at this rate to pass through an entry 12,000 feet long is $12,000 \div 200 = 60$ minutes, or 1 hour.

QUES. 12.—The quantity of air passing in a certain mine ventilated by a furnace is 150,000 cubic feet per minute when the furnace consumes 5 tons of coal in 12 hours. What increased circulation will be obtained by burning 5 additional tons of coal in the furnace in 12 hours (doubling the fuel consumption)? M., Q. 19, 1-17-10

ANS.—In furnace ventilation the power developed is proportional to the weight of coal burned per hour. When the coal burned per hour is doubled the fuel ratio and likewise the power ratio are each 2. Since, for the same mine or airway, the quantity of air in circulation varies as the cube root of the power, the quantity ratio is equal to the cube root of the power ratio; or, in this case, $\sqrt[3]{2} = 1.26$. The increased circulation would then be $1.26 \times 150,000 = 189,000$ cubic feet per minute.

QUES. 13.—What horsepower would an engine develop when yielding 60 per cent. efficiency and furnishing the power to circulate 100,000 cubic feet of air in a mine, against a water gauge of 1 inch? M., Q. 20, 1-17-10

ANS.—The indicated horsepower of the engine in this case is

$$\text{I. H. P.} = \frac{100,000 \times 1 \times 5.2}{.60 \times 33,000} = 26.26 \text{ H. P.}$$

QUES. 14.—How would you measure the quantity of air passing in an airway without an anemometer? E., Q. 5, 1-17-10

ANS.—A simple method often employed is to touch off a small quantity of powder at a certain point in the airway, and observe carefully the exact time between the flash of the powder and the first appearance of smoke at a point say 100 yards from the powder. The distance, in feet, divided by the time observed, in minutes, will give the observed velocity of air-current in the center of the airway. The average velocity may then be taken as about .8 of this observed velocity, because the air travels faster in the center than at the sides of the airway.

QUES. 15.—What is a regulator and when can it be used to advantage in the mine? E., Q. 6, 1-17-10

ANS.—A regulator, in mine ventilation, is any device for dividing the air-current proportionately between the several districts of a mine. The most common form is the box regulator, which consists of a door or brattice erected in airway or cross-cut, and provided with a small opening, the size of which can be increased or decreased at will by means of a sliding shutter. Any desired proportion of the air is thus allowed to pass through the regulator for the ventilation of a separate district or portion of the mine. It is used whenever more air is required in certain parts of the mine than is supplied by the natural division of the air-current.

QUES. 16.—What is blackdamp, how is it produced, and where found in mines? E., Q. 7, 1-17-10

ANS.—Blackdamp is any mixture of extinctive gases as they occur in mines. The mixture consists chiefly of carbon dioxide and nitrogen, and is the result of the complete combustion of carbon in air, by which the oxygen of the air combines with the carbon to form carbon dioxide, leaving an excess of nitrogen. It is found mostly in low parts of the mine and in abandoned places where ventilation is slack and these gases accumulate.

QUES. 17.—The hand of an anemometer makes 3.25 turns in 1 minute; the airway is 6.25 ft. × 8.5 ft. What is the velocity of the air-current, allowing 3 per cent. loss for resistance of the anemometer? E., Q. 11, 1-17-10

ANS.—The size of the airway is not concerned in finding the velocity of the air-current. One turn of the hand, in the type of instrument here meant, corresponds to 100 revolutions of the vane, or 100 feet of air travel, as indicated by the dial; and 3.25 turns in 1 minute indicates a velocity of the air-current of 325 feet per minute. But allowing for a loss of 3 per cent. due to friction, this velocity is $100 - 3 = 97$ per cent. of the true velocity. The actual velocity is therefore $325 \div .97 = 335+$ feet per minute.

QUES. 18.—If 5 cubic feet of gas was to explode, how many cubic feet of flame would result? E., Q. 14, 1-17-10

ANS.—The question does not specify the kind of gas or whether the same is mixed with air so as to form an explosive mixture, and in what proportion, or whether 5 cubic feet of pure (undiluted) gas is meant. If 5 cubic feet of firedamp (CH_4 and air) at its most explosive point (1 vol. gas : 9.57 vol. air) is exploded in free air (unconfined), the theoretical flame temperature is 4,173° F., giving $\frac{460 + 4,173}{460} =$ say, 10 expansions of the gases produced by the explosion; or since the volume of these gases, at the same temperature and pressure is equal to the volume of firedamp exploded, there is produced 10 volumes of flame; or, in this case, $10 \times 5 = 50$ cubic feet. In the case of carbon monoxide mixed with air, at the most explosive point (1 vol. CO : 2.39 vol. air) although theoretical flame temperature (5,287° F.) is much higher, giving $\frac{460 + 5,287}{460} = 12.5$ expansions, yet owing to the change in volume that occurs in this reaction the flame volume is reduced 15 per cent. and is $12.5 \times .85 = 10\frac{5}{8}$ volumes; or for 5 cubic feet of the original mixture of gas and air $5 \times 10\frac{5}{8} = 53\frac{1}{8}$ cubic feet of flame. If the question, however, means 5 cubic feet of gas (undiluted with air), since this gas is 9.46 per cent. of the above firedamp mixture the resulting flame volume would be $50 \div .0946 =$ say, 530 cubic feet.

QUES. 19.—A current of 9,000 cubic feet of air per minute is passing through a regulator having an opening 20 in. × 30 in. How much air will pass through the regulator if the opening is made 30 in. × 30 in., the pressure and rubbing surface being the same in each case? E., Q. 15, 1-17-10

ANS.—If the pressure due to the regulator is the same in each case, the quantity of air passing through the opening will increase with the size of the opening; or, in this case, in the ratio 30 : 20, or $\frac{3}{2}$, and the volume of air will then be $\frac{3}{2}$ (9,000) $= 13,500$ cubic feet per minute. This would, however, require that the ventilating presssure on the airway be increased in the ratio $\left(\frac{3}{2}\right)^2 = \frac{9}{4}$, or $2\frac{1}{4}$ times. It is more probable that the question means the ventilating pressure remains unchanged when the opening in the regulator is enlarged. In that case, it is necessary to know both the area and rubbing surface of the airway. Assuming, $a = 50$ square feet, and $s = 100,000$ square feet, the increased quantity passing through the regulator when the area of the opening is enlarged from $\frac{20 \times 30}{144} = 4.167$ square feet, to $\frac{30 \times 30}{144} = 6.25$ square feet is

$$q_2 = 9,000 \times \frac{6.25}{4.167} \sqrt{\frac{50^3 + .026 \times 100,000 \times 4.167^2}{50^3 + .026 \times 100,000 \times 6.25^2}}$$
$$= \text{say, } 11,700 \text{ cu. ft. per min.}$$

ORE MINING AND METALLURGY

Treatment of Broken Hill Ores

Methods of Grinding—Concentrating by the Magnetic, the Flotation and the Oil Processes

*By W. Poole, B. E.**

This paper, which was read before the Sydney University Engineering Society, is divided into three parts. Part I is the one printed in this issue and is on concentration of ores.

The immense lode of ore at Broken Hill is mined by 10 large and several small companies. The upper or oxidized portion of the lode was marvellously rich in silver and lead, besides ores and minerals of lesser value. The variety of minerals found in the Broken Hill lode is, perhaps, unequaled at any other spot in the world.

The unaltered ore consists of a mixture of galena, blende, quartz, rhodonite, garnet, and small quantities of calcite, pyrite, etc., in varying but omnipresent quantities. The ore generally contains lead and zinc in roughly equal amounts, with about as many ounces per ton of silver as there is per cent. of either lead or zinc. The average metal contents are gradually decreasing at greater depths. The galena is almost pure, except for the ever-present silver. The blende, on the other hand, is impure, with appreciable quantities of sulphides of iron and manganese.

Above the unaltered sulphides was a zone of friable sulphide ore high in lead and silver, but low in zinc. The zinc sulphide had been oxidized to sulphate, etc., and leached, leaving the ore open and friable. The stopes in this zone were perceptibly hotter and the air fouler than those in the hard sulphides—no doubt due to the chemical action of oxidation still in progress.

Above the friable sulphides was the carbonate zone, containing oxidized lead ores with high silver contents, kaolin, and highly siliceous ores, at times exceedingly high in silver, and in places containing small patches of copper. Above this zone, where the lode outcropped, was the capping of iron manganese gossan, containing in places rich silver chloride. Of the more important constituents it will be noticed that the zinc was the first to be oxidized and eliminated; later on, the copper; then lead; and last, the capping remains, composed of oxidized iron and manganese, and containing silver as chloride. The oxidized ores were smelted in blast furnaces, the iron-manganese gossan being used as flux with limestone brought from elsewhere.

A 50-head stamp battery and amalgamating plant was erected by the Broken Hill Proprietary Co. for treating dry silver ores, but was not a success. A hyposulphite lixiviation plant, built by the same company for treating dry ores, was much more successful, and ran until the remaining dry ores were required for fluxing purposes at the Port Pirie smelters. The friable sulphide, after considerable preliminary trouble, was directly treated at the metallurgical works, but the crude unaltered sulphides could not be economically smelted for either lead or zinc. Large ore-dressing plants have been built, and complicated processes have been evolved for separating the ore into four products, viz.:

1. Lead concentrate containing small quantities of zinc and gangue.

2. Zinc concentrate containing small quantities of lead and gangue. Both concentrates are shipped to various places to be smelted for their main constituent and silver.

3. The zincky (so-called) tailing, of which there are upwards of 4,000,000 tons stacked. This is really an intermediate product running high in zinc and now being treated by the various flotation processes for its large zinc and silver and small lead contents.

4. Worthless tailing from one of the flotation or magnetic processes, being the product of (3), or the continuous treatment of the crude ore.

The general practice of ore breaking is as follows: The ore from the mine is tipped on to grizzlies, the undersize going to

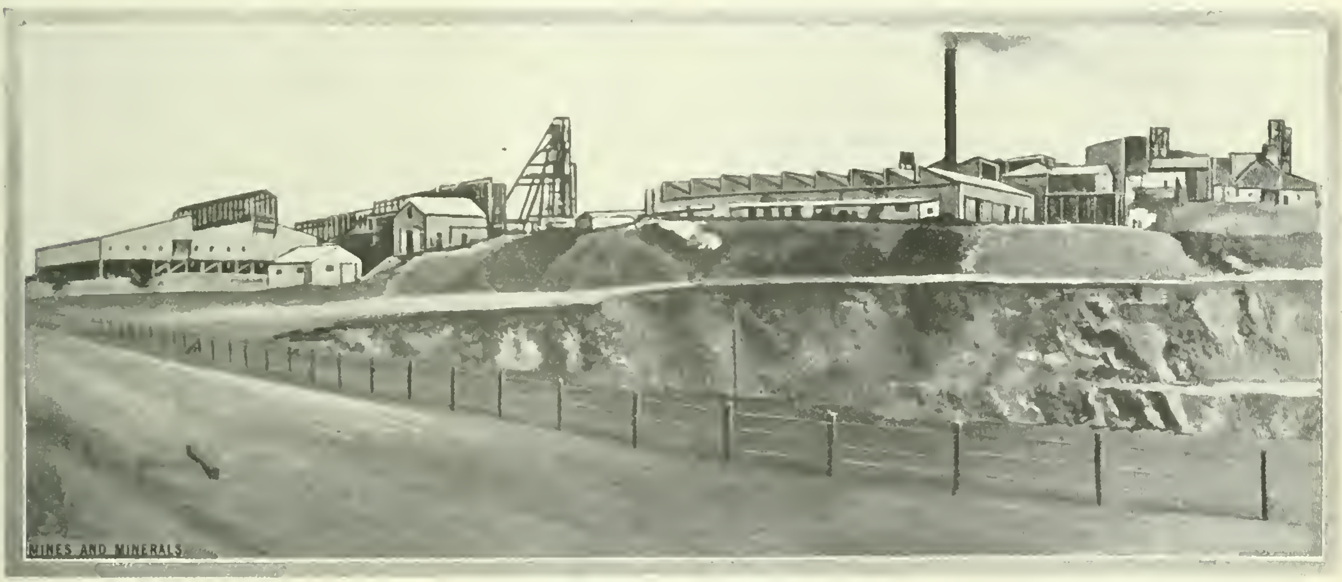

FIG. 1. SOUTH MINE' BROKEN HILL, AUSTRALIA

* Director of Charters Towers School of Mines.

the lower bin and the oversize into the breaker supply bin, from which it is fed to gyrating breakers, the broken product rejoining the undersize that passes through the grizzly.

The almost universal practice is to recrush this product with slow-speed geared Cornish rolls 30 inches to 36 inches in diameter, and making about 15 to 20 revolutions per minute. The oversize, after the product has been screened, is returned to the same rolls. The exception to the general practice is the use of high-speed Gates rolls in the Broken Hill Proprietary Co.'s new mill. This mill has a nominal capacity of 6,000 tons per

1 crusher; 2 rolls; 4 jigs; 8 classifiers; 9 concentrating tables; 15 Frue vanners; 16 tube mill; 17 spitzkasten; 18 shaking screen; *c* concentrate; *m* middling; *t* tailing

6-days of 24 hours. Here progressive comminution has been more fully applied than elsewhere at Broken Hill. There are nine sets of these rolls, each 36 inches in diameter by 15 inches wide. Ore broken to 1-inch to 2-inch gauge is, after screening, fed with a stream of water to three sets of rolls set $\frac{3}{4}$-inch to $\frac{1}{2}$-inch apart and making 30 revolutions per minute. After crushing and screening, the oversize from the shaking screen is conveyed on an endless horizontal belt to a bucket elevator, where it is elevated to bins which supply a second batch of three sets of rolls. These rolls are set $\frac{1}{8}$-inch to $\frac{3}{16}$-inch apart, and run at 45 revolutions per minute. The product is screened, and the oversize conveyed to an elevator and elevated to bins, which supply rolls Nos. 7 and 8, which are set at $\frac{1}{16}$-inch apart and running at 78 revolutions per minute. The oversize, after screening, is elevated to a bin, which supplies a No. 5 Krupp ball mill, from which no ore can escape before it is crushed to a sufficient fineness to pass the screens.*

It is interesting to note that the speed at which these rolls are driven has been reduced from time to time in order to obtain better efficiency. The rolls on 1½-inch to 2-inch ore were originally run at about 45 revolutions per minute, and the others, on finer ore, at about 90 revolutions per minute. Four new mills have been built, and the old ones remodeled, since these high-speed rolls were installed, but in no case have similar rolls been installed. It is always the slow-speed geared type. It has been found that both classes of rolls do better work when crushing wet ore than dry ore. In the former case, the fine particles cling to the rolls, thus sanding the track and giving the rolls a more effective nip.

The ore is crushed to pass through 2-millimeter holes in punched-plate screens. Formerly a pair of cylindrical trommels, about 2 feet diameter by about 6 feet long, screened the product of each set of rolls. These small trommels were covered with either woven-wire cloth or punched plate. The Broken Hill Proprietary Co. introduced large conical trommels. Nearly all revolving trommels have now been replaced by shaking screens, which admit of more ready inspection and repairs, besides require less wash water. A very effective modification of the shaking screen is in use at the British Broken Hill Co.'s mill, and consists of a punched plate with corrugations of about 2-inch radius at right angles to the direction of inclination and shake. The effect of the corrugations, in conjunction with the end shake, is to bring all particles in repeated contact with the screen, and so give the undersizes full opportunity to pass through. The oversize discharged is very free from fines.

In general, the oversize is returned for crushing to the same rolls, except in the Broken Hill Proprietary Co.'s new mill. The oversize is elevated to the rolls either by raff wheels or belt elevators, both means of elevation being largely used.

Table 1. Analyses of Crude Ore and Oversize From Trommels

Sieve*	Crude Ore Per Cent.	Raffs Per Cent.
Caught on 8	55.8	54.3
Caught on 20	14.8	33.9
Caught on 40	9.0	7.3
Caught on 60	5.0	1.0
Caught on 80	3.8	.7
Caught on 100	3.0	through 80 .8
Caught on 120	2.3	
Caught on 150	1.9	
Through 150	4.1	

	Crude Ore Per Cent.	Raffs Per Cent.
Insoluble	41.0	50.0
FeO	5.8	4.7
CaO	2.8	6.3
Pb	18.9	14.5
Zn	14.6	13.3
Ag ounces per ton	13.0	11.0

* All sieves are quoted at openings per linear inch.

The sizing analyses show that the coarse ore from the breakers contains a larger percentage of fine ore than the oversize from the trommels, and also that the former contains a larger percentage of metals and less siliceous matter than the latter.

The undersize from the screens is passed to hydraulic classifiers, the overflow going to spitzkasten and the underflow to

* G. D. Delprat, on "Ore Treatment at Broken Mill." Trans. Aust. Institute of M. E., Vol. XII.

the jigs. These classifiers do not make a clean separation of fine ore and slime, and a considerable portion of the latter passes to the jigs, as will be seen from the sieve analyses.

The Hancock jigs and May jigs are used. The Hancock jig is of movable sieve type, about 20 feet long and 2 feet 6 inches wide, with four sieve product hutches and a tailing hutch. These jigs do good work, but unless they are carefully operated splashings containing grit get into the working parts, which are mostly underneath.

The May jig is of the fixed sieve type, and is built double, i. e., has a set of plunger and sieve compartments on each side of the longitudinal center line. There are four sieve product hutches and one tailing hutch on each side, besides an overflow at the tailing hutch for surplus water and slime. The plungers are worked by rocking arms operated by cranks on a countershaft. There are two rocker-shafts with a pair of rocker-arms to each shaft, a pair of plungers on one side working in unison with each other, and in alternation with the pair on the same shaft on the other side of the jig, and also alternating with the other pair on the same side of the jig, but attached to the other rocker-shaft. The throw of the crank is adjustable, altering the stroke of its set of plungers. The stroke of each plunger may be also independently altered. The capacity of these jigs is great. They do good work, giving great satisfaction and little trouble, and are preferred to the Hancock, despite the great and justifiable reputation this latter jig has achieved in concentrating copper ores both in Australia and America. Both of these jigs were invented and perfected in South Australia. The bed sieve of the jigs is of woven brass wire held between two gridiron frames. The bedding on the sieve is granulated cast iron or disks of small diameter punched from iron plates. The May jigs on coarse feed are driven at a speed of about 180 pulsations per minute. Similar jigs on fine, i. e., reground feed, work at about 270 pulsations per minute.

The regrinding of the middling product to free the intimately associated minerals presents an interesting development. At first, narrow high-speed rolls were used; then the Herberli mill was used for this purpose, and was almost exclusively so employed for a number of years. The Herberli mill is a grinder with vertical circular disks set slightly eccentric to each other, one disk revolving at high rate of speed and the other at a slow rate in the same or opposite—usually the latter—direction. The pulp is fed under slight hydraulic head through the hollow shaft on one disk. The pressure on the disks is regulated by a screw acting against a steel coil spring. The objections to these grinders was that they sometimes gave a poorly ground product and at the same time an undue amount of slime. This undesirable result was in part due to the grinding faces of the disks not being true to each other, i. e., pressing tightly together at one side, producing slime, while the gap on the other side allowed material to pass through with little or no abrasion. This defect was partly remedied by a simple alteration, viz., instead of attaching the disks to their shaft, the end of the solid shaft was squared, and the corresponding disks were cast with a hollow-square collar, so that the disc now fitted on loosely, and, on pressure being applied by the regulation screw it fitted flat against the other disk. The effect of this simple alteration was marked. On the one hand it reduced the percentage of coarse, and on the other reduced that of slime. Wet crushing in Krupp ball mills was tried. The results were so satisfactory that the Herberli mills were rapidly discarded in their favor. The recrushing in the ball mills had the following advantages: The product has to pass through a screen; it is, therefore, under perfect control as to maximum size of issuing pulp grains, and at the same time a lessened percentage of slime is produced, giving a higher percentage of lead and silver recovery.

Grinding pans of the most modern types have since been very widely introduced, with most gratifying results, displacing or throwing out of commission many of the ball mills. Grinding pans instead of ball mills are being installed in the new mills recently completed or being erected. They have a lesser initial cost, are cheaper to operate, give less trouble, and, whilst grinding to a given maximum fineness, produce less slime than ball mills.

The success of the improved grinding pans in reducing the galena-blende ores of Broken Hill parallels its success in fine grinding auriferous ore in Western Australia and elsewhere, and for tin ores in North Queensland. It has been found by experiment in North Queensland that the ball mill is inferior to the grinding pan for fine grinding tin, wolfram, and tin-wolfram. Recently the Broken Hill Proprietary Co. has been installing tube mills in place of ball mills for regrinding coarse tailings. The result is reported to be very satisfactory.

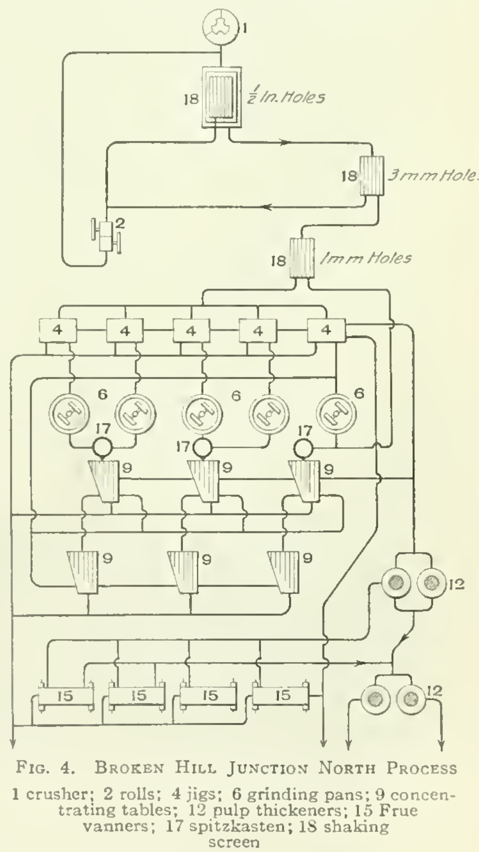

Fig. 4. Broken Hill Junction North Process

1 crusher; 2 rolls; 4 jigs; 6 grinding pans; 9 concentrating tables; 12 pulp thickeners; 15 Frue vanners; 17 spitzkasten; 18 shaking screen

After the middling product of the coarse jigs has been reground it is elevated to hydraulic classifiers, the underflow passing to fine jigs and the overflow to the pointed boxes prior to treatment on tables and vanners. Three products are made — concentrate, middling, and tailing. The middling is reground, usually in ball mills with a fine sieve, or in grinding pans, and then returned to the hydraulic classifier of the same jig.

Tables 2 and 3 show an analysis of jig products:

V. F. Stanley Low* gives two interesting tables showing that, for coarse jigs, the tailing caught on 100 and coarser mesh sieves contained 2.2 per cent. to 3.2 per cent. lead, and that through 100 mesh contains 9.6 per cent. to 12.7 per cent. lead, and for fine jigs 4.4 per cent. to 7.1 per cent. lead and 11.4 per cent. to 15.7 per cent. lead, respectively. The above figures show that the hydraulic classifiers are far from effecting a clean separation of slime. At the Broken Hill Proprietary Co.'s mills the tailing from both the coarse and fine jigs are passed over shaking screens, the oversize going to the dump and more recently to the grinding plant, and the undersize to the zinc plant (Delprat flotation process.) This simple expedient greatly lessens the percentage of lead and zinc going to the dump.

Considerable diversity of opinion exists as to the method of treatment of fine ore and slime, ranging from attempts at close and careful classification to almost none, though in most cases there is a more or less serious attempt at classification. Generally the treatment is as follows: The fine ore and slime from various sources, e. g., hydraulic classifiers, overflow from jigs, or fine screens (as at the Junction North), are passed to spitzkasten or pointed boxes with a regularly increasing cross-section toward the overflow end. The coarser material from the earlier spigots is treated on Wilfley, Card, or Krupp tables, the latter spigots on belt vanners of the Luhrig or Warren types. The end spigot may be treated on vanners or sent direct to the slime-settling pits. Companies which have not their own plants to treat the slimes make a more serious attempt to save the utmost amount of values on the tables and vanners. The heads from the various concentrating tables or vanners are concentrates to be sent to market or to the company's smelter. The middlings are generally classified and treated on separate concentrators, giving concentrates and tailings. It is generally accepted that retreating middling on the same table without reclassification is defective practice. The coarse tailing goes to the dump. The slime, which runs straight down the table, is in many cases kept as a separate table product, sent to a thickening box, and thence treated or sent direct to the slime pits. It was early recognized that a high percentage of lead in the tailing from tables of the Wilfley type was contained in the slime, which ran straight down the table. This has led to making a coarse and slime tailing product, the former carrying little value and going directly to the dump, and the latter being thickened or retreated, or saved and transformed into a product that can be smelted in blast furnaces. Tables of the Wilfley type are recognized in Australia not only as good concentrators, but also as excellent slime separators. Slime products are being obtained for further treatment in the manner mentioned not only in the concentration of lead, but also of gold and tin ores.

* Concentration of Silver-Lead Ores. Trans. Aust. I. M. E., Vol. XI.

The notable example of the non-classification of fine ore and slime is the Broken Hill South mine. Here the middling product of jigs is reground in pans of the improved Wheeler type. The whole product is directly treated on Wilfley tables, which give concentrates to market, middlings back to pans, tailings to dump, and slimes which are thickened in boxes and treated on vanners which give concentrates to market and tailings to dump. It is found that the most of the lead is recovered when the ore is ground to pass 100 to 150 mesh. It must not be overlooked that undoubtedly good results, claimed to be the best at Broken Hill, are obtained at this plant. The new 6,000-ton mill is built directly for this system of treatment. At the Broken Hill Proprietary Co.'s plant four products are obtained from the Wilfley and similar type tables and from the vanners, viz., concentrates, middlings, coarse tailings, and slimes. The middlings of the Wilfleys are retreated on other Wilfleys, giving concentrates, tailings, and middlings, the latter being retreated on the same table; the vanner middlings are run into spitzkasten, and thence on to the vanners, giving concentrates and tailings. The coarse tailings from the Wilfleys and vanners are run out into a spitzkasten to remove the small amount of slime left in them, and then sent to the zinc plant for further treatment by the flotation process. The slimes are settled, dried, heap roasted, and sent to the Port Pirie to be smelted. The slimes of most of the other companies are, for the time being, a waste product.

Tables 4 and 5 are analyses of Wilfley and vanner products:

The economical recovery of the blende as a marketable zinc concentrate has been the greatest problem which has confronted the technical men of Broken Hill during recent years. Much money, time, and ceaseless patience have been bestowed upon the solution of this problem. As previously mentioned, Broken Hill ores always contain varying quantities of garnet and rhodonite, in addition to galena and blende, also other minerals of less importance. The high specific gravity of galena enables a large percentage of that mineral to be readily recoverable by the skilful use of jigs, concentrating tables, and vanners, but no such use can be made of these appliances to make a separation of blende from the garnet and rhodonite into a marketable concentrate. The Broken Hill garnet has a specific gravity about 4.2, the blende about 4, and the rhodonite about 3.6. The garnet can frequently be seen on Wilfley tables and vanners, making a distinct reddish band

FIG. 5. BROKEN HILL PROPRIETARY MINE, BLOCK 14

slightly in advance of but blending into the body of blende, while the rhodonite hopelessly overlaps and mingles with the blende, the quartz often forming a distinct whitish band in the rear.

As it was hopeless to seek a solution by wet concentration, it was sought in a different quarter, viz., by magnetic concentration, and later by flotation processes.

The Australian Metal Co. erected a magnetic concentrating plant known as the Zinc Works, at which concentrates were made at intermittent periods. Ulrich machines, designed by the manager, were installed and used. About 8 years ago an experimental plant, using Mechernich machines, was installed at the Central mine, where, with additions, it has been working until very recently. The great drawback of these magnetic processes, apart from any economical considerations, is the amount of fine dust set free into the atmosphere, despite precautions made to keep the mills free from it, the result being an unusual amount of sickness due to lead poisoning among the employes.

The Mechernich machine is composed essentially of two bar electromagnets. The properly crushed and dried material is fed from a chute into the strong magnetic field between the adjacent north and south poles, the upper one (north) revolving. The intensity of the field gradually decreases after passing the adjacent surfaces. The ore is brought in contact with the poles at its strongest field. The paramagnetic particles adhere to the upper or revolving poles, while the diamagnetic particles fall off, and are collected in a bin. The paramagnetic particles are carried round by adhering to the pole into a constantly diminishing intensity of field, until they are dislodged by gravitation or some mechanical means. Each chute may be adjusted to suit the required conditions at the various zones of release.

It has been found that, under the influence of a powerful magnetic field, garnet and rhodonite are much more susceptible than blende, and the latter more so than galena and quartz, which are practically non-magnetic. With suitable machines three products may be made.

1. Garnet rhodonite product to waste.
2. Blende product, which may be further cleansed on another machine.
3. Galena blende quartz products, which are readily separated on wet concentrating tables and vanners into lead concentrates and a small amount of zinc concentrates and quartz to dump.

The scheme of reduction shown in Fig. 8 outlines the process used at the Central mine.

In 1901 C. V. Potter, of Melbourne, took out a patent for the recovery of sulphides from their ores by the addition of very dilute acidulated solutions to finely pulverized ores, which causes certain sulphides to rise to the surface.* Sulphuric acid is for economical reasons used of a strength from 1 to 10 per cent. Dilute sulphuric acid will not attack galena or blende to any extent. During the early days of the process the following was supposed to be the action that took place, viz., that acid attacked the sulphide of iron (FeS), which was always present in small quantities, liberating sulphuretted hydrogen (H_2S).

$$H_2SO_4 + FeS = H_2S + FeSO_4.$$

The liberated bubbles attached themselves to the sulphide particles, and when large enough lifted them to the surface. By heating the solution less acid is consumed on account of the expanded bubbles having a greater buoying-up power. When the bubbles break, the particles fall again. Various appliances have been devised to remove the floating particles from the bath before the bubbles break. This Potter process has not been a financial success in its original form, but has suggested other acid flotation processes, some of which are working with a high degree of success.

In 1902 G. D. Delprat, the general manager of the Broken Hill Proprietary Co., Ltd., took out a patent for the Delprat or salt-cake process. In this process salt cake or crude acid sulphate of soda $NaHSO_4$, is dissolved in water until its specific gravity is increased to 1.3. Sulphuric acid is added to the solution, heat is applied, and the solution and fine ore particles are treated in vats as hereafter described. Reactions similar to those in the Potter process take place, but it was very soon discovered that the real chemical reactions were different from those previously assumed to take place. It was at once observed that the process was free from the distinctive odor of sulphuretted hydrogen. On examination, the gas given off was found to be CO_2, with a trace of H_2S. The CO_2 was given off from the small amount of calcite and siderite always present. The

FIG. 6. CONCENTRATING MILL, JUNCTION MINE, BROKEN HILL

liberated CO_2 attaches itself to the clean particles of sulphides, but not to earthy or oxidized surfaces. If concentrates which have been produced by an acid flotation process are retreated by themselves, the reactions are feeble, and but a small amount is recovered unless calcite or a similar carbonate is added to the flotation vats. The material treated in the Broken Hill Proprietary Co.'s zinc plant is derived as follows from the lead concentrating mills: The tailings of both coarse and fine jigs are passed over shaking screens, to separate the coarse siliceous

*See *Aust. Mining Standard*, August 21, 1902.

particles from the finer material containing a fair percentage of both zinc and lead. The former is sent to the dump, and the latter, mixed with the tailings from the Wilfley table and the Luhrig vanners, are passed through a spitzkasten to remove slime. The coarser product is sent to the zinc plant, and the slime product to the slime-settling pits.

One of the special features of this process is the use of the Delprat patent vat. This vat is a steeply inclined inverted wooden pyramid lined with sheet lead. The vat has two pockets, one with and the other without an outlet. The blind pocket allows the ore particles to overflow steadily into the outlet pocket and at the same time collects lumps, etc., which might obstruct the outlet. The outlet is regulated by a stopper on the end of a rod, which passes down through the solution. The solution is made up in a vat and heated by a steam coil to about 180° F. The solution passes, by means of a pipe, to near the bottom of the flotation vat, into which the fine ore is fed automatically above the fluid pocket. The gas generated attaches itself to the galena and blende particles, floating them to the surface and overflowing with the excess solution into a settling vat common to several flotation units; while the gangue—principally quartz, rhodonite, and garnet—escapes through the outlet in the pocket on to an endless belt, where it drains sufficiently to allow it to be sent away, to be used for refilling stopes in the mine. The concentrate settles in the tank till it is full, when the stream is diverted to a similar tank, while the former is drained and the solution returned by air jet to the solution tank. The concentrate is then given a water wash to remove any chemical solution, and then drained. The vat concentrate may be retreated to increase the percentage of zinc, and at the same time to recover some of the galena as a lead concentrate. This may be done on Wilfley or similar tables and vanners, or, for preference, by magnetic concentrators, as the latter give richer concentrate. Some magnetic concentrators are adapted to treat wet material. The zinc and lead concentrate is then sent away for metallurgical treatment elsewhere.

Fig. 7. Workshops, North Mine, Broken Hill

Tables 6 and 7 are an analyses of the feed, concentrates, and tailings of this process.

De Bavay process makes use of the selective actions of CO_2 in attaching itself to sulphides but not to earthy particles. The CO_2 is generated externally.

The Ballot, or granulation, process was formerly known as the Cattermole process. This is an acid-oil flotation process. The H_2SO_4 is added for the purpose of cleaning the surfaces of the particles of oxidized ore, as oil does not adhere to oxidized or earthy surfaces. With freshly broken sulphide the process is said to work well without acid, but the additional acid assures cleaner surfaces, and hence a better separation. The feed, usually tailing, is ground fine in ball mills or grinding pans, the pans giving best results. This ground pulp is then fed continuously without sizing to the agitation vat, where up to 3 per cent. H_2SO_4 is added in a thin stream, and about .05 per cent. of oleic oil is added. A large range of oils can be used.

Table 6

	Feed	Concentrates	Tailings
Insoluble, per cent	49.0	8.0	65.0
FeO, per cent	7.3	10.0	4.4
CaO, per cent	3.9	2.7	4.1
Pb, per cent	3.6	5.8	2.7
Zn, per cent	16.4	14.1	5.1
Ag, ounces per ton	15.3	37.9	2.9

Table 7. Sizing Analysis

Sieve	Feed Per Cent.	Concentrates Per Cent.	Tailings Per Cent.
Caught on 20	.7		1.9
Caught on 40	6.1	4.0	8.4
Caught on 60	10.7	15.5	14.3
Caught on 80	17.8	16.5	16.1
Caught on 100	23.8	20.2	23.3
Caught on 120	12.9	12.7	11.3
Caught on 150	11.2	11.3	13.2
Through 150	16.8	20.0	11.9

After passing through the agitators the pulp passes through three spitzkasten separating boxes in series. The ore particles are floated over the lips, while gangue passes into the next for retreatment, and from the third is discharged into settling tanks, where the solution is decanted, and the drained tailings are sent to dump. The action is as follows: The acid cleans the surface of the metallic sulphides; the oil attaches itself to the clean sulphide surfaces, the agitation causing numerous small air bubbles to be carried down and held in suspension in the pulp, until they attach themselves to the greasy surfaces. The pulp then coagulates into little lumps, hence it is termed the granulation process. The concentrates assay, on the average: Zinc, 43 per cent.; lead, 11 per cent.; silver, 17 ounces. The percentage of zinc is moderate, and that of lead is so high that it might be advantageous, for both metallurgical and economical reasons, to put the granulation process concentrate through magnetic separators to remove a portion of the lead as a separate lead concentrate, as is found advisable in the Delprat process.

This process has the great advantage of giving good results in the presence of slime and has been installed on a large scale at the Central mine, Broken Hill, for the continuous treatment of tailing. The flow sheet of this mill deserves special attention, as the process is continuous, giving lead concentrate, zinc concentrate, and worthless tailings.

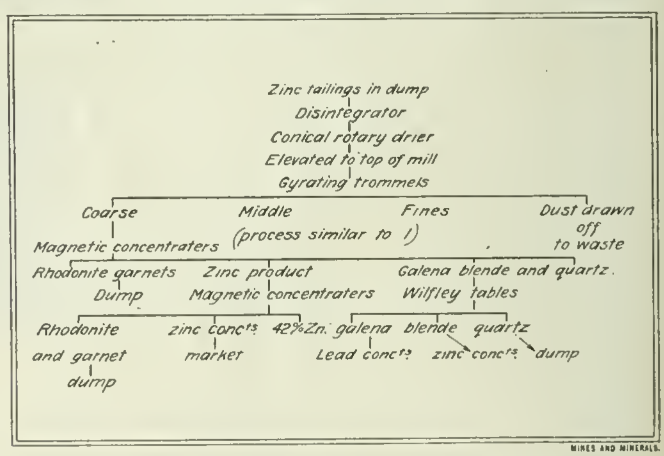

Fig. 8. Broken Hill Central Mine Process

The vacuum oil process has recently been introduced at the Zinc Corporation Works at Broken Hill.

The process is based (1) upon the fact that in flowing pulp of crushed oil and water, oil has a selective action for the mineral particles as distinct from the rocky particles or gangue. (Thus far it follows the original Elmore process.) The selective action is materially increased in some cases by the presence of acid (a modification made since the introduction of the Potter process). (2) Upon the fact that the air or gases dissolved in milling water are liberated, partly or entirely, upon subjecting the same to a pressure less than the surrounding atmosphere. These liberated gases may be augmented by the generation of gases in the pulp (as in the Potter process or the Delprat process), or by introduction from an external source (as in the De Bavay process). These liberated gases attach themselves to the greased mineral particles (as in the Cattermole process), and, being largely increased in volume as a result of the vacuum or partial vacuum applied thereto, cause the greased particles with their attendant bubbles of air or gas to float to the surface of the liquid from which they are automatically discharged in the form of a rich concentrate leaving clean tailings in the bottom of the vessel in which the operation has been conducted. The application of a vacuum to increase the floating power of the adhering gas is distinctly novel to this class of process, and takes the place of the simple expedient of heating the solution as in Potter, Delprat, Cattermole, etc., processes.

The crushed pulp from a wet crushing mill is mixed with oil and acid in an agitator. It is thence under the influence of a partial vacuum drawn up into a vacuum separating pan. The metalliferous scum overflows from the top of the separating pan, and is drawn down a long length of water-sealed pipe into a tank. The tailings are likewise, by suitable machinery, raked to the outer edge of the vacuum pans and discharged into a tank in a similar manner to the concentrates.

It is claimed that this process, like the Cattermole process, successfully deals with slimes mixed in the pulp.

It is very desirable in operating ore-dressing mills to sample and assay not only the crude ore entering, and the products leaving, the mill, but also to know the assay value of the various intermediate products at successive stages. It enables the mill superintendent to daily analyze the work under his control, and also to localize the blame on any shift or individual for indifferent results, e. g., one man on each of the three shifts looks after the same, say three jigs. Samples of concentrates and tailings for these jigs go to form one average sample of concentrate, also of tailings for each shift. Each sample should be separately assayed, and the result posted in the mill. Blame may then be localized on individual operators, the moral effect of which is good. In all cases the tonnage is determined by weighing each truck of ore before it is tipped to the breakers.

There are two general methods of determining the average assay value of the crude ore. In the first and more rational method the ore fed to each set of rolls is sampled, say a scoopful of the total stream, i. e., coarse and fine, is taken at intervals, say, of ½ to 1 hour, the total quantity going to form the average sample of the mill for the 8-hour shift or the 24-hour day. The average assay value of crude ore is fairly uniform and not patchy. The average assay value taken in conjunction with the weighed tonnage gives a firm basis to calculate the total metal contents of the crude ore, and hence, later on, after the metal contents of the product have also been ascertained, to determine the actual and percentage recovery of lead, zinc, and silver. The other method in use is to weigh or estimate the weight, sample, and assay the products, and thence by back calculation to determine the average assay value of the crude ore. This method is defective, in that it is difficult to sample and weigh the slime slurry going to temporary waste, except by the roundabout and uncertain difference in the total weight in balancing the total of the other products against that of the crude ore. The final products have high percentage of moisture when sampled. There is thus a large amount of balancing and calculation to ascertain the value of the crude feed which can be more readily and directly ascertained. It should not be overlooked that the mines using the back calculation of values usually show on paper better percentages of recovery than those directly sampling the crude feed. The intermediate products, such as the concentrates and tailings of jigs, tables, and vanners, are sampled by diverting the whole stream from the launder into a drum, a short length of launder or sheet metal being used for the purpose. The product is allowed to settle, the excess water poured off, and the sample placed with its own cosamples to form the average sample for the shift. The shipping value of concentrates is ascertained by sampling with an augur each truck if shipped loose, or each bag if bagged. The samplings are placed in a drum provided with a close-fitting lid to prevent evaporation of moisture until the bulk sample is quartered down and the moisture per cent. ascertained. Bulk samples are quartered down in the same way.

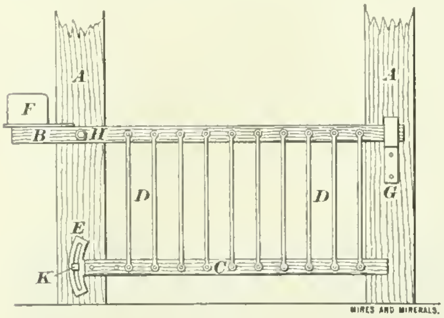
It might be well to state that the percentage of rhodonite in the ores varies very considerably at different parts of the lode. The following is said to be a fair average percentage of rhodonite in the ores of the following mines:

	Per Cent.
North Mine, rhodonite	3
South Mine, rhodonite	7
Broken Hill Proprietary, rhodonite	15
British, rhodonite	25
Junction, rhodonite	35
Junction North, rhodonite	45

In crushing, the rhodonite, i. e., manganese silicate, is left in large rounded grains, while quartz and the metal-bearing minerals, especially galena, have a great tendency to slime. These variations in the composition of the ore, which at first sight appears small, greatly affect the physical condition of the ore, and have resulted in considerable modifications of the treatment at different mines.

Shaft Gate—Strong Mine, Victor, Colo.

The shaft gate shown in the accompanying sketch is in use at the Strong shaft, Victor, Colo. The bar B is made of 4″×8″ timber or of any other convenient size. It is pivoted at H by a bolt upon the head-frame leg A and at the opposite end fits into the rest or catch G of ½″×3″ iron. F is a counterweight of the proper heaviness and distance from H to permit of the gate being raised or turned on the pivot H, by a very light upward pull.



SHAFT GATE

Suspended from the bar B by means of the rods D D, etc., is the lower bar C which may be made of lighter material than B. The rods D D, etc., are flattened at the upper and lower ends and bolted to both B and C so that they may turn freely.

Attached to the inner side and on the left end of the bar C is a slotted plate of thin iron, through which the bolt K, set in the leg A passes.

When the bar B is raised by an upward pull near G it revolves on the bolt H, and the rods D D, etc., turn on their upper and lower pivots and the plate E turns downward on the bolt K, the whole gate being, if the term is allowable, collapsed or compressed.

The gate is very simple, can be made by any mine carpenter at a reasonable cost, and is absolutely effective.

The Burt Revolving Filter

Description of the Method of Construction and Operation. The Efficiency Attained

The Burt rapid cyanide filter was invented by Edwin Burt when in charge of the cyanide department of the El Oro Mining Co., El Oro, Mex. This is especially adapted for treating slow-settling slime which usually contains a large percentage of colloidal substances.

The Burt revolving filter, a more recent invention, is designed for handling granular slime, a mixture of fine sand and slime, or similar material, which will settle quickly and form cake readily. Both are pressure filters, the compressed air used ranging from 25 to 40 pounds per square inch, depending upon the physical conditions of the material to be treated. If local conditions will permit, the slime may be made to flow by gravity direct to the filter from the slime agitation tanks, or if this is not possible the slime may be elevated sufficiently high above the filters to give the desired pressure. If conditions are such that it is impossible to adopt either gravity method suggested, then a pump may be used to force the slime into the filters from the agitation tanks and furnish the desired pressure. The Burt revolving filter, shown in Fig. 1, resembles a tube mill from the exterior, the feed end of which is supported on a trunnion *a*, while the other end is supported on the rollers *b*. The slime and wash water are charged through the hollow trunnion and the cake is discharged through the cast-iron door *c* operated by the hydraulic cylinder *d* and the system of levers *e* attached to the piston rod *f*. The filter cloths are made 28 inches wide by 10 feet long, there being five cloths in a circle. These cloths are interchangeable and held in place by the angle irons shown in Fig. 2, the irons being slipped over studs fastened in the shell at the place where two filter cloths meet. In the upper part of Fig. 2 the filter shell relative to the discharge opening in the shell is shown. Each filter cloth has its individual outlet at the center for the filtered solution. The coating which forms on the cloth due to lime put in the solution of cyanide to neutralize acidity is removed whenever necessary without removing the cloth by giving it an acid wash from time to time. There are 25 filter leaves in a 40-foot revolving cylinder and any one can be changed in a few minutes.

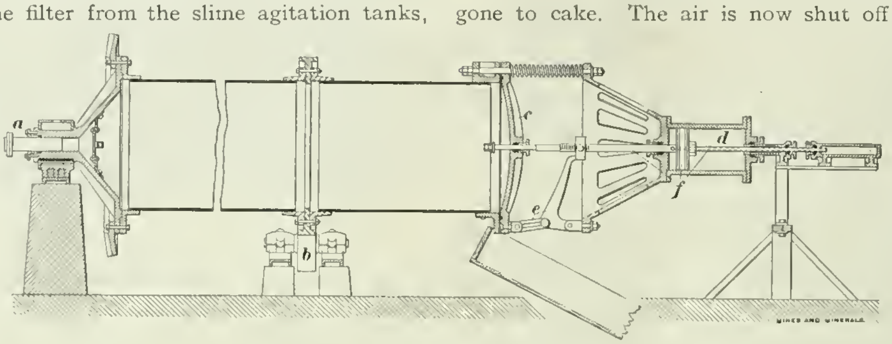


Fig. 1. Section, Burt Revolving Filter

During the cake-forming period the filtrate passes through the filter cloth and out through holes in the shell on to a cement floor, from which it flows to a receiving sump. The end period of cake forming is ascertained by the filter blowing air rather than water through the holes in the shell.

The discharge door, with opening and closing attachments, is shown in Fig. 3, and consists of a cone-shaped casting *a* to which one end of each of the six toggle arms *b* is fastened and held in position relative to the end of the filter shell by means of heavy rods or bolts that are surrounded by springs *c* which aid in closing the discharge door. The door is opened and closed by means of the piston in the cylinder, hydraulic pressure being used for the purpose. From one end of each of the six toggle arms *b* a lever *d* extends from the toggle joint to the center of the piston rod on which is located a large iron collar *e*. When the springs push the door shut the ends of the six levers converge toward the piston rod, and being in the path of the collar, as the piston rod is allowed to slide through the door a few inches after it is shut, the collar comes in contact with the ends of the levers, pushing them forward, thus straightening out the toggles and exerting a tremendous pressure at six different points of the door. In the course of operation, the discharge door being closed as shown in Fig. 3, slime is fed into the cylinder by means of a valve in the trunnion. After a proper charge has been admitted to the cylinder the slime valve is closed and an air valve opened; then from 25 to 45 pounds of air pressure is admitted to the cylinder and maintained until all the slime has gone to cake. The air is now shut off and wash solution is admitted. In case there is sufficient hydrostatic head to the wash solution to overcome the pressure of air in the filter, it is allowed to enter at once, but if there is little head to the solution the escape valve to the filter is opened and the pressure dropped sufficiently to permit the washed solution to enter the cylinder. The required amount of wash solution is run in, after which the valve is closed and more compressed air used to force the wash solution through the cake. When the filter starts blowing, the air pressure is again turned off and wash water is admitted to the cylinder in the same manner as the wash solution, and when the filtering operation is finished, the air pressure is removed and the door opened in order to discharge the cake. Little water is required in discharging slime cake, it being necessary only to add enough to make the canvas slippery so that when the cake forms into a round loaf it will slide in, and move toward the discharge door. This water is added in a small amount at one time, just as the cake falls, and is estimated to be about 100 pounds per ton of dry slime.

Table 1. Screen Analysis of Filter Feed

Mesh	Percentage
+100	2.6
+150	23.2
+200	8.4
−200	65.8

When operating this filter it is revolved continuously at 15 revolutions per minute.

In Fig. 4 the washing efficiency of the Burt revolving filter is shown in diagram made from tests conducted at El Oro, Mex. This diagram shows the average rate of removal of gold, silver, total value, and cyanide during washing, with the quantity of barren solution in tons per ton of dry ore per day. The number of charges put through a filter is 13, the average thickness of the cake produced is 4.3

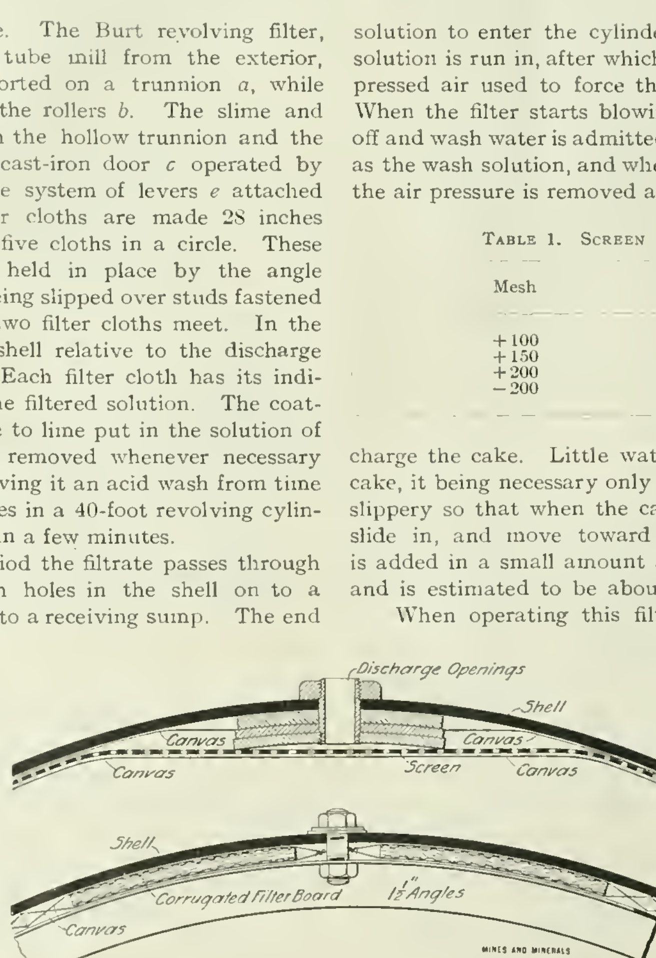

Fig. 2

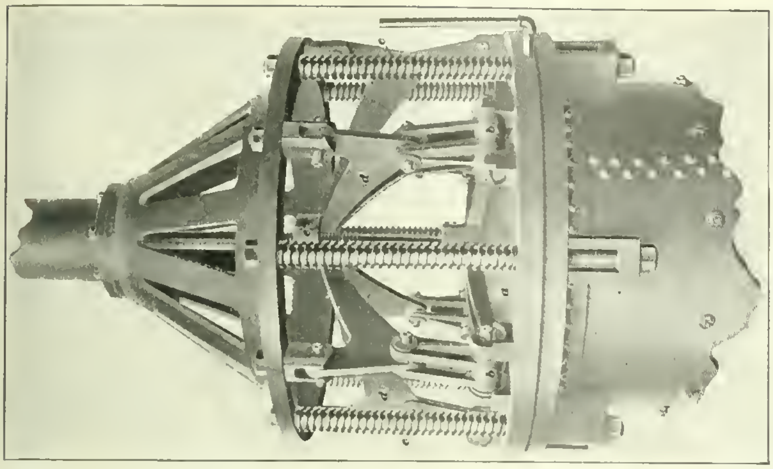

Fig. 3. Discharge Door Mechanism

inches; the average dry metric tons treated per charge is 5.24; the average pressure per square inch during the caking period is 38 pounds; the average pressure per square inch during washing is 48 pounds. The table on page 234 is given as an average screen analysis of filter feed used for the tests.

The average percentage of colloidal matter in the material fed to the filter was 38.4. The ratio of solids to liquid and pulp fed to filter was 1 to 1.126. The extraction during filter pressing was, gold, 22 cents; silver, 1.1702 ounces; total value, 80 cents.

The advantages claimed for the Burt revolving filter are that the discharge door opens wide and will admit a man to inspect the filter shell and do any necessary repairs; that there is no excess slime solution or water to be handled; that the filters can be driven from any convenient shafting or by small motor, as very little power is required; that little water is needed for discharging; that the filter requires about one-fourth to one-half of the power required to operate the vacuum filter, due to there being neither surplus slime, barren solution, wash, or wash water to return, as everything that goes into the filter comes out through the filter leaves and the shell except the solid slime.

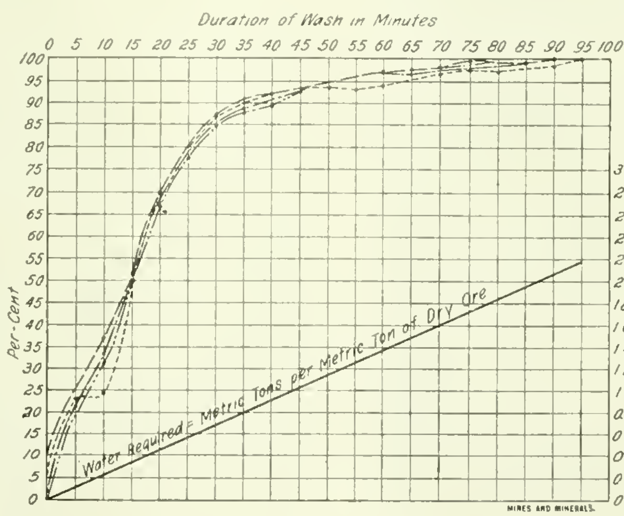

Fig. 4

In Fig. 5 is shown a battery of three Burt revolving filters in operation at the El Oro Mining and Railway Co.'s operation, El Oro, Mex. These filters are revolved at 15 revolutions per minute continuously during the operation of filtering a charge. At this plant they are filter pressing and washing over 27,000 tons of ore monthly with 2,400 square feet of filter surface. In the revolving filter ½-inch thick cake is formed in a minute or two, the balance, 3.8 inches on an average, forming on this quickly owing to the air pressure inside the cylinder forcing the solution out of the slime.

Uses of Soapstone

Laundry tubs, griddles, foot-warmers, and many other similar utensils are manufactured from soapstone. The higher grades of massive talc, free from flaws, are sawed up to make pencils or crayons, French chalk, gas tips, and many special articles.

What Brazil Offers Prospectors

A Country Known to Contain Gold, Silver, Platinum, Iron, Manganese, Diamonds and Other Gems

By George H. Mee

Glancing at a map of Brazil one finds a country covered with almost a net work of rivers, their basins being divided by long mountain ranges, whose altitudes vary up to 7,000 feet, tending north and south, with the exception of the central plateau, where the ranges run in all directions.

One of the highest of the Brazilian mountains, the Itatiaia, some 9,000 feet high, is composed chiefly of hornblende, syenite, tuff and clink-stone, characteristic of ancient volcanic centers.

It is impossible to fully describe the mountain system and the immensity of the country, so ancient, and at the same time so new and unknown, for until the nineteenth century gold was almost the only mineral mined in Brazil.

One of the principal ranges of mountains, known as the Espinhaco or in English, the Backbone, is noteworthy from the fact that the older crystalline rocks, gneiss and granite, are subordinate to the series of ancient metamorphic schists, quartzites, and limestones, and to a later series of sandstones and conglomerates.

The older crystalline and metamorphic rocks are sharply folded and the newer series rest unconformably in gentler folds on their upturned edges, forming the mountain peaks most predominant in the Espinhaco, some of which attain 6,000 to 7,000 feet.

In this series of mountains the metamorphic schists are rich in iron, manganese and gold ores, whilst the sandstone series is in places diamondiferous.

A flexible sandstone called itacolumite is a characteristic of the districts of Diamantina, Grao Mogul and Minas Novas in the state of Minas Geraes and also in certain districts in Bahia.

It is difficult to point out any particular locality as being better worth prospecting than another, as the whole of the

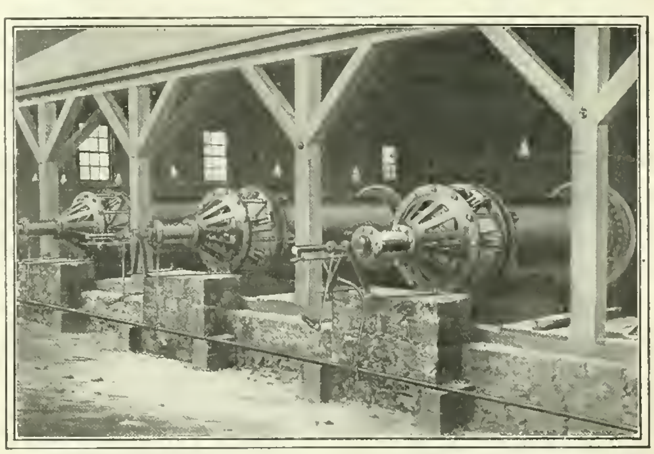

Fig. 5. Battery of Revolving Filters at El Oro

Epinhaco and its offshoots is auriferous. The state of Minas Geraes is the most important center of the gold-mining industry, although it has already been fairly well exploited. One of the richest and principal mines in the state, the Morro Velho mines yields $125,000 in gold monthly, and its expenses are about $60,000.

This mine, the deepest in South America, is over 4,250 feet deep.

The most promising speculation is placer mining, by means of dredging and hydraulic sluicing of the high banks of gravel left by ancient miners in many localities. The upper portion of the River Doce, Rio de Contas, Pardo, Paraguassa River and the Itapicuru, all falling into the sea between Espirito Santo and the Sao Francisco, are well worth prospecting; for both gold and diamonds.

The minerals usually associated with gold and diamonds in the deeper gravels, and as yet untouched, are porphyrites, chalcedony pebbles, black tourmalines, rutile, hematite, magnetite, and emery.

In spite of nearly 350 years of mining, hardly a month passes without some lucky find is reported. In 1909, nuggets were found at Montes Claros that weighed from 1 ounce to 1¼ pounds, and a diamond found at Dos Dourados in Minas weighed nearly 18 ounces, and was of the first water.

Something should be said of the diamonds found in Brazil. The most famous is the Estrella de Sul, which is 254 carats, and was found in the Bagagem River. The Dresden diamond is 177 carats, and the Coroa de Portugal 120 carats.

As stated, the river gravels are most productive of these stones in the state of Minas Geraes, the principal rivers being the Abaete, Bagagem, and Cocaes.

In the state of Bahia they are found in the Sincora and Lencoes district and at Salobro, 2 feet below a white clay decomposing soil, also in the Stapicuru River in the gravels.

Only a very small area of the alluvium has been explored and most of the river gravels are untouched at 20 to 50 feet below surface of the water, and at the very least the gravels contain enough gold to pay for the dredging.

Coal mining in Brazil seems to be in its infancy. The total thickness of the thin beds of coal at Tubera in Santa Catherina, is about 10 feet and they grade between lignite and ordinary bituminous coal. In Para there are small coal deposits, but of no commercial value. The Santa Catherina coal is suitable for making briquets and about half can be used in the ordinary way.

Manganese ores in Brazil average 45 per cent. of the minerals of commercial value, are remarkably free from sulphur and phosphorus, while iron is found everywhere.

Graphite is found in veins varying from 20 to 40 inches thick, near the Jequitinhona River, but it is not as yet mined.

In the state of Minas, galena is found in calcareous, or in quartz veins and is always argentiferous. It occurs near Diamantin, Caethe, Sete Lagoas, Montes Claros and Abaete. This Abaete deposit has been assayed, and produced 40.25 per cent. lead with about 6 ounces of silver to each 200 pounds of the metal.

Platinum is found in many of the rivers in small quantities, and zinc as a sulphide is found in the granite rocks.

Quicksilver is found in Brazil, but to no great extent.

Silver is found in various parts of the country, but the industry has not been developed, although that it was recovered by the early Spanish explorers might be assumed by the fact that some 20 years ago a relative of the writer was engaged in removing some of the contents of an old Spanish ship, which had been sunk in a few fathoms of water off the coast of Rio de Janeiro. Using a complete diving equipment, he secured at great personal risk a large number of silver coins besides a few gold pieces and other trinkets.

Amongst the collection of big brass keys and other things, were two broken ingots of silver about 4 in. × 8 in. in diameter and very roughly molded.

No authentic statement could be made as to the age of the wreck, but it was believed to be at least two centuries old.

The Brazilian mining laws are based on the best features of those elsewhere and the taxes payable are from ½ per cent. to 10 per cent., with the exception of the taxes for monazitic sands which are very heavy, but it is claimed that the profits afford sufficient recompense for this import.

The beds of monazitic sand extend from the south of Bahia to Santo Espirito, and the two main deposits are in the hands of concessioners who fix the price for oxide of thorium, there are other deposits, however, that are as yet unworked.

A large quantity of copper is mined in Rio Grande do Sul (Camaquam) and in Bahia in the vicinity of Sao Francisco River, Maranhao, and Santa Catherina district.

Amethysts are found in many of the states and even within a few miles of the city of Rio de Janeiro, in the decomposed rocks of granite base. These stones are principally found in Bahia, Minas, Minas Novas, and Rio Grande do Sul, where the great Drusy cavity was found by German agate miners. Some 15 tons were taken out and exhibited at Dusseldorf in 1902, the crystals being an inch long and of the deepest violet color. This mass was found in a coastal range at 2,000 feet above sea level. Some amethysts have been found half yellow and half violet.

Green tourmalines are found in the Riveriras de Tolha, near the Chapada Dimantina, and fine blue, yellow, white and pink gems are found at Minas Novas.

It may be stated that all the northeast of Minas is noteworthy for the abundance of this crystal, and some of it is found with green ends and pink center.

Yellow topaz is found in a short range of hills close to Ouro Preto, in the flexible sandstone, itacolumite, and clay slate. Rock crystal is plentiful in Minas and is more or less common in all the states.

Agates may be found in the Rio Grande do Sul, as rounded pebbles in the rivers, and almost every variety is encountered including crocidolite, or tiger eyes, carnelians, and onyx.

Persons who have lived in Brazil claim that the adventurer has nothing to fear from the climate, and the government report on the death rate per 1,000 in 1908, was only 20.2.

Nevertheless malarial fevers are found in the Amazon valleys and several Americans, known to the writer, were striken with the disease known as beri-beri which causes the limbs to swell from the feet up and causes death on reaching the cardiac organs. The only reliable cure for this is an immediate ocean voyage which will invariably arrest the progress of this disease if it is not too far advanced.

The bulk of menial labor in Brazil is performed by the Guaranis Indians, who are generally strong husky fellows, but the bulk of the population is crossed in all directions, the natives having mingled foreign strains amongst themselves until by far the greater proportion are divided into the following groups: Mulattoes, Mamelucos (descendants of aborigines and white men), the Cafuzos (crossed between negroes and Indians). The lowest type of Indians found in Brazil are the Tupi, who although nearly disorganized, still keep up hereditary feuds, plunder and murder whenever opportunity occurs, and avoid contact with foreigners and despise their inventions.

Transportation is improving every year and new railroads are under construction, while at present there are 12,000 miles of track in use with all modern equipment, the completion of the roads will almost double the present railroad facilities.

Like all other South American Republics, Brazil suffers from too frequent changes in its government, but in spite of all the drawbacks it is being rapidly developed in the most modern and up-to-date manner, and there is still plenty of space not yet explored, for those who hunger for pioneer work and are willing to take a few chances.

A Spanish Iron-Ore Treatment Plant

Method Employed at a Spanish Mine for Briquetting Fine Iron Ores Without the Use of a Binder

By Special Correspondent

At the present time there is a growing tendency owing to the gradual exhaustion of iron producing areas and the growing scarcity of iron ores, to combat the increasing difficulty of securing supplies by endeavoring to utilize the finer ores which formerly were considered unsuitable for the needs of iron works, and by suitable processes of briquetting to convert them into a condition suitable for the blast furnace. The last 20 years, and particularly the latter half of the period mentioned, have been particularly fruitful in the application of experimental methods on a practical scale to the briquetting of iron ores without the use of binders.

The briquetting of iron ores has been attempted by methods which may be classified into processes using organic binders, such as pitch, tar, or other substances, processes utilizing hydraulic lime or some other binding material of a calcareous nature, processes adopting the use of clay, and lastly, but by no means least, those processes which do not use any binding material whatever, but which depend on the softening and agglutination of the particles of the mass under a heating process. This latter method, which is one which in practice has been found to be most successful, is the one which it is proposed in this article to describe and illustrate by particular reference to the process adopted by the Alquife Mines and Railway Co., Ltd.

The screening and briquetting plant of this company is erected at Guadix, in the province of Granada, Spain, and was constructed by Messrs. Sutcliffe, Speakman & Co., Ltd., of Leigh, Lancashire, England. The plant has been sufficiently long in operation for an estimate to be formed both of the technical and financial success of the process. It has been found that properly made briquets have power to resist a high crushing strain have a high specific gravity, and are very porous. Hence, they are in the best mechanical condition for the furnace. Further, sulphur, even when contained by the raw ore up to 5 per cent. can be eliminated during the process down to a content not exceeding .01 per cent. The briquets in general are much richer in iron than the raw ore, due to the elimination of carbonic acid, sulphur, combined water, and other volatile matters; in some instances this enrichment is as much as 12 units of iron. When properly burnt in a neutral or oxidizing atmosphere, the oxides exist in the ferric state, leaving them in a condition the most favorable for reduction in the furnace. It has been proved by actual practice that the use of briquets

Fig. 1. Lower Part of San Jose Mine, Spain

increases the output of the blast furnaces, and it has also been proved that a blast furnace working on briquets requires less fuel to operate. From the above it will be seen that the value of briquets cannot merely be taken to be the same as lump ore; their special qualities are such that they demand a special basis of value. As instances of the result of briquetting,

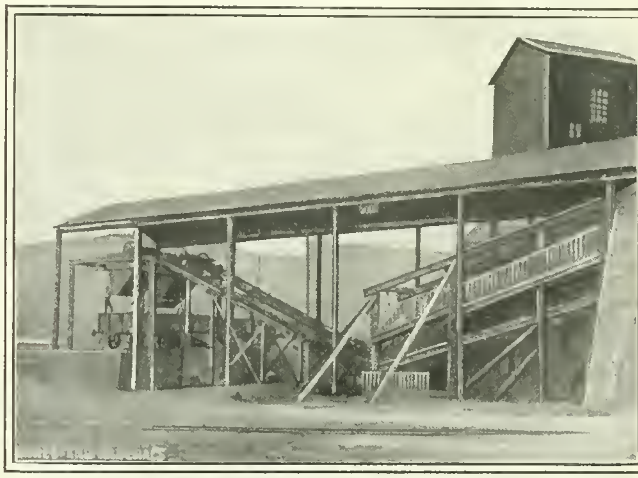

Fig. 2. Ore Screening Plant

the following analyses of Spanish ores before and after treatment are instructive:

Raw Ore When Dried at 212 Degrees

	Per Cent.
Iron	54.31
Silica	5.09
Combined moisture	13.75
Iron in same ore as received from mine	46.58

Results After Briquetting

	Per Cent.
Peroxide of iron	85.74
Peroxide of manganese	1.54
Silica	7.98
Metallic iron equals	60.02
Sulphuric acid	.20
Phosphoric acid	.10
Alumina	2.85
Actual sulphur contents	.98

Crushing strength, dry briquet, 92 kilos per square centimeter; wet briquet, 89 kilos per square centimeter; porosity, 6 per cent. of water absorbed; tensile strength, perfect, same in the interior as the exterior.

The results from another Spanish ore are interesting. The dried ore before briquetting contained, iron, 47.91 per cent.; manganese, 4.55 per cent.; silica, 11.48 per cent. While after briquetting the constituents were: Iron, 53.45 per cent.; manganese, 5.15 per cent.; and silica, 12.25 per cent.

The Sutcliffe process, adopted at the Alquife plant, consists in mixing the ore with a suitable proportion of moisture, afterwards turning it into briquets in powerful presses, and burning the briquets in suitable kilns. Fig. 2 is the ore-screening plant, Fig. 3 the entrance to the briquetting kilns, while Fig. 5 shows the briquets as they are brought from the tunnel kilns.

Some classes of ore do not require any particular preparation, being already in a proper condition for feeding direct to the briquetting press, such ores as purple ore and some pyrites coming under this class. Other ores require the addition of moisture, which can be effected in a differential mixer. This consists, as made by one firm, of two shafts running in opposite directions in a suitable trough, one shaft revolving at twice the speed of the other. The knives are cast iron, fitting over square shafts, the ends being chilled. Again other ores are improved by being ground, mixed, and kneaded in an edge-runner mixing mill, whilst others again are improved by being finely ground. The object of this preparation is to enable a briquet to be made from the mixed material as dense and solid as possible, as the denser the briquet going to the kiln, the less fuel is required to burn it. The reasons for this are, firstly, that a dense briquet transmits heat more readily than one of less density, even if made from the same material, and the burning is achieved just when a certain temperature is attained; hence, the more readily the briquet takes up the heat, the quicker it is in burning. Also the result of the burning is to soften the particles of the ore until they stick together, and the closer the particles are together, the more readily they will agglutinate. The density of a briquet is much affected by the amount of moisture used in the preparation of the material, thus in some cases high percentage is required to get a dense briquet, while others are better if pressed in a dry condition. Again, some ores are in a cellular condition and require breaking down in a pan mill before a dense briquet can be pressed from them. The Emperor presses used at the Alquife works each consist of a horizontal rotating table containing the molds, and, depending on size, there are from eight to twelve molds. The table is rotated one mold at a time in such a manner that while one mold is receiving the charge of material to be pressed, another is under pressure, and a third is under the discharge ram. The feeding is automatic, being effected by means of a circular pan in which revolves a series of stirrers which prevent the material choking up, and insures a regular and constant feed. The quantity of material fed to the molds is regulated by means of a hand wheel, and as this can be turned whilst the machine is in motion, the pressure can be regulated at will. The pressing mechanism is of the toggle and knee type, and the pressing is so effected that all the strains are on massive steel bolts, thus taking all the greater strains off the frame work. All levers and parts subject to great strains are made from cast and forged steel, and adjustments are made for taking up wear and tear. The molds are easily and quickly relined, and in putting in new liners no fitting or adjustment is required; the liners go direct into place, and thus the time taken up in relining the molds is reduced to a minimum. Furthermore, each set of liners can be reversed, giving two wearing faces. All its principal working parts are above the level of the table, thus preventing wear otherwise caused by sand and dirt falling into the bearings. A patent expression attachment operates by giving each brick two pressings, the first squeezes and presses the material from the center into the corners; the final pressure finishing the brick. By these means each brick is of even density throughout, with fine sharp corners. This arrangement is shown on the sectional drawing in Fig. 4. The mold receiving the first or preliminary pressure is shown at *a* and the final pressure at *b*. The working pressure of the machine is 100 to 150 tons, and the power required to operate it is from 5 to 10 horsepower. It operates smoothly and easily, and owing to powerful springs is evenly balanced.

Fig. 3. Entrance to Briquetting Kilns

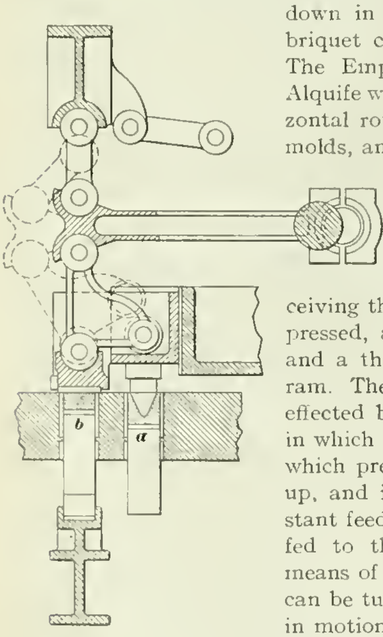

Fig. 4

The kilns used at the Alquife are of the tunnel type, consisting of a tunnel or series of tunnels 5 feet in width and in length from 150 feet to 200 feet, through which a series of cars are passed, touching each other. The briquets of convenient size are piled in two, three, or four layers on the top of the cars. The loaded car is then pushed in at one end of the furnace, a car load of burnt briquets being simultaneously forced out from the opposite end of the furnace. The sides of the cars are fitted with deep flanges which run on a trough on each side of the inner wall of the furnace, which troughs are kept filled with sand, thus ensuring the furnace being air-tight. The space below the cars is thus entirely closed off from the chamber above the cars. The cars are also covered with a thick firebrick covering; hence, damage to the car wheels or axles is entirely prevented. The combustion chamber is situated near the center of the furnace, and the arrangement is such that the products of combustion pass over the incoming briquets, to which they impart their heat, while the briquets, after passing the combustion chamber enter the cooling section and are cooled by the entering air of combustion.

The economic value of the processes above described is undeniable. Perhaps some additional interest is given to the matter in connection with Spanish minerals in that there is no doubt that an exchange trade to Spain, say with either finished American goods or even coal as an export, and the briquetted ore as an import, should be of advantage to American industry. Quite apart from that, however, the extension of knowledge with regard to the economical treatment of badly paying ores is a distinct asset, and such as will be of interest to mining engineers.

Natural Salt Deposit

There is stated to be a large natural deposit of Epsom salts on the international boundary line at Bitter Lakes in the Similkameen Valley below Keremeos, near to the Great Northern Railway, containing, it is estimated, some 70,000 tons, 98 per cent. pure. A shipment of 44 tons is said to have been recently sent to Spokane and analyzed as stated.

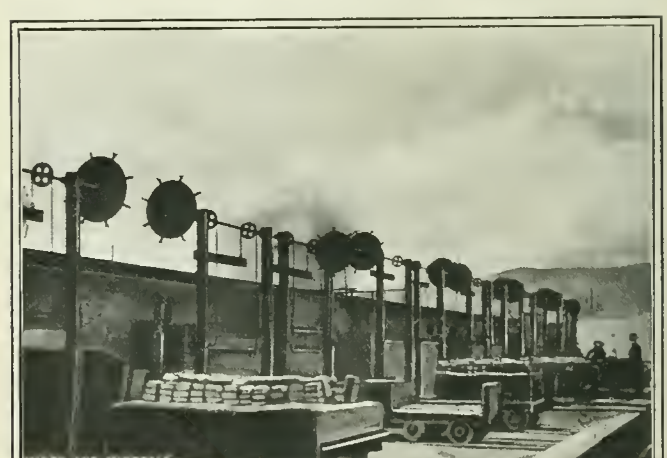

Fig. 5. Briquets Coming from Kilns

Air-Lift Agitation of Slime Pulp

The Relative Merits of Air and of Mechanical Agitation in the Operation of the Cyanide Process

*By E. J. Laschinger, M. E.**

[Note.—This article, while part of a criticism on a paper presented to the Chemical, Metallurgical, and Mining Sociey, of South Africa, by Robert Allen, M. A., B. Sc., contains so many practical hints and suggestions it becomes at once of interest to every cyanide man. Mr. Allen advocated air rather than mechanical agitation. Mr. Laschinger does not approve of this at the present stage of cyaniding because he considers that knowledge on the subject is deficient.]

If the problem on the one hand is simply to bring particles of ore into thorough contact with cyanide solution, or to keep ore from settling in water or solution, or on the other hand to also bring air for the purpose of supplying free oxygen to this intimate mixing process, the two cases are not on a par when considering simply the most economical means of agitation. If air be necessary as a chemical adjunct, it is self-evident that subsidiary mechanical stirring is superfluous if the air by its method of introduction can perform the mixing at a reasonable cost without other aids.

Mr. Allen has not proved his case in favor of air agitation in a satisfactory manner, because he has not even attempted to differentiate between the various cases above mentioned.

It requires a certain amount of power to compress air, and this power can be accurately determined. Theoretically, the minimum work required to compress air from atmospheric pressure to any other pressure is by isothermal compression; i. e., without rise of temperature during the process. The work thus required to compress a cubic foot of air is:

$$(1) \qquad \text{Work in ft.-lb.} = 144\, P_a \log_e \frac{P_1}{P_a}.$$

Where P_a is the absolute atmospheric pressure in pounds per square inch, P_1 is the absolute pressure of compression; i. e., gauge pressure plus atmospheric pressure, say, P_g P_a.

The horsepower required per cubic foot of air at atmospheric pressure compressed per minute is therefore:

$$(2) \qquad \text{H. P.} = \frac{144\, P_a}{33{,}000} \log_e \frac{P_1}{P_a}.$$

For conditions at sea level with a barometric pressure equal to 14.7 pounds per square inch, we have:

$$(3) \qquad \text{H. P.}_s = .0642 \log_e \frac{P_g + 14.7}{14.7}.$$

For conditions on the Rand with average barometric pressure equal to 12.1 pounds per square inch, we have:

$$(4) \qquad \text{H. P.}_r = .053 \log_e \frac{P_g + 12.1}{12.1}.$$

The above gives the theoretically minimum figures of power required. In practice there are power losses in compression, friction losses in the motor and compressor, heat losses in compression, and leakage losses past valves and pistons. The over-all efficiency of small compressors is probably not more than 50 per cent.; even in large compressors the total efficiency will not be much greater than 65 per cent. Assuming an all-around efficiency of 60 per cent., the actual power required will be one and two-third times the figures given by formulas (2), (3), and (4). In Fig. 1 are isothermal compression curves which show the power required to compress 10 cubic feet of air per minute from atmospheric pressure to 40 pounds per square inch gauge pressure. Curve S shows the theoretical horsepower required at sea level, and curve R the same for average Rand conditions; curves S_1 and R_1 the corresponding power with an over-all efficiency of 60 per cent.

Before using this diagram to criticise certain figures quoted by Mr. Allen a digression is made to point out a few distinctive features of air agitation. A glance at the diagram shows that it requires less work to compress a cubic foot of air at atmospheric pressure (generally called "free air") to any given gauge pressure on the Rand than at sea level. If it be assumed that the amount of work got back from the compressed air in stirring the pulp is equal to the work put into it in the two cases, the conclusion is that for the same amount of agitation more volume of free air would have to be used on the Rand than at sea level to produce the same mechanical effect. The amount of air used on the Rand would have to be increased in inverse proportion as the work per cubic foot is greater at sea level than on the Rand.

If a certain amount of air be required to satisfy chemical reactions, then the air required must be measured by weight and not by volume. Since air at sea level averages 13.2 cubic feet per pound, and on the Rand 16 cubic feet per pound, it follows that in order to deliver the same weight of air 21½ per cent. more volume of free air must be compressed on the Rand to furnish the weight of air that would be delivered at sea level. For this case, therefore, the amount of power required would also be greater on the Rand than at sea level. Curves of power required for equal weights of air delivered would on the diagram

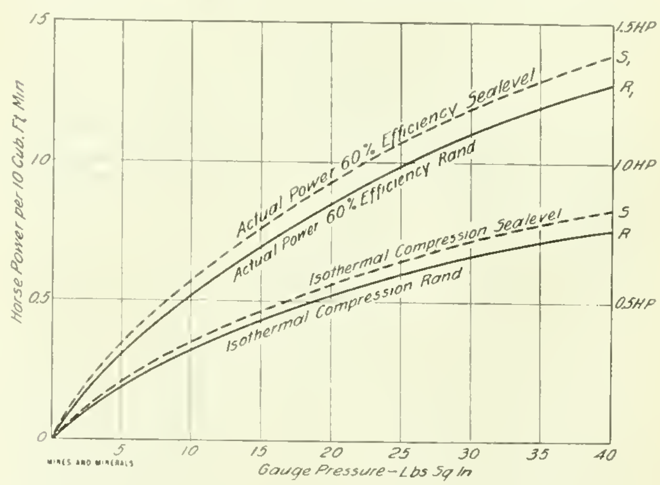

Fig. 1

show the R curve above the S curve. In general the above reasoning is true for different altitudes.

It may also be of interest to discuss the point as to how much of the power put into the air is really effective as mechanical work in agitation. Air agitation in a Brown or Pachuca tank with the central pipe is the reverse of hydraulic air compression. In tests made on this form of compression the over-all efficiency ranges between 70 per cent. and 80 per cent. It may be assumed that the same ratio holds good in air agitation. The over-all efficiency of air agitation from work in the motor to agitation in the vat is therefore $.60 \times .75 = .45$, or 45 per cent.

Taking now Mr. Allen's first table of average results of experiments by F. C. Brown, and assume for argument sea-level conditions, then for comparisons, taking the quantity of air used as correct:

	Per Table	From Diagram
First case horsepower.......	¾–1	1.1–1.4
Second case horsepower.....	⅓–½	.4–.6
Third case horsepower......	1½–2	1.6–2.2
Fourth case horsepower.....	1¾	3.9

In the fourth case the theoretical horsepower required works out at 2.4, therefore, the amount of power quoted, namely, 1¾, may be dismissed in certain familiar words of our old friend Euclid.

*Johannesburg, South Africa.

In actual practical design a liberal allowance on the power required as found from the diagram should be made.

With regard to the power required by the Pachuca system, there is simply the statement that "pulp containing 100 tons of dry slime to 150 of solution can be treated with 4½ horsepower."

Figuring out the probable power consumption for the air lift agitation in the Luippard's Vlei plant as quoted by the author, say, 85 cubic feet of free air (presumably per minute) at between 25 and 30 pounds per square inch gauge pressure the diagram gives from 8.3 to 9.3 horsepower, probably from 9 to 10 horsepower in actual practice.

The above proves that either the horsepowers quoted by Mr. Allen are wrong, or that the quantities of air as given are not correct.

In discussing the remarks anent mechanical stirrers, such as "clumsiest constructions," the necessity of "digging out the paddles after a short stoppage," it might be pointed out that mechanical devices need not be clumsy, and paddles need not be dug out if the machinery be designed properly.

Mr. Kniffen, in "Methods of Pulp Agitation," says that "if the ore only requires that fresh molecules of cyanide be brought continually to the particles of metal, and that the air which is included in the solution be sufficient for the reaction, there is no system at present better than arm agitators, raised a few feet above the bottom of the tank, and driven at 800 feet per minute at the outer ends of the arms."

In these remarks I do not advocate mechanical stirring gear rather than air agitation, but in the present state of knowledge there is no doubt but that mechanical devices and air agitation have each their sphere of usefulness in metallurgical processes.

Simple circulation of pulp could be carried out economically by means of a centrifugal pump specially constructed and used for that purpose only. As an example, it would be possible to turn over the whole of the pulp in the Luippard's Vlei vat every 50 minutes at a cost of no more than from 6 to 8 horsepower.

The trouble in the past with most centrifugal pump circulation and agitation has been that the pump has been used for other purposes besides circulation, as for instance, in transferring charges against fairly large heads. The pump was necessarily speeded up to deal with the maximum head, and is therefore very wasteful of power when circulating. The wear and tear on the pump also increases at a more rapid rate than the increase in speed. The over-all efficiency of a low-lift circulating pump, motor, and piping system should be about 50 per cent.

It is probable that the subject of air agitation *vs.* mechanical agitation will turn more on maintenance and capital cost than on power cost.

With regard to the general results found by F. C. Brown, the statement that "the higher the tank compared with the diameter the less the power required," is incomplete, the probable meaning being that this is true only for equal weights of pulp handled. The statement then falls into line with theoretical considerations. For if the height be doubled the same volume of free air is still only required for agitation at slightly less than double the gauge pressure. This means that the absolute pressure is not doubled, and as the work required does not increase at the same rate as increase in pressure, but only as the logarithm of the pressure ratios, considerably less power per ton of pulp treated is required.

Regarding the statement of there being less cyanide consumption with deep than with shallow vats, this result may also be expected to follow partly from the argument, but also because in a deeper vat, owing to the higher pressure of the air, chemical action between the air, the cyanide, and the pulp is more rapid, and the total time of reaction is thus also reduced. On the law that the intensity of chemical reaction is proportional to the mass density of reagents present, it follows that doubling air pressure doubles its density, and the total time is cut in half. Less total air per weight of cyanide present will be required, since only a very small proportion of the total oxygen supplied is really used up by the cyanide, and so again there will be less loss of cyanide by oil, etc., which is carried by the air supply.

There is, however, a very practical point to be considered in fixing the total height of a vat, that is the expense of filling the vat by pumping, because, theoretically even, only half the work done in pumping the vat full can be regained in emptying it, and in practice generally the whole of this power is lost. There is also to be considered the extra cost of building strong tall vats and furnishing suitable foundations to withstand the heavy strains, wind pressure, etc.

A good practical rule of thumb in regard to pressure of air required is to take the figures representing the total depth of the vat in feet and divide this by 2, which will give the pounds square inch gauge pressure required. For example, over-all depth 40 feet requires gauge pressure 20 pounds per square inch. If air be used at a pressure much greater than that so calculated, there is bound to be a serious waste of air, and probably inefficient circulation.

The maximum amount of cooling of the pulp charge due to the expansion of the air used can be readily calculated. If air be allowed to expand while doing work and no heat is added or abstracted during the process, the ratios of the absolute initial and final temperatures are given by the expression:

$$\frac{T_a}{T_1} = \left(\frac{P_1}{P_a}\right)^{\frac{2}{7}} \qquad (5)$$

T_a is the initial absolute temperature (°F. + 461) and T_1 the final temperature; P_a and P_1 being the pressure as used in the formula for horsepower as given previously. The amount of heat abstracted in British thermal units would be for every pound weight of air used.

$$\text{B. T. U.} = .24\,(T_a - T_1)$$

the figure for the specific heat of air being .24. The specific heat of water is 1, and of rock generally .2. Assuming the initial air temperature to be the same as that of the pulp charge and knowing the quantity of free air per minute used, the calculation becomes simple. For the Luippard's Vlei installation quoted by the author, we have the following data:

$P_a = 12.1$, P_1 average $27.5 + 12.1 = 39.6$, T_a say 70°F. = 531° abs.

Quantity of air per minute, 85 cubic feet, = say 5.3 pounds; charge of slime, 150 tons; water, 300 tons.

British thermal units required to heat pulp 1° F. = 660,000.

British thermal units taken by expansion of air per hour, per ° F. = 76.

Theoretical difference in temperature $T_a - T_1 = 152°$.

British thermal units taken by theoretical expansion of air per hour, equivalent to heat abstracted per hour, $76 \times 152 = 11{,}552$.

Cooling effect on pulp per hour, .0175° F.

It will thus be seen that this effect of cooling is absolutely negligible, and could not in practice be even measured after 10 hours of circulation. This point is mentioned because, although Mr. Allen has not touched upon it, other writers on the subject seem to have made too much of it without going into the matter thoroughly.

In this connection, if warming the pulp be necessary to hasten chemical reaction and solution of gold by cyanide, it would be advisable to introduce a jet of steam with the air, as the heat would then be applied in the initial stage of contact of air, cyanide, and pulp, and should thus be more effective in shortening the time of treatment.

The destruction of cyanide by carbon dioxide should be inappreciable for two reasons. (1) the amount of CO_2 added by normal air is very small. Allowing .06 per cent. CO_2 by weight as usual in air, 100 cubic feet per minute supplied amounts to only .22 pound per hour, which would represent .32 pound of potassium cyanide; (2) different authorities say that CO_2 is not a cyanicide in the presence of alkali in solution. In Rand practice, alkaline solutions are always used, quicklime being added for the purpose.

With reference to the air agitation vats at the Geldenhuis Deep, referred to, these were designed 3 years ago. The central pipe was made in telescopic form, so that experiments could be made on the best length of pipe to work with. The plant was finally worked with the upper telescopic pipe as far down as it would go.

Regarding the Luippard's Vlei agitation vat being probably the largest single-charge vat in the world, there are two air-agitation vats installed at the City Deep, Ltd., designed in 1909. Each vat is 32 feet in diameter, 30 feet in height of cylinder, with 8-foot depth of cone, or 38 feet high over all; each vat treating from 250 to 300 tons of dry slime at a charge. The central pipes, 16 inches in diameter, extended about two-thirds of the way up. Air for both vats is supplied by a small compressor belted to a 25-horsepower motor so as to have spare power for emergencies. An emergency air supply pipe is connected to the regular mine air service pipe.

Mr. Allen has suggested that the question of turbo blowers in series to supply air might be looked into, so as to avoid atomized oil in the air. In the present state of engineering science, small blowers would not be nearly so economical as reciprocating compressors. Oil troubles can easily be avoided by proper attention to the lubrication of the compressor cylinders. Soapy water can be used at intervals for lubrication instead of oil, and the oil can be thrown down by a water spray in a suitable receiver, and the combined oil and water emulsion drained off by a suitable trap before the air is delivered to the vats.

The advantages of the shorter central pipe, which advantages are treated of in an article by A. J. Jager, were realized in the City Deep design, more especially the two main points, that it is possible with the shorter pipe to commence operations before the vat is full, and that aeration is more thorough when a thick body of pulp lies over the top of the pipe. In fact, at the City Deep the air can be advantageously turned on when the vat is only one-third full. The air bubbles in the central pipe are comparatively large as they rise, but when they strike the more solid body of pulp over the mouth of the pipe the air is broken up and intimately incorporated with the pulp. With the pipe debouching at or near the surface of the pulp there is a violent disturbance in the center and comparative quiet round the outer circles, but with the pipe opening deeper down, the whole pulp looks whipped and light, and the general appearance of the surface is like a mushroom top, with continuous motion of the pulp from the center to the sides.

Since air agitation is still a young process on the Rand, doubtless it will develop on lines peculiar to local requirements, and Mr. Allen deserves the thanks of the society and local mining circles generally for bringing this matter up for discussion at the present time.

Denver, Colo., was located on the possibilities which Cherry Creek had to offer, first as a camping ground for transcontinental immigrants, next as a settlers' camp, then as a possibility for gold, and finally as a midcontinental city. It is an historical creek, concerning which it is said among other things, that the name boomer was derived. Be that as it may, if reports from Newlin's Gulch prove true the long-sought for original source of the gold in Cherry Creek has been discovered. What is said to be a dike carrying gold has been uncovered a short distance above the old diggings where there has recently been a revival of activity. The dike is reported to be 8 feet in width, and has been traced for a distance of 40 feet. The belief that the gold of the placers came from this dike is supported by the fact that none is found above the place where the dike is located.

Time Keeping at Crystal Falls

Methods of Recording and Checking the Reports of Timekeeper and Foremen

By James D. Vivian

The following paper was presented at the Lake Superior Mining Institute in August, 1911, under the heading "Time-Keeping System of the Crystal Falls* Iron Mining Co.":

In the employment of the number of men necessary to operate a mine, the employer is compelled to introduce a system of time keeping which will insure accuracy in the work, not only as to the distribution of the labor cost to the proper account, but also as to the correctness of the time credited to each employe for the work performed. Many different systems are used at the mines in the Lake Superior district, each

* Crystal Falls.

of which has some good points, and it is with the idea of bringing out a discussion of the various systems that this paper is presented at this meeting. The best method is one by which a check can be had on the person keeping the time, to provide safeguards against carelessness and dishonesty.

An employe is liable to be mistaken in the number of shifts that he claims to have worked during the month, and should he claim more than the timekeeper shows, a check system against the timekeeper will prove or disprove his claim. The same system would be equally effective should an employe think he had worked less time than his due bill called for. It would not be just to deduct a certain number of shifts, when a checking system might show that the employe had not kept his own time correctly.

In order to provide as many safeguards as possible, the time-keeping system adopted by the Crystal Falls Iron Mining Co., as explained herein, will show that the system has a tendency to keep not only the timekeepers in line, but also the several foremen or bosses, by whom the time is kept.

The men on going to work in the morning, report their brass check numbers to the timekeepers (at our mines this is done verbally), who record them as the men present themselves at the window The timekeeper, in taking the numbers in this manner, sees each man, and knows that the man has gone to work, whereas, if the numbers were to be deposited by the men themselves one man could deposit more than one number, and later in the shift, those for whom he deposited could slip into their working places. On returning from work at the close of the shift, the men report again in the same manner to the timekeeper.

During the shift (we are working two shifts of 10 hours each and have a timekeeper for each shift), the timekeeper sees every man at his work. On surface he makes two rounds each day, once on each half shift. Underground the timekeeper makes only one round each shift, and as he meets the men he records the place in which they are working. This enables him to classify the time according to the accounts kept or classification required for cost reports, etc. The timekeeper at the close of the shift has a good check on his own work, and taking for granted that he has faithfully performed his duties as required, the possibility of an error is remote.

Form A is the form of daily report made by the timekeeper and transmitted to the general office. This is given to show the similarity of the checking report (Form C) made out by the different foremen.

The surface foreman takes the time of the men employed on the surface, regardless of what their employment or connection with any particular branch of the organization may be. The shift boss takes the time of the men underground, likewise regardless of the work they are doing. These several bosses, therefore, take the time of all men employed around the mine.

Each foreman makes out a report for his shift, the surface foreman being obliged to get the time of the few men employed at night, when no regular night surface foreman is employed. He takes each man's number orally, and at the close of the shift fills out a blank having the check numbers on it in consecutive order, making a cross (×) after the number corresponding to the brass check number of every man whose time he has taken.

On the reverse side of this report, as shown by Form C, he makes a general classification of the men working on his shift. This classification is considered incidental to the real purpose of the report, i. e., getting a check on each man who worked on that particular shift.

This report, as made out each day by shift boss or foreman, is then placed in an envelope, sealed, addressed to the superintendent, and mailed to the general office. The bosses and timekeepers are, under no consideration, to compare notes on the time, under penalty of dismissal. These reports, as received at the general office, are checked against the report of the timekeepers, and at the end of the month, against the total days of the pay roll. In all cases they must agree.

Assuming that a discrepancy should occur between the timekeepers and foremen, a blank (Form D) is provided to be used in checking, to find where the error was made. This blank, when filled out, is referred by the general office to the captain of the mine, whose duty it then is to take the books of the timekeeper and shift boss or foreman, and in their presence check the same to locate the error. This is an easy matter and quickly done. The blank is then filled out as directed and returned to the general office and filed with the reports.

All men are paid by the cashier of the general office, the timekeepers not doing any paying. It has been found that men who were generally classed as the habitual kickers on pay days are not now heard from, as they know that when they get their due bills their time is correct, and there is no further cause for a complaint.

The method above described has been in use since the early part of 1902, and has proven very effective. At the time the reports were first introduced at the older operating mines, the shift bosses objected to the clerical work involved, but once fairly started, it has had no drawbacks and is in general favor.

FORM "D"

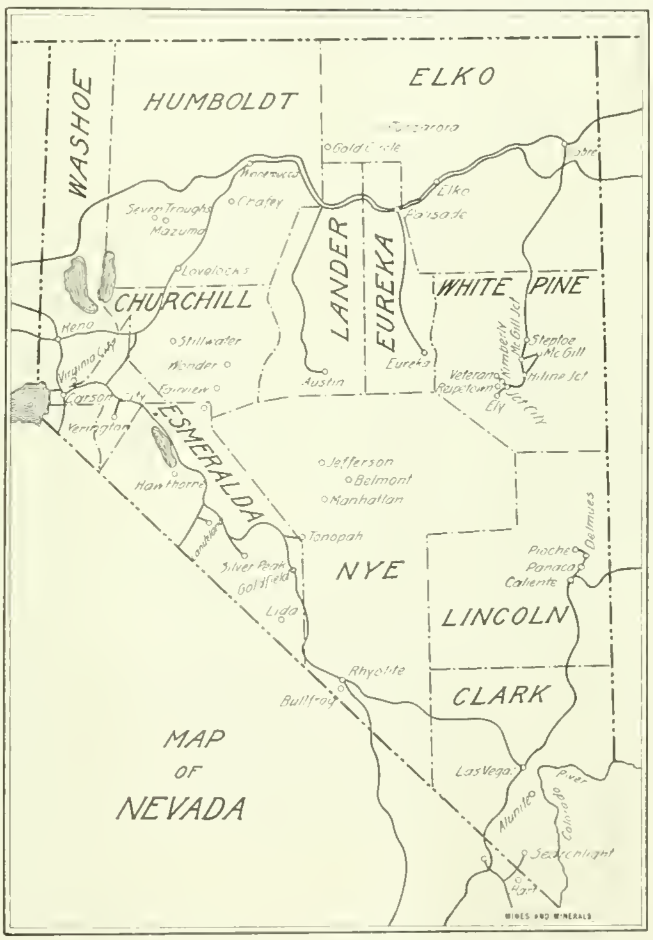
Mines in Pioche, Nevada, District

Mineralogical Conditions as Shown in the Development of Some of the Principal Mines

*By R. M. Bell**

The early operators attached very little value to the porphyry ore deposits, from the fact that when first encountered the ore was too base for treatment in their pan-amalgamation mills. When the Yuba and Mazeppa ore shoots were worked, the clean, high-grade lead carbonate smelting ores were most eagerly sought, and a great deal of the valuable second-class ore was left in the stopes, and the extensive unexplored portions of this porphyry lode is likely to prove one of the most valuable assets and important sources of profit to its owners.

Several eminent engineers who have visited Pioche consider the Yuba dike as the primary ore source or mother lode of the district; and that the rich values of the parallel and lateral quartzite fissures will unite with it at a little farther depth below the 1,500-foot level.



This is a feature that may prove of great economic importance to the district, as this great dike has been identified on its strike to the west at short intervals on the Harrison, Abe Lincoln, Morgan and other claims; and at Stampede Gap, 10 miles west, what is believed to be the same dike with similar fissuring and alteration occurs, and is associated with bands of the rich lead-silver and gold rocks, which opens up a stretch of promising territory for investigation. In addition to this, recent development has shown that the Pioche uplift is traversed by at least half a dozen similar dikes of altered rhyolite.

One of these great dikes traverses the north foot of the uplift half a mile north of the Yuba dike for 4 miles, with a strike north 50 degrees west. At the Ely Valley mine it outcrops 50 feet wide and carries a network of porous quartz stringers that may mean important mineralization at depth; and at a point 1,000 feet south of this ore on the Jefferson claim, another great dike occurs, that is fully 20 feet wide, with a similar strike and a southwesterly dip. Both these dikes should traverse the adjoining Pioche Metals Co.'s ground, where some rich lead ore has recently been developed.

Half a mile south of the Yuba dike, at Pioche, another big intrusion of similar soft altered porphyry traverses the properties of the Pacific and California Pioche Mining companies, where it has been opened in several shallow cuts in limestone and shows a strike of N 70° W, and along the west base of the uplift another altered dike was cut in the Golden Prince shaft, where it is associated with an immense ore body of iron gossan rich in gold, silver, and lead. This dike is 10 feet wide. It has a strike of N 40° W and can be traced to the north of the shaft on this company's ground for 1,000 feet, and the same distance south on the Pioche King group. There are also two cross dikes of basalt to the northeast.

Numerous similar dikes of altered porphyry, containing in some instances an interesting development of secondary minerals, including bronze mica scales, hornblende, and chlorite, are exposed in the Highland and Jack Rabbit Mountains and generally in close relation to the ore bodies. Should they prove relatively as rich in metals as the Yuba dike, their economic importance to the district can hardly be appreciated. They will certainly stand considerable investigation to this end.

The Nevada-Utah and the Ohio-Kentucky Mining companies own all the old mines that have made Pioche famous for rich ore production in the past, and amount to a mineral empire of themselves, and with railway transportation and other modern advantages, with their several well-equipped deep shafts, from whence to commence operation on extensive and proven ore bodies, should be put in shape with very little further capital to become a large and profitable mining enterprise.

Several of the more important claims of these old properties are owned jointly by these two companies, a circumstance that has stood in the way of this operation. A movement is now on foot to turn over the entire property of both companies to a holding company, which is the only logical thing to do, as it would settle all chances of further trouble and warrant the establishment of a big mining enterprise.

Any one familiar with the economic geology of Park City cannot help being impressed with future possiblities of the old mines at Pioche. The famous Ontario mine, at Park City, was worked in a steep quartzite fissure exposed by the erosion of the limestone-shale formations. At the Daly-West mine adjoining and on the same fissure the shale and limestone formations were still intact and richly mineralized with great bodies of very zincy and irony silver-lead sulphide ores.

The situation at Pioche is practically the same. The rich silver-gold quartzite fissure of the Raymond-Ely-Meadow Valley mines is succeeded to the west in the overlying shale limestone formations with fault fissure bodies of zinc-iron-lead sulphide ores, relatively rich in silver and gold. In the adjoining Greenwood and Susan Duster mines are bodies of clean mineral 15 to 40 feet wide that look from present development as if they might be put in shape to produce 1,000 tons of ore a day with 90 days additional development, that would average 5 to 10 per cent. lead and 10 ounces to 20 ounces silver, together with $1 to $3 gold per ton.

It is true that these sulphide bodies present a closer blend of the combined minerals than at Park City and doubtless present a knotty metallurgical problem, but with such combined precious values to work on, and a light shaley gangue, I think the problem is susceptible of successful and profitable solution; and it is no serious stretch of imagination to anticipate that, with the rich oxidized ore resources of the Yuba dike

* Former State Mine Inspector, Idaho.

thrown in and the enterprise intelligently gone after, these ore resources will in time repeat the great dividend history of the Ontario-Daly and Daly-West at Park City.

The spotlight of attraction in the current history-making period of Pioche is unquestionably the Prince Consolidated mine. This property is on an entirely different line of fissuring and mineralization from the old mines, and presents one of the most attractive features of the district for rich ore development. The Prince is situated 2 miles south of Pioche and on a fault fissure that traverses the southern border of the Pioche uplift, where it merges into the west valley wash, and it is believed that this fissure has been identified for a distance of nearly 4 miles. It has a strike of N 40° W and a dip of 70 degrees to the south. It is being developed at the Prince mine by a 60-degree incline shaft, now 600 feet deep, from which considerable drifting and cross-cutting has been done at 100-foot intervals.

The shaft at this property is started in a body of black manganiferous iron oxide in limestone. The extreme surface dimensions of this great body of mineral somewhat interrupted with limestone cappings, show width of 200 feet by a length of 600 feet. Some of the cross-cuts underground are over 100 feet in length, but at no place in these cross-cuts are both walls exposed. It will probably develop a great geyser-like fumarole, or double-chamber deposit, connected with the fault fissure. The foot-wall is well exposed at several points underground and shows a well marked movement breccia—a dip of about 70 degrees to the southwest, and strikes about northwest and southeast.

This great body of commercial ore is now sufficiently developed to warrant the statement that 1,000,000 tons is practically in sight and available above the fourth level, and contains an additional 2,000,000 tons of probable ore when the full section of the deposit is run out at the fourth level. This is an ideal free-smelting ore, as indicated by the following analysis, which is the result of extensive sampling by the company in an effort to get at the average values: Lead, 6.7 per cent.; silver, 4.7 ounces; gold, 40 cents; iron and manganese, 49 per cent.; silica, 12 per cent.; lime, 4 per cent.

This great body of oxide mineral is spotted with bunches, lenses, and stringers of rich carbonate of lead, with occasional cores of galena which are rich in silver, especially the galena, clean samples of which assay over 1,000 ounces silver per ton.

If the oxidation proves as deep here as at Pioche and the selective preference for precipitating rich silver and gold by quartzite walls as compared with the more mixed minerals in the overlying shale and lime, as illustrated at the old mines, is maintained here, some interesting results in the way of bonanza values may be anticipated. When the underlying quartzite is penetrated, this great body of mineral is due to contract in size, but would naturally be expected to show a marked increase in value. The company expects the vein to enter the quartzite at 700 feet.

At a depth of less than 200 feet the ore body passes through the limestone into the main shale beds of the district and has been carried down in this formation 400 feet.

At the 300- and 400-foot levels cross-cuts have been run into the foot-wall formation, where, at a short distance under the big ore body, two parallel fissure veins have been encountered that stand nearly vertical with a slight dip in the opposite direction from the main vein to the northeast.

These fissures have been proven by raises to apex. In the big manganese body 20 feet below the 200-foot level, a gangue of shale breccia in these foot-wall fissures has been changed to high-grade hard carbonate of lead, rich in silver, without changing in color or fragmental structure. They also, in places, exhibit a silicious, sandy gangue and banded structure due to subsequent motion after the ore was formed.

These rich ore courses vary in thickness from a few inches to 6 feet, and an interesting feature is the fact that they carry their richest values in the widest places, where large hand samples may be picked out well smeared with greenish yellow silver chloride that assay up into the thousands of ounces of silver per ton and several dollars in gold.

These veins, in contrast with their big neighbor, are practically devoid of manganese and iron oxides. They have been developed to a height of 200 feet above the fourth level, where they connect with the big vein, and for an extreme length, so far, of 450 feet, with good ore still showing in all the faces.

This important resource of rich ore is still intact, as no stoping has been done, and the reserve of mineral undercut by the four drifts on the No. 1 and No. 2 fissures at the 300- and 400-foot levels is estimated to contain 14,000 tons. Of the ore taken out in driving the levels and two raises on these smaller fissures, several 40-ton cars have been shipped to the Salt Lake market. The returns received from these shipments have afforded settlement results varying from 100 to 300 ounces silver, $5 to $15 gold, and 30 to 45 per cent. lead.

Another interesting feature of this remarkable ore body is that these small foot-wall fissures are connected at the 300- and 400-foot levels with a flat-dipping bedded ore deposit that conforms to the strike and dip of the enclosing shale formations. The lower bed exposed is at the bottom or fourth level, where it is 5 to 7 feet thick and filled with roughly laminated, sandy, brown, iron-stained gangue, associated with thick streaks and lenses of soft sandy carbonate of lead which, however, contrast sharply with the vertical fissure values, being very much lower in silver and gold, but it carries both and shows a combined value of about $25 per ton across the bed. This lower ore bed has been followed on its flat dip of 15 degrees a considerable distance beyond the No. 2 vertical shaft to the southeast, which would strongly indicate that the source of its ore was in still another vertical fissure in the foot-wall, as ore solutions would be more likely to feed up in a bedded deposit than down, according to the Utah examples of this form of deposits.

Norwegian Mineral Production

According to the United States Consular Report the export of Norwegian iron ore in 1910 was 75,000 tons, valued at $201,000, and the shipments of Swedish iron ore from Narvik, Norway, during the year amounted to 2,043,151 tons. The output of the mines at South Varanger, northern Norway, in 1910 was about 80,000 tons of iron ore. A portion of this was smelted by the magnetic process, and in November and December about 10,000 tons were exported. About 400 men are employed in these mines. At the Salangen mines, in the same district, there were produced during the year 25,000 tons of iron ore, of which the larger part was smelted and exported.

The largest copper mine and copper-refining works in Norway are at Sulitjelma. The production of this mine in 1910 was 146,000 tons of ore, and 1,596 tons of Bessemer copper. The United States Consular Report states that there are several other copper mines in Norway which have recently been opened, so it is estimated that the total production of copper in Norway in 1910 amounted to 320,000 tons of ore and 1,800 tons of refined copper, of a total value of $2,125,000.

Some silver, nickel, and zinc are found in Norway. There were about 650 tons of nickel and 125 tons of copper mined at Christiansand during 1910. Silver is mined at Kongsberg. Aluminum is produced at Vigeland, the output in 1910 amounting to 860 tons. The production of ferrosilicon during the year amounted to 5,000 tons. Zinc is produced by the electric process from imported raw material. The output in 1910 was about 4,000 tons. The only zinc plant in Norway is at Sunkdeloken. The exports of calcium carbide in 1910 amounted to 50,000 tons. According to the United States Consular Report the aggregate capacities of the carbide plants are about 100,000 tons annually, but on account of low prices some of the plants have closed down.

Shaft Sinking by Poetsch Method

Determining Direction of Bore Holes. Formation of the Ice Wall and Its Resistance to Pressure

Special European Correspondence

The method of shaft sinking with the aid of the freezing process dates as far back as 1883, when an engineer named Poetsch sunk the first shaft of the brown coal seam at Schneidlingen with success. From that time until the present, although many improvements have been introduced into the process, little that can be called material has been altered. The principle is a simple one consisting in freezing the water that causes the instability in certain strata between the surface and the mineral that has to be extracted. In order to do this, the diameter of the shaft having been fixed, it has to be increased by from 10 to 15 feet, the increased circumference being used for letting down the bore holes for the freezing pipes. The number of such bore holes of course is given by the circumference of the shaft. They are placed at distances of about 3 feet from each other, and as a rule there will be from 25 to 35 bore holes for a shaft of from 15 to 20 feet in diameter for normal working.

To this number have to be added certain supplementary bore holes which become necessary because of the frequent cases of deviation from the vertical line of the original bore holes intended to accommodate the freezing pipes. Such deviation naturally would be influenced by the nature of the ground and intensified by the depth of the hole. The freezing pipes will be 5 inches in diameter, of fairly heavy metal of which the bottom end is fitted with a cap, they having previously been subjected to a pressure of from 350 to 600 pounds per square inch, according to the depth of the shaft. They are then by means of suitable fitting at the top end fixed to a collecting ring.

The "downlet" pipes consist of 1- to 2-inch strong wrought-iron pipe, and after they have been let down into the freezing pipes are fixed at the top to a distributing ring. The sections are jointed so as to allow for the tension and contraction of the metal due to the differences of temperature to which the metal is subjected, thus obviating leakages. The whole system for the circulation of the brine or freezing mixture is quite simple, any difficulty consisting entirely in getting the bore holes as near the vertical as possible.

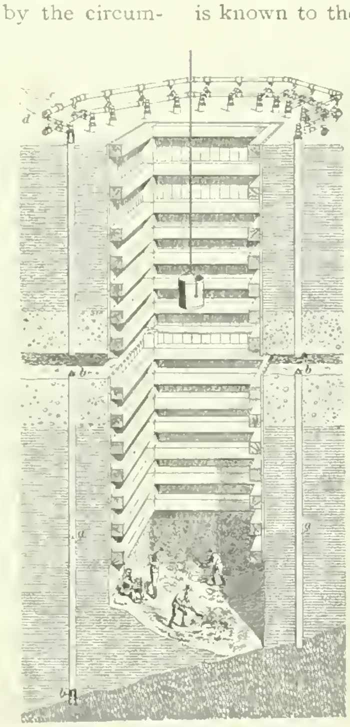


Fig. 1. Sinking in Frozen Ground

Sinking bore holes, as is known, is an expensive process and the fewer supplementary ones that can be done with the better. One of the great difficulties in handling this question is to know what direction the bore hole has taken when it has left the vertical line and how far it has left the line. Many expedients have been resorted to to get acquainted with the situation under the surface, but the one which appears to have obtained most favor by experts in shaft sinking by refrigeration is that recently described in the patent system of Gebhardt and König. It had always been held that shafts of over 500 to 600 feet deep must necessarily show deviations in the bore holes, and at length the system referred to appears to make the man on the surface acquainted, to within very narrow limits, with: (*a*) The direction of the deflection; and (*b*) its extent.

In the pipe is hung a pendulum which can be driven by clockwork at fixed intervals in point of time, and this pendulum will periodically make a mark on a strip of paper as the same is at regular intervals brought past it. It is in reading these marks, which are shown at distances of 5 to 7 yards, in the bore hole, relatively to a system of coordinates showing the degree of deviation of the bore hole, that the whole position in respect to any particular bore hole can be read above; that is, as to extent of deviation; but what is about as important is the direction, and to find this out electromagnets are used which also register the position by at intervals coming into contact with the wall of the pipe, these magnets being prevented by a special arrangement from revolving from the direction they possess at the beginning.

Such a system, however, it appears is not infallible; for it is admitted that there is a possible margin of error to be allowed for both as to deflection and direction, but it is sufficiently accurate to avoid a large proportion of the losses hitherto involved in sinking fresh bore holes, when it was not absolutely known how far the bore holes they were designed to supplement had deviated from the vertical line nor yet in what direction. It may be added here that the results obtained from each bore hole by the instruments referred to are carefully registered on a plan, and when the geology of the ground is known to the contractor, he will be able to sink his new bore holes as far as physical circumstances will allow at the right spots.

The question now simply amounts to the producing of refrigerated brine on the surface which has to circulate through the pipes and freeze the surrounding ground, including any watery strata, sufficiently to make it safe to sink through it as though through solid ground. The plant required for producing the refrigerated brine will of course depend on the diameter and depth of the shaft to be sunk. It consists usually of the compressors, the condensers, and the refrigerators. Nothing more need be said of this, because with little modification any refrigerating plant that will supply brine at a low temperature and deliver the same to the freezing pipes now supposed to be sunk to the required depth round about the ground that is to be excavated, will suit. Local conditions may decide the system to be used.

The difficulty hitherto has not consisted so much in making the bore holes and fitting the pipes as in dealing from time to time with accidents such as eruption of water when the shaft has been sunk a good way down, through some defect in what is termed the frost wall, possibly because of defective circulation of brine or perhaps, as has occurred, overconfidence on the part of the contractor trusting to the strength of the frost wall and reducing the expense in supplying the necessary brine to maintain it intact. The brine or freezing liquid commonly used is chloride of magnesia, which is reduced to a temperature of from 15° C. to 20° C. below freezing and pumped into the distributing ring, whence it finds its way through the downlet pipes, returning through the bore pipes into which these latter have been let down, returning by way of the collecting ring once more to the refrigerators, where it is cooled afresh and continues, so to speak, its cycle.

The theory is perfectly simple. The brine on its return journey extracts the heat from the surrounding ground and forms theoretically round each pipe a cylinder of frozen material which, by the continuous process of refrigeration, gradually extends until it meets the frost ring or cylinder of its neighbor; and so ultimately a complete circular frost wall is established which, if sufficiently strong, enables the sinkers to do their work without fear of invasion of water from the surrounding ground. The danger from this moment is probably only from below. As can be imagined, at the bottom of the ring of pipes the freezing takes place in the ground in such form as to produce a shape something like the bottom of a bottle. That is to say, the frost extends outwards and downwards, but weakening toward the center. There is a kind of hollow, which, however, is immaterial; as the frost wall, if refrigeration be properly directed, will extend far enough below and across the diameter of the frost ring to prevent any accident taking place from below. The difference in temperature which is gradually reduced as between the returning brine and the surrounding wall becomes ultimately one of 2 to 3 degrees and the frost wall under circumstances such as just described may be considered as closed in between 2 and 4 months and sufficiently strong to stand the pressure of the ground during sinking. The margin of time named naturally varies according to the diameter and depth of the shaft; and further, it is a consideration of great technical interest, on the nature of the ground being pierced, that is to say, its greater or lesser heat conductivity.

Respecting the observations during the freezing period and its duration, the following should be observed: As soon as the frost wall begins to close, the water in the initial shaft which serves to accommodate the stand pipe and the distributing and collecting pipes, begins to remain stationary and then to slowly rise; whereas during the initial stages of the freezing the water level falls, or, supposing the initial shaft does not reach the ground water level a hole may be bored in the center for making observations. This is the best indicator of the closing of the frost wall, for the water inside the frost wall when it is closed cannot escape outwards and must rise as the space becomes less. This middle bore hole serves at the same time as compensator for any hydraulic expansion that may occur in the strata that are impermeable to water. Should the water level rise from 3 to 6 inches in 24 hours, which would indicate the closing of the frost wall, then in the case of an initial shaft which has been sunk sufficiently deep, water should be added; and if then, in spite of this additional pressure the column of water rises further, indicating the resistance of the frost wall, then, generally speaking, the sinking can be begun.

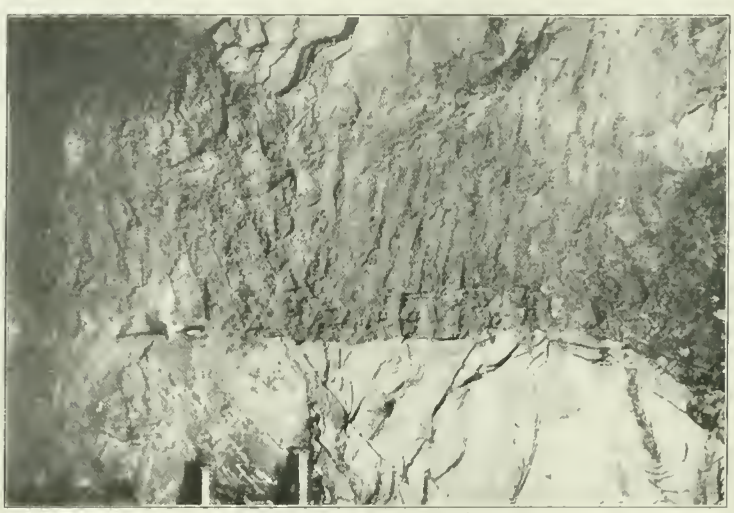

Fig. 2. Frozen Ground in Shaft

Experience in the freezing process has shown that the easiest and quickest strata to be frozen are water-saturated sands, also quicksands; whereas clayey sand or clay freezes relatively slower. The most unfavorable for the process is brown coal, which, as a bad heat conductor, naturally discourages the freezing process. This is not to say that brown coal mines are not suitable for the freezing process in sinking, for it has been shown that a large number of brown coal shafts have been successfully sunk. Respecting the resistance of the frost wall it may be said that quicksand offers the greatest resistance. A table has been published showing the relative resistance as follows: Water-saturated sand, 138 kilograms per square centimeter at a temperature of 15° C.; 200 kilograms per square centimeter at a temperature of 25° C.; sandy clay, 90 kilograms per square centimeter; fairly pure clay, 72 kilograms per square centimeter; pure ice, 18 kilograms per square centimeter, all these last three at 15° C. The resistance of the frost wall grows with increasing cold and it must be noted that when pure water is concerned or pure ice when frozen, the resistance is relatively very small; and it is shown that ice only serves as a certain binder to fill up the space between the particles of sand. Whether thereby the friction resistance is increased and the resistance of the frost wall depends on the size or forms of the grains has not yet been established, but such may be presumed.

There appears to be no limit in respect to useful depth to which the freezing process may be applied for shaft sinking. A shaft 1,325 feet deep has been undertaken at Baesweiler, on the continent, whilst numerous cases can be cited of successful sinking down to as far as 1,082 feet, this last depth having required 286 days for boring, 104 days for freezing, and 379 days for sinking, including the tubbing. This shaft belongs to the Riedel Potash Works, of Hanover. The boring was done at the rate of 144 feet per day and the sinking, including tubbing, at 2.88 feet per day. The number of shafts tabulated from which the two indicated above are selected is 56, and they include coal, potash mines, etc., in Germany, France, and England. The refrigerating agent used for cooling the brine appears to have been mainly ammonia, though in many cases carbonic acid was used; and it has been pointed out with reference to the most important shafts, respecting the sinking of which data are given in the table named, the Solvay pit No. 1 was sunk in the astonishingly short period of 36 months, as against the contract period of 68 months. It is true that at a depth of 787 feet of clayey sand a defect in the frost wall was revealed, but this was promptly and efficiently repaired. All the other strata were frozen faultlessly, and in the very lowest reaches of the shaft the frost wall was complete, compact, and free of faults; although it had to stand a very high pressure of more than 381 pounds per square inch, so that the frequently expressed view that ice, or rather a frost wall, under a pressure of from 295 to 370 pounds per square inch will give way is absolutely contradicted.

In the shafts of the Friedrich Heinrich coal mines the boring period and freezing period went through smoothly, and the sinking could be begun after 4½ months of freezing. The sinking ran normally down to 475 feet with a disturbance in the clay which interrupted the work at that depth; and it was found necessary to make a fresh series of bore holes to strengthen the frost wall on the side that gave way, whereupon the sinking was recommenced.

Enforced Development of Mining Claims

Most important, perhaps, in any amended mining law would be provision for enforced development of mining claims, a principle expressed, it is true in the present law but not effective in its workings. A requirement of actual use as a condition of occupancy of mineral land cannot be regarded as either novel or radical. As regards the large acreage of undeveloped land in many mining camps to which patent has already been issued, it is perhaps true that the situation is without relief, unless the Western Australia plan is adopted, whereby the Government steps in and permits mining under a lease, the proceeds of which are assessed, collected, and paid over to the owner. The principle involved seems to be that no property owner can rightfully oppose the development of the state.—*Geo. Otis Smith.*

The Voorspoed Diamond Mine

Geological Conditions Peculiar to this Mine. Various Minerals that Have Been Found

*By H. S. Harger, F. G. S.**

The Voorspoed mine is situated some 5 miles northeast of the Lace diamond mine in South Africa. With the exception of the Premier, it is the only large payable diamond mine that has been discovered during the last 17 years.

The formation surrounding the pipe consists mainly of shales, but these are overlain on the northeastern edge of the mine by feldspathic sandstones. These form the wall of the mine for about one-third of its circumference, a basic amygdaloidal aphanite, or cryptocrystalline basic igneous rock, constituting the remainder.

The diamondiferous portion of Voorspoed pipe covers about 800 claims, but at one time, the writer (who was the discoverer) anticipated it would cover fully 1,500 claims, for the reason that the area within the shales equaled that number. It was known that a considerable area on the south and east within the rim rock consisted of aphanite, but as a huge mass nearly 50 feet in thickness also lay in the middle of the mine, and proved to be merely a "floating" mass, it was hoped the remainder would likewise be "float" rock, and give place to kimberlite (or altered peridotite known as "blue ground") underneath, as happened in nearly all of the largest mines, to wit, Dutoitspan, Bultfontein, Jagersfontein, and Wesselton. Such, however, was not the case. On the southern portion, which consists entirely of aphanite with little patches and veinlets of kimberlite in it, several bore holes were put down, but none of them passed through the aphanite, the greatest depth reached being 600 feet. The eastern portion was similar, the aphanite having apparently been much fractured, and containing patches of kimberlite in several places, whilst in another the aphanite and kimberlite were indiscriminately mixed up.

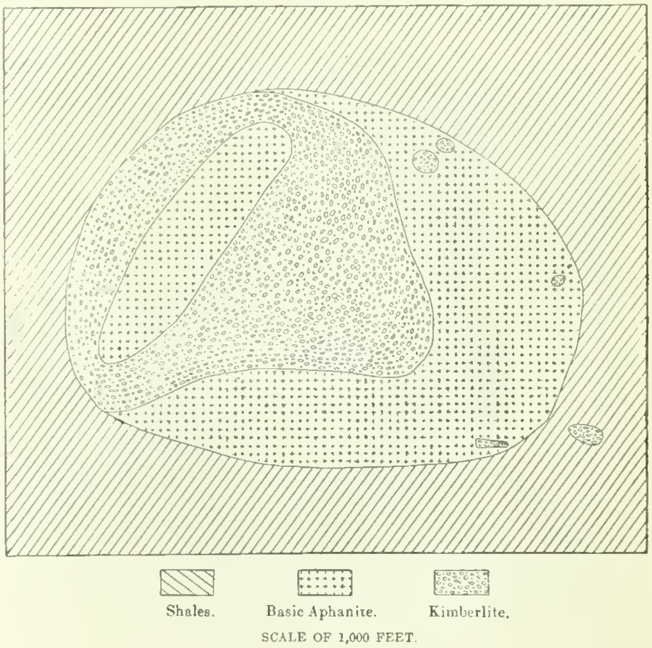
On the southern portion a fissure containing highly micaceous kimberlite (free from pebbles and boulders) was met with in two places, striking roughly east-west. The ground in these cases was typical fissure ground. In close proximity, however, was a patch several claims in extent of kimberlite, containing boulders and pebbles, and in all respects resembling the pipe kimberlite.

In addition to the masses of aphanite referred to, which occupy an area of nearly 700 claims, the mine ground, wherever met with, contains a very noticeable amount of the aphanite throughout, varying in size from microscopic dust to huge masses. In almost any hand specimen the presence of the aphanite can be detected, either with the naked eye or a lens.

After a careful study the conclusion of the writer is that a volcanic diamond pipe occurred within the neck of a preexisting volcano, the stump of which alone remains owing to denudation. The shape of the entire occurrence within the shales, as seen today, is almost truly oval, and occupies about 1 500 claims. The intrusions of kimberlite appear to have blown out more than half of the older volcanic filling, but failed to displace the remainder. The explosive forces, however, shattered the remaining aphanite in all directions, filling many cracks with kimberlite and in several places forcing out masses of rock several claims in extent, and replacing it with a true kimberlite of serpentine breccia. The tilting of the shales at the contact all round the aphanite, proves the rock to be intrusive, although owing to weathering no evidence of metamorphism was observable in the shales. The presence of shale and sandstone forming a complete girdle around the aphanite and kimberlite shows that the occurrence is not a big dike. It forms today a roughly crescent-shaped mass around three sides of the mine between the diamondiferous kimberlite and the shales, and is evidently a solid vertical column of aphanite, representing portions of an extinct volcanic neck, or, in any case, a pipe-like intrusion of a related kind.

The rock is a grayish-green basic amygdaloidal aphanite. A few blocks found loose in the kimberlite are highly vesicular, and contain almost 50 per cent. of white heulandite, a calcium aluminum silicate, and calcite—the former predominating, but the solid column of aphanite, tested to a depth of 600 feet, is but slightly vesicular, and contains much smaller amygdules, whilst the zeolites are replaced by calcite. Some of the cavities have been only partly filled, and contain much dull green chloritic matter, while an occasional speck of copper was observed. Under the microscope a thin section shows the feldspars, which are lath shaped, the interstices between them being partly filled with chloritic alteration products, and also with a greenish aggregate, containing acicular feldspar microlites. Some serpentine pseudomorphs, shaped like basal olivine sections, and the usual iron oxide accessories were plentiful.

Like almost every similar occurrence, the Voorspoed pipe is on a line of weakness occupied by a fissure containing kimberlite, and this has been traced and opened up for 4 miles. This fissure was formed before the diamond pipe, as it is found dissecting the country rock right up to the wall of the mine, but not within it. The fissure, however, like the pipe, is evidently younger than the aphanite, as a fissure with similar strike (and probably an offshoot of it) can be seen traversing the aphanite, which forms the southern wall of the mine. The fissure ground is of the micaceous variety, very fine in texture, and containing no minerals that can be discerned with the eye, except a few garnets. In places, however, it contains roundish pebbles and boulders, usually of quartzite. The latter appears to have resulted from the metamorphism of sandstone and alteration of feldspars, probably due to the heat of the magma in which they had been caught during its passage upwards. Similar heat phenomena occur in other dikes known to the writer, but have not been observed in any of the large pipes.



Horizontal Section of Pipe at Voorspoed Mine

The ground in the pipe differs entirely from that in the fissure. In the central portion of the mine the ground is bright yellow in color, rough and pebbly, and rather full of very small mica. It contains about 50 per cent. of round and oval-shaped pebbles, and small boulders, the latter consisting of aphanite,

*From J. C. Johnson's "Geological and Archeological Notes on Orangia."

granites, dolomite, quartzite, Dwyka conglomerate, etc. Ultrabasic rocks are either entirely absent or extremely rare—not having been met with by the writer.

The most interesting boulders found, however, consist of a feldspar-garnet rock, quite different to anything the writer has met with in other diamond mines; this occurs both as a coarse and medium crystalline granular rock, in which usually from one-third to half of the rock consists of much cracked, pale, clouded, mauve colored garnets attaining at times a diameter of nearly $\frac{3}{4}$ of an inch, and flakes of graphite. A thin section made from the same rock, but of finer texture than the above, was examined by Mr. Weber, of Johannesburg, who found it to be made up principally of white feldspar, garnet, quartz, and monoclinic pyroxene—the latter quite subordinate to the other minerals. All the above minerals contain systems of acicular needles, having very strong double refraction, with extinction angles varying from 0 degree to 4 degrees, and colors varying from dark brown to brownish green.

The only other boulders found at Voorspoed and requiring special notice are roundish, highly micaceous lumps of kimberlite of the fissure variety, containing an occasional garnet. These boulders are not only round and oval in shape, but have usually very smooth and unctuous exteriors. Owing to their exact resemblance to the ground found in the fissure on which the mine occurs, it seems quite probable that they represent masses or fragments of the fissure rock which were broken up, rounded, and distributed throughout the mine when the pipe burst through. It is quite reasonable to expect the fissure kimberlite to be represented in the pipe breccia as well as the other wall rocks found therein, but some local segregationists prefer to attribute their origin to magmatic segregation. The true origin of these boulders, however, like the eclogites and altered rocks, has yet to be solved.

The minerals found in the Voorspoed kimberlite are not very numerous or plentiful nor do they form a "pretty deposit" such as one sees at Jagersfontein, Koffyfontein, Bultfontein, and many other mines. The principal mineral is garnet, most commonly a clouded red in color, and much cracked. Some transparent pink to red pyropes occur, and also pale yellow to orange-red hessonite. Stones of the latter quality are much scarcer than the diamond both in this and every other known mine. The garnets seldom exceed $\frac{1}{2}$ inch in diameter. Minute octahedral crystals of picotite (chrome spinel) are plentiful. A little ilmenite occurs, and is often to be seen in dull gray very smooth grains, as if water worn. In addition to the foregoing, of which the concentrates mainly consist, a little diopside, pyrite (in both cubical and "buck-shot" forms), calcite, mica, barite, and an occasional piece of galena are found. Enstatite, which is present in most of the mines and quite plentiful in some, was not observed, but might make its appearance at lower levels. The present working faces in the mines are all above the 100-foot level.

The diamonds are of a small average size, parcels usually containing a high percentage of specimens ranging from $\frac{1}{8}$ to 3 carats, but stones of from 30 to 40 carats in weight are occasionally found. Although "bright stuff" of very good quality is constantly found, the grade in large parcels is not high, like Jagersfontein, Koffyfontein, and the Roberts-Victor mines. All shades of "white" are found, and occasionally good "blue whites." When cut, the white stones are very brilliant. Pale "yellows" and "bye-waters" are plentiful, but "deep yellows" of the "fancy" descriptions rare. Pale "rose pink" occur, but generally weigh a quarter of a carat or under, as at Bultfontein, although one of 5 carats was found, and retained its color after cutting. The crystallization of the gems is mainly of the round and elongated rhombic dodecahedron shapes, these being often very bright and smooth, and having curved faces. Perfect octahedra are seldom seen, though the Lace mine, a few miles away, contains quite a high percentage of octahedral forms. The cube, so common in South America and rare in South Africa, has also been found in Voorspoed mine, the writer having a small one weighing under $\frac{1}{8}$ of a carat. A careful examination of one parcel showed a high percentage of diamonds which had been broken. Some of these might have been fractured in the mining and washing operations, but broken stones were found in the earlier stages of exploitation, before either dynamite or machinery was in use.

A most interesting feature of the mine in relation to its genesis is the distinctly variable nature of the ground in different portions of the mine. About 60 claims in the center of the pipe consist of bright yellow ground, soft and unctuous to the touch. It is full of small mica, and contains about 50 per cent. of roundish pebbles and boulders up to 1 foot in diameter. The boulders have already been referred to. This ground breaks up freely in any direction into rough and roundish lumps. The remainder of the mine produces quite a different class of ground, grayish in color, harsh to the touch, comparatively free from boulders, and with much fewer pebbles. It is distinctly laminated and when broken up for hand specimens gives flattish lumps. The difference between the two classes of ground is so marked that one might easily conceive them to belong to independent mines.

The output of diamonds from the Voorspoed mine has been as follows:

	Loads	Carats
1906, July to December	40.096	9,244
1907, January to July	70.311	1 ,839
1907, July to December	123.041	26,813
1908, January to June	141,346	28,719
	374,794	78,615

Another "Chicken Bill" Yarn

Western mining people have either known William Loveland personally, or have read or heard about his notorious adventures. Every once in a while a new story bobs up about this character of Colorado's early mining days.

Here is one that was very recently related, which shows the clever trickery practiced by this plain prospector who twice became a very public figure; for this is the same man who salted and sold the Chrysolite claim, on Fryer Hill, Leadville, to ex-Senator H. A. W. Tabor, and who subsequently perpetrated the Mount Pisgah placer fraud just west of the present Cripple Creek district.

It seems that Bill manufactured some very clever imitations of gold nuggets by dropping molten brass into water. On one of his periodic visits to Denver he dropped into a Hebrew clothing store to make some purchases, explaining frankly to the proprietor that he was without cash, but at the same time permitting a casual glance at the contents of his sack of bogus gold nuggets. This was sufficient, and Bill was accorded permission to buy the entire stock if he wished; a permission of which he availed himself freely. After settling for his purchases with the nuggets he was dismissed with many flourishes of the hands and with a cordial invitation to call again.

The error was soon discovered and in a few hours detectives had Bill in charge. At his hearing the next morning Bill calmly admitted the manufacture of the nuggets and his methods of disposing of them, but despite the obvious deceit practiced, the court found it convenient or expedient to discharge him, for he testified that he distinctly said to the merchant, who, in gloating over the nuggets, called them "beautiful gold."

"O, no, those are only nuggets. They are not gold."

As the duped one admitted this statement, the judge ruled that Chicken Bill could not be held and the Hebrew was taxed with the costs.

In rendering this decision the court appears to have been led thereto by the same process of reasoning followed by the Supreme Court of one of the eastern states in ruling essentially, that where two rascals try to dupe one another, neither can recover in event of his being fleeced.

Bill's salting of Senator Tabor made quite a stir at the time by reason of its peculiar outcome. In the early Leadville days Tabor was teaming to the mines from Denver by way of Platte cañon. Daniels & Fisher, the well-known Denver outfitters of that day, asked Tabor to buy them a good mine in the new camp and not to be too particular as to the price paid.

Tabor appears to have talked freely of his commission. In any case Bill heard of it and salted a claim which he sold Tabor for $50,000 in cash; a large sum for those early days. After but a slight investigation the salting was proved and Daniels & Fisher declined to take the claim, leaving it on Tabor's hands. He, of course, could not stand the loss, and went to work developing the property in the hope, probably, that it might not be as bad as it looked. Be that as it may, it was not long before Tabor developed the well-known Chrysolite mine, on Fryer Hill, which laid the foundation of his subsequent fortune.

Blast-Furnace Smelting With Oil

For the practical demonstration of blast-furnace smelting with oil, the Colorado Iron Works Co., of Denver, has built a smelting furnace, of from 80 to 120 tons daily capacity, at their works. This furnace, which is shown in Fig. 1, is 4 feet in diameter at the tuyeres and 5 feet diameter at the top of bosh.

It is equipped with many refinements not usual in smelting furnaces generally; further, it requires but about one-eighth the water for cooling jackets usually used in furnaces of the same size, by reason of its utilizing the latent heat incident to vaporizing water into steam and dissipating such heat to the atmosphere instead of overflowing the water from the jackets in the common way, and thus saves seven-eighths of the amount of water commonly used and avoids also the nuisance of water flowing in open troughs around the furnace.

There are gas taps every 3 feet up and down, where the furnace gases are taken for analysis.

Temperature is also taken, as desirable, at the gas taps, with a Le Chatelier thermoelectric pyrometer.

The operation of this furnace requires fuel oil and the claim is made that the system advocated is the only logical method of smelting pyrite, pyrrhotite and associated sulphides, conserving at the same time the calorific value of these minerals.

Heat is delivered into the blast furnace near the bottom of the ore column in amount and intensity precisely as required and under complete and instantaneous control. If smelting gold and silver ores in which there is only enough iron-copper sulphides to form the matte, then no fresh air is blown in and all sulphides are melted to matte, which carries the gold and silver of the ore.

On the contrary, if the ore carries an excess of sulphides, then air is blown into the furnace in amount accurately calculated and adjusted to oxidize the excess sulphur to the predetermined proportion required for the matte, and the ultimate calorific value of the iron and sulphur so oxidized is realized in the smelting operation. The air blast entering the furnace very close to the heat ducts, strikes the ore at smelting temperature, or at any predetermined temperature, and enables the pyritic smelting of ores high in sulphides to become a simple, and a positive process, defined in all its details. All the elements of guesswork and uncertainty incident to present methods are eliminated, with the abandonment of carbonaceous fuel from the ore charge.

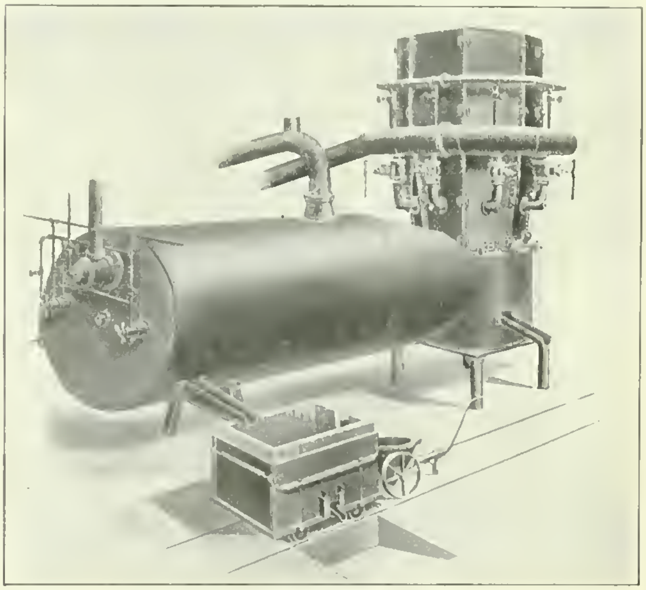
Ore and flux are charged into the top of the furnace in proportions to form a fluid slag. The air blast oxidizes the sulphides, producing heat, but if not enough heat is generated in that manner to smelt the charge, it is supplemented with whatever heat is necessary, by burning petroleum, and introducing it at the bottom of the furnace. This heat enters so near to the tuyeres that any accretions beginning to gather there are readily assimilated with the surrounding silica and melted away by applying the heat necessary, and such heat is ever attainable by this hydrocarbon method.

The comparative costs of smelting with oil and coke, based on conditions that prevail in Arizona, are calculated as follows:

Assume that coke with 14 per cent. ash costs $12 per ton; then since carbon yields 14,500 British thermal units per pound, there will be $100-.14=.86\times 14,500=12,470$, or for easy calculation, 12,500 British thermal units per pound of coke.

Assume, for comparison, that one hundred million (100,000,000) British thermal units be produced, then this divided by 12,500 gives 8,000 pounds, or 4 tons of coke as required, which will cost $48. To this 10 per cent. is to be added for unloading, waste, and charging into the blast furnace, or a total of $52.80.

Assume oil at $1.25 per barrel, specific gravity $.925=7.5$ pounds per gallon, 42 gallons = 315 pounds per barrel = .4 of a cent per pound. In a properly equipped plant there is no cost for handling, as oil is piped from the tank car to the storage tank, and again from the storage tank to the combustion chamber of the blast furnace.



Oil Blast Furnace

Assume the calorific value of oil at 19,000 British thermal units per pound, which is below the average number of heat units, then to produce the 100,000,000 British thermal units will require 5,263 pounds of oil, which, at .4 of a cent per pound amounts to $21.05.

Thus, on the basis of comparison above assumed, $21.05 worth of fuel oil will furnish the amount of heat to the blast furnace that costs $52.80 with coke fuel.

To the coke should be added the cost of the heat involved in fluxing the ash, this is 14 per cent. of 8,000 = 1,120 pounds ash, which, if the most favorable allowance possible is made, that is assuming the coke is so near self-fluxing as to require but 20 per cent. of its weight in bases for flux, then 1,120 pounds ash + 20 per cent. iron and lime = 1,344 pounds of barren material that must be smelted with every 4 tons of coke. Oil has no burden of this kind, which, of course, is in its favor.

The New Electric Hoists at Ray, Ariz.

Conditions at Ray, Large Hoists Operated by Electric Motor by Means of Rope Drive

The camp of the Ray Consolidated Copper Co. is at Ray, 6 miles north of Kelvin, Ariz., the two places being connected by a railway following up the gorge of Mineral Creek. At Ray the narrow stream bed widens out into a flat, shown in Fig. 1, upon which the camp is built, but above the camp it again cuts

Fig. 1. Camp of Ray, Arizona

a gorge through quartzites overlying the Pinal schists, while above the quartzites appear Carboniferous limestone.

On Teapot Mountain, shown on the skyline of Fig. 1, are found beds of tuffs which in turn are capped here and there by dacite. This hard rock is responsible for the striking escarpments which cap the slopes of the peaks. Evidently extensive erosion has removed the sedimentaries overlying the Pinal schists in the extensive area to the northwest and west of Ray. To the east of Mineral Creek the Pinal schists are overlain by quartzite, except for several small patches close to the stream where the quartzite has been eroded. The mineralized area is included in the great belt of Pinal schists exposed where the overlying strata have been eroded back to slopes of the surrounding mountains.

In Fig. 2 Mineral Creek is shown in the foreground with the machine shops to the left and the ore bins to the right. According to Philip Wiseman, in 1909 there were 30,000,000 tons of ore, 15,000,000 tons of which carried 2.4 per cent. copper. This ore differs from the porphyry ore of the Utah Copper Co., at Bingham, in that it is found in Pinal schists to a large extent. As is known, in order to work low-grade copper deposits satisfactorily a large tonnage must be mined and treated daily. Recently a new electric hoist has been installed by the Ray Consolidated Copper Co. at their No. 1 shaft, shown in Fig. 3, which raises heavy loads in order to keep up the large production required from this shaft. The hoist has now been in operation about 6 month and a duplicate hoist is being installed at No. 2 shaft about 1 mile distant. The electric power for operating this hoist, as well as the compressor and other machinery about the mines, is generated at a large power plant at Hayden, Ariz., 19 miles from the mines, at which point the large concentrator is located, and where a smelter for this company is being erected. The power is generated by four-cylinder triple-expansion condensing engines direct-connected to alternating-current generators, and is transmitted to the mine at 40,000 volts. The hoist motors and generators were furnished by the Allis-Chalmers Co.

The hoist, it is believed, differs from any previously designed, from the fact that it is rope driven and is connected by two sets of gears.

The hoist was designed by the Wellman-Seaver-Morgan Co., of Cleveland, Ohio, to lift a load of ore weighing 12½ tons, together with a skip weighing 8 tons, from a depth of 500 feet, at a speed of 300 feet per minute. The hoist operates with balanced skips, one of the drums being keyed fast to the shaft while the other drum is driven by a powerful modified Lane band friction clutch for adjustment to the different levels, as desired. The hoist is driven with an alternating motor, 440-volt, three-phase, 60-cycle, with a full load speed of 430 revolutions per minute and 300 horsepower continuous rating. On the motor shaft is fitted a 44-inch diameter rope wheel having grooves for thirty-two 1-inch ropes that drive the 13-foot diameter rope wheel on the pinion shaft of the hoist shown in Fig. 4.

In designing this plant, the underlying object, which was kept ever in mind, referred to making arrangements of such a nature that the motor should operate continuously in one direction, while the drums could be started, stopped, or reversed independently of the movement. As is well known, the principal electric loss in hoists operated by alternating-current motors is occasioned by the starting, and if the motor is large it becomes serious. It is desirable, therefore, not to be obliged to start the motor at each trip, since, when the motor is running idly, the current required by it is so limited that the peak losses are materially reduced. With this hoist the load is gradually accelerated by applying powerful band friction clutches.

For the benefit of those unfamiliar with band friction clutches, the following description is given:

Fig. 5 shows a band friction clutch that is attached to and revolves with the shaft *a*. The winding drum runs loosely on the same shaft and has a driving-band ring or seat *b* on one end; when the ring *c* of the clutch is tightened by means of the mechanism shown, the clutch and driving band become practically one piece and the drum revolves with the clutch. The clutch is constructed as follows: The driving disk *d* keyed to the driving shaft *a* is connected to one end of the ring *c* by a fixed arm *e*, which is bolted firmly to the disk *d* and revolves with it; a movable arm *f* that connects with the other end of the band *c* turns on the pin *g*. When the band *c* is loose, it can revolve about the seat *b* without touching it, but the band can be tightened and made to clamp *b* either when revolving or standing still, as follows: The sliding sleeve *h* may be caused to slide about 6 inches along the hub of the disk *d* by levers (not shown) and take hold of trunnions *i* on a ring on the sliding

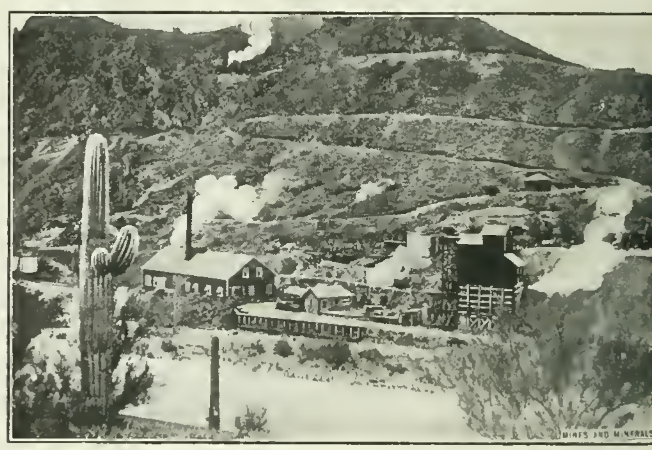


Fig. 2. Ray Consolidated Mines

Mineral Creek in foreground; Machine Shops at left; Office, center; Bins at right; Tunnel back of Bins

sleeve; this sleeve is connected to the movable arm *f* by a link *j*, and when the sleeve is on the end of the hub the link stands at an angle of about 60 degrees with the shaft; by sliding the sleeve toward the disk *d*, the link is made to move the arm *f* about 1½ inches at its outer end and to thus tighten the driving band *c*, so that it grips the ring *b*. The adjusting nuts *k* take up the wear of the wooden blocks with which the ring *c* is lined. Band lifters *l* hold the band clear of the ring when it is loose. The

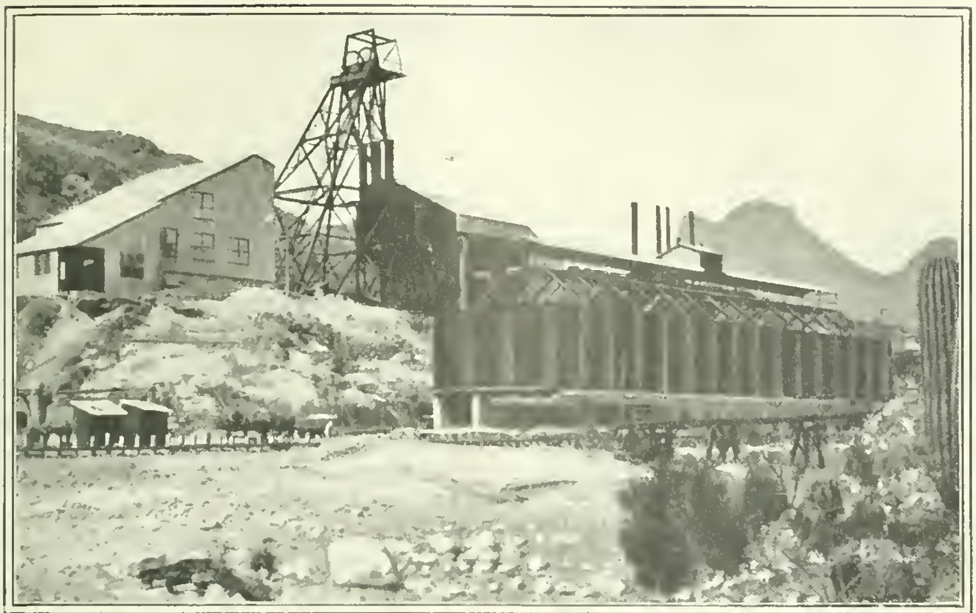

Fig. 3. Ray No. 1 Mine Shaft

clutch shown is built to run in the direction indicated by the arrow, but such clutches may be built to run in either direction; they should always be run in the direction for which they are designed, so that the load may always come on the fixed arm. If the band be tightened slowly, there will be no sudden start or jerk on the rope, as the slip of the band will prevent the entire force of the grip taking effect at once; and after the drum reaches full speed, there is little or no slipping of the driving band. It is best to keep the band only just tight enough to do the work, for should the car get off the track, or be overwound, or should a cage stick in the shaft for any reason, the band will slip and thus become a safety appliance, and not strain or break the rope, shaft timbering, or machinery, as would be the case if a positive clutch were used.

The only available illustration of the Ray mine No. 1 shaft hoist is that of Fig. 4, which was kindly furnished by the Wellman-Seaver-Morgan Co. From the illustration a general idea of the hoist is obtained, consequently only details which enter into its construction and emphasize its good and bad points are presented to the reader. The points of particular interest to the mining engineer are: the 13-foot diameter rope wheel driving the beveled pinion, the beveled gears that drive the pinion on the intermediate shaft, the brakes, and their means of application. The train of movements receives its power from the motor rope-drive, as described, but the beveled gears turn in opposite directions and so make it possible to continue a hoisting and reversing system.

Both bevel gears are loose on the intermediate shaft, but are fitted as shown with the friction rings and the band-friction clutches already described, which, in this case, are keyed to the shaft. To operate the clutches there are a series of levers connected with weights, but to release the clutches the vertical cylinders shown in the illustration are required.

The cylinder pistons are controlled in their movement by a cataract cylinder filled with oil, the power for operating the cataract being compressed air taken from the air mains supplying the mines, although there is an auxiliary motor-driven air compressor in the engine house, which automatically cuts in and provides air for operating the hoist if the mine air pressure is shut off or goes below a certain predetermined pressure. Both of the clutch-operating cylinders are manipulated by a single lever from the engineer's platform and are so arranged that either clutch may be thrown in or out of engagement, but both clutches can never be in at the same time, and one clutch must be wholly thrown out before the other can be thrown in.

The intermediate shaft that carries the beveled gears also carries the pinion which drives the 16-foot gear-wheel on the drum shaft. The drums are 12 feet in diameter and grooved for 1¾-inch hoisting rope about 600 feet in length. An examination of Fig. 4 will show that one drum is fixed to the shaft while the other is loose and fitted with a powerful modified Lane band friction clutch, such as described and illustrated by Fig. 5. This clutch has a 12-foot driving ring constructed for a possible working load of 50,000 pounds. The clutch disk is of cast steel; the fixed and movable arms which engage the driving band are of annealed steel; while the friction band is of steel lined with basswood blocks. Arrangements are provided for adjusting the wear of the band, as well as lifters for equalizing the distance of the band from the clutch ring when the clutch is released. Each drum is provided with a powerful post brake, with steel posts fitted with basswood friction blocks 14 inches wide. For the benefit of those who are not familiar with the construction of the post brake a short description is furnished. The post brake, as shown in Fig. 6, has two block brakes a a', which are applied to the drum at places diametrically

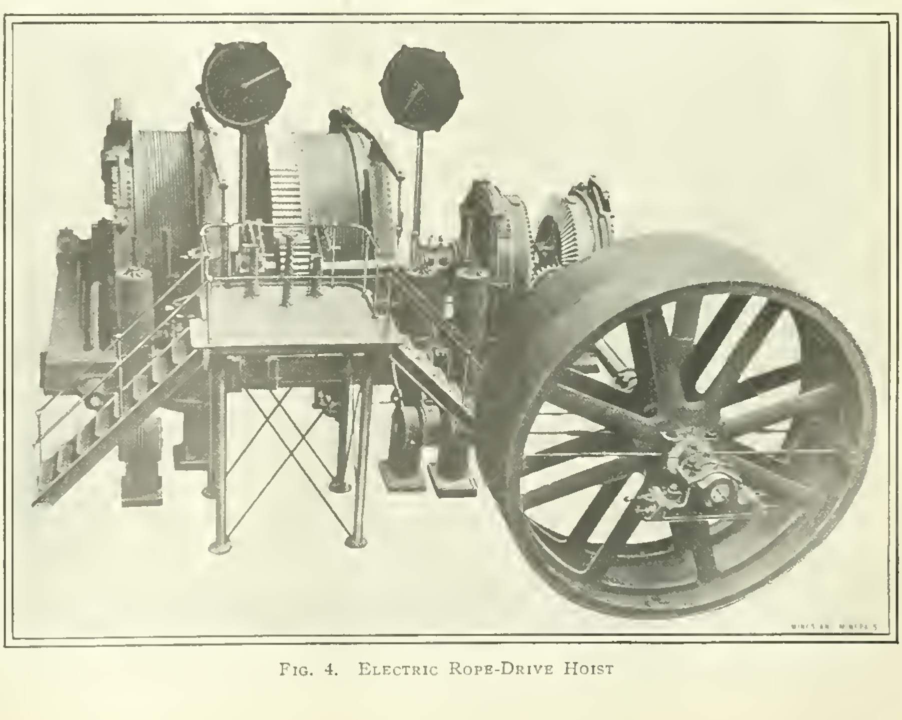

Fig. 4. Electric Rope-Drive Hoist

opposite, thus equalizing the pressure on the drum-shaft journals. To have an equal clearance at the top and bottom of the posts, $a\ a'$ are made movable at the top and bottom. The tops are moved by the tension rod b, and levers c, d, and e. The lever e is pivoted at f and transmits motion through levers g, h, and i to the fulcrums j. The brake post a is supported by the uprights k, which, pivoted at l, swing backward and

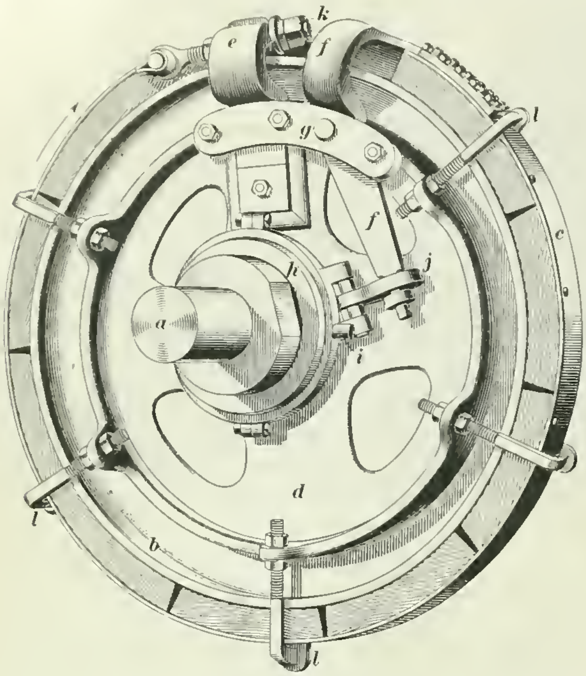

Fig. 5. Band Friction Clutch

forwards in parallel. To adjust the motion at the bottom of the post so as to give equal clearance at the top and bottom, the setscrew o is provided. In the illustration the upright m for the post brake a' is pivoted at n. The brakes, as well as the drum clutch on the Ray hoist are operated by means of a combined air and cataract cylinder fitted with floating valve gear under control of a hand lever on the operator's platform. The brakes, which are set by weights, are released by the air cylinders.

The skips used at the Ray shaft are not provided with safety dogs and appliances, on account of the extreme weight and bulkiness of such equipment for a load of this magnitude, but instead a device is provided to prevent the skips being carried into the sheaves through any neglect of the operator.

This overwinding device consists of two limit switches, one for each skip, so placed that when the skip is carried beyond the highest point for dumping, it will come in contact with an extended lever, which, moving through an arc of 35 degrees, disengages the contacts. The limit switches are connected by wires to solenoids operating quick-opening valves in the supply pipes to the air cylinders, so that if the skip passes a given point in the shaft, the solenoids come into action and at once release the pressure from the operating cylinders, allowing the weights to apply both of the powerful brakes and throw out the clutches, bringing the hoist at once to a stop without the necessity of stopping the motor.

The hoist is designed with a high factor of safety to guard against any possibility of delay from breakage or derangement.

The ore is carried underground in 5-ton steel cars running in trains propelled by electric locomotives and is dumped into a 300-ton bin on each of the two main working levels. This is accomplished with revolving cage dumps, holding three mine cars at a time, which are upset by means of an electric motor. The ore is discharged into the bin beneath, from which it is drawn to a measuring hopper holding a skip load. When a skip is to be loaded, it is spotted beneath the spout of the hoppers at any desired station and the hopper gate opened.

The ore skips are constructed of $\frac{1}{2}$-inch steel plate, 4 ft. 10 in. × 5 ft. 2 in. × 10 ft. in depth, while the total height from the center of bottom swing bearing to the top of the rope socket is 18 feet. The cast-steel bottom swing bearings and saddles have each a bearing area on the bottom of the skip of $15\frac{1}{8}$ in. × 45 in. The swing and saddle shafts are each $5\frac{1}{2}$-inch diameter, collared and placed on 22-inch centers. The dumping rollers are of cast steel, bronze bushed with cast-steel trunnions $5\frac{1}{2}$ inches in diameter. The crosshead frames are $1\frac{1}{4}$ inches in thickness by 20 inches deep and are provided with special cone roller bearings to take the lower member of the cable socket. This construction permits the cable to turn or twist freely. The forged steel skip frames are $1\frac{1}{4}$ in. × 12 in. in cross-section. The inside front and back of the main skip body is protected by $2\frac{1}{2}'' \times 1''$ bars extending from the mouth of the skip to a distance of 3 feet 6 inches from the bottom. These bars are riveted to auxiliary plates 1.4 inches thick, which are bolted to the main body by means of special $\frac{7}{8}$-inch bolts. This permits the easy removal of the bars for repairs or renewal.

No supplies, waste rock, or men are carried in the main hoisting shafts Nos. 1 and 2, but a smaller electric hoist is used in an auxiliary inclined shaft at each plant for handling waste rock and supplies, while the men go into and out of the workings by means of an easy stairway in these inclined shafts.

Barytes an Important Mineral

Barytes, or barium sulphate, is a heavy crystalline mineral, white when pure, which is very little affected by acids, alkalies, or corrosive gases. In 1910, according to a Report of the United States Geological Survey, the United States produced 42,975 short tons, valued at $121,746, a considerable decrease as compared with the figures for 1909. Barytes is an interesting and useful product. By far the greater part of the mineral produced is consumed in the manufacture of mixed paints. It is not satisfactory as a pigment if used alone in oil, for its crystalline nature renders it too transparent to give good hiding power, and to be of any advantage it must be used in only moderate percentages in mixed paints, which consist principally of the lead and zinc-white pigments. Its use as an adulterant in white lead or in any other pigment or commodity is not legitimate and should be discouraged by the producers. There are sufficient legitimate uses for this valuable mineral to create a healthy market for it if properly handled. Barytes is used also in the manufacture of lithopone, a very white pigment that is suited most particularly to interior use and is employed in enamels and wall finishes. Barium salts are reported to be used in brickmaking in order to overcome the efflorescence of bricks. Other uses for barytes are in the manufacture of rubber, wallpaper, asbestos cement, poker chips, and in tanning leather.

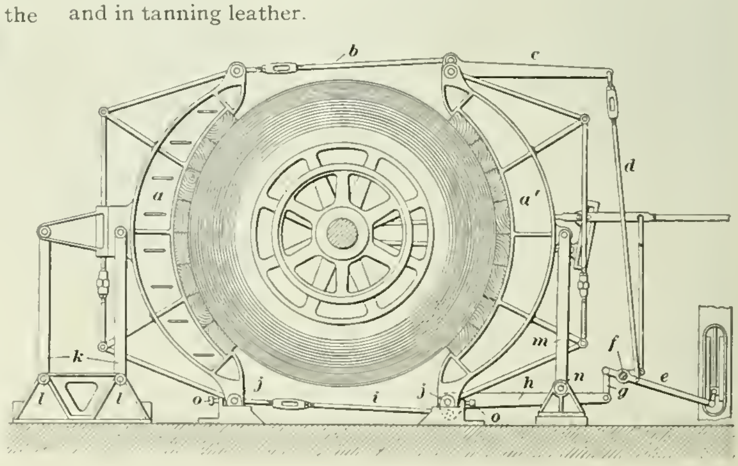

Fig 6 Post Brake

Fires in Metal Mines

Instances Showing the Dangers and Difficulties of Dealing With Metal Mine Fires

Herbert Wilson, Chief Engineer of the Bureau of Mines, in a lecture before the National Fire Protection Association in May, 1911, says:

"Fires in mines are of far greater menace to life and property than is generally appreciated." This statement, while correct, might have been emphasized by saying that more of the mine disasters in which there was great loss of life were due to fires than to explosions. With the possible exception of Le Neve Foster, writers on metal mining topics have neglected this important subject, probably owing to the difficulty in procuring authentic records of metal-mine fires. The writer having had the same difficulty, this article is necessarily incomplete, but surely a subject so important is worthy of more attention than it has been given if the lives of metal miners are to be conserved. So much attention has been given to coal-mine explosions and fires that the metal mine fires have been practically overlooked; nevertheless, it may be of interest to know that in some metal mines as much care is taken to avoid mine fires as is taken in coal mines to avoid explosions.

In 1803 a fire started in the timbering of the quicksilver mine of Idria, Austria, and getting beyond control, necessitated the mine being filled with water. This is the first record the writer has of a mine fire, and it is taken from Prof. S. B. Christy's translation of Von Lipold, on quicksilver mines in Austria. To remove the water from this mine after the fire was out required 3 years. In 1846 another fire killed several men in the same mine and involved another flooding of the mine.

E. Lord, in Monograph 4, United States Geological Survey, 1883, under the heading "Comstock Mines and Miners," says: "Fires happened several times in the timbering of the Comstock mines previous to 1869." In that year, however, a fire occurred in the 800-foot level of the Yellow Jacket mine that caused the death of 34 miners. After 2 days, when all hope of rescuing the imprisoned men was abandoned, steam was forced into the mines for 5 days. This fire was not completely subdued for 6 months, as smoldering timbers were found from time to time during that period. It was deduced from this experience that steam was not effectual in extinguishing a mine fire, although it was useful as a temporary expedient for purifying the atmosphere of a mine and checking the flames so that it was possible for men to put in dams and cut off the supply of air to the fire. Mr. Lord further states that "in a period of 17 years 49 persons were killed by fires which occurred on the Comstock Lode." Mr. Wilson in his lecture stated that "in the Comstock Lode thousands of feet of tunnels, which had been opened and timbered at great expense, are being burned out, causing falling of the roof and dislocation of the metal-bearing vein, thus rendering future recovery of the ore difficult, if not impossible."

Le Neve Foster, in his work on "Ore and Stone Mining," states that "in 1888 some of the timbers in the De Beers diamond mines, South Africa, took fire. Flames spread rapidly and soon the mines filled with smoke to such an extent that 24 white and 200 colored miners lost their lives."

In 1888 a fire in one of the shafts of the Calumet & Hecla Copper Co., at Calumet, Mich., caused the loss of eight lives in addition to a considerable loss of property.

In the St. Lawrence mine, at Butte, Mont., a fire has been burning in an extensive area about the 1,100-foot level since 1889. The fire has been fought constantly, but cannot be extinguished, although it is possible to control its progress by bulkheads to a considerable extent. A complete fire-fighting brigade is kept working 8-hour shifts. Both the ore and the timber are burning and sometimes the fumes from this fire give trouble in the adjoining mines, which are connected with the St. Lawrence. It is considered probable that the fire has crept from the St. Lawrence into the upper levels of the Anaconda mine. About 18 years ago a fire hood was developed for use when building bulkheads, air-tight cement walls, etc., that are necessary to confine the sulphur gases which occasionally find access into the mine from the burning sulphide ore in the middle levels of this deep mine. The hood, which is described in Volume 29, page 175, Mines and Minerals, was suggested by one of the miners who had been nearly smothered by one of the heavy fire-fighting helmets formerly employed. He advised that a lighter hood be made and attached by a hose direct to the compressed-air pipe, in this way obtaining a suitable air supply. The fire-fighting hoods have been used satisfactorily in other mines of the Anaconda company.

On the morning of November 20, 1901, a disastrous fire at the Smuggler Union mine, in San Miguel County, Colo., caused the death of 23 men, and had it not been for the bravery of a shift boss named Torkelson, who lost his life in warning his men, many more would have perished, as 150 men were in the mine. This fire was due to buildings near the mouth of Bullion tunnel taking fire and setting fire to the tunnel timbers. The fire in the tunnel was prevented from spreading by caving in the mouth with heavy charges of powder. While this was effective, so far as the fire was concerned, it was undertaken too late to save the men, who perished in the mine.

On July 21, 1895, a fire occurred in Block No. 11 of the Broken Hill Proprietary Co., New South Wales. This fire burned for years and cost the company about $150,000. On September 12, 1897, there was an outbreak of fire in Block No. 12 of the Proprietary company, in which three men lost their lives in being overcome by the fumes in their endeavor to reach the seat of the fire. This mining company has established a fire brigade, the members of which are equipped with smoke jackets and helmets.

The difficulties attending an outbreak of fire underground are scarcely realized by the ordinary individual. A fire on the surface and a fire underground are two very different things. In the first instance there is free vent for the poisonous gases, and therefore the fire fighters can approach the seat of the outbreak and take the necessary steps toward extinguishing it, but underground in such extensive timbered mines as the Broken Hill Co.'s, with their miles of workings, a fire is a very different matter. If it is not promptly extinguished before it attains a firm hold, the poisonous gases given off from combustion, being necessarily confined to the workings, make the approach of the men to the vicinity of the trouble impossible under ordinary conditions. In most of the Broken Hill mines fire buckets and hose are provided throughout the entire length of the different levels, so that nothing may be wanting to enable an outbreak to be promptly extinguished by the men on the spot. Should the fire obtain a firm hold, the first essential step is to provide a supply of fresh air as near to the seat of the fire as possible to enable the fire fighters to approach sufficiently close to play water on it. It is necessary in such cases to secure a constant current of air in one direction to guard against back draft.

In the case of fires in the Proprietary mine, which occur from time to time, experience taught the management that all that could be done was to isolate the affected areas. With this end in view all avenues connected with the fire were closed in order to cut off air supply. This was done in the first instance with canvas stretched across the galleries and later with more substantial barriers built of brick, or with bags of tailing sand plastered over with gypsum to make an air-tight dam. Beyond these barriers water curtains were established. These curtains were made by selecting as narrow a spot in the workings as possible and thoroughly saturating with water a certain length of ground from wall to wall of the road on each side of the fire. All the stopes below are in this manner kept constantly wet from above, and in order to insure that there is no dry timber within these curtains through which the fire may make its way, exploratory cross-cuts are put into them. Should any dry portions be discovered, additional quantities of water are directed toward the spot. Making these exploratory cross-cuts is expensive work, and keeping the curtains constantly saturated may in some instances also be expensive; however, the whole operation of successfully fighting fire underground is necessarily attended by heavy expenditure. Where a road is narrow close to the fire and timbering is not too extensive, it is possible to present a barrier by removing a section of the timbering and replacing it with filling impervious to fire. In other places which may be inaccessible to men, tailing is carried down with water. By these means the fire is restricted, cut off from air supply as much as possible, and slowly smolders itself out. This smoldering process, however, sometimes takes several years. In the meantime the workings outside the area must, by means of ventilating fans, be kept free from any poisonous gases or smoke which may escape from the fire zone. At Broken Hill, in the present system of working in the lower level the timber is neither continuous nor open, and the risk from fire in these stopes is very much less than in the upper levels with their great network of timber.

In the middle of February, 1906, a fire broke out at the Junction mine in Broken Hill. Owing to the smoke and gas penetrating the adjacent workings the fire affected the British North, Junction, and North mines. After 8 weeks' work and an expenditure of $20,000 the fire still burned and the mine was flooded, which soon extinguished the flames. The unwatering then started, and it was completed about the middle of July. As the water was lowered the necessary repairing of shafts and levels was carried on. One section suffered considerable from the collapse of the timbers and the incomplete filling of the old stopes, which brought on a creep.

On March 23, 1907, when blasting out some old mine timbers on the 500-foot level of the Homestake mine at Lead, S. Dak., a fire which proved disastrous was started. The noxious gases prevented any advances so that men could play water on the fire, and it gradually crawled up to the 400-foot level. After weeks of persistent effort to overcome the fire and when the danger to the men attempting to fight it had become acute, it was decided to flood the mine. The magnitude of the work can be understood better when it is explained that it took practically 4 months to flood the mine at the rate of 11,000 gallons per minute. By this fire 2,000 men were thrown out of employment and an expenditure of over $1,000,000 was necessary in order to flood and recover the mine. It is not always that fires can be laid to mine timbers, for in several cases the oxidation of pyrite is known to have been the cause.

In the July 20, 1907, issue of *Glückauf*, Herr Hilt writes that mine fires have to be fought in the Selbeck ore mines of Germany. These mines are worked for galena, blende, copper pyrite, and iron pyrite. The deposit is in Lower Carboniferous alum-schist, which weathers readily and permits the pyrite to oxidize. The temperature of the mine is about 82° F. and when the air-currents are strong the schist commences to burn. At one of the Michigan iron mines a somewhat similar condition occurs, so far as shale and fire is concerned. Rock high in sulphur is on fire in the Youngs mine of the Breitung estate, on the Menominee Range. The company working this property bored through to the surface and capped the opening with a smoke stack up which the fumes from the burning mass are being safely conveyed from the mines.

In November, 1909, sparks from a shifting engine set fire to the London mine head-house of the Tennessee Copper Co. Sparks from the head-house set fire to the shaft timbers and imprisoned 54 men, who fortunately were later rescued.

In February, 1911, a fire occurred in the Tonopah-Belmont mine, Tonopah, Nev., on the 1,166-foot level. The position of the fire was such that 17 men were smothered because they could not reach the shaft. In this instance, we believe, that two or three other men lost their lives in an attempt to reach and rescue the imprisoned men.

In the Hartford iron mines, near Negaunee, Mich., seven men were recently smothered by the timbering catching fire.

In September, 1911, a fire occurred in the shaft of the Giroux Consolidated mines in Nevada, which caused the death of seven men by cutting off their escape by the shaft.

It is evident that most metal-mine fires have their origin in trivial causes, and provided proper rules were enforced they might be quickly extinguished. The nature of the combustible materials found in metal mines is such that the progress of a mine fire at first must necessarily be slow in a stope, but in the case of a dry-timbered shaft the chances of its spreading quickly are very much better. If a portable chemical engine or even a hand fire extinguisher were available at the start of a fire it could be readily extinguished. These extinguishers, of course, would not be so serviceable in the case of a shaft fire. While it might be possible to extinguish a shaft fire by means of streams of water from the top, a very good plan would be to use automatic fire extinguishers, which are attached to pipes carrying water. In case of a sudden rise of temperature the fusible plug melts and turns on small streams of water which trickle from numerous holes in pipes, which in this case would be placed around the inside at various levels in the shaft. The futility of using steam alone for fire fighting has already been touched upon. The use of carbon dioxide for extinguishing mine fires has never proved satisfactory, although, theoretically, it should smother mine fires.

The Broken Hill Proprietary Co., of New South Wales, adopted oxygen helmets in 1906, as being at that time the most effective means of exploring burning portions of the mine and assisting in combating fires. By the use of this oxygen helmet a number of fires have been extinguished in metal mines. It is, however, cumbersome, and the wearer, being dependent upon a number of delicate valves and parts, is never free from danger.

The Servus apparatus, which has been adopted widely by municipal firemen, has been simplified for use in mines and is an excellent fire-fighting apparatus, and its comparative cheapness, lightness, and safety will appeal to mine managers.

Note.—It would be greatly appreciated by the editor if the readers of Mines and Minerals would furnish dates and data of metal-mine fires which have come to their notice. It would further add to the movement now going on to reduce mine accidents in metal mines if they would furnish information concerning the cause of the mine fire and the method of extinguishing it.

Twentieth Meeting of the Electrochemical Society

The twentieth meeting of the American Electrochemical Society was held in Toronto, Can., September 21, 22, and 23. The morning and afternoon of the 21st were spent in the reading and discussing of papers. Luncheon was served at the University. In the evening a smoker and entertainment by Section 2, was held in the main building of the University. On Friday, the 22d, a special train took the members to the Lambton Golf and Country Club, where papers were read and discussed, and luncheon served by the club. The afternoon was devoted to recreation and the evening to a subscription banquet. On Saturday the members went to Hamilton in special cars, where the Canadian Westinghouse Co., and the Steel Company, of Canada, were visited. After luncheon the members went to Dundas by electric cars where the Hydro-Electric Commission's 110,000-volt testing station is located. This pressure is reduced to 13,200 volts and distributed to various cities. After this the meeting adjourned.

A Standard Boiler House

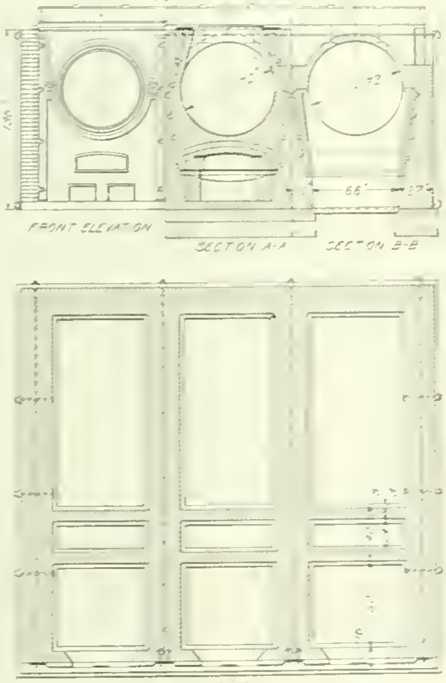
Style of Boiler—Method of Setting—Automatically Dumped Car for Bringing Coal to Boilers

*By J. S. Jacka**

The following paper was read at the August 1911 meeting of the Lake Superior Mining Institute, under the title, "Standard Boiler House and Coal-Handling System of the Crystal Falls Iron Mining Co., Menominee Range":

One of the first questions to be decided in the construction of the power plant is its location. This depends largely upon the location of the shaft, the ease with which coal may be brought to the boiler, and means of storing the coal, especially in the winter.

The first factor, the location of the shaft, is one that has an important bearing upon the location of the engine house. The building must be so situated that the cable will have as few sharp bends as possible, and still be comparatively close to the shaft. The cost of handling the coal and ashes is usually the largest item in the operating charges. In plants as found at some of the smaller mines, the amount of fuel and ash handled does not warrant the expense of an elaborate conveyer system, which would be justifiable in larger plants. In whatever way the fuel is supplied, provision must be made for storing a quantity sufficient to operate the plant for some time, in case supply is interrupted, to guard against an enforced shut-down.



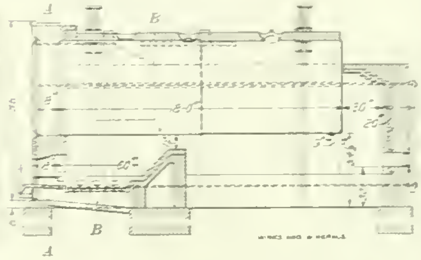


Fig. 1. Boiler and Setting

The type of building should next be considered. It must be as near fireproof as possible, cheap in construction, and should be flexible enough in the design to make it conform to the various local conditions found at the mines and still retain the same general shape or plan. This has been the aim in all of the installations at the Crystal Falls Iron Mining Co.'s properties. One set of drawings has been made and they have been used in the building of all boiler houses, with only slight variations as were necessary at the mine. For lack of a better word this has been called the "standard" boiler house of the Crystal Falls Iron Mining Co. The term is not used to imply that one boiler house is the exact counterpart of another, but that certain features of its construction and details have been so standardized that as a whole it may be termed a "standard" boiler house.

The boiler should be of a type such that its first cost will be low, and still give a maximum efficiency with a minimum amount of expense for its upkeep. As affecting fuel economy the boiler equipment is by far the most important part of the power plant and involves the largest share of the operating expense. It matters little how elaborate, modern, or well designed it may be, skill, judgment and continued vigilance are required on the part of the operator to secure the best efficiency.

Of the various types and grades of boilers on the market experience shows that most of them are capable of practically the same evaporation per pound of coal, provided they are designed with the same proportions of heating and grate surface and are operated under similar conditions. They differ however, with respect to space occupied, weight, capacity, first cost, and adaptability to particular conditions of operation and location. The boiler used by the Crystal Falls Iron Mining Co. is of the fire-tube type. This boiler is simple, inexpensive, and when properly operated is found to be durable and economical. The installation and removal of this type of boiler gives it an advantage over the water-tube boiler especially in mining work, where the life of the plant is comparatively short. The number of boilers installed at any one plant in no case exceeds six boilers, and as there is always plenty of floor space the addition of extra boilers would only involve the cost of installing the boilers themselves. For low pressure and small power the return-tubular boiler has advantage of affording a large heating surface in a small space, and large overloading capacity, a condition to be desired in furnishing steam for hoisting engines. The first cost of this boiler is low, which gives it another advantage over the water-tube boiler.

The boiler shown in Fig. 1 practically conforms to the specifications of the Hartford Steam Boiler Inspection and Insurance Co. The "standard" is a 72" × 18' horizontal return tubular boiler having sixty-eight 4-inch tubes. The shell is made of open-hearth flange steel plate ½-inch in thickness. The heads are ⅝-inch in thickness. The longitudinal seams in the shell are the butt joint double-covering strip type, triple riveted. The girth seams are single-riveted lap joint. These riveted seams are proportioned so as to secure the strongest possible joint. The braces in each case, together with their rivets, have been carefully calculated for the pressure they are to bear, and are so distributed that all parts of the surface braced may be sustained. The boiler has a 11" × 15" manhole in the front end below and in top shell above tubes. The front is the full arch flush type. The flush front costs a little more than the extended front for brick and setting, but it is more convenient to operate and the boiler is less expensive.

Fig. 1 shows longitudinal section of the boiler setting. This setting is the same regardless of the number of boilers and is made of hard red brick laid in lime (or cement) mortar and the entire setting is lined with firebrick up to the center line of the boiler, as shown in the drawing. Every fifth course is laid with headers, so that any part that might become damaged can be easily renewed without taking out the entire lining. In the drawing the grate length is 6 inches less than that of the boiler, and the side wall is battered so as to leave a space at the level where the setting closes into the boiler. The top of the bridge wall is 12 inches from the bottom of the shell and the space behind is left empty. Curving this combustion chamber to conform with the shell only reduces its size, which is a disadvantage with bituminous coal. The rear wall is 30 inches back of the rear head, which makes the chamber larger. The back connection, i. e., the connection between the rear wall and the head, is a source of more or

*Crystal Falls, Mich.

less trouble on account of the expansion and contraction of the boiler, and the difficulty of making a joint that will remain tight. One method is to spring an arch across having one end resting on the wall and the other upon an angle fastened to the back head of the boiler. The arch consists of brick resting in an iron framework. Another method used is to place steel rails across the setting laterally and fill in the spaces between the rails with brick.

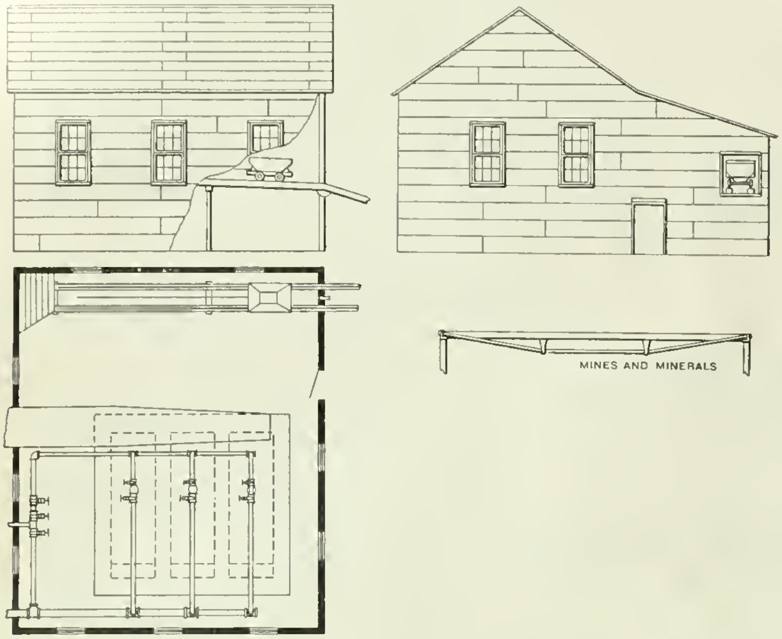

Fig. 2

It is sometimes difficult with low-grade fuels and natural draft to burn sufficient coal in the grates of a horizontal tubular boiler to produce the evaporization needed. For this reason it is necessary that the grate surface be as large as possible, and have the maximum rate of combustion per square foot of grate surface for the draft obtained.

The suspended support is used, as this seems to be the best method. The boiler, being independent of the walls, does not get out of alinement with the settling of the walls, which is almost sure to occur. When the boiler is set on the lugs the settling of the walls often throws the support of the boiler on two lugs, thus setting up severe torsional strains in the boiler shell. The boiler is set high in front in accordance with general practice. The expansion and contraction of the firebrick causes the boiler to settle in front and it invariably gets lower than the rear end; this necessitates the raising of the front end.

While this setting has been very satisfactory and has given good service it was thought advisable to try some other type of boiler in order to eliminate, if possible, the settling and cracking of the walls. With this in view a Casey-Hedges patented standard steel setting was installed after carefully considering several different types. This setting appears to present means of overcoming the defects in the all-brick setting and still retains the good features of the old setting. This setting does away with the heavy brickwork walls. It is lined first with a layer of asbestos, then a layer of red, and a layer of firebrick. There is a noticeable absence of heavy foundations, the only ones of any consequence being beneath the supporting columns from which the boiler is suspended. The barrel of the casing is semicircular in shape, being practically an inverted Dutch oven, holding the heat to the boiler as the hot gases pass from the furnace over the incandescent firebrick into the combustion chamber. This setting is cheaper to install and requires less brick. The only repairs necessary are the relining of the furnace, thus lowering the cost of maintenance as compared to the brick setting.

In selecting a grate bar that was cheap and would give adequate support to the coal and yet permit the access of sufficient air from below for combustion, it was found that the Wicks rocking grate gives the best service as compared with the stationary grate; while the initial cost is greater the rocking grate outlasts the stationary grate.

The steam line leading to the shaft is connected to an auxiliary 5-inch header, or by-pass, besides being connected to the main header. This affords a means of making repairs or additions to the main header without stopping the mine pumps. This auxiliary line also supplies the feed-pumps. The Hoppes feedwater heater or purifier is used and is the open type of heater. This style of heater has several advantages over the closed type; namely, it is lower in first cost, is more easily accessible for cleaning and repairs, scale and oil do not affect the heat transmission. It has the disadvantage in that the oil becomes mixed with the steam, but by keeping them clean and using oil traps this difficulty is reduced to a minimum.

The means by which coal may be placed within reach of the fireman presents a more difficult problem in a plant of this size than it would be in a larger one. The method used is to make a space similar to a stockpile ground. A trestle is built the entire length of this space and the railroad cars are unloaded from it. A narrow-gauge portable track is then laid from the coal pile to the boiler house and by means of an inclined track laid on timbers the car is elevated above the coal bunkers. A $1\frac{1}{2}$-ton car is used to convey the coal. The car, designed for this, works automatically. The doors are placed in the bottom and are opened by a system of levers and a spring. A dog engaging a "dump pin," which is fastened to the timbers and is adjustable as to location on the timber, releases a catch letting the doors drop open. When the car starts on its return journey a flat piece of iron attached to the runners, upon which the rails are laid, automatically closes the doors. The car, as shown in Fig. 3, is built low in order to make it easier to shovel into. A small hoisting engine in the boiler house is used to pull the car. This method of handling the coal is very simple and can be adapted to suit almost any condition that may arise in the location of the coal pile. The manner in which the car enters the boiler room is shown in Fig. 2.

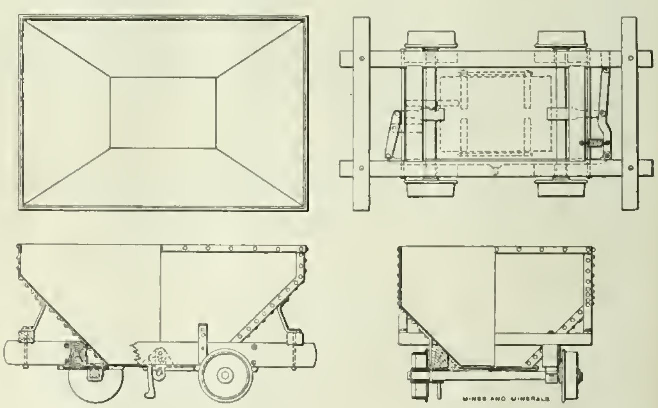

Fig. 3. Coal Car

Oil in Trinidad

It is stated in a recent United States Consular Report that in July a ship was supplied with bunker oil by a local oil company at La Brea, Island of Trinidad. This company makes regular shipments of oil to the United States for refining and is developing a trade in Argentina and other parts of South America.

Mines and Minerals

Vol. XXXII—No. 5. SCRANTON, PA.—DECEMBER, 1911—DENVER, COLO. Price, 25 Cents

PUBLISHED MONTHLY AT SCRANTON, PA.

ESTABLISHED 1881

WESTERN EDITORIAL OFFICE: 1221-1222 First Nat'l Bank Bldg., Denver, Colo.
CHICAGO OFFICE: 1006 Michigan Ave.

Entered at the Post Office at Scranton, Pa., as second-class matter

Address all business communications to MINES AND MINERALS, Scranton, Pa.

CABLE ADDRESS, "RETSOF, SCRANTON"

LONDON AGENTS: INTERNATIONAL BUILDINGS, KINGSWAY, LONDON, W.C.
SOUTH AFRICAN AGENT: MANSION HOUSE CHAMBERS, ALDERLEY STREET, CAPE TOWN.
NEW ZEALAND OFFICE: 63 DIXON STREET, WELLINGTON.
AUSTRALASIAN OFFICE: 83 PITT STREET, SIDNEY.

SUBSCRIPTION RATES

Single Copies .... 25 cents
Yearly Subscriptions, including postage:
To United States, Mexico, Cuba, Porto Rico, Hawaii, and Philippines $2.00
To Canada 2.50
To all other countries 3.00

The date after your name on the wrapper is that of the month to which your subscription has been paid. If you do not want to continue your subscription after that time, kindly notify us.

Notice to discontinue or change of address should be sent to the Scranton office.

When notifying us of a change of address always give your FORMER as well as your present address.

TABLE OF CONTENTS

Dawson-Mackenzie Coal Fields

COAL geologists will find a new theory in the article on "Weathering of Coal Seams" which is printed in this issue. That there is a mingling of botanical fossils of two different geological periods is interesting, but that coal will weather and leave botanical imprints fails to coincide with the editor's experience or meet with approval. Coal flora are found in strata above and below the coal; in the coal beds, however, all organic matter has been carbonized and so lost its identity. Under such conditions it does not seem probable that, in weathering, coal flora would revert to original forms. It is also difficult to conceive how coal could be converted into clay and at the same time retain its full mass or thickness. The article contains much interesting and useful information on coal in Queensland.

National First-Aid Meet

NEVER in the history of coal mining have such a large number of coal operators, managers, and miners, met at one time in the United States as at Pittsburg, on October 31 last.

The occasion of this gathering was the first National First-Aid Meet, and although the weather was unpropitious and the grounds muddy, the events were carried out with such precision and snap, that the rain failed to dampen the ardor of the contestants or the spirits of the spectators.

The teams taking part in the demonstration came from Alabama, Illinois, Kentucky, Maryland, New Mexico, Ohio, and Pennsylvania bituminous and anthracite fields. Washington and West Virginia, Colorado, Utah, and Wyoming, were represented, but not by teams. When the busy executive officials of large mining corporations leave their business to attend an affair of this kind, it goes a long way toward refuting the statements that appear now and again that operators care little for the safety and welfare of their men. If the general public had seen managers and operators congratulating their men it would have been a revelation as to the relations existing between them. One large operator marched at the head of his men and their band. President Taft took great interest in the events, and frequently leaned over from his box and chatted with the contestants between events. To the spectators and contestants the event will be memorable and the Federal Bureau of Mines is to be congratulated on the successful manner in which the program was carried out.

American Mining Congress

At the annual meeting of the American Mining Congress, held in Chicago, most of the general sessions were devoted to important matters pertaining to the coal-mining industry. An important matter that was treated on in papers and discussed by the Congress was governmental interference in the regulation of the coal trade. A paper on the Sherman Anti-Trust Law, with Special Reference to the Coal-Mining Industry, by D. W. Kuhn, ably showed one side of such legislation.

It was but natural that the Chicago meeting should be largely devoted to questions pertaining to the coal-mining industry, just as the Los Angeles meeting was devoted to oil mining and metallurgical questions. As the man interested in coal mining is not often interested in ore mining, it seems that it would be a good plan to separate the Congress into two sections, meeting simultaneously, one devoted to coal-mining interests and one to ore mining and metallurgy. Then when each section had thoroughly discussed matters pertaining to its field, and formulated ideas for the advancement of the branch of mining which it represented, there could be a joint meeting and a combination of forces that, working together, would be productive of much good. At the joint meeting, the views adopted by each section could be reported, brief explanations of each measure, when necessary, could be made, and then the entire Congress could ratify, indorse and pledge its support to every rational action of each section. By such a plan greater interest would be taken in the Congress by prominent mining men who do not now attend the meetings, and much more would be accomplished than is now the case.

Conservation of Coal

True conservation means the utilization of the greatest possible amount of a natural resource with the least possible waste. This can only be accomplished in the mining industry by the skilful extraction of the greatest possible percentage of the mineral in the ground and the utilization of the most improved appliances in preparing the mineral for the market or for use.

In the case of our coal resources true conservation in many fields is only possible by such restrictions in production as will maintain a regular selling price that will be sufficiently high to yield a reasonable profit over the cost of systems of mining which not only allow the extraction of the greatest possible percentage of the coal in the ground, but which will provide for the expensive dead work necessary to mine the coal in thin seams, and to prepare the coal in dirty, slaty, and bony seams, for utilization.

In the past, when coal was mined entirely by individual operators, often men with limited capital, only that portion of the largest seams that could be extracted with least possible expense, including a deplorable lack of engineering skill and foresight, was taken from the mines. As a result in all the older coal fields, and in some where development has been comparatively recent, only 50 per cent., or even less, of the coal in the seam was mined. In addition the mining was so badly done that the major portion of the coal left in these old workings has been made inaccessible by squeezes, large falls of roof, and other causes that make for extremely hazardous, expensive, and often prohibitive operations.

The advent of combinations of capitalists with large financial resources, has in recent years changed these conditions in some of the coal fields. As a result, a very much larger percentage of the coal is being taken out, and, by the expenditure of liberal sums for engineering ability and improved appliances, the percentage of coal in the ground recovered and utilized is being further increased. Seams that 20 years ago were considered worthless on account of their being only 24 to 40 inches thick, or which while thicker were more or less "dirty," are being successfully worked. This is particularly the case in the anthracite regions of Pennsylvania, where the comparatively limited extent of the fields, coupled with the market demands, result in fair market prices. In the same regions it must also be stated the mines are worked more regularly, the men employed are paid in cash and better paid, than is the case in any other American coal field. In fact, if the muck rakers who write for the yellow journals and still yellower magazines were honest, and would really investigate present conditions in the anthracite regions by interviewing old miners, the older clergymen of all denominations, and especially those of the Roman Catholic church, the older professional and business men, and then describe and illustrate present conditions as compared with those of the past, a great portion of the time of so-called statesmen and politicians at Washington, instead of being devoted to tearing down prosperity could be devoted to economic and helpful legislation.

In addition to really conserving the natural mineral resources, the same large combinations of capital, by the voluntary adoption of improved appliances, and the employment of the most skilful officials obtainable, are conserving the lives and limbs of their employes in a far greater measure than was formerly the case. If the mine owners and mine officials of today were to work the deeper and more gaseous, and in the case of bituminous coal the dustier seams now being mined, in the same manner and with the same appliances as were used 20 or 30 years ago, the toll of killed and maimed mine workers would be several times larger than it is.

The United States government has now a Bureau of Mines, which has not been in existence long enough to produce all the good it eventually will, but it has been in existence long enough for Doctor Holmes and his assistants to learn conclusively that the statements here made are absolutely correct. These gentlemen are government officials, they are not connected in any way with mining companies, they are men of character and reputation for truth, they are for the most part men skilled in mining. If the Attorney General of the United States, a member of an official family that is at least supposed to assist and support the president in his manifest desire to conserve our coal resources, will consult these gentlemen, and he is actuated by true patriotism, instead of trying to make laws more demagogical than they were ever intended to be, he will try to have them amended or at least construed so that they will not cause a return to "individual competition," or as one able man recently called it "competitive debauchery" which is now the trouble in many bituminous fields and is the cause of cheap mining methods and waste, loss to operators, and only partial time and its consequent deprivations to mine workers.

Coal is the greatest natural asset our country has. On it depends more than on any other resource the material prosperity of the country. Cheap coal to the masses does not mean their prosperity. Coal at reasonable prices does, and it also means conservation of the nation's fuel supply. Reasonable prices for bituminous coal cannot be maintained in most regions by present ruinous individual competition. The lawyers who have no compunctions in charging large and sometimes astounding fees for their own services, who at the instigation of demagogues endeavor to tear down prosperity in regions where it exists, and to prevent its growth where it is badly needed, cannot be too severely critized.

Personals

George W. Riter, secretary of the Eureka Hill Mining Co., Salt Lake City, Utah, has recently returned from a professional trip to northern California.

Dr. Jas. E. Talmadge, Bermont Building, Salt Lake City, Utah, ex-president of the Utah State School of Mines, attended the American Mining Congress at Chicago and the First-Aid Meet at Pittsburg.

H. N. Spicer, Cooper Building, Denver, Colo., is in Australia on professional work. Mr. Spicer will be in Denver about May 1, returning by way of the Mysore, India, gold fields.

A. J. Hoskin, E. M., Commonwealth Building, Denver, Colo., has been examining coal properties in Park County, Colo.

George W. Schneider, professor of mining at the Colorado School of Mines, Golden, delivered an address before the mining men of Leadville, Thursday evening, October 26, on "Business Methods in Mining." This was the second of a series of lectures to be given by various speakers in the several mining camps of the state under the auspices of the Colorado School of Mines and the Colorado Scientific Society.

Oscar Cartlidge, mine inspector, has been transferred from the Benton to the Marion district in Illinois.

Frank Rossbottom has been appointed State Mine Inspector of the eleventh district with headquarters at Benton, Ill.

Thomas Back has been appointed mine inspector of the sixth Illinois district with headquarters at Springfield.

Thomas Morgan is now mine inspector in the ninth District of Illinois with office at Belleville.

Raymond C. Benner, of the department of chemistry of the University of Arizona, has associated himself with Prof. R. K. Duncan, of the University of Pittsburg, at which place he will make a study of the smoke problem.

E. H. Wilson, consulting engineer for the Pacific Coast Smelting-Refining-Mining Co., is chief engineer for the Stewart mine, Idaho.

Fritz Cirkel, of Montreal, Canada is consulting engineer of the La Campagnie des Champs-d'Or Rigand-Vaudreuil in Quebec.

F. R. Crocker, of Spokane, has been elected vice-president and general manager of the Boyle Gold Copper Mining and Milling Co.

W. M. Briggs has been elected president of the Carbonate M. and M. Co., at Wallace, Idaho.

A. E. Goodell, of Spokane, Wash., is the northwest representative of the International S. and R. Co., of Tooele, Utah, a subsidiary company of the Amalgamated Copper Co.

Waldemar Lindgren has so far finished his studies of the Tertiary gravels of the Sierra Nevada of California as to incorporate the principal features in Professional Paper No. 72 of the United States Geological Survey.

The firm of Ropes & McIntire, consulting and mining engineers, Helena, Mont., having been dissolved, Mr. Ropes will continue in his profession in Helena with offices at the Court House. It is Mr. McIntire's intention to engage in engineering in southern countries.

Wm. Weston, M. I. M. M., of Denver, formerly mining engineer for the Moffat Railroad, has returned from a 3 months' professional visit to the City of Mexico, and is now making an exhaustive examination and report on the gold and silver property of the Colorado Smelting and Mining Co., near Pitkin, in Gunnison County, Colo.

E. R. Buckley, after 3 years with the Wisconsin Geological Survey, 7 years as director of the Missouri Bureau of Geology and Mines, and 4 years professional service as a mining expert, announces that he has opened an office as a consulting mining geologist and engineer, at 1364 Peoples Gas Building, 122 Michigan Ave., Chicago.

D. W. Obern, professor of geology at the University of Oklahoma, has been appointed director of the Oklahoma Geological Survey to succeed Chas. N. Gould, who has resigned to enter private work. The survey is at work on the oil, lead, and zinc, granite, and iron resources of the state, and separate reports will be issued on each of these products in the near future.

Sumner S. Smith, formerly in charge of Car No. 4 of the United States Bureau of Mines, at Rock Springs, Wyo., is United States Mine Inspector for Alaska, at Juneau.

The *Pacific Miner*, one of the oldest technical journals on the Pacific coast has recently been purchased by the *Mining and Engineering World*, of Chicago.

John N. Pott, now chief mining engineer of the Northwestern Improvement Co., the fuel end of the Northern Pacific Railroad, with headquarters at Tacoma, Wash., was, with his family, a guest of the American Institute of Mining Engineers at Los Angeles and San Francisco. Mr. Pott will be pleasantly remembered by mining men throughout Pennsylvania.

Benjamin W. Vallat, manager of the Newport Iron Mines, Ironwood, Mich., whose paper on the systems employed by his company was one of the features of the recent meeting of the American Institute of Mining Engineers at San Francisco, stopped at Denver for a few days on his way home.

Messrs. Philip and P. H. Argall, manager and superintendent, respectively, of Stratton's Independence, Ltd., Cripple Creek, Colo., are in London attending the annual meeting of the stockholders of their company.

Mark O. Danford has been appointed general superintendent of the Cedar Hill Coal and Coke Co. Mr. Danford will be actively engaged as heretofore with his present firm of Danford & Sanderson, civil and mining engineers, Trinidad, Colo.

Willa[illegible] H[illegible], for many years chief geologist of the United States Geological Survey, resigned recently. Alfred H. Brooks, who was tendered the position as chief geologist of the Survey, declined the offer and will continue his work on the Alaskan Division of the Geological Survey.

Waldemar Lindgren has been appointed chief geologist of the United States Geological Survey. Mr. Lindgren has been connected with the survey since 1884, and has a world-wide reputation as an authority on the geology of ore deposits.

B. G. Klodt, designing and construction engineer, has opened an office in the Gunter Building, San Antonio, Tex. Mr. Klodt has been superintendent of construction in the United States, Mexico, and Central America and corresponds in English, Spanish, and German.

O. D. Hogue has been appointed vice-president and treasurer of the Goulds Mfg. Co., of Illinois.

The American Mining Congress and the Colorado Scientific Society, which formerly had joint headquarters at 1510 Court Place, Denver, have separated. The former is at 725 Majestic Building, where E. L. Wolcott is in charge, and the latter in rooms 416, 417, and 418 Boston Building, under the direction of Miss Rebecca Riddle, assistant secretary.

Leroy A. Palmer, formerly of Salt Lake City, and an occasional contributor to the columns of Mines and Minerals, is now geologist for the Forestry Service, with headquarters in the Majestic Building, Denver.

It is announced that George W. Bowen has resigned the presidency of the Victor-American Fuel Co., of Colorado. Mr. Bowen has been with the company for many years, having been one of its founders in the early days of coal mining in Colorado.

E. B. Taylor, of Williamsburg, Ky., has been appointed general manager of the recently organized Bon Jellico Coal Co. Arthur Groves, of Knoxville, Tenn., is president of this new company, which has 1,250 acres of coal near Jellico, Tenn.

W. W. Taylor, who for a number of years has been general superintendent of the St. Paul Coal Co., has been elected president of that company. The present headquarters of the company, which are in Chicago, will be moved to the Maloney Building in Ottawa, Ill.

F. E. Fernekorn, former chief clerk of W. W. Taylor, has been elected secretary of the St. Paul Coal Co. His headquarters will be at Ottawa, Ill.

Harry S. Brady, who for 8 years was with the Youghiogheny and Ohio Coal Co., later with the Charleroi Coal Works, is now associated with W. J. Huston, manager of Ohio for the Moreland Coke Co., of Pittsburg. Their office is in the Rockefeller Building, Cleveland, Ohio.

Revision of Mineral Land Laws

The American Mining Congress, at its recent Chicago meeting, requested that Congress shall undertake a general revision of the mineral land laws of the United States.

The Mineral Land Laws of the United States and Alaska, framed in 1872, and interwoven with a mass of supplementary state legislation, differing in every state, fail to meet the present requirements of the industry. Moreover they have developed various evils, the injurious effects of which are steadily increasing. These have become so serious as to retard the development of mining and to create dissatisfaction and complaint everywhere.

At every annual session of the American Mining Congress during the past 12 years the prevailing discontent with the present code has been voiced by various resolutions calling attention to its evils and asking for the correction of this or that feature of the laws relating to mineral claims located upon the public domain. Such complaints steadily increasing in volume have found expression not only in the Mining Congress but also in the press of the mining communities, all the mining journals, in the societies of mining engineers, and in fact through every medium available for the expression of public sentiment. They have nevertheless been without result, for the reason that the mining laws are largely interdependent and it is difficult, if not impossible, to correct one fault without straightening out the entire code. Moreover, the states affected, some of which have often attempted to make improvements, find that nothing effective can be done without the action of Congress. In short, patchwork is impossible and a general revision is necessary.

Since the problems involved in the work are peculiar to the industry and are unusually difficult, it is evident that their satisfactory solution will require the aid of the most experienced judgment together with a free and direct expression of views by the mining communities themselves. Among the many questions which will arise during a revision are the following, which will illustrate the nature of the work.

Some of the problems are:

The Apex law, with the uncertainties of title and litigation caused by it. The latter includes not only the conflicts caused by the extra lateral right but also those occasioned by the consequent shapes of claims and the overlapping of lines.

The creation of a definite procedure for acquiring rights to those claims in which the mineral is not near the surface and where discovery must in consequence be long deferred.

Tunnel locations and the uncertainties of title caused by them in neighboring claims.

The present non-observance of the law of discovery.

The partial or complete non-observance through various expedients of the law of assessment.

The location of an unlimited number of claims by one individual.

Locations by proxy.

A general revision now will be particularly timely, because of the public interest in conservation and the new legislation now under consideration, for timber, oil, phosphate, and coal lands, and also power sites. To omit the "Mining Code" from any program for the betterment of laws relating to natural resources, would be to pass by the field where relief is most urgently needed.

The American Mining Congress at its last annual session therefore reached the following decision:

"That Congress be asked to undertake promptly a general revision of the mineral land laws, which in view of the difficult problems presented should be in cooperation with the mining industry. The plan adopted for this cooperation should give all sections opportunity for public hearing and the discussion of remedies. The Mining Congress will suggest a practical plan for this purpose later on if desired."

In requesting action upon this matter it is therefore suggested that if Congress will authorize a committee to act, the representatives of the American Mining Congress will be pleased to furnish such detailed information and suggestions as may aid the committee in preparing a plan, whether for a commission or otherwise, which will accomplish the ends desired. A joint resolution like the following is suggested:

"That——Committee——is instructed to prepare and submit at this session a mode of procedure whereby Congress may undertake a general revision of the mineral land laws of the United States in the way which will best promote the public welfare and meet the peculiar needs of the mining industry. The plan recommended should provide a practical means whereby Congress may utilize the best experience and judgment available in the industry and which will give the mining regions of the United States and Alaska ample opportunity for public hearings and the discussion of remedies."

COAL MINING AND PREPARATION

Penn-Mary Coal Company Plant

Description of Tipple, Combined Electric and Tail-Rope Haulage, and Power Plant Arrangements

In the central eastern part of Indiana County, Pa., the Penn-Mary Coal Co., named after the Pennsylvania and Maryland Steel companies has five mines in operation and three more in the course of development. The company started operations in 1904, and since it is not a commercial coal operation in the strict sense of the term, because coal is shipped only to the steel companies, not much is known concerning its excellent equipment and location except possibly in the immediate vicinity. To reach these mines which are high in the Alleghany Mountains it is necessary to take the Cherry Tree and Dixonville branch of the Pennsylvania and the New York Central railroads, running from Cresson and Clearfield respectively to Possum Glory, a station near the mining town of Heilwood.

Fig. 1. Steel Tipple at No. 2 Mine, Heilwood, Pa.

The coal mined in this vicinity is the Lower Freeport or D′ bed of the lower productive coal measures. This coal when low in sulphur makes an excellent coke, but as the bed is apt to vary in this element, the company keeps tab on it by taking samples from the headings and rooms and analyzing them weekly. If the coal in any one heading is high in sulphur it is kept separate from the coking coal and used either at the mine plant or at the steel plants for boiler fuel until there is a change in composition. If local changes that here and there temporarily alter conditions be neglected, the following may be considered as an average section of the D′ bed with adjacent floor and roof rocks:

Floor, fireclay resting on Freeport limestones; coal from 36 to 42 inches; draw-slate from 6 inches to 2 feet; coal from 2 to 3 inches; hard slate up to 20 feet thick with Freeport sandstone above. In this particular locality the B bed is about 140 feet below the D′, but crops out at only one point near center of field, therefore most of the seam must be reached by shafts, while the operations in D seam, at Possum Glory, with the exception of No. 3 mine, are drift mines. The pitch of the bed in the main entries is about $1\frac{1}{2}$ per cent. The butt entries, however, have a pitch of about 4 per cent. Owing to the bed being comparatively thin it is necessary to take down the roof in main entries for headroom and make them from $5\frac{1}{2}$ to 6 feet high above the rail. Most of the main entries are driven with an average width of 10 feet; Mine No. 2, however, has 18-foot wide main haulage entries for double tracks. In some places it is necessary to timber the entries. As a rule, however, the roof arches and becomes safe without timber. Cross-entries are driven 18 feet wide, the extra width being used to store the rock taken from the roof to gain height. The main entries to these mines are equipped with electric bulb lights, and mines Nos. 1, 2, and 3 are supplied with Stromberg-Carlson Co.'s mine telephone system. To hasten development Pneumelectric coal cutters are used in headings; in No. 1 mine they are worked day and night.

Fig. 2. Power House and Cooling Tower

The mines are worked on the double-entry system, cross-entries and rooms having 50-foot centers, the rooms being 26 feet wide. Owing to the low bed, the cars are made necessarily small in comparison with some other mine cars. The Penn-Mary mine car, shown in Fig. 3, is 33 inches high, 60 inches wide; has 42-inch gauge, and 24-inch wheel base. The capacity of these cars is 1.2 tons, and with the exception of the single drawbar iron, the brake lever at the rear of the car, and chain-haul hook underneath, the cars do not differ materially from others of the wooden type. Owing to the bumping and jerking to which mine cars are subjected the bolts fastening the axle boxes gradually enlarge the holes in the plank car bottoms so that in time the car body has a swaying motion that may exceed the safety point or at least require repairs. For this reason Superintendent Dowler will probably replace the old car-truck system with the angle-bar truck of the Hockensmith Wheel and Mine Car Co.

Haulage from No. 1 mine is a peculiar combination of head-rope and a Baldwin-Westinghouse electric locomotive acting as a barney. The main entries at this mine are 8,000 feet long with a $1\frac{1}{2}$-per-cent. grade and at times more. Cars are run in trips of from 35 to 65, and this being too much for a 12-ton locomotive, the locomotive and trip are hauled from the mine by a 400-horsepower, Lidgerwood steam haulage engine winding 7,500 feet of $1\frac{1}{8}$-inch rope. On going in the mine the locomotive pulls the empty cars and hauls back the wire rope. The arrangement is a most satisfactory one and is believed to be the first haulage system of this kind on record. Nos. 2, 4, and 5 mines have straight electric-locomotive haulage, while the slope No. 3 mine has an engine plane with an electric hoister.

The Penn-Mary steel tipple at No. 2 mine is made long, as shown in Fig. 1, so as to span the ravine and receive car froms three mines on a level with No. 2

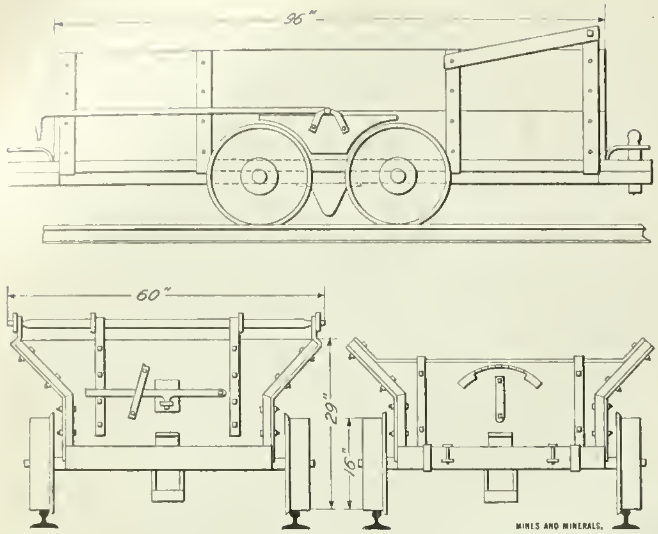

Fig. 3. Mine Car, Penn-Mary Coal Co.

mine. The tipple, which was designed and erected by the W. G. Wilkins Co., of Pittsburg, has about all the modern improvements of an up-to-date colliery structure. A plan of the main tipple floor is shown in Fig. 5. The cars come to the three Phillips cross-over dumpers at *a* in trips of from 50 to 65. Here the cars are moved forward as desired by the chain trip feeders *b*, and as fast as uncoupled, usually at the rate of four per minute, they are dumped onto the ⅝-inch screen. It will be noticed that there are three dumpers on this floor, two on one side of the tipple floor and one on the other. After dumping, the cars run down an incline to the kickbacks *d*, then back switch to a short inclined chain haul *c*, by means of which they are raised to the main tipple floor and cared for by the trip makers *f*. In case one dumper is in need of repairs the cars are run to the dumper on the other side of the tipple, a feature which saves delay inside and outside the mines. Under the tipple there are three curved loading chutes arranged to discharge the coal in the center and toward the ends of the railroad cars. At the second opening to No. 2 mine there is installed one of the latest improved J. C. Stine's centrifugal fans. It is 12 feet in diameter, is installed in a steel fan house and is driven by a noiseless Morse steel chain attached to a 100-horsepower motor. At present the fan is delivering 140,000 cubic feet of air when running at 150 revolutions per minute with 2⅜-inch water gauge and one motor. When more air is needed in the mine than this one motor can furnish, arrangements have been made so that a duplicate motor can be attached to the shaft on the other side of the fan.

The power house shown in Fig. 2 is at No. 1 mine. The water-cooling tower, shown to the right, is supplied with four 8-foot-diameter disk fans, driven by 40-horsepower direct-current motor, with the object of cooling the hot water trickling down from the top and which is used over and over to condense steam in a condenser. Around the circumference of the disk fan housings there are steam pipes perforated with holes and supplied with valves. In winter, if there is any danger of the moisture at the intake to the fan freezing, the valves are opened to admit steam to the pipes and it escaping from the small holes mentioned prevents ice forming. An arrangement of this kind at the intake of a blowing fan would increase the humidity of mine air. The original plant for generating direct current consisted of four 300-horsepower, high-speed, Fleming, side-crank engines, each of which carried a 250-volt direct-current generator, as shown in Fig. 4. As the demand for power increased with the development of the mines, it was decided to install a Westinghouse low-pressure turbine, as it was shown possible to obtain additional power from the same steam and boiler fuel with only the additional use of the necessary condensing water. The turbine installed is a 750 K. V. A., 2,400-volt, 3-phase, 60-cycle, alternating current, operating at 3,600 revolutions per minute, shown in Fig. 6. This turbine when taking steam at atmospheric pressure from the 300 horsepower engines shown in Fig. 4, and operated in connection with the condensing machinery shown in Fig. 7, will deliver 1,000 horsepower at 2,400 volts for local use or for transmission to the outlying operations. In the illustration, Fig. 6, the generator is shown on the left and the low-pressure turbine on the right. The vacuum varies from day to day according to the density of the atmosphere and is normally 27½ inches.

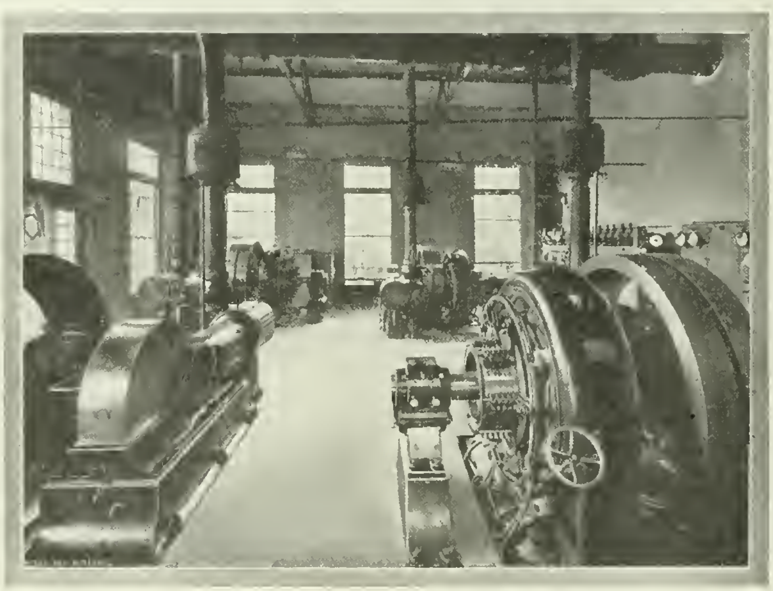

Fig. 4. Interior of Power House

The plant is not at present loaded to its full value, but with the improved conditions, due partially to the higher voltage transmission for outlying points and due to the better combined economy of the reciprocating engines and the low-pressure turbine, it has been found that a saving of about 7½ tons of coal per day is made over the work actually done previously by the non-condensing reciprocating engines.

In order to obtain so much vacuum the exhaust steam must be thoroughly condensed and this is accomplished by the condenser and machinery shown in Fig. 7. The steam enters the condenser *a* from the turbine through the pipe *b*; as it enters it meets a spray of cooling water coming from the

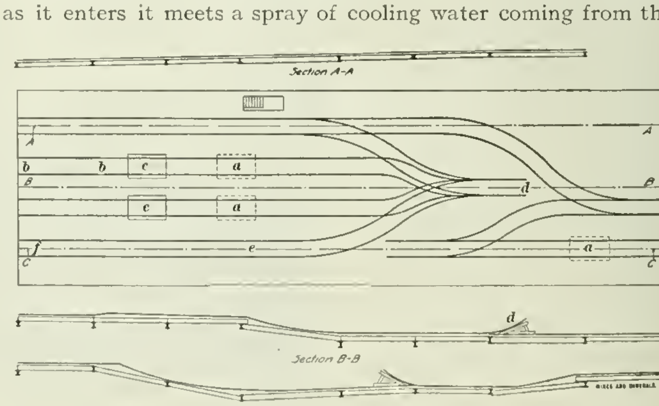

Fig. 5. Plan of Tipple Floor

cooling tower through pipe *c*. As the water from the intake falls through the condenser it is caught in the hot well below and lifted to the cooling tower by the two centrifugal pumps *d* which use the pipe *e* for the discharge. On the common pump shaft there is a Westinghouse high-pressure non-condensing steam turbine *f* that receives the live steam to run it at 1,200 revolutions per minute, direct from the boilers through pipe *g*, and exhausts through pipe *h*. All steam pipes are surrounded with W. H. Johns-Manville Co. pipe covering, to prevent radiation and condensation. Whatever condensation there is in the exhaust pipe *h* is caught in the condensed-water pump *i* and returned to the boiler feedwater heaters. To the rear and right of the condenser is a tank *j* which contains cylinder oil trapped from the engine exhaust previous to its entering the low-pressure turbine. The entire power plant is kept neatly, and evidently the engineers are proud of their machinery. To the rear of the engine room and entirely separated from it by a brick partition and wooden door is the boiler room where the boilers are hand fired. About one mile from the power house there is a substation near No. 2 mine where the 2,200-volt alternating current is stepped down by a rotary converter to 250-volt direct current. At this mine the fan and the tipple machinery are operated by alternating current and the three Baldwin-Westinghouse electric locomotives, the Pneumelectric coal punchers, the electric hoist for No. 3 mine, two Aldrich power pumps, electric lights for mine and the tipple and the auxiliary repair shop receive their power from the substation. To the left of the power house, shown in Fig. 2, is the engine house in which the 400-horsepower haulage engine mentioned as assisting in the haulage at No. 1 mine is installed. Near here, but not shown, is the roomy machine shop, where all mine cars are built and repaired, and where ordinary machinery repairs are made.

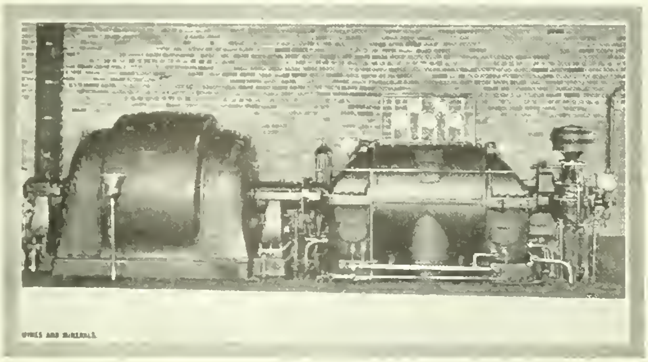

Fig. 6. Low-Pressure Turbine Generator

Near the No. 1 mine there is an electrical repair shop in which armatures are wound and other motor repairs made to the electrical machinery. At this mine Baldwin-Westinghouse electric locomotives, Allentown electric pumps, Pneumelectric coal cutters, tipple machinery, shop machinery, two deep-well pumps for Heilwood's water supply, electric-light plant for the same town and for the mine are driven by power from the central plant already described.

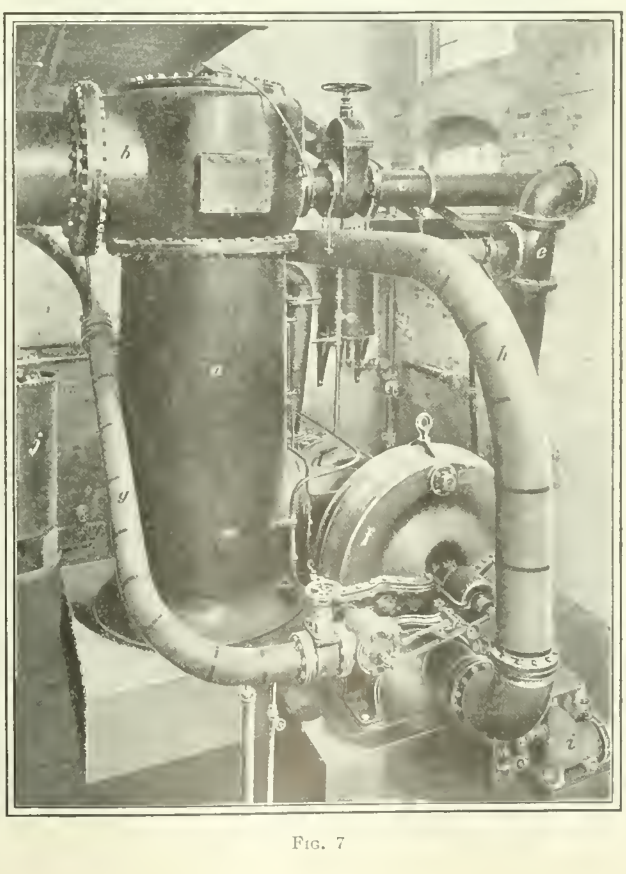

Fig. 7

The fan at the Penn-Mary No. 2 mine is of the J. C. Stine make. It was put in at night so that not a single day's time was lost in the mines. Since its installation it has been running 150 revolutions per minute 24 hours daily, and furnishing 140,000 cubic feet of air, at $2\frac{3}{4}$-inch water gauge. Because of the excellent design and mechanical workmanship the fan furnishes more air with less consumption of power than a 16-foot diameter fan of another make at No. 1 Penn-Mary mine.

The author is indebted to Superintendent H. P. Dowler who so kindly accompanied him and explained the different points of interest about the Penn-Mary mines. He states that it is planned that in the near future a central drainage plant using centrifugal pumps run by electric motors will be installed in the No. 1 mine for handling the drainage of the whole mine.

Phosphorus in Coking Coal

By Charles Catlett

The following paper was read at the San Francisco meeting of the American Institute of Mining Engineers, October, 1911. While the occurrence of phosphorus in coking coal has assumed less importance with the development of the open-hearth method of steel making, it may not be without interest to note the form in which phosphorus exists in one particular coal seam.

In the examination of what is known as the Big seam, which outcrops a few miles west of Columbiana, Ala., my attention was called to the distribution through the coal, in the form of minute veins and particles, of a resinous-looking substance. A smal amount of this was selected, and was provisionally identified as evansite ($Al_6P_2O_{14}\cdot 18\,Aq$).

Subsequently, through the courtesy of Dr. Sharshall Grasty, of the Geological Department of the University of Virginia, I was able to secure an additional amount of material, which was purified down to about .3 gram. This was examined by Prof. John J. Porter, of the University of Cincinnati, and gave the following partial analysis:

	Per Cent.
Loss on ignition	37.43
Phosphoric anhydride	10.33
Alumina	36.33

There was also a trace of silica, and quite a considerable quantity of lime and magnesia.

Professor Porter was led to think that the material was not pure, but a mixture of several of the phosphates of aluminum carrying lime and magnesia. The material available did not permit of the convenient determination of the other ingredients.

One form in which phosphorus occurs in coal is evidently as a hydrated phosphate of aluminum; and any coal which shows to the eye the occurrence of a light-colored resinous-looking material should be looked on with suspicion as being high in phosphorus.

Haulage System at Gray Creek Mine

A Difficult Haulage Problem Solved by Utilizing the Natural Features of the Location

*By F. W. Whiteside**

Gray Creek mine of the Victor-American Fuel Co. is, strictly speaking, not a new camp, being one of the older mines of the Trinidad district. It is situated in Las Animas County about 8 miles southeast of Trinidad, Colo.

A few years ago mines Nos. 1 and 2 encountered a large fault, which at its maximum, displaced the coal 110 feet. It was found impracticable to tunnel into the vein in its new position beyond the fault as the coal disappeared entirely for a short distance immediately beyond it. A new mine ahead of this trouble was therefore located and developed.

The portal of the mine is situated at an altitude of 7,285 feet above sea level and the elevation of the railroad track under the tipple on which its coal is loaded is 6,986 feet, a vertical drop of 299 feet in a horizontal distance of 6,314 feet, an average fall of 4.74 per cent

This line is over the shortest practical route which could be selected. Could the line have been made reasonably straight, the haulage problem would have been comparatively simple. Owing to the topography of the country, an outside line for electric motor haulage would have been practically 2 miles in length. A shorter and straighter line suitable for rope haulage would have required a rock tunnel at least 1,200 feet long to cut through a hill which was much too high to attempt with an open cut.

Fig. 1. Looking Down Plane from Near Wheel *A*

The route finally selected utilized two principal features which had a great deal to do with cheapening the cost of this line. These were a natural inclined plane 2,200 feet in length which required scarcely any grading, excepting some drainage ditches and the haulage entry in the old mine which provided a 900-foot tunnel through the hill above referred to. The latter required a certain amount of timbering and cleaning up of old falls, but this was not an item of serious expense.

After a number of surveys, the line finally constructed was located with the following grades: 950 feet of 3.30 per cent., used as the top landing; 1,575 feet averaging 6.985 per cent., used as a gravity plane; 625 feet of 3.28 per cent., 1,364 feet of 4.402 per cent., 900 feet of 3.67 per cent., through the old mine entry, and 910 feet averaging 2 per cent. from the portal of the old mine to the tipple, which is 26 feet above the top of rail on the loading track. These grades were all in favor of the loaded trips.

Fig. 2. Motor Landing *F-G*

*Chief Engineer, Victor-American Fuel Co., Denver, Colo.

The pit mouth, as located, is 23 feet vertically above the coal. To reach the latter a 10-per-cent. slope driven practically on the pitch of the seam was completed. It was 335 feet in length and for the greater part of the distance was driven in very hard sand rock. When the coal was reached the pitch of the slope became that of the coal or 3.32 per cent.

By referring to Fig. 4, it will be seen that a three-drum rope hoist was selected to operate the haulage on the mine slope and the gravity plane. The machine selected was furnished by the Wellman-Seaver-Morgan Co. No. 1 and No. 2 drums are 6 feet in diameter with 3 feet 4 inches face, drum No. 3 is 3 feet diameter with 1 foot 4 inches face. These are so arranged that they may be operated separately or simultaneously. No. 1 drum is equipped with one 6-foot band brake and one 6-foot friction clutch. Drum No. 2 has two 6-foot band brakes and one 6-foot friction clutch. No. 3 drum has a 47-inch band brake and a 36-inch friction clutch. The hoist is driven by a General Electric, 300-horsepower, 440-volt, three-phase, 60-cycle, 600-revolutions-per-minute electric motor with magnetic contactor equipment and resistance, operated by a master controller. The entire machine weighs 94,000 pounds.

The maximum rope pulls specified were as follows: No. 1 drum, hoisting, 13,000 pounds; No. 2, breaking, 13,000 pounds; and No. 3 drum, breaking, 4,500 pounds.

Seven-eighths-inch, plough-steel, seal-lay, 6-strand, 19-wire rope is used on drums 1 and 2, and ½-inch wire rope of the same description on drum No. 3. This rope was selected on account of its quality of combining great flexibility and strength.

The operation of the haulage is as follows: The main rope winding on drum No. 1 draws the loaded trip up the slope to a position at which the lower end is approximately 25 feet above the 18-inch sheave wheel set under the drill hole which is indicated but not shown in Fig. 4. The ½-inch rope (No. 3) is now attached and the trip continues its way out of the mine and over the knuckle until the position *B-C* is reached, the point *B* being about 20 feet ahead of the large sheave wheel *A*. No. 1 and No. 3 ropes are detached and rope No. 2 is attached at the *B* end of the trip. As it is now standing on a 3.30-per-cent. grade the trip starts itself and rolls down the plane under the control of rope No. 2 until the motor landing at *F-G*, Fig. 5, is reached. Here an electric haulage locomotive takes it to the tipple and returns with a trip of empties.

At the foot of the plane *F*, No. 2 rope is now attached to the trip of empties and lands them at *D-E* where it is detached and No. 3 rope substituted in its place. No. 1 rope is also attached to the *E* end of the trip. No. 3 rope now draws the empty trip over the knuckle and down into the mine to approximately the same position as that in which the loads stood when No. 3 rope was attached to the previous loaded trip. No. 3 rope is now detached and the trip continues to the distributing parting under the control of the No. 1 rope.

As arranged, the hoist can handle a trip on the mine slope at the same time that it is moving one on the gravity plane outside. They may be also handled separately, at the option of the operator.

FIG. 3. LOOKING DOWN GRAVITY PLANE FROM PIT MOUTH

Drums Nos. 1 and 2 develop a rope speed of 600 feet per minute, while hoisting. When lowering trips the speed is governed entirely by the condition of the cars and track. Drum No. 3 is good for a rope speed of 300 feet per minute, but as the distance traveled is short, a much lower speed is maintained.

The regular trip consists of 20 cars with an aggregate weight of 100,000 pounds when loaded with coal. The ultimate capacity of the mine will be 1,000 tons of coal per day.

The hoist-building construction consists of a steel frame covered with hyrib and plastered with cement mortar. The electric transformers stand on one side of the room near the wall. The hoist is equipped with indicator dials which show the location of the trips but the operator is governed by electric signal bells entirely.

From Fig. 4, it would appear that the hoist is set at a greater distance from the pit mouth than the requirements of the case demanded. Its location was determined by the topography of the ground. A site closer to the mouth of the mine would have placed the machine in a heavy fill, necessitating a great quantity of concrete in the foundations. The location also permits a longer lead to the first supporting rollers.

As before stated No. 3 rope is taken into the mine through a drill hole. This is cased with 10-inch rope pipe and is 61 feet from the surface to the top of the coal. It is located on a line perpendicular to the face of the drum at its center.

The total cost of the installation including tram line, hoist, motor wiring, and hoist building was $32,608.

⁂ ⁂

The power required to drive a fan varies directly as the cube of the number of revolutions. If a fan is running 80 revolutions per minute and requires 25 horsepower to drive it, what power will be required to drive the fan at 160 revolutions per minute? Stating the proportion thus: $(80)^3 : (160)^3 : : 25 : x$, then $x = 200$ horsepower.

The Conduct of First-Aid Contests

Editor Mines and Minerals:

Sir:—The recent miner's contest at Trinidad was an event of great interest, but unfortunate in that so little time was allowed it was impossible for the judges to do full justice, and consequently much ill feeling was aroused, especially in the first-aid contest. Since it is hoped that these teams will continue this work, and contest in events annually, it is but just to call attention to certain mistakes that were made. The experience of our team will well illustrate these mistakes.

The first event was as follows: Man's left hand mashed, bones crushed, and cut in palm of hand (slight). Dress with first-aid packet. In every contest we must be governed by the rules of the game, that is the instructions, and I submit that these instructions limit the man to first-aid packet alone, which contains no splint. In support of this contention I refer to the American Red Cross Bulletin, July, 1911, page 61, where this identical injury is given with instructions to dress with first-aid packet and apply splint. Believing that he must follow instructions to the letter our man dressed the injury perfectly without a splint and was deducted five (5) points for so doing. In the second event, "man lying on live wire, burned on back, treat," our team was deducted five points for not withdrawing tongue, although a number of physicians standing by were criticizing him for first pulling out tongue with forceps and then tieing out. These deductions lost us 10 points and the cup, and greatly provoked the team, knowing that they were due entirely to misunderstanding and oversight.

Our opinion is that instructions should not be specific, but simply say dress or treat, thus testing the team's knowledge as to what is proper.

We are of the opinion that no physician or surgeon not having special knowledge of a mine's interior and conditions to be found there, is a competent judge. What physician would think of safety lamps to combat shock, or could dress a fractured clavicle with a pad and one triangular bandage, meeting all indications and having the arm in a sling? What physician not familiar with a mine's interior is able to judge as to best apparatus for handling spinal injury? The decision was, no doubt, greatly influenced by the equipment of the winning team, indeed, the physician presenting the cup made special mention of their original equipment and methods. Yet in what mine can such material be found, or in what mine is supplied such an outfit? Certainly, few miners wear bandanna handkerchiefs, and tin is hardly to be found at all. An improvised stretcher may be useful on rare occasions, but who does not prefer one ready made. This may have been a splendid exhibition of first-aid materials used many years ago, but not of those in use today.

The English government requires that an ambulance box provided by St. John's Ambulance Association, or similar box, be kept at mines; the United States government recommends the Red Cross cabinet which is to be found in most mines today, but it seems to have been decided that such outfits were not practical.

We believe credit should be given for the most carefully devised and practical equipment, and thus will the first-aid man who handles the injured and knows the difficulties with which he has to contend be on the alert to make improvement.

We believe the operating department should be represented on the board of judges, for they are better qualified to judge of the practical value of an outfit.

This contest should impress on all the necessity of some organization to which competent miners should belong, such as the First-Aid Corps of the Red Cross, and every member should endeavor to make his membership of as much value and honor in this country as is membership in St. John's or St. Ambrose's abroad.

J. C. Stone, M. D.
Chandler, Colo.

Grades for Rope Hauls

Editor Mines and Minerals:

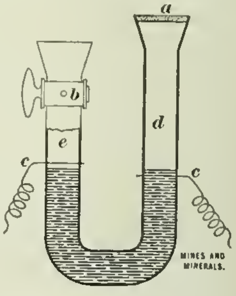
Sir:—I would like to hear through your columns, the experiences of other mining men with grips or clutches for endless-rope car hauls. I cannot find any information on this subject in my files of Mines and Minerals. What is the steepest grade on which endless-rope hauls have worked successfully with grips for attaching the cars to the ropes?

H. L. Handley, Engineer

New Firedamp Detector

In a recent report by Consul General John P. Bray, of Sydney, Australia, is described a new device for detecting firedamp in mines that has recently been invented by two young chemists, junior teachers in the Technical College in that city.

The new detector is a simple and portable bit of apparatus, designed for the purpose of detecting and indicating the presence of firedamp and other dangerous gases in coal and other mines. Its warning is given either by a loud-sounding alarm bell, or by the flashing into view of a red-glow light. The makers of this simple contrivance have based their procedure upon Graham's law of the diffusion of gases, viz.: "all gases tend to diffuse into one another at a definite rate, which varies in an inverse ratio to the square root of the density of the gases." Taking also Ansell's firedamp detector as an additional starting point, the inventors have succeeded in procuring an efficient instrument which an inspector or miner may carry in his hand and test with ease and certainty the air in any heading or at any working face.



New Firedamp Detector

The apparatus consists of merely a piece of glass tubing bent into **U** shape, with the lower curve flattened. One leg of the **U** has an ordinary "shell" funnel at its upper end, and the open mouth of this is covered by a thin disk *a* of plaster of Paris, mixed thin, so that in drying it remains porous. The other leg is crowned by a small reservoir containing additional mercury, with a little glass tap *b* to allow the metal to be run into the bent tube when required. Through each lower leg there is passed a fine platinum wire *c*, that of the funnel-crowned one being about half an inch below the level of the other, and immersed in mercury, which fills the bend of the **U** up to this level. Each wire is connected to the poles of an ordinary battery cell, and thence effective connection is made with either alarm bell or colored light.

What happens when the detector is brought into the presence of a mixture of gas and air is simply this: The foreign gas permeates the plaster of Paris seal and depressed the mercury column in *d*. This naturally causes the mercury in the other leg *e* of the **U** to rise and its rise brings it into contact with the platinum wire just above it. This slight contact is sufficient to complete the circuit, and set either bell or danger light to work. So sensitive is the apparatus that, as shown by tests during the recent exhibition, it can be adjusted to give warning of the presence of such a small proportion as 2 per cent., or even less, of an undesirable gas.

Compensation For Mine Workers

Experience With Liability and Compensation Laws in Europe. Features of a Desirable Law

*By John H. Jones**

The following paper was presented at the session of the American Mining Congress, in Chicago, on October 25, by John H. Jones, president of the Pittsburg-Buffalo Coal Co., of Pittsburg, Pa. Mr. Jones has been intimately associated with coal mining and mine workers all his life, so that no one is better qualified to speak on "Workmen's Compensation Applied to Mining." What Mr. Jones has to say is drawn from his experience with liability insurance and the faithful study of "workmen's compensation" in all its many phases. The paper is therefore worthy of the attention of all those engaged in coal and metal mining, for as one delegate said "the subject will not down" until some satisfactory solution is obtained.—Editor.

In presenting the result of the labors of the special committee appointed to consider and report upon the subject of a workmen's compensation act, I desire to call to your attention some of the things which form the basis of the reasoning of your committee.

The subject of employers' liability and workmen's compensation, in one form or another, has agitated the minds of men for years. The justice of some compensation is generally conceded, and American industry is seeking the best plan to accomplish this object.

The coal-mining industry is no stranger to either "liability" or "compensation," nor did it wait for law to compel, demand, or suggest, a reasonable care for those injured in the mines.

It is natural, then, that a subject of so vital importance to the industry should engage the serious attention of the Mining Congress.

Before deciding on a serious matter of this kind, let us examine what has been done in England, and what has been done in Germany along similar lines.

Mr. A. H. Gill, M. P., of Balton, England, and secretary of the Operative Cotton Spinners Association says:

"In England, before the 80's, the common law was the only means of adjustment, and when negligence of the employer was not proven it was hard to get compensation. The work people became dissatisfied with this state of affairs and began to agitate for a new law, and, as the result, an Employers' Liability Act was passed in 1880, and while it was an improvement on the common law, the act was not a success, as it embodied the doctrine that an employer should not be liable unless negligence was proved. It has always been difficult to succeed in an action under the act, as so many means could be found of resisting a claim. The result of the failure to secure compensation caused a further agitation for an improved method of dealing with the problem, which bore fruit, for in 1897 an act was passed, known as the Workmen's Compensation Act. This act did away with the doctrine of contributory negligence and made the employer liable to pay compensation to a workman who lost time through any accident which occurred while following his employment."

It is unnecessary to discuss this act further than to say that it required 26 years of agitation by workmen, and 26 years of study and experiment by practical men, before a Workmen's Compensation Act was passed.

The opinion of Samuel Gompers, dated Washington, D. C., December 24, 1910, was that

"The Illinois legislature should enact a liberal employers' liability act at the special session and then undertake an investigation with a view to the introduction of an automatic compensation law, for that view observers now regard as the most feasible and just solution of the vocational ills, accidents, and deaths."

Six employer members of the committee of twelve, Illinois Employers' Liability Commission, reported as follows:

"In spite of the fact that every one of the industrial nations of Europe has discarded the system of paying damages on the ground of the liability of the employer, and has adopted in its stead the payment of compensation for industrial accidents; in spite of the fact that New York has adopted a Workmen's Compensation Act, and that both Wisconsin and Minnesota are considering compensation as the only feasible solution to this problem, the Chicago Federation of Labor and its representatives on the Commission have taken a decided stand that the abrogation of the employers' defenses must precede any bill providing compensation.

"It is evident from the letter which the Federation submits that its officers not only are unfamiliar or unmindful of the economic waste involved in any employers' liability system, but that they have no knowledge of the total inadequacy of such a system, even when extended by such serious modification of the employers' defenses as the American Federation of Labor advocates.

"An employers' liability law meets none of the prime necessities of definite compensation, immediately and automatically paid. Under it every case is a gamble."

Major A. R. Piorkowski, representing the Frederick Krupp Co., of Essen, Germany, speaks for the German system as follows:

"The German Accident Insurance had its precursor in the Liability Law of 1871, by which the operators of industrial establishments were liable for the accidents caused by them. The injured workmen had to bring proof that the operator caused the accident, and the amount of compensation was determined by private societies. It is evident that such an arrangement could satisfy nobody. The consequences were long drawn out and costly law suits, by which the contrasting interests of employers and employe were glaringly brought to light.

"The more law suits between both classes, the more hatred was engendered and the farther apart they drifted in their mutual interests. Employers, employes, and the government looked eagerly for a better solution o the problem. The Germans finally determined the liability law did not work for peace between capital and labor, because it worked unjustly toward both of them. Therefore, the only logical and just way to compensate for the injuries done was by insurance.

"First, the proposed compulsory insurance, through an imperial financial institute, that contributors should be employers and the insured. The Reichstag refused this plan.

"Then the Central Association of German Industries recommended the accident insurance. The place of an imperial insurance was taken by the trade associations of the employers. Instead of contributions by the employers and communities came the burden of the first thirteen weeks to be borne by the sick funds, to which the workmen had to pay nearly 67 per cent. The administration remained with the employers. The arbitration courts consisted of employers and employes in equal numbers.

"In 1900 this law received its present shape—briefly. All workmen and administrative officers—the latter provided their annual earnings do not exceed 3,000 marks—are insured against the results of accidents in the course of their employment, if employed in mines, factories, and similar establishments specified in law. In case of disability, compensation is rendered from the beginning of the 14th week after the date of the accident.

"The injured person received free medical treatment, medicine, and other means of healing."

If any gentleman present imagines that the German system would be a success in this country, let me quote from *The New York Commercial*, of Friday, October 20, 1911, under the heading, "Liability Men Criticize State Insurance System." After

*Chairman of the Committee on Workmen's Compensation.

much discussion and an attack upon the suggestion of Governor Woodrow Wilson, as to state accident insurance, it reads:

"Nearly every speaker alluded to a recent review of the German state insurance system, written by Dr. Ferdinand Friedensburg, who has recently retired after 20 years at the head of the senate of the imperial insurance office of the German Empire. Doctor Friedensburg does not find the German system, as it has worked out in practice, by any means ideal. He does not condemn the principles underlying the workmen's compensation for accidents.

"Doctor Lott quoted him as saying that charity crept in and corrupted the system at the beginning; that workmen very soon got accustomed to bringing their complaints, doubts and claims of any nature whatever to the imperial insurance office, often without appealing to any intermediate instance; that the imperial insurance office, which is intended to handle questions of law, is overburdened with frivolous and unfounded claims; that 'the expenses of the system continued to grow as the force required increased'; that 'the number of officials in the imperial insurance office has multiplied in tune with the ever-waxing burden of work'; that 'the number of accidents grows with monstrous speed'; that 'in 1886, 100,159 accidents were reported and 10,540 (10 per cent.), compensated; in 1908, 662,321 accidents were reported and 142,965 (21 per cent.), compensated'; that 'often an accident is sought for and arranged'; that sometimes a chronically sick man swears that his old illness is the result of a recent accident and gets consequental help; that 'the communal chiefs act entirely under the belief that they ought to help their local residents, as a result of the common opinion that the insurance funds have more money than they know what to do with, and this idea strikingly deadens the conception of legality and love for the truth'; that naturally the universal laxity, the payment of unjustified claims, and the extravagance practiced justified claims, and the extravagance in equipping hospitals and sanitoria impair the integrity of insurance funds'; that 'employers do all that is possible to escape their burdens, which they feel to be unjust and in vain as enormous sums are annually exacted from them in fines,' that 'industrial unions and insurance institutions have been repeatedly on the brink of bankruptcy.'

"Doctor Friedensburg points out that the excessive cost of the insurance system, which is one result of the degradation of the system into charity, is complained of by employers, and that state insurance therefore, reacts injuriously upon Germany's industry."

He says: "As a result of the costs of insurance which have gradually become monstrous, German industry is put at a disadvantage and is hampered to the extreme in its competition with foreigners."

Indeed, Doctor Friedensburg makes the astonishing statement that the German system of workmen's compensation is held responsible for the marked rise in prices which is felt to be oppressive by all classes of the German population.

Mr. Wolfe is of the opinion that whether the state will undertake the employers' liability business to the exclusion of the companies depends upon the attitude of those companies and their disposition to cooperate with the state in the solution of the economic problem. He said that employers' liability insurance represents more than one-half of the entire liability business transacted and consequently the question of state insurance is of vital interest to the underwriter.

While heretofore the question may have seemed to the underwriters a fad or a form of socialistic doctrine and an interference with the right of contract, a discourager of thrift and an encourager of malingering and intentional accidents, public opinion is overwhelmingly in favor of entering the cost of human accidents as a part of the cost of production, and the underwriters, in the opinion of the speaker, must face the situation accordingly. Mr. Wolfe believes that a desirable law would embody the following features:

First. A statement of the circumstances under which the employer becomes responsible for an accident during the hours of employment.

Second. A definite scale of benefits to be paid by the employer when he is responsible.

Third. A requirement that every employer to whom the law applies shall file with the commission, mentioned hereafter, satisfactory evidence that his responsibility for the payment of benefits for which he becomes responsible is guaranteed by a corporation authorized to transact the business of liability insurance.

Fourth. The appointment of a commission (some of the members of which should have a knowledge of the technical side of employers' liability insurance), which would classify risks, and would, after the necessary investigation, fix the minimum and the maximum rate which would be charged any corporation authorized to furnish the guarantees.

Fifth. A provision that the commission may, after hearing evidence, order the installation of proper safety devices in order that accidents may be prevented as far as possible.

Sixth. A provision that those employers having more than a certain number of employes may, instead of becoming insured in a private company, elect to deposit with the state the minimum premium required by the commission, which deposit is to be increased from time to time as required by the commission, in order to cover the present values of benefits to be paid, and is to be withdrawn on filing with the commission satisfactory evidence that the deposit is not required for the payment of claims.

Mr. Rowe stated that obviously the trouble with state insurance, viewed from an impartial angle would be the mixing of politics with it. "Workmen's compensation insurance," he said, "can only exert its effect as a blessing if free from all exaggeration and particularly from the conscious or unconscious love-making with the 'lower classes.'"

"Such insurance," he said, "must be issued by an independent institution free from all partiality."

Employers and employes should not lose sight of the fact that less than 50 per cent. of the premiums paid, goes to the real beneficiaries. Whether or not this may be considered economic waste is for others to judge.

Here then are introduced two methods, one the "Employers' Liability Act," which has been discarded by practical men, the other the "Workmen's Compensation Act," now before us, and between these two we are called upon to choose.

Your committee urges a Workmen's Compensation Act as best fitted, by experience and practice, to the mining industry.

The Liability Act appears, to your committee, to be unjust and unreasonable, in principle and practice—the very mention of it suggests lawyers, courts, delays, annoyances, strained relations, expense to employers, and loss to workmen. In one word it means "fight." The Compensation Act means "Payment." The former is an unknown quantity, the latter is a fixed principle known and computed in advance, and provided for. The record of the Liability Act is said to be about 50 per cent. adjustment—the Compensation Act means 100 per cent. adjustment.

Adjustment under a liability act is reported, by one large coal operator, to be injurious in 80 per cent. of cases in a large disaster, in that it would shower money into the hands of the inexperienced, where value is unknown, and where money and widows are soon parted. That this is no idle dream is no doubt known to every man here, and the speaker has had enough experience to "fill a book"—just one experience will suffice to illustrate. During the past two years a certain widow, of a miner, received a so-called liability adjustment, two of the first purchases made were a gold watch and a silk dress, which added to other things made the expenditure for the first month \$900. She spent over \$3,000 a year for these two years, and now finds herself and five children objects of charity. Surely it cannot be urged that this is the compensation intended. True, it was her inexperience and failure to value money that worked the mischief. This is the very thing we argue. This woman is a fair type of those with whom the mining industry has to deal, and the illustration is from life and by no means an isolated case.

Under the Compensation Act no such temptation would have presented itself—the adjustment would have simply continued the natural earning and pay conditions for a period of years, insured the woman against her own inexperience and extravagance, insured to the children the real object of the Act, and be a blessing to the family, and to the community.

Liability law adjustment, in the judgment of the committee, is a mistake—is uncertain and unreasonable—is an injustice to all concerned, and is prejudicial to all the best interests of a miner's widow and children—that it defeats a good intention, and does not insure the care, education, and opportunities of life, supposedly vouchsafed, to the husband and father, by a law which caused him to risk and lose his life in an honest belief, and a sincere endeavor, to provide for his family. In short, it looks as though the most ardent supporters of an Employers' Liability Law, are ambulance chasers, and those who could hope to profit by a disturbed condition, as between capital and labor.

It is also conceded that labor is just as necessary for the maintenance of industry as any other commodity, and that the cost of compensation, as a fixed principle of industry, should be reckoned with in placing a price upon the finished product. Upon the grounds stated, we believe the liability act to be wrong in principle and practice, and that the injustice of it falls upon those who are least able to bear it, on the one hand, and, upon the other hand, this injustice would fall upon those who are supposed to be wealthy—which supposition is based upon opinion thoroughly unfamiliar with the facts, and therefore incompetent, an opinion of those who do not stop to consider whether or not the cost of their wishes is within the possibilities of the industry, or to take into consideration the fact that not one out of ten coal companies could stand the cost of some of the disasters, which have occurred during the past few years, under a liability act, or the further fact that less than 10 per cent. of the coal companies have as much money invested as the cost of some of the mine disasters, of the past three years, and that a liability act would bankrupt 90 per cent. of the companies, should this class of disaster visit their mines—surely such a law would endanger the industry, and therefore cannot be the sober judgment, or even the sincere desire, of either workmen or employer.

The mining industry should stand ready to bear the burden of its own accidents—it should stand ready to pay a tax of 1 cent per ton of coal mined to meet the necessities of the case and to provide the necessary funds.

It should stand ready to have this fund administered wisely in the interests of the workmen and their families.

It has always stood ready to consider, and has introduced every known precaution to prevent these accidents and to safeguard every man employed above or below the ground.

It considers all this right, reasonable, and just, and that the best direction to move in, to accomplish the best results, is the passing of the Workmen's Compensation Act.

This consideration of the subject is not based upon selfish or narrow motives. The company I have the honor to represent operates in five states—the cost, to our company, under this proposed act, which it approves, will mean \$50,000 to \$60,000 a year, and it is only one of many companies, all of which goes to show that the industry is actuated wholly by humane motives, and a sincere desire to squarely meet the conditions of the times, therefore the honesty of the mining industry's view of the matter must be self-evident to every right thinking man.

In the preceding argument we have referred to the best direction to move in to accomplish the best results, and have clearly stated our reasons in favor of the Compensation Act. There is another important matter to consider in connection with this proposed act, namely—the mining industry must give its best thoughts to the method of introducing and passing the Act—it cannot be left to the unfamiliar majority. The combined cooperative influence and wisdom of this Congress is vitally necessary to guide public opinion and legislators in this important matter. The necessity for reasonably uniform legislation by the different states of the Union must not be lost sight of. Uniformity of legislation on all subjects of common interest is one of the most important questions of the times. It was the Hon. Seth Low, president of the National Civic Federation, speaking upon this question, who said:

"If one industrial state makes a change in the law of master and servant, or of negligence, it may unwittingly greatly endanger its manufacturing industries, but if the competitive industrial states will move correspondingly along the same lines, no one of them is likely to be endangered, and the whole country may be benefited."

And, along the same lines, it was Senator Root who said:

"The time has come when each state must legislate on matters of common interest from the point of view of one of a family of states, rather than from the point of view of an individualism that is self-sufficient—the people of the country have grown together in so many ways, without regard to state lines, that, unless fairly uniform legislation can be had upon a constantly increasing number of subjects, the demand for action by the central government is likely to become irresistible, and, in time, even to require an amendment of the Constitution of the United States to give to the central government the power the states fail to use for the common benefit."

It is to bring about just this uniformity that we recommend to this Congress the appointment of a general committee, and we might go a little farther than the printed recommendation and have this committee consist of one man from each of the several states, this general committee to have charge of the enactment of the law presented by the committee, each appointee to act as chairman of a committee of five within his state, composed of himself and four others members, charged with the duty and responsibility of seeing to it that the state legislatures of these states shall pass this law.

The necessity for careful study, for the wisdom which comes from the multitude of counsel, and for definite and determined action, is clearly evident.

The American mining industry should here go on record as favorable to that solution of this problem which is right, reasonable, and just to the industry, to the employer, and to the employe.

A law that strikes at the life of the industry will be a calamity.

A law that does justice to employer and employe, that operates, and compensates, without delay, friction or loss, will be a blessing. May the "wisdom which cometh from above" lead and guide us into that which is best.

Jet Making in England

Whitby, on the North Sea coast, in Leeds district, England, has been the home of the jet industry of England. Jet, a species of lignite, is still mined at Leeds and made up into ornaments for personal wear, but only to a limited extent. Fifty years ago it was a flourishing industry, giving direct employment to 1,500 people in Whitby; now not over 30 are engaged in its production, generally old people, and no others are taking it up. The price of rough jet has fallen in that time from 25 cents an ounce to from 75 cents to \$2.90 per pound.

One old Whitby worker now plies his trade in Leeds and exposes his wares for sale at the city market twice a week. He is the only one so engaged in this city. Some Spanish jet, which is harder and more brittle than the English variety, is imported into England. Fashion has decreed the disappearance of this once important industry of Whitby.

An English Colliery Electrical Equipment

A Description of the Power Generating Plant, Tipple, and Hoisting Cage at Clock Face Colliery

[In order that Americans may see what their friends across the sea are doing in the way of colliery equipment the following article by a special correspondent will be found well worth reading. Like the Americans, the English, when installing new surface plants at coal mines, pay particular attention to electric appliances with a view to efficiency and economy in working. Editor.]

The construction work of the Clock Face colliery of the Wigan Coal and Iron Co. was begun in 1905 and in the latter part of 1906 it was so far advanced that coal shipments were started, although underground development is still being pushed to the property lines.

Clock Face colliery is 3 miles from St. Helens, in Lancaster County, England, and is a modern plant in every way, no expense having been spared to insure the maximum economy and efficiency in producing, preparing, and loading the coal for shipment.

Following British and Continental custom in the matter of shaft form, two 20-foot diameter circular shafts were sunk 2,400 feet to reach the coal bed. These two shafts are connected with the mine workings in such a way that one acts as an intake for fresh air and the other as an upcast for the air that has become vitiated in traveling through the mine workings. Connected with the upcast is a 22-foot diameter engine-driven exhaust fan for creating artificial ventilation in the mine. In order that a check may be kept on the speed of the fan and consequent volume of air passing through the mine, the revolutions are registered by a counter and also by an ordinary tachometer. The British Westinghouse Co. installed the electric power plant, which is up to date in every particular, as an examination of the illustrations accompanying this article shows.

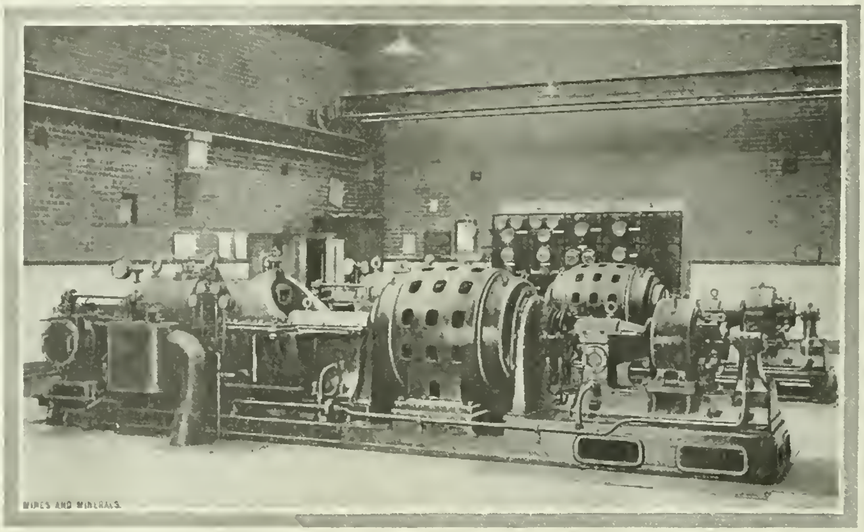


Fig. 1. Steam Turbine Generators at Clock Face Colliery

Steam for driving the machinery is generated in a battery of ten Lancashire boilers to a gauge pressure of 110 pounds per square inch. The feedwater for boilers is preheated by the exhaust steam in feedwater heaters to 180° F. before it is pumped into the boilers.

Electric energy is supplied by the plant shown in Fig. 1, which consists of two 400-kilowatt, Westinghouse-Parsons, straight-flow turbines running on live steam of 100 pounds gauge pressure and superheated 200 degrees. These are coupled to turboalternators generating three-phase, 50-cycle current, at a pressure of 2,200 volts, the speed being 3,000 revolutions per minute.

Attention is directed to the substantial brick power house and the overhead crane that may be put in commission any time that parts of machinery are to be lifted for repairs, or new machinery installed. Although not shown, there is in connection with the power plant a Westinghouse-Le Blanc condenser and air pump capable of condensing the exhaust steam from the turbines and maintaining a vacuum of 28 inches when carrying a full load. The air pump in connection with the condenser is driven by a 15-horsepower squirrel-cage motor running at 845 revolutions per minute.

To the rear of the turbogenerators is a switchboard for controlling the power from these units; it consists of five panels of black enameled slate. The panels are separated at the back by slate partitions, and the spaces formed by these panels are enclosed by expanded metal doors. The current bus-bars are carried overhead by porcelain insulators. Of the five panels, two are for the turbo sets; two for outgoing feeders, one of which controls the underground load, and the other, the surface load; while the fifth panel is provided with bus-bars, and isolating plugs for the possible extension of the plant.

The current is led to a 500-kilowatt, 2,200 to 500 volt, three-phase, 50-cycle transformer placed in the basement, and is taken out through the wall by two triple-conductor insulated cables, supported on wooden poles for about 40 yards, and thence by the wall of the hoisting engine house to the shaft mouth, where one cable goes underground, and the other to the coal screens in the tipple.

A motor-generator set shown in Fig. 2 is used for converting the alternating current to direct current for surface lighting. The cables for this current run on the same poles as those mentioned for carrying the alternating-current cables. The set comprises a 250-volt, 37.5-kilowatt, direct-current generator, direct coupled to a 60-horsepower, three-phase, 720 revolutions per minute, 500-volt squirrel-cage motor.

An oil-immersed auto starter is provided for starting the set.

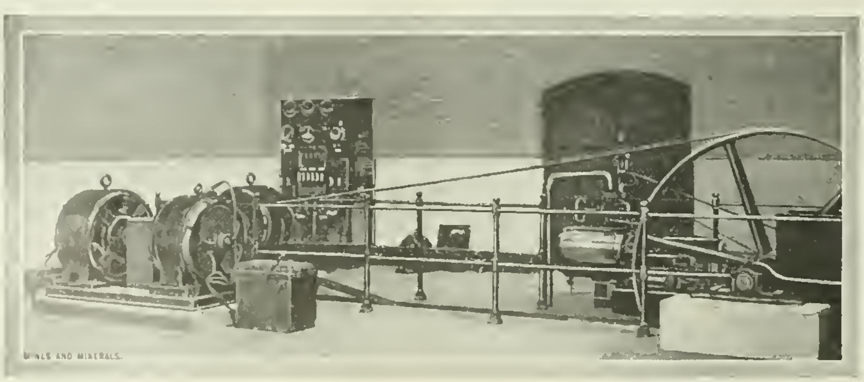

Fig. 2. Motor-Generator Set at Clock Face Colliery

There is in addition to the turbogenerators an engine-driven direct-current generator which supplies power for lighting at night and for driving the tipple machinery. Two motors for this work are shown at *a* and *b* in Fig. 3. The motor *a* drives the shaking screens *c* and the rotary tipples *d* by means of belts, while the motor b operates the picking belts, the lowering ends of which are operated from a countershaft driven by the same motor. One 10-horsepower motor drives an empty-car chain haul, while a similar motor drives a trip feeder that delivers the loaded cars e to the rotary dumping cages. The latter motors are placed below the tipple floor, and because of the dusty conditions that prevail and to prevent accidents the belting is housed as shown in Fig. 4. An examination of this illustration will show that every precaution is taken to guard against accidents and fire; even a box of rubber gloves being supplied for those who have charge of the electric machinery.

An interesting feature in connection with the tipple, and one which would be against the mine law of Great Britain were the tipple not fireproof, is that the screening plant is directly over and 29 feet above the hoisting shaft, so that the cages are wound up into the head-house. This necessitates head-gear somewhat more massive and extensive than is usually required for this work, but a great deal of time and labor is saved by this arrangement as it obviates manual labor in connection with running loaded cars on the rotary dumping cages and in pushing the empty cars back to the cage. Further, the coal is automatically tipped into the screens, conveyed on belts and delivered into the railroad cars in one continuous operation. When one considers the great quantities of shafting, gearing, and belting that would be required to perform the same work where similar machinery is steam driven the advantages of motor-driven machinery are evident.

Double-decked hoisting cages are used at the Clock Face colliery, four mine cars being carried on each deck. The total coal hoisted on one cage at one time approximates 4 tons.

To the American this seems a weak point in English colliery practice because it is evidently cheaper to hoist two 2-ton cars than eight ½-ton cars, and it is also cheaper to hoist one 4-ton car than two 2-ton cars. The conditions relative to thickness of the coal beds necessarily regulate the size of the cars; nevertheless in the United States the output from coal beds 30 inches thick and sometimes less will approximate 2,000 to 2,500 tons in 8 hours where cars holding 1 ton of coal are hoisted from depths between 700 and 900 feet. In the United States capacity is obtained by making the cars long and wide, while the English cars or tubs are made narrow and as high as the thickness of the thin bed will permit. It would appear to the American engineer not conversant with all the conditions surrounding

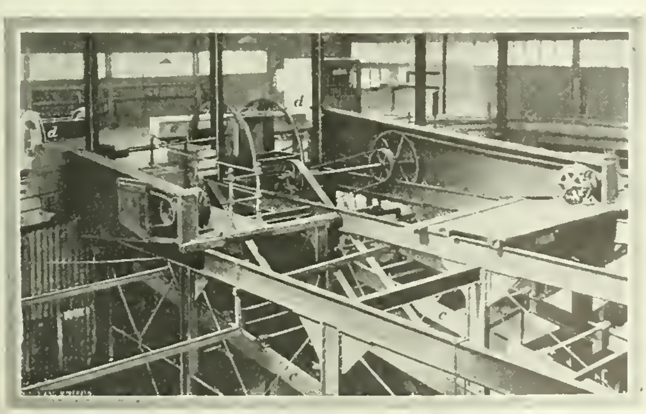

FIG. 3. MOTORS DRIVING TIPPLE MACHINERY

English coal mining, that if the small "tubs" are to be used inside the mines they should be dumped into a larger car before the coal is raised up the shaft.

At the present time the Clock Face colliery is being opened out, but when the underground developments are completed it is expected that the output of the plant will be at least 1,500 tons per day.

The whole electric installation is working in a very efficient manner, is kept in excellent condition, and has given great satisfaction to the proprietors.

Apropos to this output, several shafts in Illinois have been or are equipped to raise from 3,000 to 4,000 tons per day. Recently on single-platform cages, carrying two 2-ton mine cars

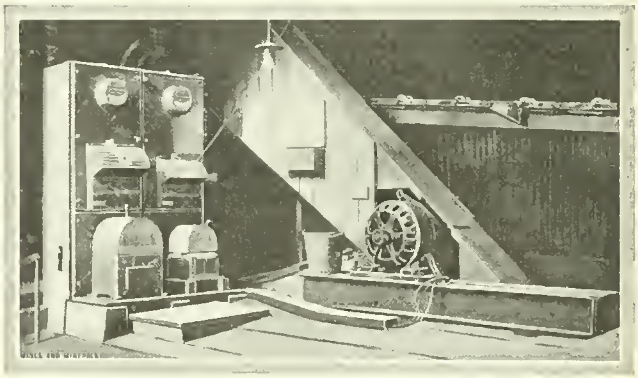

FIG. 4. PROTECTION OF MACHINERY AT CLOCK FACE COLLIERY

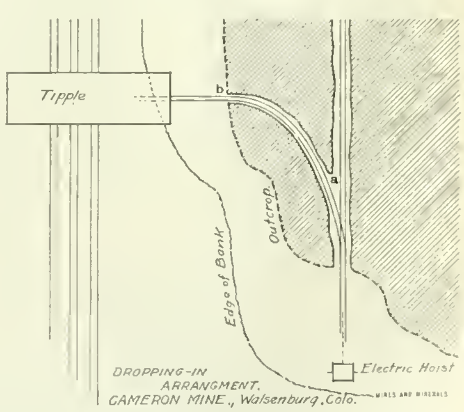
there were raised 4,260 tons of coal from a depth of 285 feet. This was a record for this mine as its usual output in 8 hours is 4,000 tons.

Dropping-In Arrangement

It is a prevailing idea among mining engineers that when once the loaded trip has left the mine it should under no circumstances be allowed to enter again. By reason of this belief, not infrequently excessive charges are incurred in cutting away hillsides or in building trestles, even in poorly locating the railroad tracks, that the loads may be properly dropped into the tipple. That this expense for outside work may, at times, be unnecessary is shown in the accompanying sketch of the arrangement at the Cameron mine, of the C. F. & I. Co., at Walsenburg, Colo. The slope could not well have been placed elsewhere and the location of the loading tracks and consequently of the tipple is fixed by the topography. Also between the outcrop of the seam and the edge of the bank the distance will not average more than 20 feet.



DROPPING-IN ARRANGEMENT

In order to secure landing room, instead of cutting away the steep hillside above the outcrop, which at best would have resulted in sharp curves in the tracks requiring the labor of two or three men to push the loaded trip around them, a curved tunnel a b is driven in the coal. The loaded cars are brought up the slope to daylight by the electric hoist situated directly in line with the slope mouth as shown in the accompanying sketch, and the trip rider having set the switch, they are dropped out through the curved tunnel a b. As the grade in this drift is heavy, the trip runs out properly and, there being no curves at the tipple, the cars are easily handled and the labor of several men is saved.

Buckner No. 2 Mine of United Coal Co.

The thick coal bed known as the No. 7 seam, in Williamson and Franklin counties, Ill., is attracting a good deal of attention at this time. The quality of the coal is said to be the best of any in Illinois, running so low as 10.4 in moisture, 7.22 in ash, and 11,887 British thermal units, when wet, but when dry, the coal averages 8.10 in ash and as high as 13,325 in British thermal units. The Williamson and Franklin counties coal field is considered the most important in the state, as here the coal bed averages 9 feet in thickness, with sometimes a good roof and again with a roof shale that requires a portion of the seam to be left for its support. For the production of prepared fuels a large portion of the fine coal is washed and graded into five sizes. In some instances there is no effort put forth to restrict the quantity of fine coal made, because it is desirable to produce the prepared sizes for market. Not all of the fine coal is washed, there being a percentage of high-grade raw screenings shipped. The quality of the coal is better than that from the No. 6 seam, which fact overcomes the difference in freight rate.

At present there is considerable coal property changing hands and new operations being started. The United Coal Mining Co., which has probably the largest and most modern plant in Illinois, commenced sinking their No. 2 mine, near Buckner, in the fall of 1910. Coal was reached in May, 1911, and its development was immediately begun through the escapement shaft while the main shaft was being fireproofed. The main shaft is 11 ft. × 19 ft. in the clear and 447 feet deep. The escapement shaft is 16 ft. 3 in. × 11 ft. 3 in., with a compartment for a stairway. According to a recent Illinois law it is necessary for main shafts to be of fireproof construction but the law does not state what this construction shall be. The main shaft of the United Coal Co. is concreted from the surface to a depth of 25 feet, and from the bottom upward 25 feet, the space between being timbered and covered with non-expanded metal plastered over with fireproof material about 1½ inches thick. The top equipment which was installed by the Roberts & Schaefer Co., Chicago, is of modern design and complete in almost every detail.

The hoisting engines are of the Danville patent, 28 in. × 48 in., with steam brake and steam reverse. The hoisting drums, two in number, are 9 feet in diameter. The electrical equipment consists of one generator, 250 kilowatts, 275 volts, direct-connected to a four-valve engine, 20 in. × 24 in.; one dynamo, 50 kilowatts, 250 volts; a six-panel switchboard of black Monson slate, with one panel for the 50-kilowatt generator, and one panel for the 250-kilowatt generator, besides one panel blank for future extensions of the electric-power plant. There is another panel with switches for distribution of the current to the mine with the necessary ammeters, circuit breakers, and recording watt meter. There is also another panel with eight switches and ammeter to distribute current to the different buildings on the surface, and still another with four gauges, one of which is a recording gauge with a clock.

On the wall beside the switchboard is a damper regulator which automatically regulates the strength of the draft and the speed of the stoker engine as the steam pressure rises or falls. For the purpose of easily and speedily handling the heavy parts of the machinery, there is an I beam equipped with tackle blocks and arranged to run the entire length of the engine house. To the south of the engine house is a 30,000-gallon steel water tank to which water is pumped from a pond, 1,800 feet distant, by a centrifugal pump, driven by a 20-horsepower motor. The pump is automatically operated by a switch on the tank which sets the motor in motion or stops it.

Another item of interest is a triplex pump, automatically regulated, which will pump water from the mine to the surface. From the main steam line in the boiler house, shown in Fig. 1, a 7-inch steam line supported on concrete piers runs to the fan engine. To this steam line is connected a horizontal tubular boiler in such a manner that in case a shut-down of the large boiler plant is necessary, steam from this boiler will operate the fan and the 50-kilowatt unit, also a small engine at the escapement shaft. This latter engine is used for lowering materials into the mine and can also be used in case of emergency to hoist men.

The ventilating fan is 16 ft. × 8 ft., and is connected to a four-valve engine, 18 in. × 24 in., with a hand cut-off. The mine plant buildings are all of red brick and all have red tile roofs. There are four water-tube boilers of 350 horsepower each, which are fed by automatic stokers. Coal is carried to the stokers by a scraper conveyer equipped with automatic weighing scales to weigh the coal as it is used. The ashes are run automatically from the stoker to a tunnel underneath the boilers, where they are pulled out by a friction hoist. The boiler water is pumped through feedwater heaters by twin pumps having automatic governor to regulate the quantity of feedwater. There are steam separators to every engine which separate the water from the steam, thus permitting the engine to use comparatively dry steam.

The tipple has four tracks and is supported on concrete pillars, with a shaker-screen structure of massive construction provided with screens for separating the coal into about nine different sizes. Underground, coal is to be cut with electric machines and gathered and hauled to the shaft with motors. The pit cars have a capacity of 4 tons and the ultimate output from this mine will be about 4,000 tons in 8 hours.

The Weathering of Coal Seams

Peculiar Geological Conditions at Mines of Charley Coal Mines Proprietary, Ltd., Queensland

*By Tom Coventry**

The Tropic of Capricorn bisects the Dawson-Mackenzie coal field, and the Queensland, Australia, Central Railway undulates from the port of Rockhampton along the tropic westerly. So far as is now known the coal trends about 200 miles north-northwest from the railway and about 200 miles south-southeast, whilst the eastern edge is near the 78-mile peg of the railway, and the westerly extension is to the 120-mile peg. Thus, the coal field has an area of 16,800 square miles. But the whole area is not productive, the anticlinal folds being non-productive. The synclines, however, are large and contain many workable seams of coal from 4 feet to 18 feet thick. Although the Dawson-Mackenzie coal measures are not folded and contorted to such a degree as the anthracite measures of Pennsylvania, yet the two fields, so far apart, are strikingly alike geologically. And this likeness is emphasized by the fact that just as Pennsylvania possesses a great bituminous coal field to the westward, so the Dawson-Mackenzie semi-anthracites are flanked to the westward by a bituminous coal field having seams of clean coal, without a band, 40 feet, 50 feet, and up to 63 feet in thickness. These are flat seams.

"A Section of the Coal Measures Half a Mile West of Trevorton Gap, Pa.," by H. D. Rogers, is a close analogy with the section of coal measures comprising the Charley syncline at the 78-mile peg, Queensland Central Railway. No other coal field in Australasia has a cleavage system, but on the Dawson-Mackenzie the cleavage is well marked and a particular feature in the Charley syncline. The monograph by the American geological observer, Campbell, on the expulsion of volatile matter along the cleavage joints of coal measures, having a cleavage system, to account for the alteration of a bituminous coal to a semianthracite or anthracite, well applies here.

Paleontological Evidences.—The Newcastle coal measures of New South Wales, Australia, form a great basin, and the top seam (Bulli), to which the Balmain shafts are sunk, underlies Sydney harbor at a vertical depth of 3,000 feet. These measures are not folded nor contorted, nor is there any cleavage. The Dawson-Mackenzie coal measures are more or less folded and mildly contorted, and have a distinct cleavage. The whole of the coal seams in the Newcastle basin are bituminous, whilst the whole of the coal seams on the Dawson-Mackenzie are semi-bituminous or anthracitic. Yet the paleontological evidence tends to prove that the two coal fields are of the same age. The fossil flora obtained from a shaft and cross-cuts in the Charley syncline were determined by Robert Etheridge, curator, Australian Museum, Sydney, and at his request W. S. Dun, paleontologist to the New South Wales Geological Survey, made notes on the range of the genera, or species, in the Newcastle coal measures. Table 1 shows the list of plants and notes thereon.

In connection with Mr. Dun's discovery that in the Balmain coal mine, at a depth of 3,000 feet, there is a mingling of botanical fossils of two different geological periods, it will be noted from the foregoing list that the same thing occurs in the Charley coal mines—that evidence has been found of the distinct passage of the fossil plants characteristic of the Permo-carboniferous coal measures of Australia upwards in the plants which are typical of the Triassic age.

FIG. 1. MAP OF QUEENSLAND, AUSTRALIA

Professor David, of the Sydney University, regards Mr. Dun's discovery as of great scientific interest, and is of opinion that the survival of the fern, Glossopteris, in Triassic time may have been connected with the situation of Balmain near to the center of the great Newcastle coal basin. He says: "Around the margin so far it appears that everywhere the Glossopteris flora was overpowered and replaced by the invading Triassic flora, the only portion of the old flora to escape being that situated in the heart of the old swamp at Balmain."

Such an explanation is of more than academic value, inasmuch as it seems to account for the coal measures of the Charley syncline being not less than 4,400 feet thick, whereas at the Queensland state coal mines, 50 miles southeast from the Charley mines, the Queensland government geologist has measured and estimated the thickness of the coal measures at that place to be 2,600 feet. Hence, if Professor David's explanation is applicable, the Charley syncline is probably the heart of the old Dawson-Mackenzie swamp.

Incidentally it may be stated that a railway is now under construction at an estimated cost of £456,000 to connect the Mount Morgan copper-gold mine with the said State coal mine.

The Solubility of Carbon.—We are taught by our most eminent chemists that carbon, or coal, is insoluble. Possibly no solvent for the element has yet been discovered; at all events, no solvent that would or could act within a reasonable time. Yet there must be a natural solvent. The whole of the fossil flora found in the Charley syncline below the zone of weathering

* Superintendent the Charley Coal Mines Proprietary, Ltd.

32—5—4

have been coalized. The fossil flora determined by Mr. R. Etheridge, as shown in the aforesaid list, were among the most

Table 1

Charley Syncline	Newcastle Coal Measures
Phyllotheca (stem and leaves) P. Hookeri, McCoy...........	Would appear to be more common in upper than lower coal measures.
Glossopteris (leaves)............	Gangamopteroid forms more common in both lower and upper, apparently.
Sphenopteris flexuosa, McCoy ..	In both lower and upper, but more in upper.
Alethopteris australis, Morris....	I have not seen this species at all but a form very close to A. Whitbiensis = A. Cladophledis Roylei is abundant in Balmain Shaft with coal.
Schizoneura. ? S. australis. Eth. fils...........................	Have not seen this yet with lower coal measures. In Balmain Shaft is occurs above the seam associated with Glossopteris. There appears to be no break stratigraphically between the Permo-carboniferous and Narrabera.
Phyllocladus (Woods)..........	Coniferous wood = Dadoxylon (araucarioxylon) occurs in both lower and upper coal measures.

perfect plants that gentleman had ever seen, the finest markings being distinct and definitely outlined. And all samples were

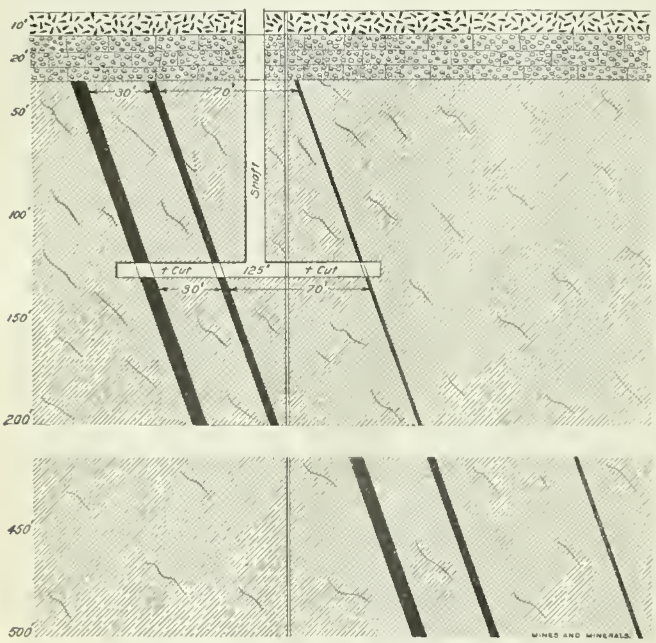

Fig. 2. Section at Charley Coal Mines

leached. Not a molecule of coal was traceable. Some pseudomorphs were limned as bas reliefs by red oxide of iron, others in sky blue, and others in brown. They were all taken from cross-cuts at a vertical depth of 120 feet, where the whole of the coal measures were altered beyond recognition by weathering.

The Weathering of Coal Seams.—If there is any literature on the weathering of coal seams, I have not found it. Of course outcrops of coal may be expected to be dirty, some very dirty. But that a seam of coal could weather to a blue-pug plastic clay seemed impossible until one saw it, and proved it unquestionably. The section Fig. 2 shows a nest of three seams of coal, one 9 feet thick, one 7 feet thick, and one 4 feet thick, and all dipping southwest at an angle of 75 degrees. They are overlaid uncomformably by horizontally bedded ferruginous conglomerate. At their junction with this conglomerate they are all distinct seams, but seams of blue-pug plastic clay in colored clays.

A vertical shaft was sunk to 125 feet, primarily to learn the line of strike and direction of dip of the coal measures. The site of this shaft is 10 feet from a diamond drill, cutting 2-inch core, bore hole. The drill had located two seams of coal, but having ground a large proportion of cores, cross-cuts were put in at right angles to the strike to determine the exact thickness of the seams. At from 171 feet to 182 feet vertical depth, the drill cut a bed of very coarse hard "Post" sandstone, but at the 125-foot level this bed showed all the structure of sandstone—yet it was all clay without a particle of grit. In such a weathered zone it was hopeless to expect the coal seams to be other than very dirty, nevertheless cross-cutting a "dig" where one man on each face could break more ground than two muckers could get away, and two men on a windlass could haul, would allow the tape to be put on the seams. Moreover, the faces were veritable herbariums, albeit the plants were leached fossil flora. Here, too, the cleavage system was seen—greasy, treacherous "heads." It seemed as though some movement in the country had taken place, but any such assumption was precluded by the fact that perfect Sphenopteris fern leaves laid unbroken over the cross-joints. The cross-cuts proceeded, and the middle seam was reached first, a purple with brown "mush," damp and so tender that it was difficult to preserve a fair-sized block. Yet the mass was stratified as cleanly as a book of cigarette papers.

Our consulting geologist, Mr. R. Logan Jack, F. G. S., ex-Government Geologist of Queensland, the discoverer of Queensland's artesian water supply, and the first observer to demonstrate that the Dawson-Mackenzie coal was anthracite, submitted a sample of this "coal seam" to Mr. R. Etheridge, who reported:

"Block of unctuous clay, the whole mass permeated with vegetable tissue in the condition known as 'skeleton leaves,' but there is no definite form or outline to the fragments."

Subsequently the other two seams were cut, the results being identical with the first. These "coal seams" were so opened in June, 1910; today, at time of writing, August, 1911, the blocks which were sun dried present a new appearance—gray, dry, crumbly slate showing indistinct forms of fossil flora. It need scarcely be added that neither of the three seams at the 120-foot level possessed the decimal of 1 per cent. of combustible.

In the bore hole, the diamond drill passed out of the said middle seam at 251 feet vertical depth. It should have commenced at 223 feet and yielded 28 feet of core. But from 222 feet to 233 feet only about 15 inches of core in fragments were recovered. These fragments were coalized Glossopteris, Sphenopteris, and Calamites in a greasy carbonaceous shale. From 233 feet to 251 feet the fair proportion of cores obtained showed small seams or layers of coal, which on analysis proved very ashy, interbedded in unctuous shale which yielded about 32 gallons of oil per ton. Thus, in 125 feet the seam had gained some combustible properties.

The bottom, or 9-foot seam, was struck by the drill at 328 feet vertical depth. More coal flowed over the casing of the bore hole than was recovered as core. The gutter was lined with diamond-grained coal, and the sumps were covered with floating particles. Withal, a proportion of core from that obtained, particularly in the run from 351 feet to 361 feet, layers of "dice," or diamond-grained coal, 1 inch to 2 inches in thickness, gave by analysis the following results:

	Per Cent.
Hygroscopic moisture..	1.2
Volatile hydrocarbons..	6.0
Fixed carbon..	86.3
Ash..	5.8
Sulphur..	.7

These layers of coal were interbedded in coaly shale with thin layers of coal, the proportion of coal being about one to five of shale. The shale is characterized by its very distinct woody structure. This unctuous variety of black coaly shale, pulverized and roasted in a muffle furnace till everything combustible had been burned, resulted in leaving 30.85 per cent. ash. Eliminating the moisture, the combustible worked out as 67.45 per cent.

Summed up, the weathering of these coal seams read:

Outcrops to, say, 100 feet = blue-pug plastic clay.
At 125 feet = skeleton leaves; no combustible.
At 250 feet = poor oil shale; 20 per cent. combustible.
And coal = moisture 1.9; volatile hydrocarbons 7 3; fixed carbon 55; ash 35.8 = 100.
At 360 feet = coal: Fixed carbon 86.3, as shown above.
Unctuous black coaly shale, woody, with 67.45 per cent. of combustible.

Thus, apart altogether from the actual coal, the combustible improved from nil at 120 feet to 67.45 per cent. at 360 feet, or in the ratio of .281 per cent. per foot. The improvement did not average .281 per foot in the upper levels, but averaged higher as vertical depth was attained.

There are cogent reasons for assuming that one of the said three seams is identical with a seam yielding coal having the following composition:

	Per Cent.
Moisture	1.7
Carbon	80.3
Hydrogen	3.1
Nitrogen	1.8
Sulphur	.6
Ash	8.2
Oxygen (by difference)	4.3

In practice this fuel used in a boiler furnace evaporates 9.7 pounds of water from and at 212° F. per pound; and used on a railway locomotive, 3 feet 6 inches gauge, the consumption per train ton-mile is .1243.

At 100 feet deeper than where now opened it is a reasonable assumption that the ash will be lower and the hydrogen higher.

The Charley Coal Mines Proprietary, Ltd., are engaged in sinking a main incline (31 degrees) shaft to cut the said three seams at a vertical depth of 500 feet. From that level a crosscut is projected for the purpose of opening up other seams of coal located by diamond drill, and for reaching the axis of the Charley syncline. The evidence forces the conviction that not a ton of coal true to type, otherwise unaltered, has yet been mined from the Dawson-Mackenzie coal field. Hence, the Charley company's policy is to produce coal from and below the 500-foot (vertical depth) level.

Trade Notices

Waterproof and Fireproof Brattice Cloth.—It has not been found difficult to make a serviceable waterproof brattice cloth, or one that was practically fireproof, but when it has been attempted to make a cloth that is both waterproof and fireproof it has usually resulted in one or the other quality being sacrificed to some extent. The American Rubberfelt Co., 209 Chamber of Commerce, Chicago, Ill., controls the Rubbertex process of waterproofing cloth which completely saturates the fiber, and has recently discovered a process whereby cloth so treated can be made fireproof while still retaining its other good qualities. Users of brattice cloth should write them for information.

Power and Transmission is the title of a catalog recently issued by the Jeffrey Mfg. Co., Columbus, Ohio. They state that more subjects are listed and there is more technical and real information in this book than in any other publication. The complete line is listed and the information given in a way that will make the book valuable to the engineer in charge of an industrial plant, mine, or mill. Besides listing dimensions and sizes of every part in this line, there is descriptive matter on the horsepowers of steel shafting, standard methods of key seating, sizes and dimensions of couplings, hangers, pillow blocks, counter shafts, belt tighteners, clutches, quills, improved split iron pulleys, wood split pulleys, and very complete description and information on rope driving. There is also a complete list of the Jeffrey gears, including spur, bevel, miter, angle reduction, and angle miter. A new method of arriving at the horsepower is given, besides complete information about dimensions and speed, horsepower of belts, and method of calculating bending and torsional moments for shafts.

Exhibit of First-Aid Outfits.—During the National first-aid meet in Pittsburg, Johnson & Johnson, of New Brunswick, N. J., had a comprehensive display of first-aid-to-the-injured appliances. The exhibit was composed of emergency outfits designed not only for mines, mills, and railways, but also for autoists, travelers, campers, and the home. The exhibit was largely attended by miners, mine managers, operators, and others interested in first-aid work. First-aid books published for the average person who wants to make himself familiar with what to do and how to act in all cases of injury go with these outfits, or can be had for 50 cents by writing to Johnson & Johnson. Several of the large coal companies in the East who have been engaged some time in first-aid work, besides the Pennsylvania, Delaware, Lackawanna & Western, and New York Central railroads, have pocket first-aid packets designed for their particular use. These are manufactured by Johnson & Johnson, as well as small and large kits containing all kinds of appliances for the relief of the wounded.

Coaling Stations.—The large amount of coal used by locomotives and the necessity of handling it quickly has caused the importance of proper coaling stations to be appreciated by the railroads. A bulletin recently issued by Roberts & Schaefer Co., of Chicago, describes and pictures a number of Holmen coal and sand stations that have been installed by that firm, who control the patents for the special machinery used in connection with them.

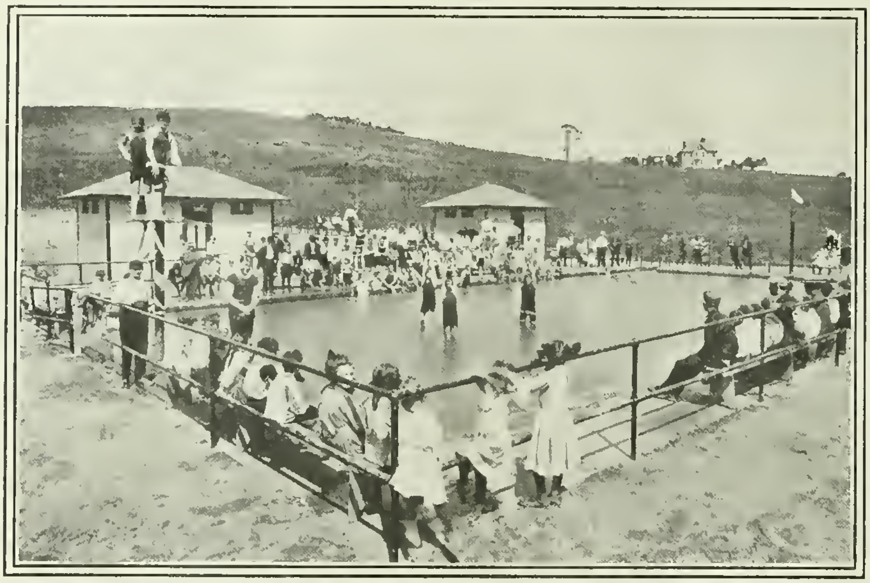
Exhibits at American Mining Congress.—The following is a list of the firms that had exhibits and representatives at the meeting of the American Mining Congress: Western Electric Co., New York, Gregory Brown; Roberts & Schaefer Co., Chicago, Ill., Warren Roberts; Fairmont Mining Machinery Co., Fairmont, W. Va., S. M. Casterline; Sanford-Day Iron Works, Knoxville, Tenn., Hugh W. Sanford; General Electric Co., Schenectady, N. Y., W. T. Dean; The Kennicott Co., Chicago; W. D. Allen Mfg. Co., Chicago; Sullivan Machinery Co., Chicago, R. D. Hunter; Leschen Wire Rope Co., St. Louis, Mo.; Goodman Mfg. Co., Chicago, Charles T. Roeder; Link-Belt Co., Chicago, J. H. D. Petersen; S. F. Bowser & Co., Ft. Wayne, Ind.; John A. Roebling's Son's Co., Trenton, N. J., H. C. Hampton; Wire Rope Lubricating Co., Newark, N. J., R. W. Tobin; Hockensmith Wheel and Mine Car Co., Penn Station, Pa., W. D. Hockensmith and C. L. Herbster; The Hill Pump Valve Co., Chicago; C. O. Bartlett & Snow Co., Cleveland, Ohio, C. O. Bartlett; The Draeger Oxygen Apparatus Co., Pittsburg, Pa., Mr. Morris; Green, Tweed & Co., New York City; Osborne High Pressure Joint and Valve Co., Chicago; Jeffrey Mfg. Co., Columbus, Ohio, R. H. Jeffrey; Eugene Dietzgen Co., Chicago, G. C. Moore; Orenstein-Arthur Koppel Co., Chicago, G. R. Rabbeitt; Streeter-Amet Weighing and Recording Co., Chicago, Will Ball; Hills-McCanna Co., Chicago; American Rubberfelt Co., Chicago, Robt. De Lacy; Christy Box Car Loader Co., Des Moines, Iowa, J. M. Christy.

Air Compressing Under Difficulties.—In the California oil fields at Moron, Kern County, is an air compressor for air-lift pumping. It is located out in the open, exposed to the full glare of the sun where the temperature runs from 105° to 125° F., at midday, even in the shade with proper ventilation, and where the slightest breeze carries dust and sand upon the machine. Under these trying conditions the compressor operates 24 hours per day and is proving satisfactory. The machine which is made by the Chicago Pneumatic Tool Co., has compound-steam, two-stage air cylinders, with mechanically moved intake valves, and is equipped with a complete gravity lubricating system with drip returned, and there is also a small pump lifting the oil from the drip to the reservoir above the machine. The satisfactory operation of this machine under these circumstances speaks well for the design and workmanship of its builders.

Automatic Trip Alarm.—An alarm to indicate the approach of a trip of cars, especially underground, is an important means of safety. A device made for this purpose by the American Safety Lamp and Mine Supply Co., operates a bell by means of the vibration of the car in motion. It is simple in construction and constitutes an "efficient alarm" under the law, and is in use extensively by the D., L. & W. Coal Co., the Delaware and Hudson Co., the H. C. Frick Coke Co., and others. Three models of the machine are now made, one consisting of an automatic bell only, another of a bell and an open torch, and a third of a bell with a storage battery electric light and a red lens for use in gaseous mines.

Canadian Branch.—The American Blower Co., of Detroit, Mich., has filed an application for charter for a Canadian company to be known as the Canadian Sirocco Co., Ltd., of Windsor, Ontario, and shop and office buildings will be built in that city at once. The company will manufacture the Sirocco fan and a full line of products of the American Blower Co., including blowers, heating, ventilating, drying apparatus, steam engines, steam traps, etc.

Temperature of Flue Gases.—The Green Fuel Economizer Co., of Matteawan, N. Y., are supplying temperature pendants free of charge to any one who may wish to determine the temperature of fuel gases. These pendants are pieces of metal which will melt at the temperatures stamped in figures upon them. All sorts of devices for valuing the different losses in the operation of steam power plants are now receiving the close attention of engineers, and these pendants and a description of their use will be furnished on application.



Swimming Pool at Leisenring Mine

New York Office.—Frederick P. Cook, formerly secretary of the Milwaukee Locomotive Mfg. Company, Milwaukee, Wis., has been placed in charge of the New York Office of the Company with head quarters at 111 Broadway. Mr. Cook will handle the sales of Milwaukee gas driven locomotives in the states of New York and New Jersey, and will also look after the company's foreign business.

Swimming Pools for Mining Towns

Cleanliness being next to godliness and swimming being the very best kind of exercise and fun, the H. C. Frick Coke Co. have at their Leisenring No. 1 mine constructed the pool shown herewith. Thomas W. Dawson,* assistant chief engineer, who kindly furnished the illustration, gives the following information concerning the innovation:

This pool is 40 feet wide, 80 feet long inside measurements, about 2 feet deep at one end, inclining toward the other end until a depth of 7 feet is reached at a point 16 feet from the end, the bottom then raises 6 inches in this 16 feet, the lowest point being the drainage one. The side walls and bottom are made of reinforced concrete. There are provided two bath houses, the larger one containing six shower baths for the men, and the smaller one four for the women. Hot and cold water is provided and any one entering the pool is required to take a shower bath.

There is a competent man in charge and he is always at the pool in case his assistance is required when there are bathers in the pool. Saturday afternoons are set apart for women only.

This pool is very popular, being used by the youngest to the oldest persons at the plant and by employes from the other mines in this vicinity, also by persons from nearby towns who are not employed by the H. C. Frick Coke Co. On account of the success of the plan there is contemplated the erection next spring of a number of pools at the other plants.

* Scottdale, Pa.

Bordeni—Roumania's Newest Oil Field

Great activity is now being displayed in the development of Bordeni-Doftanet-sec region of Roumania. The companies actively engaged in developments are the Central Roumanian Co., the Anglo-Roumanian Oil Co., the Concordia, and the Columbia companies. The absence of a pipe line has prevented transportation and hence greater production of crude oil. The Concordia company struck oil at a depth of 1,100 feet, from which it obtained 200 to 250 tons daily. This well was of importance since it proved that the Bordeni oil zone extended much further north than was expected. The Anglo-Roumanian Oil Co., at a depth of 846 feet, struck oil which flowed at the rate of 50 tons per day. In the same vicinity the Concordia company struck oil which flowed at the rate of 40 tons per day. It is now believed that only a small portion of the Bordeni oil field has been exploited.

Obituary

JAMES BENTON GRANT

Hon. James Benton Grant, one of the early governors of Colorado and a pioneer of the American ore-smelting industry in the West, died November 1, at Excelsior Springs, Mo.

Governor Grant, as he was usually called, was born near Columbus, Ala., in 1848. After the Civil War in which he was a participant, he studied civil engineering at the Iowa State Agricultural College, and at Cornell University, and mining and metallurgy, at the Royal Mining Academy, Freiberg, Germany. He joined in the first "rush" to Leadville in the latter part of 1877 where, with William H. James and Edwin Eddy, he established the ore-buying and sampling works of J. B. Grant & Co. In connection with the sampling works a smelter was erected, but its destruction by fire in 1881 led to the incorporation of the Omaha & Grant Smelting Co., with a plant at Denver, which later was absorbed by the American Smelting and Refining Co. Mr. Grant was a director of the latter concern, a position he held at the time of his death.

Western Coal Land Legislation

The Present Coal Land Law—System of Leasing to Avoid Long Time Speculative Investment

By George Otis Smith

At the American Mining Congress, at Chicago, October 27, the following paper under the title "What the West Needs in Coal-Land Legislation," was read by George Otis Smith, Director United States Geological Survey.

In any discussion of the needed revision of our public land laws, a due share of attention must be given to the statutes relating to the coal lands. While certain classes of lands in the western states have largely passed into private ownership, the public's holding of coal lands is still large enough to deserve most serious consideration. West of the one hundredth meridian lies the nation's greatest coal reserve, estimated at more than a million million tons of anthracite, bituminous, and subbituminous coal, and title to from 60 to 85 per cent. of this tonnage is in the United States. It is self-evident that this fuel reserve is the key to the present and future industrial development of the Rocky Mountain region. Utilization of the water-power resources will be an important factor locally, and for several decades fuel oil may be expected to affect the industrial situation, but so far as we can now foresee coal must be regarded as the principal source of power. Its present importance is shown by the fact that the coal production of the Rocky Mountain states was 14.7 per cent. greater in 1910 than in 1909, although for the whole United States the increase in coal output for the same period was less than 9 per cent. Utilization of these western coal deposits that will meet both present and future demands is the end that must be served in whatever public policy is adopted. The West needs, and has a right to demand, full opportunity for legitimate, energetic business development, but that does not include the right to inflict an unearned speculative tax on the future consumer.

Full opportunity on the public coal lands can be defined both from the standpoint of the coal operator and from the point of view of the consuming public. The operator can justly ask two things: First, the right to occupy an acreage sufficiently large for economic operation during an average mine-life period; and second, freedom from too great investment risks. Economic operations we will understand to mean the installation of such equipment as will secure maximum recovery at low cost with proper safeguarding of both life and property, while excessive investment risks refer to capital outlays out of proportion to expected profits of operation. Both of the factors are in reality of hardly less interest to the public than to the operator, for upon them depend in the last analysis much that determines prices and concerns general welfare. The public should also demand that no right to the public coal land shall be granted except for present use. Actual development must be made the first condition of occupancy of any part of what now remains in the public domain.

The present status of coal mining in the West is the resultant of two factors, land ownership and consumptive demand for coal. The large holdings of coal land legitimately acquired through railroad grants and those secured by coal companies through dummy entrymen, and by purchase of agricultural entries as well as those patented to the states as non-mineral lands, together constitute a coal-land supply that has practically met the demand. The strict administration of the public domain during the past few years, however, has shut off all opportunity for wholesale accumulation of coal lands under cover of the homestead and other laws. Up to the present time the acquisition of the coal land in the public domain has been largely accomplished without recourse to the coal-land law, so that the question becomes opportune—is the present coal-land law adequate to meet present and future needs?

This law relating to coal lands is less unsatisfactory than many of the mineral land laws now on the statute books. By its provision for the valuation of coal lands at an adequate price the law makes possible a selling price that may promote development and at the same time prevent monopolization. As is pointed out in a public statement by Secretary Fisher, the present governmental policy of basing the valuation of public coal lands upon the tonnage and quality of coal which underlies the tract results in prices that are neither unreasonable nor exorbitant; the purchaser instead of paying a flat rate per acre in reality pays for the coal by the ton at values graded according to the quality and the character of the coal. Consideration is also given to every known physical and commercial factor affecting the value of the coal of the particular locality. The purpose has been to protect the present interests of the West by making the selling price of coal land approach, but in no case exceed, the present purchase value of a royalty under a leasehold, such as the states of Colorado and Wyoming, or land companies in the West, grant to the lessee, and at the same time to protect the future interests of the people by having these prices such as to discourage long-time speculative holdings. We must always keep in mind the fact that large speculative holdings are sure to affect the future price of coal in two ways; through the possibility of monopoly and through the certainty of accumulated interest charges on the cost of the idle land.

The test of any policy is in the results it produces. That the prices put upon the public coal lands are not prohibitive can be shown by the record of sales. In the four years following the adoption of the policy of classifying and valuing the coal lands, the sales have increased 12½ per cent. in acreage and 36 per cent. in value as compared with the four years preceding, and this in spite of the fact that the four years since July 1, 1907, have included a period of industrial depression and slow recovery as contrasted with the preceding period of boom conditions. So far, therefore, as its provision for pricing is concerned, the present law appears to be as satisfactory as a sale law can be.

One serious defect exists in the present law which all must admit demands an immediate remedy. The restriction of legal purchases to a maximum of 160 acres for an individual or 640 acres for an association is absurdly out of accord with good mining practice. The fixed charges of a modern coal mine equipped so as to safeguard life and property and to secure maximum recovery are too high to be assessed against the tonnage of so limited a tract, especially where the coal seam is of moderate thickness. Furthermore, unless provision is made for commercial operation on the remaining lands, too great an advantage is secured to the land-grant railroads and the large coal companies already in possession of considerable areas of high-grade coal. There is no public need of having either individuals or large corporations acquire large acreages of these lands for long-time holding without development. Nor is there any sound economic reason for the disposition of the coal lands in small tracts. The homestead law expresses the spirit of American institutions in that it has encouraged every citizen to own a home, but there is neither sentiment nor sense in a proposition to sell at a low price 160 acres of coal land to an individual—every citizen does not need to own a coal mine.

In the endeavor to discourage long-time speculative investment in the coal lands and at the same time permit present development, the fixing of selling prices has involved difficulties. It has been recognized that an ideal adjustment of values is well nigh unattainable for many if not for most coal lands. These difficulties suggest the wisdom of considering the other method of disposition, namely, a leasing system. As Secretary Fisher has stated: "It may well be that a liberal but wisely protected leasing law would be found to promote development more vigorously than any system of outright purchase." Thus, under a leasehold law any uncertainties as to quality of coal or as to costs of operation would not need to be so critically estimated in advance. There will be no necessity of discounting every possible future condition, but periodic adjustment of rate of royalty could insure all equities of both operator and public, and I should expect that such adjustments might as often be downward as upward.

Under a leasing system, too, it would be comparatively easy so to adjust the relationship between ground rental and royalty as to prevent the acquisition of coal deposits until actual operation becomes profitable. The greatest advantage of the lease system to the operator directly, and to the public indirectly, is relief from the large capital outlay now required in the acquisition of the large acreage absolutely necessary for a modern mine. This argument advanced against the present policy of valuing the public coal lands at even conservative prices thus becomes an argument for a leasehold law.

The objections to a leasing system are of two classes; those based upon political theory and those based upon economic considerations. Under political objections I will place the arguments so often put forward against Federal landlordism, namely, that the Eastern coal lands were disposed of in fee and that the West deserves the same treatment; and further, that the natural resources of the West should not be made a source of profit to relieve the Eastern taxpayer. Such arguments can be easily answered. Past mistakes are poor precedents for future blunders. The citizen who argues for the continuance of the liberal, wide-open public-land policy of the past is apt to be one who wishes a middleman's profit on a small investment, and we know that East or West, the owner of coal lands acquired as agricultural lands, or in any other way, at a low price, makes his large and unearned profit out of the coal operator, and through him, out of the public. Too large a percentage of the coal output of this country is now mined under lease to justify this objection to allowing the people themselves to lease it direct. As regards the argument of reserving western resources for the West, too few people in the public land states realize that under the present system of sale, the proceeds from the coal lands go directly into western development through the Reclamation Fund, and cannot be used to relieve the eastern taxpayers except as the whole country benefits by the agricultural development of these public land states.

It is reasonable to expect that any leasing law would make similar provision for the local use of revenues resulting from leases, and indeed several of the bills already introduced in Congress have specifically recognized the wisdom of such disposition.

Much more worthy of consideration are the objections to the lease system based upon the fear that the cost of coal to the consumer would be increased, but this result is altogether improbable. The royalty paid into the United States treasury can be no greater a tax upon the consumer than the royalty paid to the state of Colorado, or to the railroad land company, or to the farmer. The average price of bituminous coal at the mine, in the United States last year, was $1.12, which usually includes either a royality or an equivalent interest charge, either of which would probably be greater than any government royalty. This amount forms so small a part of the price to the consumer that the royalty under a federal lease could be of but little concern to the public, if, indeed, it resulted in any increase in the first cost of the coal.

However, if we consider the lease as contrasted with sale outright to the coal operator, the reduction in capital necessary for original investment and the elimination of many of the risks in such investment, must result in reducing cost of operation to the mine owner, and thus make possible a correspondingly lower price of coal to the consumer.

The other objection to the lease system is that based upon fears of expensive federal management, and of inefficient administration or even maladministration. These are possibilities which we must squarely face; but faith in the efficiency of public administration is increasing to such a degree that this argument against the leasing is rapidly losing its force. The Anglo-Saxon people of the Australasian states have found the leasing system not only practicable, but indeed preferable to the sale of coal lands. In New Zealand, where for 30 years the laws have permitted to the operator a choice of either sale or lease of public mineral lands, a conclusive argument for the leasing system is given in the latest statistics of mineral production, which show that approximately 90 per cent. of the total mineral product of that country was mined under leasehold.

Uncle Sam is a landlord on a large scale—a coal baron if you please; and the question is how these millions of acres of coal lands are to be disposed of so as to serve the just needs of the operator who offers his capital, technical skill, and business experience, asking in return a fair profit, and at the same time to protect the public interests.

All that the West needs is, first, opportunity for the coal industry to develop as fast as the market justifies expansion and with the least possible risks; and second, opportunity for the public to secure its coal at prices based on a minimum cost of production and without any addition of unearned and undue tribute to private landlords who desire to speculate on the future needs of the consumer. These ends I believe can be best attained by legislation inaugurating a federal leasing system for coal lands of the public domain.

Repairing Broken Steel Tapes

Steel measuring tapes are often broken even when handled with care, consequently all surveyors who have experienced the inconvenience resulting from breaking a tape will be thankful to J. A. Smith, E. M., of the Cumberland Coal Co., Albert, W. Va., for furnishing the following simple and ready means for their repair.

The following outfit for quickly repairing a broken steel measuring tape can be carried without inconvenience by the engineers when surveying. It consists of a small vial containing a solution composed of zinc chloride ($ZnCl_2$) dissolved in as little water as possible; a few inches of $\frac{1}{8}$-inch round solder such as electricians use; several thin pieces of tin $\frac{1}{4}$-inch wide, as shown at *a*, Fig. 1, that are twice as long as the tape is wide; and a pocket knife. The zinc-chloride solution vial should be carried in a small round tin box and kept from moving about by means of cotton wool to prevent breakage. If the small strips of tin are bent in advance to form sleeves as shown at *b*, that are just large enough to slip over the ends of the broken tape, as show at *c*, the repair can be made rapidly.

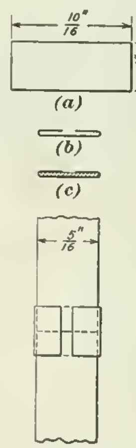


Fig. 1

To make use of the repair kit, wipe off all dirt and scrape off all rust from, and brighten with a knife, the ends to be united. Dip each end in the zinc chloride solution, then slip the tin sleeve over the ends of the tape, after which put them closely together. Hold the joint sleeve over a mine lamp flame if in the mine or over a match flame if outside. The tin and tape being thin heat rapidly, and if solder is touched to the joint it will melt and fill all spaces. To quickly cool the soldered joint, shown at *d*, it is customary to spit on it. (Pepsin gum will furnish clearer saliva than plug tobacco.) In case too much solder sticks to the joint, the surplus should be brushed over while hot and before wetting.

It is surprising how quickly and with what little practice a neat joint can be made which is as strong as the original tape, stronger than a riveted joint, and one which does not interfere or give trouble when reeling up.

Method of Supporting Mine Roofs

Blasting Down Roof and Blasting Up Floor to Form a Dam, Then Filling Back of Dam

William Griffith, mining engineer and geologist, of Scranton, Pa., has been granted patent number 1,004,419 for a method of mining. It is not claimed that the method will cover every case, for instance, where there is a steep pitching coal bed, or where there is an extra thick flat coal bed; in fact it is applicable only to moderately pitching beds and flat beds. The best possible explanation of the system is given in the patent specifications, which are reprinted in part for the benefit of our readers.

In mining in the United States and in various other countries a general system or method is used for removing the matter to be mined, especially in mining coal. The ordinary system in the United States, for instance, is to mine out part of the coal and leave part of the coal as supporting pillars for preventing the roof of the mine from caving in or collapsing. This method of mining is varied according to the position of the coal veins in the rock for permitting mining horizontal veins or pitching veins. The mining of horizontal veins by the ordinary method contemplates the sorting of the coal from the slate and other refuse in the room or that part of the mine from which the same has been removed from its natural bed. The coal is transported to the surface and disposed of as desired, while the refuse is deposited at one side of the room and in any place most convenient so that the same will not be in the way of further mining or the removal of the coal. Where the coal vein occurs in what are known as pitching veins, all of the mined material, including the slate and other refuse, falls or slides down to the car which conveys the same to the surface or to a place from which the same may be conveyed to the surface. This method necessitates the removal of all the coal mined, and the sorting of the coal from the refuse after the coal and refuse have been removed from the mine.

This invention is intended to obviate as far as possible any injury or breaking down of any property on the surface of the ground, and at the same time render available for shipment a maximum quantity of coal from a given coal field without endangering the lives of the miners or life and property on the surface of the ground.

The process or method consists in blasting up the floor, which is usually rock, or blasting down the roof of the mine, or if desired blasting up part of the floor and blasting down part of the roof directly over the same and allowing the debris of the blasting to remain where it falls and thus take advantage of the well-known characteristics of blasted rock, that it occupies considerably more space than when in the solid condition, but affords a good artificial pillar which will resist vertical strains and lateral strains. The roof and floor may be blasted up in this manner for entirely inclosing a predetermined space by the blasted material, or for closing the ends of a room into which filling material of any kind, as for instance sand and solid refuse matter is flushed for filling the chamber or inclosure made by the blasted rock until the same is entirely filled by said flushed-in matter. As will be evident the blasted-up rock will be anchored in the floor and roof and the broken rock will naturally be interlocked so that any lateral strain brought to bear against the same by the sand and other flushed-in matter will not affect detrimentally the blasted material, but on the contrary the blasted material will hold against lateral movement the flushed-in matter, so that the flushed-in matter will act as a proper support or pillar for the roof.

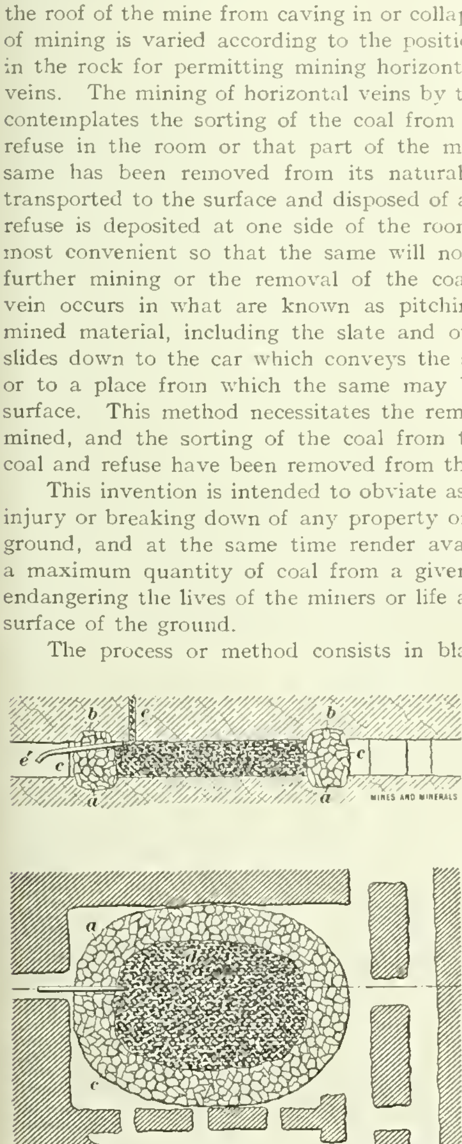

Fig. 1

In the accompanying drawings is disclosed a concrete example of the method or process involved. The drawings show how the process may be used in a flat or horizontal mine, and also in a pitching vein mine.

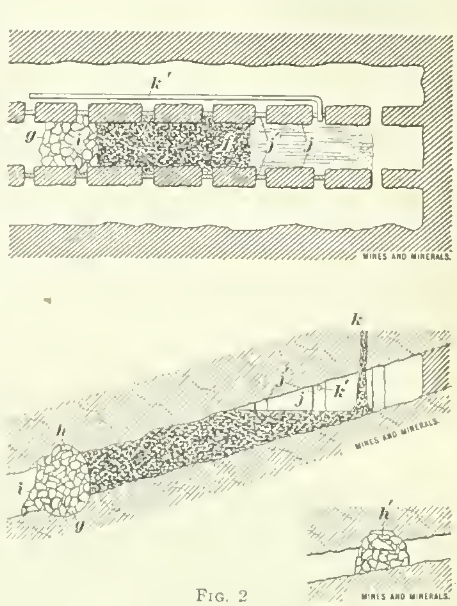

Fig. 2

Either after the mine has been partly worked or abandoned or during the mining operation, part of the floor is blasted up at *a* and part of the roof is blasted down at *b* for forming a dam or what is sometimes called a battery *c* which incloses a room or space *d*. As will be noticed from Fig. 1 the dam *c* extends entirely around the room or space *a*, and consequently will firmly support against lateral movement any matter flushed into the room through opening *e*. Opening *e* indicates a bore extending to the surface through which water, sand, and other material is flushed into room *d* where the solid matter settles and the water drains through dam *c*, and is removed from the mine in any desired manner, as for instance by the usual pumping apparatus. If desired instead of having the bore *e* extend to the surface of the earth a tube or pipe *e'* could be inserted into room *d* in any desired way and sand or other matter flushed into room *d* until the same is full of solid matter, which will consequently present a pillar for supporting the roof in addition to the support the dam *c* will afford. After the room *d* has been provided with material for a pillar the material may be mined from either side thereof to a considerable extent, and then a new dam made for an additional room which may be flushed in a similar manner. This process may be continued throughout the entire mine so that the roof will be continuously supported and yet all the coal removed so that there will be no danger to the miners, and also no material sinking of the earth's surface above the mine.

When mining a pitching vein, as disclosed in Fig. 2, the mining is done according to any of the usual methods, or any improved method desired, until a room *f* is provided which is closed by having the material from the floor blasted up at point *g*, while material from the roof is blasted down at point *h* for providing a dam *i*. Dam *i*, together with the usual pillars *j* formed of coal, supports the roof, and will form an entirely inclosed chamber. The respective pillars *j* formed of coal are connected by suitable partitions *j'* formed of any desired material. These partitions are placed in position during the mining operation and cause a proper circulation of air for the benefit of the miners. After having served this purpose they are left in position and act as lateral supports for the flushed-in material, and are especially of advantage during the settling of said flushed-in material. The pipe k' may be inserted into the chamber or room f from any part of the mine, or a boring k may be provided which extends from the surface of the ground, whereby sand and other filling material may be flushed into room f where the same settles and forms a firm, solid support, while the water drains off through dam i. After the room f has been filled the pillars on one side may be removed if desired and the space occupied by the same and the adjoining room flushed full of sand or other filling material in a similar way to the way room f is filled after a dam similar to dam i has been provided for the adjoining room. In this way the usual form of mining may be proceeded with to a certain extent and then by my improved method the roof properly supported and all the coal supporting pillars removed so that a maximum amount of coal may be delivered from a given area.

As seen in Fig. 2 the roof may be blasted down at point h' sufficiently for making a complete dam. This may be easily done where the vein is comparatively narrow, as sufficient material may be blasted from the roof without causing an undesirably strong explosion.

My improved method may be used during the first mining or in old or abandoned mines. Where the method is used in abandoned mines some of the supporting pillars are removed and an inclosure or room is made by blasting up part of the roof or floor or both for providing an inclosure for the flushed-in material. Also if desired some of the original supporting pillars may be used as one side of the room into which material is flushed, though preferably an entire space is inclosed by blasted material, as shown in Fig. 1, which is always left in place so that when the same has been once filled with flushed-in material a permanent solid supporting pillar is provided.

What I claim is:

1. The method of mining comprising the blasting of the floor of a mine for partially filling the mine at the point of blast, then blasting down a sufficient part of the roof for filling the remaining open space in the mine, the blasted material being allowed to remain where it falls for filling the open space in the mine and the space caused by blasting for providing supporting means for the roof, and then flushing of filling material in the mine at one side of said blasted material.

2. The method of mining which comprises the running of gangways along the body of material to be mined, forming rooms at one side and connected to these gangways, taking out the material to be mined and packing the refuse in said rooms on the sides of the rooms, blasting up part of the floor of the room at a point desired to be closed for partially filling the space between the floor and the roof, blasting down a sufficient part of the roof for completing the dam, forming a pipe opening into said room closed by said dam, and then flushing material into said room.

3. The method of mining which comprehends running gangways along the body of material to be mined, working out the material to be mined in proximity to the gangways, piling the waste material in the space from which the mined material has been moved, blasting down a sufficient part of the roof at any desired point for forming a dam, forming a flushing opening communicating with the space in front of said dam, and flushing filling material through said flushing opening.

4. The method of mining which comprehends running gangways along the body of material to be mined, working out rooms in proximity to the gangways, placing charges of explosives in the floor and roof of said rooms at a point where a dam is desired, successively discharging the explosives in the floor and roof for providing a dam formed of crushed material of the floor and roof for providing an auxiliary support for the roof and a dam for any material flushed in said room, forming an opening through which material may be flushed into said room, and flushing material into said room.

5. The method of mining which comprises the running of gangways along the body of material to be mined, forming rooms along one side of said gangways and connecting the rooms to said gangways, blasting up part of the floor of any of the rooms in which a dam is desired, and leaving the blasted material in the place where it falls, whereby a dam for part the height of the room is provided having an anchorage in the floor, then blasting down a sufficient part of the roof for filling the space immediately above said first mentioned blasted material for providing an artificial pillar, and a completion of the dam with an anchorage in the roof, and then flushing filling material into the room.

6. The method of mining which comprises the running of gangways along the body of material to be mined, forming rooms to one side of the gangway and connecting the rooms to the gangway, blasting up part of the floor of said rooms in such a manner as to form an inclosing fence, blasting down part of the roof of said rooms immediately above said first mentioned blasting for forming said fence into a complete dam having anchorage in the floor and roof, and then flushing material into the inclosure provided by said dam.

Book Review

Technical Analysis of Brass. John Wiley & Sons, of New York City, send for review a book entitled "Technical Analysis of Brass," by W. B. Price, chief chemist Scovill Mfg. Co., and Richard K. Meade, director of Meade Testing Laboratories. The book is divided into three parts, as follows: Introduction, Determination of Metals, and Examples of Alloy Analysis. The book contains 265 pages with index and it appears to be adapted to the use of analytical chemists generally. The price is $2 net.

Practical Geology and Mineralogy is an elementary treatise, designed for students, miners, prospectors, and those who desire to know something of geology, petrology, mineralogy, and mineral deposits in a general way. It is written by W. D. Hamman, B. Sc., from his standpoint as a practical man. In his preface he states: "Science is a dry subject to many if presented in technical language. While it is impossible to treat science in story-book fashion, it is possible to popularize mining science by cutting out unimportant matter and confining the scope to simple practical every-day phases of the mining business." There are 224 pages of text to the book, but no index. It is published by the Way's Pocket Smelter Co., South Pasadena, Cal.

Shape Book Carnegie Steel Co. We have received from John C. Neale, of the Carnegie Steel Co., Pittsburg, Pa., the new "Shape Book," of that company containing profiles, tables, and data appertaining to beams, bulb sections, channels, angles, tees, zees, and miscellaneous structural shapes; also to concrete reinforcement bars, clip sections, crescent sections, automobile sections, pipe sections, window sections and with a few unimportant exceptions all the shapes rolled by that company. It supersedes and cancels the book of Shapes issued in 1903, together with all supplements thereto.

Metallurgy of Tin. McGraw-Hill Book Co., of New York City, have published a book from the pen of Henry Louis, M. A., D. Sc., A. R. S. M., on the Metallurgy of Tin. This book is in the main a reprint of a monograph on the Metallurgy of Tin, published in Vol. V, of the Mineral Industry. The price is $2 net. The 138 pages are divided into five chapters with index. The subjects are Properties and Occurrence of Tin, Principles of the Metallurgy of Tin, Smelting in the Shaft Furnace, Smelting in the Reverberatory Furnace, Tin Plate and Tin-Plate Scrap. The author is well known to metallurgists and if anything relating to the metallurgy of tin is missing from this book, it is because the industry is surrounded with secrecy.

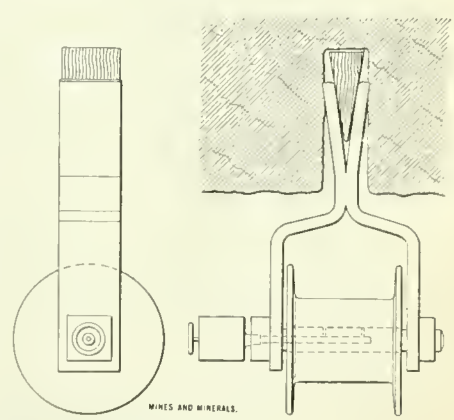
Self-Oiling Tail-Rope Roller

A cheap and effective overhead tail-rope support in use at the Thor and Globe mines of the National Fuel Co., of Denver, Colo., is shown in the accompanying sketch. It consists essentially of a cast-iron roller supported by two side pieces of $\frac{3}{8}$'' X 2'' flat iron. To form the shank, these side pieces are welded together for about 2 inches and then sprung apart into a **V** shape. The length of the shank, which is inserted in a hole drilled in the roof, is variable, being about 6 inches for rock and 8 inches for coal. In placing



Self-Oiling Roller

in position, the wooden wedge is drawn down about 2 inches, the shank fitted over it and the whole driven up as far as possible. As the wedge drives the shanks apart and into the roof, permanency is secured. In some cases additional wedges are placed outside the shank between it and the sides of the hole, and further security might be obtained if the device was cemented into place. However, at both the above mines, cementing is not employed and no falls of the sheave have been reported.

The roller turns on a 1-inch bolt, part way through the center of which is drilled a $\frac{1}{4}$-inch hole with two $\frac{1}{16}$-inch holes from this central channel to the outside of the bolt. The oil from a Bruno "00" automatic grease cup feeds in through the center $\frac{1}{4}$-inch hole and out through the two $\frac{1}{16}$-inch holes, insuring perfect lubrication. These rollers are set about 30 feet apart and make about 1,200 revolutions per minute. If made larger and set vertically they may be used to carry the rope around curves. In this latter case they would probably have to be made considerably larger and should be set in brackets.

The important principle involved is the use of the automatic oiling device which results, not only in a very material saving in lubricant, but of labor as well. The cost per piece, including grease cup, is a little less than \$2.

The National First-Aid Meet

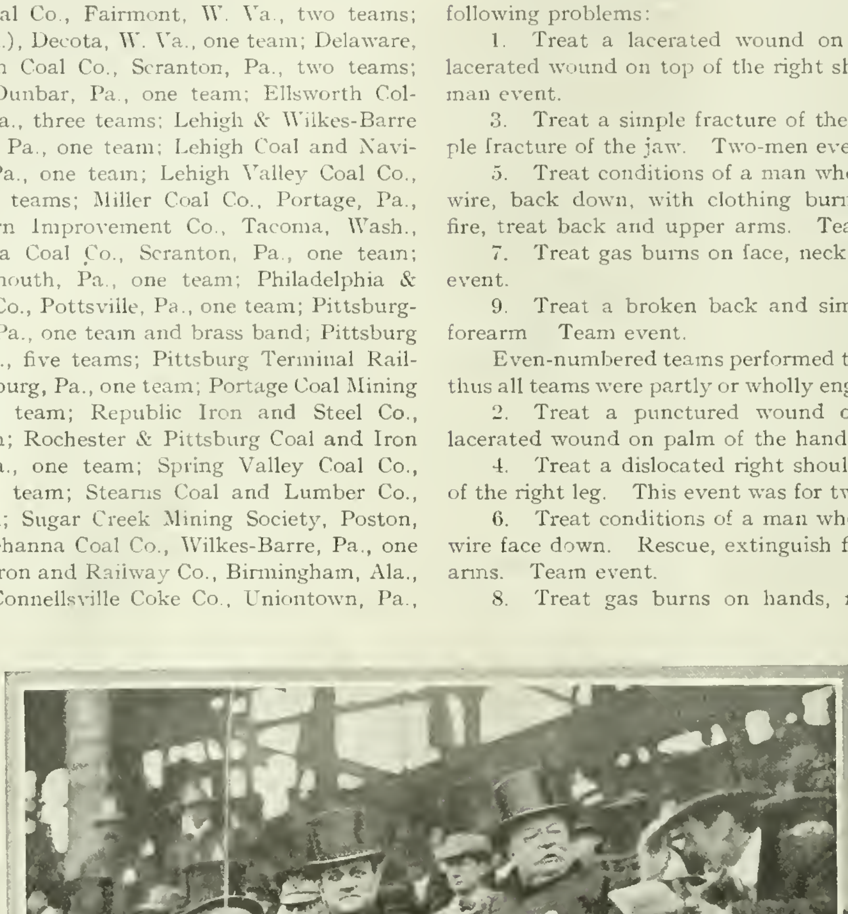
Dust Explosion and First Aid Demonstrated Before President Taft and 10,000 People

The first National First-Aid Meet, at Pittsburg, Pa., on October 31, was an affair that will long be remembered by guests and participants. It was held under the auspices of the United States Bureau of Mines, American National Red Cross, and the Pittsburg Coal Operators' Association. Although rain prevented the attendance being as large as it otherwise would have been, nevertheless there were probably 10,000 spectators, who witnessed the demonstration on Forbes Field, and among them were President Taft, Secretary Fisher, Miss Boardman, Governor Tener, of Pennsylvania, and Governor Glasscock, of Ohio.

The following coal companies were represented by first-aid teams: Berwind-White Coal Mining Co., Windber, Pa., four teams; Consolidated Coal Co., Fairmont, W. Va., two teams; Cabin Creek (Y. M. C. A.), Decota, W. Va., one team; Delaware, Lackawanna & Western Coal Co., Scranton, Pa., two teams; Dunbar Furnace Co., Dunbar, Pa., one team; Ellsworth Collieries Co., Ellsworth, Pa., three teams; Lehigh & Wilkes-Barre Coal Co., Wilkes-Barre, Pa., one team; Lehigh Coal and Navigation Co., Lansford, Pa., one team; Lehigh Valley Coal Co., Wilkes-Barre, Pa., two teams; Miller Coal Co., Portage, Pa., one team; Northwestern Improvement Co., Tacoma, Wash., one team; Pennsylvania Coal Co., Scranton, Pa., one team; Parrish Coal Co., Plymouth, Pa., one team; Philadelphia & Reading Coal and Iron Co., Pottsville, Pa., one team; Pittsburg-Buffalo Co., Marianna, Pa., one team and brass band; Pittsburg Coal Co., Pittsburg, Pa., five teams; Pittsburg Terminal Railroad and Coal Co., Pittsburg, Pa., one team; Portage Coal Mining Co., Portage, Pa., one team; Republic Iron and Steel Co., Republic, Pa., one team; Rochester & Pittsburg Coal and Iron Co., Punxsutawney, Pa., one team; Spring Valley Coal Co., Spring Valley, Ill., one team; Stearns Coal and Lumber Co., Stearns, Ky., one team; Sugar Creek Mining Society, Poston, Ohio, one team; Susquehanna Coal Co., Wilkes-Barre, Pa., one team; Tennessee Coal, Iron and Railway Co., Birmingham, Ala., one team; Tower-Hill Connellsville Coke Co., Uniontown, Pa., one team; Stag-Cañon Fuel Co., Dawson, N. Mex., one team.

The total number of teams engaged in the demonstration was 40, but representatives of first-aid teams from Utah, Colorado, and Wyoming were present, and every state mining coal in the United States, besides several foreign countries, had delegates who witnessed the events. To avoid any leaning toward professionalism the demonstration was not competitive.

If the event had been competitive the judges would have had an exceedingly difficult time in picking the winners and would probably have been treated like base-ball umpires. It is probably not amiss to repeat what has been stated previously in Mines and Minerals, viz.: That the object of first-aid work is to relieve the injured and if possible save life by preventing hemorrhages and allaying the effects of shock following a serious accident.



Watching Coal-Dust Explosion at Pittsburg
1. A. J. Barchfield, M. C.; 2. Gov. Tener, of Pa.; 3. President W. H. Taft; 4. Dr. Jos. A. Holmes

Competitive contests, while having a bearing on accuracy, despatch, and neatness in dressing wounds, are locally of much interest between local companies, for which reason they should be continued

Often life has been saved by first-aid corps who failed to take the first prize at competitive drills, which shows conclusively that the good work now being carried on is bound to save many lives in the future.

That one team is neater than another bandaging a patient until the surgeon can attend to him is due to aptitude and practice, but so long as any team learns and uses the necessary tactics to relieve the injured, the primary object is attained.

At Forbes Field odd-numbered teams were given the following problems:

1. Treat a lacerated wound on the right temple and a lacerated wound on top of the right shoulder. This was a one-man event.

3. Treat a simple fracture of the left collar bone and simple fracture of the jaw. Two-men event.

5. Treat conditions of a man who has fallen on an electric wire, back down, with clothing burning. Rescue, extinguish fire, treat back and upper arms. Team event.

7. Treat gas burns on face, neck, ears, and hands. Team event.

9. Treat a broken back and simple fracture of the right forearm Team event.

Even-numbered teams performed the even-numbered events, thus all teams were partly or wholly engaged during the exercises.

2. Treat a punctured wound over the left eye and a lacerated wound on palm of the hand. One-man event.

4. Treat a dislocated right shoulder and a simple fracture of the right leg. This event was for two men.

6. Treat conditions of a man who has fallen on an electric wire face down. Rescue, extinguish fire, treat chest and upper arms. Team event.

8. Treat gas burns on hands, right arm, and shoulder. Team event.

10. Treat a dislocated hip and simple fracture of the collar bone. Team event.

Owing to the field being muddy, canvas was laid down for the teams, but even then conditions were more favorable for operations than in a mine where light is poor and surroundings cramped.

Frequently during the demonstrations the President and spectators applauded, and between events bands in various positions in the big stand played, Pittsburg University, Carnegie Technical School, and Duquesne University students cheered, so that there was action at all times to keep the minds of those in the boxes off the wet-damp.

After the team demonstrations, G. A. Burrell, of the Bureau of Mines, entered a glass box which contained ¼ of 1 per cent. of carbon monoxide, the gas termed "whitedamp" by coal miners. He took with him three canary birds in a cage. The atmosphere was sufficiently bad in this box to overcome the birds, but not the man. Two of the birds were subsequently resuscitated by oxygen, but the writer believes the third bird failed to respond to the treatment. Directly after this demonstration President Taft pushed a button and discharged a quantity of powder which fired 153 pounds of bituminous coal dust in a steel explosion tube 150 feet long placed some distance from the stand. A rescue party made up of men from the Bureau of Mines, Illinois Mine Rescue Station, Philadelphia & Reading Coal and Iron Co., Pittsburg-Buffalo Co., and other local coal companies, wearing rescue apparatus, then entered the gallery and recovered five supposed victims of the mine explosion. A squad of foremen and first-aid men of the Bureau of Mines demonstrated first-aid treatment, using the pocket first-aid packet and such things as might be handy in a mine. C. O. Roberts treated a miner overcome by afterdamp and having a scalp wound. W. A. Radenbush and William Burke treated a patient slightly overcome by afterdamp and suffering from a simple fracture of the right thigh and compound fracture of the right forearm near the wrist. W. D. Roberts and J. T. Ryan treated a man overcome by afterdamp and suffering from simple fracture of right collar bone and simple fracture of left arm. W. A. Radenbush and William Burke treated a miner overcome by afterdamp and burned about face, neck, ears, and hands. W. D. Roberts, C. O. Roberts, and J. T. Ryan looked after a miner overcome by afterdamp and burned from the waist up.

Steel Gallery After Explosion of Coal Dust

Governor J. K. Tener then delivered an address, introducing Secretary of the Interior Walter L. Fisher, who said among other things: "This question of conservation is not a matter of sentiment; the demonstration here today proved that conclusively. The greatest waste, however, is the waste of human life, and my official duty is to further this great movement for the conservation of life in every possible way."

Governor Tener next introduced Miss Boardman, head of the American National Red Cross Society, who delivered an interesting address in which she said: "The fact that 2,000 lives are lost annually in our mines is an appalling national disaster. It is not enough to provide pensions for miners' widows and their families, provisions must be taken to guard against and prevent accidents in mines as much as possible. I take this occasion to ask the hearty and material cooperation of everybody with the Red Cross Society in the work for the conservation of human life."

Rescue Team Entering Gallery After Explosion

As a matter of form, Governor Tener, the chief executive of the largest and wealthiest coal-producing state in the Union, introduced the chief executive of the United States, who after standing or sitting 2 hours was known to every one on the field either by sight, personally, or through the lithographs which were posted in nearly all stores in Pittsburg.

President Taft said in part:

"Properly is it on the soil of Pennsylvania, where such a large part of the mining industry thrives, that this demonstration should be held.

"There are 300,000 miners and their families in Pennsylvania. There are 700,000 in the United States. In the last 20 years 30,000 men have lost their lives in the mines and 70,000 have been injured.

"That is not a record to be proud of. It is time indeed that we should take steps to restrain this great loss.

"The federal government has no direct jurisdiction, but it has the money and the authority under the Constitution to act at all times for the general welfare of the people.

"This loss of life must be brought home and emphasized on the miner himself. We are a great nation, we know it, because we admit it. (Laughter.) We have certain defects, however, and one is a security that we are not going to be hurt.

"We must overcome that idea and we must take more precautions to save life. This requires discipline, instruction, and experience.

"We must enforce these ideas so that the miners themselves must save themselves by strict attention to the instructions that must be given in turn by government and state.

"I do not know of an occasion that is more important for the development of industry than this right here today, in this hive of industry.

"We must stamp out the spirit of carelessness, the happy-go-lucky idea, which I fear prevails among American citizens generally.

"We can say such a thing about ourselves even if we would not allow any others to say it.

"It has been an inspiring sight to see these men enter that hole yonder to save a life."

The President then presented prizes to all the first-aid teams taking part in the demonstration as they paraded past the stand.

The awards consisted of medals given by the American Red Cross Society and first-aid kits by J. H. Hammond. Each first-aid corps was given an elaborate silk banner on which in gilt letters was the name and address of the coal company represented. These banners, souvenir admission badges, and miscellaneous items were donated by the Pittsburg Coal Operators' Association.

As the last miner passed the stand the Chief Executive and party walked off the field, the bands played, and the thousands of spectators dispersed, satisfied that they never had seen an exhibition so unique and so fraught with importance to the conservation of mankind.

The officers in charge of the demonstration were J. W. Paul, manager of field events; Dr. M. J. Shields, manager of first-aid events; Clarence Hall, manager of explosion; Francis Feehan, field marshal; and J. K. Clement, chief usher.

Overhead Electrical Practice in Mines

Details of Construction and Installation that Greatly Affect the Economy of Operation

The following paper, by G. H. Bolus, is reprinted by permission from the Ohio Brass Co. Bulletin:

While much has been written about the behavior or performance of electrical apparatus in mines, covering various kinds and types of motors, locomotives, etc., the overhead electrical circuit seems to have received very little consideration.

In practically all of the coal mines and some of the metal mines in the United States, direct current is used with a range in voltage of from 220 to 250. Some mines in West Virginia employ the three-wire system with 500 volts between outside wires and 250 volts between outside and neutral. There are also some alternating-current installations in use in mines, but generally speaking, it may be said that the alternating current is not as much used as direct current.

In the transmission of electrical energy, it is a generally accepted rule to limit the range of distribution to 1 mile for 250 volts and 4 miles for 500 volts. Unfortunately, in mines

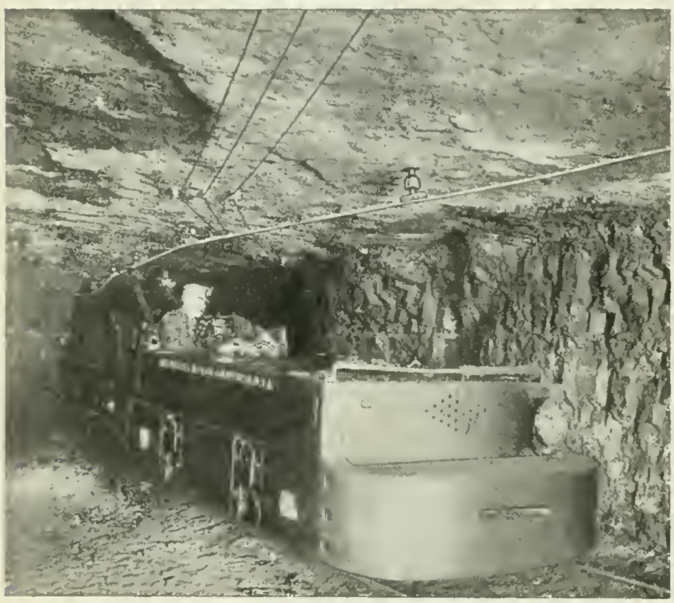


Fig. 1. Example of Good Overhead Construction in Mines

it is frequently necessary to carry electric power into a mine using 250-volt service, for a greater distance than 1 mile, and this calls for a correspondingly greater outlay for feeders. Beyond these distances, where conditions will permit, it is advisable to use alternating current of higher potential, and transmit the power by means of a high-voltage transmission line. Single-phase motors are not adapted to mine service and for this reason polyphase systems are much preferred.

Electrical apparatus and fittings for use underground are subjected to the destructive action of acid-laden mine waters and excessive dampness, and they are, therefore, designed to take care of this condition; but even with all the precautions taken in the design of a piece of apparatus or fitting, it may still prove inefficient if it is improperly installed. It seems to have been the tendency in past years for one mining company to follow the rules of its neighbor in laying out the electrical circuits, with little or no information as to whether the neighbor was right or wrong. The result is that many mine managers are now awakening to the fact that their electrical circuits are inadequate for the service required.

The temporary manner in which new operations are supplied with power transmission is frequently the cause of insufficient feeder wire being installed, and as the workings progress farther back into the seam, the mine manager finds it necessary to install more feeder in order to get the proper response from his cutting machines and locomotives. Another thing which has been the cause of considerable bad installation work in mines has been the scarcity of good workmen, proper tools, and properly designed material.

The subject of the proper percentage loss of voltage in mine circuits is a much mooted one, but, generally speaking, the writer has found that a loss of from 15 to 20 per cent. at maximum load is permissible.

Regarding the proportioning of the carrying capacity of feeders, it has been found that if the feeder is laid out to carry 60 per cent. of the total current used in a mine, the operation will be satisfactory, as it is rarely the case that all machines are operating continuously at one time, and even should this condition occur, it would only be for a short time.

Loss of Voltage in Mines (Two-Wire System)
250 Volts of Mine Entrance. Track Resistance Equal to Overhead Resistance. 100 Amperes in Circuit

Distance in Mine in Feet	Volts Loss			Volts Between Track and Trolley		
	One 4-0 Trolley Only	One 4-0 Trolley and One 4-0 Feeder	One 4-0 Trolley and Two 4-0 Feeders	One 4-0 Trolley Only	One 4-0 Trolley and One 4-0 Feeder	One 4-0 Trolley and Two 4-0 Feeders
1,000	10	5	3	240	245	247
2,000	19	10	6	231	240	244
3,000	29	14	10	221	236	240
4,000	39	19	13	211	231	237
5,000	49	24	16	201	226	234
6,000	59	29	20	191	221	230
7,000	68	34	23	182	216	227
8,000	78	39	26	172	211	224
9,000	88	44	29	162	206	221
10,000	98	48	33	152	201	214
12,000	117	59	39	133	191	211
15,000	146	73	49	104	177	201

To Find Volts at Any Other Current.—Divide current in amperes by 100 and multiply the result by the volts loss in Table.

Example.—Required, voltage between trolley and track, in a mine using 4-0 trolley and one 4-0 feeder at a point 3,000 feet from mine entrance. Current 500 amperes.

Solution.—Volts loss with 4-0 trolley and 4-0 feeder at 3,000 feet = 14. 500 amperes divided by 100 equals 5. 5 multiplied by 14 equals 70 = volts loss. 250 volts at mine entrance minus 70 volts loss equals 180 volts between trolley and track = *Answer*.

To find loss in mine using 3-0 trolley or feeder, multiply volts loss in Table by 1.261.

To find loss in mine using 2-0 trolley or feeder, multiply volts loss in Table by 1.509.

Example.—Required, voltage in mine using 3-0 trolley and two 3-0 feeders, at a point 5,000 feet from the mine entrance, current 100 amperes.

Solution.—Look in Table and find under one 4-0 trolley and two 4-0 feeders, and opposite 5,000 feet the loss to be 16 volts. Multiply 16 by 1,261 which gives 20 volts. 250 volts minus 20 volts = 240 volts = *Answer*.

To find current taken by a 250-volt motor, multiply the horsepower by three.

To find current taken by a 500-volt motor, multiply the horsepower by one and one-half.

The table herewith gives the approximate drop in voltage of a 250-volt two-wire system with conditions of trolley and feeder as ordinarily encountered in the average coal mine.

It would be extremely difficult to lay down rules for the installation of the overhead circuit in all mines, but the following rules, if carried out, will materially increase the efficiency of the electrical circuit.

A. Install all mine wiring for power on approved porcelain or glass insulators with steel or wood pins as a support. They should be placed as often as 20 feet for low roof and not to exceed 35 feet for high roof. Porcelain insulators, if thoroughly vitrified, are to be preferred to glass.

B. Install only one wire on each insulator, securely tying it to the insulator with a tie wire, preferably of the same material as the conductor. This would not, of course, apply to lead-covered conductors. Tie wire should be preferably No. 4 wire.

C. Install all trolley-wire hangers practically at the same height from the top of the rails, so as to bring the trolley wire as nearly on a level as possible. This will eliminate jumping of the trolley wheel and also arcing to a certain extent. The center of each hanger should be plumbed a certain distance outside the outer edge of track rail. This distance is governed by the mining laws of different states, and also by the size and type of locomotive used.

The severest stress which can be placed upon a hanger, and especially upon the insulation, is that encountered on a curve, and in railway practice pull-offs are used to take care of the strain on the curve, but as railway pull-offs are not practical in mines (especially in the low-veined type), a sufficient number of hangers should be installed on the curve to prevent the studs of the hangers being bent and the trolley clamps from being distorted. No fixed rule can be laid down for this as it depends entirely on the strains induced by the trolley wire and the degree of the curve; but, generally speaking, hangers should be placed from 6 to 10 feet apart on curves. For curve work, it is good practice to use a clamp in which the boss comes tightly against the insulation when the clamp is lined up. This will prevent, to a certain extent, bending of the stud (see Fig. 4). Where pull-offs can be used they should be guyed with No. 6 galvanized-steel wire and should have a conical strain insulator cut in the wire. Timber hangers, as the name would imply, are designed to be attached directly to mine timbers but in a large number of mines it has been the custom to attach the timber hangers directly to the mine roof, either by means of suitable expansion bolts or wooden plugs driven into holes in the roof, and the hanger installed by means of lag bolts. This practice is not so good as if installed on a timber or a small block, still it has proven satisfactory in service. The insulation resistance of the hanger is the same as that of an expansion-bolt hanger, and, consequently, leakage would be the same.

Expansion-bolt hangers are provided with a boss into which the end of the expansion bolt may be screwed. The hanger is usually provided with a hexagonal body so that a wrench may be applied. Spikes and nails should not be used for attaching hangers of any kind to their supports. Steel mine timbers are rapidly coming into use for timbering main entries, and a very good installation of trolley and feeder may be made by fastening the hangers directly to the bottom of the I beams. Clamps for fastening the hanger to the I beams are now being placed on the market.

D. The subject of proper placing of a trolley frog or switch pan, as it is sometimes called, has frequently been brought to the writer's attention, and on account of various sizes of locomotives used, it is a rather difficult matter to determine. Circular No. 23 of the Bureau of Standards recommends that frogs be placed 10 to 12 feet back from point of latch and held in horizontal position by properly placing hangers on the line near frogs. It has been the writer's experience that the distance specified will be satisfactory for most of the conditions encountered in mines.

Trolley frogs are provided as a rule with four pull-off rings or eyes, so that they may be guyed to the proper position by the use of guy wires. Never attach a guy wire on a frog or any other trolley device which is to carry current, without cutting in a conical strain insulator in the guy, which will properly insulate it. Frogs should always be placed on branches leaving main trolley.

Malleable iron trolley frogs are now making their appearance upon the market and can be used to advantage in mine service

E. When dead-ending trolley wire, it should be securely anchored and insulated, either by use of a conical strain insulator and ordinary turnbuckle, or a Brooklyn strain insulator, which is really a combination of the above two mentioned, or other suitable insulator. A suitable galvanized clamp should be used for holding the dead-end loop at the end of the trolley wire (see Fig. 3).

F. Allow proper clearances in all cases for the trolley wheel. It is extremely bad practice to allow the wheel to touch the roof, even though the roof may be hard sandstone or other formation, as it increases wear on the wheel and is generally unsatisfactory. It is better to install more hangers where the trolley touches the roof; that is, install them so that they will come closer together. It is still better to shoot down a little of the top and get the proper clearance, where conditions will permit.

G. The manner of making the proper connection at a point where a feeder is to be tapped into the trolley wire, should receive careful consideration. The practice of hooking feeders around the trolley clamps should not be permitted, as they invariably work loose and cause trouble. A high resistance will generate considerable heat and will produce a very vicious arc which will probably burn off the feeder. It is recommended that a good form of feeder ear or clamp be employed, and where the feeder is of such size that it will not fit the ear, two or even three ears should be installed at that point and suitable taps run from the feeder proper to the ears (see Fig. 5). The total area of copper in circular mils in the taps should be equal to the area in circular mils of the cable. Feed-in yokes, made especially for feeding in purposes, may be purchased in the market and will be found satisfactory for this purpose.

H. The selection of a proper trolley clamp is a matter that should receive proper consideration. Clamps have been designed which are too long and which, when the hanger is installed slightly out of plumb, produce a bump or projection in the trolley wire which invariably causes arcing as the trolley wheel passes the clamp (see Fig. 5). The clamp should be narrow so that the wheel will pass it without striking, and the nut or other clamping means should be located high enough on the clamp proper so as not to strike a badly worn trolley wheel. A great deal of the sparking of the trolley at hanger points could be eliminated by the use of a well-designed clamp and keeping the hangers carefully plumbed.

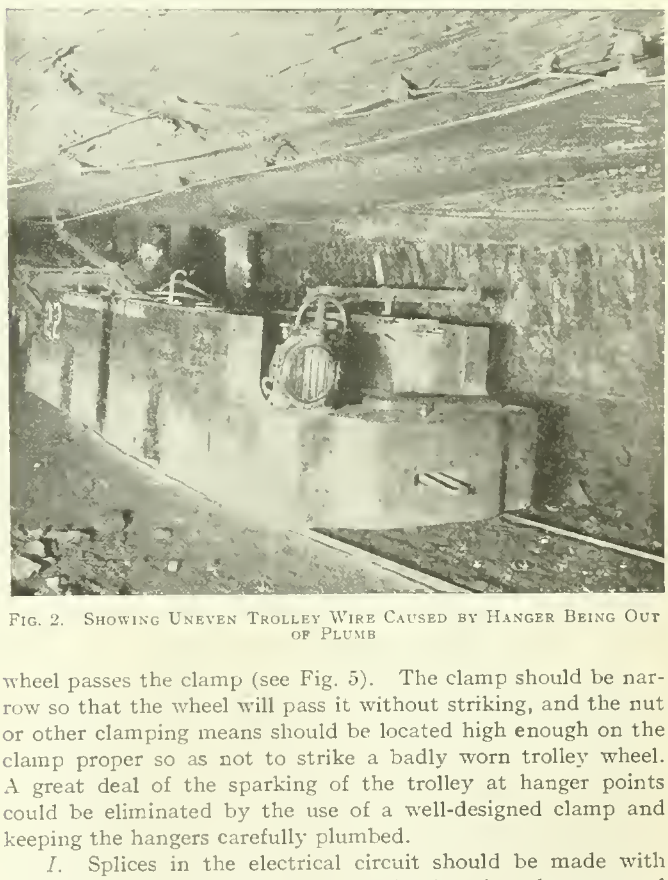

FIG. 2. SHOWING UNEVEN TROLLEY WIRE CAUSED BY HANGER BEING OUT OF PLUMB

I. Splices in the electrical circuit should be made with care, as it is astonishing to observe the drop in voltage caused from poorly made joints. Splices in the trolley circuit may be made by suitable splicers designed for this purpose, and may be either soldered or mechanical. Splices in feeders should be made by the use of a good splicer and may be either of the soldered or mechanical type.

It is known that where two dissimilar metals are joined together, as would be the case where two copper wires were joined by means of a soldered connector, that due to the excessively moist atmosphere there will be set up a local electrolytic action which in time will destroy the joint. A remedy for this is to simply tape the joint so that it will be protected from the moisture.

J. Section insulators for sectionalizing the trolley circuit may be purchased in the market and they should be installed in such a manner as to prevent their wobbling when the trolley wheel passes under them. It is generally considered good practice to install a section insulator on a hanger. They may also

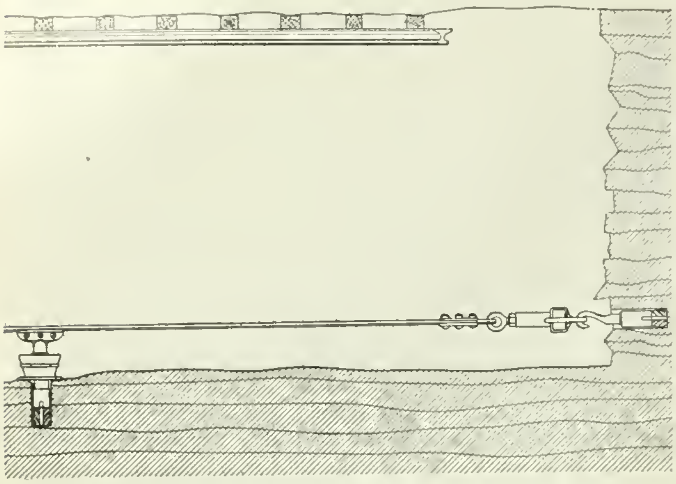

Fig. 3. Approved Method of Dead Ending Trolley Wire

be supported by hangers installed a short distance on each side of the insulator.

Section insulators are of three general kinds: the ordinary, automatic, and hand operated. The ordinary type of section insulator is used where it is desired simply to sectionalize the trolley, as, for instance, in a case where one feeder would feed one section of trolley and another feeder another section of trolley. There is no means provided for connecting the two sections of trolley together, except by the use of a jumper in an emergency.

The automatic section insulator is designed with a rocker arm so placed that the action of the trolley wheel in passing under the section insulator will cut in a section of trolley wire ahead of the locomotive. They have operated satisfactorily, but are open to the objection that they frequently get out of order and the movable parts give trouble.

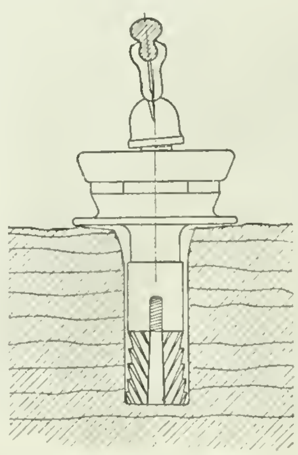

Fig. 4. Bending of Stud on Curve Due to Clamp Not Being Screwed Up Tight Against the Hanger

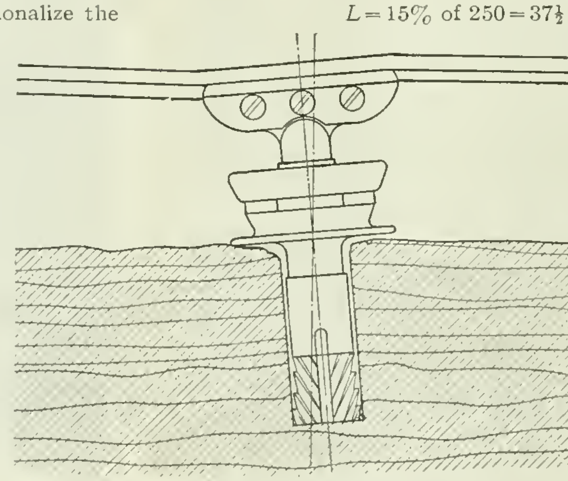

Fig. 5. Effect on Trolley Wire of Installing Hanger Out of Plumb

The section insulator with switch is an ordinary section insulator with a knife switch placed on one side. The handle of the switch is brought out at an angle of about 45 degrees and is so placed that the locomotive driver in passing under the section insulator may throw the switch. It has the advantage of few working parts, very rugged construction, and light weight.

K. In wiring entries where a grounded circuit is used, care should be taken to install the positive or hot wire next to the rib, with the negative or cold wire installed 10 inches on the outside of the hot wire.

No electrical conductors of any kind should be installed in mines unless they are put on suitable insulators or hangers. This, of course, would not apply to cases where conduit is used, but this latter condition is rather rare.

The installation of incandescent lamps in a mine should be done as thoroughly as that employed in house wiring. The practice of soldering a wire to the base of a lamp and hooking the other end across the circuit should be discontinued. Special precautions should be taken in gaseous mines to enclose all incandescent lamps in air-tight globes. The rules covering this will be found in the mining laws of various states.

L. Whenever there is danger of the wires being touched, as, for example, where they cross an entry, they should be protected either by trenching the roof or other suitable means. If trenches are used they should then be covered by 1-inch boards fastened by wooden pegs or other means. The wires must not touch the roof but must be thoroughly insulated and well separated from it.

It should be understood that the above suggestions are for the average conditions encountered in a mine. Special conditions, of course, would require special treatment and cannot be covered here.

Appreciating that the lack of a good simple formula for determining the amount of feeder necessary to handle any installation is quite keenly felt, a formula which is quite generally accepted is given below:

We will take a concrete example:

Required size of feeder to transmit 300 amperes, total distance from power house to center of distribution 3,000 feet, 15 per cent. allowable drop in voltage. From formula, $CM = \frac{22D \times I \times}{L}$, we have the following, where D = the distance in feet, I = current, and L = voltage loss, 22 is a constant:

$$L = 15\% \text{ of } 250 = 37\tfrac{1}{2} \text{ volts}$$

$$CM = \frac{22 \times 3{,}000 \times 300}{37\frac{1}{2}} = \frac{19{,}800{,}000}{37\frac{1}{2}} = 528{,}000 \text{ C. M.}$$

In practice, a 500,000 C. M. cable would probably be installed, or, under some conditions, a 4-0 feeder and a 4-0 trolley could be tied together and used to take care of this condition, although not quite up to the required area. In these calculations, it is assumed in all cases that the track return resistance is equal to the trolley resistance, as this is the most economical condition for the transmission of power using the track return. The subject of the proper care and maintenance of the track return circuit is intimately connected with that of the overhead construction, as if it is not properly attended to, much of the advantage of the good construction overhead may be neutralized.

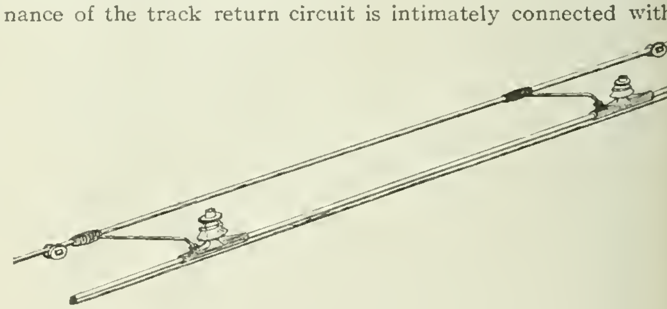

Fig. 6. Method of Connecting Feeder Wire to the Trolley By Means of Two or More Taps to Obtain Full Capacity of Feeder Wire

Turbine Mine Pumps

Experience in Pumping With Turbine Pumps Compared With Ordinary Steam Pumps

When dealing with machines for unwatering mines the term efficiency may or may not mean the power of producing effects continuously. It would seem therefore that the phrase economical efficiency is the more appropriate.

When water buckets such as those at the Hampton colliery of the Delaware, Lackawanna & Western Coal Co. produce an efficiency of over 80 per cent., and compound steam pumps an efficiency of 70 per cent., while an electrically driven turbine furnishes an efficiency of about 60 per cent., it would naturally appear as if every mine should be equipped with water buckets. At a depth of 500 feet water buckets are probably the most efficient unwatering devices, and, provided they are automatic in action and do not require the services of an engineer, most economically efficient; but the expense of installation, if shafts must be sunk purposely for them, may make the first cost so excessive as to preclude their use. If this be the case the next most efficient machine, theoretically, is the compound mine pump, yet the conditions of pumping may be such that the first cost with subsequent repairs and attendance will be so great that the economical efficiency will not compare favorably with the turbine. In the use of the electrically driven turbine, or centrifugal stage pump, difficulties may be encountered which will render it less economically efficient than a plunger pump working expansively. When conditions under which pumps must work vary as they do in the anthracite fields, it is not uncommon to find the same companies using all three devices mentioned. With gritty acid water the pump most in favor seems to be the turbine, but where the water is clean and clear the compound steam pump is ordered, and where the lift is over 500 feet and there is a central drainage for several mines some of the large anthracite companies use water buckets.

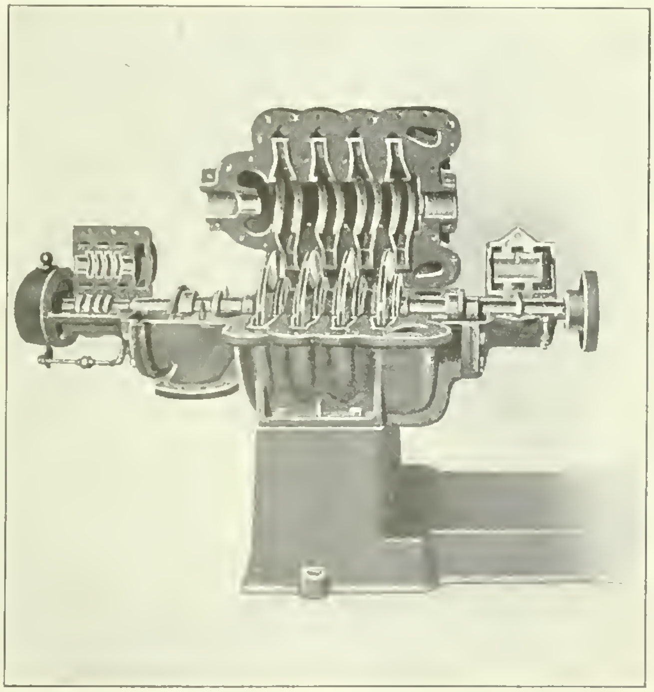

FIG. 1. DOUBLE-SUCTION TURBINE PUMP, CASING OPEN

The impression pretty generally prevails that anthracite mining is equivalent to Calumet & Hecla copper mining, when, as a matter of fact the margin of profit is smaller generally than in bituminous mining, owing to the large amount of money invested and the greater expense for timber and working.

The Lackawanna field is probably the most favored by nature for cheap mining, but in this field from 12 to 16 tons of water must be lifted to the surface for each ton of coal mined, and since anywhere from \$10,000 to \$50,000 is involved in the installation of a pumping plant, not to mention auxiliary pumps, a great many thousand tons of coal must be mined before the pumps have paid for themselves. It is no wonder therefore, when the purchase of a pump involves both theoretical and practical conditions, that the theoretical efficiency must in some cases at least be neglected for the more economical practical results.

There is no question but that the turbine pump is in many respects ideal for mine work, and that since its introduction in the anthracite fields it has been greatly improved; however, there is still room for improvement. During the short time it has been in service it has been improved to a greater degree than any plunger pump in the same period, for which reason it is probable that its theoretical efficiency will be increased.

All the large anthracite companies have installed these pumps, and the Delaware, Lackawanna & Western uses them attached to small steam turbines as boiler feed-pumps.

In 1905 A. B. Jennings, now vice-president of the Jeanesville Iron Works, canvassed the anthracite fields of Pennsylvania in the interest of the Worthington Steam Pump Co. The introduction of electrically driven turbine pumps into these fields was due to his endeavors, and an official report of their work has been looked forward to with considerable interest. The first of these pumps installed was intended as a supplementary pump to aid two 20″×9″×38″ direct-acting steam pumps in time of floods.

At first considerable trouble was experienced by the thrust due to the pressure of water coming direct on the end of the journal shaft. This was eventually overcome, however, by making use of the slotted brasses and shaft end previously adopted in marine work, and shown in Fig. 1

No trouble has been experienced with these thrust boxes so long as they have been kept properly lubricated, and as there is an automatically worked sight feed-lubricator, only extreme carelessness on the part of the pumpman in not supplying oil can produce a hot box.

The first difficulty being overcome, attention was next directed to the wear on the impeller blades. The conditions at anthracite collieries are unusually severe on pumps, the water being acid usually, and in addition fine grit finds its way into the sump, particularly during the thaws at the breaking up of winter or after a series of abundant rains. The speed of an 18-inch diameter impeller wheel being about 4,700 feet per minute, the grit in the water traveling at this speed obtains sufficient momentum to wear away the impeller blades and tips of the diffusion vanes unless those parts are constructed of suitable metal to resist the abrasion. It appears that the difficulty in finding a non-corrosive metal to withstand the acid water was not so great as to find a hard non-corrosive metal that would withstand abrasion from the grit. After experimenting with a number of alloys one was found that answers fairly well for fine grit.

To determine the cost of electric current for pumping any number of gallons of water per day, it is necessary to know the cost (c) of the current per kilowatt hour (K. W.) the efficiency of the motor ($e\,m$), mechanical efficiency of the pump ($e\,p$), and the height (h) to which the water is pumped. Since 1.34 horsepower = 1 kilowatt; 8.334 pounds = weight 1 gallon of water; and 33,000 foot pounds = 1 horsepower.

$$\text{Cost} = 24 \times c \times \frac{\text{gals. per min.} \times 8.334 \times h}{1.34 \times e\,m \times e\,p \times 33{,}000}$$

That turbine mine pumps are appreciated can be understood when in the space of a few years one large company ordered about 60 and another between 20 and 30.

Coal Mining Notes

Machine-Mined Coal in Kentucky.—Kentucky is one of the leading machine-mining states. Of the total output of coal over 62 per cent. was cut by machine. The amount so mined in each district was as follows:

District	Machine Mined Tons	Per Cent. of Total Prodution
Western	6,258,184	74.26
Southeastern	1,544,241	36.30
Northeastern	1,351,661	66.34
	9,154,086	62.18

The figures for the western district shows a gain of 1,812,914 in the machine-mined tonnage over that for 1909, but a decrease of 5.43 in the percentage. The Southeastern district shows an increase of 531,858 in the tonnage, and an increase of 9 in the percentage. The Northeastern district shows a gain of 706,453 in tonnage, and of 19.45 in percentage.

Coal Mine Arbitration.—A joint interstate agreement was entered into between the operators and miners for the states of Missouri, Arkansas, Kansas, and Oklahoma on September 18, 1910, and will end March 31, 1912. Under this contract W. L. A. Johnson was elected arbitrator and has the sole power of deciding all cases of dispute arising under the contract with certain limitations.

It has always been my opinion that arbitration and an arbitrator is a step in the right direction, and so far the arbitrator has decided a great many cases of dispute and the men have continued at work. Some cases decided by him have not been altogether satisfactory to the operators, and we would judge that the same is true with the miners, but on the whole I am frank to admit that I think an arbitrator is a good thing and has resulted in much benefit to both parties.—J. E.

New Mexico Coal and Coke.—The demand for coal and coke of New Mexico mines was restricted in 1911 by reason of the revolution in Mexico practically closing the market during the first 9 months. Railroad operation was almost entirely suspended and no coal used on the railroads, and as a consequence coal and coke could not be transported to the mines and smelters. The shipments of ore to the smelters in the United States were also suspended, lessening the demand for coal and coke at the smelters on this side of the line. The stagnation of the copper market also had a restraining influence on the demand for New Mexico coal and coke. With the restoration of normal conditions in Mexico that market will again be opened to the products of the New Mexico coal mines, which, together with the demand for the winter supplies in the domestic markets of the Pacific coast states will furnish a demand for the full production of the mines during the balance of the year.

The general depression in business conditions has been felt but little in the coal mine operations of the territory, and had it not been for the revolution in Mexico it is quite certain New Mexico's increase of production of coal and coke would have been greater than in any preceding year.

Coal in Indiana.—The coal output in Indiana for 1911 is going to be considerably less than in 1910, which was the banner year for the state. In that year an early agreement was reached by the miners and operators, and the strike in Illinois, together with the general demand for coal, greatly increased the output over the normal.

Coke-Making Record.—The Pocahontas coal mined at Gary, W. Va., carries only about 17 per cent. of volatile matter, and although it will coke in beehive ovens it does so at the expense of the fixed carbon. The steel corporation, therefore, ships the coal to Joliet, Ill., and Gary, Ind., where it is mixed with 20 per cent. of Illinois coal and then coked in Koppers by-product ovens. The Illinois coal does not coke by itself, and the Pocahontas coal swells considerably by itself, but the mixture works together so well that 84 per cent. of coke is obtained. This is probably a record for coke making from coal of any description.

Scranton District Mining Institute Banquet.—The third annual banquet of the Scranton District Mining Institute was held in the Thirteenth Regiment Armory, Scranton, Pa., October 21. In point of numbers—1,600—it was the largest banquet ever held in Scranton. Almost every class connected with the anthracite mining industry was present, and in this respect the affair was extremely democratic. This institute was organized in January, 1908, with a membership of 120. At present it has a membership of 1,756. The membership is made up of 849 miners, 180 mine laborers, 152 fire bosses, and assistant foremen, 16 superintendents, 77 foremen; the balance being made up of managers, clerks, mining engineers, etc. C. E. Tobey, assistant coal mine manager of the D., L. & W., is president of the institute, and his speech on the history and objects of the institute was exceedingly interesting.

Electrically Operated Cautionary Signals in Coal Mines. W. J. Murray, vice-president and general manager of the Victor-American Fuel Co., has recently introduced at his mines at Hastings and Delagua, Colo., an electrically operated cautionary signal which should prove of service to others. The device consists essentially of the ordinary "flash" sign familiar in street advertising. The warning, "Always be careful," as shown below is cut from a steel plate (to prevent possible breakage) in letters 3 inches high and in five languages:

ALWAYS BE CAREFUL
BODITE VEDNO PAZLJIVI
PAZPR PRI RADU
STATE SEMPRE ATTENTI
VAZDA SE CUVAJTE

This plate is placed over an ordinary glass-faced box, 20 in. × 24 in. in size. Within the box are four electric lamps operated by a 250-volt D C current from the mining machine feed-wires. The first warning sign is some 100 feet within the manway and others are placed throughout the mine at points where they will attract the most attention. As arranged at these mines, the light is "on" for 1½ seconds and "off" from 6 to 8 seconds.

Explosion of Powder at O'Gara Mine.—What is said to have been an explosion of powder in mine No. 9 of the O'Gara Coal Co., 1 mile from Harrisburg, Ill., occurred October 23. It is not known definitely just what caused the explosion, but it is presumed that it was due to an electric wire coming in contact with some loose powder in some way not known, because the explosion tore down the wires in the vicinity. Eight miners were killed by this explosion, and eight others were rendered unconscious, but were removed from the mines by rescuers. Dr. C. W. Turner and two others were overcome by gas, and for a time their condition was serious, but medical treatment at the hospital resuscitated them.—C. T. H.

The Study of Knots.—More than 50 of the students of the Massachusetts Institute of Technology have applied for instruction in the new course in knots and splices that Major E. T. Cole is to provide. It seems an odd study for a man whose profession is to be exercised on land, but an engineer must be able to solve all sorts of problems, and there is little in the way of practical education from lighting a fire to tight-rope walking that will not be of service to him. The need of windings and knots in scaffolding, shears, and the like is too evident to require argument. The *Tech*, the college paper, characterized the study as "A knotty-cal course."

Answers to Examination Questions

Selected Questions of the Illinois Examinations Held at Springfield, 1910

NOTE.—The questions selected are here numbered consecutively. The date of the examination and the true number of the question is given at the end of each question. M. = mine managers examination; E. = mine examiners.

QUES. 1.—With 52 horsepower an air-current of 120,000 cubic feet per minute is produced; how many cubic feet per minute will be produced with 44 horsepower? M., Apr. 11, Q. 3

ANS.—For the same mine or airway, the quantity of air in circulation will vary as the cube root of the power; or, in other words, the quantity ratio is equal to the cube root of the power ratio. Therefore, calling the required quantity of air x, we have,

$$\frac{x}{120,000}=\sqrt[3]{\frac{44}{52}}=\sqrt[3]{.846153+}=.94584$$

$$x=120,000\times .94584=113,500 \text{ cu. ft. per min.}$$

QUES. 2.—If 2 horsepower will produce 10,000 cubic feet of air per minute in single airway 10 ft. $\times$ 10 ft.; what horsepower will be required to produce the same amount of air in three airways, each airway being 6 ft. $\times$ 5.5 ft. and of the same length as the single airway? M., Apr. 11, Q. 4

ANS.—The formula expressing the work or power in terms of the dimensions of the airway is

$$u=\frac{k\,l\,o\,q^3}{a^3}$$

Since, in comparing these two circulations, k, l, and q are constant, or the same in each case, it is easy to observe that u varies as the expression $\frac{o}{a^3}$; or, in other words, the power varies directly as the perimeter and inversely as the cube of the area. Hence, the power ratio, in this case, is equal to the perimeter ratio multiplied by the cube of the inverse area ratio. For the single airway, $o=4\times 10=40$ feet; $a=10\times 10=100$ square feet. For the three airways together $o=3\times 2\,(6+5.5)=69$ feet; $a=3\,(6\times 5.5)=99$ square feet. Then, calling the required power x,

$$\frac{x}{2}=\frac{69}{40}\times\left(\frac{100}{99}\right)^3=1.778$$

$$x=2\times 1.77+=\text{say, } 3.5 \text{ H. P.}$$

QUES. 3.—What load will break a white-oak timber 10 in. $\times$ 12 in. and 15 feet between supports? The load is to be equally distributed along the length of the timber. M., Apr. 11, Q. 7

ANS.—The breaking load for a rectangular beam is found by multiplying the breadth of the beam in inches by the square of the depth in inches, and dividing that product by the distance between supports in feet; then multiply this quotient by one-ninth of the ultimate fiber stress (white oak = 8,500 pounds per square inch) to obtain the breaking load when uniformly distributed. Thus, in this case,

$$\text{Breaking load}=\frac{8,500\times 10\times 12^2}{9\times 15}=90,666 \text{ lb., say 45 tons}$$

QUES. 4.—Give the breaking strain of a $\frac{9}{16}$-inch, crucible-steel, hoisting rope having 6 strands of 19 wires each. Also give the safe working load for this rope. M., Apr. 11, Q. 8

ANS.—To find the breaking strain in tons, of a crucible-steel, 6-strand, 19-wire, hoisting rope, multiply the square of the diameter of the rope, in inches by 39; because 39 tons is the breaking strain of such a rope, 1 inch in diameter, and the strength of the rope increases as the square of the diameter of the rope increases. Thus, for a $\frac{9}{16}$-inch rope,

$$\text{breaking strain}=39\left(\tfrac{9}{16}\right)^2=12.34 \text{ tons}$$

The safe working load for wire ropes is generally taken, in practice, as one-fifth of the breaking strain, except in special cases of deep hoisting where the factor of safety is generally increased. In this case, the safe working load may be taken as, say 2.5 tons.

QUES. 5.—How many horsepower will it take to haul 25 loaded cars up an incline 500 feet long, in 1 minute, each loaded car weighing 4,000 pounds, allowing 20 per cent. for the resistance of rope and pulleys; the grade of the slope being 10 per cent.? M., Apr. 11, Q. 10

ANS.—The weight of the loaded trip is $\frac{25\times 4,000}{2,000}=50$ tons. To this must be added the weight of the rope. The diameter of extra-strong cast-steel, 6-strand, 7-wire, haulage rope required for this work, using a factor of safety 5, is

$$d=\sqrt{\frac{5\times 50\times .25}{37+\frac{1.58\times 5\times 500\times .25}{2,000}}}=1.3 \text{ say } 1\tfrac{3}{8} \text{ in.}$$

The weight of a $1\frac{3}{8}$-inch rope 500 feet long is

$$500\times 1.58\times (1\tfrac{3}{8})^2=\text{say } 1,500 \text{ lb.}$$

The total load hoisted when the trip starts from the foot of the incline is $50\times 2,000+1,500=101,500$ pounds. The gravity pull of this load on a 10-per-cent. grade is $101,500\times .1=10,150$ pounds. To this must be added the friction pull of the loaded trip, which is $\frac{1}{40}\,(50\times 2,000)=2,500$ pounds, making in all $10,150+2,500=12,650$. Then, allowing 20 per cent. for the resistance of rope and pulleys (friction), we have for the gross load on the rope $12,650\div .80=15,812.5$ If this load is to be hauled up the slope in 1 minute (60 sec.) it may be assumed for the purpose of calculation that 10 seconds are consumed in starting and stopping each trip, and that it would require only 50 seconds to haul the load 500 feet at the full maximum speed of winding, which would give a maximum required speed of 10 feet a second or 600 feet per minute. Finally, taking the efficiency of the haulage engine as 85 per cent., the indicated horsepower of the engine required for this hoist is

$$\text{I. H. P.}=\frac{15,812.5\times 600}{.85\times 33,000}=338+, \text{ say 350 H. P.}$$

QUES. 6.—The temperature of the air in the downcast shaft of a certain mine is 60° F., and in the upcast 100° F., the quantity of air entering the mine by the downcast is 20,000 cubic feet per minute; each shaft is 15 feet in diameter. What will be the velocity of the air passing in each shaft, in feet per minute? M., Apr. 11, Q. 12

ANS.—The sectional area of each shaft is $.7854\times 15^2=176.7+$ square feet. The velocity of air in the downcast is $20,000\div 176.7=113.18$ feet per minute. Assuming there is no increase of the air-current from the addition of mine gases or otherwise, the volume of the return current, and (for the same area) the velocity is proportional to the absolute temperature. The velocity of air in the upcast is therefore,

$$113.18\times\frac{460+100}{460+60}=121.89 \text{ ft. per min.}$$

QUES. 7.—A pair of entries 300 feet long have five cross-cuts connecting them, at 60 feet apart; the pillar between the entries is 30 feet wide. These entries and cross-cuts are all filled with marsh gas (CH_4). If an air-current of 6,000 feet per minute is available, what is the least time that will be required to clear out this gas without fouling the air-current further than to cause a small cap on a safety lamp? All the places mentioned are 8 feet wide and 5 feet high. M., Apr. 11, Q. 13

ANS.—The entire length of entries and cross-cuts is $2\times 300+5\times 30=750$ feet; the sectional area being $5\times 8=40$ square feet; the volume of gas filling this space, ignoring possible stoppings in the cross-cuts, is $750\times 40=30,000$ cubic feet. The first small cap on the flame of an unbonneted Davy is generally observed when the air-current contains 2.5 per cent. of gas. An air-current of 6,000 feet per minute would then carry off $6,000 \times .025 = 150$ cubic feet of gas. Under these conditions it would require $30,000 \div 150 = 200$ minutes, or 3 hours, 20 minutes, to clear the entries of gas.

Ques. 8.—The downcast shaft, in a certain mine is 600 feet deep and has a temperature of 50° F.; the upcast shaft, in the same mine, is 900 feet deep and its temperature 100° F.; what water gauge should these conditions produce, the barometer being 30 inches? M., Apr. 11, Q. 14

Ans.—The motive column in terms of the upcast air is

$$M = \frac{100 - 50}{460 + 50} \times 900 = 88.23 \text{ ft.}$$

The weight of 1 cubic foot of upcast air is $\frac{1.3273 \times 30}{460 + 100} = .0711$ pounds. The pressure due to this upcast column is $88.23 \times .0711 = 6.27$, and the corresponding water gauge is $6.27 \div 5.2 = 1.2+$ in.

Ques. 9.—If 20,000 cubic feet of air is produced in an airway 8 feet wide, 4 feet high, and 3,000 feet long; how many cubic feet of air will the same power produce in three airways or splits; namely, the first airway being as given above; the second airway being 9 feet wide, 5 feet high, and 3,600 feet long; and the third airway being 10 feet wide, 6 feet high, and 4,800 feet long? M., Apr. 11, Q. 15

Ans.—This question is most readily solved by first finding the potential values for each of the splits or airways; thus,

airway $8' \times 4'$, 3,000′ long; $a = 32$; $o = 24$; $l = 3,000$
airway $9' \times 5'$, 3,600′ long; $a = 45$; $o = 28$; $l = 3,600$
airway $10' \times 6'$, 4,800′ long; $a = 60$; $o = 32$; $l = 4,800$

The lowest relative areas, perimeters, and lengths for these airways are

1st airway, $a = 32$; $o = 6$; $l = 5$
2d airway, $a = 45$; $o = 7$; $l = 6$
3d airway, $a = 60$; $o = 8$; $l = 8$

The relative potential values are then

First airway, $X = 32\sqrt{\frac{32}{6 \times 5}} = 33.05$

Second airway, $X = 45\sqrt{\frac{45}{7 \times 6}} = 46.58$

Third airway, $X = 60\sqrt{\frac{60}{8 \times 8}} = 58.09$

Sum of potentials.............137.72

The total quantity of air circulated in the three given splits by the same power that will circulate 20,000 cubic feet of air in a single airway 8 ft. × 4 ft., 3,000 feet long, is then

$$Q = 20,000\sqrt[3]{\left(\frac{137.72}{33.05}\right)^2} = 51,790 \text{ cu. ft. per min.}$$

Ques. 10.—What kind and size of hoisting engines would you use to hoist 1,200 tons of coal in 8 hours from a shaft 400 feet deep? The weight of coal in each car is 3,000 pounds; the steam pressure 70 pounds per square inch. Allow 20 per cent. for the resistance of engine, ropes, and pulleys, and give time for caging the coal. M., Apr. 11, Q. 19

Ans.—Allowing, say ½ hour each day for unavoidable delays, the actual time of hoisting is $8 \times 60 - 30 = 450$ minutes. The rate of hoisting is then $(1,200 \times 2,000) \div 450 = 5,333$ + pounds per minute. Since one car carries 3,000 pounds of coal, the time per hoist is $\frac{3,000}{5,333} \times 60 =$ say, 34 seconds. Now, allowing say 14 seconds for caging cars each trip, and to cover time lost in starting and stopping each trip, the actual time of hoisting this depth, at maximum speed, would be $34 - 14 = 20$ seconds; and the maximum speed of winding is $400 \div 20 = 20$ feet per second, or 1,200 feet per minute.

It is necessary, now, to calculate the size and weight of hoisting rope required, as follows Load on rope = coal 3,000 pounds; car, say 1,400 pounds; cage, say 2,000 pounds; total of these = 6,400; and adding one-tenth for friction makes the total load exclusive of the weight of the rope itself, say 7,000 pounds, or 3.5 tons. The diameter of a cast-steel, six-strand, 19-wire hoisting rope for this load, and depth of shaft, using a factor of safety of 8, is

$$d = \sqrt{\frac{8 \times 3.5}{34 - \frac{8 \times 1.58 \times 400}{2,000}}} = .94, \text{ say, 1-inch rope}$$

The weight of this rope is $400 \times 1.58 = 632$, say, 700 pounds. The next step is to find the load on the engine, which, for a double-compartment shaft, is the unbalanced weight of coal and rope, plus the friction of the hoist; thus, coal 3,000 + rope $700 = 3,700$ pounds. Allowing 20 per cent., as stated in question, for resistance of engines, ropes, and pulleys, gives for the total load on the engine $3,700 \div .80 = 4,625$ pounds. To hoist this load at a speed of 1,200 feet per minute will require $(4,625 \times 1,200) \div 33,000 = 168$, say 175 indicated horsepower of engine. A duplex, geared, or second-motion engine will be used, each cylinder being calculated for the full horsepower required. For a steam pressure of 70 pounds at the throttle, and say a ⅝ cut-off, the mean effective pressure in the cylinders is $.9\,[(14.7 + 70)\ .904 - 17] = 53.6$ pounds per square inch. Now, assuming an efficiency of the engine of, say 85 per cent., and a piston speed of, say 630 feet per minute, the diameter of a steam cylinder required to develop 175 horsepower, is

$$d = 205\sqrt{\frac{175}{.85 \times 53.6 \times 630}} = 16 \text{ in.}$$

Assuming a length of stroke of 20 inches, the engine must make $\frac{630 \times 12}{2 \times 20} = 189$ revolutions per minute. If the ratio of gearing is 1 : 3 the winding drum will make $189 \div 3 = 63$ revolutions per minute. For a rope speed of 1,200 feet per minute the diameter of coils on the drum will be $\frac{1,200}{3.1416 \times 63} = 6.06$, or practically 6 feet 1 inch. Since the diameter of the rope is 1 inch, the diameter of the drum is 6 feet. The size of the engine is as given above, 16 in. × 20 in.

Ques. 11.—(*a*) What constitutes a safety lamp? (*b*) Describe the Davy lamp and state under what conditions it is unsafe. E., June 27, Q. 2

Ans.—(*a*) Any lamp in which the flame or other source of light is more or less completely isolated from the atmosphere surrounding the lamp comes within the meaning of the term "safety lamp," as applied to mining. The general acceptance of the term at present, however, includes only those types of lamp in which the flame is inclosed in a chimney of wire gauze or glass and wire gauze combined. But since electric lamps are rapidly coming into use in mines, the meaning of the term safety lamp must be extended to include all incandescent lamps designed for mining use. (*b*) The Davy lamp consists ordinarily of a brass or aluminum oil vessel surmounted by a cylindrical wire-gauze chimney varying in height from 4½ inches to 6 inches and being generally 1½ inches in diameter. The standard wire gauze in use has a mesh of 28 wires (No. 28, B. W. G.) to the inch, making $28^2 = 784$ openings per square inch. This gauze chimney is closed at the top where it is further protected by a gauze cap that fits snugly over the top of the chimney. There are many types of Davy lamps; some are protected by a glass or a steel bonnet covering a portion of the gauze chimney; others are provided with a metal shield on one side of the chimney; still others (tin-can Davy) are quite enclosed in a metal case with a glass window, resembling a lantern. The unbonneted Davy lamp is unsafe when exposed to a gaseous current having a velocity exceeding 6 feet a second. The lamp is also unsafe when improperly or carelessly handled, or not properly put together, or when the gauze is dirty or defective, or has become heated by too long exposure to gas.

ORE MINING AND METALLURGY

Petroleum in Oklahoma

Location of the Oil District. History. Geological Conditions. Quality and Quantity of Output

By Lucius L. Wittich

Early operations in search of crude petroleum were launched in Oklahoma (then the Indian Territory) as early as 1882, but it was not until 1906 that the first great discoveries in the Glenn Pool district were made.

Prior to the opening of the Glenn Pool district, the region between Bartlesville and Tulsa had been tested to some extent. Prospectors then pushed southward, and during the early summer of 1906, Glenn well, No. 1, was brought in, featuring the opening of one of the greatest oil pools so far known. Since then the field has expanded and the production of crude petroleum in Oklahoma increased to such an extent that in 1907 and 1908 Oklahoma led the United States in production.

Although crude oil development in Kansas was launched long before development was started on an extensive scale in Oklahoma, the oil fields of the two states have become intimately associated under the common caption, "The Mid-Continent Field" and because of this relationship it has been more or less difficult to keep the production of the two states separate. In 1906 the Mid-Continent field produced 22,000,000 barrels, and it is estimated that of this quantity Oklahoma produced more than 16,000,000 barrels. Last year the production of Oklahoma alone was 54,000,000 barrels. A glance at the map, Fig. 2, shows to what extent the oil regions of Oklahoma may be developed. Fig. 1, showing one view of the Glenn Pool district, gives an idea of the uses to which concrete is put in the construction of reservoirs for crude oil.

FIG. 1. CONCRETE OIL RESERVOIR, GLEN POOL, OKLAHOMA

After two years of scattered prospecting on the part of residents of the Indian Territory, the Cherokee and Choctaw nations, in 1884, awakened to a realization of the possibilities of buried wealth. In that year the Choctaw Council passed a law creating the Choctaw Oil and Refining Co., "for the purpose of finding petroleum, or rock oil, and increasing the revenue of the Choctaw Nation." The act was approved by the principal chief, Edmund McCurtain. The Cherokee Nation passed a similar law a few weeks later, and D. W. Bushyhead, the principal chief, signed the bill. Companies were organized in each Nation and the prospecting concerns united in associating themselves with Dr. H. W. Faucett, of New York, for the purpose of development. Preliminary prospecting was started about 14 miles west of Atoka; another well was drilled about 20 miles north of Talequah, the capital of the Indian Territory. Adverse legislation came in 1885 and operations were suspended. Eastern investors were frightened from the field and despite the reinstatement of the charter by the next Cherokee Council it was difficult to interest foreign capital in the project While things were at a standstill in the Cherokee Nation some work was being done in the Choctaw Nation, St. Louis capitalists having been interested in the undertaking. In 1888 important development had been made, holes having been sunk to almost 2,000 feet. Indications of oil were encountered at various depths, the first evidence of oil being found at a depth of 454 to 524 feet. More oil was encountered at a depth of 917 feet. At 1,235 feet a still better showing of oil was encountered. Again at 1,302 feet there was a small showing of oil. Indications of both oil and gas were encountered at 1,347 feet and 1,391 feet.

Extensive oil development was launched in 1894 by the Cudahy Oil Co., of Omaha, this concern having secured a blanket lease on the Creek Nation. McBride and Bloom, of Independence, Kans., were employed to drill the first wells, the initial boring being done on what is now a portion of the Muskogee townsite. Oil was found at 1,120 feet. At a depth of 1,800 feet the hole was lost. In the second hole, 900 feet southwest of the first location, high-grade oil was discovered at a depth of 645 feet. The sand was shot and production was recorded. The hole was sunk deeper for prospecting purposes, work being abandoned at 1,300 feet. In 1904, when titles to the land could be procured, drilling was resumed, and in the vicinity of Muskogee much work is still in progress.

In March, 1896, the Osage Council passed a bill permitting oil and gas exploitation. Edwin B. Foster acquired a lease which gave him an exclusive franchise to operate in the Osage country. A five-barrel producer was the result of the first well sunk, three miles south of Chautauqua Springs. The oil was encountered at a depth of 1,100 feet.

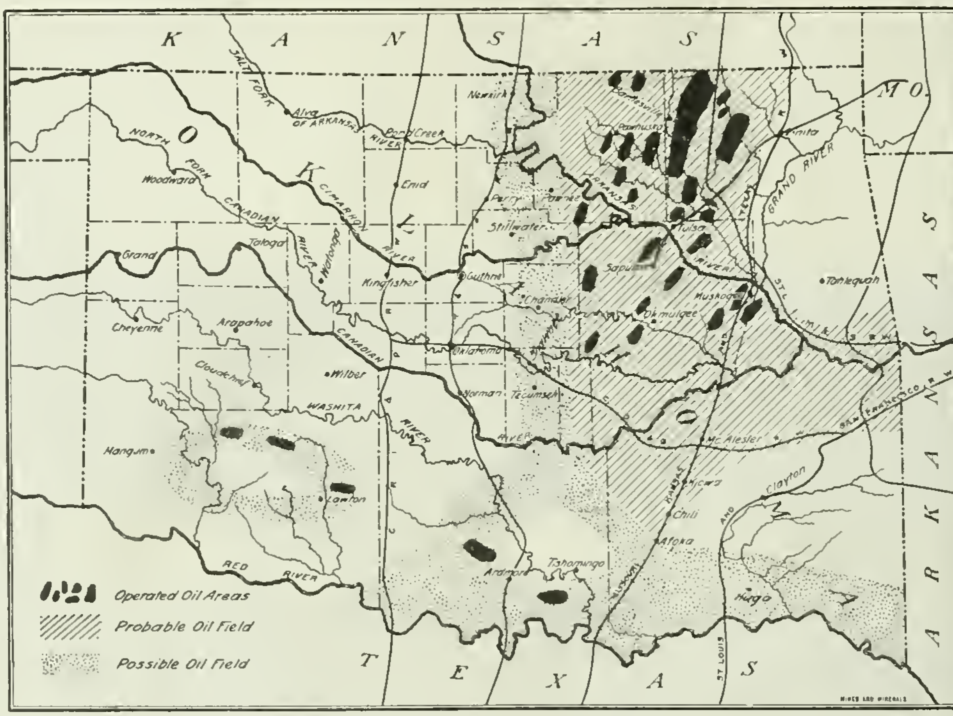

Fig. 2. Oklahoma Oil Regions

In 1897, McBride and Bloom, encouraged by their efforts near Muskogee, sunk a well at Eufaulfa on their own responsibility. Drilling was continued to 2,575 feet, oil being encountered at three horizons and gas enough at 2,475 feet to fire the boiler.

While these efforts were in progress in the Indian Territory, some drilling was being done without success in Oklahoma Territory. However, a good pool was opened at Cleveland, Okla., in 1904.

As far back as 1886 extensive development was undertaken by Edward Bird, west of Chelsea, and in 1891, 11 wells were producing oil on this tract. Unsatisfactory governmental conditions caused a temporary discontinuance of operations in this field as they had in other portions of the Indian Territory. The leases passed into the hands of the Cherokee Oil and Gas Co. The holdings of this concern were materially decreased by the Curtiss Bill, of 1896. Various companies were shorn of all unproved territory by this measure. Unsettled conditions resulted in little work being done until 1904. Since then development has been almost phenomenal, drill rigs having been stationed throughout the entire north central portion of the new state.

In the Creek Nation, in which the Glenn Pool is located, the first development of note was conducted by Dr. Fred S. Clinton, of Tulsa, and Dr. J. C. W. Bland, of Red Fork, who drilled near Red Fork. Colcord and Calbreth opened Glenn well, No. 1, in 1906.

Pipe-line facilities are now ample to care for the heavy production of crude petroleum in Oklahoma. Recently the Oklahoma Pipe Line Co. completed an 8-inch line to the Gulf. Improvements and extensions have been made in the lines of the Prairie Oil and Gas Co., the Gulf Pipe Line Co. and the Texas Co. Prior to 1910, producers were handicapped because of inadequate pipe-line facilities. Statistics gathered early this year show that the Prairie Oil and Gas Co. had 801 steel storage tanks in Oklahoma, running from 35,000 barrels to 55,000 barrels. The Gulf Pipe Line Co. was reported to have 120 steel tanks and the Texas Co. 64. In addition to these, 101 tanks were reported to be owned by various producers throughout the field, making a total of 1,086 tanks, bull's-eyes for stray lightning bolts that chanced to be playing about the heavens. Heavy damage has resulted from lightning striking tanks, Fig. 3 showing a steel tank thus struck. An idea of the resulting loss in such cases may be had from the instance in hand. The tank, the capacity of which was 55,000 barrels, and which was the property of the Prairie Oil and Gas Co., was valued at $13,500. The value of the oil on hand was about $20,000, making the total loss $33,500. The possibility of loss from lightning is a factor with which the majority of the oil producers of California do not have to contend, chain lightning in Southern California being almost unknown.

Table 1

Field	Number Wells	Daily Production Barrels	Average Per Well Barrels
Glenn Pool	2,101	38,227	18¾
Hamilton (Preston)	74	1,991	24¼
Bald Hill	136	3,306	23

It is estimated that the total storage of Mid-Continent oil aggregates 58,000,000 barrels, of which the greater part is in Oklahoma. Estimates place the aggregate trunk line mileage between 1,200 and 1,500 miles.

Recent estimates by the Oklahoma Geological Survey place the average daily production of oil at 121,837 barrels, the total producing wells at more than 15,000, and the average production per well per day eight barrels. The producing districts are divided as shown in Table 1.

Figures of the United States Geological Survey show the initial average daily production of oil wells in Oklahoma to be as follows: Average per well, 1905, 54.1 barrels; 1906, 71.1 barrels; 1907, 131.7 barrels; 1908, 87.1 barrels; 1909, 75.3 barrels; 1910, 60 barrels.

During the past fiscal year, according to the report of the oil and gas inspector of Oklahoma, the value of petroleum and gas produced and sold aggregated $18,000,000. Within the year 3,340 wells were drilled, of which number 2,803 were oil wells and 135 were gas wells. Four hundred and two were "dusters."

Refinery tests of Oklahoma crude oil of 36 gravity show the following results:

	Per Cent.
Benzine products	20
Illuminating oil	32
Light neutral distillate	18
Fuel oil	28
Lost by evaporation	2

The greater part of the oil is purchased by three companies, the Prairie Oil and Gas Co., which is a subsidiary of the Standard Oil Co., the Texas Co., and the Gulf Co.

Geologically, the formation of the Oklahoma oil fields is, for convenience, divided into the Main field and the Arbuckle-Wichita region. The main field takes in the northeast part of the state, the probable oil areas extending well south toward Texas. The Arbuckle-Wichita field is to the west, where geological conditions are more complex than in the main field. The indications are that both fields were lifted above sea level at the same time.

Both oil and gas at Wheeler, Lawton, Gotebo, and Granite, are found along or near the old unconformity, probably between the Carboniferous and the Permo-Carboniferous rocks, and the theory is advanced that the liquid seeped into the Permian Red Beds from older rocks, rather than originating in the Red Beds themselves.

In the Main field, the rocks merely consist of alternating strata of limestone, shale, sandstone, and occasional beds of workable coal. The oils and gases are found in rocks of the Carboniferous period, although some gas is reported to have been found in the more ancient rocks of the Mississippian. Rocks of the Carboniferous system outcrop in Northeastern Oklahoma, Southeastern Kansas, and at a few points in Southwest Missouri, in which region some prospecting for oil has been conducted without success, although some petroleum has been encountered at great depth north of Alba, Mo. The outcrop of the Carboniferous rocks follows the course of Spring River as it winds through portions of the three states mentioned. At many places along this stream, rocks of the Mississippian form the surface on one side but dip beneath the outcropping Carboniferous on the other. As the Mississippian gradually dips toward the west, averaging about 20 or 30 feet fall to the mile, the thickness of the Carboniferous increases proportionately and in the extreme west portion of the oil fields drill holes have been sunk to almost 3,000 feet without encountering the Mississippi limestone. The greatest oil pools are found along or just above the unconformity between the Mississippian and the Carboniferous rocks. Immediately above the Mississipian comes the Cherokee shales, with an average thickness of 400 to 500 feet and these are capped by the Fort Scott limestone, above which are alternating shales and limestones extending to the surface. The great sandstone beds, some in the form of lenses, shaped like pumpkin seed, and others of uniform thickness extending over a greater area, occur, for the most part, in or at the base of the Cherokee shales. Near the top of the Cherokee shales another horizon of "oil" is found, and still another is encountered above the Fort Scott limestone. No geological connection seems to exist between the oil fields of the Mid-Continent region and those of other portions of the United States.

Fig. 3. Oil Tank Struck by Lightning

Charles N. Gould, director of the Oklahoma Geological Survey, makes the statement that it is a geological impossibility for the Mid-Continent field oils to be connected with the fields of Corsicana and Beaumont, in Texas.

Geological conditions in Oklahoma have proven ideal for the storage of vast quantities of petroleum and gas. First, the source of supply was extensive, extending over a great area as already proven by the producing wells; second, the great beds of sands, acting as reservoirs in which the products have been stored; and third, the almost impervious Fort Scott limestone, forming a cap rock through which the oil and gas escape through natural crevices only at rare intervals. The absence of any one of these conditions would have broken the happy combination which has resulted in Oklahoma being famous as a producer of petroleum. The gentle undulations of the surface correspond in a great degree to the folds of the earth hundreds of feet beneath, and from these surface indications oil prospectors secure valuable hints on locating wells. Along the crests of the anticlines the greater part of the oil and gas is naturally found. A hole sunk into a syncline almost invariably goes into salt water, for the oil, gas and salt water, obeying an elementary law of physics, will arrange themselves in the order of their specific gravities. A shot of from 10 to 100 quarts of nitroglycerine, Fig. 4, discharged at the bottom of a freshly sunk well, will open the oil sand, leaving a clear space in which the liquid can accumulate and from which it can be pumped if the pressure is not great enough to form a gusher.

Churn drills are used in sinking the wells, the derricks, because of the great depth to which the majority of the holes are sunk, being substantially constructed, and not of the fragile type encountered in many of the metal mining regions where the greatest depth of drilling is only a few hundred feet. All holes are cased entirely to the bottom.

Well shooting is a distinct profession in the Oklahoma oil fields. Rigid laws prevent the promiscuous handling of nitroglycerine on railroads, and as a result the greater portion of this dangerous explosive is conveyed across country in wagons. Following the lowering of a nitroglycerine cartridge into the well, a "go-devil," weighing 75 or 100 pounds, is dropped into the opening. The force of the impact when the sharp-pointed "go-devil" strikes the charge causes the explosion, and if a heavy pressure is behind the oil the thick, black fluid will shoot

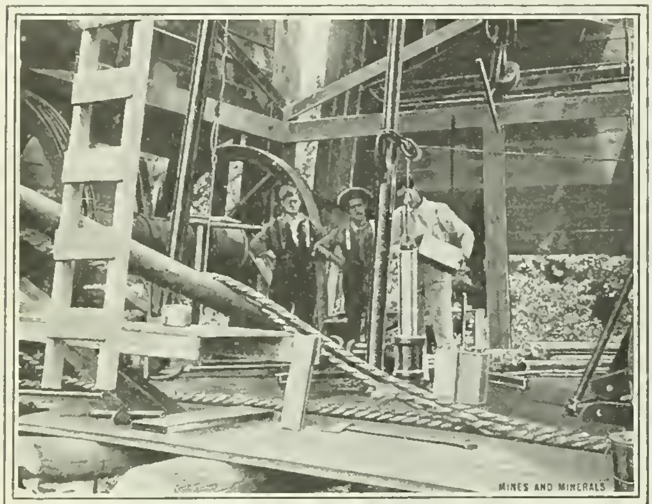

Fig. 4. Loading a Well with Nitroglycerine

high into the air. Often the flow will continue for weeks or even months, after which the oil can be raised by pumping jacks, many of which can be operated from one central pumping station. Two men, one for the day shift, the other for the night, can care for a central pumping station operating as many as 20 wells.

Operators, as a rule, own their own lands, an unwritten law of the field requiring them to put down wells at a reasonable distance from their boundary lines. This rule almost invariably is observed to the letter and crowding of wells is not one of the evils of the field. Where operators lease their lands the customary royalty charged is 12½ per cent.

Production of Natural Gas

The entire output of natural gas in the West Virginia oil fields is estimated by H. A. Danne, in Metallurgical and Chemical Engineer, at 1,300,000,000 cubic feet per day, of which about 300,000,000 cubic feet are wasted. The thermal efficiency may attain as much as 1,134 British thermal units per cubic foot, but after compression of the gas it falls to about 900 British thermal units owing to the deposition of liquefied hydrocarbons. It is employed for power purposes, zinc smelting, and the manufacture of glass, bricks, pottery, electrodes, and lampblack. Judging from the fact that the oil and gas are accompanied by coal and salt water, and that the pressure of the gas is nearly always affected by seismic disturbances, the author considers that these hydrocarbons are generated from natural carbonaceous deposits, by the earth's interior heat brought into proximity to these deposits by seismic disturbances; that they are still being generated under enormous pressure, and that on the release of some of the pressure, and consequent changes in the temperature of the hydrocarbons, some of the constituents are deposited in the dips of the strata and in the pockets known as oil-bearing pools.

American Institute of Mining Engineers

An Account of the California Meeting and Excursions Preliminary to Starting for Japan

As one of the visiting members remarked: "While the avowed object of the meetings of the Institute is the reading and discussion of papers upon technical subjects, yet the chief pleasure of these meetings consists in the trips, in sight seeing under unusually favorable circumstances, in the lavish hospitality accorded at all stopping places, and in the renewal of old friendships and the making of new ones; the papers may be read later and at any time, but the trips may be made but once." As this is generally admitted, a report of the San Francisco meeting of the American Institute of Mining Engineers must necessarily include some account of the trip.

Leaving Chicago at 10 o'clock on the night of Saturday, September 30, a special train of six cars in charge of Mr. Clarence Eaton, as representative of the railroad, started over the Santa Fe with 66 members and guests on the 2,265-mile journey to Los Angeles. Albuquerque was reached at noon, Monday, where a stop of an hour was made to inspect the Fred. Harvey collection of relics of Indians of the Southwest, probably the best of its kind extant. The same afternoon a stop of half an hour was made at Laguna, N. Mex., to visit the Indian village at that point.

The Grand Cañon of the Colorado was reached early Tuesday morning, where two delightful days were spent at the magnificent Hotel El Tovar. While the cañon was more or less familiar to all, either through Moran's painting or college textbooks, no preconceived idea is comparable with that derived from actually seeing what may be called "the eighth wonder of the world."

Los Angeles was reached at 2:30 on Thursday afternoon, October 5th, where the visitors were met at the depot by a committee of the local members of the institute, headed by R. W. Hadden, and consisting of A. A. Burnand, T. B. Comstock, A. Doerr, G. Johnson, Jr., L. Lindsay, F. J. H. Merrill, R. H. Norton, S. F. Parrish, and W. F. Staunton, who escorted them to the Hotel Alexandria, the local headquarters, where an informal reception was held by the ladies committee, Mesdames Theo. B. Comstock, R. W. Hadden, C. Colcock Jones, Seeley W. Mudd, R. H. Norton, and W. H. Wiley. The same evening the Sierra Madre Club members of the Institute entertained the visitors at dinner, at which Mr. William Mulholland gave an interesting illustrated lecture on the Los Angeles aqueduct, of which he is engineer in charge.

Friday, the 6th, the party made a trolley trip to many points of interest round about Los Angeles, visiting Hollywood, the Soldier's Home, Santa Monica, Ocean Park, Venice, and Redondo. At Redondo the power plant of the Pacific Light and Power Corporation was visited, a bath taken in the plunge where the ocean water is maintained at a constant temperature, and the day concluded by a fish dinner at Hepburn & Terry's restaurant.

On Saturday, the 7th, a majority of the party toured the city in automobiles in the morning, visiting friends or resting in the afternoon, while some few passed the entire day in making the trip to and from Avalon on Santa Catalina Island, a trip as memorable in its way as that to the Grand Cañon.

Leaving Los Angeles at midnight Saturday, Santa Barbara was reached early Sunday morning, the 8th, where the day was spent in driving, bathing, and resting up after the strenuous visit at hospitable Los Angeles. Leaving again at midnight, the party reached Del Monte several hours behind schedule on Monday afternoon, the 9th, and only a portion of the program could be carried out. However, all will remember with pleasure the beautiful 17-mile drive.

San Francisco was reached the same evening, Monday, and the party at once went to the Institute headquarters at the Hotel Saint Francis, where the management of the meeting was in the hands of a committee consisting of W. C. Ralston, S. B. Christy, F. W. Bradley, M. L. Requa, H. Foster Bain, and E. H. Benjamin, who left nothing undone to add to the pleasure and comfort of the guests.

The opening session of the meeting was called to order in the red room of the St. Francis on Tuesday afternoon, the 10th, by R. W. Hunt, after a short address of welcome by Hon. W. C. Ralston, chairman of the local committee. Following the sending of a telegram to President Kirchoff expressing regret at his unavoidable absence, E. B. Durham, of Berkeley, Cal., read a most interesting paper on the electrolytic methods of refining used at the San Francisco mint. This was followed by a paper by Bernard MacDonald on the "Parral Tank System of Agitation," describing a new system recently introduced by him in Mexico. B. W. Vallat's illustrated talk on the "Geology and Operation of the Newport, Mich., Mine," of which he is manager, was one of the features of the meeting; few, if any of those present having any idea of the advanced practice prevailing in the iron mines of that state. This paper was discussed at length by Gardner Williams, and some interesting comparisons made with conditions on the Rand. The session closed with another illustrated lecture by Prof. S. B. Christy, of Berkeley, Cal., on "Progress in Electro-Amalgamation," describing at length the results of his many experiments extending over the past 10 years.

At the session Wednesday morning a letter from Lewis E. Aubury, state mineralogist, was read, extending to the members a cordial invitation to visit the state mining exhibit in the Ferry Building. John A. Brittain, representing the Panama-Pacific International Exposition, in a witty speech requested the delegates to revisit San Francisco in 1915. A telegram from New York was read announcing the establishment at Columbia University of a research scholarship in economic geology in memory of Samuel Franklin Emmons. The intention is to raise a fund of $25,000 for this purpose, subscriptions to be sent to Benjamin B. Lawrence, treasurer, 60 Wall Street, New York, N. Y. The first paper of the day was a most interesting one on "California Oil," by Mark L. Requa, which was discussed at some length by Doctor Raymond. This was followed by a paper on "Present-Day Problems in Dredging," by Charles Jannin and Francis J. Dennis, both of San Francisco, Cal., and read by Mr. Dennis, which aroused an interesting discussion. Followed, the paper of Charles G. Yale, of San Francisco, Cal., on "Gold Production of California," with the statistics of which he has had many years experience. A feature of this session was the paper by Thos. T. Read, associate editor of *The Mining and Scientific Press*, San Francisco, Cal., on the "Mineral Resources of China," a subject with which the author was thoroughly familiar from many years residence in the country. The illustrations showing the peculiar metallurgical and mining methods employed in that country, and the statements of labor costs and efficiency were much appreciated.

Wednesday afternoon the delegates left on a special train for the Leland Stanford, Jr., University, at Palo Alto, where they were welcomed at the station by a delegation from the senior class, escorted to the college grounds in special trolley cars, and after visiting the buildings, including the magnificent art gallery, were served with a lunch at the Delta Upsilon fraternity house.

At the Thursday morning technical session Robert W. Hunt presided, subsequently being succeeded in the chair by secretary-emeritus Rossiter W. Raymond. Reija Kanda, consulting engineer, who arrived that morning from Tokyo, Japan, to accompany the visitors to the Orient, was introduced and spoke at length upon what the visitors were about to see, comparing the differences between his own country and the United States. Prof. Jos. Daniels, of South Bethlehem, Pa., read a most interesting paper on "The Fritz and Coxe Laboratories" at Lehigh University. Followed, the paper of Prof. Geo. T. Young, of Reno, Nev., on slime filtration, describing recent advances in this branch of metallurgy. The address of H. Foster Bain, editor of *The Mining and Scientific Press*, San Francisco, Cal., on some features concerned with the coal land situation in Alaska brought out a most animated discussion. Mr. Bain took the progressive stand that the national resources are the property of the people as a whole and should be administered on this basis for the good of all the people, advocating the opening of a mine by the Government in Alaska pending the enactment of proper legislation looking to the equable disposition of the public domain. In this he was ably seconded by Dr. E. W. Parker, of Washington, D. C., who called attention to the fact that probably less than 100,000 tons of coal a year were at present consumed or required in that territory. Doctor Raymond took the opposite and conservative stand, claiming that the Government should place the remaining resources of the country freely, without price, let, or hindrance in the hands of the first comers, who should be free to combine or not as best suited their own interests. Doctor Raymond complained bitterly of the multiplicity of our land and mining laws and the various and peculiar ways they have been interpreted by the courts, stating no man knew whether he was a criminal or not in the present state of legislation.

Thursday afternoon the Institute visited the University of California, at Berkeley, where, after inspecting the beautiful buildings and grounds, they listened in the Greek Theatre, to a most enjoyable lecture by Doctor Raymond on "Reminiscences of the Beginning of the Institute." Unfortunately, Dr. G. T. Becker was unable to be present and his "Biographical Notes On S. F. Emmons" were not read.

Friday morning, the 13th, many of the visiting members left on a special train for a trip of inspection to the dredging operations of Natomas Consolidated of California, at Natoma. After a most delightful lunch on the lawn of the residence of General Manager Newton Cleaveland, whose guests the party were, the two largest dredges (bucket capacity 15 cubic feet) in California were inspected, and after a short trip by rail the rock-crushing plant of the same company at Fair Oaks, where some 1,500 tons daily of boulders from the dredging operations are converted into material for concrete, road making, and railroad track ballast. The most interesting feature of this trip was perhaps not the two enormous dredges, but rather the evidences of the extreme care with which the hitherto unused by-products were rendered useful. Not only is the waste rock, as stated, converted into ballast, concrete, and macadam-making material of value, but the very ground itself, consisting of large pebbles and apparently destitute of soil, is planted in eucalyptus, grapes, and fruit trees.

Saturday, the 14th, except for an automobile trip to Golden Gate Park, where President Taft turned the first shovel full of earth for the Panama Pacific International Exposition, was largely a day of rest or passed in visiting local plants of interest.

Early Sunday morning, as guests of the Bohemian Club of San Francisco, the visitors left for Bohemia, the beautiful grove of big trees, one of the few remaining, where the club holds its annual revels. Lunch was served in the grove and after that the delegates listened to the "Music of Bohemia," largely written by members of the club and rendered by Sabin's orchestra.

Monday was a day of rest, and on Tuesday, the 17th, about half the party left for home at 10:40 in the morning via the Southern Pacific, Union Pacific, and Chicago, Milwaukee & St. Paul Railroads. The remainder of the visitors, together with a sufficient number who came directly to San Francisco to make a party of 85, left at 1:30 o'clock the same afternoon on the "Manchuria" for Japan, where they will be guests of the Mine Owner's Association of that country. Eighteen days, both going and coming will be passed on the Pacific, with stops of one day in Honolulu and of 17 days in the Island Kingdom.

Common Features of Silver Districts

With Special Reference to the Geological Features of the Silver Producing Areas of Colorado

*By W. G. Matteson, E. M.**

In listing the world's greatest silver districts, one is necessarily limited by certain factors such as the richness of deposit and extent of production. Neither one of these facts can be disregarded absolutely in favor of the other, although there are instances where the quantity of production has so far overbalanced other considerations as to cause camps producing a relatively low-grade ore to be placed in the front ranks of the greatest silver districts.

Mosquito Range from Iron Hill, Leadville, Colo.

In attempting this classification, however, one cannot confine himself to regions producing silver almost exclusively, for the greatest source of silver supply can be attributed to mines in which lead, copper, zinc, or gold have also been found and mined in great abundance. With these limitations, therefore, a fair and conservative classification would include the well-known districts of Guanajuato and Pachuca, Mexico; Broken Hill, Australia; the Cobalt district of Canada; and the Comstock Lode, Leadville, Aspen, Tonopah, and the Park City regions of the United States.

Guanajuato has the reputation of having been the most productive silver mining district in the world, its total output exceeding a thousand million ounces. Cobalt takes rank as one of the richest silver producing regions ever known, its minerals assaying up to 7,000 ounces of silver per ton. The Broken Hill field is classed among the greatest mineral exploitations of man and has been characterized as one of the largest and most consistent silver-lead lodes in the world. The Comstock Lode has produced 300,000,000 ounces of silver, some ore running as high as 3,000 ounces to the ton. Pachuca has yielded 112,000,000 ounces of silver since it was first worked, while the Cœur d'Alene field is responsible annually for one-third the total output of the United States. The high grade and wonderful extent of the Aspen ores in conjunction with the neighboring camp of Leadville has served to place Colorado among the most important precious metal producing regions of the country.

The chief silver deposits of the world may be divided into:

1. Those in which the formations are essentially sedimentary in character.
2. Those in which intense volcanic activity has been the most widespread factor.

It is a significant fact, however, that not a single instance can be recorded where volcanic activity or igneous intrusion, especially, has not had a most important influence upon mineral deposition. Moreover, a striking similarity in the character of these eruptives seems to exist and persist with such frequent regularity as to lead to the conclusion that perhaps the great silver deposits of this class, although widely scattered over the earth's crust, were formed at approximately the same time and under the same conditions. Thus the Comstock Lode, in Nevada, is found to lie in Tertiary eruptive rocks, chiefly andesites, which cover an extensive area and which have undergone widespread decomposition and propylitic alteration. Proceeding a few miles to the southeast in the same state, similar occurrences are encountered at Tonopah where Tertiary lavas, chiefly andesites and rhyolitic breccias and tuffs, cover the greater part of the ore bearing district. All of the Pachuca range of Mexico is formed from volcanic Tertiary rocks which may be classed as andesites, rhyolites, and basalts. The ore deposits are found in andesite of Miocene age, as at the Tonopah and Comstock lodes. Guanajuato has also seen great volcanic activity. The entire district is covered with a long series of andesitic and rhyolitic breccias and tuffs, the latter carrying some of the most important silver veins in the world.

At Leadville, which is situated on a terrace at the bottom of one of the western spurs of the Mosquito Range, near the head of the Arkansas valley, the geological formations may be described as a succession of metamorphic and sedimentary rocks, such as quartzites and limestones resting upon the older Archean granite. Large and numerous flows of porphyry in the form of dikes, horizontal sheets and overflows have intruded between and across the strata. These flows have had an immense influence upon ore deposition and represent intermittent eruptions covering an indefinite time. After them came the mineral bearing solutions and gases, which penetrated the neighboring rocks along the cracks and lines produced by the porphyry intrusions and, dissolving out portions of the more soluble formations, subsequently deposited their metallic contents instead. This period of ore deposition was followed by one of faulting and general uplifting of which the Mosquito Range is the result. Finally, settling and erosion took place, leaving the district, topographically, as it is today.

The famous silver district of Aspen is found in the same group of mountains as Leadville, located, however, on the west flank of the Sawatch Range. As at Leadville, the fundamental rock is a granite with occasional gneissic structure. Above the granite is found the sedimentary beds of the Cambrian, Silurian, Devonian, Carboniferous, Jura Trias, and Cretaceous in the order named.

Carbonate Hill, Leadville, Colo.

Two distinct types of igneous rocks, a diorite porphyry and a quartz porphyry, have been intruded into these sedimentaries in Cretaceous time, mainly as sheets parallel to the bedding planes, although occasional cross-cutting dikes are observed. Subsequently the formations were much folded and faulted, the center of greatest uplift and disturbance being the chief center of ore deposition. The important faults occurred previous to ore deposition and the mineral bearing solutions following the fractures thus formed and deposited their contents. In some places, the neighboring rock has been con-

* Denver, Colo.

siderably permeated by these solutions which have dissolved out the more soluble parts and have replaced such portions with valuable mineral.

Sedimentary formations also make up the greater part of the Cœur d'Alene district. The prevailing rocks are arenaceous and argillaceous and include sandstones, slates, and quartzites of Algonkian age. These sedimentaries are cut by a number of masses of syenite, most of which have the form of small intrusive stocks. The rocks in the district have been complexly folded and faulted amid strong compression with the result that slaty cleavage is a prominent structural feature. The main ore bodies of the district are found in a fine-grained, serecitic quartzite.

The Wasatch Range, comprising the district of Park City, Utah, consists of extensive sediments of Paleozoic and early Mesozoic rock systems deposited around an Archean core. After this deposition, there was a general uplift with complex folding and faulting. During the Mesozoic era, the Paleozoic formations were cut by numerous igneous intrusions of an even grained diorite and a coarse porphyry. In Tertiary times, there were great volcanic eruptions, followed by the extrusion of andesitic and basaltic rocks. The faulting of these igneous intrusions or dikes by the vein fissures is conclusive proof that ore deposition occurred at a later period. These dikes are important as by cutting through and fracturing the strata they opened the rocks for the mineral-bearing solutions. Here quartzite and limestone of Carboniferous age are also the main ore-bearing formations.

In the Broken Hill district, Australia, also the rocks consist of highly altered slates, conglomerates, sandstones, limestones, and micaceous schists, classified as of Silurian age. Broken Hill itself has been described by Pittman as a low range about 2 miles in length, composed of crystalline gneisses, passing into banded quartzites, micaceous hornblende schists and garnetiferous sandstones. These rocks have been intruded by dikes of very coarse granite and amphibolite, and have been crumpled, contorted and so highly metamorphosed as to leave doubt as to whether they are altered sedimentary or igneous rocks. The position of the lode, it is claimed, was determined by a series of principal faults.

Comparison of the Districts.—A geological section of several of the silver districts will bring out more clearly perhaps the most important similar features, as noted in a description of the areal geology. Thus, from the following order of rock succession, it is seen that the formations of Leadville, Aspen, Cobalt, Guanajuato, Comstock, and Park City regions rest upon a basement complex of granite. At Leadville, Aspen, and Park City, the order of deposition in point of geologic age and character of the formation is almost identical throughout, a series of white Cambrian quartzite, Silurian limestone, Devonian parting quartzite, and Carboniferous limestone following the basement complex of granite in each particular instance. Furthermore, in all three camps, the rich ore is invariably associated with the Carboniferous blue limestone.

GEOLOGICAL SECTION, COMSTOCK LODE, NEV.

General system of rocks, Tertiary volcanics.

1. Granite.
2. Metamorphics.
3. Granular diorites.
4. Porphyritic diorites.
5. Metamorphic diorites.
6. Quartz porphyry.
7. Earlier diabase.
8. Later diabase.
9. Earlier hornblende-andesite.
10. Augite andesite.
11. Later hornblende-andesite.
12. Basalt (youngest).

GEOLOGICAL SECTION, TONOPAH, NEV.

General system of rocks, Tertiary volcanics.

1. Earlier andesite.
2. Earlier rhyolite and breccias.
3. Later andesite.
4. Erosion interval.
5. Volcanic breccias and flows.
6. Great water-laid tuff formation containing infusorial silica.
7. Later rhyolite.
8. Latest lava flow.

GEOLOGICAL SECTION, LEADVILLE, COLO.

1. Granite and gneiss (basement complex).
2. White quartzite (Cambrian) 200 feet thick.
3. Drab dolomitic limestone (Silurian) 160 feet.
4. Parting quartzite (Devonian) 40 feet.
5. Gray monzonite porphyry (Pre-Cretaceous).
6. Blue limestone (Carboniferous) 200 feet thick.
7. White rhyolite porphyry (Carboniferous).
8. Calcareous and carboniferous shales.

GEOLOGICAL SECTION, ASPEN, COLO.

1. Archean granite.
2. White Cambrian quartzite, 200 feet thick.
3. Light gray dolomitic limestone (Cambrian), 100 feet thick.
4. White quartzite, 20 feet to 50 feet thick.
5. Drab dolomite (Silurian) 200 feet thick
6. Brown quartzite (Silurian) 20 feet thick.
7. Drab dolomite (Silurian) 100 feet thick.
8. Blue limestone (Carboniferous) 120 feet thick.
9. Black calcareous and carboniferous shales.
10. Diorite.

GEOLOGICAL SECTION, CŒUR D'ALENE, IDAHO

General kind of rocks, arenaceous and argillaceous sediments cut by igneous intrusions.

1. Prichard slate. Blue, black, and gray slates.
2. Burke formation. Fine grained sandstones and shales with interbedded quartzite.
3. Revett quartzite. White quartzite.
4. St. Regis formation. Fine grained sandstones.
5. Wallace formation. Sandy shales with thin beds of calcareous sandstones and impure limestones.
6. Sandstones.

GEOLOGICAL SECTION, COBALT, CANADA

1. Basement complex, diabases and granite porphyries, Keewatin.
2. Great unconformity.
3. Coarse conglomerate, impure quartzite, greywacke slate, conglomerate. Lower Huronian.
4. Unconformity.
5. Lorrain arkose, quartzite, and conglomerate. Middle Huronian.
6. Quartz-diabase. Post Middle Huronian.
7. Great unconformity.
8. Niagara limestone.
9. Boulders, clays, sands, and gravels. Glacial and Recent.

GEOLOGICAL SECTION, GUANAJUATO, MEX.

General kinds of rock, andesitic and rhyolitic breccias.

1. Basement complex.
2. Cretaceous shales.
3. Intrusive granite.
4. La Luz schists.
5. Conglomerate.
6. Bufa sandstone.
7. Rhyolitic breccias.
8. Andesitic breccias.
9. Later rhyolites.

GEOLOGICAL SECTION, PARK CITY, UTAH

1. Archean granites.
2. White Cambrian quartzite.
3. Black limestone, calcareous shale, and slate. Silurian.
4. Devonian quartzites.
5. Siliceous and blue limestones, quartzites. Carboniferous age.
6. Gray shales, red shales, calcareous sandstones, light gray, and blue limestones. Mesozoic age.

GEOLOGICAL SECTION, ASPEN (SPURR)

1. Granite, often changing into gneisses and schists.
2. Thin bed Cambrian conglomerate.
3. Cambrian, 200 to 400 feet thick. Dolomitic quartzite, Glauconitic grit, Sandy dolomite.
4. Silurian (Dolomite), 250 to 400 feet thick.
5. Devonian (Parting quartzite, 60 feet thick).
6. Carboniferous. Leadville limestone, dolomite 350 feet thick, Blue lime. Intrusive white porphyry, like Leadville white porphyry, 250 to 400 feet thick. Weber limestones and shales, 1,000 feet thick. Maroon formation, 4,000 feet thick.
7. Triassic. Red sandstones, 2,600 feet thick.
8. Jura Trias. Yellow sandstone and shale, 400 feet thick.
9. Cretaceous. Dakota formation, white sandstone, 250 feet thick. Benton shales, 350 feet thick. Niobrara limestone (gray or blue limestone), 100 feet thick. Montana formation (gray or black shale), 4,000 feet thick. Laramie formation, sandstone, 600 feet thick.

Similar beds at Leadville and Aspen are also approximately of the same thickness. To illustrate, there occurs a bed of parting quartzite separating the dolomite of the Silurian from that of the Carboniferous and running 40 to 70 feet in thickness. Practically the same quartzite is found at Aspen, occurring in the same horizon, of the same thickness and bearing evidence of deposition under closely similar circumstances. The ore-bearing formation at Aspen is known as the "Leadville limestone," due to its close similarity to the ore-bearing strata of the latter camp. In fact, practically the only important differences between the geological sections of these two districts are:

1. The "blue limestone" at Leadville, although identical in geological position with the "blue limestone" of Aspen, is dolomitic or magnesian, while the Aspen formation is nearly pure carbonate of lime and non-magnesian.

2. The position of the "porphyry" is slightly different. The quartz porphyry at Leadville immediately overlies the "blue limestone"; at Aspen there is an interval of 50 to 100 feet of black "Weber" shale between the limestone and porphyry.

3. The ore body at Leadville lies at the contact between the white quartz porphyry and the blue limestone; at Aspen it is between the blue limestone and pale dolomite.

The ore bodies at Park City also occur in frequent and intimate association with the porphyry. Fissures occupied by ore bodies, cut indiscriminately across porphyry and all other formations.

In the Cœur d'Alene district, 99 per cent. of the ore is found in the Burke formation of fine-grained sandstone and shale and in the Revett formation of white quartzite. The ore bodies of Cobalt, in comparison, are found in the lower Huronian, which comprises coarse conglomerates, quartzites, and slates.

Conclusions.—Thus a marked similarity, amounting in several instances to absolute identity, is revealed in the geologic structure of the silver deposits of sedimentary formation. The same is true also of the ores found in regions of widespread volcanic activity. Among the most important features common to some of the districts in question are:

1. Almost universal similiarity in the areal geology of the eruptive formations of the Comstock Lode, Tonopah, Pachuca, and Guanajuato districts, which are composed of Tertiary volcanics, andesites predominating.

2. Identity in age, type of the formation, and order of succession of the various strata of the Leadville, Aspen, and Park City districts.

3. The close and important association of porphyry with the ore bodies of Leadville, Aspen, and Park City.

4. The marked tendency of the ores of Leadville, Aspen, and Park City, for the Carboniferous limestone formation.

5. Similarity in the formations in which the ore bodies of the Cœur d'Alene and Cobalt districts are found.

6. Extensive occurrence of the ore deposits of the Comstock Lode, Pachuca, and Tonopah, in the same kind of igneous rocks.

7. Strong similarity in the character of the porphyry intrusives at Leadville and Aspen.

Gold Mining Progress in South Dakota

By Jesse Simmons

President Taft visited Deadwood and Lead, S. Dak., on October 21, and was the recipient of a unique gift from the mining companies operating in the Black Hills district. They clubbed together and furnished one Troy pound of pure gold, which was run into an ingot, suitably engraved, with the names of the companies donating the gold, the date, etc., and presented at a luncheon which was tendered the President at the Franklin Hotel, Deadwood. During his visit to Lead the President and party went down the Ellison shaft of the Homestake mine and later examined the large surface plants at the mine.

Assayer in charge, L. P. Jenkins, of the United States Assay Office, at Deadwood, states that the bullion purchased by this institution for the quarter ending September 30 had a value of $1,855,000. This production was all from the mines of the Black Hills district. At this rate the mills are turning out more than $7,000,000 per year, which amount added to shipments made to smelters would probably bring the grand total for the year to a figure far in excess of any previous year. There have been times in the Black Hills when more development was under way than at the present, but on the whole work on new properties is going forward at a very satisfactory pace. Several new mills are being constructed in the region and two of the largest now operating are being enlarged so that it is expected that the output for next year will be even larger than usual.

In the Black Hills district the ores show very little gold by the pan test, so that it is necessary to assay very thoroughly and systematically in order to keep track of the values. Knowing this, the Deadwood Business Club recently inaugurated a plan whereby it is able to do free assaying for prospectors. The club made arrangements with six mining companies having assay offices, to make assays for prospectors free of charge. The prospector leaves his samples with the secretary of the Club, who turns them over to the assayers, and when they make their report to him he issues a certificate of assay in the name of the Club. There are only three restrictions connected with the offer, viz.: Samples are accepted from prospector's only, samples must not exceed 5 pounds in weight, each, and not more than ten samples will be assayed per month for any individual. The plan seems to be working satisfactorily and has done a great deal to stimulate prospecting in the region.

The Homestake Mining Co. is rapidly completing its hydro-electric plant on Spearfish Creek, where 6,000 horsepower will be generated for transmission to the mines and mills. The electricity will be used to operate stamps, rock breakers, machine shop, pumps, cyanide plants, and slime plants. This power development is not sufficient to operate the entire plant of the Homestake company, so that it is proposed to continue hoisting by steam power, as in the past. The company operates 1,000 stamps, and as a 25-horsepower motor is being installed to operate each ten stamps it will require 2,500 horsepower for this purpose alone. Twenty 35-horsepower flywheel motors will be used for driving the No. 6 Gates rock crushers, which reduce the rock to 4 inches in diameter preliminary to the stamp milling. The poles for the transmission line from Spearfish Creek, Idaho, are of cedar, in 40-, 45-, and 50-foot lengths. This line will be 12 miles in length, over a rough portion of the Black Hills. A reinforced concrete building is being erected at Lead City as the main substation and from this point the power will be distributed to the various places where it will be used. In connection with this project the company has installed an equipment for wireless telegraphy, stations being located at the main office at Lead and the power plant. The principal necessity for putting in this wireless system was to overcome the delay which might be occasioned by electric storms destroying telephone communication. So far as known this is the first wireless installation that has been made by an inland mining company.

The first gasoline locomotive to be used in the Black Hills for ore hauling has been installed by the Trojan Mining Co. at its property near Deadwood. This locomotive was manufactured by the Milwaukee Locomotive Mfg. Co. It weighs 7 tons, has four cylinders similar to an automobile, developing 35 horsepower, giving a drawbar pull of 2,340 pounds. From the mine to the mill is a distance of a little over 4,000 feet, the steepest grade on the route being 3 per cent. The locomotive easily handles 15 cars of 1-ton capacity each, over this track. The track is 18-inch gauge and is laid with 24-pound steel rails.

The first dredge to be installed in the Black Hills has been completed and put in commission at Mystic, Pennington County, by the Castle Creek Hydraulic Gold Mining Co. The boat is up to date in all particulars, being electric driven from a power plant located convenient to the tracks of the Chicago, Burlington & Quincy Railway. Buckets are eighty in number, of 5 cubic feet capacity each.

A revolving screen 26 feet in length and 6 feet in diameter is used. The capacity is about 2,500 cubic yards per day. Among the special features of the construction of this boat might be mentioned the entire absence of cast iron, high-grade steel being used throughout. Manganese steel is used at points where heavy wear comes, such as the bucket lips, etc., and Tisco steel in nearly all of the other parts of the equipment. Very satisfactory results are being obtained, and many little difficulties incident to the initial operation have been overcome, so that still greater success is confidently anticipated for the future.

The Edison Crusher Rolls

Steam Power vs. Dynamite for Breaking Rock. Illustrated by Rolls Crushing 20-Ton Pieces

By W. H. Mason

Until a few years ago, rock for feeding crushers could be at most only two-man stone, requiring block holing, mud capping, blasting and sledging in the quarries to obtain the necessary sizes. The demand for enormously increased output in lime-stone quarries, open-cut iron, and porphyry copper mines in the past few years, has necessitated the design and development of larger, more powerful and efficient crushing machinery. This increased output has been attended with a corresponding increase in the size of the individual pieces; therefore, making it imperative that the crushing apparatus used should be capable of handling the larger pieces as quarried and of reducing them to sizes that would conform with the demands of the cement manufacturer, the blast furnace manager, and the millman.

In approaching this problem of crushing, Mr. Edison reasoned that the total heat energy of 1 pound of pea coal is approximately 12,500 heat units, but only about 15 per cent. of this, or 1,875 British thermal units, is available in mechanical energy through the medium of boilers and steam engines, while the available British thermal units in 1 pound of nitroglycerine is approximately 3,650. Therefore, in 50-per-cent. dynamite there is available 1,825 British thermal units, or practically the same mechanical power that can be derived from 1 pound of pea coal. But 1 ton of pea coal is worth approximately $2.50, while 1 ton of dynamite is worth about $250, making the commercial advantage of the coal over the dynamite approximately 100 to 1.

The largest jaw crusher that the writer is familiar with is one installed at the Cornwall ore bank, and has an opening 60 in.×42 in., while the largest gyratories have approximately the same size opening. The Edison Giant crushing rolls, shown in Figs. 1 and 2, are the first rolls constructed to crush large pieces of rock, and their introduction will aid materially in the treatment of some kinds of ore.

In crushing large pieces of stone by the Edison Giant rolls, there are two distinct actions involved. First, when the large stone is delivered to the rolls, it is shattered by a sledging blow delivered by two rows of extra-high knobs on one of the rolls. After the stone is shattered by the sledging blow, it is caught by the angle of the rolls and forced through, reducing the stone to about 6-inch size. Thus, in one crusher, stone is reduced from 20-ton pieces to 6-inch size.

Three sizes of rolls have been constructed so far; 5 feet in diameter by 5-foot face; 6 feet in diameter by 6-foot face; 6 feet in diameter and 7-foot face. The smallest size rolls will handle material weighing 10 tons, while the large size will crush up to 20-ton pieces. Before Mr. Edison constructed the "Giant" rolls, the largest Cornish rolls were 42 in.×16 in. For various reasons these rolls were not popular for fine grinding and were too light for coarse crushing. In fact it is probable that no one except Mr. Edison ever thought of rolls as more than comparatively fine crushers for rock material. An idea of the enormous increase in power of these new rolls over the old-style Cornish rolls may be arrived at by a comparison of the speed and kinetic energy of the two types. The Cornish roll, 30 in.×16 in. running at 100 revolutions per minute, had a kinetic energy of 8,100 foot-pounds, while the 6′×7′ Edison Giant rolls, running at 175 revolutions per minute, have a kinetic energy of 4,217,000 foot-pounds, or in ratio of 520 to 1, while the weights of the rotating parts are as 33 to 1, respectively. It is by use of this kinetic energy that the Edison rolls are able to receive and crush the large pieces of stone at such a rapid rate.

In the arrangement of the crushing plant of the Edison Portland Cement Co., at Stewartville, N. J., one set of 5′×5′ rolls is placed above two sets of 36″×28″ rolls and one set of 36″×20″ rolls. All of these are engine driven. The coarse roll crushes and delivers to the others in sequence and the total product is delivered to a traveling belt at the bottom of the crusher house. This plant handles stone as quarried up to 10-ton pieces at the rate of 3,000 tons in 10 hours. The operating equipment in the quarry consists of one 90-ton Bucyrus steam shovel and one 90-ton Vulcan steam shovel. The quarry is approximately 70 feet deep and about 1,000 feet face. Holes 6 inches in diameter are drilled with churn drilling machines. These holes are 20 to 40 feet centers and are placed 20 to 35 feet back from the face of the quarry. The usual blast is from 6 to 14 holes loaded with 400 to 800 pounds of dynamite each, and breaks down from 40,000 to 70,000 tons of rock. When the hole is drilled it is usually chambered by putting in from 30 to 50 pounds of dynamite and exploding it.

An application of these powerful rolls to crushed stone for ballast, concrete stone, etc., is shown in perspective in Fig. 3. This is the Tomkins Cove Stone Co.'s plant at Tomkins Cove, N. Y. It consists of one set each of 6′×7′ rolls, 4′×4′ rolls, and 4′×3′ rolls, engine driven and having a capacity of 7,000 tons for 10 hours.

To effectively size the large quantity of crushed material coming from the Edison rolls, it has been necessary to design special screens. The bank of screens designed for the Tomkins Cove plant is shown in Fig. 4 The absence of moving parts,

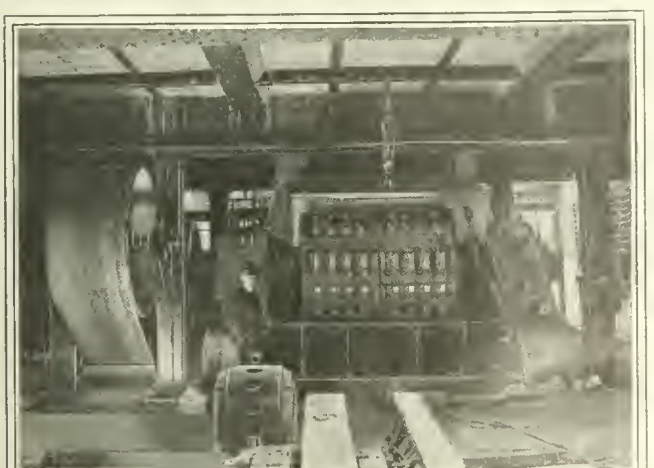

FIG. 1. EDISON 6′×7′ ROLLS

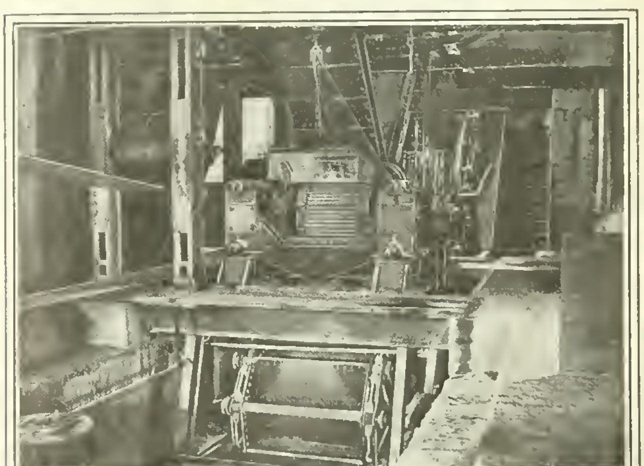

FIG. 2. EDISON 4′×3′ ROLLS AND CONVEYER

compactness of the bank of screens, the comparatively small floor space, and the simplicity of the system appeal to those familiar with the rotary screens as a decided improvement. The stone at Tomkins Cove, after being loaded with steam shovels in the quarry, is dumped into a pair of $6' \times 7'$ rolls, which reduce it approximately to 6-inch sizes. Under these rolls there is a hopper having a capacity of about 30 tons. The stone is fed from this hopper by feed rolls to a set of $4' \times 4'$ rolls which run at the rate of 250 revolutions per minute. This reduces the stone to about $3\frac{1}{2}$-inch sizes, when it goes directly to a set of $4' \times 3'$ rolls and is reduced to about $1\frac{1}{2}$-inch size. A large pan conveyer receives the stone and lifts it to the Edison stationary screen which is shown in Fig. 4. Anything that goes over the screen, that is over $1\frac{1}{2}$ inch, is returned to the lower rolls of the crushing plant for recrushing.

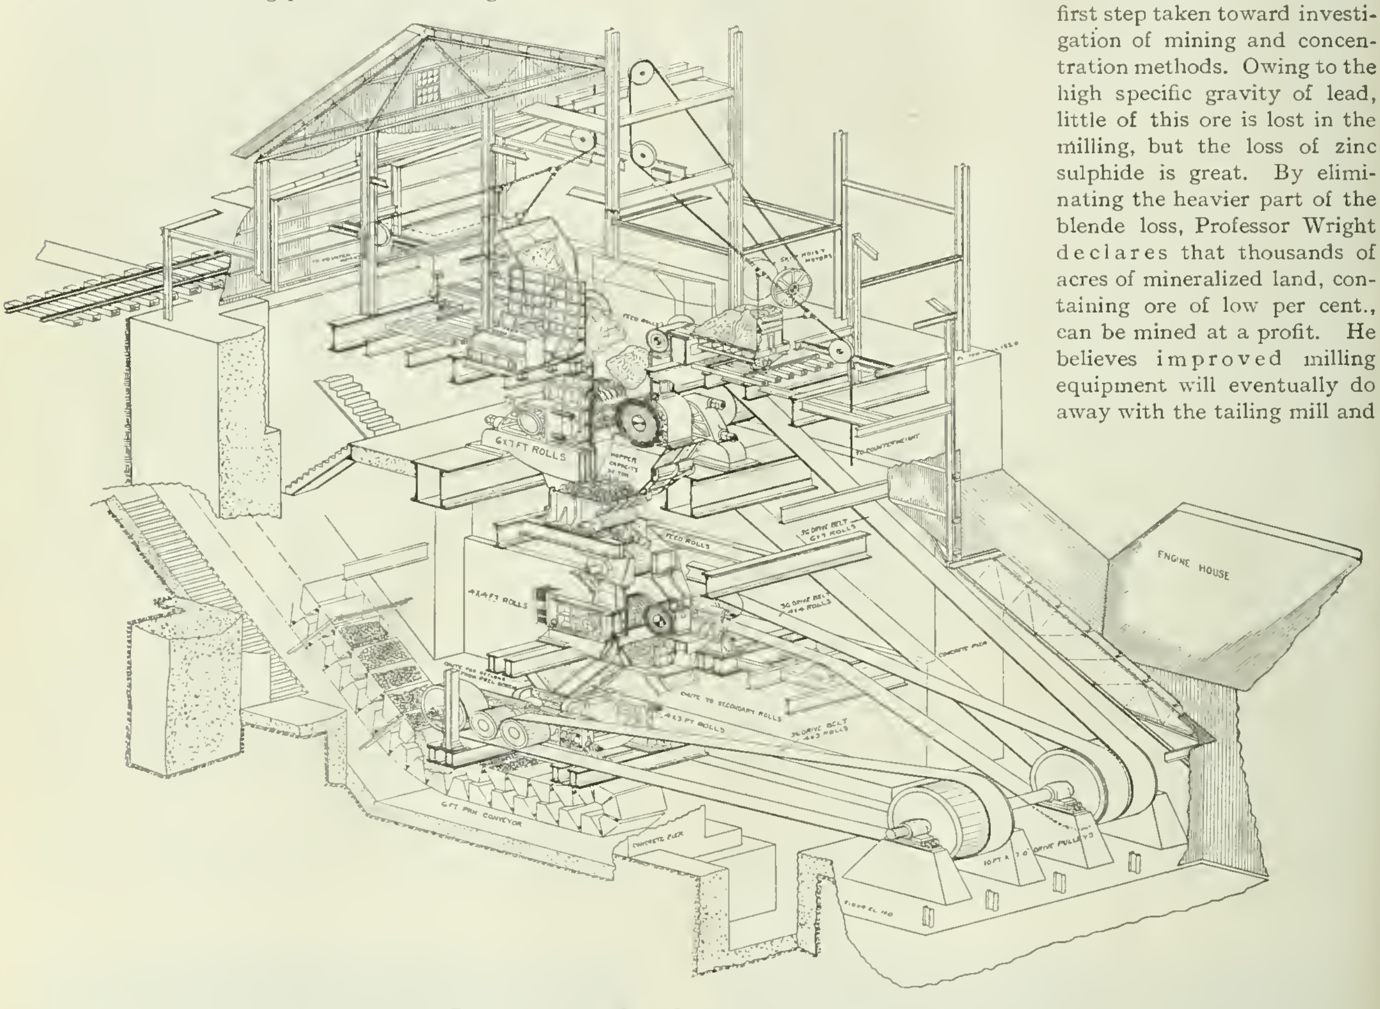

Fig. 3. Tomkins Cove Crushing and Sizing Plant

As will be noted from the drawing, the stone is divided into three sizes, known as $1\frac{1}{2}$-inch, $\frac{3}{4}$-inch, and $\frac{3}{8}$-inch stone. The finished product is carried by belt conveyers to bins having a capacity of 20,000 tons, from which it can be drawn and delivered by belt conveyers direct to barges on the river or to railroad cars.

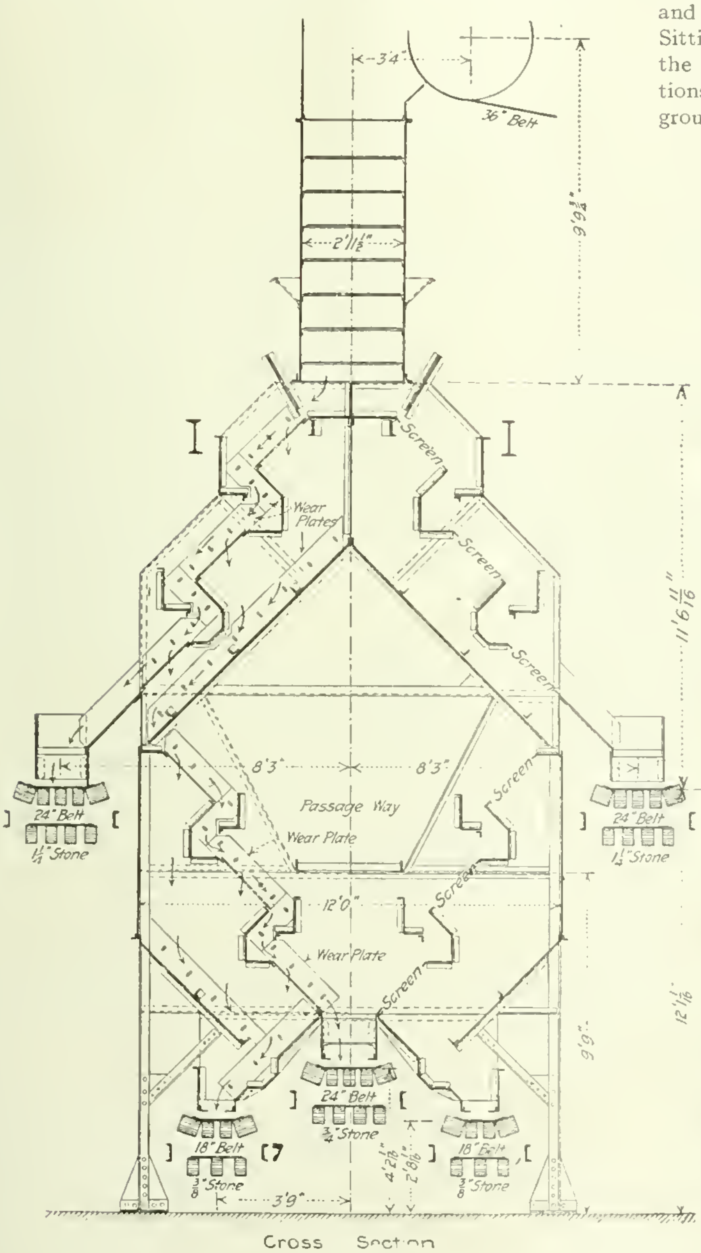
The quantity of asphalt taken from Pitch Lake, Trinidad, which covers an area of 100 acres, during 1910 exceeded that of any previous year. At the present rate of operation, the surface level is lowered about 6 inches a year. The depth of the deposit of asphalt over the center of the lake is unknown, as it cannot be sounded by rods, but the supply is supposed to equal the demand for many years; possibly it is inexhaustible.

Zinc and Lead Notes

Government to Aid of Operators.—C. A. Wright, representing the United States Bureau of Mines, is in the Joplin, Mo., district with the view of remaining until next June, his mission being to secure all data possible relative to mining and milling methods and costs and to offer advice and suggestions by which operators may reap a wider margin of profit from the handling of zinc and lead ores. The interest shown by the government in undertaking to improve local conditions is appreciated by the majority of operators who are aiding Professor Wright in his work. At the close of his stay in Joplin, Professor Wright intends to issue a pamphlet on his study of local conditions. While the government has made quite complete geological studies of the ore formations in the Joplin district, this is the first step taken toward investigation of mining and concentration methods. Owing to the high specific gravity of lead, little of this ore is lost in the milling, but the loss of zinc sulphide is great. By eliminating the heavier part of the blende loss, Professor Wright declares that thousands of acres of mineralized land, containing ore of low per cent., can be mined at a profit. He believes improved milling equipment will eventually do away with the tailing mill and will make it useless to try to work at a profit tailings that have once passed through a concentrating plant.

The Ore Market.—Talk of exporting zinc sulphides to Europe is heard on every hand. A. O. Ihlseng, who engineered the exportation of zinc sulphide to Swansea, Wales, in 1898, is trying to arouse interest in a similar move. He claims local ore prices are not high enough to warrant producers disposing of their output. Spelter, at East St. Louis, is strong, prices ranging between \$5.85 and \$6, while producers are experiencing difficulty getting what they think a fair price. According to the old "eight to one" basis that once prevailed throughout the district, 60 per cent. grades should be commanding \$47 and \$48 a ton. At no time recently, despite the fact that spelter climbed to \$6.05 not many weeks ago, has the price exceeded \$45 a ton, assay basis of 60 per cent. metallic zinc. From this it has ranged down to $38 in carload lots, and producers of smaller lots have received as low as $30 a ton. Producers of calamine, on the other hand, have enjoyed phenomenally high prices, the basis offering for grades running 40 per cent. metallic zinc having ranged from $22 to $25, with choice lots commanding as high as $32. Floods curtailed the calamine production in August and since then the buyers have experienced difficulty in securing enough ore to meet their demands. Shipments, of late, have averaged 700 tons weekly. Lead ore shipments continue strong and 1911 will be the banner year in lead production in the history of the Joplin district. The aggregate value also will be the highest of any year in the district. The price has ranged from $56 to $63 per ton. Metal at East St. Louis remains strong, ranging from $5.35 to $5.45.

New Soft Ground District.—The ability of mining tracts to enjoy a second or even third period of productiveness, after once being thought exhausted, is one of the features that has distinguished the Joplin district, but never before has the truth of this condition been so unmistakably proven as in the case of Thoms Station, a "new-old" camp, several miles north of Joplin, Mo. A dozen or more years ago, in the days of the old Sherwood mines in that locality, that section was considered a phenomenal producer of high-grade zinc blende. Following the suspension of work at the Sherwood, Thoms Station remained idle for years, little or no production coming from the district. Today this long-abandoned camp is producing more than 1,500,000 pounds of blende weekly, more than 50 per cent. of the total production of the Joplin camp. The chief producer is the Mexico-Joplin land, embracing several hundred acres, on which are situated the Mary C mine, the Katy mine, the Catharine mine, the High Tariff mine, all of which are mill propositions, and several smaller properties. On adjoining tracts are the Sitting Bull mine, the Modoc mine, the Big Irishman mine, the Little Israelite mine, the Federated mine, all mill propositions, and scores of rich prospects. The ore occurs in soft ground and in places runs 25 per cent. of the dirt milled. In some instances the quality of the concentrates is lowered by the presence of iron pyrite, but the bulk of the ore will run close to 60 per cent. metallic content.



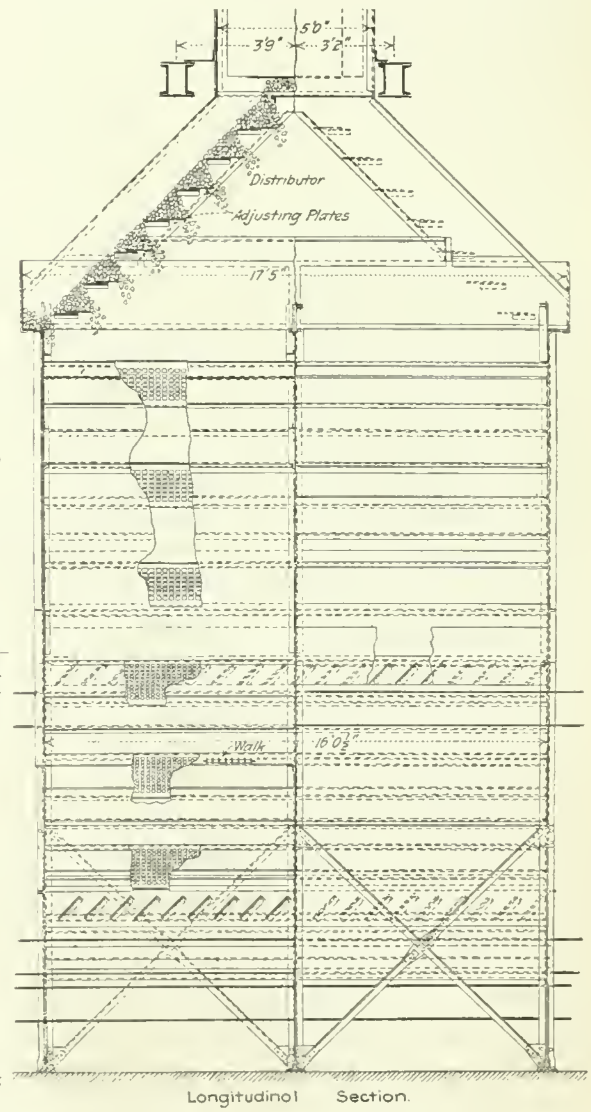


FIG. 4. DIAGRAM OF SCREENS, TOMKINS COVE PLANT

In the Spring City Camp.—Development in the Spring City district, south of Joplin, has been somewhat handicapped by the lack of transportation facilities, but despite this condition, some excellent strikes have been made on the land of O. D. Bittick, more than a mile west of the main portion of the camp, and in virgin territory. Marcum, Smith, Congdon, and Myers have a shaft into blende, lead, and calamine, at a depth of 156 feet, the strike verifying the drillings made several months ago.

Proposed Modification of the Square Set

Method of Timbering by Which Greater Resistance to Uneven Pressure is Attained

By A. J. Moore

The following paper, by A. J. Moore, describing a modification of the square set appeared in the Transactions of the Australian Institute of Mining Engineers.

When the writer first saw the square-set timbering, he was at once impressed with the fact that the frames made by the sets, along the lode and across it, were composed of panels with rectangular openings, and it was puzzling to understand how such a collapsible construction could resist pressure that came unevenly on it. Later he learned that the sets did not satisfactorily resist such pressure, but that filling had, to a great extent, to undertake this duty for them. So it appeared that the sets were practically an expensive scaffolding, enabling the miners to work in the face and carry the stope forward, till the filling was put in behind them to take the pressure of the roof and sides of the excavation. Of course some of the pressure is taken by the sets, but this is because the set timbers prevent the filling being done perfectly; if it were practicable to remove the sets before filling, the filling by itself would more effectively support the back and wall, than do the combined sets and filling. On the whole therefore the sets can hardly be said to be of much benefit where pressure has to be resisted. Despite this, the system has been of immense service in mining wide lodes, but for all that, it can only be pronounced a makeshift. This is no reflection on Deidesheimer, the famous originator of the square set, for, as will be shown later on, this way of using the square set was not his way, a fact of which the writer only lately became aware.

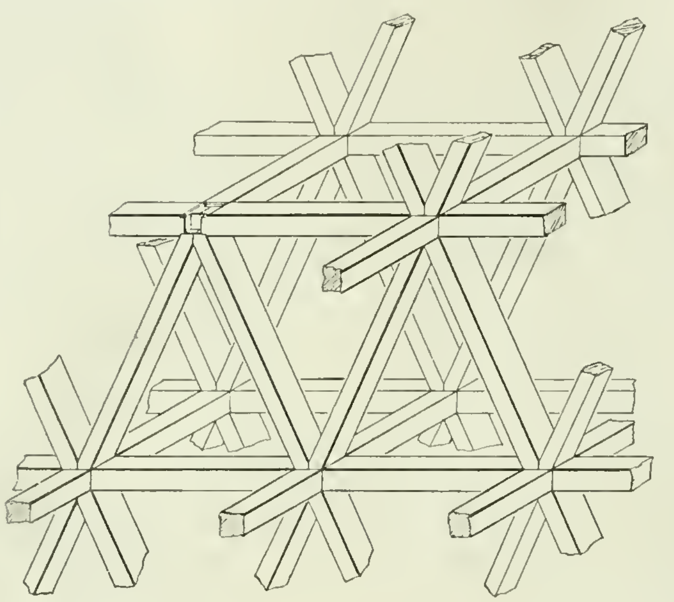

Fig. 1

At odd times during the last few years, the writer has often tried to think out a way of applying the triangular principle to the sets, but, as it appeared necessary to do this along the lode, as well as across it, the problem was apparently quite insoluble; however, when the fact was properly appreciated, that the pressure strutways (along the lode) was usually insignificant compared to the pressures of the back, and hanging wall, the problem was simplified; and by treating the caps and legs as a series of frames supporting these two weights—to which frames the struts act merely as distance pieces—it was then seen that it was only necessary to triangulate these cross frames. This was done as shown in Fig. 1, by dispensing with the leg and substituting two diagonals.

There is of course nothing original in the triangulation principle that is applied, because (according to W. H. Storms) it is the principle that Deidesheimer adopted 50 years ago, in his first application of the square-set system. His manner of application, however, was different, as he secured the triangulation by putting a diagonal piece in every panel across the lode, and also had wall plates up the hanging wall and foot-wall, into which each frame, made by the caps, legs, and diagonals, was jointed. This jointing was very elaborate, and made the wall plates a most expensive matter. For this reason they have long since been discarded, and, in addition, the systematic use of the diagonals was dropped. These deprivations greatly weakened the frames, and it was soon learned, from disastrous experience, that the sets could not stand without the aid of filling. But it is proved sufficiently that the principle applied by Deidesheimer was the right one, by the fact that the big stope, which was from 60 to over 100 feet wide and several hundred feet long—timbered under his personal supervision at the Ophir mine—was not filled till it had reached the great height of 400 feet. It was only a phenomenally rich stope such as this, that could bear the expense of such elaborate timbering; and unsatisfactory as is the present system of skeleton sets—plus filling—it must be a considerably cheaper method.

The writer believes that his way of applying the principle combines the strength of the Deidesheimer system with the cheapness of the later method, and has additional advantages of strength and convenience due to the fact that the diagonals are in two directions.

Before going into the details of the proposed construction, it is interesting to notice the effect the triangulation principle has on the frames. Fig. 2 represents a cross-section of a stope timbered: (*a*) With the ordinary square set; (*b*) with the proposed modification of the square set; (*c*) with the Deidesheimer sets; *M* is a loose cylinder of rock whose weight comes on the corner "*A*" of a set in each case.

In case (*a*), this weight will be supported by the line of caps *A C* and line of legs *A B*. All the other members of the frame, being at right angles to one or other of these, are unable to give any assistance to them.

In case (*b*) the weight is supported as before by *A C* and *A B*. In a high stope, it will be seen that in this case *A B* will get to solid support on the foot-wall in a much shorter distance than in case (*a*). But there is more in it than this. Suppose for some reason that any link —say *m n*—of *A C* or *A B* fails. The pressure along *A m* would then be split along *m p* and *m q*, and similarly at *p* and *q* there are three members that are capable of sharing the stress, and if these ramifications are followed up, it will be found that every member of the frame can share in the stress applied at *A*.

In case (*c*) similarly, all the members enclosed between *A B* and *A C* and the foot-wall can share the stress. But the members above *A C*, and on the hanging wall side of *A B* are not able to lend any assistance.

Where an isolated weight from the back comes on a joint, the superiority of the proposed construction is further demonstrated. In case (*a*) the line of the legs directly under the weight, alone supports it. In case (*b*) every member as before shares the stress. In case (*c*) all the members on the hanging wall side of the line of legs immediately below the weight do not give any assistance.

In fact it almost appears in case (*b*) as though the weight of the hanging wall and the weight of the back becomes mutually supporting, and possibly it would be found that when these pressures come unevenly on the various corners of the sets, the stress is, however, distributed evenly over the frame. In any case it is apparent that the form of construction of (*b*) has great superiority in strength and stability over that of case (*a*) and in a lesser degree over that of case (*c*).

The proposed construction of the set is shown in Fig. 1

The caps and struts are of 10″×8″ timbers, the diagonals of 10 in.×6 in., all of them put in with their wider sides downwards. The angle of the diagonals may be whatever best suits the particular case to be dealt with. Properly speaking the angle should correspond to the angle of the hanging wall, but in practice this will not always be convenient. The angle the diagonals in the figure make with the horizontal (and which the writer thinks will be found suitable to most cases) is 65 degrees. Taking the center lines of the caps as 8 feet apart vertically, this will give a cap length of 7 feet 6 inches; strutways the caps are 5-foot centers, 6 feet would not be perhaps too much, but it gives too great a span between the drive sets.

The joint is of course the vital part of the set; but before going into that question, it is as well to point out one or two things about the present joint. Fig. 3 is an isometric projection of this joint; it is designed to resist top pressure mainly. In America this form is seldom used, and in that country the joint has been greatly varied by different fields to suit local requirements. With the joint shown in Fig. 3 the leg becomes the weaker member of the set, whereas it should be the strongest; whilst the strut is the strongest, though it should be the weakest. It is in the 4″×4″ spill that the leg is weak. If the face be heavy, it is necessary to put in face boards whose ends press on the legs, and if there be much weight on the boards there is only the strength of the 4″×4″ spill in resistance, and a breakage in such a case is fairly common. Similarly, when a rock is blasted from the face against the leg, there is only the 4″×4″ spill to resist breakage. In the former case it is often necessary to put under the cap a 10″×2″ or 10″×4″ liner whose ends bear against the full width of the legs. In the case of the cap, a liner is also often necessary when a heavy back weight comes on it; the 1-inch hold the cap has (at the sides of the spill) on the shoulder of the leg is not sufficient as that part of the top of the leg will chip away, and the cap tends to sink into the leg.

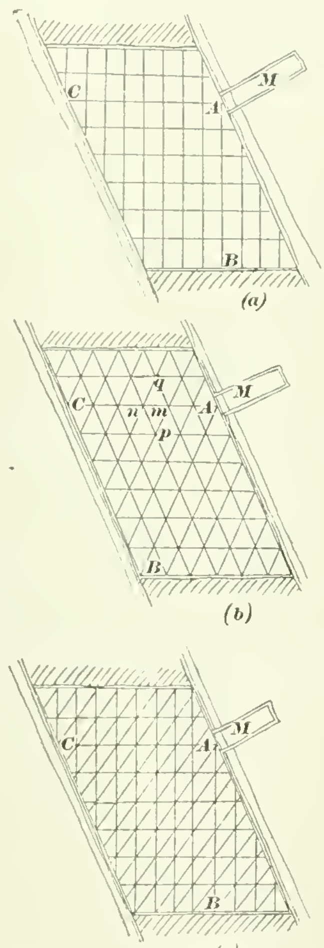

FIG. 2

Fig. 4 (*a*) is a projection of the proposed joint. As the top pressure becomes translated partly into side pressure, and vice versa, there is no need to design the joint to resist either in particular. It is convenient to have the caps butting against one another. This is done by spills of 5 in.×5 in. section and 3½ inches deep. The strut spill is 7 in.×5 in. and 2½ inches deep. These dimensions allow the ends of the diagonals to be housed in for a depth of 1½ inches. The area of the faces of the diagonals pressing against one another is 10 in.×5 in. The cap has a bearing surface for its full width of over 2 inches (taking in the bevel) on the diagonal, in addition to its spill bearing. The cap's full depth also bears against the strut shoulder practically for 1½ inches. It will be seen, therefore, that the cap has its full section to depend on for a blow from the face, or for any weight on its top side. Similarly the diagonal opposes a section of 10 in.×5 in. area to the side weight; this section has about eight times the strength of the 4″×4″ spill section. It will be seen also that the caps and diagonals are edge on to the face and can stand a heavier blow than if lying the other way. Further, if there is any tendency of the diagonals to crush the joint (which is unlikely, as the pressure cannot be concentrated on single lines as in the ordinary set), this across-grain pressure becomes to a great extent translated into a pressure along the grain, by means of the beveled face on the cap. The strut spill is not so strong as in the square-set case, but is strong enough.

This joint will be more expensive to cut. The diagonals are simpler and cheaper to cut than the legs, but the strut is a little more expensive, and the cap more so. The writer believes that the increase of expense will not be very marked, and will by no means counterbalance the advantages of the joint.

A cheaper form of the joint is shown at Fig. 4 (*b*). This gives a strut spill of 8½ in.×5 in., but reduces the full width bearing of the cap on the diagonal to the beveled surface, which is, however, over 1½ inches in depth.

Two more variations of the joint can be got by making the cap spill 6 in.×6 in. section in these two cases; this will reduce the depth of the strut spill from 2½ inches to 2 inches and the housing in of the diagonals to 1 inch, and will increase the thickness of the strut spill to 6 inches.

In practice the most suitable joint would soon be evolved. The drive set is shown in Fig. 5. Its form is arrived at by simply removing two of the diagonals and putting a 10″×10″ upright under each end of the cap and afterwards lining with 10″×10″ timber the underside of the diagonals as shown, the outside of the drive being lagged with 10″×4″ timber. It may be pointed out here that the vertical load of filling on these 10″×4″ timbers will be less than half what it would be if they were lying flat.

On the drive cap and two legs, the pressure is nearly all along the grain, though there is a bending moment on each of them, but in each case near to the point of support. The crushing on the cap ends, however, is likely to be severe, and for this reason it would be preferable to have the cap of hard wood. It will be seen that a good deal of any necessary repairing could be done without interrupting the traffic, and room also is left for further reinforcement of the sets if required. In putting in this drive set it would not be done all in one stage. Probably, in standing ground, the sill with the legs and cap (or internal set) would be put in first and the 10″×4″ lagging laid on the top for the time being. Later, the two diagonals would be added at the side and lagged with 10″×4″ timbers and, when the second floor of sets was being put in, the upper part of the drive would be put in and lagged, and the lining with 10″×10″ timbers done when desired. In heavy ground a somewhat similar method would be adopted with driving laths, probably in the place of the temporary 10″×4″ timbers on the caps.

In Fig. 6 is shown a way of putting in the sets, where the wall is vertical, or where a pillar is left. At every second floor a half cap will be put in, its spill on the pillar end being a plain 5″×5″ spill to accommodate the top of a 10″×5″ or 10″×4″ upright, and 10″×5″ or 10″×4″ struts as shown (the office of these 10″×5″ timbers being mainly to keep the end of the cap up to its work). The 10″×5″ uprights will fit into the spill of the 10″×8″ struts above and below the half cap; all these joints being well blocked against the ground.

In the case of pillar, the filling could then be done in the manner of the Broken Hill Proprietary mine, by laying, as the filling rises, 5″×2″ paddock laths (3 inches apart) horizontally with their ends against these 10″×4″ uprights and, for residue filling, putting waste candlebox pieces and sawmill slabs to block the 3-inch openings. An advantage of the sets is that the chutes can be put in on the slope, or vertically, as desired.

For working the sets in the admirable method, used so extensively in the Broken Hill Proprietary mine, of hanging the sets from a boom and stoping underhand, there is to the writer no apparent difficulty The difference would be that the sets would be carried down on a rill, and in running ground this would be rather an advantage. There would not be so much weight on the boom as in the case of vertical sets.

To arrive at the amount of timber used by the proposed set, the writer took a space 24 ft. high × 30 ft. × 30 ft. and calculated the amount of material required to timber it in the case of the 7′×6′×5′ square set, and the 8′×6′×6′ square set with 10″×10″ timber; and the proposed set with 7-foot 6-inch caps, spaced 8-foot centers vertically and 5-foot center strut-

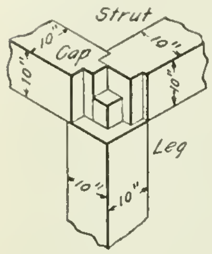

Fig. 3

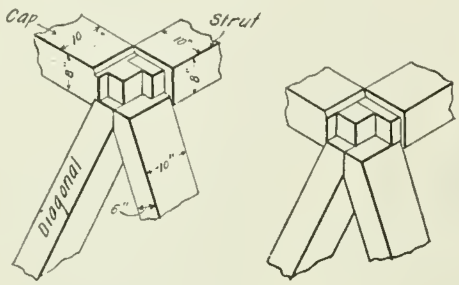

(a) (b)

Fig. 4

ways, caps and struts of 10 in. × 8 in. and diagonals of 10 in. × 6 in. with the following result:

	Equivalent Length of 10″×10″ Timber Required Feet	Amount Used in the Frames Across the Lode Feet	Percentage Used in the Cross-Frames Per Cent.
Square set, 7 ft. × 6 ft. × 5 ft..	1,850	1,340	72½
Square set, 8 ft. × 6 ft. × 6 ft..	1,500	1,050	70
Proposed set..............	1,483	1,200	81

It will be seen that, in comparison with the most favorable case for the square set (and making no allowance for diagonals, liners, etc., in the square set case) the proposed set uses about 1 per cent. less timber, but has 14 per cent. more timber in its cross-frames, where it is most required.

In conclusion, the writer admits the slight extra expense of cutting the timbers for the joint, and also foresees some slight difficulties in using the set, but these, he expects, will in practice be easily overcome. On the other hand he believes that the

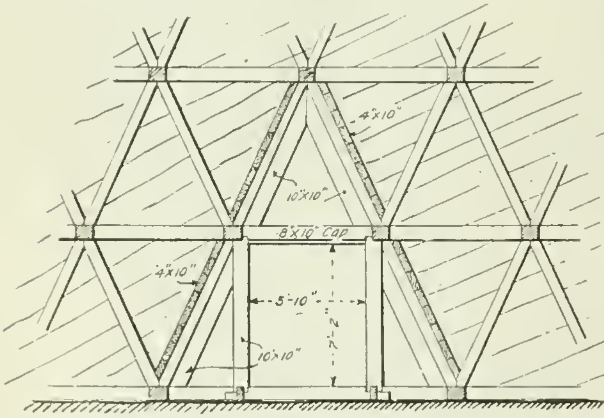

Fig. 5

proposed modification may be said to have the following advantages:

(1) Far greater strength, without any more timber being used.

(2) Much greater stability under uneven pressure.

(3) Filling will not be required in many cases.

(4) Where filling is required, it can be done more cheaply because the face can be carried forward much further in advance of the older filling, and so the newer filling can be put in, in greater quantities at a time.

(5) It is stronger than the Deidesheimer set, which was admittedly much stronger than the present set.

(6) It has a flexibility of application, as the angle of the diagonals can be varied to a certain extent.

(7) The joint is much stronger than the present joint.

(8) A much stronger drive set can be used with it.

(9) Chutes can be put in more conveniently.

(10) It has a greater proportion of its timber in the frames across the lode.

(11) The timbers are lighter to handle.

Mining Regulations in China

In a recent United States Consular Report, Consul General Bergholz, of Canton, gives the following facts in regard to mining regulations in that country:

Mining in China has been handicapped by fees, royalties, transit, likin, and export charges, etc., imposed upon the output of mines by the central government. Mines are not to be opened until there has been obtained from the Board of Commerce a permit to prospect and a permit to operate. Mining concessions must not be over 30 square li (li = ⅓ mile) in area and the length may not be more than four times the width. Should there be graves upon the land included in the concession, care must be taken in sinking shafts to avoid them, and when such avoidance is absolutely impossible a liberal allowance must be made for removing the graves. The permit to prospect allows merely an examination of the surface outcrop of the vein, and such examination "must not be carried to too great a depth or over too great an extent of ground." Foreign capital may be admitted to only equal shares with Chinese capital in any original mining enterprise.

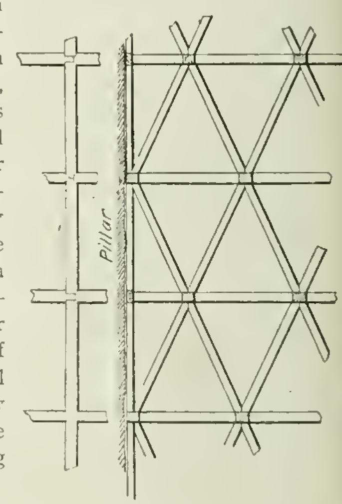

Fig. 6

Should a company consisting solely of Chinese capital find its funds too limited to conduct the undertaking properly, it may raise a foreign loan upon the security of its machinery and plant, but it can not mortgage the mine for this purpose. The ordinary land tax must be paid on all private land affected by a permit to prospect. Public lands affected by such a permit shall pay an annual rental of 1 kuping tael (67 cents) per mow (⅙ of an acre). The fee for a permit to prospect is established at $33.50 and before prospecting may begin one year's rental on all government land thereby affected must be paid. The fee for a permit to work a mine is established at $67 for any area of 10 square li or less, and for every additional square li, $6.70. A tax must be paid on the gross output of all mines as follows: (1) Coal, antimony, iron, alum, and borax, 5 per cent. ad valorem; (2) petroleum, copper, tin, lead, sulphur, and cinnabar, 7½ per cent.; (3) gold, platinum, silver, mercury, and zinc, 10 per cent.; (4) quartz crystal and all sorts of precious stones, 20 per cent. Export duty must be paid on all ore or minerals exported, according to the custom's regulations. Upon receipt of a permit to prospect, a bond of 5,000 taels ($3,350) must be filed, and on receipt of a permit to work a bond of 10,000 taels ($6,700) is required by the authorities.

When to these provisions of the law are added the long and complicated process by which such permits can alone be obtained, and the numerous and indefinite but necessary payments involved therein, the difficulties encountered by mine operators in China are apparent.

Parral Tank as a Slime Agitator

Details of Construction and Method of Operation Compared with Pachuca Tank

During the San Francisco, Cal., meeting of the American Institute of Mining Engineers, in October, 1911, Bernard MacDonald, of Pasadena, Cal., presented a paper on "The Parral Tank System of Slime Agitation." The paper announced a new and improved system of slime agitation which Mr. MacDonald has devised and patented, and which is in operation at the Veta Colorado M. & S. Co. cyanide mill, Parral, Mex. The following is abstracted from that paper:

Agitation is an essential part of the treatment of slime in cyanidation, for by agitation the solids in the slime pulp are kept in suspension and mixed with a solution in the proper proportions required for the treatment. If the proper weight of solution to solids be determined as two parts by weight of water to one part of dry ore, which is approximately 5 to 1 by volume, this proportion should be maintained in every part of the charge; that is, each solid particle of the pulp, whether it be 180- or 400-mesh size, should be surrounded by five times its own volume of solution throughout the whole period of treatment. The reason for this is that the quantity of chemicals necessary for dissolving the gold and silver contained in the slime is held in uniform solution, and therefore the determined portions of solutions and solids must be maintained at all times during treatment. For, if the pulp should be allowed to thicken at the bottom of the tank so as to contain say only four parts by volume of the solution to one part of solid, there would be only four-fifths of the chemicals present in this part of the tank charge, while the other one-fifth would be present in another part of the tank charge where it was not required. Besides maintaining the proper proportional mixture of solution and ore, agitation is designed to furnish aeration to the slime pulp during treatment. The superior economy of air-lift agitation, or the Pachuca tank system of slime agitation, and the energy of the patentee of this system, soon brought this method into popularity and most of the recently constructed cyanide plants have adopted it.

FIG. 1. TRANSFER PIPES IN TANK

F'gs. 4 and 5 respectively show standard Pachuca and Parral tanks of approximately equal holding capacities. The corresponding items in the two tanks are as follows:

	Pachuca	Parral
Height in feet	45	15
Diameter in feet	15	25
Horizontal area in square feet	176.7	490 8
Effective holding height in feet	39	14
Holding capacity in cubic feet	6891 2	7671 2
—Holding capacity in Metric Tons—		
Pulp: Solution 2, Solids 1	83.38	92.8
Pulp: Solution 2, Solids 1	139.5	155 3

32—5—5

As may be seen from Fig. 1, the Pachuca tank is a tall cylinder *a* having a cone bottom. In the center of the tank is fixed the air-lift tube *b*, which, commencing about 18 inches from the apex of the cone bottom, extends to within a few inches of the top of the tank. The diameter of this tube is proportioned to the diameter of the tank, approximately as 1 to 12.

The explanation of the pipe equipment in Fig. 4 is as follows: *a* is the side of the tank; *b* is the air-lift tube; *c* is the pipe which delivers the compressed air into the bottom of the air-lift tube; *d* is the foot-rest which holds the compressed-air pipe in the center of the air-lift tube; *e* is an auxiliary compressed-air pipe used for delivering compressed air at the bottom of the tank to keep the pulp in agitation while the charge is being received; *f* is a system of pipes extending radially from a hollow "bustle" or distributor attached to the air-lift tube to which is connected a feed pipe leading from the air main at the top of the tank, through which compressed air or solution under pressure may be turned into the bottom of the tank to assist in agitating the pulp while the tank is being charged, or to restore the pulp, in case of packing, to a fluidal consistency so it can be transferred through the air-lift tube.

The compressed air, high-pressure solution, and pulp charging mains for the pipe connections are shown at the top of the tank. It should be noted that the end of the compressed-air pipe *c* is capped, and for a length of about 7 inches above the cap is perforated by a number of small holes through which the compressed air escapes into the air-lift tube. To prevent the pulp from entering these holes and choking the pipe when the compressed air is shut off, a tight-fitting rubber stocking or tube is drawn over the holes and clamped to the pipe above them. When the air is on, the stocking expands and the air flows underneath it and escapes at its lower end, which is left open. When the air is shut off, the stocking closes over the perforations and prevents the pulp from entering them.

In operation, when the tank is receiving its charge from the pulp-charging main, compressed air is turned on through pipe *c* to keep the pulp in agitation and prevent it from settling in and around the bottom of the air-lift tube.

In case the compressed air fails during the charging of the tank and the pulp packs around the bottom of the air-lift tube and the rubber stocking, so hard as to prevent the operation of the air lift when the compressed air comes on, air or solution, or both, may be turned into the auxiliary pipes *e* and *f* to bring back the packed pulp to fluidal consistency, and, in case this fails, the tank is provided with a manhole shown in the figure, which may be opened and the packed pulp excavated.

When the tank has received its full charge of pulp, compressed air is turned on in pipe *c*, which starts the operation of the air-lift tube, and the auxiliary-air agitation pipes are then closed off. By the operation of the air-lift tube the thick pulp at the bottom of the tank is drawn into and carried up through it and discharged at the top where it falls back on the tank charge and mingles with the thin pulp there.

The transfer of the pulp from the bottom to the top of the tank continues throughout the treatment period and preserves the proper proportional mixture of solution and solids. By these means and in this manner the agitation of slime pulp is effected by the Pachuca tank system.

All defects in the Pachuca tank system result from the design of the tank and the apparatus with which it is equipped. Its great height and small diameter make its holding capacity comparatively small, and consequently its cost of construction per unit of holding capacity high. The height of the tank and the large diameter of the air-lift tube necessitates a corresponding high pressure and large volume of compressed air to effect the transfer of the pulp, which adds to the cost of agitation.

The pulp transferred through the air-lift tube overflows on the top of the charge close around the tube, in which relative position the solid particles settle vertically to the bottom, where the steeply sloping sides of the cone bottom carry them to intake of the lift tube, which throws them back again on the top of the charge. Under normal conditions of operation, the air-lift tube turns over the entire charge in a Pachuca tank of standard size in about 15 minutes. The violence of this operation would not be necessary to keep the pulp in proper mixture, but, on account of the tall narrow tank and the cone bottom it is necessary, in order to keep the air-lift tube and the air nozzle from being choked.

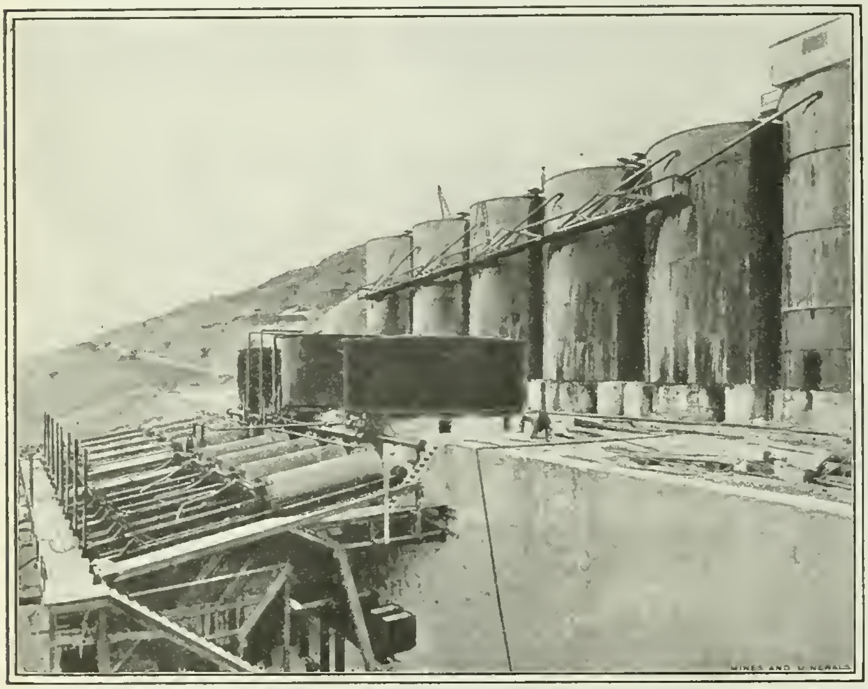

Fig. 2. Parral and Pachuca Tanks

The air nozzle within the lift tube is a crude mechanical device, expensive to operate and expensive to maintain.

Before the reasons for these assertions are submitted, the principles of air-lift pumping should be reviewed.

At the starting of agitation, after the tank has received its charge, the pulp level is the same within and without the air-lift tube, which extends say 3 or 4 inches above the pulp level. If the pulp has the consistency of 2 to 1 of solution and solids, the pulp pressure on the bottom of the tank will be .54 pound for each foot in height of tank charge. The air pressure for the agitation of such charge should be 10 per cent. greater, or say .60 pound for each foot in height of tank charge. When the compressed air of .60 pound foot pressure is turned on in the air pipe terminating near the bottom of the lift tube, it flows into the pulp there which only has a pressure of .54 pound per foot in height. The compressed air on entering the pulp in the lift pipe assumes the form of bubbles, which, rising through the pulp, immediately join together, forming a large flattened bubble which, extending to the sides of the pipe, takes the form of a disk or piston, in which form it rises to the surface, pushing the pulp before it. Rivalry now begins between the pulp and compressed air for the privilege of filling the space being vacated by the ascending air disk. The pulp, endeavoring to restore the hydrostatic equilibrium between the contents of the air-lift tube and the tank outside, and, by reason of its greater volume. owing to the disparity of size between the compressed air and air-lift tubes, rushes past the air nozzle holding back the issue of air, momentarily. But, immediately, the air on account of its higher pressure, again succeeds in entering the lift tube in sufficient quantity to form another air disk with the same result as before. Thus, by jets of compressed air alternating with rushes of pulp of great frequency into the bottom of the air-lift tube, the lifting operation is effected.

It is not improbable, however, that in certain kinds of liquids having great viscosity, the inflow of compressed air would be imprisoned in it as numerous small individual bubbles, and would, in this way form an emulsion of the liquid within the tube, and this being lighter than the pulp outside, would be lifted or shoved upward by the heavier pulp coming in to displace it. But this condition would not be probable in the case of an ore slime.

Regarding the defects of the air nozzle of the Pachuca tank, the principal one is the amount of ineffective work that must be done by the compressed air in making its numerous jet-like escapes into the air-lift tube. The superficial area of the exterior of the rubber stocking that must open and close for each jet of air escaping, is 36 square inches at least, and on each inch of this area there is a continuous pressure of .54 pound per inch per foot in height of the tank charge. As filled in operating, there are 43 feet of pulp in the tank which makes an external pressure of 23.22 pounds on each square inch, or a total of 836 pounds on the movable part of the stocking, which weight must be lifted by each jet of air admitted to the air-lift tube. Owing to the great frequency of the air jets the enormous amount of useless work which this form of valve necessitates will be apparent. The numerous alternate openings and closings of the rubber stocking soon destroy its elasticity and wear it out.*

It should also be understood that the efficiency of air pumping is affected differently from that of mechanical pumping. For instance, a mechanical pump designed for a 6-inch discharge pipe will pump as easily the same quantity through a 16-inch discharge. But in case of air-lift pumping, the volume and pressure of compressed air that would be sufficient to pump violently through a 6-inch discharge pipe will have no lifting effect, whatever, through a 16-inch pipe; for the compressed air would rise in a stream of separate bubbles through the liquid in the lift tube, and would be not of sufficient volume to form

*The difficulties attending agitation in Pachuca tanks are described by Huntington Adams, in a paper read at the Wilkes-Barre meeting of the Institute, June, 1911, and need not be repeated here.

solid air disks that would reach from wall to wall of the lift pipe, and the liquid column would be unbroken and maintain itself in hydrostatic balance with that outside the lift tube and no displacement would result. This points to the economy of using the smallest air-lift tube consistent with the volume of liquid to be pumped.

In the Parral tank system of slime agitation, which was designed and developed by the writer, and for which United States and Mexican patents have been obtained, the defects in the Pachuca tank system, above referred to, have been eliminated and corresponding advantages secured.

A complete tank equipment of this system having the capacity of treating 500 tons daily, and consisting of five tanks, has been installed at the milling plant of the Veta Colorado M. & S. Co., at Parral, Mex. Along with the Parral tanks are installed two of the standard Pachuca tanks, one of which is used as a treatment tank and the other for holding the wash water for the filter-press plant.

The Parral tanks are equipped with the special piping and the apparatus peculiar to this system, while the Pachuca tank is equipped with the piping and apparatus common to that system. The treatment tanks, that is the one Pachuca and five Parral tanks, have been piped for individual and continuous systems of treatment, and each of these systems has been tried out separately and a complete record of the results carefully kept. No advantage has been shown in the extraction of values by either of these systems over the other, but the continuous system is more economically operated by reason of its great simplicity and fool-proofness.

Fig. 2 shows the battery of treatment tanks, the Pachuca tanks being on the extreme right, on top of which is the deck house used for the titration of samples, while in the same row and to the left, are the five Parral tanks. Along the front of the tanks near their tops is seen the piping for the continuous-treatment system, and the sampling platform. In the center and lower left corner are shown the "excess" tanks and the battery of Kelly filter presses appurtenant to the plant.

The object of the Parral tank system of agitation is the same as that of the Pachuca tank system, but the tank design and the mechanical equipment are entirely different from that of the Pachuca system.

The Parral tank is flat bottomed, 25 feet in diameter and 42 feet in height with a capacity two and a half times as great as the standard Pachuca tank. For raising slime pulp from the bottom to the top of the tank, four transfer pipes *a*, shown in Fig. 5, are installed, each 12 inches in diameter and set 12 inches from the bottom and 4 feet from the tank side and equidistant from each other. The compressed air is admitted into these pipes through a patented nozzle fitted with a ball valve, which automatically opens and closes, intermittently, as required in the jet feeding of the compressed air.

In case the compressed air should fail, and in the momentary intervals between the jet issues, the air nozzle is securely and automatically sealed by the ball *a*, Fig. 7, falling back on its seat, and the entrance of the pulp to the air pipes is prevented.

On the delivery or top ends of the transfer pipes, tees of equal diameter are bolted with the run in line with the pipes and the outlets so directed as to discharge the pulp in line of segment cords to the circumference of the tank. The discharge of all the transfer pipes is in the same direction, and the force of the discharge sets up a spiral or rotary flow in the tank charge which in a short time extends down to the bottom of the tank.

Fig. 3 shows the pulp discharging from the transfer pipes and the undulations of the rotary flow set up in the tank charge. When Parral tanks are receiving their charge for individual-charge treatment, an auxiliary air pipe is extended down alongside each transfer pipe to a point near the bottom of the tank, and the compressed air issuing from these pipes keeps the pulp in agitation and prevents its settling on the bottom. In the continuous system this pipe is never used.

When the tank is filled to within 10 or 12 feet of the top, the air is closed off the auxiliary pipes *b*, Fig. 5, and turned on within the transfer pipes. Fig. 1 shows a workman making this change and the transfer of the pulp (lift at this time) commencing. This illustration also shows the method of fastening the transfer pipes fast to the tank in a secure and simple manner.

The spiral flow set up in the tank carries the pulp particles round and round, so that the distance traveled by the pulp from the time it is delivered at the top until it reaches the bottom, is many times greater than if it settled vertically, as in the Pachuca tank. The solids carried in suspension by the rotary flow of the solution and their settlement thus retarded, the necessity for frequently transferring the pulp from the bottom of the tank to its top is lessened and the cost of the work compared with the Pachuca tank reduced.

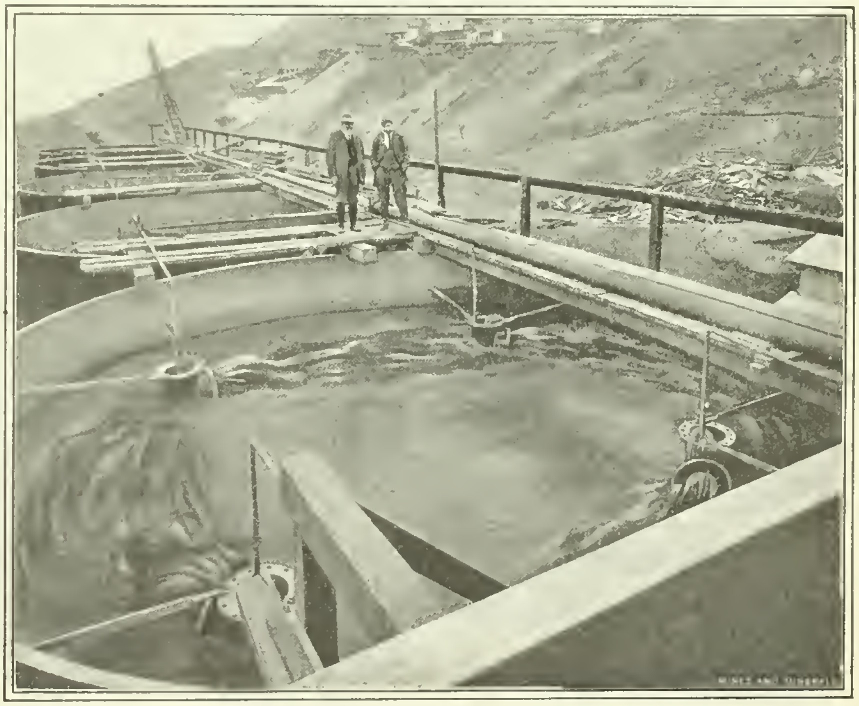

Fig. 3. Rotary Flow in Tanks

In the Parral tank system no special diameter of tank need be adhered to as in the Pachuca system. The relation of the diameter to the height of the tank may be whatever is economical in holding capacity, which should be the main consideration in designing tank diameter.

To secure perfect agitation and the necessary rotary flow in tanks of 30 feet or more in diameter it would be necessary to install a proper number of transfer pipes with the discharge outlets placed so as to set up and maintain the rotary flow.

The compressed-air nozzle with its ball valve, which may be used in any air lift, makes for the highest possible efficiency of compressed air used as a lifting agency. Fig. 7 illustrates the construction and operating methods of the ball valve. An analysis of the operation will show that the pressure on the ball due to the hydrostatic head of the pulp charge, is balanced,

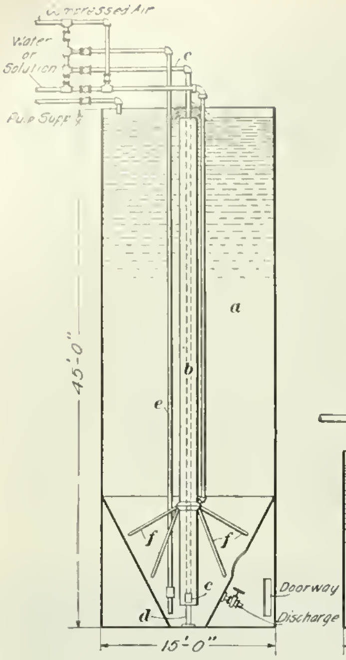

Fig. 4. Pachuca Tank

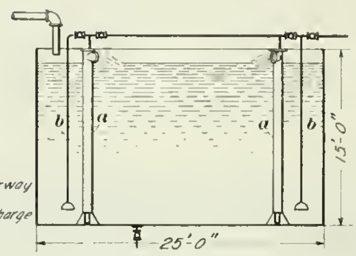

Fig. 5. Parral Tank (Same capacity as Fig. 1)

except for that area of the ball which rests on the seat. The seat area of the valve which is 2 inches in diameter (equal to a horizontal area of 3.1416 square inches), leaves an unbalanced weight of 73 pounds on the ball, if it were to replace the rubber stocking in the Pachuca tank, or 763 pounds in favor of the ball valve.

As the air nozzle is called upon to open and close several times each second in permitting the jet discharge of compressed air into the transfer pipe, the aggregate of the useless work the rubber stocking imposes on the compressed air, and the comparative advantage which the ball valve possesses over it, will be easily estimated. The reason for stating that the probable frequency of the air-jet discharge will amount to several each second is that the sound of the seatings of the ball valves, as heard by one going underneath the tank, seem almost as frequent as the blows of an air hammer.

For comparison between the life of the two kinds of valves, the Panilla mill is taken, where equipment includes 12 standard Pachuca tanks, 10 of which were equipped with the rubber-stocking valve and two with the nozzle and ball valve. These tanks began operation on January 1, 1911. The rubber stockings soon wore out and were replaced by Parral valves while the original Parral valves are apparently as good as when first installed. In this plant and in that of the Veta Colorado M. & S. Co. the Parral valves never gave any trouble in starting up, even after the air had been closed off for 3 hours at a time, while under the same conditions the valves of the Pachuca tanks were only started after a great amount of trouble.

Although the transfer pipes in the Parral tanks are 12 inches in diameter, probably pipes 8 inches in diameter would produce sufficient rotary flow in the tank charge to give the required agitation. When the transfer of the pulp is started and a strong rotary motion (about 6 feet per second) communicated to the charge, the air valve is partly closed until the flow of pulp from the transfer pipes is reduced to one-third of their normal capacity and so continued to the end of the treatment. From repeated tests, it has been shown that the extraction of gold and silver was equally as good under these conditions as when they were being operated at full capacity. From these tests it has been deduced that so long as the spiral flow in the tanks is maintained at a speed sufficient to materially retard the vertical settlement of the solids the extraction of gold and silver proceeds just as rapidly as when the pulp is violently agitated.

Table 1. Pachuca and Parral Tanks Compared

Points of Comparison	Dimensions or Number	
	Pachuca	Parral
Height in feet	45	42
Diameter in feet	15	25
Area of bottom of tanks in square feet	176.7	490.8
Holding capacity for each foot in height, cubic feet	176.7	490.8
Number of air lift or transfer pipes	1	4
Diameter of each air-lift pipe in inches	16	12
Total cross-sectional area of air-lift pipes, square inches	201	452
Diameter of each compressed-air pipe in lift pipes	$1\frac{1}{2}$	1
Total cross-sectional areas of air pipes in lift tubes	1.7671	3.1416
Proportional area of tank bottom for each square inch of cross-section air-lift tubes, square feet	.8	1.8
Area of tank bottom for each square inch of compressed air pipe, square feet	100	156

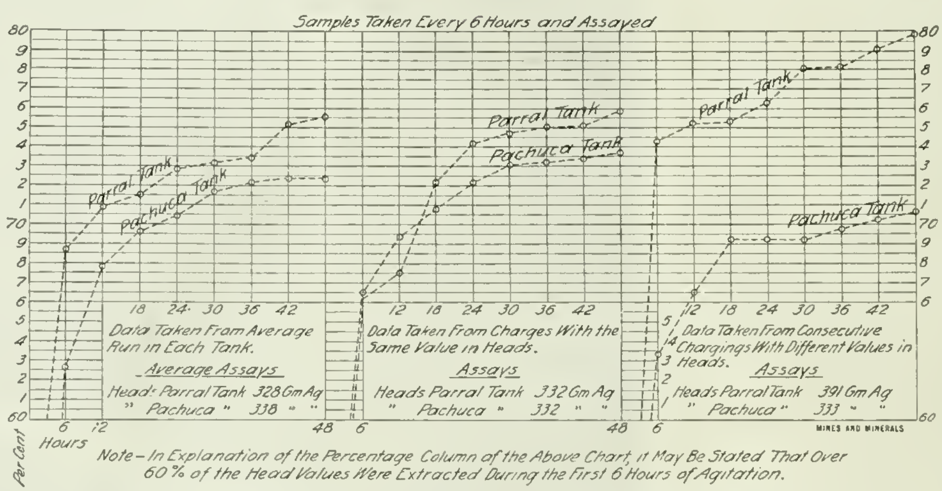

Fig. 6. Records of Regular Operations of Parral and Pachuca Tanks
Chemical Constituents of Solution KCN, 15 per cent.; Protective Alkalinity, 850 Gm.; Lead. 3 Gm.
Physical Condition of Pulp: Dilution 2 to 1; Specific Gravity 1.26; Screen Sizes +200, 15 to 20 per cent.; −200, 75 to 80 per cent.

There are no exact data from which to estimate the comparative amount of air consumed per ton of pulp treated in the two systems, for the air has never been metered, but engineers who operated the valves on the air pipes of both tanks experimentally, with a view of estimating the flow of air, by the proportional valve openings, have reached the conclusion that it requires no more air to operate the four 12-inch transfer pipes of the Parral tanks than the one 16-inch transfer pipe of the Pachuca tank.

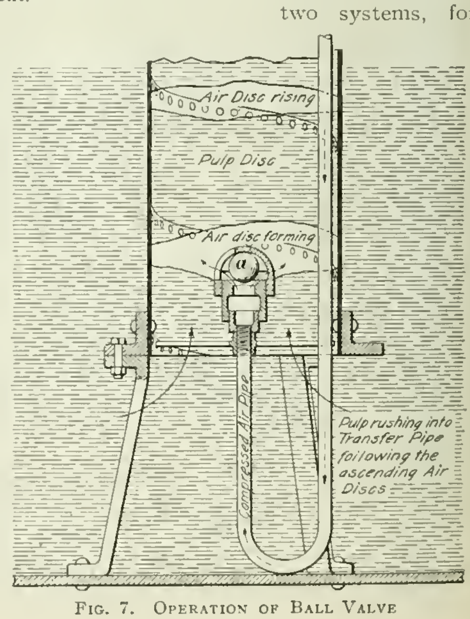

Fig. 7. Operation of Ball Valve

The comparative dimensions of the Parral tanks, as installed at the mill of the Veta Colorado M. & S. Co. and of the standard Pachuca tanks, with the individual equipment of each, may be seen in Table 1.

It may be repeated in this connection that 15 feet is the largest diameter that can be given to the Pachuca tank, while the diameter of the Parral tank may be made as great and the height as low as desirable.

An unexpected result became manifested in plotting the time extraction curves shown in Fig. 6, from the assay records of the samples taken during the treatment operations, from the Parral and Pachuca tanks when operating on the individual-charge method. In the figure the curves show parallel results obtained from the two tanks treating similar pulp under three different conditions.

Ore Mining Notes

Loretto Iron Mine, Michigan.—Among the numerous places of interest visited by the members of the Lake Superior Mining Institute during their recent annual meeting was the Loretto iron mine. This mine is at Loretto in the eastern part of Dickinson County on the Sturgeon River, a tributary of the Menominee River. As the Sturgeon River formerly passed over the ore body the mine was worked by the room-and-pillar system to a depth of 800 feet. In 1908 the course of the river was diverted to the west of the ore body by excavating a new river channel, a part of which is shown in Fig. 1. Since that time mining has consisted in working out by the top-slicing system the pillars that were left.

Leadville Sugar Loaf District. Development at depth in the Sugar Loaf section of the Leadville, Colo., district indicates the coming transformation of the region into a copper camp. Placer mining for gold was the first activity in Leadville. Then followed the discovery of immense silver-bearing lead carbonate deposits of blanket formations. Later some of the mines became producers of high-grade gold ore. In recent years the production of manganese and zinc sulphide ores has been an important industry, and only last year large deposits of zinc carbonates that had previously escaped detection were found and have added largely to the output of the district. Within the last few years also, exploration has disclosed large ore shoots in fissure veins that extend through the overlying limestone and quartzite down into the granite. Two years ago, J. D. Irving, then with the United States Geological Survey, was quoted as saying: "The Sugar Loaf section will be a second Butte when it has attained the depth. The formation is exactly the same and if a Butte man was put into one of the Sugar Loaf properties without letting him know where he was, he would say he was in Butte." Ore running from 3 to 8 per cent. in copper is now taken from Sugar Loaf mines, and mining men here believe that in a few years Leadville will be a great copper camp, the first in Colorado.

Spokane Interstate Fair.—Attractive mineral exhibits from various parts of the Inland Empire were shown. The following awards were made in competitions: Best display of mine products, maps and notes, the East Pacific mine, Winston, Mont. Best district display, Covada Commercial Club, Covada, Wash. Finest ore display, Princess Republic mine, Republic, Wash. Finest display of tungsten ores and products, the Tungsten Consolidated Co., Loon Lake, Wash. Best cabinet exhibit, Oriole mine, Metaline, Wash. Finest coal exhibit, Boundary Mining and Exploration Co., beating the Crows Nest Co., winner of the silver trophy cup in 1910. Best petrographical exhibit, University of Idaho, Moscow. Finest assaying exhibit, State College of Washington, Pullman. Exhibit of paleontology and mineralogy, Spokane College. Ore display of the North Fork, Cœur d'Alene, honorable mention. A. W.

The Bureau of Mines in Colorado.—Plans for experiment work in mining and metallurgy are taking more definite shape. To provide for undertaking investigations that would reduce the costs of metal production, and thus open to profitable mining large ore deposits that cannot now be worked, was one of the purposes for which the United States Bureau of Mines was established, and the last appropriation made for the support of the Bureau gives it $40,000 that can be used for this purpose. When Dr. Joseph A. Holmes was in Denver, on his way to Alaska, a conference of mining men was called to discuss with him the various plans for beginning the investigations in Colorado. Representatives of the San Juan district, where there are exceptionally large deposits of mixed sulphide ores, are urging the establishment of a metallurgical experiment station at Silverton. Others believe that the site should be more central, at Denver or Pueblo, for example; and still others think that advantage should be taken of the equipment available at the mining schools. No decision was reached but the adoption of some one of the plans appears probable. The Colorado School of Mines at Golden is now building a large testing plant in which ore can be handled on a commercial scale, and it has been suggested that cooperation, between this school and the Bureau of Mines would be desirable.

California Natural Gas Law.—All persons, firms, corporations, and associations in California are prohibited from wilfully permitting any natural gas wastefully to escape into the atmosphere. This act is now in effect and as a misdemeanor a violation of it is subject to a penalty of $1,000 fine, a year in the county jail, or both fine and imprisonment. The necessity for a measure of this kind arose from the fact that at different places in the state where wells have been drilled for oil and other purposes, only gas has been met with. Where it has been possible to utilize this gas for domestic or other purposes, it has been done, but there are many instances where the wells have been abandoned and countless millions of cubic feet of gas have been allowed to go to waste in the atmosphere and no attempts were made to cap the wells. Some of these wells have been flowing for years. Demonstrations that gasoline can be profitably extracted from natural gas have been made in Ohio, West Virginia, and Pennsylvania, where a number of plants have been installed. It is reported that a large plant is soon to be established in Kern County, on the Honolulu gas well, where it is expected to handle 4,000,000 cubic feet of gas daily, which is expected to yield 8,000 gallons of gasoline per day. In some instances it has been found difficult and almost impossible to control the flow of gas in wells. Owners have made every attempt to do so; but, in numerous instances where oil was sought for and only gas encountered, the wells have been abandoned without any attempt to check them. Hence, with a knowledge of these facts, State Mineralogist Aubury brought the matter to the attention of the Conservation Commission where the above bill was prepared and presented to the legislature.

FIG. 1. NEW RIVER CHANNEL, STURGEON RIVER

Necessary Amendments to Mineral Laws.—In an address at the twenty-first anniversary of the Michigan School of Mines, Houghton, Mich., George Otis Smith, director of the United States Geological Survey, talked on "The Mining Industry and the Public Lands," and "The Necessary Amendments to the Mineral Laws." It is regretted that the entire speech cannot be reprinted. Abstracts from the speech follow, and the suggestion is made that the western readers of Mines and Minerals send to Washington, D. C., for the entire speech.

Legislation for United States Oil Lands.—The need for remedial oil legislation is somewhat less acute than it was two years ago, by reason of the passage of the act approved March 2, 1911, the effect of which is to validate a class of oil claims which, while clouded by the construction which the Department of the Interior was forced to place upon the misfit placer law, under which title to oil lands must now be made, were bona fide, in that the inception of their development antedated the oil land withdrawals. This enactment was in accord with the spirit of the withdrawal act, which provides for the protection of equities already established. The need for a better law is, however, imperative and the legislative action demanded by the situation should not be limited to an attempt to revamp the general placer law.—Geo. Otis Smith.

Repeal of the Apex Law.—The same knowledge of natural conditions that leads to the suggestion of a repeal of the law of the apex forces the further suggestion that discovery of ore in place cannot be made universally a prerequisite to the location of a mining claim. Geologic study of ore deposits has furnished examples in a number of regions where the present law cannot be complied with, although rich deposits exist underground and their extent can be more definitely surmised than in most cases where ore is discovered at the surface. To meet such actual conditions the law should provide for the acquisition of metalliferous mineral land classified as such upon the basis of adequate geologic evidence, whether actual outcrops are present or not.—Geo. Otis Smith.

Square Mine Claims Advocated.—The unit of disposition should be the claim, preferably square, limited on its four sides by vertical planes, and of a size sufficient to allow the miner occupying two contiguous claims to follow the vein or lode to considerable depth, even if its dip is only 45 degrees. Such definition of a mining claim is found practicable in both Mexico and British Columbia, and in the latter country the change from the apex law was effected without trouble or confusion. Geo. Otis Smith.

Results From Grubstake.—The richest sample of ore received from the prospectors sent out by the grubstake committee of the Denver Chamber of Commerce assayed $460 to the ton. It was found in the La Plata district, about 2 miles from Durango, by O. N. Kee. "There have been stampedes to new mining districts for strikes of less promise than this," said Ernest LeNeve Foster, a member of the committee.

Quebec Placer Mine.—Owing to the name "Dominion" being associated with mining schemes of more or less "wildcatty" nature in various parts of Canada, the directors of the Dominion Gold Fields, Limited, in Beauce, Quebec, have changed the name to "La Compagnie des Champs-d'Or Rigand-Vaudreuil." This company was the one mentioned in the Report of Mining Operations in the Province of Quebec, 1910, issued by the Quebec Department of Mines.

Tungsten in Colorado.—Because of the depressed condition of the steel industry, and the contracted market for tungsten, there has been less activity than usual the past year in the tungsten fields of Boulder County, but the gold output of the country is increasing. The tonnage handled by the Chamberlain-Dillingham sampler at Boulder is 23 per cent. heavier, while there has been a gain of 80 per cent. in the total value of the ore sampled. To some extent the increased production is due to the distribution of central station power throughout the country.—C. S. I.

Platinum in Colorado.—Platinum assaying $500 a ton is reported in what is said to be a sandstone deposit that was recently discovered in the Naturita Valley, near Norwood, in San Miguel County. In appearance the ore resembles the vanadium ore found in the same region. The platinum discovery was made on claims located a month or two ago. Assays of the first samples gave gold, one $80 and one $64 a ton. The latest assays give $500 in platinum, $84 in gold, and a trace of silver.—C. S. I.

Clear Creek County Gains.—Gains of 15 to 20 per cent. in the quantity of ore handled each month this past year are reported by the management of the Chamberlain & Dillingham sampler at Idaho Springs. The tonnage for July was 2,200 compared with 1,720 for the same month a year ago. The Hudson mill, at Idaho Springs, is to be converted into a cyanide plant, and the manager, A. B. Roller, is confident that he will be able to treat at a profit ore running as low as $2.75 a ton.

Alaskan Gold.—He—The last boat from Alaska brought $1,800,000 in gold. She—Was any of it yours? Nome.

Vanadium Reduction Plant.—According to advices the only local plant in Colorado that treats the vanadium ores of Paradox Valley is the Primos Chemical Co., of Newmire, Colo. The product obtained is vanadic acid and no attempt is made to recover the uranium in the ore.

Cripple Creek Independence Mine.—The gross production of Stratton's Independence, Limited, computed to January 1, 1912, has been $22,200,000. John Hays Hammond, in a report made in October, 1900, said that the production up to that time had been $8,250,000, and placed an estimated value of $2,290,000 on the ore then in reserve. It is now believed that the mine has at least another 10 years of profitable production.—C. B. I.

Cripple Creek Drainage.—Work has begun on an extension of the Roosevelt tunnel, which provides deep drainage for the mines of the Cripple Creek district. In the 12 months since the completion of the tunnel the water level has been lowered 65 feet. The present flow is about 6,000 gallons per minute, and pumping has been stopped in the Portland, Elkton, and other large mines. Before drainage provided by the tunnel became effective, the pumping expense in the Elkton alone amounted to $375 a day. The extension on which work has just been started will be 2,000 feet in length. In about 1,000 feet it is expected to cut the Gold Dollar water courses, thus increasing the flow from the tunnel and the rate at which the water level is lowered. A fund for extending the tunnel has been raised, the principal contributors being the Portland, Elkton, Vindicator, Strong, Gold Dollar, Cresson, Blue Bird, Stratton's Cripple Creek, and Granite companies and the railroads of the district. The El Paso will soon start drifting on the C. K. & H. vein from the point where it was intersected by the Fuller crosscut from the Roosevelt tunnel. The flow from this vein, which is now 1,200 gallons a minute, will increase as the drifting proceeds.—C. S. B.

Hecla Mining Co., Idaho.—By the payment of its ninety-ninth dividend this company has paid almost 10 times the par value of the capital stock.—A. W.

Kendall Mine, Mont.—This company, incorporated for $500,000, has paid $2,000,000 dividends to date.

Discovery of Platinum.—Discovery of platinum near Slocan Junction, B. C., has resulted in a rush of locators to the Kootenai River. The assays from samples range in value from $72 to $176 a ton. The extent to which claims are being located will be understood when it is known that one prospector staked a claim, which included the city power plant at Nelson. Ranchers in the district are defending their holdings against invaders. —A W.

Idaho Placer Rediscovered.—James Daniels, deputy collector for the United States Custom House in Spokane, has received advices from Ah Yen, a local Chinese trader, of the rediscovery of rich placer ground in the Blackfoot district, in

Idaho, 93 miles southeast of Spokane, where fortunes were washed from the sand and gravel more than 30 years ago. Yen asserts that the original find was made by two Chinese miners who were killed and robbed by a white claim jumper following a clean-up in 1882 The placers are 4 miles from a flowing stream, Yen says, adding that it would require 15 miles of flumes to convey water to the deposits. Ah Yen said he would not locate the claims, as he feared meeting the fate of his countrymen.—A. W.

Independence Placer Claims Co. is organizing a crew to work its properties on Moose and Independence creeks, below Moose City, Idaho, which was a prominent mining center 47 years ago. Recent discoveries of gold are the causes leading to this renewed activity in one of the oldest placer camps in the Coeur d'Alene district.—A. W.
